American Oceans Campaign's Mission Statement

The Earth's environment is dependent upon a healthy ocean. Healthy oceans are in turn dependent upon our willingness to protect and preserve marine ecosystems. American Oceans Campaign (AOC) is using all of its resources to protect the vitality of America's and the world's coastal waters, estuaries, wetlands, and deep oceans.

AOC's approach to fulfilling this responsibility is to educate the public and local, state, federal, and international decision-makers on the need to stop abusing marine and coastal environments. AOC focuses on establishing strong public policy to protect these resources. AOC is committed to active grassroots support and scientific information as the key ingredients to making public policy.

AOC is equally committed to bringing to the ocean debate diverse coalitions of local, regional, and national environmental groups, elected officials, corporations, religious groups, labor, people of color, Native Americans and the women's movement. Ours is a mission of change. We invite all segments of society to join us.

With offices in Santa Monica, California and Washington, D.C, AOC has a full-time staff of ten, consisting of environmental attorneys and marine/coastal policy experts.

Acknowledgements

American Oceans Campaign wishes to extend a special thank you to the following people for their work on behalf of the National Coastal Caucus; for researching, writing, and reviewing segments of this report; and for sharing with us their wisdom and valuable insight into the inner-workings of the National Estuary Program:

Ray Allen, John Atkin, Terry Backer, Diane Barile, Steve Barnes, Nina Bell, David Bulloch, Samra Buskins, Luciana Castro, Peter Clark, Nicole Cromwell, Doug Daigle, Mark Davis, Ellie Dorsey, Kathy Fletcher, Mark Gold, Roger Gorke, Joan Hartmann, Laura Lynch, Gayle Marriner-Smith, David Miller, Todd Miller, Vito Minei, Barry Nelson, Beth Nicholson, Jeff Parsons, Joe Payne, Cynthia Poten, Til Purnell, Mark Rasmussen, Gloria Rains, Kristin Rowles, Cheryl Seavey, Linda Shead, Peter Shelley, Curt Spalding, Naki Stevens, Jodi Sugerman, Bruce Taylor, Pamela Truesdale, Maya van Rossum, Andy Willner and Marianne Yamaguchi.

In addition, AOC would like to thank the following people for their assistance in preparing this report:

Jill Abelson, Darrell Brown, Barbara Cairns, Cheryl Grady, Dawn Hamilton, Michael Herz, Rob Hudson, Eileen Kane, Steven Kinberg, Michael Lozeau, Mimi McConnell, Russ McGurk, Jane-Kerin Moffat, Bill Mott, Scott and Becky of Rock Creek Publishing, Rob Rocha, Eric Slaughter, Suzanne Schwartz, Richard Schween, Sharron Stewart, Steve Taylor, Gabrielle Tenzer, Jim Townsend, Lisa Weil, Jennifer Welsh and Mark Wheeler.

Special thanks to the Environmental Protection Agency which provided the watershed maps used in this report. Numerous other federal and state employs, dedicated to their agencies and the environment, provided information and suggestions.

Thanks also to the countless friends, family and colleagues, who are too numerous to list here, that have helped and supported us throughout this project.

AOC applauds the following members of Congress and their staffs for their long-standing commitment to protecting estuaries by working to strengthen the National Estuary Program: Representatives Rosa DeLauro (D-CT) and Nita Lowey (D-NY), and Senators Joseph I. Lieberman (D-CT) and Christopher J. Dodd (D-CT).

American Oceans Campaign gratefully acknowledges The Pew Charitable Trusts, the Turner Foundation, Inc., Surf Industry Manufacturers Association, Ted Danson and our Board of Directors for their generous contributions and support of the National Coastal Caucus.

Finally, in my capacity as project director, I would like to express my deepest gratitude to Ted, Tanya and Bethany for their tireless efforts and tremendous dedication to this report. Ted's capacity to go for days without sleep, as we came down to the wire — time and again — with our numerous deadlines was absolutely amazing. When confronted with what appeared to be insurmountable odds, he remained ever-vigilant and persistent in his efforts, always looking for new and amazing facts to add to his "estuary trivia" game. Tanya's relentless passion to ensure "grammatical correctness" in the face of often overwhelming resistance from the rest of our team was truly admirable. As the resident "bio-brain," her constant lectures appealed to even the most clueless "bird-brains" and fish-heads." Bethany's ability to keep her sense of humor as 1,357,892 simultaneous demands were being made of her, and her ability to keep us within our budget for this short, little "50 page report" was astonishing. And last, but certainly not least, I would also like to thank our colleagues in the environmental community for their support, understanding and patience during what can only be described as an "interesting" last few months. No more excuses, so let's schedule a meeting.

—Dawn

Foreword

by Ted Danson, President of American Oceans Campaign

Oceans are truly miraculous bodies of water spanning across 70 percent of the surface of this planet. Like the Earth, the human body is comprised of 70 percent water. Ironically, we also share the same percentage of salt in our veins as that found in the ocean.

Estuaries are the life force of the oceans. Serving as the transition zone between the land and the sea, estuaries provide the perfect metaphor to help us better understand the connections between ourselves and the oceans. Almost everything we put on the land runs off into the rivers and streams that wind through the country, eventually flowing into our estuaries and oceans. Freshwater from these rivers and streams, when mingled with the ocean's saltwater, forms the basis of the estuarine ecosystem. Saltwater makes up 97.5 percent of all the water on earth, leaving only 2.5 percent as freshwater. Therefore, the importance of allowing this natural mixing to occur without the invasion of pollutants is critical.

Estuaries, like the oceans and the human race, are resilient. Although fraught with pollution and suffering from the loss of habitat, they are still some of the most biologically productive and valuable ecosystems on earth. Amazingly, they produce more food per acre than the most productive midwestern farmland. The richness provided by estuaries can be seen both in terms of supporting living aquatic resources and in their role as economic engines for our society. About 75 percent of all fish and shellfish in the United States use estuaries as primary habitat, or as spawning or nursery grounds. This gains added significance when you realize that commercial and recreational fishing contribute $111 billion to the nation's economy and 1.5 million jobs.

Within reason, estuaries have the ability to protect themselves and the oceans from abuse. For example, most estuaries are bordered by protective natural barriers known as wetlands, that filter out pollution before it reaches the water. Some estuaries have sand dunes or surrounding barrier islands that absorb storm surges and protect against upland flooding. However, our natural coastlines have become so seriously degraded and developed that many of these natural filters and protective barriers no longer exist. All systems, be they estuarine or human, have limitations. If we continue the current level of assault and abuse, they will eventually fail to function and die. We must now work to restore these important resources.

American Oceans Campaign is a growing movement of individuals who understand the significance of our links to the oceans — and who want to actively work to protect these gifts for future generations. We view the oceans as our life-support system that we must work together to protect. We know that the health of our bodies is truly connected to the health of the oceans. As humans, we are dependent on the oceans for the oxygen that we breathe and for the food that sustains us. Yet, unfortunately, most of our daily actions on land inevitably harm the sustainability of the oceans.

American Oceans Campaign is pleased and honored to have the opportunity to work with such a renowned group of local experts as the members of the National Coastal Caucus. It is their expertise that has guided us in our efforts and their dedication that gives us hope for the future.

It is because of this valuable link to the oceans and ultimately to us, that American Oceans Campaign works fervently to protect estuaries. We hope that as you read this report, you will grow in your understanding of these connections and join with us. The oceans gave us life, it is time we returned the favor.

2

Overview

by Robert Sulnick, Executive Director of American Oceans Campaign

Without a healthy ocean you can not have a healthy planet. The life force of the ocean germinates in the estuaries, from the wetlands out to the continental shelf. What this means is that all of the toxic waste to which we are addicted ultimately winds up in these tremendously rich and productive ecosystems. In addition to the toxic poisons, habitat destruction and sewage produced by our communities wreak havoc on our nation's estuaries. As the human population continues to increase by 90 million people each year, the stresses on our coastal waters become even more immense.

The resulting problems can, however, be resolved. In the United States, the protection of our nation's waters is governed by a number of federal and state laws, including: the Clean Water Act, Ocean Dumping Ban Act, Coastal Zone Management Act, Coastal Barriers Resources Act, Marine Plastics Pollution Research and Control Act, Marine Protection Research and Sanctuaries Act, and Oil Pollution Act. Clearly, the most important statute overseeing the protection of our estuaries is the Clean Water Act.

The original Clean Water Act (CWA) was signed into law in 1972. Since that time, with every reauthorization, Congress has acted to strengthen the law protecting our nation's waters. Then suddenly in January, 1995 we were faced with the new 104th Congress, which brought a dramatic change to our nation. The new Republican leadership proudly announced the agenda for their "revolution" and for the first time in history we were faced with a Congress intent on turning back the clock on environmental protections!

The dismantling of the CWA and other major environmental statutes began with what the new Congressional leadership referred to as their "Contract with America." Under the guise of ridding the country of bureaucracy and big government, and without ever mentioning the word "environment," the House of Representatives passed legislation to repeal 25 years of environmental and public health protections. Hidden in technical language, within budget bills, and in other unlikely pieces of legislation, they slipped in proposals to repeal some of the most important laws on the books. It took quite a while before the nation became apprised of what was really happening. Since this secret attack occurred with very little public debate, most Americans were unaware of the consequences of their actions in support of the Contract.

Unbelievably, this stealth attack was not enough to satisfy the corporate allies of the new Congressional leadership. Their actions became more direct. Feeling confident after a few initial victories, the new Congress began to blatantly reveal their extremist agenda by developing proposals to exempt certain big industries from complying with environmental laws.

Probably the most egregious assault was conducted by the House of Representatives in May of 1995. Although our nation has made tremendous strides in improving water quality since the first Clean Water Act was enacted, the 104th Congress was intent on gutting the Act. On May 16, 1995 the House passed H.R. 961 a bill that essentially repealed the Clean Water Act and gave special exemptions to big business and industry, thereby allowing pollution with impunity. The health of the nation's coastal waters, in particular estuaries, is absolutely dependent upon a strong CWA. Yet, H.R. 961 put these tremendously valuable resources in jeopardy by weakening virtually every provision of the existing law. The provisions in H.R. 961 mean that estuaries are likely to suffer some of the most dire consequences of these politically motivated actions.

Estuaries are among the most productive natural systems on earth, but they are extremely sensitive to changes in water quality and the loss of habitat. A

VOL 12

3649

few examples of how passage of H.R. 961 puts estuaries at risk include: weakening the toxic industrial discharge permitting program; exempting municipalities from the secondary treatment standard for sewage; gutting the program that addresses polluted runoff in coastal areas; interminably postponing the stormwater control program; and accepting a completely unscientific definition of wetlands resulting in the abolishment of any meaningful national protections. Since so many upland waters eventually end up in the ocean by passing through rivers and into estuaries, the weakening of any of the Clean Water Act's numerous provisions will mean less protection for our estuaries.

The National Estuary Program (NEP), section 320 of the CWA, directs the Environmental Protection Agency to identify estuaries of "national significance" and to assist communities in developing a plan to protect and restore them. If anything even closely resembling H.R. 961 becomes law, the NEP will become meaningless. It has been proven time and again that it is more efficient and cost-effective to prevent pollution in the first place, rather than to clean it up after the fact. By allowing polluters to have a free hand in regulating themselves, Congress is essentially giving away irreplaceable national resources in an act of blatant disregard for the public interest.

This report examines the values of and the threats to 28 estuaries, and how the NEP is working to help protect these valuable resources. The clock is ticking for these "nationally significant" estuaries, which have already been polluted and need further protection. As my friend Representative George Miller (D-CA) once said: "American Oceans Campaign is about a generational gift from one generation to another. Eventually all of our bad habits end up in the ocean and coastal waters, either through acid rain or water pollution, and we've got to understand that we must change those habits because if we in fact preserve the oceans, we have preserved the planet."

Now is the time to act to strengthen estuary protections, not to turn our back on them. We hope you agree and find this a valuable resource to help you meet this task.

Introduction

Estuaries: Ecosystems on the Edge

Estuaries are dynamic bodies of water along our nation's coasts that are formed by the mixing of freshwater from rivers and streams with saltwater from the ocean. Typically, these waters are semi-enclosed by surrounding mainland, fringing wetlands, peninsulas, or barrier islands. Many of the renowned water bodies of the United States are estuaries — San Francisco Bay, Chesapeake Bay, Puget Sound, Long Island Sound, Casco Bay, and Tampa Bay, for example. In addition to bays and sounds, estuaries are commonly known as lagoons, sloughs, bayous, and inlets.

The intermixing of fresh and saltwater in this transition zone creates a distinct environment where aquatic communities thrive. An abundance of land and ocean nutrients, ample light which promotes the growth of aquatic vegetation, and a continuous mixing of the system by winds, tides, and river inflows create conditions which give life to some of the richest and most productive ecosystems in the world.

Each estuary is a unique blend of ecological, climatological, and geographical features. A sound, such as Puget Sound with an average depth of 450 feet,[1] is typically a deep estuary comprised of a long and wide ocean inlet. A lagoon, such as the Indian River Lagoon with an average depth of three feet,[2] is a shallow water body separated from the ocean by sandbars or coral reefs. A bay may have varying depths but can be distinguished by the fact that its outlet to the ocean allows currents to create distinct water circulation patterns.[3] The Chesapeake Bay, with a average depth of 24 feet, is the largest estuary in the United States.[4]

The values and functions of estuaries are considerable. Estuaries and their fringing wetlands play important roles in flood and erosion control, pollution filtration, water quality protection, wildlife conservation, fish production, coastal storm protection, and recreation. Many finfish and shellfish species depend upon estuarine habitats as primary habitat, or as spawning and nursery grounds. Estuaries provide essential habitat for over 75 percent of the United States' commercial fish catch.[5] In some areas of the nation, this percentage is even higher. In the Gulf of Mexico region, an estimated 90 percent of the commercial fish and shellfish species use coastal wetlands during one or more stages of their life.[6] Scientists have determined that estuaries produce more food per acre than the most productive mid-western farmland.[7]

Ironically, the allure of these areas jeopardizes their health and productivity. To support growing populations along the coasts, estuaries are frequently overused and misused by society. Over 45 percent of the nation's population lives in estuarine areas[8] — this percentage is expected to grow dramatically during the next few decades. Unfortunately, estuaries are disposal sites for human and industrial wastes; are dredged to create navigational routes for large ships, oil tankers, and other boats; supply "cooling waters" needed by power generation plants and other industrial operations; and receive various contaminants that stormwater picks up from streets, lawns, and construction sites. Estuarine wetlands, such as salt marshes and mangrove forests, are destroyed in order to open up areas for more shoreline development. The floors of estuaries are damaged by the accumulation of sediments, toxics, and nutrients, and by the dumping of dredged materials. These activities, along with others, have diminished the once-unquestioned appeal of these areas.

However, it is not just human activities along the coasts of estuaries that threaten these waters; activities throughout the estuary's entire watershed affect its water quality and productivity. Watersheds are generally defined as the geographic land area in which water runs off or drains into rivers, lakes, coastal waters, or estuaries. Many of the nation's estuaries have extensive watersheds which encompass portions of several states. For example, the watershed of Long Island Sound includes portions of New York, Connecticut, Rhode Island, Massachusetts, New Hampshire, Vermont and Canada.

The countless benefits that estuaries provide make it essential that society protect these valuable ecosystems. Fortunately, the public is beginning to understand that significant economic resources are directly dependent upon the health and stability of estuaries. A national poll conducted after the "first 100 days" of the 104th Congress revealed that almost 69 percent of the public believes that environmental protection and economic development can go hand-in-hand.' Even when a choice must be made between the two, the public elects environmental protection over economic development — 63 percent to 23 percent in this May, 1995 poll.[10] In addition, 91 percent of the public thinks that laws and regulations designed to control water pollution are just about right or are not strict enough.[11]

With increased public education and the support of national, state, and local policymakers, we can overcome the failings of the past and protect our nation's estuaries for the future. The facts are clear, efforts at estuarine protection must advance, not retreat.

The Values of Estuaries

Estuaries are biologically rich and productive systems.

Since estuaries exist in the zone where rivers and streams meet the sea, plants and animals which are adapted to saltwater, freshwater, and brackish water inhabit these ecosystems. Transitional zones, or areas where two ecological zones meet, are more biologically rich because species from both zones coexist, forming unique ecological communities. In addition, many terrestrial and aquatic species inhabit estuarine areas.

The constant interchange of nutrients and the availability of sunlight in estuaries make these waters so productive. The shallow depth of some estuarine waters creates an environment in which significant amounts of sunlight can reach submerged aquatic plants, producing thriving benthic (bottom) plant communities. Microscopic organisms, known as phytoplankton, form the basis of the estuarine food chain. Large populations of aquatic life which depend on phytoplankton and lush underwater grasses flourish beneath the shallows of these waters. As a result, estuaries with high phytoplankton productivity support many animals. Studies in the early 1980s revealed an average of 8,700 organisms per square meter inhabited Casco Bay.[12]

Estuaries provide valuable commercial benefits and recreational opportunities.

The ecological productivity and broad appeal of estuaries make these coastal areas some of the most valuable "living places" in our nation. By the year 2010, it is estimated that more than 75 percent of the United States population will live within 50 miles of the coast.[13] The richness that estuaries bring to communities ranges from providing economic necessities to offering enjoyment for tourists. The beautiful vistas provided by our coasts have awed and inspired humans for centuries.

For many residents of coastal communities, estuaries and their resources are important for the livelihood of families. Approximately 28 million jobs are generated by commercial fishing, tourism, water-dependent recreation, and other industries based near estuaries and other coastal waters.[14] It is estimated that commercial and recreational fishing contribute $111 billion to the nation's economy and generate 1.5 million jobs.[15]

The nation's commercial fishing industry depends heavily on healthy estuaries and estuarine wetlands. Approximately 75 percent of the United States' fish catch uses estuaries during at least one stage of life — usually, the early stages of life. For juvenile fish and shellfish, lush eelgrass beds, seagrass beds, marshes, mangroves, and coral reefs provide food and shelter. Many of these species migrate to other waters, where they are commercially and recreationally caught.

Just as coastal populations have grown, so have the number of tourists who vacation along ocean and estuarine beaches. Sunbathing, swimming, surfing, beach combing, diving, snorkeling, nature watching, fishing, and pleasure boating provide enjoyment for millions of

VOL 12

Why Protect Estuaries?

- Estuaries are among the most productive natural systems on earth. Estuaries produce more food per acre than the most productive midwestern farmland.
- Estuarine areas are home to over 45 percent of the United States' population.
- Estuaries and other coastal waters provide more than 28 million jobs for our nation.
- Over 75 percent of the United States' commercial fish catch depends on estuaries. In the Southeastern United States, 98 percent of the commercial catch and over 50 percent of the recreational catch are comprised of fish and shellfish that are dependent on estuarine and coastal wetlands.[1]
- An estimated 75 percent of Florida's game fish species and 90 percent of its commercial fish species depend on mangroves, a distinctive type of coastal wetland.[2]
- The economic value of commercial fisheries supported by estuaries is at least $18 billion annually.[3]
- Commercial and recreational fishing contribute $111 billion to the nation's economy and support 1.5 million jobs.
- Gulf of Mexico coastal wetlands provide essential habitat for 75 percent of United States' migratory waterfowl.[4]
- Approximately 45 percent of the nation's endangered and threatened species inhabit coastal areas. Almost 75 percent of the endangered and threatened mammals and birds rely on these coastal habitats.[5]
- About 80 percent of all fish and shellfish world-wide use estuaries as primary habitat, or as spawning or nursery grounds.[6]
- Thirty-one percent of the United States Gross National Product is produced in coastal counties.[7]

3653

people who visit our nation's coasts. However, very little national data have been compiled to help quantify the economic benefits derived from these activities. Thus, placing a dollar figure on these values is a difficult, if not impossible, task. Yet, some have tried to develop calculation methods. The existing information is sparse and hard to assess because most communities use different economic assumptions and baseline data in their analyses. Several studies simply highlight the vast numbers of people who depend upon clean and healthy coastal resources for recreational enjoyment. Examples of some of the more interesting statistics are listed below:

- In 1993, more than 180 million Americans visited coastal waters nationwide.[16]
- In 1991, 73.4 million recreational boaters spent $10.5 billion for products and services.[17]
- Over 35.5 million fresh- and saltwater anglers spent 511 million days fishing, in 1991.[18]

The tourism industry is beginning to gather data demonstrating the importance of coastal tourism to the national economy. Recent calculations of the revenue generated by coastal tourism include the following: $21.6 billion in Florida (1994); $12.1 billion in New Jersey (1994); $4.6 billion in Texas (1993), and $38 billion in California (1992).[19] The tourism industries of these and other coastal states depend on clean, safe waters.

In terms of economic output, the sport fishing industry contributes more to the United States' economy than the commercial fishing industry. Of the $111 billion in economic output that fishing generates for the national economy, sport fishing accounts for $69.4 billion.[20] Angler expenditures for fishing equipment, boats, and other trip-related services support thousands of small businesses across the nation. It is estimated that the sport fishing industry of the United States supports a total of 924,600 full-time jobs.[21] Over 205,000 of these full-time jobs are generated by saltwater sport fishing.[22]

As more research has uncovered the economic value of estuaries, people's willingness to support and maintain the environmental health of these systems has become more evident. For example, in the Galveston Bay area, a recent study indicates that the average household is willing to add seven dollars per month to its utility bill to restore the Bay.[23] Increasing property taxes within coastal communities also contribute significantly to local economies. Waterfront real estate taxes in the coastal counties of Florida sometimes comprise as much as 20 percent of the total property taxes paid.[24]

Estuarine systems improve water quality and perform life-sustaining functions.

Estuarine systems serve as filters for pollution. For example, the roots of mangroves and the shoots of salt marsh plants, situated along the shoreline of estuaries and their tributaries trap sediments, nutrients, toxic chemicals, pathogens, and other contaminants carried by water flowing into the wetland area. The contaminants eventually settle into the soils and are neutralized. By reducing the amounts and concentrations of contaminants, these natural areas protect the estuary's water quality, habitat, and wildlife. However, due to their shoreline location, many of these areas are primary targets for coastal development projects. When shorelines are developed and replaced by impervious surfaces, such as roofs and pavement, the beneficial filtering functions of these natural areas are lost.

Estuaries also support many filter-feeding organisms which help maintain clean waters. Healthy populations of filtering organisms, such as oysters, clams, and mollusks, contribute significantly to water filtration. One oyster, for example, while feeding on plankton, filters 25 gallons of seawater per day, or 27,375 gallons in a four-year life span.[25] Filter-feeding organisms accumulate pollutants in their tissues as they filter contaminated waters. Pathogens in these molluscan shellfish may be passed on to humans eating raw or partially cooked shellfish.[26]

The connection between human health and estuarine health is obvious for certain activities, such as eating estuarine-dependent fish and shellfish, or swimming. What is less obvious is that estuarine watersheds also provide critical drinking water sources for much of the nation. Approximately 10 percent of the entire United States' population, from New York City to Wilmington, Delaware, relies on tributaries of the Delaware Estuary watershed for drinking water.[27] Likewise, the freshwater of the San Francisco Bay's watershed is a precious commodity, supplying drinking water to 20 million people. Further, many competing agricultural and industrial uses of this water provide for economic stability in the San Francisco Bay region.[28] This further attests to the direct link between human health and estuaries, and the need to protect these life-sustaining waters.

Estuarine wetlands and barrier islands protect shorelines and inland areas from coastal storms and flooding.

Salt marshes, mangrove forests, freshwater marshes, forested wetlands, and barrier islands create natural buffers that minimize the impacts of coastal storms and wind on coastal and inland habitats. Coastal wetlands are able to withstand major storms without suffering lasting damage, while at the same time, protecting inland communities. In Florida, for example, thick mangrove stands stabilize the shore and prevent the damaging impacts of storm events.

VOL 12

3654

R0036962

In addition, wetlands have the capacity to temporarily store large quantities of flood waters, releasing waters over an extended period of time into groundwater and adjacent waterbodies.

Estuaries support many plant and animal species.

Estuaries and their adjacent lands support a variety of habitats for plants and animals. Distinctive estuarine habitat types include eelgrass beds, seagrass beds, kelp beds, mangrove forests, salt marshes, freshwater marshes, upland forested wetlands, barrier islands, sand dunes, open waters, and others.

Many of these habitats support commercial and sport fish species. Lobsters, crabs, shrimp, oysters, scallops, and clams are examples of shellfish that depend on estuarine systems. Estuarine-dependent finfish species include menhaden, cod, flounder, spotted seatrout, mullet, and striped bass. In addition, anadromous fish (species that migrate from the ocean to freshwater streams in order to spawn), such as salmon, steelhead, shad, smelt, and alewife use estuaries during their migrations.

Colonial waterbirds, shorebirds, songbirds, seabirds, waterfowl, and raptors use estuaries and estuarine wetlands for a variety of purposes, including breeding, nesting, and foraging. In addition, estuaries provide feeding and resting points during bird migrations. Dynamic and colorful songbird species flourish in estuaries, estuarine wetlands, and adjacent upland habitats. Approximately 50 percent of the nation's migratory songbirds are linked to coastal habitats; while nearly 30 percent of North American waterfowl depend upon coastal habitat for wintering grounds.[29] For several endangered and threatened bird species, estuaries provide critical habitat. The bald eagle, piping plover, roseate tern, least tern, Aleutian Canada goose, wood stork, and whooping crane are a few of these protected species for which estuarine areas are vital.

Finally, both marine and terrestrial mammals inhabit estuarine areas. Some examples of these inhabitants include manatees, bottle-nosed dolphins, porpoises, seals, muskrats, beavers, and otters. Reptiles and amphibians, including numerous sea turtle species which are threatened or endangered worldwide, also use these aquatic habitats.

Threats to our Estuaries

Estuaries are adaptable ecosystems. However, they have not been able to adapt to the human impacts associated with rapid development and population growth. Because of their shallow depths and limited circulation, estuaries are highly susceptible to environmental degradation.[30] Historically, these waters have served as repositories for society's sewage, toxins, and garbage. In addition, estuarine wetlands and shorelines have been destroyed or modified to accommodate the pressures of development. After decades of abuse, these waters have become severely stressed.

In recent years, accounts of the impaired quality of estuarine waters and the diminishing productivity of these areas have been noted. Throughout the nation, degraded estuaries have led to the loss of commercial fishing jobs, closed shellfish harvesting areas, oxygen-depleting algal blooms and subsequent fish kills, and increased coastal storm damage due to the loss of wetlands and other natural lands. We are learning that our misuse and overuse of estuaries are threatening the viability of these ecologically and economically valuable waters.

The predominant human-induced threats to estuaries and estuarine waters are population growth and development, habitat loss, and pollution. According to State water quality reports submitted to EPA, 43 percent of the nation's assessed estuaries do not fully support one or more of their designated uses due to pollution and habitat degradation.[31] The degradation of our nation's estuaries should serve as an impetus to change our attitudes and behavior. The continued vitality of these systems and the economic stability of coastal communities and states hang in the balance.

Estuaries are harmed by population growth and coastal development.

The proximity of most estuaries to major population centers makes them especially vulnerable to pollution and dramatic habitat losses. In fact, human impacts are so far-reaching that even estuaries that are not considered urbanized are experiencing degradation. According to the National Academy of Sciences, unmanaged growth and development are the principal causes of water quality degradation, and of fish and wildlife declines in coastal areas.[32] A rising population means the generation of more waste, and in turn, increased stress on the systems designed to treat waste. Sewage treatment plants and individual septic systems have to be rigorously maintained in order to prevent malfunctions and the release of raw or partially treated sewage into estuaries. In addition, more nutrients, toxic chemicals, and other pollutants are inputted into the estuarine watershed as a result of population growth. Finally, as soils and wetlands are covered by impervious surfaces, such as pavement and roofs, their natural functions of pollution filtration and water absorption are lost.

Though coastal counties only comprise 11 percent of the nation's total land area (excluding Alaska),[33] during the past few decades estuarine areas have become popular places for people to live. Currently, population densities in coastal areas are four times greater than the national average.[34] Forty-five percent of the nation's population resides in estuarine areas.[35]

Large numbers of tourists visit our nation's coasts throughout the year, adding to the stresses already put upon these areas by year-round residents. For example, during the summer months, the Peconic Bays' area population exceeds 280,000 people — an increase of 165,000 people (or 143 percent) from the year-round resident population.[36] By the year 2000, the area's summer population is expected to be 365,000.[37] Although these conditions are normally limited to certain seasons, population surges do affect the water quality and habitat of estuaries.

Estuarine systems are degraded by the destruction of essential habitat.

Activities to support coastal populations and the growing recreational uses of estuaries are destroying their vital, natural habitats. Physical modifications of habitat and increased pollution loadings to estuaries are major causes of impairment of these waters.

Coastal wetlands, submerged aquatic vegetation, sand dunes, and beaches are typically the most threatened habitats of estuarine systems. Wetlands which line the shores of estuaries, such as mangroves and marshes, have been destroyed for commercial and residential development, mosquito control projects, marina and pier construction, agricultural production, highway construction, and other projects. The valuable functions of wetlands, ranging from providing fishery habitat to filtering pollution, are lost after these areas are destroyed.

In the 48 contiguous United States, over 104 million acres of our original wetlands base have been lost[38] — roughly, an area the size of California.[39] In addition, 92 percent of the original wetlands base of the San Francisco Bay area has been lost.[40] Presently, the United States continues to lose wetlands at a rate of 290,000 acres per year.[41] The State of Louisiana loses approximately 60 square miles of wetlands each year — many of which are coastal marshes.[42]

Submerged aquatic vegetation, such as eelgrass and seagrass beds, is damaged by dredging activities, boating activities and increased sediment and nutrient loadings into the estuary. Dredging operations to deepen navigational routes for ships occasionally dump dredged spoils on the estuary's floor, smothering submerged aquatic vegetation. In addition, increasing amounts of land-based sediments and nutrients associated with human activities are carried by rivers and streams to estuaries, creating turbid, cloudy conditions. When estuarine waters become too cloudy, sunlight cannot penetrate to the bottom, thereby, inhibiting plant growth. Between 1950 and 1982, seagrass coverage in Tampa Bay decreased from 40,627 acres to 21,647 acres — a 47 percent reduction[43] — because of increased pollution, development, and boating activities. Since 1982, seagrass coverage in the Bay has increased due to replanting efforts organized by local communities.

Sand dunes serve as natural protective barriers for inland coastal areas, buffering wind and wave action from storms. However, as development has affected areas closer to the water, sand dunes have become replaced by man-made erosion control structures, such as groins and jetties. Groins and jetties are built to keep sands from being deposited in shipping channels and currents. However, these

VOL 12

3556

R0036964

structures also trap sand that, as part of the natural cycle of ocean currents, is likely destined for a neighboring beach, accelerating erosion.[44]

The rapid rate of development in many coastal communities has resulted in the destruction and modification of natural soils and vegetation. Replacing these natural areas with impervious surfaces, such as pavement and roads, allows greater concentrations of contaminants to discharge into estuaries through stormwater and snow melts. Unlike the natural soils and vegetation found in the estuarine watershed, concrete does not filter pollutants. The nutrients, pathogens, and toxic chemicals found in polluted runoff, stormwater, and snow melt impair the water quality and submerged aquatic vegetation of estuaries. With less natural soil coverage to absorb excess waters during storm events, greater flows of stormwater drain into estuaries. The increased flows also scour stream banks and deposit more sediments into estuaries.

In addition, loss of estuarine habitat causes dire consequences for aquatic animal populations. Underwater eelgrass beds serve as critical habitat for commercial and recreational shellfish and fish. As a result of pollution and habitat loss, shellfish populations have been reduced to fractions of their historic levels. Numerous species of threatened and endangered animals and plants depend on estuaries and coastal areas for essential habitat. These population declines should alert us to the importance of restoring these vitally important systems.

Pathogen contamination in estuaries closes shellfish beds and beaches.

Pathogens are disease-causing agents, such as bacteria and viruses, found in human and animal wastes. Pathogen contamination results when raw or inadequately treated sewage is discharged into estuaries. There are a number of potential sources of pathogens in the nation's estuaries, including individual septic systems, sewage treatment plants, combined sewer overflows (CSOs), agricultural runoff from pastures and farms, stormwater, and recreational boats.

In many estuaries, problems associated with human waste disposal are leading to pathogen contamination. Malfunctioning or improperly-sited individual septic systems can lead to wastewater leaching into the soil, eventually contaminating groundwater that leads to estuaries. In addition to septic systems, overloaded sewage treatment plants are responsible for introducing raw or partially treated sewage into estuaries. If too many homes and businesses are connected to a public treatment plant, the facility cannot adequately treat the wastewater prior to discharge.[45] In many communities, concerted efforts are underway to upgrade sewage treatment infrastructure and provide alternatives for homes with septic systems, in an attempt to reduce levels of pathogen contamination. Combined sewer overflows (CSOs) occur in sewer systems which combine stormwater drains with sewage conveyance lines. During heavy rains, these combined pipes are diverted to outfall points rather than proceeding to the wastewater treatment plant. As a result, raw or partially treated sewage is discharged into the nation's waters. Combined sewer systems serve over 40 million people in the United States[46] — including many residents of coastal cities. Finally, boaters who illegally dispose their waste directly overboard introduce pathogens to estuaries. According to federal law, boat owners must either use on-board toilets or pump out their wastes at approved on-shore facilities.

People swimming in contaminated waters or eating contaminated seafood risk contracting cholera, gastroenteritis, hepatitis, typhoid, and other illnesses. For this reason, many coastal communities monitor bathing beaches and shellfish beds for the presence of pathogens. Protocols for monitoring beaches to promote swimmer safety and notifying the public when standards are exceeded vary from state to state, and frequently vary from county to county. New Jersey is the only State with a statewide beach testing program which uses a bacteria standard and testing protocol, and has compulsory beach closure/public notification requirements.[47] Since 1988, 12,472 bathing beaches throughout the United States were either closed or posted health advisories due to swimmer safety concerns.[48] This total number is low and does not account for the number of unsafe beaches that remained open due to

VOL 12

3657

the lack of regular monitoring in some areas of the nation.

Consumption advisories for seafood and fish have become commonplace throughout the nation. One out of every three shellfish beds is closed to harvesting because of contaminated shellfish.[49] For many estuaries, the percentage of harvest-limited (either closed, restricted, or conditionally open) shellfish beds was 100 percent in 1990. Sarasota Bay, Tillamook Bay, Morro Bay, San Francisco Bay, and Hudson River/Raritan Bay were a few of the estuaries with no shellfish harvesting acreage classified as "approved" in 1990.[50]

Excessive loadings of nutrients create oxygen-poor conditions in estuaries that sometimes lead to massive fish kills.

Nutrient over-enrichment is becoming a leading problem in our nation's estuaries. In fact, many estuary restoration plans point to excessive nitrogen loading as the greatest threat to the sustainability of the system. Low concentrations of nitrogen and phosphorus in estuaries enable algae and phytoplankton to grow. However, human-induced loadings of nitrogen and phosphorus are significantly upsetting the balance of estuarine life. Nitrogen and phosphorus are introduced to estuaries by municipal wastewater treatment plant effluent; agricultural runoff and stormwater containing crop and lawn fertilizers; and atmospheric deposition.

Excessive levels of nitrogen and phosphorus can adversely affect estuarine life by stimulating the intense growth of algae. Frequently, algae will grow so densely that they block valuable sunlight needed for the growth of submerged aquatic plants. After the algae die, their decomposition requires a great amount of dissolved oxygen. This depletes dissolved oxygen levels for other aquatic life of the estuary. The resulting low oxygen ("hypoxia") and no oxygen ("anoxia") conditions can sometimes lead to massive fish kills in estuarine waters. During the fall of 1995, the lower Neuse River, a tributary of the Albemarle-Pamlico Sounds, was the site of a massive fish kill. It is estimated that up to five million fish died from the toxic alga, *Pfiesteria piscimorte*.[51] Algal blooms in estuarine waters can also cause foul odors and respiratory discomfort for humans. The inundation of waters by excessive levels of nutrients is often referred to as eutrophication.

One of the leading sources of nitrogen in estuaries is atmospheric deposition. Fossil fuel combustive processes in electrical production and automobile use are major sources of nitrogen loadings to coastal waters. In the Chesapeake Bay region, for example, between 18 and 30 percent of the nitrogen entering the Bay comes from atmospheric deposition, a large portion of which is generated by motor vehicles.[52]

Toxic chemicals contaminate the sediments of estuaries and afflict aquatic life.

Heavy metals and organic chemicals impair many of our nation's estuaries and often cause reproductive and developmental complications, and diseases in aquatic life. These toxic substances enter estuaries through industrial and municipal discharges, polluted stormwater, agricultural runoff, marine vessels, and atmospheric deposition.

Many toxic substances do not degrade, but persist in the sediments of the estuary's bottom habitat where they are absorbed by plankton and other bottom-dwelling species which make up the basis of the estuarine food chain. Eventually, toxics "bioaccumulate" in the tissues of organisms and make their way throughout higher levels of the food chain, ultimately affecting fish, birds, and humans. Toxic contamination in humans may cause increased risk of cancer, neurological disorders, and birth defects. The "bioaccumulation" of toxic chemicals throughout the food chain presents particular problems for subsistence fishers in urbanized waters.

Some heavy metals commonly found in elevated levels in estuaries include arsenic, cadmium, chromium, copper, lead, mercury, and zinc. Organic chemicals, such as pesticides, polychlorinated biphenyls (PCBs), polyaromatic hydrocarbons (PAHs), and dioxin, are also causing significant problems in our estuaries. Compounds containing chlorine and bromine are some of the most persistent toxic chemicals. PCBs and the banned pesticide DDT are familiar halogenated compounds that have remained in the estuarine environment for decades after their initial loading.[53] Dioxin is another persis-

VOL 12

3558

R0036966

tent organic chemical that threatens estuarine aquatic life and increases human risk of cancer. Dioxin is a by-product of many industrial processes, such as bleaching paper pulp with chlorine and incinerating plastic-containing wastes. In February, 1994, health officials in Maine issued a consumption advisory for lobster tomalley due to unacceptably high levels of dioxin. Pregnant women, nursing women, and women of child-bearing age were warned that eating the tomalley would increase the risk of cancer.[14] In addition, a 1993 study conducted by American Oceans Campaign and the University of California at Los Angeles revealed the presence of 160 different toxins, many of which were mutagens and carcinogens, in five storm drains entering Santa Monica Bay. Both polychlorinated biphenyls (PCBs) and chlordane, banned from use in the 1970s, were among the poisons found in urban Los Angeles stormwater.[15]

Conclusion

The wealth of resources we gain from estuaries is in danger. As the human population has moved to these ecological edges, our insolent, polluting ways have followed closely behind. Our nation's estuaries deserve better. Estuaries have brought us life, nourishment, economic rewards, and cultural enrichment. It is time we strengthen our committment to protecting estuaries.

National Estuary Program

In the mid-1980's, Congress began to recognize the need to focus federal attention on the environmental problems plaguing our nation's estuaries. Estuaries, the places where salt water and freshwater merge, are unique and highly productive waters that are critical to the ecological and economic bases of our nation. In particular, fisheries, wildlife, recreation, and tourism are heavily dependent on healthy estuarine systems. Yet, despite their value, almost every estuary in the United States is experiencing tremendous stress from pollution, development, and rapid population growth in coastal cities and counties.

Legislative History

During its consideration of the 1987 Amendments to the Clean Water Act (the Water Quality Act of 1987), Congress created the National Estuary Program (NEP). The NEP was established under section 320 of the Clean Water Act and was modeled after two other Clean Water Act (CWA) programs: the Great Lakes Program (section 118), and the Chesapeake Bay Program (section 117).

The Great Lakes Program is the oldest watershed program in the nation. Authorized in 1970, it includes both the United States and Canada. The Great Lakes Program involves a phased-in process that identifies and defines priority problems in the Lakes, establishes their probable causes, and develops solutions to address them. The 1977 Chesapeake Bay Program is a federal/state partnership, involving three States and the District of Columbia, created to improve the environmental quality of the Bay. The Chesapeake Program uses a collaborative problem-solving approach that involves all interested stakeholders in each phase of the Program, and secures commitments to carry out recommended actions. The lessons learned by these two federal legislative initiatives have helped lay the foundation for the NEP.

In the debate surrounding the authorization of the NEP, Congress clearly stated that it was in the national interest to maintain the ecological integrity of estuaries through the long-term planning and management program set forth under section 320. The purpose of the NEP is to address the many complex issues, including the increase in coastal population and the resulting demands for development, that contribute to the deterioration of the major estuaries in the United States. The goals of the Program include the protection and improvement of water quality, as well as the enhancement of living resources.

Background

The National Estuary Program is managed by the Environmental Protection Agency (EPA). The EPA is required to identify "nationally significant" estuaries and to coordinate the development of Comprehensive Conservation and Management Plans (CCMPs) to restore and protect the ecological health and biological integrity of these estuaries. Individual estuaries are nominated into the NEP by their respective Governors. The EPA Administrator then reviews the nominations and accepts estuaries into the Program on the basis of the following factors:

- the ecological significance of the estuary;
- the biological productivity of the estuary and its contribution to commercial and recreational fish and wildlife resources;
- the impact of commercial, residential, recreational, or industrial activities on the health of the estuary; and
- the degree to which comprehensive planning management may contribute to the ecological integrity of the estuary.

Over the years, the appeal of the participatory nature of the Program, and its goals have grown quite significantly. Since its formation, the NEP has expanded from six estuaries to its current list of 28. Of the

VOL 12

3661

R0036969

estuaries that EPA has designated as "nationally significant," each is at a different stage of development: either creating a management framework; characterizing problems impairing the estuary; developing a comprehensive plan to address the problems; or implementing actions of the management plan.

Participation

Of the 23 States which border oceans, 17 have estuaries in the National Estuary Program. Although it does not border the Atlantic Ocean, Pennsylvania participates in the Delaware Estuary Program, due to the fact that a significant portion of the State lies in the watershed of the Estuary. Pennsylvania also participates in the Chesapeake Bay Program. In addition, Puerto Rico is involved in the NEP due to the designation of San Juan Bay as an estuary of "national significance."

The 18 States that currently participate in the NEP include: Alabama, California, Connecticut, Delaware, Florida, Louisiana, Maine, Maryland, Massachusetts, New Hampshire, New Jersey, New York, North Carolina, Oregon, Pennsylvania, Rhode Island, Texas, and Washington. The estuaries and their corresponding States were integrated into the NEP in a phased-in process or "tiered" approach. Since 1987, EPA has expanded the Program every few years by designating a new "Tier" for inclusion in the NEP. Thus far, five "Tiers" (or groups) of estuaries have been established. The first Tier was established in 1987-88, Tier 2 was set up in 1988, Tier 3 in 1990, Tier 4 in 1992, and Tier 5 estuaries were designated in 1995.

The roots of the NEP actually go back further than the 1987 Amendments to the CWA. In response to a Congressional directive in 1985, EPA established four estuary programs: Narragansett Bay in Rhode Island, Buzzards Bay in Massachusetts, Long Island Sound in New York and Connecticut, and Puget Sound in Washington. A year later, EPA determined that the Program should be extended to two new coastal areas. So, in 1986 EPA added San Francisco Bay in California and Albemarle/Pamlico Sounds in North Carolina. Up to this point these Programs were supported by broad legislative authorities; but upon passage of the 1987 Amendments they were soon incorporated into the NEP.

In 1987 and 1988, NEP management conferences were convened for the six estuaries mentioned above, as well as for: New York - New Jersey Harbor Estuary, Delaware Inland Bays, Santa Monica Bay, Sarasota Bay, Galveston Bay, and Delaware Estuary. Five additional estuaries were added to the Program in 1990: Casco Bay, Massachusetts Bays, Indian River Lagoon, Tampa Bay, and Barataria-Terrebonne Estuary Complex. Peconic Bays, Tillamook Bay, San Juan Bay, Corpus Christi Bay were added in 1992. Finally, the most recent group of estuaries were added to the NEP in 1995. They included: Barnegat Bay, Maryland Coastal Bays, Columbia River, Mobile Bay, Morro Bay, New Hampshire Estuaries, and Charlotte Harbor.

Management Plan

The development of the CCMP is an arduous process. Identifying the priority problems and their solutions, and maintaining concurrence among all stakeholders throughout the process can be a difficult task. The CCMP is intended to address all uses affecting the restoration and maintenance of the chemical, physical, and biological integrity of the estuary. The plans typically include recommended actions on a full range of issues, such as habitat protection, polluted runoff controls, stormwater pollution, resource management, and land-use planning. The challenges addressed in the Plan can sometimes take decades to overcome. Therefore, it's critical that the Program ensure a high level of citizen participation in order to maintain long-term community support for implementation of the Plan.

Management Conference

Before work on developing the CCMP can commence, the EPA and the State(s) negotiate a Conference Agreement and convene a Management Conference. Members of the Management Conference include representatives of the relevant federal, state, and regional government agencies, local governments, affected industries, educational institutions, local citizens, and other users of the waterbody. The primary purpose of the Management Conference is to oversee the development of the CCMP for the estuary.

One of the first duties of the Management Conference is to set up a management structure for developing the CCMP. The Management Conference usually consists of working committees such as a Policy Committee, Management Committee, Science and Technical Advisory Committee, and a Citizens Advisory Committee. Some structures also include a Local Government Committee and a Financial Planning Committee. The Management Conference is then charged with identifying the environmental problems facing the estuary, recommending interim corrective actions, outlining compliance schedules to address the pollution problems, and ultimately, constructing a CCMP that gains approval of the State Governor(s) and the EPA Administrator. Once the CCMP is formally approved and actual implementation is set to begin, the involvement of the Management Conference varies among different Programs. In some situations, the Management Conference stays in place to oversee implementation of the CCMP; in others, a new entity is established; and in still others, the structure dissolves, and thus full implementation is much less likely to occur.

The CWA states that Management Conferences shall be convened for "up to" five years. The Management Conferences set up in the early stages of the NEP were given a full five years (some even longer) to identify and prioritize problems, to oversee interim corrective actions, and to develop a CCMP. During the last few years, the timeframe for the newer Programs has been gradually reduced. In 1992, EPA determined that new estuaries in the NEP would have four years to complete the process, and the estuaries entering the Program in 1995 were given only three years to conduct a "streamlined" NEP planning process.

The reduction in the time period for developing CCMPs and the movement toward "streamlined" Programs have raised concern among members of the National Coastal Caucus (NCC) and other environmental and citizen participants in local NEPs. Many believe that by shortening the process they will not have adequate opportunity to educate the public, ensure broad-based citizen involvement, and ultimately, have their own voices heard. Although most participants want to move from planning to implementation as quickly as possible, they have explained that it can take several years to develop the level of trust among stakeholders necessary to hammer out a mutually agreeable CCMP. Flexibility and non-duplication of efforts are important, but the process should not be so rushed that it defeats its purpose. There is also concern that "streamlined" NEPs are based on pre-existing information and research that may have been gathered in such a way as to exclude or limit public comment. To try to address these issues, the NCC recommends the option of extending, for the full five years, the planning process for estuaries that may need more time for studying and planning, or that have had a difficult time incorporating the concerns of citizens into the Program.

Implementation

Whether it takes three, four or five years, implementationstudying and planning alone will not restore these estuaries. Although implementation of some interim actions does occur prior to approval of the CCMP, full implementation of the Plan is not guaranteed. Clearly, the success of the NEP depends upon implementation; yet, the funding necessary for implementation efforts is not always available. The lack of federal commitment to the implementation phase of the Program has proven to be a significant shortcoming. The CWA provides that funding for interim actions may come from the NEP, from the Management Conference participants, or from other sources. Federal assistance is also provided to aid in the development of the CCMP; however, the certainty of direct federal financial support for the Program ends after the CCMP is approved. For this reason, it has been left up to the Management Conference to establish a strategy for securing the funds needed for implementing the restoration plans.

Notwithstanding the fact that section 320(f)(2) of the CWA states that "[u]pon approval of a conservation and management plan under this section, such plan ***shall be implemented***" (emphasis added), it simply does not always occur. The section continues to state that "[f]unds authorized to be appropriated under title II and VI and section 319 of this Act ***may*** (emphasis added) be used in accordance with the applicable requirements of this Act to assist States with the implementation of such plan."

Title II is the section of the CWA that authorizes federal grants for the construction of wastewater treatment plants. Title VI provides for the distribution of capitalization grants to each State for the purpose of establishing a water pollution control revolving loan fund. Finally, section 319 allows for federal grants to be

VOL 12

3563

R0036971

made for implementation of management programs to control polluted runoff. Access to these CWA funds, in addition to State and local resources, is usually considered by Management Conferences in developing the financing mechanisms for CCMP implementation. However, once this limited funding is made available it is up to the State(s) to determine how the NEP will fare as it competes with other programs for its funding allocation.

Several alternative forms of financing have also been used to fund implementation of CCMPs, including: attracting private capital, issuing municipal bonds, securing intergovernmental transfers, collecting fees, and levying taxes. Washington State, for example, issued an eight-cent-per-pack cigarette tax to help finance its water quality protection plan. In addition, several wastewater treatment plants in California were financed with fees paid by land developers, based on the amount of treatment that their new developments would require.

Recommendation

It is an undeniable truth that as the NEP expands, fewer federal dollars will be available for planning or implementation of CCMPs. It is for this reason that the NCC urges the EPA to proceed cautiously as it considers the addition of new estuaries into the Program. It is the belief of the NCC representatives that it is better to have a few estuaries develop and implement solid plans, than to have a whole host of estuaries participate in a program that has very few resources to ensure its success.

The NEP has taken several important steps forward in reaching its goals. One of its strengths is its watershed approach to addressing the problems of the estuary. By identifying, examining, and correcting environmental problems that may originate upstream, the restoration plans of the estuary have a substantially better chance of success.

A related strength of the NEP is its thorough examination of the sources of the estuary's degradation. The CCMPs are designed to consider a myriad of issues: stormwater pollution, nutrient enrichment, heavy metals, sewage treatment, septic systems, industrial discharges, wetlands losses, fishery landing trends, wildlife populations, land-use practices, and others. Past approaches to restoration and protection have typically concentrated on just one type or source of pollution. Although many of these limited efforts are making progress, a more complete understanding of the cumulative effect of all the estuary's problems will produce more tangible and longer-lasting results. There is some concern that the new "streamlined" NEP process may also provide a less comprehensive review of the estuary.

A third strength of the NEP is the range of participation it attracts from interested parties. Theoretically, the Management Conference of each estuary is composed of stakeholders or user groups with a wide diversity of interests. The Conference provides an opportunity for collaboration and building consensus among the varied interests. Joint decision-making in the planning stage, although difficult to achieve, can lead to far fewer hurdles during the implementation phase.

In summary, the NEP under its current financial constraints can only be expected to achieve a limited amount of success. To improve its effectiveness, there needs to be greater access to federal dollars for implementing restoration plans, and stronger mechanisms to ensure full citizen participation during the development and implementation of the CCMP. If the NEP is ever to achieve its objective of fully restoring these "nationally significant" estuaries, it is essential that the Program undergo a smooth transition from the identification of problems to the implementation phase. To aid in this progression, true citizen participation must be deemed more than a goal — it should become a stringent requirement of the NEP.

During the last several years, American Oceans Campaign through the National Coastal Caucus, has been gathering comments on how best to strengthen the NEP. It has worked cooperatively with local Program Directors, as well as with the EPA, to strengthen and continue to improve the NEP. The NEP is an important and worthwhile program that can and does serve as an important model for other watershed planning programs. However, the participatory nature of the NEP makes its process vulnerable to manipulation by political pressures and economic interests. It is our hope that the Program will build on its wide range of experiences and continue to develop new and innovative ways to resolve problems and to engage citizens in the Program.

Regional Characteristics of Estuaries

The blending of salt and fresh water makes estuaries unique among aquatic ecosystems. Although estuaries are similar in composition, they have unique characteristics that distinguish them from one another. The National Oceanic and Atmospheric Administration (NOAA) has divided the estuaries of the United States into five distinct regions (not including the Tropical region) based on their physical and hydrologic features: North Atlantic, Middle Atlantic, South Atlantic, Gulf of Mexico, and Pacific. The major characteristics of these estuarine regions are summarized below.

North Atlantic Estuaries

Estuaries of National Significance
- Casco Bay in Maine
- Massachusetts Bays in Massachusetts
- New Hampshire Estuaries in New Hampshire

Estuaries in the North Atlantic span from the U.S./Canadian border in the north to Cape Cod Bay in the south. Rocky shorelines and steep river beds formed by glacial movement characterize these estuaries. Salt marshes are less common in North Atlantic estuaries due to the steep, rocky terrain within the region. With tides generally exceeding ten feet in height, circulation in these waters is strong.

Middle Atlantic Estuaries

Estuaries of National Significance
- Buzzards Bay in Massachusetts
- Narragansett Bay in Rhode Island
- Long Island Sound in Connecticut and New York
- New York-New Jersey Harbor in New York and New Jersey
- Peconic Bays in New York
- Delaware Estuary in Delaware, New Jersey, and Pennsylvania
- Delaware Inland Bays in Delaware
- Maryland Coastal Bays in Maryland
- Barnegat Bay in New Jersey

Formed by glacial melting, the Middle Atlantic estuaries extend from Buzzards Bay down to the Chesapeake Bay. Forested wetlands and salt marshes are the most common wetland types in this region. These relatively shallow estuaries experience tides of less than ten feet. Freshwater inflows and tidal influences produce complex circulation patterns in this region. Chesapeake Bay in Maryland, Virginia, and Pennsylvania has served as a model program for estuaries of national significance.

VOL 12

3566

VOL 12

South Atlantic Estuaries

Estuaries of National Significance
- Albemarle-Pamlico Sounds in North Carolina
- Indian River Lagoon in Florida

Extending from North Carolina to southern Florida, estuaries in the South Atlantic contain a diversity of habitats, including extensive marshes, and barrier island systems. Due to this region's flat coastal plain, barrier islands, and small tidal range (between two and seven feet), estuarine circulation in the South Atlantic heavily depends upon wind currents. Due to their characteristically shallow depths, total water volume in the South Atlantic estuaries is remarkably low.

Gulf of Mexico Estuaries

Estuaries of National Significance
- Sarasota Bay in Florida
- Tampa Bay in Florida
- Barataria-Terrebonne Estuarine Complex in Louisiana
- Galveston Bay in Texas
- Corpus Christi Bay in Texas
- Charlotte Harbor in Florida
- Mobile Bay in Alabama

Estuaries in the Gulf of Mexico extend from the southern tip of Florida, westward to the border of Texas and Mexico. Many of these estuaries are characterized by channels that were formed by major river deltas, such as the Mississippi and Atchafalaya Rivers, that flow into the Gulf. This region contains the greatest amount of coastal wetlands in the country. Forested wetlands, such as mangrove swamps, dominate the eastern Gulf; salt marshes dominate the west.

Pacific Estuaries

Estuaries of National Significance
- Puget Sound in Washington
- Tillamook Bay in Oregon
- San Francisco Bay in California
- Santa Monica Bay in California
- Morro Bay in California
- Columbia River in Oregon and Washington

Spanning the entire Pacific Coast, estuaries in the Pacific region are characterized by narrow water bodies surrounded by immense rock formations. Much of the Pacific coastline is mountainous with some low-lying coastal plains and rivers. The Pacific Coast's estuaries contain the least number of coastal wetlands among all estuaries. Water depths in these estuaries range from over 1,000 feet in Santa Monica Bay to six feet in Tillamook Bay.

Tropical Estuaries

Estuaries of National Significance
- San Juan Bay in Puerto Rico

Tropical aquatic systems differ significantly from temperate aquatic systems in a variety of ways. Specifically, tropical aquatic systems are characterized by higher and more constant water temperatures, fewer nutrients, and greater biological diversity. In addition, these systems contain some of the most sensitive and biologically-rich habitats in the world, including coral reefs and mangrove forests.

Nationally Significant Estuaries

The National Estuary Program (NEP) was established under the 1987 Amendments to the Clean Water Act. In authorizing the NEP, Congress recognized the need to protect an important but endangered resource — our nation's estuaries.

Since 1987, 28 of the nation's estuaries have been deemed "nationally significant" and accepted into the National Estuary Program. These 28 estuaries span each of our nation's coasts — from Casco Bay, Maine to Indian River Lagoon, Florida on the Atlantic Coast; from Charlotte Harbor, Florida to Corpus Christi Bay, Texas on the Gulf of Mexico Coast; and from Santa Monica Bay, California to Puget Sound, Washington on the Pacific Coast.

Governors nominate estuaries for inclusion in the National Estuary Program and must demonstrate why their particular estuary is considered to be "nationally significant." The Environmental Protection Agency reviews the nomination on the basis of the following factors:

- the ecological significance of the estuary;
- the estuary's biological productivity and its contribution to commercial and recreational fish and wildlife resources;
- the impact of commercial, residential, recreational, or industrial activities on the health of the estuary; and
- the degree to which comprehensive planning management may contribute to the ecological integrity of the estuary.

Realizing the scope of the NEP and balancing the need for national representation, EPA then weighs the information against the criteria and makes its selection.

The EPA Administrator has accepted new estuaries into the National Estuary Program every few years. Thus far, five "Tiers" (or groups) of estuaries have been designated and have received federal funding to assist in the development of a locally-driven Comprehensive Conservation and Management Plan (CCMP). Each of the local estuary programs is at a distinct stage in its CCMP development: creating a management framework; characterizing problems impairing the estuary; drafting the CCMP; or implementing actions of an approved CCMP.

This chapter of *Estuaries on the Edge* reviews all 28 estuaries of the National Estuary Program. However, comparatively less information is available for the seven, "Tier 5" estuaries than for others in the Program. Each excerpt presents a brief physical "portrait" of the estuary, a survey of the ecological and economic values of the estuary, and a review of the identified threats to the continued vitality of the estuary. This is followed by an examination of the local program's operation and activities to restore the estuary. Finally, a brief introduction to the activities of the National Coastal Caucus and other local conservation and environmental organizations to protect and restore these valuable waters is presented.

Albemarle-Pamlico Sounds
in North Carolina

Our estuaries and our Sounds support a way of life, a vital economy, and a healthy future for our children.

—Todd Miller, Executive Director
North Carolina Coastal Federation

Portrait of the Sounds

In 1987, the Albemarle-Pamlico Estuarine Study began examining the water quality and habitat problems of the Sounds and the impact that the greater watershed area has on the estuarine system. The Albemarle-Pamlico system, situated in northeastern North Carolina, is the second largest estuary in the United States (only the Chesapeake Bay is larger). The system is actually made up of seven Sounds — Albemarle, Pamlico, Currituck, Croatan, Bogue, Core, and Roanoke. It also includes five major river basins, as well as beaches, marshes, and bottomland forests. The Sounds contain approximately 3,000 square miles of estuarine waters.[1] The Albemarle-Pamlico Sounds are relatively shallow, with an average depth of 13 feet.[2] The estuary is 26 feet at its deepest point.[3]

The watershed area of the Sounds measures 30,000 square miles and includes portions of 36 counties in North Carolina and 16 counties and independent cities in southeastern Virginia.[4] Nearly

Albemarle-Pamlico Sounds

Area of surface water	3,000 square miles
Area of watershed	30,000 square miles
Average depth	13 feet
Population	2 million people
Values	• Fisheries generate $98 million* • Sport fishing generates $1.3 billion in economic output* • Home to 11 National Wildlife Refuges
Threats	• Pathogen contamination • Toxic pollution • Nutrient loadings and Hog production • Habitat loss and degradation
CCMP status	Approved in 1994

Designated as a "Nationally Significant" Estuary in 1987.

two million people live in this massive watershed, which covers approximately one-third of the land area in North Carolina.[5] The watershed includes almost 9,300 miles of freshwater rivers and streams.[6] Groundwater sources and five major rivers — the Chowan, Roanoke, Pasquotank, Tar-Pamlico, and Neuse Rivers — deliver freshwater to the Sounds.[7] A chain of barrier islands, with only a few inlets, separates the Sounds from the Atlantic Ocean.

Various types of habitat can be found within the watershed, including pocosins, pine savannas, hardwood swamp forests, bald cypress swamps, salt marshes, brackish marshes, freshwater marshes, and submerged aquatic vegetation.[8]

Values of the Sounds

The physical beauty of the Sounds and the commercial and recreational opportunities they offer lure many residents and tourists to the area. The Albemarle-Pamlico system is one of the most biologically productive estuaries in the United States.[9] Due to their variety of habitat and high level of productivity, the Sounds support numerous species of wildlife, fish, shellfish, and plants. Eleven National Wildlife Refuges can also be found in the area.

Recreation/Tourism

A variety of recreational activities attract millions of visitors to the Albemarle-Pamlico Sounds each year. Currently, ten percent of the local work force is employed by the tourism industry of the Sounds.[10] The populations of the counties in the Sounds swell significantly with tourists during the summer months. In 1990, for instance, Brunswick County's population increased by 300 percent during the tourist season.[11] Sport fishing, boating, sunbathing, camping, and bird watching are a few of the popular activities of the area. Between 1970 and 1984, the number of registered boats in the Albemarle-Pamlico Sounds increased by 155 percent. Between 1971 and 1991, the number of marinas increased by almost 300 percent.[12]

Recreational fishing is a booming industry in the estuary. More than 60 percent of the recreational fish in North Carolina use the Sounds for spawning and nursery grounds.[13] In 1991, recreational fishing in North Carolina generated approximately $1.3 billion in economic output and employed nearly 22,000 people.[14] In 1991, approximately 626,000 saltwater anglers spent over 3.5 million days fishing off the coasts of North Carolina.[15] Fifty-two percent of the anglers were non-residents of the State.[16]

The watershed of the Sounds includes 11 National Wildlife Refuges — Great Dismal Swamp, Back Bay, Mackay Island, Currituck, Roanoke River, Alligator River, Pocosin Lakes, Pea Island, Mattamuskeet, Swan Quarter and Cedar Island. The watershed also contains the Cape Lookout and Cape Hatteras National Seashores, the Croatan National Forest, and many state-owned parklands. These public lands offer fishing, hiking, and boating opportunities to visitors, and provide havens for a variety of wildlife.

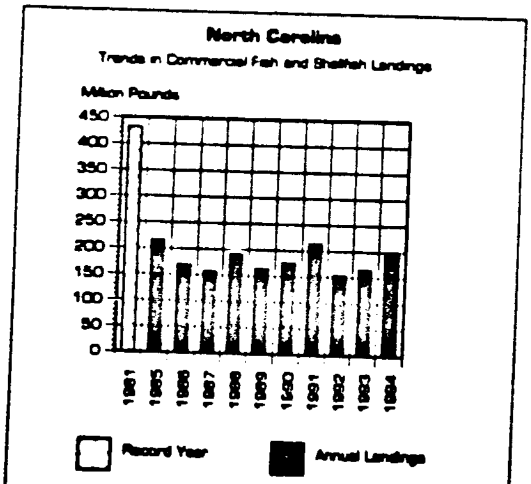
Fisheries/Seafood

In 1994, the combined value of the South Atlantic region's commercial finfish and shellfish industries totaled approximately $215 million. Many of the commercially valuable species in the South Atlantic region depend upon the health of the Albemarle-Pamlico Sounds for survival. In 1994, North Carolina's total commercial finfish and shellfish landings totaled nearly 197 million pounds, valued at $98 million.[17] The Albemarle-Pamlico Sounds produce more than 50 percent of North Carolina's total commercial fishery landings each year.[18]

Despite its abundant fisheries production, fish and shellfish populations in the Sounds are declining due to overfishing, habitat loss, pollution, and disease. Over the past decade declines have been noted in the Sounds' populations of river herring, Atlantic croaker, Atlantic sturgeon, Eastern oyster, red drum, striped bass, summer flounder, and weakfish,[19] jeopardizing more than 20,000 jobs in North Carolina and a billion dollar (combined commercial and recreational) fishing industry.[20] Although disease has contributed to reduced oyster landings since a record year in 1987 when 1.4 million pounds were harvested, the Albemarle-Pamlico system is the largest oyster-producing estuary in the South Atlantic region.[21]

VOL 12

3673



Data Source: U.S. Department of Commerce, National Oceanic and Atmospheric Administration, National Marine Fisheries Service

Approximately 90 percent of the commercially valuable fish species in North Carolina depend upon estuaries like the Albemarle-Pamlico Sounds during some part of their life cycle.[22] The Sounds' tributaries and shallow embayments provide an estimated 25,000 acres of primary nursery area for over 75 species of finfish and shellfish.[23] These nursery areas are used by many fish species which populate other east coast fisheries, and provide numerous commercial and recreational benefits to local communities.

Wildlife

The Sounds provide essential habitat for a variety of animal populations. Snow geese, tundra swans, sea ducks, and other migratory birds use the estuary for wintering habitat. In addition, egrets, herons, geese, and ducks rely on the estuary's salt marshes for feeding grounds.[24] Pamlico Sound provides important feeding grounds for juvenile loggerhead sea turtles.[25] Non-tidal wetlands and swamps are used by black bears, racoons, marsh rabbits, deer, otters, and bobcats.[26]

Many federally-protected endangered and threatened species use the valuable estuarine habitats found in the Albemarle-Pamlico Sounds watershed. For instance, the green sea turtle, loggerhead sea turtle, bald eagle, brown pelican, and piping plover are threatened species whose populations depend upon estuarine wetlands in North Carolina. The hawksbill sea turtle, Kemp's ridley sea turtle, leatherback sea turtle, roseate tern, red wolf, and West Indian manatee are endangered species whose populations depend upon estuarine wetlands.[27] The Albemarle-Pamlico region is home to fourteen endangered plant and animal species, five threatened species, and several species of special concern.[28]

The Alligator River National Wildlife Refuge borders Pamlico Sound. This Refuge is the site of a reintroduction program for the red wolf, once extinct in the wild. Endangered red cockaded woodpeckers and many songbird species can also be found in the Refuge.[29]

Threats to the Sounds

The Albemarle-Pamlico Estuarine Study has identified habitat loss and water quality declines caused by pathogen contamination, toxic pollution, and nutrient loadings as the foremost problems affecting the health of the Sounds.[30] Agricultural runoff, stormwater discharges, and runoff from construction sites and forested lands are significant sources of the habitat degradation and pollution currently plaguing the system.

North Carolina is the leading meat producer in the nation.[31] Large animal industries in North Carolina have contributed overwhelmingly to pollution loadings in the State's estuaries. Inadequately treated hog waste has become a particular concern as of late because of the increasing number of hog farms in North Carolina, and the impact that their wastes have on estuaries and their tributaries. Corporate hog farming is an expanding business in the State of North Carolina, especially in the coastal region. In fact, more than 75 percent of North Carolina's hog population is raised in the State's 15 coastal counties. In Duplin County, which borders three counties in the Sound's watershed area, hogs outnumber people 25 to one. North Carolina is second only to Iowa in hog production.[32]

Pathogen Contamination

Pathogens are disease-causing bacteria and

VOL 12

3674

viruses found in human and animal wastes which enter estuaries through many sources including, contaminated agricultural and urban runoff, sewage treatment plant discharges, boating waste and septic systems. Pathogens in coastal waters pose risks to humans who eat contaminated shellfish or who recreate in beach waters. Gastroenteritis, hepatitis, and other diseases can result from the incidental ingestion of pathogens in contaminated water. For this reason, beaches and shellfish beds are closed or restricted when water monitoring indicates high levels of fecal coliform bacteria (an indicator of pathogen contamination) are present in coastal waters. The State of North Carolina does not regularly test its beach waters for pathogen contamination. If beaches are closed or health advisories issued, it is done by county health departments.[33]

The areas most susceptible to fecal contamination in the Sounds are the shallow, near-shore areas, which often provide the highest-quality and most productive shellfish habitat. Pathogen contamination is responsible for the closure of over 21,000 acres of the Sounds' productive shellfish harvesting acres. An additional 15,000 acres are closed temporarily following storm events.[34] Between 1980 and 1990, the amount of shellfish harvesting area subject to closure increased by 98 percent in the Croatan Sounds, 62 percent in the Roanoke Sound,[35] and 54 percent in the combined Core/Bogue Sound portion of the Albemarle-Pamlico estuary.[36]

Toxic Pollution

Pesticides and toxic chemicals severely impair the water quality of the Sounds. The subwatersheds of Albemarle and Pamlico Sounds have the first and fifth highest pesticide use, respectively, per unit of cropland, of the nation's estuarine watersheds.[37] A 1992 toxic pollution study in the region identified four river systems — the Chowan, Pasquotank, Roanoke, and Neuse — as having levels of toxins capable of harming aquatic life, wildlife, and human health.[38] Zinc, copper, lead, mercury, cadmium, and dioxin are of particular concern.[39] Probable sources of toxic contamination in the Albemarle-Pamlico system include metal-plating operations on the Neuse River; textile manufacturing on the Pamlico, Roanoke, Chowan, and Neuse Rivers; and Department of Defense activities at Cherry Point Marine Station.[40]

Particles of toxic metals and organic chemicals settle in the sediments of the estuary and its tributaries. These toxins can persist in the system for decades; and eventually they are consumed by aquatic organisms and passed through various levels of the food chain. Fish tissue samples gathered at 75 sites in the region have revealed levels of copper, mercury, lead, and cadmium that surpass healthy levels for wildlife. In some portions of the estuary, fish contain levels of mercury and dioxin that are unsafe for human consumption.[41] Fish consumption advisories have been issued in many portions of the Sounds and their tributaries.

Nutrient Loading and Hog Production

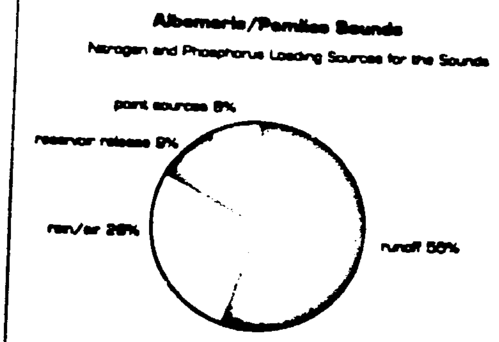
Nutrients such as nitrogen and phosphorus are introduced to the estuary by agricultural runoff, hog production, sewage treatment plants, urban stormwater, atmospheric deposition, and boater discharges. Excessive levels of these nutrients stimulate the growth of algae in the Sounds and their tributaries. As algae grow, they not only block sunlight needed by the submerged aquatic vegetation of the Sounds, but they also require a great amount of dissolved oxygen to decompose. Low dissolved oxygen conditions (called hypoxia) can result in large fish kills.

Numerous algal blooms and fish kills have been documented in the Sounds over the past decade. During the summer of 1995, a massive fish kill occurred after a so-called "hog waste lagoon" breached and spilled 25 million gallons of waste into the New River.[42] Hog waste spills can kill aquatic life in rivers and streams, and can contaminate the groundwater with high levels of nitrogen. According to a North Carolina State University report, there are potentially hundreds of hog waste lagoons in the State with sizable leaks that can contaminate groundwater.[43] Ammonia gas emitted from hog waste lagoons and barns enters the atmosphere and returns to the earth through rainfall. Scientists in the State are linking ammonia with algal blooms because of its nitrogen content.[44] Other problems arise when hog

VOL 12

3675

R0036983



Source: Albemarle-Pamlico Estuarine Study. A Guide to Environmental and Economic Stewardship in the Albemarle-Pamlico Region: A Comprehensive Conservation and Management Plan Summary 7

waste is applied to agricultural land as fertilizer. Runoff from these lands can damage the rivers and streams by pouring excess nutrients and pathogens into them. Finally, the odor from corporate hog farms severely reduces the quality of life for residents and diminishes property values in the area.

In the fall of 1995, the lower Neuse River was the sight of a massive fish kill. Up to five million fish died from a toxic alga which was believed to be triggered by nutrient over-enrichment.[45] A North Carolina State University scientist has recently discovered that the alga causes open sores in fish.[46] Blooms of this toxic dinoflagellate, *Pfiesteria piscimorte*, are believed to be responsible for almost one-quarter of the fish kills in the Neuse and Pamlico Rivers in 1992 and 1993.[47]

As a result of nutrient loading, the Neuse River has been designated as one of the nation's 20 most threatened rivers.[48] The Chowan River was afflicted by a major algal bloom in the summer of 1993.[49] In the Tar-Pamlico River, 90 algal bloom occurrences were documented between 1986 and 1989; and 140 fish and crab kills were reported between 1985 and 1989.[50] In 1987, a Red Tide algal bloom decimated the bay scallop population in the Core and Bogue Sounds.[51] Between 1986 and 1989, three large fish kills occurred in the Roanoke River basin[52] and 41 fish kills were recorded in the Neuse River Basin.[53] Many of these were caused by low dissolved oxygen levels.

Habitat Loss and Degradation

Only one percent of North Carolina's coastal plain remains in its natural state.[54] Losses among coastal wetlands, freshwater wetlands, and forested lands in the watershed threaten the long-term sustainability of the Sounds. The State of North Carolina has lost 49 percent of its original 11 million acres of wetlands;[55] one-half of these losses have occurred in the coastal plain.[56] The United States Fish and Wildlife Service reports that between 1973 and 1983, North Carolina lost more wetlands than any other southeastern State.[57]

In the Albemarle-Pamlico Sounds watershed, wetlands have been converted primarily for agricultural, forestry, and urban uses. The greatest losses and alterations of wetlands have occurred in the area's pine savannahs and pocosins.[58] The old growth longleaf virgin pine forests, which had previously blanketed the North Carolina coastline, are gone. Fragmented stands of old second-growth pines and rows of loblolly pines (a non-native tree species in the State) have replaced these once-magnificent forests.[59]

Regardless of their location and type, wetlands are critical to a healthy estuary. As previously stated, in North Carolina, 90 percent of the commercially valuable fish and more than 60 percent of the recreationally valuable fish use spawning and nursery areas in the estuaries of the Sounds that are closely linked to wetlands. In addition to their importance to fisheries, wetlands naturally filter nutrients and pollutants before these contaminants reach the water.[60]

As development pressures mount within the watershed, natural coverage is being replaced by more impervious surfaces, such as pavement and roofs. Once these areas are replaced, the system loses its natural filtering and absorption capabilities. Thus, stormwater enters the estuary and its tributaries in greater volumes and with higher concentrations of pollutants. Water quality impairments and erosion of shorelines and riverbanks are typical results of uncontrolled coastal development. Coordinated land use management is essential to ensure that population growth does not severely degrade the water quality and living resources of the Sounds.

Additional Concerns

The dramatic rate of population growth and development in the region presents great obstacles to the restoration of the Sounds. Since 1960, 250,000 people have moved to the coastal counties of North Carolina, an increase of more than 50 percent. By 1990, 710,000 people resided in the State's coastal counties. Currently North Carolina has the 10th highest population in the nation.[61] In addition to the demands placed on the estuary by the growing number of residents, millions of tourists visit the Sounds each year.

Increased population places greater demands on freshwater resources in the region. Specifically, the expanding use of groundwater by businesses, farms, and residents in the watershed is depleting the aquifers which feed the Sounds with freshwater. Withdrawals from Black Creek aquifer have increased from 100,000 gallons per day in 1900 to 40 million gallons per day in 1990. Approximately 3.7 million people, 60 percent of the State's population, rely on groundwater for their source of water.[62]

Trash accumulated on estuarine beaches also threatens the ecosystem and its wildlife inhabitants. On September 17, 1994, volunteers cleared 395,793 pounds of marine debris from 450 miles of beach area in North Carolina. Of the total amount of marine debris collected, 56.1 percent was plastic, 13.4 percent was metal, 12.2 percent was paper, and miscellaneous materials totaled 18.3 percent.[63]

Albemarle-Pamlico Estuarine Study

The Albemarle-Pamlico estuary was accepted into the National Estuary Program in 1987 when it was designated as an estuary of "national significance." At that time the Albemarle-Pamlico Estuarine Study (APES) was established to provide a cooperative research and management program between the EPA and the North Carolina Department of Environment, Health and Natural Resources. Representatives of municipal and state governments, federal agencies, academic institutions, and citizens groups participated in developing a Comprehensive Conservation and Management Plan (CCMP). The APES program has significantly raised the visibility of estuarine issues in the entire region. For instance, citizen involvement and interest in coastal issues have increased and government programs protecting estuaries have been expanded. Full implementation of the CCMP is the critical next step in ensuring that the Albemarle-Pamlico resources be preserved for future generations.

The planning process was guided by a Management Conference that consisted of 95 individuals representing four committees. These individual stakeholders came from many diverse groups, including farmers, foresters, fishers, environmentalists, developers, business and industry leaders, university researchers, government agencies, and local elected officials.[64] The third and final draft CCMP was completed in November, 1993. It was signed by the Governor of North Carolina and approved by the EPA Administrator in 1994. Unfortunately, however, once the plan was approved, the APES program office was disbanded. As a result, no agency is officially responsible for ensuring that the plan is implemented, and there has been very little coordination between agencies overseeing current programs of the plans.

The CCMP identifies five major goals, with objectives and management actions designed to accomplish each goal. Action Plans have been developed for the following categories: water quality, vital habitats, fisheries, stewardship, and implementation. During the six years it took to develop the plan, APES participated in several interim action and public education projects. New methods were demonstrated to protect marshes and aquatic habitat, control storm runoff, compost waste from crab processing and agricultural practices, and reduce fisheries bycatch by using new types of fishing gear. As a result, historic spawning areas for shad and herring have been reopened, and scallop beds that were decimated by the 1987 Red Tide have been replenished. Due to the extensive research conducted by the APES program, more is known about the estuary than ever before. For instance, scientists have discovered more about the toxic dinoflagellate that has been responsible for a significant number of the estuary's major fish kills; seagrass beds have been identified; and a mapping system has been developed to help local governments assess the environmental impacts of proposed projects.[41]

The "Implementation" section of the CCMP states that the success of the CCMP and the future of the estuary depend upon continuing communication among the stakeholders that developed the plan. However, it does not recommend any viable process to ensure that coordination and implementation actually occur. Although it recommends the formation of a Coordinating Council and five Regional Councils, it is up to individual policymakers to decide whether to implement these recommendations, and so far it appears that this process is going very slowly. For instance, to date only one Regional Council — the Neuse River Basin Council — has been created. Deadlines for the creation of the Tar-Pamlico Basin Council and others, however, have been postponed on numerous occasions. In order to ensure that implementation of the CCMP occurs in a timely fashion, the North Carolina Department of Environment, Health and Natural Resources must move forward with council formation.

The CCMP is a common sense guide for environmental protection of the estuary. It provides the necessary tools for continued management, coordination, and cooperation; but without a body to ensure that the guidelines are adhered to, many believe that the plan will simply end up on a shelf collecting dust. Although committees have been created to implement the CCMP, efforts aimed at implementing even the most basic elements of the plan have been minimal.

National Coastal Caucus

Founded in 1982, the North Carolina Coastal Federation (NCCF) is a private, nonprofit conservation organization working with citizens for a clean coastal environment. NCCF seeks to protect the area's coastal environment, culture, and economy through: regulatory reform, government accountability, environmental law, coordination of citizen advocacy groups, and environmental education.

Members, staff, volunteers, and the Board of Directors of NCCF have served in numerous capacities in the development of the CCMP of the APES. Specifically, NCCF has served on the Citizens Advisory Committee and has consistently encouraged implementation of both the interim actions identified in the CCMP, as well as the full plan.

The Pamlico-Tar River Foundation (PTRF) was founded in 1980 to protect and improve the environmental quality of the Pamlico-Tar River, its estuaries, and watershed. Over the past 16 years, the organization has developed into a strong grassroots organization with a diverse membership from throughout the watershed. Through education, advocacy, and research, PTRF has achieved its mission of providing a voice for the river. PTRF was instrumental in including the Pamlico systems in the National Estuary Program.

Members, staff, and volunteers of PTRF served in numerous capacities in the APES program. PTRF conducted several environmental education and outreach projects for the APES region and started the Albemarle-Pamlico Citizens Water Quality Monitoring Network. PTRF played an active role in the development of the CCMP through the Citizens Advisory Committee. Currently, PTRF supports and encourages implementation of the actions recommended in the CCMP. The current Executive Director of PTRF was formerly a policy analyst for APES who helped to develop the CCMP.

Currently, the NCCF is working to enhance protection of estuarine habitats, including wetlands, shorelines, and submerged aquatic vegetation. The NCCF is helping to establish more comprehensive riverbasin-wide planning to protect watersheds, reduce water pollution from runoff, and restore water quality and usefulness of degraded waters, including the South River and others. NCCF also encourages the State to buy and otherwise protect outstanding natural areas and to better protect and restore vital wetlands habitat. For instance, NCCF has been working to stop the development of Bird Island by encouraging the State to purchase it and by offering sizeable private contributions. Bird Island is the only undeveloped barrier island in North Carolina west of the Cape Fear River. Surrounded by almost 1,800 acres of salt marsh, the island is a last refuge for both migratory and resident wildlife. In the face of proposals to turn the island into oceanfront housing, NCCF is committed to keeping it the way it is now.

VOL 12

3578

Over the years, the NCCF has participated in other activities designed to protect the Sounds. It is working to make land-use planning under the Coastal Area Management Act (CAMA) work more efficiently and to bring state and local resources together to improve the process. The NCCF encourages the use of more sophisticated technology, including Geographic Information Systems (GIS), to make the process swifter and simpler. The NCCF also encourages broad public support and State action to reverse the precipitous downward trends in living marine resources. To this end, the NCCF works towards better management of marine fisheries, and better enforcement of existing fisheries laws and regulations. The NCCF sought and received financial resources to ensure that the now-obsolete Quaker Neck Dam near Goldsboro be removed. The grants make it possible to open up more than 130 miles of the Neuse River for spawning by open-ocean fish such as shad, striped bass, and river herring.

"Coastal Adventures" is a program conducted by the NCCF education staff to increase knowledge about the value of the Sounds. This program takes participants through coastal estuarine habitats such as hardwood and pine forests, and tidal marshes. In addition, participants examine habitats for rare plant and animal species, and explore the back salt marshes to observe fish, crabs, and other marine life. The NCCF will continue its restoration and educational efforts through public outreach programs and the distribution of its newsletter *Coastal Review*, and will simultaneously work to ensure that six years committed to the APES planning process is not wasted. The advocacy programs of the NCCF consistently stress the need for the coordination and non-duplication of efforts by different governmental agencies.

Since 1980, PTRF has believed that the informed public is necessary for the protection of our natural resources. As a result, the organization maintains a library of their own educational materials, including guides and displays for teachers, students, and the general public. PTRF presents about 100 lectures and programs each year to schools, civic groups, and local government bodies. They hope to establish a permanent education center to focus on the issues of estuarine resource management. In addition, PTRF has produced and published important research on wastewater treatment, manna siting, and water quality.

Barataria-Terrebonne Estuarine Complex *in Louisiana*

The Barataria-Terrebonne Estuary has fed the most productive fishery in the lower forty-eight states, but is now the fastest disappearing coastline in the country. The time is increasingly short to decide which will be its legacy.

—Doug Daigle, Programs Director
Coalition to Restore Coastal Louisiana

Portrait of the Estuary

The Barataria-Terrebonne National Estuary Program is examining the problems of water quality, hydrology change, and habitat loss in the Barataria-Terrebonne Estuarine Complex and the impact that the greater watershed has on the estuarine system. The complex lies between the Mississippi River and the Atchafalaya Basin in south-central Louisiana. It is comprised of the Barataria, Terrebonne, Bastion and Timbalier bays and a number of channels and freshwater lakes. The Estuary's northern boundary is the city of Morganza and its southern boundary is the city of Grand Isle. The total water and wetland surface area of the Estuary is 6,300 square miles.[1] The average depths of the two largest Bays in the system, Barataria and Terrebonne, are a shallow five and six feet, respectively.[2]

Barataria-Terrebonne Estuarine Complex

Area of surface water	6,300 square miles
Average depth	5 to 6 feet
Population	591,000 people
Values	• Sport fishing generates $1.2 billion in economic output* • Fisheries generate $336 million* • 25% of North America's dabbling duck winter in the coastal marshes*
Threats	• Alteration of water flows • Habitat loss and degradation • Nutrient loadings • Pathogen contamination • Toxic pollution
CCMP status	Final expected in 1996

Designated as a "Nationally Significant" Estuary in 1990.

*State figures

The greater watershed area of the system, which covers all or portions of 16 parishes, has a population of approximately 591,000 people.[3] The population density for the watershed is 142 people per square mile.[4] The population of Jefferson Parish, portions of which are in the watershed, is expected to increase by 104,000 people between 1988 and 2010.[5]

Both natural rivers and artificial channels carry freshwater through the northern part of the system. Some of the more significant channels include the Bayou Perot, Bayou Rigollets, Houma Navigation Channel, and the Barataria Waterway.[6] Large volumes of freshwater flowing from the Mississippi River enter the deep waters of the Gulf. The freshwater is then carried westward by strong currents to the Barataria Bay. So, as tides bring the diluted waters back to shore, the salinity levels of the southern portion of Barataria Bay are decreased.[7] Three barrier island chains separate most of the Estuary from the open waters of the Gulf of Mexico. Numerous passes and inlets provide the connection with the Gulf waters.

An abundance of habitat types can be found in the Barataria-Terrebonne Estuarine Complex. These include upland forests, baldcypress and tupelogum swamps, marshes, freshwater lakes, ridges, and open water. The coastal marshes are an integral part of this ecosystem and are a special national resource. An estimated 14 percent of the system is comprised of marshes.[8]

Within the watershed, agriculture is a significant land use. Over 295,000 acres in the watershed are used for sugarcane production and over 46,000 acres are used for pasture and rangeland.[9]

Values of the Estuary

The waters and coastal marshes of the Barataria-Terrebonne estuarine system are symbolic of the wealth of natural resources along Louisiana's Gulf coast. But, for the residents of the watershed, they are significantly more than symbols. The system supports a commercial shellfish and fish harvest that, in volume, rivals the harvests of the entire Atlantic coast. The wetlands of the system provide numerous benefits to the State of Louisiana. A recent academic study examined the economic value of wetlands for fishery production, storm protection, recreation and other functions and calculated the total value of one acre of Louisiana wetland to be as high as $8,977. The market value of one Louisiana wetland acre on the real estate market is as high as $400.[10]

The Barataria-Terrebonne Estuary provides numerous recreational opportunities, such as sport fishing, hunting, bird watching, and photography, that attract visitors from across the nation. Revenues from commercial seafood landings, sport fishing, and hunting in the Estuary approach $1 billion annually.[11]

The area also contains valuable mineral resources, including crude oil, natural gas, sulphur, and salts. The extraction of these minerals, however, has contributed to the destruction of coastal wetlands. Ensuring that the natural resources of the estuarine system are preserved and sustained is often placed in direct competition with human activities.

Recreation/Tourism

The fisheries, wildlife, and natural areas of coastal Louisiana are important components of the tourism industry of the entire State. In 1991, recreational fishing (including freshwater fishing) in Louisiana generated approximately $1.2 billion in economic output and employed nearly 18,500 people.[12] In the same year, about 240,000 saltwater anglers spent over 2.6 million days fishing off the coasts of Louisiana.[13] The licensed saltwater anglers in the State have invested almost $1 billion in boats, gear, and other equipment in their recreational hobby.[14]

In addition to providing a wealth of sport fishing resources, the Barataria-Terrebonne system's swamps and marshes are among the leading areas in the nation for watching birds.[15] Organized swamp and marsh tours are common. Photography, boating, camping, and picnicking are other activities which bring residents and visitors to the region.

Fisheries/Seafood

Many of the commercially valuable species in the Gulf of Mexico region depend upon the health of the Barataria-Terrebonne Estuary for survival. In 1994, the combined market value of commercial finfish and shellfish landings in the Gulf totaled approximately $806 million. For the same year, the State of Louisiana's commercial finfish and shellfish landings totalled approximately 1.7 billion pounds, valued at $336 million.[16]

Louisiana has the most valuable and the greatest finfish and shellfish landings in the continental United States.[17] Estuaries are critical to fisheries production in Louisiana. In fact, 95 percent of the State's total finfish and shellfish catch for 1992 was estuarine-dependent.[18] The Barataria-Terrebonne Estuary's landings averaged 70 percent of the State's total value for the four-year period between 1989 and 1992.[19] Over 35,000 people are employed by the commercial fishing industry of Louisiana.[20]

The Barataria-Terrebonne region is often referred to as the nation's "fishmarket," due to its immense commercial fishery yields. The Estuary's annual commercial harvest of fish and shellfish is over 611 million pounds.[21] The coastal marshes of the Estuary provide important spawning and nursery grounds and provide shelter for substantial numbers of fish and shellfish.

Some of the more prominent commercial finfish of the area include menhaden, black drum, spotted sea trout, mullet, and red snapper, all fish which depend upon estuaries for at least one stage of their life cycles. Brown shrimp, white shrimp, hard-shell blue crabs, oysters, and crawfish are some of the leading shellfish and crustacean fisheries of the system.[22] For the four-year period between 1989 and 1992, the Barataria-Terrebonne Estuary accounted for an average of 86 percent of Louisiana's total oyster landings.[23]

Wildlife

The Barataria-Terrebonne system provides habitat for an abundance of wildlife. The Estuary is inhabited by over 200 bird species, 30 mammal species, 26 reptile species, and 14 amphibian species, along with numerous species of fish and invertebrates.[24] At least 187 different finfish species inhabit the estuarine complex.[25]

The Barataria-Terrebonne Estuary provides important nesting and wintering habitat for a large number of waterbirds and waterfowl. In addition, it contains unique foraging habitat for wading birds, sea birds, and migratory birds. The Estuary supports 71 of the State's 143 waterbird nesting colonies, including white ibis, great egret, and little blue heron. Millions of resident and migratory ducks and geese use the Estuary's forested wetlands and marshes. Nesting colonies of pelicans, terns, and skimmers use its barrier islands and beaches. It is estimated that over 400,000 geese and 25 percent of North America's dabbling duck population use the State's coastal marshes for wintering grounds.[26] In addition, 50 percent of the continental population of mottled duck dwells in the Estuary year-round.[27] Throughout North America, duck populations are steadily declining, due in part to disappearing breeding and migratory habitat. Local, state, federal and private initiatives are being taken to protect wetlands habitat for waterfowl populations.

Minks, otters, racoons, nutria, muskrats, alligators, and diamondback terrapins are a few of the other animals which inhabit the Estuary. Nutria and muskrat eating habits are affecting the species composition and density of wetland vegetation.[28] Muskrats feed on brackish marsh plants and nutria eat baldcypress seedlings and other plants of the Estuary's freshwater marshes to such a degree that large areas of the system are being "eaten out" by the growing populations of these animals. It is estimated that 55,000 acres of marsh have been destroyed by these "eat outs," which often result in erosion problems.[29]

Of Louisiana's 31 animal species that are federally-listed as threatened or endangered, 14 are dependent on wetland habitats.[30] The endangered hawksbill sea turtle, Kemp's ridley sea turtle, least tern, and bald eagle; and the threatened green sea turtle, loggerhead sea turtle, piping plover,[31] and leatherback sea turtle,[32] use the wetlands and estuaries in Louisiana. Due to habitat loss and degradation, a number of additional species are considered to be at risk. These include the diamondback terrapin, American alligator, snapping turtle, black skimmer, North American dabbling duck, and the mottled duck.[33]

Threats to the Estuary

The Barataria-Terrebonne Estuary System is a great economic and ecological resource for Louisiana and the nation. Although natural conditions have played a part in changing the nature of the Estuary, the human activities that have put it at risk may be easier to resolve. Various studies initiated by the Barataria-Terrebonne National Estuary Program point to a compelling need to preserve and restore the Estuary and its resources. The priority problems of the Estuary Complex are identified as the alteration of natural water flows, habitat loss, toxic pollution, nutrient loadings, and pathogen contamination. Increased population growth and urban development are concerns that intensify each of these priority problems. One risk associated with industrial development can be seen in the fact that between 1990 and 1994 there were 597 oil spills in the Bayou Lafourche.[34]

Alteration of Water Flows

The alteration of freshwater pathways to the Estuary is reducing the natural levels of sediment loadings in the system. Normally, the streams and rivers that feed into the Estuary deposit sediments, especially during periodic floods, when the stream banks overflow. As this sediment accumulates, a natural process of land-building occurs. The marshes that form as a result of this process provide innumerable benefits to the wildlife resources of the Estuary.

Since the turn of the twentieth century, a variety of human actions have combined to disrupt nature's marsh construction. Dams built along the Missouri and Arkansas rivers reduce the volume of sediments which ultimately reach the bottom of the Mississippi River. Flood control levees prohibit the natural riverbank overflows that sustain the estuarine marshes. Channelization of the lower Mississippi River impedes its tendency to alter course. Finally, the closing of the Bayou Lafourche at Donaldsonville affects the delivery of water and sediment to the Estuary.[35] These and other factors are altering the balance of habitat types and actually causing the land in the Barataria-Terrebonne Estuary Complex to disappear! The rate of loss for all land (most of this land is wetlands) in the Barataria Bay area was 7,120 acres per year between 1978 and 1990. For the Terrebonne Bay area, the rate of loss was 6,500 acres per year.[36]

The construction of channels and canals within the Barataria-Terrebonne watershed is leading to saltwater intrusion into historic freshwater portions of the Estuary.[37] An estimated 6,950 miles of canals have been built in the coastal plain to support oil and gas exploration and production.[38] The increased traffic along these canals also increases soil erosion along the banks. As a result of these and other projects, the coverage of marshes in the Barataria-Terrebonne system is reduced; greater portions of the Estuary are more saline; water circulation is disrupted; and the natural pollutant filtering processes are hindered. In order to decrease water salinities and restore marshes, one of the CCMP Action Plans calls for the construction of water control structures and the reintroduction of freshwater to the Estuary.[39]

Habitat Loss and Degradation

Forty-one percent of the nation's coastal wetlands are in Louisiana.[40] However, these wetlands are disappearing at an alarming rate. Between 1978 and 1990, the average annual loss of coastal wetlands was 24,203 acres (37.8 square miles).[41] In other words, during this period an area of Louisiana's coastal wetlands the size of Washington, D.C. was destroyed every 20 months. The Barataria-Terrebonne region of Louisiana's coast is suffering the greatest losses of wetlands.

Natural and human activities are responsible for the wetland losses in coastal Louisiana. The natural causes of wetlands loss include sea level rise, subsidence, lack of sedimentation, saltwater intrusion, "eat outs" by muskrats and nutria, tidal scour, and waves. Canal construction, dredging and filling, levee building, and toxic discharges are human actions which destroy wetlands.[42]

Not only do the system's wetlands provide critical habitat for a significant portion of the nation's estuarine-dependent fisheries and for migratory birds along the Mississippi Flyway, but they also serve important public protection functions. Coastal wetlands reduce the impact of storm tides, absorb flood waters, filter pollutants, and in many areas of the nation provide a source of ground and surface waters needed for drinking water

VOL 12

3586

supplies. The values coastal wetlands alone provide for the region are virtually inestimable. However, a recent study conducted by the University of Maryland has come up with a way to assign a dollar value to the wetlands habitat in Louisiana. The study estimates that one acre of Louisiana wetland yields up to $846 in commercial fishery benefits; $181 in recreational benefits; and $7,549 in storm protection benefits. The study also concluded that since Louisiana loses wetlands at a rate of 60 square miles per year, it loses $93 million annually.[43]

Barrier islands are also disappearing. Barrier island beaches are eroding at a rate of 15 to 30 feet per year.[44] Since 1880, the State has lost approximately 16,000 acres of barrier islands.[45] As this process continues, the estuarine habitat and coastal communities will receive less protection from coastal storms. Also, significant losses of estuarine habitat are likely to result after barrier islands are permanently washed over by tides from the Gulf of Mexico.[46]

Efforts to restore the marshes and barrier islands of the estuarine system are in process. Some of the initiatives call for pumping sand to increase the width of barrier island beaches, limiting groins and seawalls on islands largely untouched by human activity, and using water control structures to deliver more water and sediments to the marshes.[47]

Nutrient Loadings

Nutrients, such as nitrogen and phosphorus, are introduced to the Estuary by urban stormwater, sewage treatment plants, atmospheric deposition, agricultural runoff, and boater discharges. The loadings of nitrogen and phosphorus into the Estuary from the Mississippi and Atchafalaya rivers doubled between 1950 and 1995.[48] Excessive levels of these nutrients stimulate the growth of algae in the Estuary. As the algae grow, they not only block sunlight needed by the submerged aquatic vegetation, but also require a great amount of dissolved oxygen to decompose. The decomposition process depletes the levels of oxygen for other aquatic life. Low oxygen conditions (called hypoxia) can result in large fish kills.

Since 1980, 188 fish kills have been documented in the Estuary. Some of these kills have been attributed to the runoff of herbicides and other toxic contamination associated with oil and gas extraction activities.[49] An algal bloom during September of 1994 killed approximately 200,000 fish.[50]

In the nearby waters of the Gulf of Mexico, nutrients carried by the Mississippi River are causing a massive "dead zone" measuring 6,000 square miles (greater than the size of Connecticut).[51] Each summer off the coasts of Louisiana and Texas, this "dead zone" appears after hypoxic conditions result from the delivery of excessive levels of nutrients. The water does not contain the necessary levels of dissolved oxygen required to sustain most marine life. It is widely believed that the nutrients loading into the system are derived from non-point sources throughout the Mississippi River drainage basin (the Mississippi River drains 41 percent of the continental United States).[52]

Pathogen Contamination

Pathogens are disease-causing microorganisms found in human and animal wastes which enter estuaries through sewage treatment plant discharges, polluted urban stormwater, agricultural runoff, boating waste, and septic systems. Pathogens in coastal waters pose risks to humans who eat contaminated shellfish or who recreate in beach waters. Gastroenteritis, hepatitis, and other diseases can result from the ingestion of pathogen-contaminated waters. For this reason, beaches and shellfish beds are closed or restricted when water monitoring indicates high levels of fecal coliform bacteria (an indicator of pathogen contamination) are present in coastal waters.

In 1994, State water quality inventories indicated that fecal coliform was a suspected or potential problem in 33 of the 55 assessed waterbodies in the Terrebonne Basin, and in 18 of the 27 assessed waterbodies in the Barataria Basin.[53] Almost one-half of the Barataria Estuary's oyster beds are closed each year because of sewage-related contamination.[54] The oyster harvest areas of Bay Junop were closed in 1973, 1987, and 1988 because of pathogens.[55]

Louisiana abandoned its official program of testing its ocean and bay beach waters for swimmer

VOL 12 3587

R0036995

safety in 1988. A more limited approach of testing for "hot spots" is being considered but has not been accepted. Since the State has been monitoring its shellfish beds, it has discovered that 28 percent of the assessed estuarine areas do not meet State standards for primary body contact activities.[56]

Toxic Pollution

The water quality of the Barataria-Terrebonne Estuary System is currently threatened by pesticides, herbicides, polycyclic aromatic hydrocarbons (PAHs), DDT, chlorinated aromatic compounds (such as polychlorinated biphenyls), and heavy metals. Heavy metals which are found in elevated levels include cadmium, arsenic, lead, copper, and mercury. In addition, the pesticides mirex, aldrin, dieldrin, and heptachlor have been identified in fish tissue samples taken from the bays and lakes of the system.[57] Industrial, petrochemical and municipal discharges, septic systems, polluted urban stormwater, agricultural runoff, and atmospheric deposition are the primary sources of these chemical contaminants in the Estuary.[58]

Over 60 facilities are located along the stretch of the Mississippi River between Baton Rouge and New Orleans.[59] These plants threaten the Estuary with a variety of municipal and industrial chemical inputs. In 1993 alone, toxic emissions from industries State-wide exceeded 465 million pounds, making Louisiana the State with the greatest amount of toxic discharges into air, land and water for the fifth consecutive year.[60] Since high levels of contaminants are carried by the Mississippi and Atchafalaya rivers to the Estuary, the impacts of toxic contamination are more pronounced at the fringes of the system. Some of the identified toxic "hot spots" of the system are Segnette, Bayou Choctaw, Lower Grand River, Lake Verret, and Lake Palourde.[61]

Particles of toxic metals and organic chemicals settle in the sediments of the Estuary. Many of these toxins persist in the system and are eventually consumed by aquatic organisms. Over time, these toxins "bio-accumulate," and are passed up the food chain. Because of the persistent nature of these contaminants, chemicals which were introduced to the system decades ago may have a present-day effect on the wildlife, water quality, and human populations of the estuarine system. Toxic contamination impairs the immune, reproductive and endocrine systems of aquatic wildlife. In addition, there is growing concern about the human health risks associated with eating contaminated seafood. This is a special concern for individuals who subsist on fish and shellfish caught in urban waters.

Floatable Debris

Trash accumulated on estuarine beaches threatens the ecosystem and its wildlife inhabitants. The amount found in just one day was staggering — on September 17, 1994, volunteers cleared over 139,000 pounds of marine debris from 217 miles of Louisiana beach area. Of that total amount, 70.4 percent consisted of plastics, 11 percent was metal, 6.9 percent was glass, and 11.7 percent was other debris.[62]

The Barataria-Terrebonne National Estuary Program

The Barataria-Terrebonne Estuarine Complex was officially designated as an estuary of "national significance" in 1990 when it became part of the National Estuary Program. The Barataria-Terrebonne National Estuary Program (BTNEP) was established to help in the development of a Comprehensive Conservation and Management Plan (CCMP) for the Estuary. In December, 1993 the Management Conference of the BTNEP finalized a draft framework for the CCMP. In 1994, this framework for the CCMP was distributed for public review and comment. In December, 1995 a detailed draft CCMP was completed and made available for public review and comment. The final CCMP is expected to be approved by the Governor and the Administrator of the EPA in June, 1996.

The consensus nature of the Program laid the groundwork for many stakeholders to become engaged in the BTNEP, including: fishing and agricultural interests, oil and gas industry, shipbuilding industry, landowners, environmentalists, and the general public. The BTNEP was also responsible for

VOL 12

3588

ensuring the coordination of efforts among multiple agencies, and to facilitate joint scientific research and CCMP implementation.

The start-up phase required the BTNEP to organize a Management Conference with five committees to oversee and develop all program efforts. The second phase was the Characterization Phase. One of the first steps in this planning process was to identify the Estuary's priority problems. Seven problems were identified by the BTNEP, these include: hydrological modification, reduced sediment flows, habitat loss and modification, changes in living resources, oxygen-starved water bodies, pathogen contamination, and toxic substances.[61] Today, as part of the CCMP Development phase, the program is developing detailed action plans to address these critical pollution problems.

To accomplish all of this the BTNEP conducts numerous ongoing technical studies and public participation projects. Some of these projects include the following: Reduction of Biological Oxygen Demand in Seafood Processing Wastewater Study; Mapping Oyster-Producing Areas in the Estuarine System; Storm Water Drainage Stations: Location, Mapping, and Recommendations for Evaluation Study; Survey of Nutria Vegetation Damage; Conversion of Abandoned, Dead-End Canals to Marshlands; Monitoring Fecal Coliform; and Estuarine Workshops for Teachers.

To evaluate the success of management scenarios, the BTNEP uses state-of-the-art predictive models. These models simulate the impacts of hydrologic alterations and landscape changes on the environment.[64] This type of information is then used to support restoration advocacy and specific projects as a joint effort of the BTNEP, local grassroots groups like the Coalition to Restore Coastal Louisiana, and the State of Louisiana.[65]

As the planning phase of the BTNEP drew to a close, a major step was taken with the creation of the Barataria-Terrebonne Estuary Foundation (BTEF). This is to ensure that the plans developed by the BTNEP are actually implemented and that the public will have a major role in that work. Historically, the weak point of resource management plans created under the National Estuary Program has been the lack of any independent entity dedicated to making sure that the various agencies and interests who drafted the plans actually abide by them. The hope is that the BTEF will fill that void.

The BTEF is a nonprofit, charitable organization with a 15-member Board of Directors. The creation of the Foundation was called for in the CCMP currently being finalized by the BTNEP. The Coalition to Restore Coastal Louisiana (CRCL) helped with the preparation of the Foundation's organizational documents and is committed to helping the Foundation get off to a strong start. The Coalition's Executive Director was one of the incorporators and will serve on the Foundation's board of directors. Besides ensuring that the BTEF is funded and serves as a "watch dog" group for implementation of the CCMP, the CRCL is particularly concerned that the Program's Ecological Management Action Plans are adequately implemented. CRCL is trying to ensure that key Ecological Management Action Plans such as "Preservation and Restoration of Barrier Islands, and Freshwater and Sediment Diversions" do two essential things. First, they urge that the Coastal Wetlands Planning, Protection and Restoration Act and the Louisiana Department of Natural Resources Plans for restoration be accepted, supported, and incorporated into the CCMP by reference. Second, CRCL recommends the Action Plans detail who the implementing agencies and entities are, and how the actions will be accomplished.

Probably the biggest remaining problem challenging the restoration of the Estuary is the lack of funding. A plan exists to restore the Estuary, yet there are limited resources to aid in this task. Federal assistance can no longer be assured and the State will have difficulty allocating any funding for the Program.[66] The creation of the BTEF is a good first step but it is critical that its priority be addressing the lack of funding for implementation of the Plan.

National Coastal Caucus

The Coalition to Restore Coastal Louisiana (CRCL) is a non-profit organization formed in 1988 to address and advocate for the restoration and preservation of the Mississippi River Delta. Years of neglect and cavalier treatment have significantly impaired this unique national resource. Simply put, coastal Louisiana is disappearing at a rate of 25-40 square miles per year. Indeed, roughly every fifteen minutes an area of coastal land the size of a football field vanishes and is replaced by open water. The CRCL believes that unless major steps are taken to address this situation the entire coastal ecosystem faces collapse within the next several decades.

From the onset, the CRCL recognized that because many of the problems facing coastal Louisiana were the result of human activity, it would take human intervention to solve them. This could only be accomplished by forging a working partnership between the public, state and local governments, and the federal government, which is the very nature of the BTNEP.

The Coalition has been involved in the BTNEP since its inception. Early on, the staff and members of CRCL became integral parts of the Management Conference which developed the goals and objectives that have since driven the BTNEP process. As the BTNEP program progressed, CRCL staff and members were active on several Management Alliances, including the Ecological, Water Quality and Coordinated Planning Alliance, and drafted several Action Plans.

The CRCL has received and executed several contracts with the BTNEP. These contracts include the Public Outreach Conferences to receive feedback on the draft Action Plans, Wetland Science Workshops, and hands-on events for the public and educators. The CRCL will soon execute a contract to conduct an Environmental Technology Expo which will serve as an educational showcase and a forum for the BTNEP to exchange information with technology vendors on available technologies and unmet needs. In what may be the most important Coalition contribution, the organization was instrumental in forming the Barataria-Terrebonne Estuary Foundation, a non-governmental organization, to ensure that the CCMP is implemented. CRCL has also been involved in efforts to get the Atchafalaya River Basin included as a "mini" estuary program with reduced levels of funding, in the study area of the BTNEP. This branch of the Mississippi is the only portion of the coast that is actually building a delta, and therefore needs to be protected.

The CRCL is involved in a wide range of other activities and issues. On the grassroots level, Coalition board members are joining with parishes and local governments in southwestern Louisiana to oppose plans for "Trans-Texas Waterway" that would (as planned) divert 600 million gallons of freshwater from the Sabine River daily to serve Houston and outlying areas. Given the already severe coastal losses in southwest Louisiana, cutting off a substantial part of the flow of freshwater and sediments from the Sabine seems short-sighted.

CRCL is also engaged in advocacy programs at the federal level. CRCL, along with a number of grassroots groups are working to counter the bills going through Congress, especially H.R. 961 and its counterparts in the Senate. These groups are especially concerned about the new wetlands declassification and its effects on coastal Louisiana.

Barnegat Bay
in New Jersey

Portrait of the Bay

The Barnegat Bay National Estuary Program was established to examine the water quality and habitat problems of the Barnegat Bay estuarine system and the impact that the greater watershed has on the estuary. Barnegat Bay and Little Egg Harbor comprise the Barnegat Bay estuarine system. This system, located along the central shore of New Jersey, borders Ocean County. With a maximum depth of about 23 feet in some areas, Little Egg Harbor is a deeper estuary than Barnegat Bay.[1] The depth of Barnegat Bay ranges from 3 to 13 feet.[2]

The entire watershed of the Barnegat Bay system measures 660 square miles.[3] Residential development is the primary land use in the watershed.[4] Only five square miles of the watershed (less than one percent) is used for traditional agricultural production, farms, and berry production.[5] Since 1950, Ocean County's population (the watershed contains most of Ocean City) has expanded by 775 percent.[6] More development in the area is concentrated around the Barnegat Bay area rather than Little Egg Harbor.

Barnegat Bay	
Area of watershed	660 square miles
Depth	Ranges from 3 to 23 feet
Values	• Recreational fishing generates $1.3 billion* • Tourism in Ocean County generates over $1 million • Habitat for several federally listed threatened and endangered species
Threats	• Stormwater and polluted runoff • Nutrient loadings • Pathogen contamination • Habitat loss and degradation
CCMP status	Expected in 1998

Designated as a "Nationally Significant" Estuary in 1995

*State figure

The principal sources of freshwater to the system include the Metedeconk River, Kettle Creek, Toms River, Cedar Creek, Forked River, Mill Creek, West Creek, and Tuckerton Creek.[7] In the northern section of the system, the Manasquan River connects with Barnegat Bay via the Bay Head-Manasquan Canal; however, there is not a substantial interchange of fresh and saltwater between the Bay and River.[8] Portions of the Manasquan River are also included in the study.

A barrier island system runs along the eastern edge of Barnegat Bay, separating it from the Atlantic Ocean. The Bay's main connection to the Atlantic Ocean is through the Barnegat Inlet. Historical data on the influence of the Inlet may no longer be applicable. The United States Army Corps of Engineers recently completed a large-scale reconfiguration of the Inlet; the full impact of this project on the circulation and flushing patterns of the estuarine system are beginning to be examined.

Barrier islands also adjoin the shallower portions of Little Egg Harbor. Marshes fringe the southern and western edges of Little Egg Harbor.[9]

Values of the Bay

Barnegat Bay and Little Egg Harbor provide immeasurable benefits for both the wildlife that depend on its plentiful resources and for the surrounding communities that count on it to help generate jobs and revenue for the local economy. The Barnegat Bay system also supports diverse

fisheries, tourist attractions, recreational opportunities, and critical wildlife habitat.

Tourism/Recreation

Tourism in Ocean County generates about $1 million annually.[10] Recreational activities, such as boating and fishing, are attractive activities which lure many visitors to this portion of the New Jersey coast. Motor boats, sail boats and yachts also use portions of the system. In 1988, over 53,000 boats used Barnegat Bay.[11] A total of 116 marinas and other boat launching sites are situated within the watershed.[12] Canoeists and kayakers are drawn to the waters within the Island Beach State Park, the Edward B. Forsythe National Wildlife Refuge, and the Manahawkin Wildlife Management Area.

Both Little Egg Harbor and Barnegat Bay are important to the State's recreational fishing industry as fishing grounds and as important habitat for juvenile fish which may be caught in other areas of the State. Recreational fishing is a popular summer activity in the Little Egg Harbor, and thereby helps to support a number of small businesses which cater to anglers. In 1991, recreational fishing in New Jersey generated approximately $1.3 billion in economic output and employed approximately 17,000 people.[13] In 1991, approximately 746,000 saltwater anglers spent over six million days fishing off the coast of New Jersey. Thirty-two percent of the anglers were non-residents of the State.[14]

Fisheries/Seafood

The Barnegat Bay system contributes valuable fishery resources to the mid-Atlantic region of the United States. In 1994, the combined value of the mid-Atlantic commercial finfish and shellfish landings totaled approximately $149 million. In that same year the State of New Jersey's commercial finfish and shellfish landings totaled approximately 202 million pounds, valued at approximately $100 million.[15]

Barnegat Bay and Little Egg Harbor sustain important local and regional fisheries. The estuaries and their surrounding wetlands are important nursery areas for a variety of shellfish and finfish, many of which are commercially valuable and/or prized by recreational anglers. In 1988, the estimated value of commercial landings of inshore hard clams, blue crabs, white perch, and American eels in Ocean County was $2.7 million.[16] Prominent species of finfish found in the system include winter flounder, white perch, inland silverside, northern pipefish, bluefish, and striped bass.

The most valuable commercially-caught species in the area is the inshore hard clam. In some years revenues derived from hard clam represent as much as 60 percent of the total value of commercial fisheries in Ocean County.[17] In 1988, the value of hard clam landings was nearly $2.2 million.[18] Between 40 and 50 percent of all commercial inshore hard clam landings in New Jersey occur in Ocean County waters.[19] Another important species found in Barnegat Bay is the blue crab. Blue crab landings from this area comprise about 10 to 15 percent of the State's total blue crab landings.[20]

Wildlife

The Barnegat Bay system is used by an abundance of wildlife. Thousands of waterfowl and shorebirds use the estuarine area for nesting and wintering grounds, and for stopover points during migrations. Common bird species which nest in the Bay area include the great egret, piping plover, herring gull, and laughing gull. Additionally, tri-colored herons, least terns, black skimmers, and snowy egrets nest in the area, however, the populations of these bird species are in decline. Migratory birds using the Atlantic flyway can be spotted during the fall months on the Island Beach State Park, a large tract of undeveloped shore.[21]

New Jersey has nineteen species federally-listed as threatened or endangered.[22] The Bay system provides important habitat for several of these species, including the endangered least tern, piping plover and the threatened Ipswich sparrow.[23] The diamondback terrapin, a candidate for federal protection, also uses the Bay area for breeding grounds.[24]

Threats to the Bay

The problems of the Barnegat Bay estuary system are currently being explored. Studies indicate that the most significant threats to the system are contaminated stormwater and polluted runoff, nutrient loadings, pathogen contamination, and habitat loss. Population growth and accompanying development within the watershed are principal factors of each of these environmental problems.

Stormwater and Polluted Runoff

To support the rapidly growing population in the region, land usage within the watershed has increasingly become more developed and urbanized. As a result of this development, wetlands, forests and other natural areas have been replaced with impervious surfaces, such as roofs and pavement. The increase in impervious surface area affects the water quality of the Barnegat Bay system and its tributaries. Without natural land to absorb excess rain and filter contaminants, greater concentrations of contaminants in more significant flows reach the estuary. Oil and grease from streets and parking lots, bacteria, lawn care products, and heavy metals are introduced to the estuary by stormwater. Due to the land use patterns of the Bay system, polluted runoff is a greater concern in the northern portion of the system. There is a significant need for a more detailed analysis regarding the impact that human land-based activities have on the water quality of the estuary.

Nutrient Loadings

Nutrients, such as nitrogen and phosphorus, are introduced to the estuary by urban stormwater, sewage treatment plants, atmospheric deposition, and boater discharges. Excessive levels of these nutrients stimulate the growth of algae in the Bay. As the algae grow, they not only block sunlight needed by the submerged aquatic vegetation of the Bay, but also require a great amount of dissolved oxygen to decompose. The decomposition process reduces the levels of oxygen for other aquatic life. Low oxygen conditions (called hypoxia) can result in large fish kills. Thus, excessive nutrient loadings in estuaries can jeopardize economic stability of fisheries-dependent communities. The over-enrichment of nutrients in waterbodies is called eutrophication.

In the Barnegat Bay and Little Egg Harbor, fertilizers and pesticides used on domestic lawns are considered to be major contributors to the high nitrogen levels of the estuary. The shallow Barnegat Bay and embayments of the system are susceptible to the effects of nutrient loadings. Recently, a "brown tide" organism, *Aureococcus anophagefferens*, has been observed in the Bay. This organism has afflicted submerged aquatic vegetation and shellfish populations of the Peconic Bays.

Pathogen Contamination

Pathogens are disease-causing microorganisms found in human and animal wastes which enter estuaries through urban stormwater, sewage treatment plant discharges, boating waste, and individual septic systems. Pathogens in coastal waters pose risks to humans who eat contaminated shellfish or who recreate in beach waters. Gastroenteritis, hepatitis, and other diseases can result from ingestion of pathogen-contaminated seafood or water. For this reason, beaches and shellfish beds are closed or restricted when standards for fecal coliform bacteria or total coliform are exceeded. Fecal coliform and total coliform are indicators of pathogens. New Jersey has an extensive recreational beach monitoring program that includes mandatory closure requirements when water quality standards for swimmer safety are exceeded. Following heavy rains, many beaches along the New Jersey shore are closed for public health reasons.

Shellfish bed restrictions caused by high levels of pathogens are common in the northern portion of Barnegat Bay and its tributaries.[25] In 1990, 44 percent of all shellfish beds in Barnegat Bay were harvested-limited, primarily due to pathogen contamination.[26]

Habitat Loss and Degradation

The loss or modification of habitat is another concern that jeopardizes the health of Barnegat Bay. Issues that will continue to be addressed include the impacts of dredging operations on marinas and the Intracoastal Waterway, as well as the protection of barrier islands, coastal wetlands, and submerged aquatic vegetation.[27]

Eelgrass in the estuary has been adversely affected by increased nutrient inputs and human activities, such as dredging and boating. However,the extent of the damage is unknown because mapping of the eelgrass coverage has not been conducted since 1986, and therefore, current information is not complete.

New Jersey has lost over 584,000 acres, or 39 percent, of its original wetlands.[28] Many of these wetlands losses have occurred along New Jersey's coasts. In the Barnegat Bay watershed, significant acreage of both coastal and freshwater wetlands has been modified or destroyed. Between 1953 and 1973, over 37,000 acres of tidal wetlands were destroyed in Ocean County — a loss of over 30 percent.[29]

The local population of the Barnegat Bay area has participated in campaigns to acquire critical habitat for the public trust.[30] The coordination of habitat acquisitions for the protection of wildlife has been identified as a priority by the Management Conference of the Barnegat Bay Estuary Program.

Floatable Debris

Trash accumulated on estuarine beaches also threatens the ecosystem. The amount found in just two days was staggering — on October 15 and 22, 1994, volunteers cleared over 73,700 pounds of marine debris from 171 miles of New Jersey's beaches. Of the total amount of marine debris collected, 66.3 percent was plastics, 10.4 percent was paper, 8.2 percent was metal, and 15.1 percent was from other materials.[31]

The Barnegat Bay National Estuary Program

With the Environmental Protection Agency's acceptance of Barnegat Bay into the National Estuary Program, it became one of the most recent group of seven estuaries added to the Program. On July 6, 1995 Barnegat Bay was officially designated an estuary of "national significance" under the National Estuary Program of the Clean Water Act. Shortly thereafter, the EPA convened a Management Conference responsible for coordinating the development of a Comprehensive Conservation and Management Plan (CCMP) to restore and protect the Barnegat Bay. The CCMP is expected to be completed in three years.

A management plan for Barnegat Bay already exists due to a decade of work by interested parties. Local citizens have played integral roles in developing the existing plan and in nominating Barnegat Bay to be included in the NEP. These citizens are interested in commencing interim actions of the existing restoration plan.

Buzzards Bay
in Massachusetts

Buzzards Bay is a multiple use estuary. We rely on its waters for food and shellfish production, in addition to its value for recreation, tourism and pleasure. On the darker side, Buzzards Bay is also used as an outfall for sewage discharges and road runoff, and as a major shipping and transit route through the Cape Cod Canal. Despite large areas of undeveloped land remaining within its watershed, one of the major threats to Buzzards Bay is excessive nutrient loading. We are slowly learning how to balance these uses, with emphasis on the regional challenges of proper watershed planning, development, and protection of natural resources. Our vision for the future is to stay vigilant and protective of this beautiful and diverse estuary for generations to come.

— Pamela Truesdale, Executive Director
The Coalition for Buzzards Bay

Portrait of the Bay

The Coalition for Buzzards Bay is working in concert with the Buzzards Bay Project to examine the water quality and habitat problems of the Bay and the impact that the greater watershed area has on the estuarine system. The surface water area of Buzzards Bay measures approximately 228 square

Buzzards Bay

Area of surface water	228 square miles
Area of watershed	432 square miles
Average depth	36 feet
Shoreline	280 miles
Population	236,000 people
Values	• Fisheries generate $206 million*
	• Sport fishing generates $767 million in economic output*
	• Habitat for 98% of endangered roseate terns in North America
Threats	• Nutrient loadings
	• Pathogen contamination
	• Toxic pollution
	• Population growth and development
	• Floatable debris
CCMP status	Approved in 1992

Designated as a "Nationally Significant" Estuary in 1988.

miles.[1] The Bay is bordered by southeastern Massachusetts to the west, the Elizabeth Islands to the south, and Cape Cod to the east. The Cape Cod Canal in the northern part of the Bay connects Buzzards Bay to Cape Cod Bay. Buzzards Bay contains 280 miles of jagged shoreline, of which 11 miles are public beach. The average depth of the Bay is 36 feet.[2]

The Buzzards Bay watershed area encompasses approximately 432 square miles. Within this area, the population exceeds 236,000 people, representing a density of 540 people per square mile. Seventeen municipalities are entirely or partially located within the watershed.[3] Of these, the city of New Bedford and the coastal communities of Dartmouth, Falmouth, and Fairhaven have the largest populations. In fact, New Bedford constitutes approximately 40 percent of the watershed population.[4] Also included in the watershed are two of the fastest growing counties in New England, Barnstable and Plymouth counties.[5]

Groundwater and a number of rivers provide the freshwater flow into the Bay. Along the western shore, the prominent rivers delivering freshwater to the Bay include the Agawam, Wankinco, Weweantic, Mattapoisett, Acushnet, Paskamanset, Westport and several others. Groundwater is the major freshwater source on the eastern shore. The smaller streams that drain this portion of the watershed include the Herring Brook and the Back, Pocasset, and Wild Harbor rivers.[6]

The jagged coastline creates a wealth of diverse tidal habitat for marine life, including, approximately 5,000 acres of salt marsh, 5,000 acres of tidal flats, 1,700 acres of barrier beaches, and subtidal areas.[7] More than 10,500 acres of eelgrass beds, which support a diversity of marine life, can also be found in the Bay.[8]

Values of the Bay

Buzzards Bay affords numerous benefits for residents and tourists of southeastern Massachusetts. Valuable commercial shellfishing resources, tourist attractions, scenic vistas, and good water quality are just a few of the reasons why people flock to Buzzards Bay. In addition, nearby academic and scientific institutions, such as Woods Hole Oceanographic Institution (WHOI) and the Marine Biological Laboratory, conduct extensive research on coastal waters in the Bay.

Recreation/Tourism

Buzzards Bay provides numerous recreational opportunities for tourists and residents within the watershed. Tourists in the coastal counties of Massachusetts spent an estimated $1.5 billion in 1993.[9] Boating, sport fishing, and sunbathing on area beaches are common activities in the area. Nearly 20,000 marine vessels pass through Cape Cod Canal annually and about 10,000 vessels anchor in the Bay throughout the summer.[10]

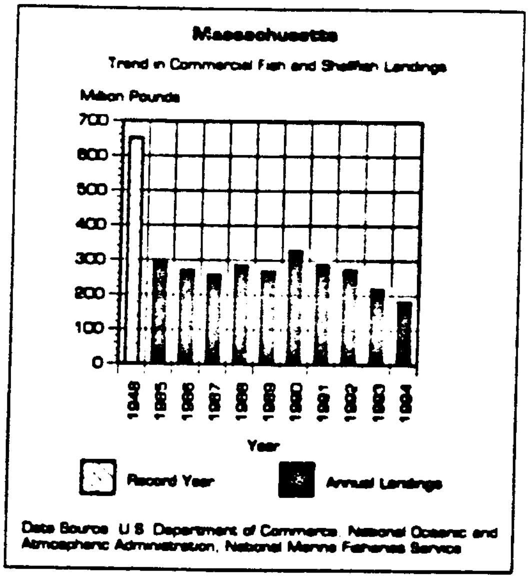
In order to maintain the interests of tourists and to expand the tourist and recreational revenues generated in the Bay area, it is essential that the water and beaches are kept clean. A significant amount of revenue is generated each year by public beach parking. For example, parking sticker sales at just three Massachusetts' beaches netted $1.6 million in 1990.[11]

Recreational fishing in Massachusetts generated approximately $767 million in economic output and employed nearly 10,450 people in 1991.[12] Saltwater fishing alone draws thousands of persons to Massachusetts each year. In 1991, approximately 393,000 saltwater anglers fished a total of 3.2 million days off the Massachusetts coast. Thirty percent of these fishermen were non-residents of Massachusetts.[13]

Fisheries/Seafood

In 1994, the combined market value of commercial finfish and shellfish landings in the New England region totaled approximately $583 million.[14] Many of the commercially valuable species in the New England region depend upon the health of Buzzards Bay for survival. In 1994, the State of Massachusetts' commercial finfish and shellfish landings totaled approximately 183 million pounds, valued at $206 million.[15] Massachusetts is second only to Maine in annual landings of lobster.

Buzzards Bay is highly acclaimed for its shellfish harvests. In 1988, the value of the Bay's commercial



shellfish harvest was $4.5 million — almost 24 percent of the total State shellfish harvest.[16] Bay towns issued 485 commercial, 9,144 nonresident, and 3,168 recreational shellfish permits in 1994.[17] In the same year, the Bay's combined commercial and recreational quahog, bay scallop, soft shell clam, and oyster harvest was valued at $6 million.[18]

While Buzzards Bay provides critical nursery habitat for lobster larvae, its warmer temperatures and sandy bottom inhibit the development of a larger fishery for adult lobsters, which prefer colder waters. Nevertheless, the Bay's lobster harvest produces approximately 253,000 pounds, an average annual retail value of one million dollars to the local economy. In 1988, the total value of the Buzzards Bay lobster fishery, including lobster landings, gear, and vessels was approximately $2.3 million. In that same year, approximately 250 commercial lobstermen fished for lobsters in Buzzards Bay.[19]

Wildlife

Geographically, Cape Cod represents the division between the colder climate waters of the Gulf of Maine and the more temperate, mid-Atlantic coastal region.[20] As a result, species diversity is uncommonly high in the Bay. Since the Bay is situated on the edge of this transition zone, it is in the southernmost range for many northern species and the northernmost for many semi-tropical creatures.

Waterbirds, including the osprey, populate the islands and shoreline of Buzzards Bay. Decades ago, the osprey population was decimated by DDT-related reproductive problems. By the late 1980s, years after the banning of DDT, osprey sightings began to slowly occur again throughout the Bay. Wading birds, such as snowy egrets and black-crowned night herons, use the shoreline of the Bay for nesting grounds. A number of waterfowl, such as common eiders, Canada geese, canvasbacks, and black ducks also inhabit Buzzards Bay.[21]

A few species of marine mammals can also be found in the Bay. The most common is the harbor seal, which primarily uses Gull Island in the Bay for wintering habitat. On rare occasions, grey seals, whales, porpoises, and dolphins can be observed in the Bay.[22]

Massachusetts has twenty-two species on the federal endangered and threatened species list,[23] of which seven are wetlands-dependent.[24] The threatened bald eagle and piping plover, and the endangered roseate tern are protected bird species which use the estuarine wetlands in Massachusetts during their life cycles.[25] Bird Island of Buzzards Bay remains a critical nesting area for 98 percent of the roseate terns in North America. In addition, endangered leatherback and Kemp's ridley sea turtles live in the Bay.[26]

Threats to the Bay

Despite localized toxic contamination in the Acushnet River adjacent to New Bedford, the site of the largest marine Superfund project in the nation, Buzzards Bay has avoided many of the Bay-wide water quality problems to the degree that they plague other more urbanized coastal watersheds on the eastern seaboard. Nevertheless, land use practices and a growing population have degraded the Bay's natural resources, particularly in the Bay's 32 small embayments and harbors where the impacts of inappropriate development activities affect the estuary most severely. The limited flushing capacity of these areas further intensifies the decline of valuable resources such as eelgrass and shellfish habitat.

The Buzzards Bay Program has identified excessive nutrient loadings, pathogen contamination, and toxic contamination as the priority threats to the health of the ecosystem.[27] Land use practices and marine debris pose additional threats to the Bay system.

Nutrient Loadings

Excessive nutrient loading poses the greatest long-term threat to Buzzards Bay. Nutrients, such as nitrogen and phosphorus, are introduced to the estuary through a variety of sources, such as individual septic systems, sewage treatment plants, agricultural runoff, atmospheric deposition, and lawn care products. Groundwater underflows, point source outfalls, and stormwater deliver the nutrients to the estuary. Nutrient enrichment causes increased algae growth that eventually starves the water of oxygen. Nutrient impacted waters can become visibly cloudy thereby blocking sunlight needed by eelgrass beds. In addition, drift algae smother shellfish beds. Algae require a great amount of dissolved oxygen to decompose, creating low oxygen conditions which stress fish life and cause foul odors.

Over 62 percent of the nitrogen contribution to the Bay comes from sewage treatment plants and combined sewer overflows.[28] The sewage outfalls are situated in the deeper and better flushed portions of the Bay; as a result, the effects of nitrogen loadings are restricted to the areas around the outfall.[29] In the shallower embayments of the estuary, the majority of nitrogen is from individual septic systems. In fact, septic systems far from the coast can contribute excessive nutrient loadings through groundwater transport if they lie in the watershed of an embayment or harbor. Due to the diminished flushing capacities of these embayments, the effects of nitrogen inputs are more significant.

Pathogen Contamination

Pathogens are disease-causing microorganisms found in human and animal wastes which enter estuaries through sewage treatment plant discharges, combined sewer overflows (CSOs), polluted urban stormwater, agricultural runoff, boating waste, and septic systems. Pathogens in coastal waters pose risks to humans who eat contaminated shellfish or who recreate in beach waters. Gastroenteritis, hepatitis, and other diseases can result from ingestion of pathogens. For this reason, beaches and shellfish beds are closed or restricted when water monitoring indicates high levels of fecal coliform bacteria or enterococcus (indicators of pathogen contamination) are present in coastal waters.

Sewage treatment plants and individual septic systems are significant sources of pathogens which enter Buzzards Bay. Over 37 million gallons of treated sewage from five municipal wastewater treatment plants enter Buzzards Bay each day.[30] Occasionally, these plants will malfunction and release wastewater containing pathogens. The construction of a secondary treatment facility in New Bedford will soon eliminate the largest source of primary treated sewage to the Bay. Combined sewer overflows in New Bedford, however, continue to discharge large amounts of untreated, raw sewage during significant rainfalls when the city's antiquated collection system is unable to handle the combined sewage and stormwater flow. There are 38 CSO discharges in the New Bedford and Clark Cove areas of the Bay.[31]

Localized pathogen contamination of many smaller embayments and the resulting closure of shellfish beds and swimming beaches are mainly attributed to old, failing septic systems along the shore and the conversion of many summer communities into year-round neighborhoods. Almost one-half of the watershed's residents use septic systems and cesspools to dispose of their sanitary waste.[32]

Between 1985 and 1990, the percentage of harvest-limited shellfish beds in Buzzards Bay increased from seven to 48 percent.[33] In January 1995, 13,648 acres of shellfish beds were closed due to fecal coliform contamination, and 3,949 acres were conditionally restricted based on rainfall and seasonal events.[34] Closed shellfish beds create economic problems for the shellfishermen and local communities dependent upon shellfish resources. In the New Bedford Harbor, it is estimated that the lost value of closed quahog beds is $5 million. In addition, the annual loss of revenue caused by the closed lobster fishery in the Harbor is $250,000.[15] These closures cause fishermen to begin fishing for less desirable species. As more commercial fishermen seek fewer fish, increased pressures for maintaining productive populations arise.

The positive effects of shellfish bed reopenings were revealed in 1992, when Clark's Cove in New Bedford was reopened after nearly 80 years of public health closure. The first year of shellfish revenues from the Cove resulted in more than one million dollars.[16]

Toxic Pollution

Between the 1940s and 1970s, industries within the greater New Bedford area contaminated the Bay with polychlorinated biphenyls (PCBs), hydrocarbons, and trace metals. High PCB levels are responsible for the closure of 18,000 acres of productive lobster and fishing grounds around New Bedford Harbor.[17] Sediment, lobster, fish and shellfish samples from the New Bedford area reveal significant levels of toxic pollutants. Samples of lobster tomalley and hepatopancreas are sometimes close to the FDA limit.[18]

Population Growth and Development

Each of the major threats mentioned above is directly related to the region's historic and continuing population growth and the misuse of land. Since 40 percent of the land situated within one-half mile of the Bay's coast is forested, land management is critical to the future of this estuary. Maintaining the benefits of forests, wetlands, and other natural habitats will assist in restoring the Bay. Wetlands and other natural lands absorb and filter pollutants before they can enter the Bay, as opposed to pavement, roofs, and other impervious surfaces that aid in the direct discharge of pollution into the Bay. Thus far, Bay-wide efforts have not adequately addressed open space protection and land use planning. Communities surrounding the Bay must better manage the effects of polluted stormwater resulting from urban and residential development.

Floatable Debris

Trash accumulated on estuarine beaches threatens the ecosystem and its wildlife inhabitants. During the period between September 17 and October 10, 1994 several beach clean-ups were conducted in which volunteers cleared 50,000 pounds of marine debris from 200 miles of Massachusetts beaches. Of the total amount of marine debris, 61.8 percent was plastic, 13.9 percent was paper, 8.9 percent was metal, and 15.4 percent was other debris.[19]

The Buzzards Bay Project

In 1985, the Environmental Protection Agency completed a study of estuaries which revealed the ecological health crises facing the nation's coastal waters. As a result of this research, Buzzards Bay was selected in 1988 as one of the original estuaries of "national significance" to be included in the National Estuary Program. The Massachusetts Office of Coastal Zone Management in cooperation with EPA Region I has authority over the Buzzards Bay Project (BBP). In 1992, the Buzzards Bay Comprehensive Conservation and Management Plan (CCMP) became the second plan in the NEP to be approved by the EPA Administrator. It is now in its fourth year of implementation. In the same year, the Buzzards Bay Action Compact which endorsed the implementation of the eleven action plans outlined in the CCMP, was also signed by the twelve coastal municipalities in the watershed.[20]

Key stakeholders of the Bay Project are the citizens and the municipalities, each of which has its own needs and priorities that are not always consistent with one another. As a result, the Citizens Advisory Committee of the BBP split into two independent non-profit organizations during the early stages of the planning process. The voice of the citizens and environmental groups joined under the umbrella of the Coalition for Buzzards Bay, while the cities and towns have representation under the Buzzards Bay Action Committee.

The principal mission of the Buzzards Bay Project is to provide financial and technical assistance to municipal governments to help reverse the major problems of the Bay. The BBP

VOL 12

3704

engaged the municipal governments early on in the process of developing the CCMP. It was clear that the local governments had the greatest authority, particularly under the "home rule" concept in Massachusetts, as well as the capacity to manage the polluted runoff problems plaguing the Bay. Through NEP funding, mini-grants are provided to communities to fund model projects addressing water quality declines and resource management issues. Modest forms of financial assistance have been able to augment considerable local actions to protect the Bay. Tax incentives have also proven to be a valuable land use tool contained in the CCMP. Land owners are offered tax incentives in exchange for the development rights to their properties.

National Coastal Caucus

The Coalition for Buzzards Bay is leading citizen efforts to save the Bay. The Coalition for Buzzards Bay (CBB), a private non-profit organization founded in 1987, currently includes nearly 2,800 members. CBB promotes environmental education and awareness in its work to protect and restore Buzzards Bay and its greater watershed.

The CBB currently has three programs which enlist citizen participation. The Coalition was granted NEP funding to establish a citizen monitoring network. This network of 100 volunteers tests 87 sites within embayments throughout the Bay on a weekly basis.[41] This program is one of the most ambitious citizen monitoring projects in the nation. Results are used to assess current conditions and trends as well as target areas for cleanup activities. The CBB's Water Quality Monitoring Program involves citizens in hands-on action and is the largest, ongoing monitoring effort in the Bay. CBB has completed four years of data collections from the water quality monitoring program, and has provided a "snapshot" view of the health of Buzzards Bay. This analysis, in turn, is used by the communities within the watershed to determine nitrogen loading limits and developmental buildouts. The Program has also developed a model nitrogen management strategy to control the residential nitrogen inputs to Buttermilk Bay, a small embayment near the Cape Cod Canal. This land use approach to coastal resource planning is currently being applied to four additional embayments in Buzzards Bay.

CBB also has a corps of trained volunteers who monitor key local governing boards such as Conservation Commissions, Boards of Health, and Planning Boards, who are responsible for decisions which affect Buzzards Bay. Under the "home rule" concept, local ordinances can be written to be more protective than state laws. These Coalition monitors work to ensure that the decisions made by these agencies reflect a consistency throughout the region to protect the Bay and its watershed.

Educational efforts include school projects in the City of New Bedford as well as community efforts to discourage dumping into local storm drain systems. CBB has created a nature trail for the schools, organized beach cleanups and promoted bi-lingual stenciling of storm drains which discharge directly into Buzzards Bay. They have also sponsored an annual 1.18 mile swim across part of the Bay to celebrate the improving water quality.

The "Municipal Report Card" is a progress report released annually by the CBB that critiques municipal governments' efforts to meet CCMP goals, and has been highly effective at targeting and engaging communities in Bay restoration.

VOL 12

Casco Bay
in Maine

Casco Bay isn't dead. It doesn't have a fatal wound either. But, it's suffering from a lot of cuts. This presents an inescapable opportunity for us. As in dozens of estuaries around the country, the problems are of a human scale — we can work on them; we can see the results; we can win. It is vitally important that Friends of Casco Bay continues its activities toward improving the health of the Bay and that the community support implementation of the Casco Bay Estuary Project Management Plan. We have the opportunity to get to a point where we won't have to revive what isn't dead; we won't have to save what isn't threatened; we won't have to pay big dollars for mistakes we didn't make.

— Joe Payne, Casco BayKeeper
Friends of Casco Bay

Portrait of the Bay

Casco Bay is located on the southeastern coast of Maine. The Bay's shoreline stretches for 578 miles from Cape Elizabeth on the west to Cape Small Point on the east. The Bay measures 229 square miles in size.[1] Its average depth is 42 feet.[2]

The Casco Bay watershed area encompasses 985 square miles in southern Maine.[3] It is the most industrialized watershed in the State.[4] Forty-one municipalities are located within the Casco Bay watershed, including the cities of Freeport, Falmouth, Westbrook, Portland and South Portland.[5] The watershed's population is 251,000.[6] Twenty-seven percent of Maine's coastal population lives near Casco Bay.[7]

3707

Casco Bay

Area of surface water	229 square miles
Area of watershed	985 square miles
Shoreline	578 miles
Average depth	42 feet
Population	251,000 people
Values	• Fisheries generate $243 million*
	• Boating generates $85.2 million*
	• 750 islands provide habitat in the Bay
Threats	• Pathogen contamination
	• Nutrient loadings
	• Toxics/contaminated sediments
	• Floatable debris
CCMP status	Final CCMP expected in 1996

Designated as a "Nationally Significant" Estuary in 1990.

Freshwater is delivered to the Bay by the Fore, Presumpscot, Stroudwater, and Royal rivers and a number of smaller rivers and streams. In addition, waters from Sebago Lake feed the estuary.[8] However, compared to the nation's other estuaries, the amount of freshwater inflow to Casco Bay is less than average.

The Bay's rocky coastline and more than 750 islands, provide unique habitats for invertebrates and nesting areas for waterbirds.[9] Other common types of habitat include sand and mud flats, eelgrass beds, mussel bars, salt marshes, and freshwater wetlands.[10] Geographic Information System (GIS) mapping in 14 coastal communities of the Casco Bay area has measured approximately 12,100 acres of flats; 1,355 acres of eelgrass beds; 4,100 acres of salt marsh; and 15,200 acres of freshwater wetlands.[11]

Values of the Bay

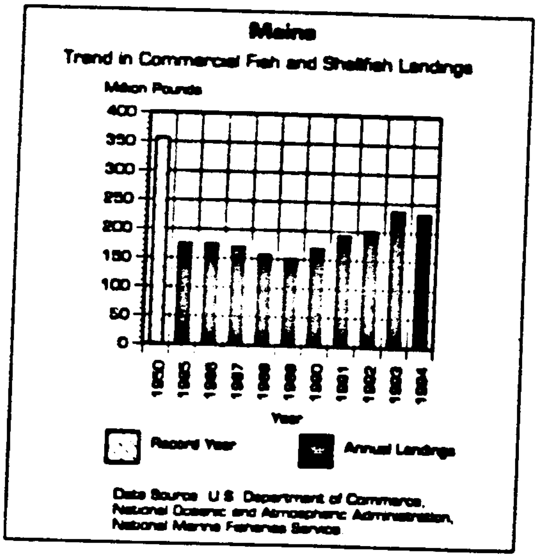
Casco Bay and its living resources attract both in-state and out-of-state residents. The Bay's intrinsic beauty and its popularity as a hub for recreational boating and fishing add significant revenue to the local and regional economies. The variety of productive habitats within the Casco Bay watershed also support a number of invertebrate, fish, and bird species.

Fisheries/Seafood

In 1994, the combined market value of finfish and shellfish landings in the New England region totaled approximately $583 million. Many of the commercially valuable species in the New England region depend upon the health of Casco Bay for survival. In 1994, the State of Maine's commercial finfish and shellfish landings totaled approximately 231 million pounds, valued at $243 million.[12]

Lobster is one of Maine's most commercially valuable fisheries. Twenty percent of Maine's lobster landings occur in Cumberland County, which borders the Bay.[13] The Bay's ledges, rocky bottoms, and high salinity levels provide ideal habitat for lobster. In addition, soft-shell clams and crabs caught from Casco Bay account for a large portion of Maine's total landings. Mussels and scallops are also caught in Casco Bay.

At least 36 finfish species inhabit the Bay.[14] Herring and menhaden are two chief commercial finfisheries of Casco Bay. Other fish species which inhabit the Bay include winter flounder, pollock, sculpin, rock gunnel, Atlantic shad, and skate.[15] Striped bass, alewife, rainbow smelt, and shad are anadromous fish which pass through Casco Bay to reach freshwater spawning grounds. Bluefin tuna also use the Bay.[16]



Recreation/Tourism

Maine's coasts provide a popular vacation spot for visitors, recreational boaters, and sport fishermen. Although the figures date back to the late 1980s, the data in the Estuary Project's preliminary plan for Casco Bay indicate that the annual revenue generated from tourist and recreational activities in the Casco Bay area was over $250 million.[17] Clearly, those values have increased today. The growing recreational use of the Bay and the resulting revenue, have raised public awareness about the potential adverse effects — such as reductions in water quality — that personal actions can have on the Bay.

The islands and coves of Casco Bay draw many sail and power boats to the area. There are at least 19 marinas in the Bay, with an average of 100 slips per marina, and about 3,400 moorings.[18] In 1989, the towns of the Casco Bay region had more than 12,000 boats registered, which generated over $328,000 from excise taxes and registration fees.[19] Figures for 1990 reveal that the State of Maine registered 112,559 boats, generating $85.2 million in boating equipment, sales and rentals for that year.[20]

Recreational fishing is another common activity for residents and visitors. In 1991, fresh- and saltwater recreational fishing in Maine generated $340 million and employed nearly 6,500 people.[21] Mackerel, pollock, flounder, haddock, cod, bluefish, bluefin tuna, and striped bass are the most sought-after sport fish in the Bay.[22] In 1991, approximately 143,000 saltwater anglers spent 843,000 fishing days off the coast of Maine. Fifty-four percent of these anglers were non-residents of the State.[23]

Other popular recreational activities around Casco Bay include sea kayaking, birdwatching, hiking, and camping. Three state parks — Two Lights in Cape Elizabeth, Wolf Neck Woods in Freeport, and Andrews Beach on Long Island — are situated in the Casco Bay region. In 1988, attendance records for these three parks indicated that there were 129,736 visitors. Of these three parks, Wolf Neck Woods is the only one that charges visitor parking fees. In 1988, the revenue generated from these parking fees at Wolf Neck Woods was almost $46,000.[24]

Wildlife

In the late nineteenth century, marine biologists began seriously studying Casco Bay and its wildlife diversity. The Bay has a range of habitat which supports species native to both northern and southern ecoregions.[25] Therefore, this estuarine transition zone hosts an abundance of life. For example, a 1983 study of the Bay revealed that the mean density of organisms inhabiting the Bay was 8,743 organisms per square meter; in contrast, Delaware Bay's mean density was 722 organisms per square meter.[26]

Over 150 waterbird species inhabit the coastal areas of Maine. About 164 seabird colonies of double-crested cormorants, eiders, black guillemots, and others are found on the unpopulated islands of Casco Bay.[27] Loons, grebes, and snow geese use the Casco Bay area for wintering habitat. Other common wildlife species observed around the Bay include harbor seals, whales, porpoises, and dolphins.

Federally-listed endangered and threatened species also depend on the Bay habitats for survival. The endangered bald eagle feeds in areas along the Bay, and the endangered roseate tern nests on two islands of the Bay.[28] In addition, the threatened piping plover depends on Maine's estuarine wetlands.[29]

Threats to the Bay

During the past twenty years, the amount of developed area in the lower Casco Bay watershed doubled because of the growth in Portland, South Portland, and Westbrook.[30] This urban sprawl has resulted in the construction of more impervious surface areas, such as roofs and pavements, within the watershed. The loss of natural areas that absorb and filter contaminants, such as wetlands and vegetated lands, has significantly contributed to water quality declines throughout the region.

Polluted urban stormwater is one of the leading sources of pollution in Casco Bay.[31] Stormwater delivers a substantial amount of heavy metals, nutrients, pathogens, organic chemicals, sediments, and floatable debris to Casco Bay during snow melts and heavy storms. This source of pollution accounts for 50 percent of the hydrocarbons and over 80 percent of the lead entering the Bay.[32] In the Portland region of Casco Bay, water quality standards are regularly exceeded during storm events. To better manage this problem, the municipalities of Portland, South Portland, and Westbrook are planning stormwater infrastructure upgrades.[33]

Evidence of Casco Bay's pollution problems has been mounting since the early 1980s. Due to past industrial activities within the region, toxic contaminants have accumulated in Casco Bay's sediments and waterways. However, most of the build-up is concentrated in Portland Harbor. In addition to toxic pollution, excess nutrients and pathogens contribute to the Bay's water quality problems and adversely affect the aquatic life. Finally, because Portland is an active shipping port, potential threats from shipping traffic and accidental vessel and tanker spills are of great concern.[34]

Through the Casco Bay National Estuary Program, the priority problems afflicting Casco Bay are being identified, and actions to restore the Bay are being developed. To date, priority problems of the Bay include pathogen contamination and increased nutrient loadings resulting from polluted urban stormwater, combined sewer overflows, and failed septic systems. In addition, toxics, contaminated sediments, poor land use planning, population growth, and floatable debris pose threats to the vitality of the Bay system.[35]

Pathogen Contamination

Pathogens are disease-causing microorganisms often found in human and animal wastes. Pathogens enter Casco Bay through several sources including combined sewer overflows (CSOs), polluted urban stormwater, direct boater discharge, and septic system failures. CSOs occur when the volume of water collected during rainstorms exceeds the holding capacity of combined sewer and stormwater conveyance lines. The result is the discharge of raw sewage and industrial wastewater into the Bay. There are approximately 75 CSO outfall pipes along Casco Bay and its tributaries.[36]

Overboard discharge systems are a type of septic system prevalent in the Casco Bay region. They were installed to replace straight pipes that discharged raw waste into the Bay. However, because these systems were deemed ineffective due to the high level of maintenance required, the Federal Food and Drug Administration determined that overboard discharge systems are a potential source of pathogens and their mere presence warrants the closure of nearby shellfish beds.[37] Although 355 systems are licensed within the Bay area to discharge up to 300 gallons of treated effluent each day, the State legislature has prohibited the issuance of new overboard discharge permits and has initiated a grant program to encourage their removal or replacement.[38]

Pathogens in coastal waters pose health risks to humans who eat contaminated shellfish or ingest polluted beach waters. Gastroenteritis, hepatitis, and other diseases can result from the ingestion of pathogen-contaminated water. For this reason, beaches and shellfish harvest areas are closed or restricted when water monitoring indicates that high levels of enterococcus or fecal coliform bacteria (indicators of pathogens) are present in Maine's coastal waters.

Three beaches on Peaks Islands have been permanently closed since 1991 because of high levels of pathogens. Portland's East End Beach was closed for approximately two weeks during the summer of 1994 for the same reason.[39] Clam beds are also affected by pathogen contamination in the Bay. In 1990, 43 percent of the Bay's 11,112 acres of clam flats were closed — up from 38 percent in 1989.[40]

Nutrient Loadings

Nutrients, such as nitrogen and phosphorus, reach the estuary in a path similar to pathogens. Leading sources of nutrients into the Bay include polluted urban stormwater, CSOs, sewage treatment plants, failed septic systems, boater discharges, agricultural runoff, and atmospheric deposition. More than 25 percent of the total input of nitrogen and phosphorus to the Bay originates from fertilizer runoff from agricultural land.[41]

Individual septic and overboard discharge systems, which are not designed to remove nitrogen, are a major source of nutrient contamination in the Bay. There are 230,000 septic systems in the State of Maine, many of which are situated within the Bay's watershed.[42]

Excessive levels of these nutrients stimulate the growth of algae, which can lead to oxygen depletion in the Bay. The over-enrichment of nutrients is called eutrophication. As algae grow, they not only block sunlight needed by the submerged aquatic vegetation of the Bay, but they also require a great amount of dissolved oxygen to decompose. The decomposition process reduces the level of oxygen available for other aquatic life. Oxygen-deficient conditions (called hypoxia) can result in large fish kills. During the summer of 1992, approximately one million menhaden suffocated because of oxygen depletion in the New Meadows River.[43]

Toxics/Contaminated Sediments

Toxic metals, organic chemicals, and other pollutants settle and accumulate on the bottom of the Bay and its tributaries. Tides, erosion, dredging, and the movement of aquatic life can agitate the

VOL 12

3711

VOL 12

sediments and free contaminants to float through the aquatic system. Organisms eat and absorb toxins, passing these contaminants to higher levels of the food chain, such as fish, birds, and humans.

Until 1983, Casco Bay was believed to be pristine. Yet, later that year several assessments of the Bay's sediments revealed the presence of polychlorinated biphenyls (PCBs), hydrocarbons (PAHs), lead, cadmium, silver, mercury, chromium, zinc, chlordane, and dioxin.[44] These toxic metals and organic chemicals can accumulate in the tissues of worms, clams, fish, and birds. Lead, cadmium, mercury and silver are found in "high" levels in Casco Bay compared to other estuaries in the United States.[45] As more toxins are released in the environment, wildlife are increasingly threatened by the possibility of diminished reproductive and developmental abilities, increased rates of cancer, and early mortality.[46]

High levels of sediment contamination, found in the Fore River, Back Cove, and Presumpscot River, are responsible for declines in populations of fish and shellfish species.[47] Blue mussels with elevated levels of lead and mercury have been harvested in these areas.[48] In addition, studies of flounder indicate high levels of toxic contaminants in their livers.[49] Dioxin contamination contributed to the East Coast-wide consumption restrictions for lobster tomalley (liver) in 1994. The tomalley were found to have dioxin levels 20 to 30 times greater than other lobster meat.[50]

Most of the heavy metals found in the Bay originate from vehicular discharges and industrial waste, and are concentrated near Portland Harbor in the Inner Bay.[51] Petroleum and petroleum byproducts are the most widespread contaminants of the Bay.[52] Therefore, hydrocarbons, chemicals resulting from petroleum combustion, are the most common toxins found in the Bay. Historically, a major source of hydrocarbons in the Fore River was coal tar from the gasworks near the Million Dollar Bridge. Oils still ooze from this site on hot summer days. Chlordane, a dangerous pesticide that is currently banned, is another chemical that can be found in the Bay, particularly in the Inner Bay and the Back Cove areas.[53] The levels of hydrocarbons and chlordane found in Casco Bay are "high" relative to other estuaries in the nation.[54] Chlorine, an unmonitored disinfectant used in overboard discharge sewage systems and sewage treatment plants, poses other serious ecological consequences for the Bay and its living inhabitants.[55]

Floatable Debris

Trash accumulated on estuarine beaches also threatens the ecosystem. During the week of October 8, 1994, volunteers cleared 18,800 pounds of marine debris from 172 miles of Maine's beaches. Of the total amount of marine debris collected, 59.2 percent was plastic, 12.4 percent was glass, 9.8 percent was metal, and 18.6 percent was from other materials.[56]

The Casco Bay Estuary Project

Casco Bay was designated under the National Estuary Program as an estuary of "national significance" in 1990.[57] The Preliminary Comprehensive Conservation and Management Plan (CCMP) was completed in 1992. The draft CCMP was completed in 1995. The Preliminary CCMP for the Casco Bay Estuary Project (CBEP) followed an action-oriented agenda focusing on immediate steps to reduce pollutants and improve the Bay. The Plan emphasizes habitat protection, ecological research, public education to encourage stewardship, pollution prevention, and management techniques to ensure the future health of the Bay.[58]

To assist in determining how best to proceed, the CBEP conducted an assessment of existing and past water quality planning programs for their effectiveness and applicability to the CBEP. An assessment of the effectiveness and transferability of actions taken in other estuary programs was also conducted. To help identify the key problems and likely sources of pollution to the Bay a "dirty history" was conducted in South Portland, Portland and the Stroudwater River area. The study involved identifying sites of former tanneries, dumps, foundries, machine shops, gas works, and shipyards to determine the types of pollutants that may have been associated with these industries or businesses. The

3712

final lesson learned from this history is that pollution endures for centuries. Activities from 150 years ago are still polluting the estuary today.

Watershed management planning, emphasizing best management practices, and wetlands restoration have been the focus of many of the interim actions adopted by the Preliminary CCMP. The CBEP realizes that long-term protection of the Bay will depend on the participation of local communities. Therefore, the Project has given local governments the tools they need to make good environmental decisions. For instance, Geographic Information System (GIS) mapping is being used to store and map information about shellfish beds, wetlands, combined sewer overflows, and point-source pollution. GIS also maps things such as roads, drainage ways and existing development sites. This information provides an invaluable service for community leaders for the wise management of environmental resources. It gives the local officials the opportunity to see the effect of decisions before they are made. This type of informed decision-making is instrumental in preventing pollution in Casco Bay.

Additional CBEP projects have provided more tangible results, such as restoration of some commercial shellfish harvests. In the fall of 1994, the Town of Harpswell reopened 20 acres of clam flats in Doughty Cove which had been closed for seven years. With the assistance of NEP funding and the efforts of citizens, the flats were restored after pollution in the area was reduced.[31] An education campaign was also initiated to teach homeowners about cleaner waste disposal techniques, such as maintaining septic systems.[32]

The CBEP is also working with the U.S. Fish and Wildlife Service's Gulf of Maine Project on two studies, the Casco Bay Critical Habitats and Development Study and the Casco Bay/Sheepscot Bay Habitat Modeling Study. These studies attempt to look ahead at the impact of development on fish and wildlife habitat if current trends are allowed to continue. The CBEP is also developing models to identify critical habitat for eight estuarine and nearshore species. These species include American lobster, softshell clam, alewife, tomcod, mummichog, winter flounder, sand lance, and Atlantic salmon.

Although many of the CBEP's efforts to date have been successful, a few obstacles continue to interfere with the ultimate goal of implementing the CCMP. Most importantly, the lack of a federal commitment to funding, as well as a shortage of political will, has raised concerns about how the plan will be implemented once the CCMP has been approved.

There are also concerns over whether or not the most critical ecological problems will be addressed. Due to the fact that the Management Conference that developed the CCMP includes certain stakeholders that have tremendous political influence, problems that are of priority to the environmental community and other citizens organizations may go unaddressed. This is especially likely, since the amount and quality of public involvement in the NEP process has been inadequate. Public involvement in the restoration of Casco Bay would be enhanced if the CBEP geared budget and staff toward developing an effective public relations campaign. In some circumstances it has also been noted that the process used to identify leaders for the different committees has not always produced those with the greatest expertise and experience.

National Coastal Caucus

Friends of Casco Bay and the Conservation Law Foundation have been actively involved in the protection and restoration of Casco Bay. These organizations continue to work towards strengthening support for interim implementation projects under the CCMP. The staff, Board of Directors, and members of Friends of Casco Bay (FOCB) and the Conservation Law Foundation (CLF) have been involved in the Casco Bay Estuary Project in numerous capacities. In particular, FOCB and CLF have played key roles on the Citizens Advisory Committee. In addition, FOCB has served on the Management Committee, Technical Advisory Committee, and Implementation Committee.

Since 1989, Friends of Casco Bay has been a lead organization working to improve and protect the environmental health of Maine's beautiful Casco Bay. As professional steward for the Bay, the BayKeeper

VOL 12

3713

VOL 12

works with concerned citizens and businesses to cooperatively solve pollution problems, and educate people on the importance of caring about the Bay.

FOCB programs actively address broad problems affecting the Bay — pollution discharges, clam flat closures, pogy die-offs, dredging, oil spill management, and sewage pollution. By advocating for sustainable management of the Bay's resources, FOCB combines environmental protection with economic opportunities. They continue to build coalitions among diverse groups, to monitor water quality and critical habitats, to promote stewardship, and to respond daily to concerns of citizens and marine communities.

The Estuary Project has provided a grant to FOCB to organize and run a volunteer monitoring program. The BayKeeper has trained approximately 200 volunteers who regularly monitor the Bay at 104 stations. The data gathered from the monitoring program will serve to develop baseline information for Casco Bay, to identify problem areas, to help determine whether closed clam flats could be reopened, and to involve citizens in the protection of the Bay.

The Conservation Law Foundation is a non-profit public interest and environmental law organization founded in 1966. CLF's lawyers and scientists work to improve resource management, environmental protection, and public health throughout New England. CLF currently has projects in energy conservation, marine resources protection, transportation planning, land protection, and environmental health. Its marine resources project has focused on preventing oil and gas development on Georges Bank, reducing pollution from municipal sewage treatment plants, ending overfishing of New England groundfish, and protecting marine habitat. CLF has offices in Boston, MA; Rockland, ME; and Montpelier, VT.

CLF and the Island Institute of Rockland, ME, focused attention on Casco Bay in 1988 with the release of *Troubled Waters: Report on the Environmental Health of Casco Bay*. The report detailed early warning signals of degradation in the Bay and recommended, among other actions, that Casco Bay be included in the National Estuary Program. In 1989, CLF filed a lawsuit against the Portland Water District for repeated violations of the federal Clean Water Act due to inadequate sewage treatment. The suit was settled with the court ordering the District to upgrade its Portland plant in order to reduce the discharge of pollutants to Casco Bay.

VOL 12

Charlotte Harbor
in Florida

Portrait of the Estuary

The Charlotte Harbor National Estuary Program is beginning to examine the water quality and habitat problems of the Charlotte Harbor estuarine system and the impact that the larger watershed area has on the estuary. Charlotte Harbor, located in southwest Florida, is the ninth largest estuary in the Gulf of Mexico.[1] The water surface area of the Harbor is about 270 square miles[2] and the average depth is eight feet.[3]

Stretching from the headwaters of the Peace River in Polk County southward to Estero Bay, the greater watershed of Charlotte Harbor covers 4,360 square miles.[4] Portions or all of Sarasota, Lee, Charlotte, DeSoto, Hardee, and Polk Counties are in the watershed. Cape Coral, Fort Myers, Port Charlotte, Punta Gorda and Fort Myers Beach are some of the larger residential communities located in the watershed.

A number of lagoons and embayments, including Lemon Bay, Bull Bay, Turtle Bay, San Carlos Bay, and Estero Bay, are located within the Charlotte Harbor system.[5] Gasparilla Sound is a large, open body of water which is also situated in this estuarine system.[6] Several barrier islands are situated off the coastline in this section of Florida.

Freshwater flows into the Charlotte Harbor estuarine system through three large rivers (the Myakka, Peace, and Caloosahatchee Rivers), navigational and drainage canals, and a number of smaller creeks.[7] Over the years, sections of the Peace River have been drained and diverted to support farming, mining and increasing municipal demands.[8] The section of the Myakka River which runs through Sarasota County has been designated as a wild and scenic river by the State of Florida. This portion of the River also supports many of the freshwater and tidal wetlands of the Charlotte Harbor area.[9] The southern portion of the Harbor system receives its freshwater from the Caloosahatchee River, which is managed by federal and State officials as part of the Lake Okeechobee management project and the Everglades restoration program.[10]

Charlotte Harbor	
Area of watershed	4,360 square miles
Area of surface water	270 square miles
Average depth	8 feet
Values	• Tourists spend more than $1 billion • Recreational fishing generates $3.5 billion in economic output* • 5 National Wildlife Refuges and 8 Florida State Aquatic Preserves
Threats	• Hydrologic alterations • Nutrient loadings • Habitat loss and degradation
CCMP status	Expected in 1998

Designated as a "Nationally Significant" Estuary in 1995.
*State figure

Values of the Harbor

Tourism and commercial fishing are integral to the economy of the Charlotte Harbor area and the State of Florida. Local communities recognize the critical link between economic stability and the protection of diverse habitat and wildlife populations. For this reason, estuary protection and restoration plans are being developed in areas along Florida's coastline. Estuaries of Florida are critical to commercial and recreational fish and shellfish.

Almost 90 percent of the commercial fish and 70 percent of the recreational fish species caught in the State use estuaries for all or part of their lives.[11]

Fisheries/Seafood

In 1994, the combined market value of commercial fish and shellfish landings in the Gulf Coast region of the United States was approximately $806 million. Many of the valuable fish species in the region depend on Charlotte Harbor and other Gulf of Mexico estuaries. In fact, 90 percent of the combined recreational and commerical fish catch in the Gulf of Mexico use estuaries and coastal wetlands during their life cycles.[12] Also in 1994, the State of Florida's commercial finfish and shellfish landings totaled approximately 177 million pounds, valued at $239 million.[13]

Commercial and recreational fisheries found in the Charlotte Harbor estuary system include black mullet, spotted sea trout, king whiting, flounder, bluefish, grouper, king mackerel, and several species of sharks.[14] The Charlotte Harbor also supports blue crab, pink shrimp, stone crab, hard clam, and scallop populations. Since 1945, tidal flats, salt marshes and oyster reefs have declined, as have landings of pink shrimp, blue crab, and scallops.[15]

Recreation/Tourism

In 1993, over 1.6 million tourists visited three coastal counties of the Charlotte Harbor estuary system (Charlotte, Lee, and Sarasota) and spent over $1.1 billion.[16] The natural beauty and resources of the Charlotte Harbor entice tourists to the beaches and barrier islands of the area. Favorite recreational activities within the Charlotte Harbor area include sport fishing, swimming, and sunbathing. Another popular activity in the Harbor is boating; over 100 recreational marinas are situated in Charlotte, Lee and Sarasota Counties.[17]

In 1991, recreational fishing in Florida generated approximately $3.5 billion in economic output and employed approximately 58,000 people.[18] In the same year, approximately 2 million saltwater anglers spent over 22 million days fishing off the coast of Florida. Thirty-four percent of the anglers were non-residents of the State.[19] It has been estimated that saltwater fishing in the Charlotte Harbor generates nearly $37 million from angler expenditures annually.[20] Part of this revenue originates from the nation's largest sustainable tarpon tournament, which is held in the Charlotte Harbor.[21]

Wildlife

The Charlotte Harbor area supports a great diversity of wildlife. Approximately 316 bird, 44 mammal, 591 invertebrate, 55 reptile, and 273 marine fish species are found throughout the Charlotte Harbor watershed.[22] Two of the most recognized inhabitants are bottlenose dolphins and West Indian manatees. Both manatees and dolphins use the Harbor for calving grounds. In addition, sawfish, a State-protected species, can be found near the mouth of the Myakka River.[23]

The Charlotte Harbor area provides important habitat for rare, threatened and endangered species. In 1990, 86 federal- and State-protected species were found in the Charlotte Harbor area.[24] Currently, the State of Florida has 97 federally-protected endangered and threatened species.[25] Of these, the endangered bald eagle, West Indian manatee, shortnose sturgeon, green sea turtle, hawksbill sea turtle, Kemp's ridley sea turtle, leatherback sea turtle, wood stork, American crocodile, Cape Sable seaside sparrow, Florida salt marsh vole, and Lower Keys rabbit, plus the threatened piping plover, Florida scrub jay, Atlantic saltmarsh snake, and loggerhead sea turtle depend upon Florida's estuarine wetlands.[26] Many of these protected species use the Charlotte Harbor estuarine system.

The abundance of wildlife can be attributed to the diversity of habitat types in the area. Habitats include freshwater wooded wetlands, tidal wetlands, tidal mud flats, submerged aquatic vegetation (58,495 acres), and mangroves (56,631 acres).[27] Five National Wildlife Refuges and eight Florida State Aquatic Preserves are situated within the Charlotte Harbor watershed.

Threats to the Harbor

The Charlotte Harbor estuary system has been the subject of numerous inter-governmental and independent studies during the past few decades.

Based on that data, the issues prioritized for action include changes in freshwater flow, nutrient loadings, and habitat loss. It is likely that the Harbor Estuary Program will address these and other issues.

Hydrologic Alterations

Human activities have significantly altered the level of freshwater flowing into the Charlotte Harbor system. The upper Peace River's flow of freshwater is one-third less than its historic levels.[28] In this portion of the watershed, freshwater is being diverted for farming, mining, aquifer supplies and other projects. At the same time that diminished flows of freshwater have been reaching the Harbor via the Peace River, the lower portion of the Harbor has been deluged with excess levels of freshwater from the Caloosahatchee River. The significant inputs of freshwater from this river are the result of the management of Lake Okeechobee's lock system. Although management practices have improved, submerged aquatic vegetation, oyster reef coverage, and bay scallop populations have been drastically harmed by the sudden, large freshwater infusions.[29]

Nutrient Loadings

Nutrients, such as nitrogen and phosphorus, are introduced to the estuary by urban stormwater, sewage treatment plants, malfunctioning individual septic systems, atmospheric deposition, agricultural runoff, and boater discharges. Excessive levels of these nutrients stimulate the growth of algae in the Harbor. As the algae grow, they not only block sunlight needed by the submerged aquatic vegetation of the Harbor, but also require a great amount of dissolved oxygen to decompose. The decomposition process reduces the levels of oxygen for other aquatic life. Low oxygen conditions (called hypoxia) can result in large fish kills.

The loadings of nutrients into Charlotte Harbor are increasing. As forests and pasture lands are being converted to agricultural lands, more pesticides and fertilizers run off into the Harbor's tributaries, especially the Peace River. Increasing population growth within the watershed is leading to more wastewater discharges from sewage treatment plants. Projections are showing that the volume of wastewater discharge will likely increase by 26 million gallons per day by 2000.[30] Population growth and development are also causing natural lands to be replaced with more impervious surface areas, such as pavement and roofs. By losing the natural filtering and absorbing qualities of natural lands, the effects of storm events are intensified as increased flows of stormwater carrying greater concentrations of nutrients and other contaminants reach estuarine waters.

Habitat Loss and Degradation

Development activities of the past have destroyed a significant portion of the habitat in the Charlotte Harbor area. Between 1945 and 1982, approximately 51 percent of the area's salt marsh and 29 percent of the seagrass acreage was lost.[31] Since 1945, 76 percent of the non-vegetated tidal flats have been destroyed.[32]

The remaining salt marshes and mangrove forests provide substantial benefits for the wildlife and the coastal communities of the Charlotte Harbor area. These wetland areas provide important spawning, nursing and feeding grounds for fish and shellfish and nesting areas for birds. In addition, coastal wetlands filter pollutants carried by stormwater and surface runoff before they flow into the estuary or its tributaries. As a result, these areas are important for maintaining the water quality along the coasts. They also absorb excess flood waters and protect upland areas from coastal storms. Among their other functions, coastal wetlands also provide places for recreation, such as canoeing and bird watching.

Seagrass habitat has greatly declined in San Carlos Bay. This decline is attributed to the sudden alterations in water salinity levels caused by the release of freshwater from Lake Okeechobee via the Caloosahatchee River.[33]

The Gulf Coast of Florida is one of the nation's fastest growing areas. Two counties within the Charlotte Harbor watershed, Charlotte and Lee Counties, are projected to be among the nation's leading coastal counties in terms of the percentage of population change between 1988 and 2010. Charlotte and Lee County expect a 62 percent and 52 percent increase in population between 1988 and 2010, respectively.[34]

VOL 12

3/1/9

R0037027

Additional Concerns

Trash accumulated on estuarine beaches also poses a threat to the ecosystem. The amount found in just one day was staggering — on September 17, 1994, volunteers cleared over 368,000 pounds of marine debris from 1,267 miles of Florida beaches. Of the total amount of marine debris collected, 61.4 percent was plastic, 12.5 percent was metal, 11 percent was glass, and 15.1 percent was from other materials.[19]

Charlotte Harbor National Estuary Program

With the Environmental Protection Agency's acceptance of Charlotte Harbor into the National Estuary Program, it became one of the most recent group of seven estuaries added to the Program. Of the four estuaries nominated by Governor Chiles on March 7, 1995 — Charlotte Harbor, the Lower St. Johns River, St. Andrew Bay, and Lake Worth Lagoon — only the Charlotte Harbor estuary was accepted. On July 6, 1995 Charlotte Harbor was officially designated an estuary of "national significance" under the National Estuary Program of the Clean Water Act. Shortly thereafter, the EPA convened a Management Conference responsible for coordinating the development of a Comprehensive Conservation and Management Plan (CCMP) to restore and protect Charlotte Harbor. Due to the large amount of information already available about the problems facing the Harbor, the Program has proposed a three-year process rather than the customary four-to-five year timeframe. As a result, the CCMP is scheduled for completion in 1998.

VOL 12

Columbia River
in Oregon and Washington

The Lower Columbia River Estuary is unique — with aspects of both a classic estuary and a wild river. It may be the most neglected estuary in the country; even evidence of toxic contamination manifested in bald eagle reproductive failure has been widely ignored. While we (Northwest Environmental Advocates) will continue to enforce the Clean Water Act at the courthouse, we think the National Estuary Program offers the opportunity to do what the law cannot do, such as restore some of the wetlands that have been destroyed.

— Nina Bell, Executive Director
Northwest Environmental Advocates

Columbia River	
Area of watershed	259,000 square miles
Population	1.36 million people
Values	• Sport fishing generates $1.9 billion (WA) and $941 million (OR) in economic output* • Fisheries generate $175 million (WA) $66 million (OR)* • Most valuable waterway for salmon in U.S.
Threats	• Toxic contamination • Habitat loss and modification • Pathogen contamination • Fishery declines
CCMP status	Final expected in 1998

Designated as a "Nationally Significant" Estuary in 1995

* State figures

Portrait of the Estuary

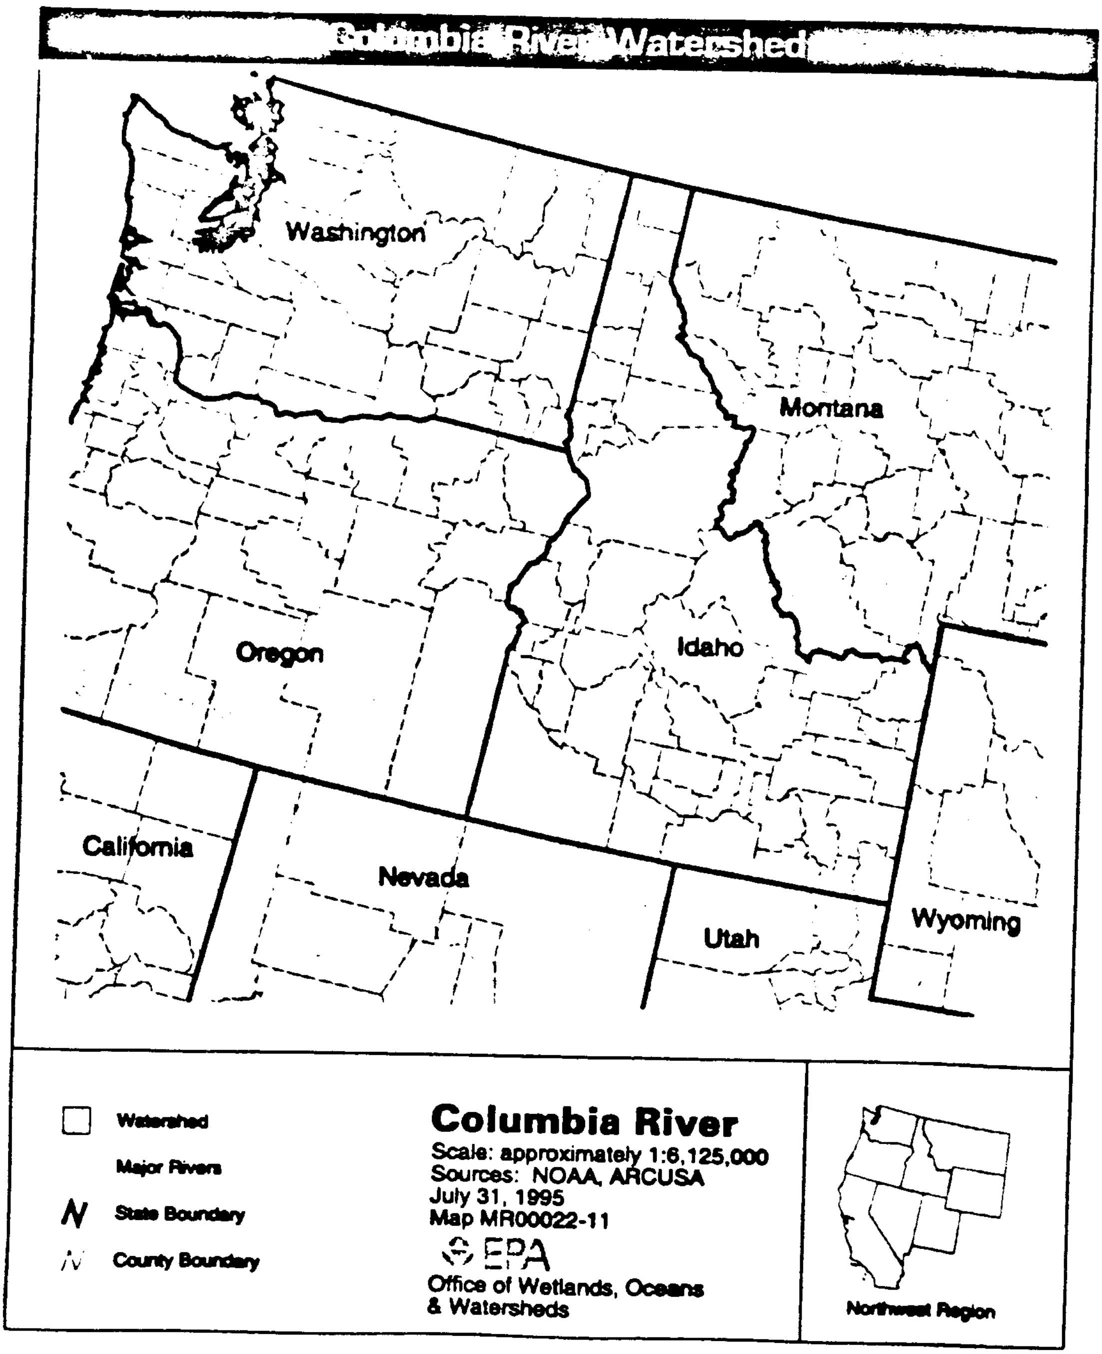
The Columbia River's waterfalls, forested cliffs, and miles of tidelands distinguish it as one of the most scenic areas in the nation. Based on volume of water flow, the Columbia River is the second largest river in the United States.[1] From its headwaters in Canada, the Columbia River flows 1,214 miles before reaching the Pacific Ocean, and forms 300 miles of the border between Washington and Oregon.[2] The Lower Columbia River Estuary Program will study the tidally-influenced portions of the Columbia River and its tributaries. This area includes the Lower Columbia River from the Bonneville Dam at River Mile (RM) 146 down to the River's mouth and through the near-coastal waters to the 3-mile limit of the Pacific Ocean. The tidally-influenced areas include the urbanized portions of the Willamette River at Portland, Oregon. Some of the larger tributaries within the tidally-influenced zone of the Estuary include the Willamette, Lewis and Clark, Kalama, Lewis, Sandy, Washougal, and Cowlitz Rivers. Throughout this report, the study area will be referred to as the Lower Columbia River Estuary.

The entire Columbia River has the fourth largest watershed in the United States,[3] measuring a total of 259,000 square miles.[4] Waters originating in seven States (Washington, Oregon, Idaho, Montana, Wyoming, Utah, and Nevada) and British Columbia drain into the Columbia River and ultimately into the Estuary. Due to its enormous size, the entire watershed area of the Columbia River is not included in the study area. However, the States of Oregon and Washington have agreed not to limit the Comprehensive Conservation and Management Plan (CCMP) solely to the study area if actions can be taken in the greater watershed to improve the water quality and habitat of the Lower Columbia River Estuary. The watershed area of the entire Columbia River system is divided by the Cascade Mountain range. The eastern range of the Cascades, which

3722

VOL 12

37223



R0037031

receives about eight inches of rain per year, is characterized by dry conditions.[5] Much of the drainage from the eastern section of the Cascades occurs during the snow melts of spring and early summer. In great contrast, the western range of the Cascades receives up to 200 inches of rain per year.[6]

The Lower Columbia River Estuary includes portions of five Washington counties (Pacific, Wahkiakum, Cowlitz, Clark and Skamania) and portions of four Oregon counties (Clatsop, Columbia, Washington, and Multnomah). In 1993, the combined population of these nine counties totaled approximately 1.36 million people.[7]

A unique feature of this region is its cultural composition. Several Native American tribes have treaty rights to cultural and natural resources within the Columbia River system. They are particularly concerned about the need to restore the anadromous salmon runs of the Columbia River.

Values of the Estuary

The Lower Columbia River Estuary is ecologically and economically critical to the Pacific Northwest. The area hosts a diversity of wildlife; provides nursery habitat for anadromous, resident, and ocean-dwelling fish and shellfish; attracts millions of outdoor enthusiasts; and is important for fishing, forestry, agriculture and maritime trade.

Tourism/Recreation

Numerous recreational and tourist opportunities attract millions of individuals to the Lower Columbia River Estuary (including the lower Willamette River) each year. Boating is a popular activity in the Columbia River, supporting over 644,000 use days by registered boaters in Oregon during 1993.[8]

Sport fishing is another lure of the Estuary. In 1993, recreational anglers made approximately 332,000 trips to the area to fish for salmon, sturgeon, and shad.[9] In 1991, recreational fishing in Oregon generated approximately $941 million in economic output and employed nearly 16,000 people. In Washington, recreational fishing generated approximately $1.9 billion in economic output and employed nearly 27,000 people.[10] Also in 1991, approximately 225,000 saltwater anglers spent over one million days fishing off the coast of Oregon. Over 500,000 saltwater anglers spent over 3.5 million days fishing off the coast of Washington in that year.[11]

The Lower Columbia River Estuary includes several national and State parks which offer hiking, fishing, crabbing, boating, and swimming opportunities. In 1989, 1.4 million people visited the four Washington State parks which border the Columbia River Estuary.[12] Since its creation in 1986, the downstream portion of the Columbia River Gorge National Scenic Area has been an attractive destination for visitors of the Pacific Northwest. This area is a popular destination for windsurfers.

Fisheries/Seafood

Several species of fish depend on the Lower Columbia River Estuary during their life cycles. Numerous stocks of salmon and steelhead use the Lower Columbia River Estuary to make the transition from fresh to salt water and back again as they migrate to and from the sea. In fact, the Columbia River is recognized as the most valuable salmonid waterway in the continental United States.[13] For a number of other fish species, the Estuary provides essential spawning and nursery habitat. A few of the species which use the Estuary include longfin smelt, American shad, sturgeon, sockeye salmon, Pacific herring, chinook salmon, and steelhead.

The Columbia River Estuary contributes valuable fishery resources to the Pacific Coast of the United States. In 1994, the combined value of the Pacific Coast's commercial finfish and shellfish industries (excluding Alaska) totaled approximately $401 million. In 1994, Oregon's commercial finfish and shellfish landings totaled approximately 246 million pounds, valued at $66 million. In 1994, Washington's commercial finfish and shellfish landings totaled approximately 528 million pounds, valued at $175 million.[14]

The Columbia River contains the world's largest runs of chinook salmon and steelhead.[15] However, these legendary runs have declined substantially due to habitat losses, the overappropriation of water, changes in water flow, and poor water quality throughout the greater watershed and in the Estuary. In particular, hydroprojects along the entire Columbia River system have taken a huge toll on salmon runs. Many stocks have gone extinct, and many

VOL 12

3724

R0037032

others are threatened by extinction. Still, an estimated 220 million juvenile salmon use the Lower Columbia River Estuary each year.[16] The declines in salmon and steelhead populations have prompted authorities to reduce allowable fishing days for these fish. Since 1980, an average of 39 days per year have been open to fishing; fifty years ago, anglers could fish for salmon and steelhead an average of 270 days per year.[17] In 1993, the commercial mainstem fishery below Bonneville Dam had 23 allowable fishing days. The 1993 catch was a record low — 559,500 pounds with a landing value of approximately $966,000.[18]

Wildlife

The Lower Columbia River Estuary includes tracts of publicly-owned parkland and reserves that support an abundance of wildlife. The Julia Butler Hansen Columbia White-tailed Deer National Wildlife Refuge and the Lewis and Clark National Wildlife Refuge both support wildlife in the area. The Lower Columbia River also includes Oregon's Lower Sauvie Island which provides feeding and wintering habitat for endangered wildlife and thousands of migratory birds.[19]

The Estuary provides important habitat for about 175 different migratory and resident bird species.[20] Bald eagles, peregrine falcons, Aleutian Canada geese, marbled murrelets, terns, great blue herons, mallards, and trumpeter swans are a few of the migratory and resident species which can be found in the Estuary.

The State of Oregon has 32 federally-listed threatened or endangered species, and the State of Washington has 22 listed species.[21] A number of these listed species depend upon the estuarine wetlands of the Columbia River system for survival. The threatened bald eagle, for instance, relies on the wetlands of the Lower Columbia River Estuary to support its populations, which are suffering from reproductive failure due to toxic contamination.[22]

Pacific harbor seals use the Estuary for breeding grounds. Other mammals which inhabit the Estuary area include sea lions, elk, fox, mink, river otters, and Columbia white-tailed deer.

Threats to the Estuary

Water quality assessments of the Lower Columbia River Estuary have already been conducted by the Lower Columbia River Bi-State Water Quality Program. The Bi-State Program was established in 1990 as a joint project of the Washington Department of Ecology and the Oregon Department of Environmental Quality, funded in part by public ports and pulp mills. The Lower Columbia River Estuary Program will build on the work produced by the Bi-State Program. Toxic contamination, habitat loss and modification, pathogen contamination, and fishery declines have been identified as the most significant threats to the health of the Lower Columbia River Estuary.

Toxic Contamination

Toxic contamination in the Lower Columbia River Estuary is a serious concern for the health and continued survival of wildlife populations. This is due to pollution sources throughout the enormous Columbia River watershed and an abundance of industrial polluters in the study area. Active industrial polluters in the Lower Columbia River Estuary include pulp and paper mills, lumber and plywood mills, metals production facilities, chemical industry facilities, and power generating plants.[23] These polluting industries have contributed to the fact that the Lower Columbia River Estuary contains seven Superfund sites. In addition to industrial pollution, the entire Columbia River system and Estuary have been afflicted with a toxic legacy owing to the proximity of the Hanford Nuclear Reservation. Between 1941 and 1977, the waters of the Columbia River were used to cool eight military nuclear reactors at the Hanford Reservation, where waters passing over radioactive fuels were discharged directly back into the Columbia River. Consequently, the Columbia River has earned the distinction of "the most radioactive river in the world."[24]

Examples of toxic contaminants (including heavy metals and radioactive wastes) which persist in the Lower Columbia River Estuary include polychlorinated biphenyls (PCBs), dioxin, DDT, plutonium, cesium, and strontium-90.[25] The State of Oregon recently concluded that a total of 26 toxic pollutants, including trichlorobenzene, arsenic, and chromium, were found at levels in violation of State water quality standards in the Lower Columbia River.[26]

VOL 12 3725

Toxic contaminants reach the Estuary and its tributaries in a variety of ways, including point source discharges, polluted stormwater, dredging operations, farming, mining, logging, toxic sites, and atmospheric fallout.

The damaging effects of toxic contaminants on the living resources of the Columbia River system are far-reaching. For instance, resident fish of the Lower Columbia River Estuary contain levels of PCBs, dioxin, and DDT in their tissues which affect animals at higher levels of the food chain. PCBs are found at levels that can cause complete reproductive failure in mink, which rely on fish from the Estuary and its tributaries as a food source. DDE, a breakdown product of the banned pesticide DDT, is causing egg shell-thinning in threatened bald eagle populations, which are currently suffering reproductive failure in the Lower Columbia River Estuary. Studies have also revealed high levels of toxic contamination in otters and harbor seals.[27] The reproductive processes in otter populations have also been threatened, as male otters have been found with significantly altered reproductive organs.

Recent studies have revealed that the ingestion of contaminated fish caught from the Estuary poses a higher risk of cancer and reproductive failure in humans.[28] Researchers are studying the consumption patterns of the Native American populations in the area (typically, fish consumption is nine times greater for tribal members) and the increased risk to subsistence fishers.[29]

Habitat Loss and Modification

Over the years, much of the estuarine habitat of the Columbia River has been altered by building upriver dams, diking, dredging, and converting natural lands to urban or agricultural uses. Today, the Columbia River system is controlled almost entirely for human uses, such as hydropower, irrigation, flood control, and navigation.[30] The construction of these water-related projects has claimed an enormous amount of valuable natural habitat in the entire Columbia River system. Approximately 86 percent of the original 722,000 acres of historic wetlands in the Lower Columbia River Estuary have been destroyed.[31] In addition, up to 77 percent of the Estuary's original tidal wetlands and 65 percent of its original marsh swamps have been destroyed.[32] Most of the remaining wetlands are located in the protected National Wildlife Refuges. The Bi-State Program intends to create a wetlands Geographic Information Systems (GIS) map which will assist in locating areas that need stronger protections.[33]

Estuarine and freshwater wetlands provide critical breeding, spawning, nursery, and sheltering areas for many fish, birds and other wildlife. In addition to the benefits they provide for wildlife, wetlands serve numerous functions for communities. Wetlands provide buffers for inland areas during storms, preventing shoreline erosion and absorbing excess flood waters. Wetlands filter pollutants which are carried by stormwater and runoff from agricultural and urban areas, thereby protecting water quality in other receiving surface waters and groundwater.

Pathogen Contamination

Pathogens are disease-causing microorganisms found in human and animal wastes which enter estuaries through sewage treatment plant discharges, industrial point sources, combined and sanitary sewer overflows (CSOs and SSOs), polluted urban stormwater, agricultural runoff, boating wastes, and septic systems. Pathogens pose risks to humans who eat contaminated shellfish or who are exposed to pathogen-contaminated waters through recreation. Gastroenteritis, hepatitis, and other diseases can result from the ingestion of contaminated shellfish or water. For this reason, shellfish beds are closed or restricted when water monitoring indicates high levels of fecal coliform bacteria (an indicator of pathogen contamination). However, swimming areas are not regularly monitored, and therefore are not closed on a regular basis.[34]

Monitoring has indicated that bacterial levels exceed safe standards for shellfish harvesting in certain areas of the Lower Columbia River Estuary. In 1990, all of the Estuary's 2,000 acres of shellfish beds were closed to commercial harvest.[35] Bacterial levels also pose threats to recreational users of the Lower Columbia River — of particular concern is the stretch along the River between Portland, Oregon and Longview, Washington.[36]

VOL 12

3726

R0037034

VOL 12

Fishery Declines

In the early 1800s, the Columbia River supported runs of 16 million salmon per year. Due to the large number of hydroprojects along the River, and the accompanying habitat loss and water quality declines, present-day runs only support 2.5 million salmon annually.[37] Dam construction and operations are among the primary reasons for today's crippled salmon populations. Currently, 211 major dams are situated in the entire Columbia River watershed.[38] As part of their natural life cycles, salmon migrate from fresh to salt water and back to freshwater for spawning purposes. However, dams pose physical obstacles along their spectacular migration routes, often blocking access to their original spawning grounds. It is estimated that up to 30 percent of young salmon are killed at each dam they encounter as they try to make their way to the ocean.[39]

The lack of instream flow and impaired water quality in spawning and migration waters throughout the watershed pose equally serious risks to already-struggling salmon populations. The disappearance of estuarine wetlands, which provide critical nursery habitat, restricts the Estuary's carrying capacity for salmon. In addition, during the spring, water flows in the Columbia River are held back for summer irrigation projects. Thus, salmon smolts, which require large volumes of water to flow seaward in a physiologically-set time period, often die before reaching ocean waters. Currently, 67 Columbia River salmon stocks are extinct and 72 are at risk.[40]

The Lower Columbia River Estuary Program

With the Environmental Protection agency's acceptance of the Lower Columbia River Estuary into the National Estuary Program (NEP), it was included among the most recent group of seven estuaries added to the Program. In July, 1995, the Lower Columbia River Estuary was officially designated as an estuary of "national significance" under the National Estuary Program of the Clean Water Act. Representatives from both Washington and Oregon will participate in the Management Conference.

The Lower Columbia River Estuary Program includes a streamliped NEP since it builds on the Bi-State Water Quality Program. Although much of the initial planning required to begin a local estuary program has already been conducted by the Bi-State Program, serious concerns remain about whether the NEP will follow the Bi-State Program with respect to decision-making and management structure. Specifically, there is much concern over the lack of inclusion of all stakeholders in the decision-making process involved in the management conference of the local NEP. Currently, the role of industry and States far exceeds that of citizens and the environmental community. Therefore, it is imperative that the Lower Columbia River Estuary Program do a better job than the Bi-State program to include citizens in the local NEP.

National Coastal Caucus

Northwest Environmental Advocates (NWEA) is a 27-year old membership organization focused on water quality and wetlands protection in Oregon and Washington. Northwest Environmental Advocates was the first to publicly raise the issue of Columbia River water quality in 1988. In seeking to obtain the support of the Oregon and Washington governors for National Estuary Program nomination in 1989, NWEA helped to establish the Bi-State Program on Lower Columbia River Water Quality. NWEA's Executive Director co-chaired the Steering Committee for this program for two and one-half years. In 1992, NWEA again spearheaded an unsuccessful drive to obtain NEP status for the Columbia, a move which eventually led to its designation in 1995.

NWEA works on the full range of issues related to implementation of the Clean Water Act's water quality-based approach in Oregon and Washington, serving on advisory committees, educating the public, and bringing lawsuits to force the development of Total Maximum Daily Loads (TMDLs) on polluted waters throughout the two States. NWEA's educational program is called Columbia/Willamette RiverWatch. RiverWatch has taken thousands of people to see first-hand the wonder and problems of the Columbia River Estuary and its tributaries. The program also produced the nationally-acclaimed environmental maps *Columbia River: Troubled Waters* and *Portland/Vancouver: Toxic Waters*, as well as cross-discipline environmental curricula.

Corpus Christi Bay
in Texas

Our bays and estuaries are our most precious resources. In the Corpus Christi area, we have an opportunity to avoid many of the problems that have damaged natural resources elsewhere. By implementing an effective Bay management plan now, we can assure healthy and productive Bays for the future.

— Ray Allen, Chairman
Coastal Bend Bays Foundation

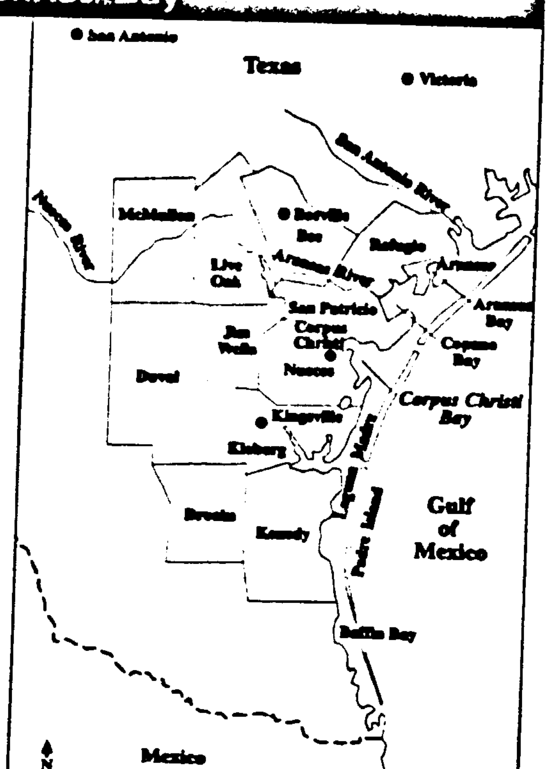
Portrait of the Bay

The Corpus Christi Bay Estuary Program is examining the water quality and habitat problems of the Bay and the impact that the greater watershed area has on the estuarine system. Corpus Christi Bay is located along the south central Texas coast. The study area of the Corpus Christi Bay system extends from the brackish Aransas and Copano Bays at its northern boundary to Baffin Bay and the hypersaline Upper Laguna Madre at its southern boundary.[1] In sum, the estuarine system comprises over 25 bays

Corpus Christi Bay

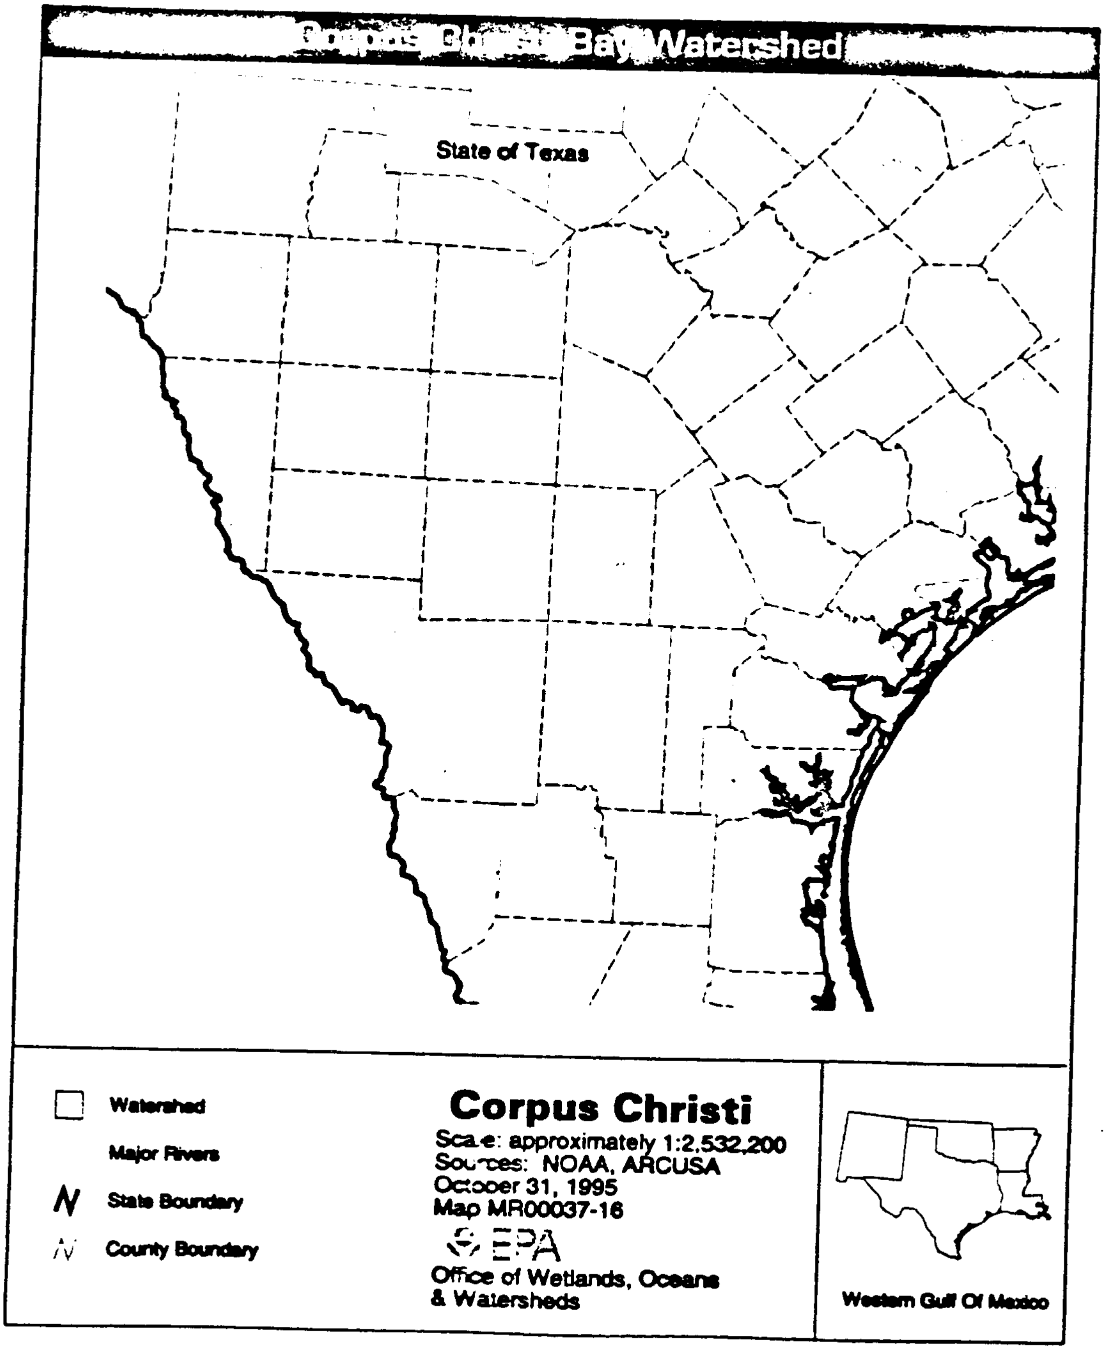
Area of surface water	600 square miles
Area of watershed	11,000 square miles
Length	75 miles
Average depth	3 to 8 feet
Population	500,000 people
Value	• Commercial and recreational fisheries generate $364 million • Tourism generates $1.3 billion in economic output • Home to Padre Island, the world's longest barrier island
hreats	• Freshwater inflow • Habitat loss • Water quality degradation • Brown tide • Floatable debris
CCMP Status	Final expected in 1998

Designated as a "Nationally Significant" Estuary in 1992.



VOL 12

3730



VOL 12

R0037039

and saltwater bayous.[2] The estuarine area of the Corpus Christi Bay system measures 600 square miles.[3] Barrier islands — including Padre Island, the world's largest barrier island — separate the estuary from the Gulf of Mexico.

The greater watershed area of the Corpus Christi Bay system extends into the south-central portion of Texas. The watershed study area of the Corpus Christi Bay National Estuary Program covers approximately 11,000 square miles.[4] The Bay system stretches along 75 miles of Texas coast and includes portions or all of twelve counties — Nueces, Kleberg, Kenedy, San Patricio, Aransas, Refugio, McMullen, Live Oak, Bee, Jim Wells, Duval, and Brooks counties.[5] This region of Texas is often called the Coastal Bend.

The Corpus Christi Bay system is the second most populated estuary in Texas.[6] The current watershed population of approximately 500,000 people is expected to increase by 20 percent between 1990 and 2000,[7] and double by the year 2040.[8] Corpus Christi, the seventh largest city in Texas, is home to over one-half of the watershed's population.[9]

The Bays in the system are relatively shallow compared to other estuaries along the Gulf of Mexico and in other parts of the nation. Corpus Christi Bay's average depth is eight feet; Aransas Bay's is five feet; and the Upper Laguna Madre's is three feet. For comparison, the average depth of Gulf of Mexico estuaries is eight feet and the national average is 23 feet.[10]

The inland areas of the Corpus Christi watershed are semi-arid. The Bay area's average annual rainfall is 24 to 36 inches; however, its annual surface evaporation rate is 60 inches.[11] The system's primary sources of freshwater are the San Antonio, Mission, Aransas, and Nueces rivers. In recent years, the freshwater inflows have declined due to increasing diversions and demands by municipalities, industries, farmers, and other residents. The resulting change in water salinity levels in the Bay is having serious impacts on fishery and other aquatic resources.

Values of the Bay

Corpus Christi Bay provides many economic and recreational benefits to visitors and residents of the area. In addition, the Bay system provides critical habitat for a great diversity of animal and plant species. The economic impact of the area's commercial and recreational fisheries is calculated to be $364 million per year.[12] The Port of Corpus Christi, the deepest port in the Gulf of Mexico, is used to support many commercial activities in the area. Minor oil spills and bilge discharges are a frequent by-product of this Port activity. Since the natural environment of Corpus Christi Bay is greatly tied to the economic successes of this region, restoring and protecting the Bay is imperative.

Recreation/Tourism

The Corpus Christi Bay system is a well known and very popular tourist destination which contributes significantly to the local and State economies. Approximately 2.8 million people visit the city of Corpus Christi each year. The tourist industry alone in this region employs 10,600 persons.[13] In 1991, tourist expenditures were $530 million — a $180 million increase from 1989.[14] The average, total economic output from tourism in the city is $1.3 billion per year.[15]

A few of the popular activities which attract visitors and residents to the area include sport fishing, sunbathing at beaches, swimming, camping, bird watching, hiking, and wind surfing. Padre Island (the world's longest barrier island), Padre Island National Seashore, Aransas National Wildlife Refuge, and many State parks are some of the favorite sites which highlight the ecological richness of Texas' Gulf coast. Padre Island National Seashore alone caters to between 750,000 and one million visitors annually.[16]

In 1991, recreational fishing in Texas generated $2.8 billion in economic output and employed nearly 40,000 people.[17] In the same year, over 828,000 saltwater anglers spent over 6.8 million days fishing off the coast of Texas.[18] In 1986, the most recent year for which data is available, sport fishing in just the Corpus Christi and Aransas bays contributed a total of $246 million to the region. During the same year, the total output of other water-related activities in Corpus Christi and Aransas bays was $133.6 million.[19]

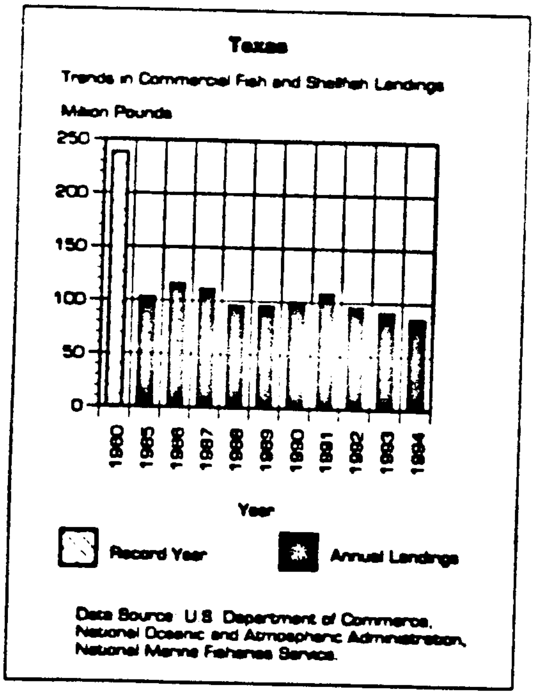
Fisheries/Seafood

In 1994, the combined market value of commercial finfish and shellfish landings in the Gulf region

VOL 12

3732

R0037040



totaled approximately $806 million.[20] Many of the commercially valuable species in the Gulf region depend upon the health of Corpus Christi Bay for survival. In 1994, Texas' commercial finfish and shellfish landings totaled approximately 85 million pounds, valued at $207 million in dockside revenues.[21]

The Corpus Christi Bay system provides critical spawning and nursery habitat for the Gulf of Mexico's shrimp and finfish species. Important commercial and recreational fisheries of the area include redfish, spotted sea trout, shrimp, black drum, Atlantic croaker, blue crab, and flounder.[22] Approximately 136 fish species live in the upper Laguna Madre estuary and 213 species live in Aransas Bay.[23]

Wildlife

The coastal areas around Corpus Christi Bay provide important habitat for a diversity of wildlife. The most popular wildlife inhabitants are whooping cranes. These endangered birds, which can grow to a height of five feet, use the Aransas National Wildlife Refuge and nearby areas as wintering grounds. White-tailed deer, American alligators, armadillos, bobcats, brown pelicans, sandhill cranes, and other waterfowl also inhabit the Refuge.[24] In sum, 389 bird species, 64 amphibian and reptile, 46 mammal, and 213 fish species are found in the Refuge.[25] Seventy-five percent of the bird species in North America use Corpus Christi Bay to establish permanent nests or to rest along migratory routes.[26]

Many federally-protected threatened and endangered species rely upon Corpus Christi Bay and other estuaries of Texas. Specifically, the Kemp's ridley sea turtle, piping plover, and whooping crane are endangered species which depend upon estuarine wetlands in Texas. The threatened loggerhead sea turtle also depends upon these areas for habitat.[27]

Threats to the Bay

Public concern about the health and future of the Corpus Christi Bay system started mounting when shrimp landings began declining significantly and large algal blooms began appearing in the coastal waters a few years ago. Since then, the Corpus Christi Bay National Estuary Program (CCBNEP) has compiled a list of priority issues of concern that affect the Bay. The seven priority issues of concern are reduced freshwater inflow, wildlife population declines, habitat loss, water quality impairment, altered circulation, floatable debris,[28] and public health.[29] A mysterious and prolonged brown tide has invaded portions of the Bay system and will also be studied. As the population in the region continues to grow, these problems will likely escalate.

Freshwater Inflow

The alteration of freshwater flow into the Bay is probably the most controversial management issue within the estuarine system. As communities surrounding Corpus Christi Bay grow, more freshwater is required to meet the demands of residents. In addition, industrial operations and agricultural producers need freshwater to conduct their businesses. Yet, adequate amounts of freshwater must also be delivered to the Bay system so that the

VOL 12

3733

aquatic life found in these productive waters is sustained. Without healthy populations of fish, shellfish and other wildlife, many jobs within the fishing and tourism industries would be jeopardized. Unfortunately, this policy delute has, on occasion, digressed into a "people versus fish" controversy, instead of examining how the entire ecosystem can balance its freshwater needs.

Diverting freshwater from the Bay can disrupt the delicate ecological balance of the estuary. Low-salinity waters are required to maintain vital nursery habitats for the Bay's juvenile fish and shellfish. Declining freshwater inflows, in combination with water quality impairments and changes in circulation patterns, are suspected causes of decreasing shrimp and fish populations.[30] Lack of freshwater inflow, and the resulting decrease in flushing capacity in the system, may also be responsible for pollutant and sediment concentrations in the Bay region.[31]

The Choke Canyon Dam and Lake Corpus Christi reservoir operate to ensure a steady flow of freshwater distribution to users within the watershed and an adequate release of freshwater for Nueces Bay. Following concerns that freshwater releases were inadequate to support aquatic life in the Bay, an Order by the Texas Water Commission establishing monthly inflow requirements was issued and a freshwater advisory council was established.[32] Since then, an alternative freshwater inflow plan, which attempts to balance human needs with needs of the Bay and the estuaries, has been approved by the State.

As more people move to the region and the tourism appeal of the area grows, freshwater will be in even greater demand to sustain the diverse needs of humans and natural resources in the watershed. Examining the full effects of diminished freshwater flow to the estuaries will be a part of the planning process; and hopefully innovative measures to solve the problem will result.

Habitat Loss

The coastal wetlands and submerged aquatic vegetation of the Corpus Christi Bay system provide important nursery, spawning, and feeding grounds for an abundance of fish, shellfish, and wildlife. Coastal development, dredging activities, pollution, and other factors can damage and destroy these vital habitats and thereby reduce populations of estuarine wildlife.

Besides providing spawning and nursery grounds for aquatic life, wetlands benefit the Corpus Christi Bay system by filtering nutrients and toxic pollutants. Contaminants running off agricultural and urban lands can enter coastal waters unless they are trapped by wetlands bordering the aquatic system. Wetlands located above drinking water aquifers will filter these contaminants before they reach the groundwater. In addition, wetlands protect inland areas from coastal storms and flooding by absorbing much of the excess water and reducing the impact of storm tides and waves.

Seagrass is another essential aquatic resource of the Corpus Christi Bay system. Seagrass meadows provide valuable habitat for fish and shellfish in the Bay. Shoal grass is the prevalent seagrass of the system. Most of the seagrass cover is found in the Upper Laguna Madre. In fact, over 75 percent of this lagoon's bottom is vegetated with seagrass, while twelve percent of Corpus Christi Bay's bottom is covered by seagrass.[33] The shoal grass of the Upper Laguna Madre attracts 75 percent of the world's red duck population to the Upper and Lower Laguna Madre and the Laguna Madre de Tamaulipas in Mexico during the winters.[34] However, the brown tide which has been in the Upper Laguna Madre since 1989, is growing so densely that it is blocking sunlight needed by the shoal grass, causing losses among this habitat.[35]

Approximately 35 percent of Texas' coastal marshes were destroyed between the mid-1950s and 1979.[36] The Corpus Christi Bay area includes over 20,000 acres of emergent wetlands and 46,000 acres of seagrasses.[37]

Water Quality Degradation

Nutrients, chemicals, metals, sediments, and oil enter the Corpus Christi Bay system, impairing the water quality. Pesticides, nutrients from animal waste, and fertilizers that run off agricultural lands, present pollution problems for the Bay. Ranching and agricultural production are important land uses

VOL 12

3734

throughout the watershed; however, there is a concern that these activities may be contributing significant amounts of pesticides and nutrients to the Bay. The Corpus Christi Bay system has the fourth highest agricultural acreage of the nation's 92 estuaries.[38]

Heavy metals which have been found in the Bays include cadmium, selenium, zinc and silver.[39] Accidental oil spills that occur in the harbor channel occasionally reach other portions of the Bays and threaten habitat and wildlife populations. Because the watershed area hosts the nation's third largest petro-chemical complex, and shipping traffic in the Bays is heavy, the threat of major oil spills and barge collisions is a concern in the area.

Brown Tide

Since 1989, the system has been plagued by a brown tide which began in Baffin Bay and then spread northward. The brown tide alga, *Aureococcus anophagefferens*, is microscopic, yet it grows very quickly. It impairs the system because it is harmful to other aquatic organisms. In the Laguna Madre, the shallow water has been infested by thick, sunlight-blocking algae. Except for a similar problem in the Peconic Bays, this situation is virtually unheard of any where else in the world.[40]

Brown tide algae block sunlight from seagrass beds thereby destroying submerged habitat which provides important nursery areas for juvenile aquatic animals. Another problem with the takeover of the brown tide in the system is that it is not as palatable to zooplankton and fish larvae as is regular phytoplankton. Thus, it disrupts the basis of the food chain.

Floatable Debris

Trash floating in waters and accumulating on estuarine and ocean beaches threatens the ecosystem and its wildlife inhabitants. The amount found in just one day can be staggering — on September 17, 1994, volunteers cleared 334,200 pounds of marine debris from 167.8 miles of beach area in Texas. Of the total amount of marine debris collected, 70.7 percent consisted of plastics, 8.4 percent was metals, 8.2 percent was glass, 12.7 percent was from other materials. One of the heaviest pieces of garbage collected was a submerged Pontiac Fiero that was hauled in on North Padre Island.[41]

Padre Island National Seashore is the longest undeveloped beach in the United States. Due to the convergent currents occurring off the coasts, it has more accumulated marine debris than any other shoreline. Ninety percent of the trash that plagues its shores consists of plastics.[42] In a study conducted between March 1994 and February 1995, the National Park Service collected 40,580 debris items. The sources of these items were then identified and percentages were allocated based on this data. The study found that the shrimping industry was directly responsible for generating 30 percent of the debris and "suspected" of contributing an additional 35 percent. The offshore oil and gas industry was responsible for 13 percent and the remaining 22 percent of the debris consisted of items from an unknown source.[43] Continuing efforts are needed to stem the amount of marine debris found along Gulf shores in order to protect visitors and wildlife from potentially harmful materials. It is believed that sea turtle populations are most threatened by the ingestion of floatable debris.[44]

The Corpus Christi Bay National Estuary Program

With its inclusion into the National Estuary Program in 1992, Corpus Christi Bay was designated an estuary of "national significance." The NEP agreement between the EPA and the Texas Natural Resources Conservation Commission includes a plan for conducting a four-year study to develop a Comprehensive Conservation and Management Plan, referred to as the Coastal Bend Bay Plan (CBBP). The Corpus Christi Bay National Estuary Program (CCBNEP) is overseen by a Management Conference which consists of the following five committees: Policy Committee, Management Committee, Local Governments Advisory Committee, Citizens Advisory Committee, and Scientific-Technical Advisory Committee. The structure is designed to solicit input and participation from all

VOL 12

3735

R0037043

users of the estuary system — industry, farmers, ranchers, small business owners, the military, bird watchers, boaters, windsurfers, local and State officials and resource managers, citizens, scientists, and environmental advocates. These committees are responsible for assisting in the development of the CBBP, which will serve as the basis for the implementation of management actions. The first Draft CBBP was released in March, 1996. The goal for completion of the CBBP is September 1998.

The CCBNEP had its first public activity, a conference, in the fall of 1994. The primary focus of many of the 130 participants was concern over freshwater releases to Nueces Bay. Another workshop was held in February of 1995 which focused on educating local communities and creating a vision for the future of the Bay. This meeting marked the first time all members of the CCBNEP were able to work together as a group.

The Corpus Christi NEP has focused its initial efforts on developing water conservation and reuse strategies, as well as, using freshwater releases from reservoirs during high salinity periods. These efforts are ultimately intended to lead to improved water quality for the surrounding human population, and the endangered marine life. After conducting a series of 13 public workshops to solicit comments on the list of priorities, the following seven issues of concern were identified: altered freshwater inflow to bays and estuaries; condition of living resources; loss of wetlands and estuarine habitats; degradation of water quality; altered estuarine circulation; bay debris; and selected public health issues. This list will continue to evolve and be prioritized as more information becomes available.

"Best Management Practices for Sediment, Nutrients, and Chemicals from Agricultural Croplands" is what the CCBNEP labeled its first Action Plan Demonstration Project. Since the CCBNEP study area includes so much agricultural land, implementation of agricultural best management practices (BMPs) is key to addressing the problem of polluted runoff. The project monitors runoff for sediments, nutrients and commonly-used agricultural chemicals over at least 10 rainfall events. The area being monitored covers 2,700 acres of cropland in San Patricio County that drain into Nueces Bay. The data are then analyzed and used to assess local agricultural practices and their contribution to the polluted runoff problems in the Bay. The Project then evaluates current BMPs and recommends actions to enhance their effectiveness. The results are also expected to provide an opportunity for farmers to increase economic profitability.

The second year of the CCBNEP is focused on eight major studies. Three of these will address aquatic vegetation and bay bottom habitats and will be completed by August, 1996. The first will analyze the impact of human activities — such as shrimping, commercial tug and barge operations, construction, oil and gas operations, recreational boating, historic shell and maintenance channel dredging, and the placement of maintenance dredge materials — on bay habitat. It will describe the extent, magnitude, and periodicity of effects of these activities on the physical, chemical and biological characteristics of bay habitat. The second study will undertake a major initiative to map the seagrass beds; conduct a trends analysis to determine if the beds are expanding or shrinking; and determine the cause of any losses. The final habitat study will use existing data to assess the status and trends of freshwater and saltwater wetlands and other aquatic habitats, natural and dredged material islands, natural and artificial hardened shorelines, and riparian woodlands within the CCBNEP study area.

One of the biggest and most important challenges of the CCBNEP will be to help residents of the Coastal Bend understand the interdependence of the environment and the economy and the necessity of striking a complementary balance between the two.

Local Grassroots Efforts

The Coastal Bend Bays Foundation (CBBF) is a non-profit organization dedicated to the conservation and responsible use of our natural resources. Representatives of environmental groups, industry, commercial and recreational fishing, tourism, resource agencies, shipping and developmental interests have joined together to identify problems

VOL 12

3736

R0037044

and seek solutions to issues involving South Texas bays and estuaries.

To accomplish its mission, the CBBF has established five goals: Facilitation, Conservation, Education, Advocacy, and Research. Each of these goals corresponds quite well with the goals of the CCBNEP. CBBF intends to provide a forum for dialogue among the diverse users of the Corpus Christi Bay system. It develops projects for the purpose of preserving and enhancing the natural resources of the bays, estuaries and freshwater wetlands of south Texas. CBBF acts as a "land trust" for the purpose of acquiring, preserving, and enhancing wetlands and other ecologically important areas.

Education is another important element of the organization. CBBF provides resources and guidance for education projects with the purpose of developing a motivated constituency to protect the Bay. The organization works to empower educated citizens to become strong advocates of the natural resources of the Coastal Bend area. Finally, CBBF supports and encourages the allocation of public and private resources for research into the resources of the bays, estuaries, and wetlands of South Texas.

The philosophy of the organization, as articulated in each of its goals, has helped CBBF become a key voice on behalf of the environment and the citizens of the Coastal Bend Bays during the development of its Plan. Members, Board of Directors and staff of CBBF have served in numerous capacities in the development of the CBBP and in monitoring the interim actions and other steps taken in the Plan. Specifically, they serve on the Management Conference, as well as the Policy Committee and the Scientific Advisory Committee. CBBF has been involved in the CCBNEP since its inception and was instrumental in promoting the designation of Corpus Christi Bay as an estuary of "national significance".

Delaware Estuary
in Delaware, New Jersey and Pennsylvania

The key to protecting the Delaware River and Estuary is to listen to the River and what it has to say. The River communicates in sign language—the signs it uses are water quality, fish and wildlife populations, and the abundance or absence of habitat and plant species. It is up to us to learn the River's language, to read its signs, and to take its message to heart in our daily lives.

—Maya K. van Rossum, Executive Director
Delaware Riverkeeper Network

Portrait of the Estuary

The Delaware Estuary Program is examining the water quality and habitat problems of the Delaware Estuary and the impact that the greater watershed area has on the estuarine system. The Delaware Estuary extends 134 miles from its mouth between Cape May, New Jersey and Cape Henlopen, Delaware, northward to Trenton Falls, New Jersey.[1] With a water surface area of 768 square miles, the

Delaware Estuary

Area of surface water	768 square miles
Area of watershed	13,500 square miles
Average depth	21 feet
Population	• 8 million people
Values	• Sport fishing generates $25 million in economic output • The Estuary generates $28.7 billion in sales and wages • Home to the world's largest horseshoe crab population
Threats	• Habitat loss and degradation • Water diversion • Population growth and land use • Toxic pollution • Pathogen contamination • Nutrient loadings
CCMP status	Draft completed in 1995 Final approval expected in 1996

Designated as a "Nationally Significant" Estuary in 1988.

Mid Atlantic

Delaware Estuary is one of the largest estuaries along the Atlantic coast.[2] The average depth of the Estuary is 21 feet.[3]

The Delaware Estuary is one of the most relied-upon estuaries in the world. The watershed area of the Delaware Estuary includes portions of Pennsylvania, New Jersey, Delaware and New York. The Delaware River drainage basin, also referred to as the watershed, measures 13,500 square miles.[4] The watershed contains the population centers of Philadelphia, Pennsylvania; Trenton and Camden, New Jersey; and Wilmington, Delaware. In total, it includes 22 counties and 500 municipalities.[5]

An estimated 8 million people live within the watershed,[6] creating a density of 942 persons per square mile.[7] Six million people live in the portion of the watershed south of Trenton.[8] Projections indicate population growth rates of 52 percent for the State of New Jersey, 32 percent for Pennsylvania and 16 percent for Delaware by the year 2020.[9] The Delaware River provides the source of drinking water for over 20 million persons.[10] New York City, for example, diverts water from the upper Delaware River for its drinking water. To ensure that this critical service continues, maintaining the health of this system is crucial.

Most of the freshwater which enters the Delaware Estuary is carried by the Delaware and Schuylkill Rivers.[11] The remainder of the freshwater inflow originates from the Chesapeake and Delaware Canal and smaller tributaries.[12]

The Delaware Estuary system contains three ecologically defined zones — the upper zone, the transition zone, and the lower zone. The upper zone, consisting of tidal freshwater, is the most developed, and therefore, the most polluted part of the Estuary. The transition zone is characterized by high turbidity, low biological productivity, and a wide salinity range (0 to 15 parts per thousand).[13] The lower zone, with its shallow waters and high salinity, is considered the most biologically productive area.[14] The Delaware Estuary has an unusually strong tidal flow, one of the reasons for its naturally high dissolved oxygen levels. In addition, it only takes the whole system approximately 90 days to flush, or replace, all of its water content.[15]

Various habitat types can be found within the Delaware Estuary's watershed. Some of the more prominent habitats include coastal marshes, intertidal mudflats, beaches, and upland forests.

Values of the Estuary

The Delaware Estuary is a valuable resource for the many residents and visitors of the mid-Atlantic area. The Estuary supports large populations of birds, shellfish, and other wildlife which attract numerous bird-watchers, recreational fishermen, hikers, and photographers. The Delaware Estuary includes over 1.1 million acres of wetlands and subtidal habitats that support numerous animal and plant species and provide a buffer zone from residential areas. In addition, wetlands of the Delaware Estuary provide critical habitat for 35 percent of the region's threatened and endangered species.[16]

Population centers throughout the mid-Atlantic region depend upon the health and vitality of this natural resource. The Delaware Estuary watershed provides a source of drinking water for almost ten percent of the nation's population.[17] In addition, regional towns depend upon fishery and tourist industries supported by the Delaware Estuary to keep their economies afloat.

Recreation/Tourism

The Estuary provides a wealth of recreational opportunities — from swimming and nature watching to sport fishing — for millions of individuals each year. The economic benefits derived from these recreational activities are great. In addition to the resources it offers visitors, the Delaware Bay provides a solid base of employment opportunities for its surrounding residents. A Department of Commerce analysis approximates that the Delaware Estuary supported 123,000 jobs, and generated $4.3 billion in wages and $24.4 billion in sales in 1990.[18]

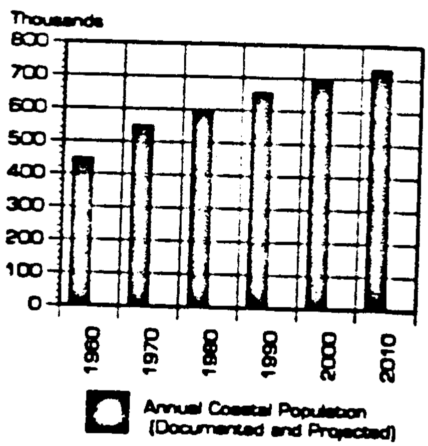
Sport fishing is a popular and valuable activity in the Delaware Estuary. In 1990, the value of sport fishing in the Estuary was estimated at $25 million.[19] State-specific numbers are available for as recent as 1991. Recreational fishing in the State of Delaware

VOL 12

3741

R0037049

Delaware Coastal Population



Data Source: U.S. Department of Commerce, National Oceanic and Atmospheric Administration, National Ocean Service

generated approximately $110 million and employed nearly 2,000 people in 1991. In the same year recreational fishing in New Jersey generated approximately $1.3 billion in economic output and employed nearly 16,800 people; and in Pennsylvania it generated approximately $1 billion and employed nearly 16,000 people.[20]

For the States of New Jersey and Delaware, saltwater fishing accounts for a large portion of the revenue derived from recreation. In 1991, 130,000 saltwater anglers fished off the Delaware coast, spending a total of 759,000 fishing days.[21] Over 66 percent of the fishermen were nonresidents of Delaware.[22] During the same year, 746,000 individuals spent a total of over 6 million days fishing off the coast of New Jersey.[23] The Delaware Estuary is important for many of the saltwater species caught off the mid-Atlantic coast since it provides feeding, spawning, and nursery grounds for the aquatic life which make up the intricate food web.

In 1988, birdwatchers contributed $5.5 million to the local economy of Cape May, New Jersey.[24] A number of state parks and national wildlife refuges provide great vantage points to observe birds and other wildlife.

Fisheries/Seafood

In 1994, the combined market value of finfish and shellfish landings in the Middle Atlantic region totaled approximately $149 million.[25] Many of the commercially valuable species in the Middle Atlantic region depend upon the health of the Delaware Estuary for survival.

In 1994, the State of Delaware's commercial finfish and shellfish landings totaled approximately seven million pounds, valued at $6 million.[26] In the same year, New Jersey's commercial finfish and shellfish landings totaled approximately 202 million pounds, valued at $100 million.[27] Pennsylvania's 1994 commercial finfish and shellfish landings totaled 371,000 pounds, and were valued at $292,000.[28]

The American oyster and the blue crab have historically been among the most economically valuable species in the Delaware Estuary. However, the economic contributions of the Estuary's oyster population have declined steadily since the early 1950s, primarily due to disease. As recently as 1980, over 640,000 pounds of oysters were commercially landed in the Estuary; in 1985 the landings had dropped to 39,000 pounds.[29] By 1989, there was no significant oyster harvest remaining.[30]

Landings of clam in the Estuary also dropped significantly — from 500,000 pounds in 1985 to 37,000 pounds in 1989.[31] The blue crab population, however, has remained viable in the face of human-induced environmental pressures, due to its rapid rate of reproduction and short life span.[32] In 1989, the blue crab fishery alone generated over $2 million for the local economy.[33]

Over 200 migrant and resident finfish species use the Delaware Estuary. Some of the more prevalent species include sharks, skates, sturgeon, American eel, blueback herring, Atlantic menhaden, alewife, American shad, striped bass, bluefish, weakfish and flounder. Overall finfish populations in the Delaware Estuary have been declining since the early 1900s due to overfishing, habitat loss, and water quality declines. Over the same period, commercial harvesting has shifted to the lower portions of the Estuary.[34] Currently, 31 finfish species are caught commercially in the Delaware Estuary.[35] In 1990, commercial finfish of the Delaware Estuary generated approximately $1.4 million.[36]

Wildlife

The Delaware Estuary supports a wide range of plants and wildlife, including oysters, crabs, sturgeon, pheasants, diamondback terrapins, ducks, and humpback whales. The Estuary has achieved a phenomenal reputation for the abundance of migratory birds which use the area as wintering and resting habitat. Over 70,000 greater snow geese use the Bombay Hook National Wildlife Refuge in Delaware in the early fall.[37] Canada geese, pintail ducks, green-winged teal ducks, black ducks, and wood ducks use the rich wetlands of this Refuge. Seventy percent of the North American red knot population has been found using the Estuary at one time.[38]

The Estuary is home to the world's largest horseshoe crab population.[39] Recent medical research has been conducted on the blood of the horseshoe crab. It is being used to help detect minute amounts of bacterial toxins associated with bacterial diseases, fever, shock and death in humans.[40] The annual, late-spring mating and nesting of the horseshoe crab is an inspiring spectacle for avid bird-watchers who travel to the bay shore to gaze at hundreds of thousands of red knots, ruddy turnstones, sanderlings, semipalmated sandpipers, and other migratory birds feasting on horseshoe crab eggs. Some migratory birds can gain as much as 50 percent of their body weight from the crab eggs.[41]

The Delaware Estuary also contains the largest heron, ibis, and egret rookeries on the east coast.[42] Humpback whales can be observed in the estuarine area.[43] Several estuarine-and wetlands-dependent federally threatened and endangered species can be found in Delaware, New Jersey, and Pennsylvania. The endangered roseate tern, and the threatened bald eagle and piping plover live in the Delaware Estuary.[44]

Threats to the Estuary

The Delaware Estuary includes the world's largest freshwater port (Port of Philadelphia), the nation's second largest petrochemical center, and several major population centers. For these and other reasons, the Estuary is vulnerable to human disturbance. Approximately 70 percent of the oil arriving on the Atlantic Coast is transported through the Estuary, placing the region at great risk from harmful oil spills.[45] The Trenton-Wilmington area has the world's greatest concentration of heavy industry.[46] Thus, the Estuary suffers from both historic and current effects of industrial pollution and oil spills as well as the continued pressures to convert natural areas into residential and commercial areas.

In order for the Estuary to continue to sustain the needs and activities of such an overwhelming population, measures must be taken to keep the quality of its aquatic and living resources intact. The Comprehensive Conservation and Management Plan (CCMP) of the Delaware Estuary Program identifies the priority threats to the Estuary system as habitat loss, water diversion, population growth, pathogen contamination, nutrient loading, and toxic pollution.[47]

Habitat Loss and Degradation

The Delaware Estuary includes approximately 405,000 acres of wetlands.[48] It is estimated that up to 24 percent of the Estuary's original wetlands have been destroyed.[49] Over the last 50 years, more than 39,000 acres of mostly freshwater and forested wetlands have been lost due to draining, filling, and other activities.[50]

The loss of wetlands habitat impairs the Estuary system in a variety of ways. Without wetlands to filter and absorb contaminants washed from urban streets, shoreline dredging, and agricultural lands, greater numbers of pollutants in higher concentrations reach the water and degrade the water quality. Secondly, without wetlands, the effects of storms are heightened due to the system's lack of protection from erosion and reduced ability to absorb tides and storm waters. Because many fish species rely on wetlands for nursery grounds, the loss of wetlands results in declines among fish populations. Finally, the ability of wetlands to retain and recharge groundwater is hampered by their decline. All of these factors affect the communities which are situated near the Delaware Estuary. In fact, it was calculated that wetlands conversions resulted in costs of about $166 million from lost flood controls, wildlife habitats, recreational uses, and waste treatment processes.[51]

The introduction of non-native species into the system is another cause of natural habitat loss.

VOL 12

Phragmites, a common reed, has strangled out native vegetation, destroying valuable habitat and eliminating species diversity in the Estuary. It is estimated that one-third of the tidal wetlands in the Estuary are infested with *Phragmites*.[12] Wetlands of the Delaware Estuary are found in the jurisdictions of three States and hundreds of municipalities and counties. Efforts to protect these vital resources must be better coordinated in order to be successful.

Water Diversion

The diversion of surface water and groundwater supplies for human uses is seriously harming the Estuary's living resources by increasing the salinity levels of the Estuary system. Used to generate power and provide drinking water, combined water withdrawals from the Delaware River Basin are estimated at 7.3 billion gallons per day. New York City, the largest user of the Estuary's water supply, is licensed to take 800 million gallons per day for its public drinking water system. Power generation accounts for 68 percent of the total water withdrawals.[13] Water withdrawals threaten the integrity of the ecosystem by altering the balance between freshwater and saltwater, thereby threatening the biological productivity of the ecosystem.

Population Growth and Land Use

The biological integrity of the Delaware Estuary is threatened by the fact that it is used by such a wide number of municipalities and industries for transporting goods and commerce and for receiving wastewater discharges. The Trenton-Wilmington corridor of the Estuary is considered to be the most heavily industrialized region per square mile in the world.[14] In 1990, the Estuary contained 181 industrial and 153 municipal point sources of pollution.[15]

Due to the area's large population size, a substantial amount of land within the region surrounding the Estuary continues to be developed for residential and commercial uses. Populations in the region are expected to increase during the next few decades. By 2020, an overall population increase of 1.1 million individuals (14 percent) is anticipated in this region.[16] Individual State populations are expected to grow by the following percentages: 52 percent in New Jersey; 32 percent in Pennsylvania; and 16 percent in Delaware. Population growth in the region will increase freshwater consumption by an anticipated 28 percent (up from 344 million gallons per day to 440 million gallons per day).[17]

In addition to increased water usage, population growth encourages more development activities, thus, infringing upon valuable wildlife habitat and creating more water quality problems for the Estuary. The replacement of natural lands by impervious surfaces, such as pavement and roofs, harms the water quality of the system. For instance, during heavy rain events, contaminants carried by urban stormwater are more likely to reach the Estuary without the filtration provided by soils and other natural areas. Thus, the ever-growing population within the Estuary, and the subsequent impact of human activities, present enormous obstacles to estuarine health and stability.

Toxic Pollution

Heavy metals and organic contaminants are a serious problem in the Delaware Estuary. High levels of toxic contamination can be found in sediments, the water column, and in the tissues of aquatic animals. Due to its extensive history as an industrial center, the Estuary is affected by high concentrations of toxins, particularly in urbanized areas. Not only do these contaminants persist in the estuarine environment for up to decades, but also many "bioaccumulate" and are carried to higher levels of the food chain, harming shellfish, fish, birds, and even humans. Reproductive rates for peregrine falcons, osprey, and bald eagles are lower for those nesting along the Estuary than they are for nesting populations in other areas of the mid-Atlantic due to their exposure to toxins.[18] In addition, there are growing concerns that subsistence fishers in urban and rural areas are increasing their risks of developing cancer by consuming higher than usual amounts of contaminated seafood.

Zinc, copper, nickel, chromium, silver, arsenic and lead are common contaminants of the Estuary which enter the system through point source discharges, urban stormwater, atmospheric deposition, agricultural runoff and groundwater. Approximately 110 tons of arsenic, chromium, copper and

3744

lead are loaded into the Estuary each year.[59] Copper, lead, and zinc are entering the Estuary through over 50 possible point source discharges and numerous nonpoint sources.[60] In addition, nearly 11 tons of mercury enter the Estuary each year. The concentrations of polychlorinated biphenyls (PCBs) are increasing in all three zones of the Estuary.[61]

PCBs, chlordane and DDT have been found in fish tissue and have led to fish consumption advisories throughout the Delaware Estuary. Specifically, Pennsylvania and New Jersey have issued fish consumption advisories for channel catfish caught from the upper Delaware River; and Delaware has issued a statewide advisory for striped bass during the past few years. Other fish species which have been subject to recent fish consumption advisories in portions of the Estuary include white perch, American eel, bluefish, and white catfish.[62] Finally, all fishing in Camden, New Jersey has been shut down due to the presence of chlordane, a pesticide which is officially banned due to its destructive human health effects.[63] Currently, there are no uniform standards for sampling potential sites of contamination and issuing advisories in the three States.[64] The lack of coordination of fish monitoring and public notification is recognized as a critical defect in efforts to protect and inform the public about the safety and quality of the Estuary's resources.

The Delaware Estuary is consistently one of the most widely-used shipping ports in the eastern United States. In 1993, the Delaware River had the second highest tonnage of maritime imports of all United States' rivers — second only to the Mississippi River.[65] Over one billion barrels of oil are transported via the Ports of Camden, Philadelphia, Gloucester City, Salem and Wilmington, placing the area at great risk from the effects of a damaging oil spill.[66]

Pathogen Contamination

Pathogen contamination, as measured by fecal coliform levels, does not seem to be as pervasive a problem in the Delaware Estuary compared to other coastal waters. However, pathogens (disease-causing microorganisms found in human and animal wastes) enter the Estuary system from over 300 combined sewer overflow outlets and the large number of municipal wastewater treatment plants.[67] Due to high levels of bacteria, "fishable and swimmable" standards for water quality are not often met in the Estuary between Camden, NJ and Philadelphia, PA.[68]

Pathogens in coastal waters pose risks to humans who eat contaminated shellfish or who recreate in beach waters. Gastroenteritis, hepatitis, and other diseases can result from the ingestion of pathogen-contaminated waters. For this reason, beaches and shellfish beds are closed or restricted when water monitoring indicates high levels of fecal coliform bacteria are present in coastal waters.

Between 1985 and 1990, the number of shellfish beds approved for harvesting decreased from 351,000 acres to 311,000 acres, a reduction of nine percent.[69] In both New Jersey and Delaware, sewage treatment plants were identified as significant pollution sources, contributing to the restriction of harvest areas.[70] Delaware, Pennsylvania, and New Jersey have all issued fish consumption advisories due to public health concerns about pathogen contamination.[71]

Nutrient Loadings

Nutrients, such as nitrogen and phosphorus are dumped into estuaries by urban stormwater, sewage treatment plants, atmospheric deposition, agricultural runoff, combined sewer overflows, and boater discharges. Due to the large number of urban wastewater plants in the Delaware Estuary, sewage discharges are considered to be the principal source of nitrogen and phosphorus in the Estuary.[72]

Excessive levels of these nutrients stimulate the growth of algae in the Estuary. As the algae grow, they not only block sunlight needed by the submerged aquatic vegetation of the Estuary, but also require a great amount of dissolved oxygen as they decompose. The decomposition process depletes the levels of oxygen for other aquatic life. Low oxygen conditions (called hypoxia) can result in large fish kills. Wastewater upgrades in communities throughout the watershed since the 1970s have diminished the levels of harmful contaminants reaching the Estuary through wastewater.[73]

In some portions of the Estuary, polluted runoff from farmland is a major source of phosphorus entering the Estuary. A study of the Upper Perkiomen watershed indicated that agricultural runoff contributes 80 percent of the nonpoint source pollution in the sub-watershed.[74]

Floatable Debris

Trash accumulated on estuarine beaches threatens the ecosystem and its wildlife inhabitants. The amount found in just a few days is staggering — on September 17, 1994, volunteers cleared 46,000 pounds of marine debris from 115 miles of Delaware's beaches. Of the total amount of marine debris collected, 60.4 percent was plastic, 10.7 percent was metal, 14.2 percent was paper, and 14.7 percent was from other materials.[75] In the same year, on October 15th and 27th volunteers cleared 73,782 pounds marine debris from 171 miles of New Jersey's beaches. Of the total amount of marine debris collected, 66.3 percent was plastic, 10.4 percent was paper, 8.2 percent was metal, and 15.1 percent was from other materials.[76] On September 17, 1994 in Pennsylvania, volunteers cleared 2,600 pounds of marine debris from 12.38 miles of the state's beaches. Of the total amount of marine debris collected, 69.1 percent was plastic, 8.8 percent was metal, 13.9 percent was paper, and 8.2 percent was from other materials.[77]

The Delaware Estuary Program

In 1988, the Delaware Estuary was nominated by the States of Delaware, Pennsylvania, and New Jersey for inclusion in the National Estuary Program. Later that year, it was officially designated an estuary of "national significance." Delaware, New Jersey and Pennsylvania, as well as Regions II and III of the EPA were jointly tasked with administering the Delaware Estuary Program (DELEP). The DELEP was given the responsibility of developing a Comprehensive Conservation and Management Plan (CCMP) to address the problems facing the Estuary and to recommend solutions to those problems. The framework of the DELEP consisted of a Management Committee, Policy Committee, Scientific and Technical Advisory Committee, Local Government Committee, Financial Planning Committee and Citizens Advisory Committee.

Recognizing that the DELEP is in a unique position as the only tri-state estuary program, the lack of a central staff focus made coordination among agencies particularly challenging. The level of outreach needed to communicate with the wide array of other non-governmental stakeholders in the DELEP adds additional responsibilities. These interests include representatives from recreational groups, business, industry, ports, watermen, scientists, educators and environmentalists. Communication was also problematic because Program Directors were spread out over such a wide geographic territory.

By August of 1992, the Management Committee decided to hire a Program Coordinator to assist in both the coordination and communication among the stakeholders. This significantly helped move the Program toward completing its Draft CCMP which was released for public review and comment in January of 1995. However, several critical issues must be resolved before the final plan is approved. Most of the issues involve mechanisms for implementing the CCMP once it is approved.

It has taken the DELEP six years to develop the CCMP. The complexities involved in negotiating a plan with so many key stakeholders can not be understated. Maintaining a high degree of participation among all stakeholders, especially citizens, both in the planning and the implementation phase is critical to the success of the program. For instance, without the financial commitments of the States, the CCMP is unlikely to be implemented. Similarly without full participation of citizens, community support would be difficult to attain. Experience has shown that the lack of community "buy-in" to the Plan could also lead to resentment and potential opposition. Those NEPs that have the highest degree of citizen involvement have proven to be the most successful.

The three States involved in the DELEP have expressed varying degrees of commitment to implementing the CCMP. The biggest points of contention seem to involve the level of citizen participation, financial contribution and cash match, and early implementation actions. The communication and coordination problems experi-

VOL 12

3746

enced during the first three years of the planning phase of the DELEP should be a reminder that all stakeholders, including citizens, need to remain involved throughout the life of the process. It should also be clear that a central office with authority to encourage implementation actions is critical to the success of the Program.

The draft CCMP recommends 77 actions to address problems and threats standing in the way of a healthy Estuary. These actions are divided into the following seven issue areas: monitoring; Regional Information Management Services; water use management; land management; toxics; habitat and living resources; and education and involvement. The Delaware Estuary Program provides mini-grants to grassroots organizations in the watershed. One project identified in the CCMP and funded by the DELEP is the restoration of the heavily contaminated Alcyon Lake in Gloucester County, New Jersey. Another project developed a method to filter out pollutants in the runoff by using terraces and grassy channels along streambanks. Due to the success of these programs and the commitment of the agricultural community, these methods have been used by local farmers and gardeners throughout the watershed.

The DELEP's ultimate goal for the Delaware Estuary is to implement specific measures which will ensure sustainable development within the system. In a watershed subject to explosive population bursts such as the Delaware Estuary, balancing development initiatives with the laws of nature is vital to the future of the Estuary

National Coastal Caucus

The Delaware Riverkeeper Network, an affiliate of the American Littoral Society, is a non-profit membership organization that has been working since 1988 to promote public education and action, and to protect, restore, and enhance the Delaware River environment. Riverkeeper works throughout 12,765 square miles and portions of four states (New York, New Jersey, Pennsylvania and Delaware) of the Delaware Watershed. Riverkeeper serves watershed residents, volunteers, schools, fishermen, service organizations, citizens groups, scouts, farm organizations and environmental groups. Since its creation, Riverkeeper has significantly improved stewardship on the Delaware River.

The Delaware River is one of about ten waterbodies nationwide that has a Keeper Program. The Keeper approach emphasizes the ecological functions of watersheds, the hydrologic cycle and nature's food web. It also emphasizes local action and enforcement of the Clean Water Act and other environmental laws. As a citizens organization, it accomplishes its mission by patrolling, investigating, intervening and raising public awareness of the problems of the River and its Estuary.

Members, staff and volunteers of the Delaware Riverkeeper Network have served in numerous capacities in the development of the CCMP and in the monitoring of the interim actions and other steps necessary to encourage implementation of the CCMP for the DELEP. Specifically, they have served on the Citizens Advisory Committee and Public Participation Subcommittee.

The Riverkeeper works to strengthen citizen protection of the Delaware River, its habitats and tributary watersheds. Volunteer efforts are the core of Riverkeeper's programs. Citizen monitoring of streams in the watershed helps agencies and private citizens enforce environmental laws and provides information for managing human impacts on the ecosystem. Riverkeeper's citizen monitoring program, which includes sites from Handcock, NY to Delaware Bay, is a comprehensive program involving streamwatch programs, chemical water quality tests, and macroinvertebrate testing. A related program includes the Home Waters program which establishes task forces in tributary watersheds and helps citizens learn to make full use of the public processes available to them.

Riverkeeper also maintains a pollution hotline, an enforcement program that spots and reports violations of environmental regulations; helps organize and implement stream bank restoration projects; and patrols the Delaware Estuary (in a recently donated boat) to find threats to water quality and to follow up on pollution reports.

Delaware Inland Bays
in Delaware

Every newspaper has headlines that scream warnings to Delaware. 'Crab Populations Down,' 'Poor Trout Season,' 'Fish Stocks Endangered,' 'Clam Harvest Down 90 percent since 1990,' 'Black Ducks Scarce,' and so on.... Yet, Delaware's Inland Bays' nursery and larval areas continue to be polluted and over-exploited. The contribution these Bays make financially to the State and local area is enormous, both from tourism and fishing supplies; yet the valuable, irreplaceable resource has almost no protection except that provided by the Clean Water Act.

—Til Purnell, Executive Secretary
Save Wetlands and Bays

Portrait of the Bays

The Delaware Inland Bays Estuary Program is examining the water quality and habitat problems of the Delaware Inland Bays and the impact that the greater watershed area has on the estuarine system. The Delaware Inland Bays are actually three bays — Rehoboth, Indian River, and Little Assawoman bays — located along the southern Delaware coast. The surface water of the Bays covers 32 square miles.[1] The average depth of the Delaware Inland Bays is a shallow four feet.[2]

The watershed area of the Bays measures 300 square miles and extends to include portions of

Delaware Inland Bays

Area of surface water	32 square miles
Area of watershed	300 square miles
Average depth	4 feet
Population	120,000 people
Values	• The hard clam fishery generates $48,000 • Sport fishing generates $110 million in economic output* • Recreational boating generates $14.7 million
Threats	• Nutrient loadings • Habitat loss and degradation
CCMP status	Approved in 1995

Designated as a "Nationally Significant" Estuary in 1988.

northern Maryland. Approximately 120,000 persons live within the watershed.[3] Portions of Sussex County, including the communities of Millsboro, Rehoboth Beach, and Bethany Beach, are situated within the watershed. The area is experiencing sizable population increases. The population of Sussex County grew from 80,356 in 1970 to 113,225 in 1990 and is expected to increase to approximately 150,000 by 2011.[4] During the summer months, the resort communities along bay and ocean shores in the region host hundreds of thousands of visitors.

The Bays have a number of features which distinguish them from other estuaries in the United States. First, physical connections with the Atlantic Ocean are limited. Saltwater reaches the Bays via the Indian River Inlet, Lewes and Rehoboth Canal, Roosevelt Inlet, and the Assawoman Canal.[5] Projects to deepen the Indian River Inlet have significantly altered the Inland Bays. During the past 60 years, the Bays have changed from a predominantly fresh water estuary to a marine-dominated one.[6] Barrier islands separate each of the Bays from the Atlantic Ocean. Second, unlike most estuaries which receive the bulk of their freshwater inflow from rivers, the Delaware Inland Bays receive as much as 80 percent of their freshwater, six to nine million gallons a day,[7] from groundwater sources.[8] The main tributaries that carry freshwater to the Bays are Indian River, Love Creek, and Herring Creek. Overall, the freshwater inflow, calculated to be 300 cubic feet per second,[9] is relatively low compared to other estuaries in the nation.[10] Finally, the shallowness of the Bays, coupled with limited freshwater inflow and flushing capacity make them particularly vulnerable to harmful contaminants.

Various types of habitat can be found within the watershed. These habitats include approximately nine square miles of salt marshes and wetlands, which provide critically productive buffer zones between the Bays and uplands.[11] Forested wetlands and sand dunes are other habitat types which support wildlife in the Bays.[12] The Inland Bays are stressed by 495 acres of "dead-end," unflushable lagoons in developments.[13] Many of these are anoxic and thus devoid of life.

Agriculture is the primary industry and the predominant land use in the watershed. Forty-seven percent of the land surrounding the Bays is used for agriculture.[14] Within the entire watershed, urbanized and publicly-owned lands comprise less than 25 percent of the land.[15]

Values of the Bays

The values of the Delaware Inland Bays system are inestimable. Numerous beaches, commercial and recreational fishing grounds, and abundant natural resources are found within this estuary system. Approximately 5,000 acres of public lands exist within the watershed area,[16] including Fenwick Island, Cape Henlopen, Holts Landing, and Delaware Seashore State Parks. These areas provide outdoor enthusiasts with a variety of recreational opportunities. According to a 1995 study, more than five million people visit Delaware every year.[17] Not surprisingly, 78 percent of those surveyed said visiting the beach and partaking in outdoor recreation activities were the primary purposes of their visit.[18] In 1992, domestic travellers spent $813.3 million and international visitors spent an additional $62 million in the State.[19]

Fisheries/Seafood

The Delaware Inland Bays provide important spawning and nursery grounds for commercially valuable fish and shellfish caught in the mid-Atlantic region of the United States. Of the approximately 30 square miles of classified shellfish harvesting areas within the Delaware Inland Bays, nineteen square miles are approved for harvesting.[20] Blue crab and hard clam form the basis of the Inland Bays' commercial and recreational fishing industries.[21] In 1990, the commercial landings for hard clam in the Delaware Inland Bays totaled 45,700 pounds, valued at $46,000.[22] Weakfish, spot, bluefish, and Atlantic menhaden represent the majority of the commercial finfish catch in the Delaware Inland Bays.[23] In 1994, commercial finfish landings for these four fish species in the Delaware Inland Bays totaled 23,166 pounds, valued at $10,900.[24]

In the past, the Bays supported bay scallop, oyster, and other shellfish fisheries as well as runs of anadromous fish such as alewife, herring, shad, and striped bass.[25] However, pollution, habitat alterations, channeling projects, and overfishing have resulted in declining populations of these fish and shellfish. The clam population has been depleted to less than 10 percent of its former size, and sport fishing stocks are also declining.[26] The loss of these resources has a deleterious effect not only on the livelihoods of local fishermen, but also on the economy of the area.

Recreation/Tourism

The shores of the Inland Bays and the Atlantic Ocean attract millions of tourists and outdoor enthusiasts each year. In 1985, approximately three million persons visited the Delaware Inland Bays.[27] In 1986, over 750,000 people visited the state parks near the Bays.[28] In 1987, Rehoboth beach was designated one of the top ten beaches in the U.S. The present-day number of visitors to the Bays and parks has grown exponentially since the late 1980s. Rehoboth Beach, although on the ocean and not the Bays, is a very popular vacation area in the Inland Bays region. The Bays provide an ideal spot for residents of Washington, D.C. and other major cities to spend a relaxing weekend. Sailing, swimming, sport fishing, water skiing, and hiking are a few of the popular activities which can be pursued in and near the Bays.

Economies of the local communities benefit from the recreational activities which lure visitors to the area. A 1984 study estimated that the recreation industry was responsible for 12.3 percent of the employment in Sussex County. In the same year, tourism and recreation generated visitor expenditures of $140 million and provided $4 million in taxes to state and local governments.[29]

Recreational fishing and boating help to support the coastal communities of Delaware. In the Delaware Inland Bays, recreational boating expenses alone account for an estimated $14.7 million per year.[30] Bluefish is the most commonly-caught recreational fish in the Bays. In 1991, recreational fishing in Delaware generated $110 million in economic output and employed nearly 2,000 people.[31] In that year, 45,000 freshwater and 130,000 saltwater anglers spent a total of 1.2 million days fishing in the waters of Delaware.[32] Two-thirds of the saltwater anglers were nonresidents of the State.[33]

Wildlife

The Delaware Inland Bays support and maintain a plentitude of plant and animal life. Migratory birds use the Delaware Inland Bays and its wetlands as wintering habitat and resting areas along the Atlantic Flyway. These migratory birds supplement the year-round waterbird populations which inhabit the Bays. A few of the many bird species which rely on the Bays include hooded mergansers, canvasback ducks, eagles, cormorants, ospreys, Arctic brant, snow geese, blue herons, glossy ibises, and oyster catchers.[34]

Delaware has 17 animal species on the federal threatened and endangered species list.[35] The endangered bald eagle and the threatened piping plover are protected species which rely on estuarine wetlands and beach habitats.[36]

Threats to the Bays

A full range of environmental stresses threaten the natural environment of the Delaware Inland Bays. Agricultural runoff, urban stormwater, wastewater outfalls, septic system discharges, recreational activities, dredging and coastal development all burden the estuary by destroying pristine habitat and degrading water quality.[37]

The Comprehensive Conservation and Management Plan of the Delaware Inland Bays Estuary Program has highlighted nutrient over-enrichment and habitat degradation as the primary threats to the system's water quality and natural resources. Other areas of concern are circulation patterns, pathogen contamination, and sea level rise.[38]

Nutrient Loadings

Sussex County's landscape and economy is dominated by agricultural production. Throughout the Bays, agricultural operations are the leading source of nitrogen and phosphorus inputs to the Bays.[39] Other nutrient sources include septic systems, sewage treatment plants, urban stormwater, atmospheric deposition, and forested areas.

Excessive levels of these nutrients stimulate the growth of algae in the Bays. As the algae grow and thicken, they not only block essential sunlight from bottom-dwelling plant communities, but also deplete aquatic systems of dissolved oxygen. The process of algal decomposition requires a large amount of oxygen and thereby, levels of oxygen for other aquatic life are reduced. Low oxygen conditions (called hypoxia) can result in large fish kills. Compared to other middle-Atlantic estuaries, the Delaware Inland Bays, are highly eutrophic.[40] Massive fish kills plagued the Indian River in the late spring of 1987 and 1988.[41]

The application of fertilizer on agricultural lands and residential lawns is a significant source of the nitrogen and phosphorus loadings which enter the Indian River and Little Assawoman Bays. In these areas, the nutrients leach through the sandy, porous soil and eventually permeate the groundwater aquifers in the watershed. The quality of groundwater aquifers is of grave concern, not only from an ecological perspective but also because the population of Sussex County depends on groundwater as the source of its drinking water supply.[42] Groundwater flow within the watershed is extremely slow. It is reported that nitrogen currently being discharged to the Bays was initially applied to lands 20 to 40 years ago.[43] Therefore, fertilizers being used today are likely to be a persistent problem for the Bays for the next several decades. As a result, the problems associated with nitrogen loadings will continue to reappear and present ongoing challenges to efforts to restore the Bays.

Poultry production is a growing industry in Sussex County and Delaware. It is estimated that Delaware produces 18 percent of the nation's broilers.[44] In Sussex County, 83 million chickens, creating over 95,000 tons of manure, are produced each year.[45] Chicken manure and by-products derived from chicken production are spread on agricultural lands in the watershed as fertilizer and are major sources of nutrients which enter the Bays.

Habitat Loss and Degradation

The wetlands and submerged aquatic vegetation that are part of the Delaware Inland Bays ecosystem are threatened and destroyed by eutrophication, high turbidity, sedimentation, natural events, and human activities. Examples of human activities which have modified and destroyed habitat in the estuary include dredging, filling, channelization, inlet stabilization, and construction.[46] Developing lands close to the Bays and its wetlands typically results in increased sedimentation due to land erosion; toxic and organic pollution due to more impervious surface areas — such as pavement and roofs; increased sewage discharges; and changes in water flow patterns and volume.

Eelgrass and widgeongrass are believed to be the only species of submerged aquatic vegetation that were historically found in the Bays.[47] During the past few decades, these grasses have disappeared as a result of the over-enrichment of nutrients and the resulting high turbidity.[48] In 1990, an unsuccessful attempt was made at re-planting eelgrass in the Bays; these beds later died.[49] Since seagrasses provide rich habitat for fish and shellfish, their loss has had an adverse affect on the populations of desirable estuarine resources.

Not only are the Bays losing seagrass habitat, but important wetlands acreage is also disappearing. Between 1938 and 1973, 24 percent of the area's tidal wetland acreage was destroyed,[50] primarily as a result of dredging and filling of the habitat.[51] Tidal wetlands provide important habitat for spawning, nursing, migration, and feeding for a variety of fish, shellfish, insects, birds, amphibians, and mammals. It is estimated that more than 60 percent of the area's freshwater wetlands have been destroyed since 1950 because of channelization and ditching.[52] The freshwater wetlands of the Bays provide critical habitat for anadromous fish, waterfowl, and mammals and filter nutrients, pollutants and sediments. Loss of habitat within the Inland Bays, increased human disturbance, and poor water quality have devastated many plant and animal populations. In addition, economic benefits of wetlands, such as flood control and water quality enhancement, are jeopardized by losses of wetlands in the Delaware Inland Bays area.

Projects to stabilize the Indian River Inlet, conducted in the late nineteenth and early twentieth centuries, have seriously altered the estuarine habitat. The Inlet provided the historical connection between the Atlantic Ocean and the Bays. Originally a freshwater, landlocked system, the Bays have been converted to a marine-dominated estuary. The almost total loss of the tidal freshwater portion of the Inland Bays has virtually eliminated nursery habitat for once-common fish such as striped bass, shad, and herring.[53] The objectives of these stabilization projects were to provide a commercial navigational route; to increase salinity and to decrease stagnation

VOL 12

3754

of the Bays; and to allow more tidal activities in order to control mosquitos. However, the effects on the Bays have been widespread and far worse than anticipated. Shoreline accretion and beach erosion have occurred on nearby coasts. Erosion of the channel banks and channel bottom have widened and deepened the Inlet.[55] These changes have seriously altered the habitats and living resources of the Bays.

Additional Concerns

Pathogen contamination poses another threat to the health of Delaware Inland Bays. Pathogens are disease-causing microorganisms found in human and animal wastes which enter estuaries through sewage treatment plant discharges, combined sewer overflows (CSOs), polluted urban stormwater, agricultural runoff, boating waste, and septic systems. Pathogens in coastal waters pose risks to humans who eat contaminated shellfish or who recreate in beach waters. Gastroenteritis, hepatitis, and other diseases can result from the ingestion of pathogen-contaminated waters. For this reason, beaches and shellfish beds are closed or restricted when water monitoring indicates high levels of enterococcus or fecal coliform bacteria (indicators of pathogen contamination) are present in coastal waters. In the Delaware Inland Bays, the number of closed shellfish beds increased by 75 percent over the past two decades.[56]

The trash accumulated on estuarine beaches threatens the ecosystem and its wildlife inhabitants. The amount found in just one day can be staggering — on September 17, 1994 volunteers cleared 46,000 pounds of marine debris from 115 miles of Delaware's beaches. Of the total amount of marine debris collected, 60.4 percent was plastic, 10.7 percent was metal, 14.2 percent was paper, and 14.7 percent was from other materials.[57]

The Delaware Inland Bays Estuary Program

In June, 1987 Delaware Inland Bays was nominated for inclusion in the National Estuary Program. It was accepted and officially designated an estuary of "national significance" in 1988. The Delaware Department of Natural Resources and Environmental Control, the Department of Health and Social Services, Sussex County and the EPA are coordinating the administration of the Delaware Inland Bays Estuary Program (DIBEP). The DIBEP was created to assess water quality in the Inland Bays; to make recommendations to address problems; and to bring together federal, state and local initiatives to ensure coordination of efforts to solve problems.

After significant public comment, much negotiating, and revisions to four different drafts, the plan to restore the Bays was finally approved. The EPA and the Governor of Delaware approved the final Comprehensive Conservation and Management Plan (CCMP) for Delaware Inland Bays in June, 1995. The Center for the Inland Bays (Center), a nonprofit organization, was established at the recommendation of the DIBEP's Citizens Advisory Committee to oversee and facilitate the implementation of the CCMP. Other post-CCMP activities of the Center include developing a strategic implementation plan, revising the monitoring plan and conducting public education and outreach projects. The Center has stated that it is a neutral arbiter. Unfortunately, the center has decided not to take any action on activities such as protecting eelgrass replanting areas.

From April 1991 through June 1993 the DIBEP convened a series of five "vision" workshops which were used to develop a framework for the CCMP. These workshops proved to be quite instrumental in jump-starting the process to move the CCMP development forward. Throughout the process the DIBEP has emphasized the use of regulatory and non-regulatory tools, ranging from erosion control requirements to landowner stewardship, as mechanisms to encourage wise management of the Bays system. Although the Center does not plan to use regulatory measures in its efforts to facilitate the implementation of the CCMP, some believe that this entity needs to consider both regulatory and non-regulatory mechanisms in order to achieve the community's goals most effectively.

The DIBEP has already made some progress in restoring the Bay. Stormwater management and sediment controls have been implemented for new development projects with the assistance of the DIBEP funding. Conservation plans, which outline ways to

VOL 12

3755

prevent soil erosion and agricultural runoff, have also been developed through the DIBEP for 49,274 out of 60,000 acres of cropland. In addition, the DIBEP is implementing two monitoring programs, one involving grassroots citizen participation as well as a more comprehensive scientific program. Additional educational efforts have focused on proper maintenance of septic tanks by homeowners in the watershed, including the replacement of 4,600 septic systems.

There have, however, been some weaknesses in the program that need to be addressed. Five Action Plans are outlined in the CCMP including an Education and Outreach Plan; Agricultural Source Action Plan; Industrial, Municipal, and Septic System Action Plan; Land-Use Action Plan; and Habitat Protection Action Plan. However, there is no water use plan included in the CCMP. This is particularly troubling since the Inland Bays are already enormously overburdened with boats and the recreational use of the estuary is only expected to increase. The CCMP references "A Water-Use Activity Impacts Report" that was prepared in 1989 which is supposed to serve as a basis for developing a Water-Use Plan for managing use of the Bays' waters. Yet no indication of movement in this direction has been seen.

In addition, although a Land-Use Action Plan exists in the CCMP, there is little mention made in the Plan for ways to control poor development, which is the primary cause of habitat destruction. Many believe that this issue should have been addressed more thoroughly by the DIBEP rather than relying on the Coastal Sussex Land-Use Plan. Although Sussex County is currently reviewing its land-use goals, the State is also developing a new transportation plan which is expected to cause further delays for the Land-Use Plan.

National Coastal Caucus

Save Wetlands and Bays (SWAB) is a nonprofit organization founded in 1980, with its established headquarters in Millsboro, Delaware. Devoted to protecting and restoring the Delaware Inland Bays, SWAB involves itself in issues that threaten the vitality of the water quality and living resources of the Bays.

SWAB has been involved in the NEP since its earliest days. Members, Board of Directors, and volunteers of SWAB have served in numerous capacities in the development of the CCMP and in monitoring of the interim actions and other steps taken to implement the plan. SWAB has played a key role in raising the voice of the citizens and ensuring that public participation remain an important part of the process. Specifically, SWAB has served on the Citizens Advisory Committee, the Scientific and Technical Advisory Committee as the Citizens Advisory Committee liaison, and the Monitoring Committee.

SWAB is an activist organization and its philosophy is one of cooperation and inclusion. Therefore, it works in coalition with a full range of local, state and national organizations, including such groups as the Conservation Network of Delaware, the Audubon Society, The Groundwater Foundation, League of Women Voters, Common Cause, Sierra Club, The Nature Conservancy, and the Chesapeake Bay Foundation. SWAB coordinates and submits public comments on regulatory and legislative proposals affecting the Bays. SWAB works to ensure citizens concerns are raised during public hearings and supports efforts by other local organizations to implement actions identified in the CCMP guidelines.

Galveston Bay
in Texas

Galveston Bay is the most productive estuary in Texas. Thanks to the successes of regulations under the Clean Water Act, one of its major tributaries has been brought back from a dead body of water (and one of the most polluted in the country) to one with a surprising diversity of aquatic life. The challenge ahead for the Bay is to continue balancing all of its diverse uses while maintaining and restoring its health. Implementation of the Galveston Bay Plan is integral to that effort.

—Linda Shead, Executive Director
Galveston Bay Foundation

Portrait of the Bay

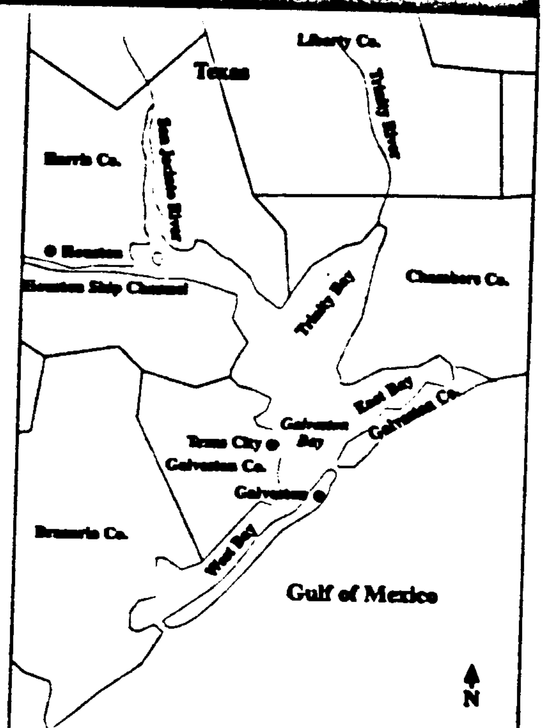
The Galveston Bay National Estuary Program is examining the water quality and habitat problems of Galveston Bay and the impact of the greater watershed on the estuarine system. Galveston Bay, located to the east and south of Houston, is one of the largest estuaries in Texas. The Galveston Bay system is composed of four large and two small bays — Galveston, Trinity, West, East, Bastrop and Christmas bays. It has a water surface area of 600 square miles.[1] Compared to other estuaries, Galveston Bay, with an average depth of six feet, is a

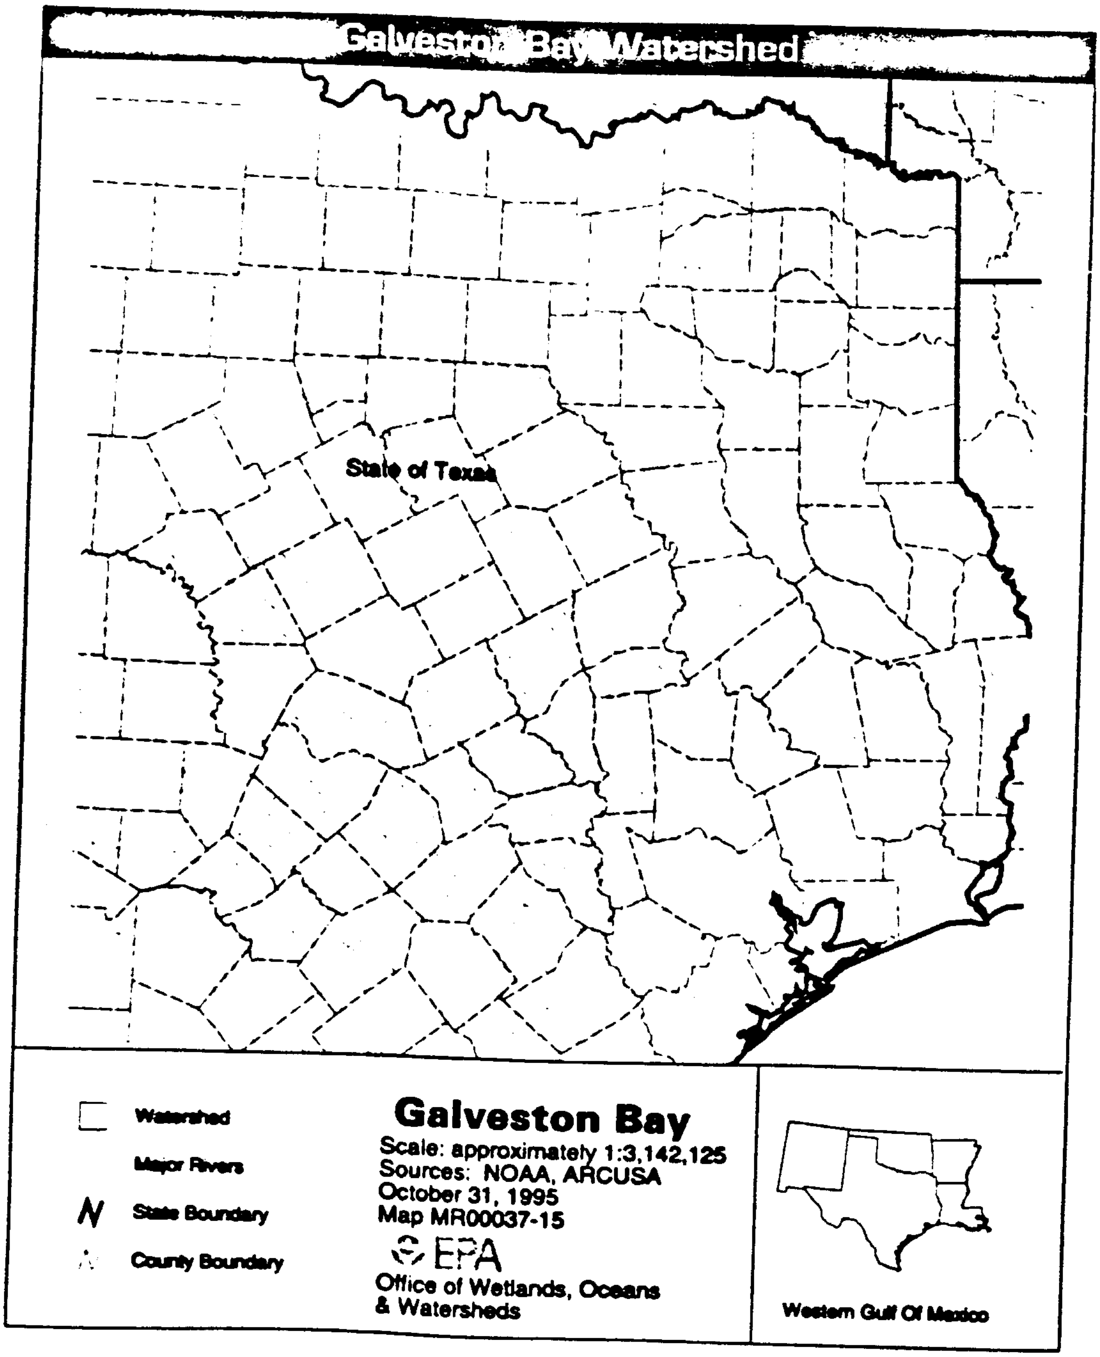
Galveston Bay

Area of surface water	600 square miles
Area of watershed	22,000 square miles
Average depth	6 feet
Population	6.7 million people
Values	• Tourism generates $7.5 billion • Sport fishing generates $2.8 billion in economic output* • The second most productive U.S. Estuary for seafood
Threats	• Habitat loss and degradation • Freshwater diversion • Toxic pollution • Pathogen contamination • Floatable Debris
CCMP status	Approved in 1995

Designated as a "Nationally Significant" Estuary in 1988.

*State figure





VOL 12

3760

R0037068

shallow estuary.[2] Not including dredged channels, the maximum depth of the Bay is ten feet.[3]

The Galveston Bay watershed area measures 22,000 square miles and includes the large metropolitan areas of Houston, Dallas, and Fort Worth. Over 6.7 million persons live in this watershed.[4] Four populous counties — Brazoria, Galveston, Chambers, and Harris — border the Galveston Bay shoreline. The combined population of these four counties totaled 3.2 million in 1990, comprising 73 percent of Texas' coastal population.[5] Projections indicate that the population in this area will continue to grow steadily over the next fifteen years. It is estimated that Harris County's population alone will increase by over 900,000 persons between 1988 and 2010; and the county's population density will surpass 2,100 persons per square mile by 2010.[6]

Galveston Bay has the largest volume of freshwater inflow of any estuary in Texas.[7] The principal source of freshwater into the Bay is the Trinity River.[8] The abundance of freshwater in the Bay mixes with saltwater from the Gulf of Mexico and creates ideal living conditions for finfish, shrimp, crabs, and oysters. As a result, it is the second most productive estuary in the United States for seafood.[9]

Distinctive types of habitat which can be found around Galveston Bay include river delta, marshes, mudflats, seagrass beds, oyster reefs, and open bay waters. Within the local watershed there are 183 square miles of salt marsh that border the Bay, 14 square miles of forested wetlands, and 35 square miles of freshwater ponds and lakes.[10]

Galveston Bay supports the sixth largest port in the world, used by ships servicing the petroleum and petrochemical industries.[11] The Houston Ship Channel, which cuts through Galveston Bay, is a major cargo route which connects the port of Houston with the Gulf of Mexico. Maintaining a proper balance between the health of the Bay's natural resources and the heavy industrial use of this waterbody has proven to be a tremendous challenge.

Values of the Bay

Commercial fishing, recreational activities and tourism provide the people of the Galveston Bay area with significant revenue and enjoyment. Maintaining healthy and productive coastal waters is important for continuing these desirable uses. Area residents have shown that they are willing to contribute financially to protect these waters. According to a 1994 survey, the average household in the Greater Houston-Galveston area is willing to add an additional $7 per month to its utility bills to clean up and restore the Bay. Over 90 percent of the respondents to the survey believed that reducing water pollution in the Bay was important, and a majority indicated that their primary motive in decreasing water pollution was to leave a healthy Bay to future generations.[12]

Recreation/Tourism

Sport fishing is an expanding industry in Texas. In 1991, recreational fishing in Texas generated approximately $2.8 billion in economic output and employed nearly 40,000 people.[13] Fifty percent of sport fishing activity and expenditures in all of Texas occur in Galveston Bay.[14] Saltwater fishing drew approximately 828,000 saltwater anglers to fish for a total of 6.8 million days in coastal and ocean waters off Texas during 1991.[15] Some of the most popular sport fish caught in the Bay area include red fish, red drum, sea trout, sea bass, and blue marlin. The third largest recreational boating fleet in the U.S. can be found in the Bay.

Tourism in the Bay area supported 80,000 jobs and generated $7.5 billion in travel and payroll dollars in 1992. Ecotourism is the fastest growing segment of the tourism industry.[16] Nature-related activities, such as bird watching at High Island, lure people from all over the world. Galveston Bay is home to 139 colonial, colonial inland, and open water bird species.[17] The coastal woodlands of the Bay are an important resting place for migrating neotropical birds.

Fisheries/Seafood

In 1994, the combined market value of finfish and shellfish landings in the Gulf region totaled approximately $806 million.[18] Over 90 percent of the commercially and recreationally important fish and shellfish species in the entire Gulf region use the coastal wetlands of estuaries of the Gulf, like Galveston Bay, during their life cycles.[19]

VOL 12

3761

Galveston Bay is the most productive bay fishery in Texas, generating over 11 million pounds of fish and shellfish, a total economic impact to the state of up to $358 million each year.[20] At least 162 species of finfish inhabit the estuary.[21] Some of the most commercially valuable species include white shrimp, pink shrimp, brown shrimp, oysters, blue crabs, and Gulf menhaden. Annual shrimp harvests from Galveston Bay are valued at $46 million.[22] Oysters represent the cornerstone of the Galveston Bay fishery, yielding 60 to 70 percent of the total oyster production in Texas.[23]

Wildlife

Galveston Bay is home to a great diversity of wildlife. Two National Wildlife Refuges, the Anahuac and Brazoria, are located in the Bay system. The Bay provides a congregating point for the largest number of waterfowl along the Central Flyway.[24] In addition, the American alligator, spotted seatrout, Atlantic croaker, sanderling, and brown pelican have experienced significant population increases in the Bay. However, due to habitat destruction in the region, several other species, such as the diamondback terrapin and striped bass, have suffered long-term population declines. More recent declines have been noted for white shrimp, blue crab, mottled ducks, and other species of near-shore feeding colonial waterbirds.[25]

Several of the 71 federally threatened and endangered species in Texas are present in Galveston Bay. Some of these species include the brown pelican, piping plover, whooping crane, American alligator, and Kemp's ridley, leatherback, loggerhead, and green sea turtles.[26] In addition, the bald eagle and Attwater prairie chicken are coastal prairie species that use estuaries.

Threats to the Bay

The urbanization of the Galveston Bay area has contributed to the estuary's past and present water pollution problems. Over time, however, the primary sources of pollution have changed. Decades ago, industrial and municipal discharges were considered the main sources of water quality impairment in Galveston Bay. Galveston Bay still has the greatest concentration of point sources among Gulf Coast estuaries — 747 industrial sources and 566 municipal wastewater treatment plants in 1990. However, polluted runoff and stormwater carrying pollutants from streets, lawns, development sites, and farmland in the watershed are currently responsible for a large portion of the area's water pollution problems.

The problems that the Galveston Bay Plan identifies as priority threats to the health of the Bay system include habitat loss, freshwater diversion, toxic contamination, and pathogen contamination.[27] In order to solve many of these problems, efforts to combat polluted runoff and stormwater discharges must be addressed. In addition, floatable debris found along coastal areas harms the integrity of the ecosystem and repels tourists from shoreline areas.

Habitat Loss and Degradation

Loss of valuable wetlands and seagrasses is the most critical problem facing the health of Galveston Bay.[28] The loss of habitat is the primary cause of species declines in the region. It not only displaces species from their homes, but also disrupts the food chain since the decline of one species impacts others. In addition, because wetlands filter contaminants before they reach waters, the loss of habitat has severely negative consequences for water quality. Thus, habitat protection is critical to the ecological health of Galveston Bay.

Between the 1950s and 1989, over 32,000 acres of Galveston Bay wetlands were destroyed. During this time, a 21 percent net loss of area fresh- and saltwater marshes occurred.[29] The conversion of wetlands to open water and upland areas for urban, agricultural, and oil and gas development is the leading cause of wetlands losses in the Galveston Bay system.[30]

In addition to the tremendous loss of wetlands, seagrass acreage declined from 5,000 acres in the mid-1950s to only 700 acres in 1989 — a loss of 85 percent. Reasons for the destruction of seagrasses in the Galveston Bay system range from chemical spills to coastal development, dredging, trawling, and wastewater discharges.[31] Only five percent of the Bay has any seagrass beds, most of which can be found in Christmas

VOL 12

3762

R0037070

Bay.[32] Efforts to restore seagrasses in Christmas Bay are proving successful. Between 1987 and 1989, seagrass acreage in this area increased by 185 acres.[33]

Coastal wetlands and seagrass meadows are critical nursery grounds for fish and shellfish, and provide habitat for a variety of shorebirds and migratory birds. The loss of coastal wetlands and seagrass meadows jeopardizes aquatic wildlife, and furthermore, threatens jobs which are connected to the natural resources of the Bay system.

Freshwater Diversion

The population of the Galveston Bay watershed has experienced steady growth. Almost 650,000 persons live within two miles of the Bay.[34] As population growth continues to occur, competition over limited Bay resources, such as freshwater for drinking water supplies, irrigation and municipal purposes, will intensify. Among the top issues governing the health of the Bay are the volume, timing, and quality of freshwater inflows, and the resulting water circulation patterns.[35]

The productivity of estuaries is dependent on the delicate balance between fresh- and saltwater. In order to sustain its valuable resources, the Galveston Bay system relies upon the continual inflow of freshwater from rivers and tributaries. Precipitation also plays an important role in providing freshwater to the system. However, freshwater diversions may alter salinity levels of the Bay, and thereby threaten organisms that depend on freshwater availability.[36] Oysters are one such species that relies on a stable balance of fresh- and saltwater. Balancing the diversion of freshwater to meet both the demands of humans and of nature is one of the many difficult issues under consideration in the Galveston Bay Program.

Toxic Pollution

Although shipping and industrial activities in Galveston Bay contribute trillions of dollars in revenue to the State, such revenue does not come without costs. In the 1960s, toxic pollutants plagued Galveston Bay and the upper Houston Ship Channel to the extent that massive fish kills occurred, and many feared the Bay's potential flammability. During this time, a calculated 500,000 pounds of biochemical oxygen demand (a measure of oxygen-robbing pollutants) entered the system each day primarily from industrial and municipal wastewater treatment facilities.[37] Today, despite efforts to control these activities, certain segments of the Houston Ship Channel still exceed water quality standards for toxic contaminants, such as polychlorinated biphenyls (PCBs), DDT, and heavy metals.[38] In fact, six of the top ten problems affecting Galveston Bay are related to toxic contaminants derived from petroleum compounds.[39]

Even though large amounts of toxic waste have been reduced by point source permitting controls, Galveston Bay still suffers from toxic contamination caused by polluted runoff. For instance, the amount of oil deposited into Galveston Bay yearly from urban polluted runoff is equivalent to 40 percent of the amount of the Alaskan oil spill of 1989. Between November 1993 and January 1994, a recreational area on Clear Creek (a tributary of Galveston Bay), was closed for several weeks due to the presence of toxic materials that originated from a Superfund site.[40] In addition, residues from the banned pesticides, DDT and dieldrin, have been found in the tissues of oysters caught in Galveston Bay.[41] Other types of seafood caught in the upper areas of the Bay pose public health risks for recreational and subsistence consumers because of their unacceptably high levels of toxic contamination.[42]

Pathogen Contamination

Harmful pathogens (disease-causing bacteria and viruses found in animal and human wastes) originating from wastewater discharges and polluted runoff from farmland, urban streets and lawns, also enter Galveston Bay. Galveston Bay receives about 60 percent of the total permitted wastewater discharged in all of Texas.[43] With such a heavy volume of wastewater being received in one bay, the threats associated with pathogenic contamination are extreme. Pathogens also have the potential to severely stress the aquatic life of the system. Fecal coliform contamination, from polluted runoff delivered to the Bay, has resulted in the permanent closure of 50 percent of the Bay to shellfish harvesting.[44]

In addition, bacterial contamination of beach waters

VOL 12

3763

poses health concerns for swimmers, divers, and other users. Throughout the nation, beaches are frequently closed because of unhealthy levels of bacterial contamination in bay and ocean waters. Galveston County monitors ten rotating sites along the Gulf of Mexico on a quarterly basis.[45] The Bay beaches are not generally used for swimming, and therefore, are not monitored.

Floatable Debris

Trash accumulated on estuarine beaches threatens the ecosystem and its wildlife inhabitants. On September 17, 1994, volunteers cleared 334,200 pounds of marine debris from 167.8 miles of Texas beaches. Of the total amount of marine debris collected, 70.7 percent was plastics, 8.4 percent was metal, 8.2 percent was glass, and 12.7 percent was from other materials.[46]

Galveston Bay National Estuary Program

Galveston Bay joined the National Estuary Program in 1988. In 1994, the Galveston Bay National Estuary Program (GBNEP) released the Galveston Bay Plan for public comment. The plan outlines actions to improve the future health and sustainability of the Bay and its valuable resources. Based on scientific data and community input, the Comprehensive Conservation and Management Plan (CCMP) contains strategies to remedy the problems caused by pollution, development, and resource overuse. Included in the CCMP are 17 priority problems and 82 suggested management and restoration initiatives. In April 1995, the CCMP for Galveston Bay was the seventh such project of the NEP to gain approval by the EPA.

In developing the plan, the first step was to reach consensus among the stakeholders on the Bay's problems. The CCMP was developed as part of a highly collaborative process among government agencies, business interests, environmental organizations and the general public. The fact that all levels of the community were truly involved in developing the plan, and not just those with special interests, may be the greatest strength of the Program. This high level of participation by the community during the planning phase created the momentum necessary to ensure support for the implementation of the restoration plan.

After bringing all the interested parties together, the next stage was to conduct scientific research to more specifically define the problems and to determine the source of these problems. After reviewing these results and gaining public comment, the outlines of the CCMP had fallen into place. The planning process was balanced with on-the-ground demonstration projects. These activities included establishing two new coastal preserves, sponsoring the restoration of oyster reefs and salt marshes, and working with the ship channel industries to implement a pollution prevention program. Other objectives include reducing polluted runoff by ten percent, reducing the amount of marine debris and illegal dumping by 50 percent, and establishing a seafood advisory program.

The implementation of the Galveston Bay Plan is being carried out jointly by the Galveston Bay Estuary Program of the Texas Natural Resource Conservation Commission (TNRCC) and the Texas General Lands Office (GLO). From the CCMP emerged four management initiatives to address habitat loss: wetlands management and protection, erosion mitigation, beneficial use of dredged materials, and subsidence reduction. The loss of habitat in Texas is particularly troubling because of the direct financial impact on the fisheries economy. Coastal salt marshes serve as a nursery for over 90 percent of coastal marine organisms and they produce far more vegetation than any intensive agricultural crop.[47]

Although these and other elements of the Plan have a tremendously high likelihood of success, there were a few stumbling blocks experienced along the way. For example, governance of the implementation effort was highly debated. Initially, a regional authority with taxing power was suggested. Some particular local governments did not want to create a new entity or allow additional taxing authority in their areas. The Galveston Bay Plan ultimately suggested implementation by the TNRCC. The State legislation decreed joint administration by the TNRCC and GLO (with base funding through the Coastal Protection Fund which is administered by GLO). The GBEP is now a program within the TNRCC.

VOL 12

3764

National Coastal Caucus

The Galveston Bay Foundation (GBF) has been intimately involved in the GBNEP since its inception. In most cases, a former or the current Chair of the GBF Executive Committee served as the official representative on the main committees, including the Policy Committee and Management Committee. Several other GBF trustees, sometimes representing other entities with a common interest, also served on the Scientific/Technical Advisory Committee, Citizens Advisory Steering Committee, and Public Forum to help develop the plan to restore the Bay. In addition to the committees, GBF trustees and members served on a variety of task forces for the GBNEP. GBF entered into a number of contracts from GBNEP for programs of shared interest: the Bay Day festival, citizens water quality monitoring, environmental inventories of coastal preserves, citizen pollution reporting hotline, boater education (marine sanitation), and Bay Ambassadors (speaker's bureau).

Three key GBF programs that are in keeping with the goals of the Galveston Bay Plan are habitat restoration, volunteer water quality monitoring, and the Bay Day educational festival.

Acknowledging that habitat loss was identified early on by the GBNEP as the number one priority problem, GBF began marsh restoration in 1989 with twenty volunteers creating a few hundred square feet of smooth cordgrass (*Spartina alterniflora*) marsh in the Galveston Bay System. By 1994, the program had grown to involve over 200 volunteers, and over 150,000 square feet of marsh were created. Cordgrass stabilizes the Bay's shoreline, preventing further erosion and creating buffers to filter pollution. Today the seeds from these matured plants have naturally reseeded themselves on the opposite shore with seeds carried across the bayou's waters.

Currently, GBF is in the middle of a two year project to restore nine acres of marsh in the Clear Lake watershed (a subwatershed of Galveston Bay). During the marsh restoration activities, over 500 volunteers have been educated in the values of coastal wetlands.

GBF has an extensive program of volunteer water quality monitoring, with over 35 sites in the base program. An additional dozen volunteers are participating in an NEP demonstration project to show the value of citizen monitoring in watershed management. GBF's program has been recognized by the Texas Natural Resource Conservation Commission as one of the premier programs in the State.

In 1991, in order to maintain the high level of buy-in and public support for protecting and restoring the Bay, GBF and GBNEP began an annual family festival to celebrate the resources and uses of Galveston Bay. The festival brings together all of the users of the Bay system and gives them an opportunity to tell the story of their relationship to Galveston Bay.

Indian River Lagoon
in Florida

Indian River Lagoon is the most diverse estuary in North America and is home to many endangered species. The Lagoon area also includes two of the fastest growing cities of the United States. This estuary deserves the dedication and commitment of local citizens who love the place.

—Diane Barile, Executive Director
Marine Resources Council of East Florida

Portrait of the Lagoon

The Indian River Lagoon National Estuary Program is examining the water quality and habitat problems of the Indian River Lagoon and the impact that the greater watershed area has on the estuarine system. The system includes the Indian River Lagoon, Mosquito Lagoon, and the Banana River. The Lagoon is a long, narrow estuarine system which forms 40 percent of Florida's east coast.[1] It extends from the Ponce de Leon Inlet near New Smyrna Beach southward to the Jupiter Inlet near Palm Beach—a total of 155 miles. The Lagoon's water surface area is 353 square miles.[2] The Lagoon's average depth is a shallow three feet; the depth extends to 12 feet along the Intracoastal Waterway.[3]

The Indian River Lagoon watershed measures approximately 2,300 square miles and includes portions of Volusia, Brevard, Indian River, Saint

Indian River Lagoon

Area of surface water	353 square miles
Area of watershed	2,300 square miles
Average depth	3 feet
Population	678,000 people
Values	• Fisheries generate $239 million* • Tourism generates $33.4 billion* • One-third of U.S. manatee population uses the Lagoon
Threats	• Habitat loss and degradation • Nutrient loadings • Stormwater • Pathogen contamination
CCMP status	Final expected in 1996

Designated as a "Nationally Significant" Estuary in 1990.

Florida

Lucie, Martin, and Okeechobee counties.[4] Two of the nation's fastest growing cities, Port Saint Lucie and Palm Bay, are located within the watershed. Other municipalities in the watershed include Melbourne, Fort Pierce, Titusville, Vero Beach, Cocoa, and Cocoa Beach. In 1990, more than 678,000 people resided within the watershed — a 124 percent increase since 1970.[5] The area's population is projected to surpass one million by 2010.[6]

The Lagoon receives a substantial amount of its freshwater from direct rainfall into the estuary and land drainage carried by creeks and canals, especially after heavy storms. The Lagoon is connected to the Atlantic Ocean through the Jupiter, Port Canaveral, St. Lucie, Fort Pierce, Sebastian, and Ponce de Leon inlets. The narrow width of these inlets causes limited water exchange between the ocean and the estuary. Winds have more influence on the movement of the estuary's brackish water than tides.

The Lagoon is located in a transition area between tropical and temperate zones. As a result, it provides a comfortable home to both tropical and subtropical species of flora and fauna. The diverse habitat types that can be found in the Lagoon include open water, seagrass meadows, mangrove forests, salt marshes, spoil islands, and shoal habitats. Over 200 spoil islands were created after dredged materials and sediments were deposited into open waters of the Lagoon during the 1950s.[7] Fortunately, the creation of new spoil islands is currently prohibited. Some of the effects of these massive dumping projects were increased turbidity and significant losses among seagrass habitat. Citizens from the town of Satellite Beach planted mangroves and other native vegetation to create a wildlife sanctuary out of a spoil island.

Values of the Lagoon

The Indian River Lagoon is an ecologically rich estuary which supports over 4,300 plant and animal species and contains a significant portion of eastern Florida's mangroves and salt marshes. The natural beauty of the Lagoon lures many vacationers to the area. Added features of the area include ocean beaches, recreational opportunities, public parks and refuges (including Pelican Island National Wildlife Refuge, established as the nation's first refuge in 1903), and various other tourist attractions. The biological productivity and tourist appeal of the Lagoon bring significant economic benefits to the region. The Lagoon area also helps support a $2.1 billion citrus industry that is distinguished worldwide.[8] Recognition of the connection between the ecological and economic values of the Indian River Lagoon is generating local interest in its preservation and restoration.

Recreation/Tourism

Florida's coastal waters lure millions of tourists and recreational enthusiasts to the State each year. In 1994, tourism revenues for Florida totaled approximately $33.4 billion.[9] A number of the State's most popular visitor destinations are located in the Indian River Lagoon area, including the Kennedy Space Center, the Cape Canaveral National Seashore, and Sebastian Inlet State Park, the most-frequented State park in Florida.

Sport fishing also generates significant revenue for the State. In 1991, the recreational fresh- and saltwater fishing industries employed over 58,000 people and generated approximately $3.5 billion in economic output.[10] In 1991, over two million saltwater anglers spent a total of 22.6 million days fishing off the coasts of Florida.[11] Over one-third of these anglers were non-residents of the State. In that year, approximately 30 percent of the total saltwater fishing days in the entire nation occurred off the coasts of Florida.[12]

Boating, swimming, waterskiing, windsurfing, sunbathing, camping, and hiking are some of the other recreational activities which engage visitors and residents of the Indian River Lagoon area. It is estimated that revenues from recreational fishing in the Lagoon totaled $54 million in 1990. In addition, more than 75,000 boats are registered in the area and marine/boating sales are estimated to exceed $300 million annually.[13]

Fisheries/Seafood

In 1994, the combined market value of commercial finfish and shellfish landings in the South Atlantic region totaled approximately $215 million.

VOL 12

3769

R0037077

Many of the commercially valuable species in the South Atlantic region depend upon the health of the Indian River Lagoon for survival. In 1994, the State of Florida's Gulf of Mexico and Atlantic Coast commercial landings of finfish and shellfish totaled approximately 177 million pounds and $239 million in dockside value.[14]

Fish caught from the Lagoon and nearby ocean waters account for 50 percent of Florida's total Atlantic Coast fish catch. In addition, clams harvested in the Lagoon comprise 90 percent of Florida's, and 15 percent of the nation's total clam landings. It is estimated that the total revenue generated from fisheries of the Lagoon is $300 million.[15] Spotted seatrout, red drum, mullet, blue crab, American oyster, and stone crab are other commercially valuable fisheries found in the area.

Unfortunately, population declines among commercial fisheries are affecting the productivity of the estuary, as well as the local economy. In an attempt to address the problem of population declines, there is a prohibition on the use of all commercial fishing nets in the State's inshore waters. Significant declines in the landings of spotted seatrout, American oyster, and hard clams have also occurred in the Lagoon due to overfishing, habitat destruction, and water quality impairments. The clam harvest, for instance, dropped from 1.5 million pounds in 1985 to 306,000 pounds in 1989.[16]

Wildlife

The Indian River Lagoon system includes five State parks, four National Wildlife Refuges, and a national seashore. All of these protected areas provide important habitat for the wildlife of the estuary. Approximately 680 fish, 367 bird, 52 reptile, 16 amphibian, and 30 mammal species can be found in the Lagoon ecosystem. Almost one-third of the bird species found in the Lagoon use the estuary for wintering habitat and 125 species breed in the area.[17] Very few, if any, estuaries in the United States can boast such a diversity of fishes and birds.

Of the 4,300 plant and animal species found in the Lagoon, 208 are classified as endangered, threatened, rare, or species of special concern by federal and State wildlife agencies.[18] No other estuary in the United States supports more protected species.[19] In addition, the Merritt Island National Wildlife Refuge, located in the central portion of the Lagoon, sustains the most endangered and threatened species of any National Wildlife Refuge in the continental United States.[20] The abundance and diversity of the area's wildlife appeal to the residents and visitors of the area. Measures to acquire vital habitats for wildlife, especially the rare, threatened and endangered species, are being considered in the comprehensive restoration plan.

Endangered species which depend on the Lagoon and its habitats include the Atlantic green sea turtle, Atlantic hawksbill sea turtle, Kemp's ridley sea turtle, wood stork, West Indian manatee, leatherback sea turtle, and red-cockaded woodpecker. Threatened species of the system include the Atlantic loggerhead turtle, Atlantic salt marsh snake, bald eagle, Florida scrub jay, piping plover, and roseate tern.[21]

For several protected species, the Indian River Lagoon provides crucial habitat. One of the Western Hemisphere's densest sea turtle nesting areas is found along the ocean beaches of the Lagoon.[22] The North Atlantic right whale uses the Indian River Lagoon and other coastal areas in Florida and Georgia as its exclusive calving area. The natural range of the Atlantic salt marsh snake is limited to this estuary.[23] Certain subspecies of Florida scrub jay, which are nearing extinction due to habitat destruction, live only on the barrier islands and Pleistocene dunes lining this estuary.

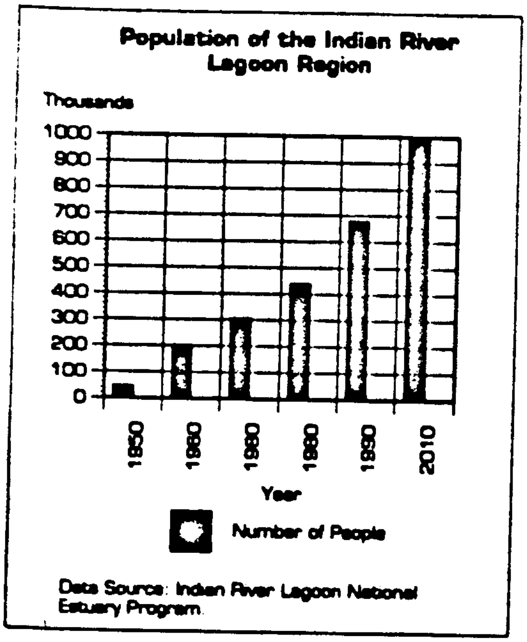
Manatees and bottlenose dolphins are also found in the Lagoon throughout the year. It is estimated that one-third of the total United States manatee population uses the Indian River Lagoon. An estimated 300 Atlantic bottlenose dolphins also live in the Lagoon year-round.[24] However, increased boating activities, habitat loss, and pollution are major threats to the area's manatee and dolphin populations.

Threats to the Lagoon

The natural beauty and resources of the Indian River Lagoon continue to attract more people to the

VOL 12

3770



area each year, providing increased revenues to local communities. However, the appeal of the Lagoon also exposes the estuary to increased pollution, habitat alterations, and other stresses associated with extensive human activities. The Indian River Lagoon National Estuary Program identifies habitat loss, nutrient loadings, pathogen contamination, polluted stormwater, and loss of biological diversity as priority threats to the system. In addition, marine debris is a concern in the area. Rapid population growth and development in the area affect each of the identified problems.

Habitat Loss and Degradation

Seagrasses, salt marshes, and mangrove forests of the Lagoon are used by wildlife for spawning, nursery, and feeding grounds, and for shelter. These habitats were greatly altered by past activities conducted to encourage human settlement and commerce in the region. Flood and mosquito control projects, navigational projects, and urbanized development have taken their toll on the natural habitats of this estuary. For example, the ditching or re-routing of many wild, inland streams to control drainage and flood waters has effectively reduced groundwater tables and changed freshwater flow patterns.[25] That, in turn, has changed salinity rates in the Lagoon, which can harm wildlife, such as oysters, clams, spotted seatrout and many other fish.[26] Also, the dumping of dredged spoils from the channelization of the Intracoastal Waterway have destroyed seagrass beds. Salt marshes have been impounded (or separated from the Lagoon by manmade dikes) in order to reduce mosquito breeding grounds.

As the Lagoon's watershed has become more urbanized, its seagrass beds have rapidly declined. The Lagoon is a seagrass-based ecosystem rather than a phytoplankton-based ecosystem like most other estuaries. This means that seagrass is a basic part of the Lagoon's food chain, providing most of the food for animals in the system.[27] The extent of seagrass coverage is a strong indicator of the overall health of the estuarine system. Currently, more than 170,000 acres of the Lagoon are six feet deep or less, providing an ideal environment for seagrass growth. However, less than 50 percent of that area is covered by these productive aquatic plants — a substantial decline in seagrass coverage from a few decades ago.[28] Since the 1930s, the Lagoon has lost approximately 30 percent of its total seagrass coverage.[29] In the portions of the Lagoon near Palm Bay, Melbourne, and south of Vero Beach, and in the southern portion of the Banana River, seagrass loss exceeds 50 percent.[30] The creation of spoil islands, increased freshwater inputs, and turbid conditions are some of the major reasons for the loss of this valuable habitat.

Development projects also threaten salt marsh and mangrove habitats. Since 1950, more than 75 percent of the area's salt marshes and mangrove forests have been destroyed, modified, or isolated by impoundments.[31] The impoundments retain flood waters in former salt marshes where mosquitos would lay eggs. Culverts are being installed in many areas in order to reconnect the Lagoon with the impounded marshes so that fish can travel to these areas and marsh vegetation can recover. Although a different type of shallow water habitat replaces the

VOL 12

3771

salt marshes, and some restoration efforts are under way, these altered areas do not provide the same shelter and feeding advantages as the natural marsh.

The loss of marsh, mangrove and seagrass habitat in the estuary is directly linked to steep declines in many wildlife populations. Habitat loss is the primary cause of population declines for the majority of the Lagoon's animals facing the threat of extinction.[32] For instance, modifications in salt marsh habitat are responsible for the extinction of the dusky seaside sparrow.[33]

Wetlands provide breeding, nesting, and feeding grounds for fish and wildlife; however, they also serve other functions which benefit coastal communities. Marshes and mangroves filter pollutants which run off streets and lands, absorb the forceful impacts of coastal storms before they reach upland areas, and reduce flows of flood waters. Despite the significant losses of natural wetlands, the Indian River Lagoon area contains 20 percent of the mangrove forests located on the nation's east coast and 27 percent of the salt marshes on Florida's east coast.[34]

For the past several years, concerted efforts to acquire important habitats with local and State monies have occurred throughout the Indian River Lagoon. In addition, a private land trust was founded in 1991 by the Marine Resources Council of East Florida to purchase lands surrounding the Lagoon. These efforts have supplemented federal efforts to expand the Pelican Island National Wildlife Refuge and the proposed Archie Carr National Wildlife Refuge, and Governor Chiles' designation of Indian River Lagoon as a State "Greenway." These programs are becoming more important as the number of building permits in the area is dramatically increasing. Providing a balance between population growth and development, and the protection of vital habitats will be a challenge as people continue to move to the area.

Nutrient Loadings

Nutrients, such as nitrogen and phosphorus, are introduced to the estuary by sewage treatment plants, agricultural runoff, stormwater, atmospheric deposition, septic systems, and boater discharges. Excessive levels of these nutrients stimulate the growth of algae in the Lagoon. As the algae grow, they not only block sunlight needed by the submerged aquatic vegetation of the estuary, but also require a great amount of dissolved oxygen to decompose. The decomposition process reduces the levels of oxygen needed by other aquatic life. Low oxygen conditions (called hypoxia) can result in large fish kills. The inundation of waterbodies with excessive levels of nutrients is called eutrophication.

In the Lagoon, sewage treatment plants are the primary source of nitrogen loadings; whereas agricultural runoff delivers most of the phosphorus to the estuary. Levels of nitrogen are greatest in the Banana River and the Cocoa and Cocoa Beach areas of the Lagoon. Additionally, several tributaries, including Turkey Creek, Sebastian River, and Vero Main Canal receive a significant amount of nitrogen. High levels of phosphorus are generally confined to the south-central Lagoon and the mouths of the Eau Gallie River and Crane Creek near Melbourne.[35] The northern portion of the Lagoon is especially sensitive to nutrient pollution because of its limited tidal flushing.[36]

The impacts of wastewater treatment discharges and stormwater on the Indian River Lagoon have been intensively studied. These studies indicate that the water quality of the Lagoon will deteriorate even further unless these pollutant loadings are reduced. In 1987, the Florida State Legislature passed the Surface Water Improvement and Management Act (SWIM) which addressed the abatement of stormwater impacts. In 1990, the Marine Resources Council worked to ensure the introduction of the Indian River Lagoon Water Quality Improvement Act calling for the elimination of domestic wastewater treatment plant discharges into Indian River Lagoon by July 1995. Recommended alternatives to discharging the effluent include wastewater reuse, land application, and deep well injection.[37] The cities of Cocoa and Cocoa Beach are employing wastewater reuse for city landscaping and lawn applications.

Polluted Stormwater

The Indian River Lagoon watershed receives about 50 inches of rain per year.[38] Stormwater carries

VOL 12

3772

R0037080

nutrients, bacteria, toxins, chemicals, sediments, and litter from the land to the Lagoon. As more impervious surfaces, such as pavement and roofs, replace natural lands, greater concentrations of pollutants in larger volumes enter the Lagoon.

Sediments discharged into the Lagoon affect water clarity, hindering the ability of light to penetrate through the water. Consequently, seagrass growth is inhibited, and in turn populations of aquatic life decline. In addition, stormwater inflows reduce salinity levels in wide areas of the Lagoon, especially the St. Lucie estuary and the mouths of Turkey Creek and Sebastian River. These alterations affect the estuarine ecosystem by disrupting the productivity of aquatic plant life and organisms. Declining populations of oysters and clams are being linked to salinity modifications caused by storm events.[39]

Pathogen Contamination

Pathogens are disease-causing microorganisms found in human and animal wastes which enter the Lagoon from wastewater treatment plants, septic system discharges, boating waste, stormwater, and runoff from pastures.[40] Pathogens in coastal waters pose risks to humans who eat contaminated shellfish or who recreate in beach waters. Gastroenteritis, hepatitis, and other diseases can result from ingesting pathogen-contaminated waters or seafood. For this reason, beaches and shellfish beds are closed or restricted when water monitoring indicates high levels of fecal coliform bacteria (an indicator of pathogen contamination) are present in coastal waters.

The State of Florida does not have a statewide beach water monitoring program; nor does any of the five counties bordering the Lagoon monitor their ocean or estuarine beaches for bacteria to ensure swimmer safety. During 1994, government authorities did not close or issue health advisories due to bacterial contamination for any of the swimming beaches in the five counties — even after heavy rains.[41] Between 1985 and 1990, the percentage of shellfish beds approved for harvest dropped from 32 percent to 14 percent.[42] After storm events, several shellfish harvest areas of the Lagoon, especially those areas near Port St. John and Grant are routinely closed.

Soil conditions in the watershed are unsuitable for the large numbers of septic systems found throughout the watershed.[43] Septic systems are situated on over 270,000 acres of these well-drained, sandy soils. Septic system discharges tend to move quickly through these soils and enter the groundwater before the bacteria can be neutralized.[44] Some of the more productive shellfish beds are situated near Volusia and Brevard counties — areas with high densities of septic systems.[45]

Additional Concerns

Population growth, loss of living resources, and marine debris are other threats to the health of the estuary. The combined population of the five coastal counties bordering Indian River Lagoon is projected to increase by 346,000 people between 1988 and 2010. Over this 22-year period, the population growth rate for Martin and Indian River counties is anticipated to be 61 and 50 percent, respectively.[46] For the sake of comparison, fewer than 20 coastal counties in the nation are expected to surpass a 50 percent growth rate between 1988 and 2010.[47] As the population in the watershed continues to grow, additional transportation, dredging, and construction projects will negatively affect circulation, flushing patterns, and water quality of the Lagoon.

Marine debris which accumulates on estuarine beaches and in waters, endangers the birds, sea turtles, and other living resources of the Lagoon. On September 17, 1994, volunteers cleared 368,255 pounds of marine debris from 1,267 miles of Florida's beaches. Of the total amount of debris, 61.4 percent was plastic, 12.5 percent was metal, 11 percent was glass, and 15.1 was other materials.[48] Citizens and civic groups have adopted several ocean and estuarine beaches for regular clean-ups.

The Indian River Lagoon National Estuary Program

In 1981, scientists, researchers, government agency officials, and citizens assembled for a symposium in Melbourne, Florida, coordinated by the Florida Institute of Technology. As a result of the

VOL 12

3773

VOL 12

gathering, the Marine Resources Council of East Florida (MRC), consisting of leaders in business, industry, government, development, environmental groups, and commercial fishing was founded. By 1989, the MRC had persuaded then-Governor Martinez to nominate the Indian River Lagoon for inclusion into the National Estuary Program (NEP) established under the Clean Water Act. On April 13, 1990, EPA granted the petition which declared the Lagoon an estuary of "national significance." Less than a year later the Indian River Lagoon National Estuary Program (IRLNEP) was established and began to take shape. The IRLNEP is currently in the final stages of drafting its Comprehensive Conservation and Management Plan (CCMP). It is expected to be released for public comment in March, 1996 and final approval by the Governor and the EPA Administrator is expected by September, 1996.

The framework of the IRLNEP mirrored the committee structure established by the MRC. In its characterization of the problems in the Lagoon, the IRLNEP Policy Committee adopted the priority problems already identified by MRC and the nomination documentation. The Management Conference was established to identify and ensure coordination among various State, local, and regional programs, to incorporate those programs into the CCMP, and to initiate early action activities to begin addressing the problems.

The geography of the region has made it challenging for members of different committees to participate in all of the necessary meetings. The IRLNEP decided that the length of the study area for the Lagoon required the development of sub-regional management plans. North, Central, and South IRLNEP regions were formed to establish management centers along the entire length of the Lagoon. Although the decision to sub-divide the watershed may have allowed for greater participation, it was criticized for its rejection of pre-existing efforts to erase subjective regional boundaries so that the entire watershed population could work together on developing one plan. In addition, many believe that regional partitioning of the watershed has caused division and competition among the separate regions. In the end, the Program and meetings were centered in Melbourne and one comprehensive plan for the entire system was produced.

One of the early action projects identified as part of the CCMP was a demonstration project to reconnect 75 acres of coastal salt marsh to the Lagoon which had previously been separated for mosquito control purposes.[49] To begin to address some of the adverse effects of these impoundments, a Rotational Impoundment Management (RIM) system was created. Through RIM, water levels in these areas are maintained at levels appropriate to control mosquitos during the breeding season; and during the remainder of the year, the system allows the marshes to be reconnected with the Lagoon. Currently, about 70 percent of the impoundments have some type of connection to the waters of the Lagoon. However, private ownership of the remaining impounded areas may delay further implementation of plans.

The IRLNEP is also helping to conduct seagrass studies in order to quantify vegetation losses and determine possible restoration measures. Studies thus far indicate that the low-salinity waters in the Melbourne-Palm Bay area have suffered the greatest seagrass loss. Another study is determining the amount of light needed for seagrass to flourish. Water clarity standards are likely to be necessary in order to restore seagrass beds in many of the 100,000 acres of shallow waters where there is currently no growth.

The IRLNEP has also worked in conjunction with the State of Florida's Surface Water Improvement and Management program (SWIM), which develops federal, state, and local agency networks. These networks develop and implement plans to restore and protect the water quality throughout the State.[50] In the Indian River watershed, this inter-agency coordination has reduced duplication among various government bodies to facilitate comprehensive coastal resource management. An electronic bulletin board has been created by the IRLNEP to facilitate informational exchange among Lagoon stakeholders.[51]

Other projects promoted by the IRLNEP include educational workshops to train teachers throughout the watershed about Lagoon ecology, a

3774

seagrass initiative, and a data coordinating group. Each of these programs has been formed in order to help build public consensus around the actions needed to protect and restore the Indian River Lagoon. In addition, IRLNEP funded the Marine Resources Council's Water Quality Monitoring Program, which was initiated in the late-1980s. However, the relationship between the two groups has suffered over the years. Unfortunately, Marine Resources Council and the Indian River Lagoon National Estuary Program have for the most part, worked on parallel tracks with little mutual support. A disappointing outcome of the split has been a less harmonious working relationship among the partners dedicated to the Lagoon.

National Coastal Caucus

As mentioned above, the Marine Resources Council of East Florida was formed in 1982 following a symposium entitled "Future of the Indian River System" (FIRST), which brought together researchers, local residents, and area officials concerned about the deterioration of the Lagoon. The MRC has played an immense role in the preservation of the Indian River Lagoon and was essentially responsible for its inclusion in the NEP. Today, more than 700 individuals and organizations have been brought together by the MRC, based on the common understanding that everyone depends on natural resources for jobs, recreation, and lifestyle.

MRC members, as well as private and public citizens meet every two years in an "American Assembly" to build consensus for action on wisely managing barrier islands, beaches, and estuarine watersheds. During the 1980s, MRC defined the problems of the Lagoon and asked for a three-year NEP program so that implementation plans could be speedily adopted.

Actions taken by the MRC have ensured that future plans for use of the Indian River Lagoon resources have been incorporated into the six counties' and 33 cities' comprehensive plans, in addition to State management policy. The State Legislature now regularly addresses Lagoon issues and has dedicated funding, totaling more than $8 million to Lagoon restoration efforts. The MRC has served as a model for international, national and state consensus and research-based estuarine planning. In 1991 President Bush awarded MRC one of the first nine Presidential Environmental Challenge and Conservation Awards for fostering partnerships among environmental organizations, businesses and government.

Today, MRC programs focus on citizen education and action projects. Marine Resources Council's Citizen Volunteer Water Quality Program enlists 103 citizens for weekly shoreline monitoring of the Lagoon and tributaries. Sixty-five students, representing eight schools, also monitor areas of the Lagoon. The Greenway Committee has assisted local governments in receiving more than $7 million in grants to acquire wetlands and open space for the purposes of habitat restoration and recreation. Many canoe trails, bike paths and wildlife corridors are being planned as a result of these grants. MRC's Pepper Buster program relies on volunteers to cut Brazilian Pepper trees (exotic plants which have invaded natural mangrove habitats) and restore mangrove wetlands. So far, more than six miles of shoreline have been improved by this program. Finally, over 115 volunteer right whale spotters monitor and report on the endangered whales' behavior and migration patterns off the ocean beaches.

Long Island Sound
in Connecticut and New York

Not only is Long Island Sound an invaluable economic and recreational resource, it is also a provider of immeasurable pleasure and happiness for tens of thousands of residents and visitors alike.

—John Atkin, Executive Director
Save the Sound, Inc.

Portrait of the Sound

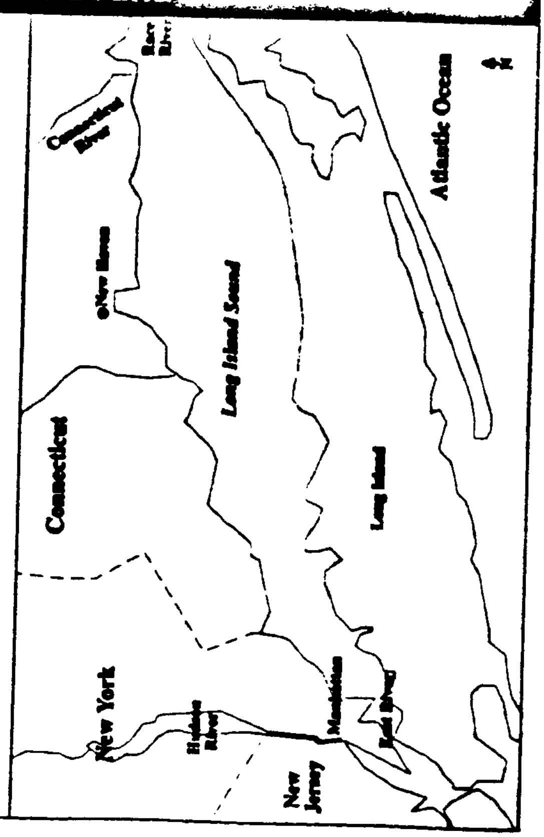
The Long Island Sound Study is examining the water quality and habitat problems of the Long Island Sound and the impact that the greater watershed area has on the estuarine system. Long Island Sound is the second largest waterbody in the mid-Atlantic region (although the Sound is sometimes perceived to be in New England). The mid-Atlantic is the most densely populated area in the United States, with a population

Long Island Sound

Area of surface water	1,320 square miles
Area of watershed	16,820 square miles
Average depth	63 feet
Shoreline	600 miles
Population	8.4 million people
Values	• Economic output for recreational fishing — $425 million (CT)* $1.4 billion (NY)*
	• Sound-related activities generate $5.5 billion
	• Habitat for a variety of endangered species
Threats	• Hypoxia
	• Pathogen contamination
	• Toxic pollution
	• Habitat loss and degradation
	• Floatable Debris
CCMP status	Approved in 1994

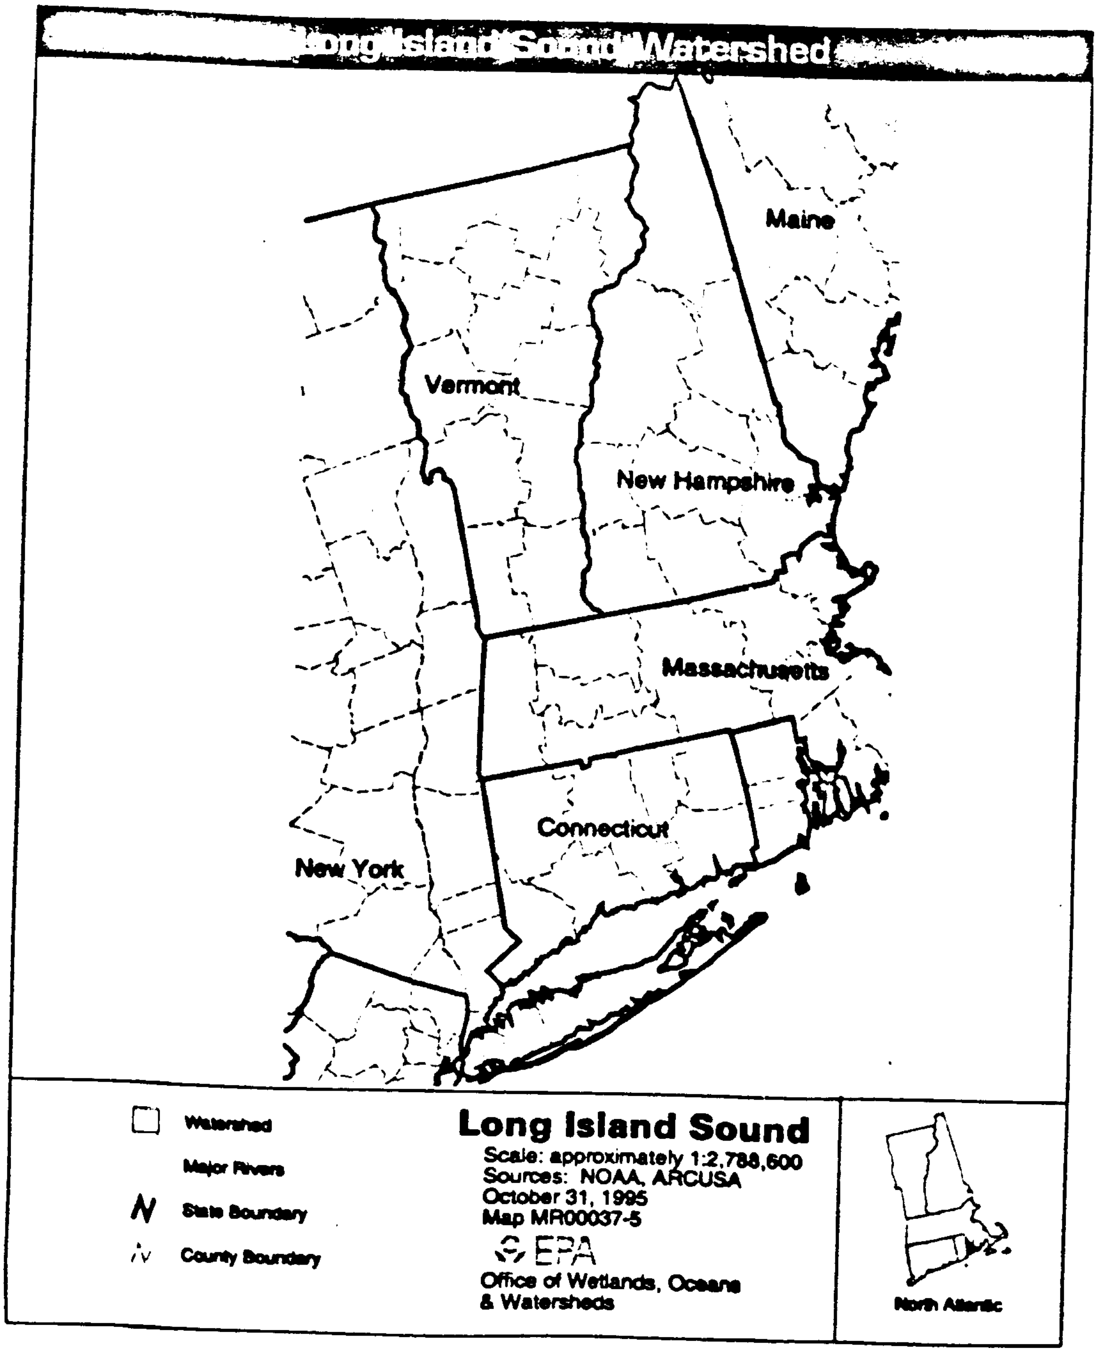
Designated as a "Nationally Significant" Estuary in 1987.

*State figures



VOL 12

3778



VOL 12

3779

R0037087

density 40 times greater than the national average.[1] This region stretches from Buzzards Bay, Massachusetts to Chesapeake Bay in Virginia.

The water surface area of Long Island Sound measures 1,320 square miles.[2] Long Island Sound is approximately 100 miles long and spans 21 miles at its greatest width. The average depth of the Sound is 63 feet; however, some portions reach depths of 120 feet.[3]

The watershed of Long Island Sound covers 16,820 square miles and stretches to include most of Connecticut, and portions of New York, Rhode Island, Massachusetts, New Hampshire, Vermont and Canada.[4] Over 8.4 million people live in the watershed of the Sound.[5] Long Island Sound is bordered by a nearly unbroken chain of urban cities and towns along its 600-mile coastline. The Sound is bounded to the west by New York City; to the north by Stamford, Norwalk, Bridgeport, New Haven, and Clinton, Connecticut and Westchester County, New York; and to the south by Long Island, New York.

An unusual feature that distinguishes the Sound from most estuaries is its lack of a major, direct freshwater source at its head. The East River tidal straits are at the head of the estuary. A series of rivers, including the Connecticut, Thames, and Housatonic rivers, deliver freshwater to other areas of the Sound. Long Island Sound has two major connections to the Atlantic Ocean — one on each end of the estuary. The East River and the Upper Bay of New York Harbor link the western portion of the Sound with the ocean. The eastern opening to the Atlantic Ocean is through Block Island Sound and The Race. The Sound's circulation and flushing patterns are quite complex as a result of the unusual interchanges of fresh- and saltwater.[6]

Distinctive habitat types of the Sound include tidal wetlands, tidal flats, beaches, dunes, bluffs, rocky tidal areas, eelgrass, kelp beds, coastal shorelands, and open waters. Unfortunately, many of these habitats are stressed by increasing urbanization, population growth, and pollution.

Values of the Sound

"Long Island Sound is a national treasure and one of the nation's most important waterways," according to EPA Administrator Carol Browner.[7] The recreational value of this estuary, its proximity to New York City, and the fact that it provides an escape from the surrounding urbanization are some of the major attractions of the Sound and its coastline.

In 1990, the economic value of the Sound's resources was estimated to be more than $5.5 billion. Boating activities generated $3.3 billion of this total; sport fishing generated $1.1 billion; swimming produced $843 million; commercial fishing generated $148 million; and "intrinsic" values generated $152 million.[8] In assessing these figures, it is important to note that they have been understated. For instance, the commercial fishing data does not include the value of the processing, wholesaling and retailing sectors; nor does the recreational data include a full range of activities such as camping or hiking.[9] Furthermore, dollar figures cannot be placed on all values of the Sound. For instance, the value of the Sound as a natural resource and the importance of natural habitats and good water quality to near-shore residents are immeasurable.

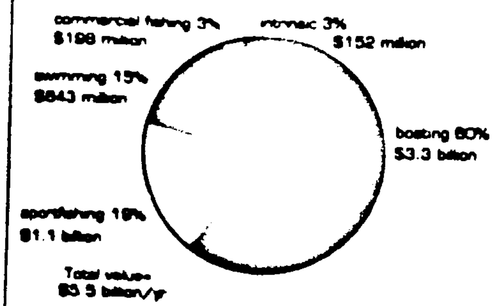
Recreation/Tourism

Of the approximately $5.5 billion generated each year from Sound-related activities, boating, sport fishing and swimming account for a large portion of this revenue — $5.2 billion. Two factors help to explain why the Long Island Sound is so popular. First, Long Island Sound is close to millions of people; a total of 15 million people live within 50 miles of the estuary.[10] The number of sunbathers, swimmers, and boaters using the Sound on a summer weekend day is often greater than the combined populations of Delaware and Alaska.[11] Second, Long Island Sound surpasses most other middle-Atlantic estuaries in the number of public outdoor recreational sites in its vicinity.[12] This combination ensures a steady flow of recreational enthusiasts to the Sound for fishing, camping, touring historical sites, boating and other activities.

Large numbers of boaters and anglers use the Sound. The estuary supports over 200,000 recreational boats and the Long Island Sound area has over 750,000 registered recreational fishermen.[13] For both Connecticut and New York, Long Island Sound is an important part of the States' recreational fishing industries. In 1991, freshwater and saltwater recreational fisheries

Long Island Sound

Estimated Value of Resources in the Sound



Source: Dr. Marilyn Altobello, University of Connecticut, The Economic Importance of Long Island Sound's Water Quality Dependent Activities (1992) 23

generated approximately $425 million in economic output and employed nearly 5,400 people in Connecticut; while in New York, sport fishing generated approximately $1.4 billion in economic outputand employed nearly 17,700 people.[14]

Fisheries/Seafood

Long Island Sound contributes valuable fishery resources to the Middle Atlantic and New England fishery regions of the United States.[15] In 1994, the market value of commercial finfish and shellfish landings in the Middle Atlantic region totaled approximately $149 million. In the same year, the New England region's total commercial landings value was $583 million.[16] Long Island Sound provides spawning and nursery habitat for many of these commercially valuable finfish and shellfish. In 1994, Connecticut reported an estimated 19.8 million pounds of commercial finfish and shellfish landings, valued at $44 million. In the same year, New York's commercial finfish and shellfish landings totaled approximately 44.7 million pounds of finfish and shellfish and were valued at $43 million.[17]

Prominent commercial fisheries of the Long Island Sound area include oyster, hard clam, American lobster, blackfish, bluefish, butterfish, mackerel, striped bass, winter flounder, and summer flounder. Long Island Sound is reputed as the leading producer of oysters along the east coast.[18] However, shellfish resources in the Sound are being adversely affected by pollution. In 1990, there were approximately 118,500 acres of productive shellfish beds in Long Island Sound. Of these productive beds, only 51,945 acres were approved for harvesting.[19]

Wildlife

Long Island Sound provides habitat for an abundance and diversity of wildlife. Although some plants and animals may not provide a direct economic benefit or aesthetic value, they are important because they are interconnected with other organisms in the food web and can be used as a barometer for the health of the Sound.

Hundreds of bird species, including osprey, cormorants, peregrine falcons, herons, egrets, and mallards use the area for nesting and feeding grounds, and for resting habitat along migratory routes.

Three marine mammals — bottle-nosed dolphins, harbor porpoises, and harbor seals — were once common inhabitants of the Sound, although their current numbers have been dramatically reduced. Today, only a few small schools of bottle-nosed dolphins can be found in the eastern and central Sound and porpoises can be observed using the estuary between Plum Gut and the mouth of the Thames River. The cause of their declines is believed to be either increased boating activities, a collapse of sea herring in the 1970s (a major food source), degraded water quality, or a combination of the three.[20] In contrast, after years of decline, populations of harbor seals have increased from 400 to 4,000 during the last decade.[21]

Other species designated as endangered, threatened, and of special concern use Long Island Sound and its wetlands for habitat. Piping plovers, roseate terns, least terns, Kemp's ridley turtles, osprey, and harbor seals are a few of these protected species which use Long Island Sound.

Threats to the Sound

Long Island Sound has been described as an "urban sea under siege."[22] The Sound has endured the stresses associated with over a century of industrial activities and over five decades of substantial population growth, with its accompanying residential

VOL 12

3781

R0037089

and commercial development. All of these activities restricted access to the estuary, altered natural habitats, increased pollution, and reduced open spaces. The estuary became a convenient disposal site for human and other wastes.

Beginning in 1985, the Long Island Sound became the focus of several studies which assessed the quality of the estuary. Based on the results of these and subsequent studies, the Comprehensive Conservation and Management Plan for Long Island Sound identifies low dissolved oxygen levels (hypoxia), pathogen contamination, toxic pollution, habitat loss, and floatable debris as the most serious threats to the estuary system.[23]

Hypoxia (Low Dissolved Oxygen Levels)

Hypoxia, considered the primary threat to Long Island Sound, is the result of over-enrichment by nutrients.[24] Excessive loadings of nitrogen, phosphorus, and other nutrients from municipal wastewater discharges, combined sewer overflows, air deposition, stormwater, and urban runoff stimulate the growth of algae in the Sound. As the algae grow, they not only block sunlight needed by the estuary's submerged aquatic vegetation, but also require massive amounts of dissolved oxygen to decompose. As the algae are decomposed, the oxygen supply needed by other aquatic life in the Sound is depleted.

Low levels of dissolved oxygen cause adverse ecological effects in the bottom water habitats of the Sound. Research shows that hypoxic conditions result in reduced abundance and diversity of adult finfish; reduced growth rates among lobster and juvenile white flounder; reduced disease resistance in lobster; and death for immobile and slow-moving species.[25]

Hypoxic conditions were responsible for massive fish kills in the western portion of the Sound during the late 1980s. In 1989, scientists discovered hypoxic conditions in 40 percent of the Sound's bottom. This minimal level of oxygen was unsuitable for the survival of many aquatic species. Between July and mid-August of 1994, hypoxic conditions were experienced on the bottoms of the East River, the Narrows, and the Western Basin.[26] Hypoxic conditions have improved over the past few years. In 1995, only 22 percent of the bottom dissolved oxygen readings were hypoxic, compared to 33.3 percent in 1994.[27]

The total nitrogen load to Long Island Sound is 93,600 tons per year.[28] A significant percentage of this load originates from sewage treatment plant discharges, since only specifically designed treatment plants remove nitrogen from sewage prior to discharging the wastewater into receiving waters.[29] This is a particular concern for Long Island Sound due to the significant, nearby human population. Each day, Long Island Sound receives over one billion gallons of wastewater from 44 municipal sewage treatment plants.[30] For this reason, reducing nitrogen loadings from sewage treatment plants and other point sources is a priority of the restoration plan.

Pathogen Contamination

Pathogens are disease-causing microorganisms found in human and animal wastes which enter the estuary through sewage treatment plant discharges, combined sewer overflows (CSOs), polluted urban stormwater, and boating waste. Pathogens in coastal waters pose risks to humans who eat contaminated shellfish or who recreate in beach waters. Gastroenteritis, hepatitis, and other diseases can result from contact with pathogens. For this reason, beaches and shellfish beds are closed or restricted when water monitoring indicates high levels of fecal coliform bacteria or enterococcus (indicators of pathogen contamination) are present in coastal waters.

The sewage treatment infrastructure for some of the municipalities that border the Sound is inadequate and outdated. Combined sewer systems are a leading source of pathogen contamination in Long Island Sound, particularly in the western portion of the Sound. In combined sewer systems, sewage conveyance lines and stormwater drains are linked. During severe rain storms, combined sewer overflows (CSOs) occur, releasing raw and partially treated sewage into the Sound and its tributaries through storm water pipes. In addition to combined sewer overflows, overloaded sewage treatment plants and marine vessel sewage discharges contribute to the amount of improperly treated sewage discharged into the Sound. Finally, contaminated stormwater also carries animal wastes washed from lawns and farmlands into the Sound.

Many shellfish beds in the Sound have been closed or restricted from harvesting for long periods

VOL 12

3782

due to the cumulative impact of pathogen contamination. In 1990, 73 percent of the Sound's productive shellfish beds in New York and 35 percent of its productive beds in Connecticut were closed to harvest due to pathogen contamination.[31]

Between 1986 and 1990, the following ten beaches were "chronically" closed to swimmers due to pathogen contamination: Scudder Park, Gold Star Battalion, the Mamaroneck area, Huntington Beach Community, the Hempstead Harbor area, Centerport Yacht Club, Fleets Cove, the Mamaroneck Beach Cabana and Yacht Club in New York; and the Norwalk and Milford beach areas in Connecticut.[32] In 1994, unsafe levels of bacteria resulted in the issuance of beach closures and health advisories at least 162 times at Connecticut's, and 227 times at New York's ocean and estuarine beaches.[33]

Toxic Pollution

Toxic chemicals enter the Sound through urban stormwater, polluted runoff, sewage discharges, industrial discharges, atmospheric deposition, and household waste disposal. Other sources of contamination include power plants, old land fills, chemical and oil spills and boating operations.[34]

Heavy metals and organic chemicals have contaminated the sediments in urbanized embayments of the Sound. Metals of greatest concern are cadmium, chromium, copper, lead, mercury and zinc. Long Island Sound is consistently one of the nation's most contaminated sites for copper; in addition, high levels of mercury have contaminated portions of the East River.[35] In many sites, toxic contamination of the underwater sediments is actually much worse than water column pollution. This is primarily due to discharges that predated current controls under the Clean Water Act.[36] However, in the western Sound the sediments are highly reactive chemically and exert considerable influence on the quality of the overlying waters.

Chemicals discharged into the Sound can accumulate in the tissues of fish species, harming fish populations and posing health risks to consumers. In recent years, high concentrations of PCBs found in the tissues of striped bass, bluefish, eel, lobster and crab have led authorities to issue consumption advisories.[37] There is also concern over contaminant levels found in the tissues of waterfowl. New York has issued an advisory for the consumption of mergansers and other waterfowl. Connecticut has funded research to examine contamination of a diving duck known as the greater scaup.[38]

Potential toxic hotspots in the Sound include: Bridgeport, Mamaroneck, Hempstead, the Lower Housatonic River near Devon, and Throgs Neck. Mussels and oysters in these regions have been documented with higher levels of heavy metals and organic compounds in their tissues relative to those found in other places in the Sound. Most of the contamination is believed to flow from the Connecticut, Housatonic, Quinnipiac, and Thames Rivers. In general, toxic contamination of the Sound worsens as one travels from the eastern portion to the west and is particularly severe in Throgs Neck.[39]

Habitat Loss and Degredation

Population growth and development activities after World War II significantly impaired the quality of water flowing into the Sound by increasing the overall level of pollution discharged into the estuary system and by destroying critical wetlands, upland habitat, and eel-grass beds. Wetlands losses in the Sound have far-reaching impacts on the biological diversity and water quality of the estuary due to the many valuable functions these natural areas perform. Wetlands provide important spawning and nursery areas for finfish and shellfish and nesting areas for birds. Coastal wetlands prevent shoreline erosion and protect inland areas from coastal storms. Finally, wetlands absorb flood waters, remove pollutants before the contaminants can reach the estuary, provide places for recreation, and serve other beneficial purposes.

The State of New York has lost 1.5 million acres of its original wetlands — a 60 percent loss. Connecticut has lost 500,000 acres — 74 percent of its original wetlands.[40] Over the past century, up to 35 percent of the Sound's tidal wetlands were destroyed by development.[41]

Urbanization and development in the watershed increase pollution in the Sound due to the replacement of natural lands with impervious surfaces, such as pavement and roofs. The replacement of naturally porous areas, such as wetlands, grasslands or barren earth, with impervious surfaces significantly restricts the filtration of pollutants. Therefore, more pollutants reach the estuary.

Hydrologic projects along the Sound's rivers and tributaries are also of concern. Dams and utility projects destroy habitat and block fish migration routes. These projects prevent migrating fish, such as alewives, smelt, blueback, herring, shad, and Atlantic salmon from reaching upstream spawning habitats.[42]

Floatable Debris

During the summer of 1988, the Sound's regional economy suffered severe losses as a result of litter and medical waste washing up on beaches. The litter caused beach closures and fueled a widespread scare among the public about potential health hazards. Public health concerns caused a decrease in attendance at area beaches for the entire summer, resulting in the loss of up to $2 billion in local revenues.[43] Floating litter from runoff and CSOs continues to reduce tourism and degrade the overall health of the estuary.

Trash which has accumulated on estuarine beaches also threatens the ecosystem and its wildlife inhabitants. On September 17 and 18, 1994, volunteers cleared 102,758 pounds of marine debris from 543.1 miles of New York's beaches. Of the total amount of marine debris collected in New York, 59.4 percent was plastic, 13 percent was glass, 10.2 percent was metal, and 17.4 percent was from other materials.[44] In the same year, on September 17, volunteers collected 7,256 pounds of marine debris from 35.3 miles of Connecticut's beaches. Of the total amount of marine debris collected in Connecticut, 61.4 percent was plastic, 9.8 percent was glass, 14.3 percent was paper, and 14.5 percent was from other materials.[45]

The Long Island Sound Study

In 1985 the U.S. Congress directed the States of New York and Connecticut, as well as the Environmental Protection Agency, to establish the Long Island Sound Study (LISS), the purpose of which was to assess the water quality of the Sound. In 1987 the LISS became one of the original six estuaries designated under the National Estuary Program of the Clean Water Act. A Management Committee and Citizens Advisory Committee were established to coordinate the Study and facilitate community involvement. Implementation commitments and bi-state cooperation are distinctive elements of the LISS.[46]

The LISS completed its Comprehensive Conservation and Management Plan (CCMP) in 1994 in an atypical manner. After the CCMP was approved by the lead regional and state environmental agency directors, a Long Island Sound Restoration Agreement was crafted which embodied the goals of the CCMP and committed the federal and state governments to its implementation. The Agreement was signed by the EPA Administrator and the Governors of New York and Connecticut. This federal/multi-state agreement is similar to agreements crafted for the Chesapeake Bay and Great Lakes programs. Local citizens hope the restoration initiative will strengthen and expand current partnerships for site-specific restoration projects, establish restoration priorities, and identify sites around the Sound that are candidates for restoration.

While the Sound Study and completion of the CCMP took nine years, there was enormous citizen involvement throughout the process. This level of participation was a major factor in establishing the agreement. Local, state, regional and national organizations not only participated heavily in EPA's Citizens Advisory Committee for the Sound, but also created private/public involvement programs and Sound-wide coalitions. For instance, in 1990, National Audubon Society organized a program entitled "Listen to the Sound." Hosting 15 citizen hearings around the Sound and attracting more than 1,500 participants, the findings of these hearings were put forth in a Citizen Agenda report in 1991. This Citizen Agenda for the Sound was the basis for the Long Island Sound Watershed Alliance (LISWA), a coalition of over 200 environmental, educational, local business and community organizations around the Sound. The Citizen Agenda served as the public measuring stick for reviewing CCMP proposals and had a major role in strengthening the final plan.

Other non-traditional coalitions were also created. The LISWA, in conjunction with other groups like the Long Island Soundkeeper Fund, worked to unite trade unions, environmentalists, and the construction industry into the Clean Water/Jobs Coalition, in order to address the problems of an aging and inadequate sewage and wastewater treatment infrastructure throughout the New York metropolitan region. The Clean Water/Jobs Coalition commissioned a study that showed how investing in Long Island Sound's and other estuaries' water quality improvements would not only benefit the estuarine environment, but also create more than 50,000 direct construction and indirect water-dependent jobs for every one billion dollars spent.

Public outreach continues to be a critical component of the implementation phase. Beyond helping to shape the content of the CCMP, citizens groups now closely monitor the implementation schedule. Organizations like the LISWA, the Soundkeeper, and Save the Sound, in addition to the Citizens Advisory Committee, are providing significant public support for action. The LISS office coordinates the activities of the federal and two state governments in the CCMP implementation, while providing the official mechanism to ensure public involvement.

To revitalize the estuary and reduce hypoxic conditions, the LISS promoted the use of innovative technologies for the removal of nitrogen from sewage treatment plant discharges.[47] The CCMP calls for a three-phase program to reduce such loadings. The first phase, which has since been achieved, calls for a no net-increase of nitrogen loadings, based on 1990 levels. The second phase, currently underway, calls for reduction of nitrogen loadings by 25 percent in New York and 15 percent in Connecticut. The third phase, to begin in late 1996, calls for major nitrogen loading reductions from both point and non-point sources to be achieved in the next century. This third phase is using new computer modeling results designed specifically for the Sound and is estimated to cost between $2-$6 billion depending on advancements in water pollution control technologies. Nitrogen reductions of up to 83 percent were achieved at the Stamford waste-water treatment plant as a result of using biological nutrient removal (BNR) technology.[48]

LISS also proposes a three-point solution to the problem of loss and degradation of living resources. This plan includes: (1) enhancement of federal and state wetlands protection, (2) restoration of fish migration routes and shellfish beds, and (3) creation of a reserve system.[49] Many believe that these actions alone are not sufficient, rather they are simply a first step to ensure that the living aquatic resources of the Sound are adequately protected. In order to avoid massive fish kills, the program has funded water quality monitoring projects to help better respond to and prevent hypoxic conditions.[50]

Finally, to reduce pathogen pollution, the Study has facilitated CSO abatement projects, initiated a stormwater permit program for construction sites, and created "no-discharge" areas for marine vessels in select embayments.[51]

Education is a primary focus of the CCMP. However, governmental cutbacks have stalled efforts to launch partnership programs between the EPA and private organizations to educate the public. The EPA Long Island Sound Office itself is seriously threatened by federal budget cuts. Without this office there would not be any entity charged with the responsibility to ensure that implementation actions are taking place and to coordinate the activities of the state and federal agencies on the Management Conference.

National Coastal Caucus

Long Island Sound is known for the grassroots activities of local, regional, and national organizations. The boards, staffs and members of these groups have participated in different ways in the LISS. Staff for Save the Sound (STS) and National Audubon Society act as Connecticut and New York co-chairs, respectively, of the Citizens Advisory Committee and utilize information provided by the governments to track CCMP implementation and keep the public-at-large informed. The Long Island Soundkeeper Fund also serves on the Citizens Advisory Committee, the Long Island Sound Advisory Council, and Connecticut's Council on Environmental Quality.

Save the Sound's mission is to protect and restore Long Island Sound and its watershed. It has extensive programs in education, research and advocacy. STS's "Soundshore Ecology" program is a model program for educating children and adults about the Sound. The "Sea Camp" program offers youngsters a unique opportunity to study Long Island Sound through hands-on activities. The research and advocacy components of STS programs call for the development of strong environmental policy at the local, state, regional and national levels. Its Adopt-a-Harbor program uses over 100 volunteers to monitor the water quality of 50 stations in 11 harbors. STS also has a laboratory to help determine the connection between algal blooms and hypoxia.

Save the Sound recently assumed management responsibilities of the operations of the Long Island Sound Watershed Alliance (LISWA) and currently coordinates its activities with a Steering Committee of Alliance members. LISWA, originally founded by National Audubon Society, is the network that brings 200 concerned organizations together to jointly advocate for the implementation of the CCMP, the enhancement and safeguarding of our federal/state environmental laws, the funding of Long Island Sound programs, and the creation of joint educational and public awareness programs. In addition, the Alliance hosts an Annual Citizen Summit Conference on the state of the Sound.

Soundkeeper is a nonprofit citizens watchdog organization dedicated to the protection and enhancement of the biological, physical and chemical integrity of Long Island Sound. It accomplishes its mission by patrolling, investigating, intervening and raising public awareness about the Sound's problems. Soundkeeper was founded in 1987 by the shellfishing and fishing communities concerned about the progressive pollution and destruction of habitat in the marine environment of the Sound.

The Soundkeeper Fund employs many tactics in preserving the Sound. These include bringing citizen action lawsuits; working on lead abatement efforts; mobilizing volunteers; providing a pollution hotline for citizen complaints, observations and tips regarding pollution in the Sound; and educating the public on watershed issues. Engaging in habitat protection and shellfish bed restoration projects is an important part of the work of the Soundkeeper Fund. The Soundkeeper, in a coalition with other organizations, helped to obtain $3 million from Congress to purchase 370 acres of Connecticut's largest remaining salt marsh, the Great Meadows Salt Marsh in Stratford, which were included in the Stewart B. McKinney - National Wildlife Refuge. The Soundkeeper also aided in the creation of a three-year, $4 million State restoration project of Connecticut's public shellfish beds. Between 1991 and 1995, 3,000 acres were restored and the project was nationally recognized as a model for sustainable aquaculture.

in Maryland

Portrait of the Bays

The Maryland Coastal Bays Estuary Program is beginning to examine the water quality and habitat problems of the Maryland Coastal Bays system and the impact that the larger watershed area has on the estuary. The Maryland Coastal Bays are located off Maryland's Eastern Shore and stretch across the coast to include small portions of Delaware and Virginia. The estuarine study area includes four large, shallow bays — the Assawoman, Isle of Wight, Sinepuxent, and Chincoteague Bays — as well as some smaller embayments. The average depth of the Bays is about seven feet.[1]

Maryland Coastal Bays	
Area of watershed	119,187 acres in Maryland
Average depth	7 feet
Values	• Tourists spend over $2.1 billion • Fisheries generate $162 million* • Sportfishing generates $524 million in economic output* • Home of the wild ponies in the Chincoteague National Wildlife Refuge
Threats	• Nutrient loadings • Habitat loss and degradation • Pathogen contamination
CCMP status	Expected in 1998

Designated as a "Nationally Significant" Estuary in 1995.

*State figure

The watershed of the Coastal Bays totals 119,187 acres in Worcester County, Maryland and extends into portions of Delaware and Virginia.[2] The northern portion of the Bays (Assawoman and Isle of Wight Bays) is quickly developing and supporting more recreational activities. In contrast, the southern portion of the Bays maintains a significant amount of forested and agricultural land. However, areas surrounding Sinepuxent Bay are beginning to be developed. The Chincoteague-Sinepuxent Bay complex, to the south of Ocean City Inlet, is bounded by approximately 23,000 acres of tidal salt marsh.[3]

Four major tributaries deliver freshwater to the Bays. These tributaries are the St. Martin River, Turville Creek, Herring Creek, and Trappe Creek.[4] In addition, groundwater delivers freshwater to the Bays. Two barrier islands, Fenwick Island and Assateague Island, run along the eastern edge of Maryland's Coastal Bays separating them from the Atlantic Ocean. Saltwater from the Atlantic Ocean enters the Bays through the Ocean City Inlet and the Chincoteague Inlet.

Values of the Bays

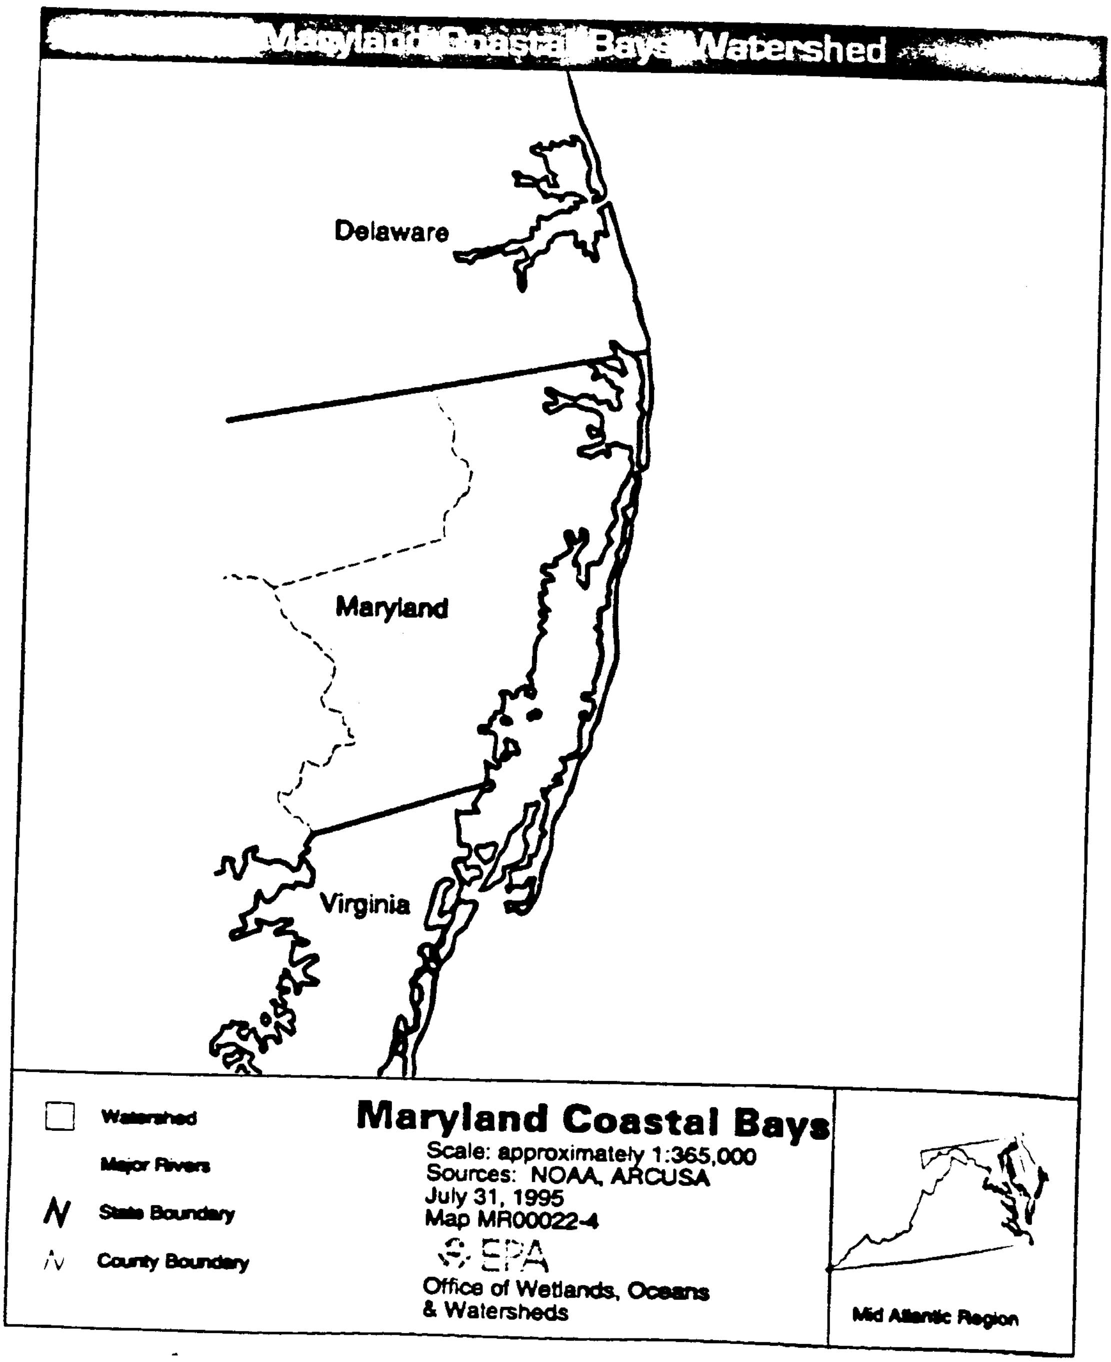
Maryland's Coastal Bays are ecologically and economically important to the communities of the Eastern Shore and to the entire State. These estuaries support commercially valuable fish and shellfish species, provide habitat for a variety of wildlife, and provide opportunities for numerous recreational activities.

Tourism/Recreation

Ocean City, a popular East Coast resort located in the northern section of the Bays, is visited by over 7.5 million tourists each year.[5] In 1988, direct tourist spending in the entire Coastal Bays area amounted

3789

VOL 12



3790

R0037098

to $2.1 billion and the tourism industry of the area helped to support 27,000 local jobs.[6] Sailing, swimming, camping, clamming, crabbing, fishing, and water skiing are favorite activities of the area.

Recreational boating is a popular weekend activity for residents and visitors of the Coastal Bays. In 1990, over 3,000 boats were registered with Worcester County residents. In addition, there are over 7,000 boat slips and numerous public access points located along the Coastal Bays.[7]

In the Coastal Bays and in the State of Maryland, sport fishing is a common recreational pursuit. For example, as many as 900 fishermen a day can be counted along a five-mile stretch of the Bays during the summer months.[8] Recreational fishing in the Bays helps to support a number of local businesses which service anglers. In 1991, recreational fishing in Maryland generated approximately $524 million in economic output and employed 8,315 people.[9] In that same year, approximately 431,000 saltwater anglers spent over 2.5 million days fishing off the coast of Maryland. Thirty-seven percent of the anglers were non-residents of the State.[10]

Fisheries/Seafood

In 1994, the combined value of the Chesapeake (Maryland and Virginia) region's commercial finfish and shellfish landings totaled approximately $162 million. Many of the fish and shellfish landed in these two States depend upon the estuaries of the Maryland Coastal Bays for spawning, nursing, and feeding grounds. In 1994, Maryland's commercial finfish and shellfish landings totaled approximately 68 million pounds, valued at $61 million.[11]

Twenty-five percent of Maryland's commercial fishery landings occur in the Coastal Bays.[12] Commercial shellfish and crustaceans harvested in the Bays include hard and soft crabs, oysters, and hard clams. Blue crab landings have been known to surpass one million pounds per year.[13] Sea trout, bluefish, flounder, and spot are some of the commercially valuable finfish species that inhabit the Bays. In four of the years between 1986 and 1991, finfish landings reached as high as 100,000 pounds.[14]

Wildlife

A number of protected lands and wildlife management areas are located within the Maryland Coastal Bays' watershed. The Assateague Island National Seashore, Chincoteague National Wildlife Refuge, Assateague State Park, and Sinepuxent Bay Wildlife Management Area host a variety of wildlife species and provide opportunities for bird watching and nature photography.

The Chincoteague National Wildlife Refuge is a well-known refuge along the nation's east coast. It provides year-round habitat and essential stopover points along the migratory flyways for thousands of birds, including snow geese, brant, dabbling ducks, hawks, peregrine falcons, and piping plovers. In addition, it is the famous home of a herd of wild ponies. Up to 1.5 million visits are made to the Chincoteague National Wildlife Refuge each year.[15]

Threats to the Bays

Existing information on the quality of the Coastal Bays points to a number of priority threats to the system. These problems will receive greater attention during the Bays' restoration planning process. The identified threats to the Bays include excessive nutrient loadings, habitat modifications and losses, finfish population declines, and pathogen contamination. In addition, the local program will study the impacts of polluted runoff from both agricultural and urban lands and the increasing human uses of the Bays.

Nutrient Loadings

Nutrients, such as nitrogen and phosphorus, are introduced to the estuary by urban stormwater, agricultural runoff, sewage treatment plants, atmospheric deposition, and boater discharges. Excessive levels of these nutrients stimulate the growth of algae in the Bays. As the algae grow, they not only block sunlight needed by the submerged aquatic vegetation of the Bays, but also require a great amount of dissolved oxygen to decompose. The decomposition process reduces the levels of oxygen for other aquatic life. Low oxygen conditions (called hypoxia) can result in large fish kills. The inundation of waterbody with excessive amounts of nutrients is called eutrophication.

Studies of the Coastal Bays reveal that excessive nutrient loading is a prominent environmental problem for the estuary.[16] The greatest concentrations of nutrients are generally found in the upper portion of the Bays near the mouths of rivers. Losses of submerged aquatic vegetation in the upper Bays, plus the declines of benthic populations can be tied to the over-enrichment of nutrients.[17] In the Maryland Coastal Bays, stormwater, agricultural runoff, and groundwater are considered to be the principal sources of nutrient loadings.[18] Previous studies have shown that groundwater delivers up to 51 percent of the total nitrogen load and over 40 percent of the total phosphorus load to the Isle of Wight.[19] Further information about the extent of nutrient inputs into the Coastal Bays from groundwater is needed.

Habitat Loss

The State of Maryland has lost approximately 1.2 million acres of its historic wetlands — a 73 percent loss.[20] Many of the losses have occurred along the shorelines of the State. Tidal marshes near the Ocean City Inlet and other northern Bays locations have disappeared due to residential, marina, and other development. The loss of coastal wetlands adversely affects both the wildlife and human populations of the Bays. Coastal wetlands provide important spawning, nursing, and feeding habitat for fish and shellfish. In addition, they provide nesting grounds for birds. Coastal wetlands also perform a number of functions which benefit coastal communities. For example, they protect inland areas from the ravages of tidal storms, absorb flood waters and filter land-based contaminants before they can reach nearby surface waters and groundwater underflows. In the Coastal Bays area, wetlands are widely used for recreational activities, such as canoeing, kayaking, and bird watching.

Both the actual acreage loss and the reduced quality of submerged aquatic vegetation in the northern section of the Coastal Bays have been noted with concern by scientists studying the area. Because submerged aquatic plants are key habitats for shellfish and fish, declining populations of oysters, crabs, and finfish is one of the results of habitat degradation in the Bays.

Pathogen Contamination

Pathogens are disease-causing microorganisms found in human and animal wastes which enter estuaries through agricultural runoff, polluted urban stormwater, sewage treatment plant discharges, boating waste, and septic systems. Pathogens in coastal waters pose risks to humans who eat contaminated shellfish or who recreate in contaminated beach waters. Gastroenteritis, hepatitis, and other diseases can result from ingestion of contaminated seafood or waters. For this reason, beaches and shellfish beds are closed or restricted when water monitoring indicates high levels of fecal coliform bacteria (an indicator of pathogen contamination) are present in coastal waters.

Shellfish harvesting has been limited in some areas of the Coastal Bays. Harvest closures and restrictions are usually the result of high levels of fecal coliform bacteria. Harvesting of shellfish in the St. Martin River has been restricted since 1974 because of high levels of bacteria and the proximity to sewage treatment plant outfalls.[21] As the year-round and seasonal populations of the Coastal Bays region continues to grow, more detailed studies about the extent of pathogen contamination in the Bays should be conducted.

Toxic Contamination

Analyses of the sediments in the Coastal Bays areas have revealed higher than normal levels of DDT, arsenic, chlordane, dieldrin and fluorine.[22] Significant amounts of the toxic chemicals which are found in sediment samples of the Bays have persisted in the estuarine environment for years. Presently, the major sources of toxic chemicals in the Bays are agricultural chemicals which run off farmlands and stormwater which carries oil and grease residues from streets and chemicals from lawns.[23]

Floatable Debris

Trash accumulated on estuarine beaches also threatens the ecosystem. The amount collected in just one day was staggering — on September 17, 1994, volunteers cleared over 14,000 pounds of marine debris from 48 miles of Maryland beaches. Of the total amount of marine debris collected, 55.1

VOL 12

3792

R0037100

percent was plastics, 12.6 percent was metal, 11.9 percent was glass, and 20.4 percent was from other materials.[24]

Maryland Coastal Bays National Estuary Program

With the Environmental Protection Agency's acceptance of Maryland's Coastal Bays into the National Estuary Program, it became one of the most recent group of seven estuaries added to the Program. On July 6, 1995 Maryland's Coastal Bays was officially designated an estuary of "national significance" under the National Estuary Program of the Clean Water Act. Shortly thereafter, the EPA convened a Management Conference responsible for coordinating the development of a Comprehensive Conservation and Management Plan (CCMP) to restore and protect Maryland's Coastal Bays. The CCMP is expected to be completed in three years.

Massachusetts Bays
in Massachusetts

Boston Harbor is unique among major urban estuaries in that nearly as much of its freshwater inflow comes from sewage effluent as from the major rivers (the Charles, Mystic, and Neponset) which empty there. In the past five years, proper treatment of sewage from the Greater Boston area has markedly improved water quality in the Bays. Now, the time has come to address non-sewage pollution to the Harbor and its tributaries, and the Massachusetts Bays Program has laid the groundwork with its Comprehensive Conservation and Management Plan.

—Jodi Sugerman, Policy Director
Save the Harbor/Save the Bay

Portrait of the Bays

The Massachusetts Bays Program is examining the water quality and habitat problems of the Massachusetts and Cape Cod Bays and the impact that the greater watershed area has on the estuary system. The study area under the Massachusetts Bays Program (MBP) includes Cape Cod Bay, Massachusetts Bay, Boston Harbor, the Merrimack River, the North and South Shores, and the portion of Ipswich Bay in Massachusetts. The Massachusetts Bays system encompasses 1,650 square miles of water surface area and includes over 1,800 miles of historic shoreline.[1]

Massachusetts Bays

Area of surface water	1,650 square miles
Area of watershed	7,000 square miles
Shoreline	1,800 miles
Population	4 million people
Average depth	77 feet
Values	• Fisheries generate $53 million • Tourists spend $1.5 billion* • Recreational boating generates $472 million
Threats	• Pathogen contamination • Habitat loss and degradation • Toxic pollution • Floatable debris
CCMP status	Final CCMP expected in 1996

Designated as a "Nationally Significant" Estuary in 1990.

North Atlantic

The Massachusetts Bays watershed measures 7,000 square miles. One-half of the watershed is located in the State of Massachusetts. The other half includes portions of New Hampshire that drain into the Merrimack River.[2] The MBP is dealing with one of the most densely populated estuarine regions in the nation. In 1990, the population density in Massachusetts' coastal area was 1,272 people per square mile.[3] Approximately 4 million persons,[4] most of whom reside in the Boston metropolitan area, live within the watershed and its more than 150 communities.[5]

Water depths in the Bays system vary greatly. Both Massachusetts Bay and Cape Cod Bay have average depths of 77 feet; whereas, the Merrimack River has an average depth of only 12 feet.[6] Compared to other estuaries, the Massachusetts Bays have higher salinity levels because they receive less than average freshwater inflows. The majority of the freshwater feeding into the Bays originates from the Merrimack and Charles Rivers. The Merrimack River flows into the northern end of the Bays, strongly influencing the water circulation of the system. Within the Cape Cod region much of the freshwater flows originate from groundwater sources.[7]

Around the Boston area, land use is dominated by urban activities. In other portions of the watershed, forests, salt marshes, tidal flats, rocky shorelines, coastal dunes and barrier islands are prevalent. Stellwagen Bank National Marine Sanctuary lies on the eastern edge of Massachusetts Bay.

Values of the Bays

The historical value and beautiful coastline of the Massachusetts estuary system attract millions of tourists annually. The rocky shores and coastal dunes provide scenic vistas of the Atlantic Ocean. The estuarine system is comprised of other diverse habitats including tidal flats, eelgrass meadows and barrier beaches that provide countless values difficult to measure in economic terms. These areas are home to diverse populations of wildlife and aquatic species, many of which are threatened or endangered. The Bays' habitats also provide spawning grounds for some of our nation's most valued fisheries, as well as opportunities for recreation.

Recreation/Tourism

Tourism is a prominent industry in the coastal region of Massachusetts. Tourists in the coastal counties of Massachusetts spent an estimated $1.5 billion in travel expenditures during 1993.[8] It is estimated that by cleaning up Boston Harbor beaches, millions of dollars could be added to the area's economy each year.[9]

Some of the popular activities for residents and tourists of this area are fishing, swimming, camping, sunbathing, and whalewatching. Although there is no easy way to analyze the economic benefit of beach-going (because most beaches are free and attendance data is not available), recreating on the system's more than 150 beaches remains one of the most popular uses of the Bays. Revenues generated just from the sale of parking stickers at Crane Beach, Cape Cod National Seashore, and Duxbury totalled over $1.6 million in 1990.[10] Significant revenue is also generated from recreational boating activities in the Bays, which account for up to $472 million annually.[11] In addition, an estimated 1.5 million whale watchers generate $23 million for the Massachusetts economy each year.[12]

In 1991, recreational fishing in Massachusetts generated approximately $770 million and employed nearly 10,500 people.[13] Currently, recreational fishing in the Bays yields a net benefit value of up to $355 million per year (in 1989 dollars), based on approximately 2.5 million individual fishing visits.[14] Saltwater fishing alone draws thousands of persons to Massachusetts each year. In 1991, approximately 393,000 saltwater anglers fished off the Massachusetts coast. Thirty percent of these fishermen were residents of other states.[15] Recreational shellfishing in Massachusetts and Cape Cod Bays accounted for an average of 7,000 bushels of shellfish each year between 1987 and 1990.[16]

Fisheries/Seafood

In 1994, the combined market value of finfish and shellfish landings in the New England region totaled approximately $583 million.[17] Many of the commercially valuable species in New England depend upon the health of the Massachusetts Bays for nursery habitat and feeding areas.

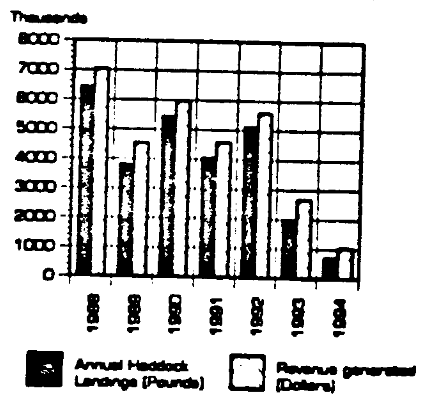
VOL 12

3796

VOL 12

3797

U.S. Domestic Haddock Landings



Data Source: U.S. Department of Commerce, National Oceanic and Atmospheric Administration, National Marine Fisheries Service

In 1987, Massachusetts' fisheries were ranked third in the United States in national value.[18] However, in recent years, troubling population declines have been noted among some of the most prominent fish species. The well-publicized, dramatic declines in the landings of haddock, flounder, and cod in this region due to overfishing and habitat destruction are contributing to economic hardships for many New England fishing communities. In 1985, Massachusetts' commercial finfish and shellfish landings were approximately 300 million pounds;[19] by 1994, the State's landings had dropped to 183 million pounds.[20]

In 1990, the combined revenue from commercial finfish and shellfish harvests in Massachusetts Bays was $53 million. Of the total combined harvest, lobsters accounted for almost 60 percent of the value in the Bays[21] and 85 percent of the value in Boston Harbor.[22] Shellfish commonly harvested in the Massachusetts Bays region include soft shell clams, quahogs, oysters, bay scallops, and blue mussels. Nearly 35 percent of the 1990 fish catch consisted of finfish landings.[23] The most valuable finfish caught in the Bays region include bluefin tuna, Atlantic cod, winter flounder, Atlantic flounder, Atlantic herring, and spiny dogfish. Bluefin tuna made up forty percent of the total value of the finfish catch for 1990,[24] currently the most commercially valuable fish in the region.[25]

Wildlife

Salt marshes and tidal flats, providing feeding and dwelling habitat for migratory waterfowl and other aquatic animals, line much of the Bays' shorelines. Forty seabird species have been sighted in the outer limits of the Bays near Stellwagen Bank, including kittiwakes, shearwaters, terns, and storm petrels.[26] Other coastal areas of the Bays attract larger diversities of bird species. South of the Merrimack River's mouth lies Parker River National Wildlife Refuge, a 4,660 acre barrier island. Over 300 bird species, including warblers, cormorants, snowy owls, Canada geese, and snowy egrets, have been spotted using the refuge for nesting, feeding, and resting along their migration routes.[27]

Several endangered and threatened species are dependent on the Bays ecosystem. Nine federally endangered species — the blue whale, fin whale, sei whale, humpback whale, North Atlantic right whale, Kemp's ridley sea turtle, shortnose sturgeon and roseate tern — and two federally threatened species — the loggerhead sea turtle and piping plover — can be found in the Massachusetts Bays region.[28]

The Stellwagen Bank National Marine Sanctuary is one of the most important areas in the North Atlantic for marine mammals, particularly whales. Its nutrient-rich waters provide critical habitat for 12 species of whales, dolphins, and porpoises. Endangered right whales, with a world-wide population of 200, are drawn to the abundance of life-supporting plankton found in Cape Cod Bay and the Stellwagen basin. In addition, loggerhead, leatherback, Kemp's ridley, and green sea turtles (federally-protected, threatened, or endangered species) use these waters.[29]

Threats to the Bays

For hundreds of years, Boston Harbor and the Charles, Mystic and Neponset Rivers were considered convenient sites for sewage disposal. These discharges, along with the dumping of industrial wastes, have played a major role in the degradation of the Bays' water quality. During the past two decades, however, efforts to abate the industrial and municipal sources of water pollution have taken center stage.

In the early 1980s, two inadequate and outdated sewage treatment plants servicing forty-three communities surrounding Boston Harbor regularly dumped untreated and partially treated sewage into the Harbor. As a result, the EPA sued Massachusetts for violating sewage treatment requirements under the Clean Water Act of 1972. This suit resulted in the creation of the Massachusetts Water Resources Authority and sparked the development of a multi-billion dollar project to repair Boston's sewage treatment system.[30] Although seven billion dollars of unfunded wastewater needs remain, the construction of these facilities has greatly improved the water quality of the Bays.[31]

The ongoing urbanization of the Massachusetts coastline brings additional pollution problems, such as polluted urban stormwater, combined sewer overflows, failed septic systems and boating discharges. The 1995 Comprehensive Conservation and Management Plan (CCMP) for Massachusetts Bays identifies pathogen contamination, habitat loss, and toxic pollution as priority problems affecting the water quality and living resources of the Bays.[32]

Pathogen Contamination

Pathogens are disease-causing bacteria and viruses found in animal and human wastes which enter estuaries through sewage treatment plant discharges, combined sewer overflows (CSOs), polluted urban stormwater, agricultural runoff, boating waste, and septic systems. Pathogens in coastal waters pose risks to humans who eat shellfish or recreate in beach waters. Gastroenteritis, hepatitis and other diseases can result from the ingestion of pathogens.

For the Massachusetts Bays, combined sewer systems, sewage treatment plants, and stormwater are significant sources of pathogens. In older cities, where the infrastructure is often more than 100 years old, combined sewer systems are a major cause of water quality declines in the Bays.[33] Each year, two billion gallons of waste from approximately 80 CSO outfall pipes enter Boston Harbor.[34] The Deer Island sewage treatment plant alone, which services over two million people in the Greater Boston area, discharges 455 million gallons of treated sewage into the Boston Harbor each day.[35]

Currently, more than 90,000 acres of Massachusetts' productive shellfish beds are closed permanently, seasonally, or conditionally.[36] Between 1985 and 1990, the acreage of shellfish beds that were prohibited from harvest in the Massachusetts Bay drastically increased from 12,000 to 92,000 acres. In Cape Cod Bay, the acreage of prohibited shellfish beds increased from 3,000 to 8,000 acres over the same period.[37] Even Plum Island Sound, bordered to the east by Parker River National Wildlife Refuge and reputed for its living resources and beaches, has experienced shellfish bed closures and declining fish populations due to bacterial contamination.[38]

Closed or restricted shellfish beds result in significant economic losses. For example, the town of Ipswich's local economy lost an estimated $3.4 million in harvest revenues in 1990.[39] Despite the restrictions on shellfish harvesting, many individuals are still becoming ill from eating contaminated seafood. The cost of seafood-born disease results in a loss of over $60 million a year to the State economy from lost work, medical bills, and liability suits.[40]

Contact with pathogen-contaminated water also raises health concerns for swimmers and recreational enthusiasts. An average of 44 documented beach closures occurred each year between 1988 and 1991 at North Shore, South Shore, and Boston Harbor beaches due to pathogen contamination.[41] Annually, an estimated 10,000 individuals become ill from the ingestion of pathogen-contaminated waters from the Massachusetts Bays.[42] In 1994, 59 beach closures and health advisories were issued in Massachusetts due to the occurrence of bacterial contamination and CSOs at bay and ocean beaches.[43]

Habitat Loss and Degradation

Urbanization in the Massachusetts Bays watershed is a contributing factor to many of the water quality problems in the estuary. As the population along the Massachusetts coast grows, pressure to convert salt marshes and tidal flats for human use continues to mount. However, the ecological integrity of the Bays system relies on the protection of these coastal habitats, as they support a number of

VOL 12

3798

fish, shellfish, and bird species and protect inland areas from coastal storms.

The State of Massachusetts has lost more than 50 percent of its original salt marsh acres. Currently, 48,000 acres remain.[44] Approximately 1,000 acres of coastal and inland wetlands are lost each year to development activities and projects. Only 36,000 acres of salt marsh remain in the Massachusetts Bays region.[45]

The surge of development activities in the coastal region of Massachusetts has resulted in the replacement of natural areas by impervious surfaces (roads, roofs, parking lots). These changes in the natural landscape hinder water and contaminant filtration by wetlands, soil, and other habitat types. As a result, more toxics, oil and grease residues, fertilizers, and nutrients enter the Bays from polluted urban runoff, stormwater and agricultural runoff. Currently, over 70 percent of the rivers and coastal areas in Massachusetts show evidence of impairment from these sources.[46] These contaminants degrade overall water quality, upsetting the balance of plant and animal life in the Bays.

Valuable eelgrass beds of the Massachusetts Bays are rapidly declining, especially in the Merrimack River estuary, Essex Bay, Cape Cod Bay, and the North Shore.[47] Eelgrass beds provide important nursery and feeding areas for finfish and shellfish. A variety of factors are responsible for the decline. Excessive amounts of nutrients carried by polluted urban stormwater, sewage discharge and agricultural runoff stimulate the growth of algae. Large algal blooms block sunlight needed for the growth of submerged aquatic vegetation, such as eelgrass meadows. As algae decompose, they require substantial amounts of dissolved oxygen, severely limiting the availability of oxygen for other aquatic life. The resulting low-oxygen condition, known as hypoxia, can lead to massive fish kills.

Toxic Pollution

Years of industrial activities and population growth in the Massachusetts Bays' watershed contribute to the present-day toxic contamination of the Bays' waters and sediments. Of the North Atlantic estuaries, the Massachusetts Bays have the largest number of industrial and municipal wastewater treatment discharge points. In 1990, Boston Harbor had 69 point sources, Massachusetts Bay had 72, and the Merrimack River estuary had 36 sources.[48] Stormwater discharge and atmospheric deposition are other sources of toxic pollution.

In a 1991 survey of the Bays, the North Shore and Boston Harbor were identified as the most serious spots for toxic contamination. Toxic contaminants found in the survey include polycyclic aromatic hydrocarbons (PAHs), copper, arsenic, lead, cadmium, mercury, chromium, nickel, zinc, polychlorinated biphenyls (PCBs), and pesticides.[49] Many of these toxic contaminants persist in the water column and sediments of the Bays. Over time, they can accumulate in the food chain and pose risks to aquatic life and humans. According to a 1994 EPA report, 84 percent of the estuaries surveyed in Massachusetts do not support fish consumption.[50] Winter flounder and lobsters in Boston Harbor and Salem Sound have revealed high PCB and PAH concentrations. Consumption advisories are in place for tomalley from lobsters caught in the Massachusetts Bay. An EPA report found that the risk of developing cancer from eating lobster tomalley is one in 100. Limited consumption advisories exist for lobster, flounder, bivalves, and bluefish caught in other portions of the Bays.[51]

Floatable Debris

Trash accumulated on estuarine beaches threatens the ecosystem and its wildlife inhabitants. In 1990, Massachusetts was ranked second in the nation for the highest incidence of sewage-related debris.[52] During the short period between September 17 and October 10, 1994, volunteers cleared 50,000 pounds of marine debris from 200 miles of Massachusetts beach area. Of the total amount of marine debris collected, 61.8 percent was plastic, 13.9 percent was paper, 8.9 percent was metal, and 15.4 percent was from other materials.[53]

The Massachusetts Bays Program

In the early 1980's, public awareness about the deterioration of Boston Harbor and the massive pollution problems of the surrounding Bays laid the groundwork for restoring the coastal water quality of the area. The Massachusetts Bays Program (MBP) was created in 1989 to bring together federal, state and local initiatives to address the threat of pollution in the Massachusetts and Cape Cod Bays. In 1990, the Massachusetts Bays system was officially designated under the NEP as an estuary of "national significance."

Due to the large number of communities bordering the Bays, the MBP has focused on developing regional collaboration among cities and towns. Fourteen communities within the watershed have already accepted the CCMP, while the remaining communities are in the process of signing on to the plan. The CCMP is expected to be approved by the EPA in 1996.

The MBP funds research projects to assess the health of the Bays and to determine the sources, transport, and effects of coastal pollution. The Program also encourages active public participation in designing solutions to the Bays' pollution problems. The MBP has developed educational materials for communities and landowners on topics such as proper land use practices to reduce polluted runoff. Land use restrictions instituted by local governments have proven to be successful, particularly in the protection of coastal ponds. The MBP also organizes educational workshops for municipal officials (planners, conservation commissioners, etc.), public works officials, and citizen volunteers on non-point source and stormwater pollution management.

In 1991, the MBP decided to implement three, five-year mini-bay demonstration projects for the Fore River Estuary, Wellfleet Harbor, and Plum Island Sound. Pollution problems within the mini-bays result from a wide variety of activities, ranging from recreational boating to intensive development. The bordering communities will rally public support and work to identify the sources of pollution, apply cost-effective management tools, and create monitoring programs. Another goal of the MBP is to restore 12 coastal wetland areas that have been degraded because of restricted saltwater flow.

The MBP Shellfish Bed Restoration Program's first success was the re-opening of 407 acres of shellfish beds in Cohasset and Scituate. These shellfish beds, which contain mussels and soft-shelled clams, were closed in 1985 due to water quality contamination. The two main sources of contamination that have since been corrected involved a failed septic system on the Cohasset side of the Harbor and an illegal sewer hookup to a storm drain in Scituate. A recently passed Betterment Bill, initiated by the NEP, will provide loans to landowners to replace failing septic systems.

National Coastal Caucus

Save The Harbor/Save The Bay (SHSB) and the Conservation Law Foundation of New England (CLF) have been actively involved in the development of the CCMP, as well as the interim measures taken to clean up the Bay. SHSB and CLF both have taken on leadership roles in the Coastal Advocacy Network (CAN), which represents over twenty citizen advocacy groups from across the region. It began as a citizens' advisory panel and has evolved into an active coastal advocacy coalition. The staff, Board of Directors, and members of CLF and SHSB have been involved in numerous capacities. As co-chair of and active participant in the Coastal Advocacy Network, SHSB and CLF, respectively, report regularly to the Management Committee of the MBP. In addition, CAN works closely with the MBP on the development of the CCMP.

SHSB was founded in 1986 by a group of citizens who realized that Boston Harbor was badly polluted, that it was getting worse, and that no citizen constituency existed for the Harbor. Now comprised of over 1,100 members, volunteers, and staff, SHSB's mission is to foster a positive vision of Boston Harbor and Massachusetts Bay and to build a constituency to promote the restoration and protection of these valuable resources. SHSB conducts an annual Swim for Boston Harbor, with about 150 swimmers and hundreds of spectators, to demonstrate that investments in Boston Harbor are truly paying off.

SHSB officially launched its Estuary Project during the summer of 1995 to address various pollution sources and protect Massachusetts Bays' estuarine ecosystems. As part of this project, SHSB was awarded a Massachusetts Bays Program Bays Action Grant to implement its "Storm Drain Detectives" volunteer monitoring program. Working collaboratively with the Mystic and Neponset River Watershed Associations, SHSB is training volunteers to test for pH levels, temperature, dissolved oxygen, biological oxygen demand, and turbidity and to sample for bacteria and nutrients. The Estuary Project also organizes educational workshops for municipal officials (planners, conservation commissioners, etc.), public works officials, and citizen volunteers.

SHSB's BayWatch Project patrols the water by using the boat "Shamrock," a public hotline, and a volunteer corps. The Project has repaired broken fish ladders, notified the public of broken sewer pipes to help prompt repair, monitored dredging activities, and documented the return of record numbers of harbor porpoises in 1995 to Boston Harbor.

The Sediment Security Project has focused mainly on the proposed dredging and disposal of Boston Harbor sediments, which are highly contaminated with heavy metals, PCBs, and other toxic chemicals, such as arsenic. SHSB has worked closely with the Army Corps of Engineers on project planning and environmental review to ensure that dumping does not occur adjacent to Stellwagen Bank where endangered right whales feed, and that other environmental safeguards are incorporated into the proposed dredging method.

CLF is a non-profit public interest environmental law organization founded in 1966. CLF employs a program staff of fourteen attorneys and five scientists who use the law to improve resource management, environmental protection, and public health throughout New England. CLF has a twenty year history of defending New England's fishing industry and the marine environment that supports the fisheries. In addition, CLF brought about the original litigation that resulted in the creation of the Harbor Cleanup Program.

Mobile Bay
in Alabama

Portrait of the Bay

The Mobile Bay National Estuary Program is beginning to examine the water quality and habitat problems of Mobile Bay and the impact that the greater watershed area has on the estuarine system. The designated study area of the Mobile Bay Program includes the Bay, surrounding ocean waters, the Mobile-Tensaw River Delta, and the northern reaches of Mobile and Baldwin Counties. Mobile Bay is a drowned river valley located on the Alabama Coast of the Gulf of Mexico. The surface waters of the Bay measure 248,000 acres. The Bay's average depth is ten feet;[1] it is approximately 31 feet long and ten feet wide.[2]

Mobile Bay	
Area of watershed	44,170 square miles
Area of surface water	248,000 acres
Average depth	10 feet
Population	484,000 (Mobile and Baldwin Counties)
Values	• Tourist spend approximately $200 million
	• Sport fishing generates $1 billion in economic output*
	• The rare black-knobbed sawback turtle lives exclusively in this area
Threats	• Toxic contamination
	• Nutrient loadings
	• Pathogen contamination
	• Habitat loss and degradation
	• Polluted urban stormwater
CCMP status	Final expected in 1998
Designated as a "Nationally Significant" Estuary in 1995.	
*State figure	

At the northern edge of the Bay is the Mobile-Tensaw River Delta. Extending northward to the confluence of the Alabama and Tombigbee Rivers, the Delta covers approximately 185,000 acres of primarily marsh, swamp, and forested wetlands.[3] Mobile Bay's watershed is the sixth largest drainage basin in the United States.[4] Sixty-four percent of Alabama and portions of Georgia, Tennessee, and Mississippi comprise the watershed, which measures 44,170 square miles.[5] The following major tributaries provide the Mobile Bay and Delta with freshwater: Mobile-Tensaw, Blakely, Apalachee, Dog, Deer, Fowl, and Fish Rivers.[6] In addition to freshwater, these rivers carry approximately 4.7 million metric tons of suspended sediment to Mobile Bay each year.[7] The Bay's primary opening to the Gulf of Mexico, Main Pass, is located between Dauphin Island (a barrier island) and the Fort Morgan Peninsula.

The City of Mobile, Baldwin County, and Mobile County surround the Bay. In 1990, the combined population of Baldwin and Mobile Counties was approximately 484,000 people — a 22 percent increase from the 1970 population. Another 54,000 people are projected to move to the two counties between 1990 and 2010.[8] The Eastern Shore of Baldwin County and the Fort Morgan Peninsula areas of the Bay are being intensively developed. The predominant land uses in the Mobile Bay area are residential development and undeveloped wetlands.[9]

Values of the Bay

and economic benefits for the visitors and residents of the area. The various habitats of the Bay and Delta include brackish waters, marshes, swamps, inland rivers, and bottomland forests. These provide nursery and spawning grounds for fish, shellfish, waterfowl, and other wildlife.

Recreation/Tourism

Mobile Bay is an attractive destination for individuals interested in sportfishing, kayaking, yachting, water skiing, bird watching, swimming, camping, and hunting. A 1988 estimate of the tourist expenditures in the south Alabama planning area, which includes Mobile, Baldwin and Escambia Counties, was approximately $200 million.[10] The Weeks Bay National Estuarine Research Reserve, the Audubon Bird Sanctuary on Dauphin Island, and several State parks border the Bay. The area also boasts historic properties, Native American shell mounds, and early eighteenth century fortresses.

Boating is a popular activity in coastal Alabama. In the Bay area, there are over 24,000 registered boats greater than 25 feet in length. Twelve marinas and numerous launching areas are situated along the Bay. [11]

Sport fishing is an important component of the local and State economies. In 1991, saltwater and freshwater recreational fishing in alabama generated approximately $1 billion in economic output and employed almost 17,000 people. [12] In the same year, approximately 137,000 saltwater anglers spent over 1.1 million days fishing off the coast of Alabama. An estimated 37 percent of these fishers were non-residents of the State.[13]

Fisheries/Seafood

Mobile Bay contributes valuable fishery resources to the Gulf Coast of the United States. In 1994, the combined value of the gulf Coast commercial finfish and shellfish industries totaled approximately $806 million. In the same year, commercial finfish and shellfish landings in the State of Alabama totaled approximately 23 million pounds and were valued at $48 million.[14]

It is estimated that Mobile Bay produces over one-third of Alabama's total seafood landings.[15]

Shrimp, blue crab, oyster, flounder, croaker, and mullet are important commercial fisheries based in the Mobile Bay area. However, between 1992 and 1993 there were dramatic decreases in landings of finfish, oysters, and crabs in the Bay. Commercial landings of finfish and oysters each dropped 23 percent, while crab landings fell 27 percent over this short period.[16] These recent declines in seafood production have caused fishers and residents of the area to express great concerns about the water quality of Mobile Bay.

Wildlife

An abundance of animal species, including approximately 425 fish, 15 shrimp, 300 bird, 57 mammal, and 21 turtle species, inhabit the Mobile Bay and Delta.[17] The Bay is distinguished for the diversity of birds which use its tidal marshes and barrier islands. Like many estuaries, Mobile Bay provides a critical stopping point for birds migrating to and from Central and South America. Thousands of ducks winter in the area.[18] Alligators, beavers, black bears, and river otters are a few of the mammals and reptiles that reside in the Bay and Delta.

The Bay and Delta provide special habitat for several species. The black-knobbed sawback turtle's entire habitat range is confined to this area.[19] In addition, two uncommon bird species, the Mississippi kite and the swallowtailed kite, dwell in the area.[20]

Threats to the Bay

In documents supporting the Bay's nomination into the National Estuary Program, State officials noted some of the principal water quality problems of the Bay. Priority problems that will be addressed during the development of a restoration plan are toxic contamination, nutrient enrichment, pathogen contamination, and habitat loss. The source of much of this pollution is uncontrolled, contaminated stormwater.

Toxic Contamination

Compared to other Gulf of Mexico estuaries, Mobile Bay sediment samples contain above-average levels of toxic contamination.[21] The Bay receives

VOL 12

3805

most of its heavy metals and organic chemical inputs from industrial and municipal discharges, dredging operations, and polluted urban stormwater. Some of the industrial sources of chemical toxics include paper mills, petrochemical plants, refineries, and paint pigment plants.[22] Significant levels of two heavy metals, zinc and mercury, have been detected in the Bay's sediments and aquatic life. In fact, a small area of Mobile Bay was closed to finfishing in the early 1990's due to high levels of mercury.[23]

Particles of toxic metals and organic chemicals settle on the floor of the Bay. These toxins persist in the system and are eventually consumed by aquatic organisms and passed throughout higher levels of the food chain. Because of the persistent nature of these contaminants, chemicals which were discharged into the system decades ago often have a present-day effect on the wildlife, water quality, and human populations of the Bay's watershed. Toxic contamination impairs the immune, reproductive and endocrine systems of aquatic wildlife. In addition, there is growing concern about the human health risks associated with eating contaminated seafood. This is a special concern for individuals who subsist on fish and shellfish caught in urban waters.

Nutrient Loadings

Nutrients, such as nitrogen and phosphorus, are deposited in the estuary by urban stormwater, sewage treatment plants, atmospheric deposition, and agricultural runoff. Excessive levels of these nutrients stimulate the growth of algae in the Bay. As the algae grow, they not only block sunlight needed by submerged aquatic vegetation, but also require a great amount of dissolved oxygen for decomposition. The decomposition process reduces the levels of oxygen for other aquatic life. Low oxygen conditions (called hypoxia) can result in large fish kills. The inundation of nutrients in a waterbody is called eutrophication.

Algal blooms are becoming a common occurrence in Mobile Bay. Increased amounts of nitrogen and phosphorus enter the Bay after heavy rainfalls. During 1992 and 1993, six documented fish kills occurred in Mobile Bay. Four of the kills were suspected to be caused by hypoxic conditions.[24]

Pathogen Contamination

Pathogens are disease-causing microorganisms found in human and animal wastes which enter estuaries through sewage treatment plant discharges, polluted urban stormwater, agricultural runoff, boating waste, and septic systems. Pathogens in coastal waters pose risks to humans who eat contaminated shellfish or who recreate in beach waters. Gastroenteritis, hepatitis, and other diseases can result from the incidental ingestion of pathogen-contaminated waters. Despite the known human health risks, Alabama does not conduct any monitoring or testing designed for swimmer safety or to inform beachgoers of potential hazards.

In 1990, all of the shellfish beds in Mobile Bay were harvest-limited.[25] Most shellfish harvest areas of the Bay are closed when intermittent bacterial pollution exists. In the summers of 1991 and 1992, Dauphin Island Bay was closed to oyster harvesting after *Vibrio cholerae* was detected.[26] The probable source of the bacteria was determined to be ballast and/or bilge water released from shipping vessels.[27]

Polluted Urban Stormwater

The Mobile Bay area receives an average annual rainfall of 62 inches.[28] Stormwater is the source of many of the contaminants which impair the water quality and natural resources of Mobile Bay. Stormwater carries fecal coliform bacteria, oil and grease, nutrients, and suspended sediments. As the population of the Mobile Bay area continues to grow, and as residential and commercial development projects are undertaken, the problems of stormwater are likely to intensify. The replacement of natural lands with impervious surface areas, such as pavement and roofs, results in more significant flows of stormwater carrying greater concentrations of contaminants into the estuary. Without natural lands along the Bay to absorb excess waters and filter out harmful contaminants, the aquatic system is placed at greater risk of degradation.

Habitat Loss and Degradation

Approximately 3.7 million acres of Alabama's historic wetlands have been destroyed — a 50 percent loss.[29] A significant amount of the lost acreage has been situated around the coastal areas of

VOL 12

3806

R0037114

the State. It is estimated that the wetland losses around Mobile Bay during the past 40 to 50 years have been four times greater than the national average.[10] Coastal wetlands not only provide important habitat for fish, shellfish, and birds, but they also provide many benefits to coastal communities. For example, coastal wetlands filter pollutants carried by stormwater, absorb flood waters, and buffer inland areas from strong coastal storms. They also host numerous recreational activities and in some areas provide recharge groundwater which is used to support community drinking water supplies.

Floatable Debris

Trash accumulated on estuarine beaches also threatens the ecosystem. The amount of debris collected in just one day can be staggering — on September 17, 1994, volunteers cleared 64,365 pounds of marine debris from 125 miles of Alabama's beaches. Of the total amount of marine debris collected, 60 percent was plastics, 15.1 percent was metal, 10.2 percent was glass, and 14.7 percent was from other materials.[11]

Mobile Bay National Estuary Program

With the Environmental Protection Agency's acceptance of Mobile Bay into the National Estuary Program, it was included among the most recent group of seven estuaries added to the Program. On July 6, 1995 Mobile Bay was officially designated by the EPA as an estuary of "national significance" under the National Estuary Program of the Clean Water Act. Shortly thereafter, the EPA convened a Management Conference responsible for coordinating the development of a Comprehensive Conservation and Management Plan (CCMP) to restore and protect the Mobile Bay. The CCMP is expected to be completed in three years.

Morro Bay
in California

Portrait of the Bay

The Morro Bay National Estuary Program is beginning to examine the water quality and habitat problems of the Morro Bay system and the impact that the greater watershed area has on the estuary. Morro Bay, situated along California's south central coast, is actually contained within a larger estuary, called Estero Bay. The water surface area of Morro Bay is 2,300 acres.[1] Two creeks, Chorro and Los Osos, provide the majority of freshwater to the estuary. The Bay's average depth is a shallow three feet.[2]

The Morro Bay watershed area encompasses 44,000 acres of San Luis Obispo County.[3] Over 35,000 people reside within the watershed — a population density of about 400 persons per square mile.[4] Since 1960, the population within the watershed has tripled.[5] It is estimated that the population of San Luis Obispo County will increase by 46 percent between 1988 and 2010.[6]

Approximately 60 percent of the land within the Morro Bay watershed is used as rangeland, primarily for beef production.[7] Publicly-owned lands within the Montana de Oro and the Morro Bay State Parks account for a sizeable amount of land within the watershed. Residential development and light industry are the typical urbanized land uses within the watershed.[8]

Morro Bay contains a great diversity of habitat types, including what has been described as the "largest and most unspoiled wetland habitat in south central and southern California."[9] The area contains over 700 acres of subtidal and intertidal eelgrass; 600 acres of salt, brackish, and freshwater marshes; and mudflats.[10] The Morro Bay Sandspit, a four-mile barrier beach along the western edge of the estuary, contains sand dunes undisturbed by roads or trails. The sand spit sustains thriving habitat for a variety of plants and animals.

Morro Bay	
Area of watershed	44,000 acres
Area of surface water	2,300 acres
Average depth	3 feet
Population	35,000 people
Values	• Sport fishing generates $3.2 billion in economic output*
	• Fisheries generate $159 million*
	• 270 bird species use the Bay
Threats	• Sedimentation
	• Pathogen contamination
	• Nutrient loadings
	• Toxic contamination
CCMP status	Expected in 1998

Designated as a "Nationally Significant" Estuary in 1995.

*State figures

Values of the Bay

Morro Bay provides wonderful, recreational opportunities and natural resources for the tourists and residents of California's south central coast.

Recreation/Tourism

Tourism represents the major component of the Bay area's local economy. Each year, an estimated 1.5 million visitors come to the Bay. Tourism revenues provide one-third of the general fund revenues and support 37 percent of the jobs in the City of Morro Bay.[11] Camping, fishing, swimming, bird watching, boating, kayaking, duck hunting, and clamming are some of the activities that residents and visitors of the Morro Bay area commonly enjoy.

The boating harbor at Morro Bay is the only all-weather, year-round port between Santa Barbara and Monterey Bay (a distance of 225 miles). This access to the Pacific Ocean draws large numbers of boaters and fishers to the Morro Bay. Lingcod, rockfish, halibut and king salmon are abundant in the waters off the coast of this area. Most of the shellfish harvesting of the Bay is conducted by recreational fishers. Gross revenues from Bay fishing excursions total up to $1.5 million each year.[12] In 1991, approximately 1.1 million saltwater anglers spent over 5.5 million days fishing off the coast of California.[13] In the same year, recreational fishing in the State generated approximately $3.2 billion in economic output and employed approximately 40,000 people.[14]

One of the favorite tourist destinations of the area is Morro Bay State Park, which hosts over 500,000 people each year.[15] This State Park contains a 100-boat marina, 130 campsites and a major heron rookery.[16] A prominent landmark of the Bay area is Morro Rock, a 587-foot high volcanic plug, used by peregrine falcons for nests.[17]

Fisheries/Seafood

Morro Bay contributes valuable fishery resources to the Pacific coast of the United States. In 1994, the combined value of the Pacific region's (excluding Alaska) commercial finfish and shellfish landings totaled approximately $401 million. In 1994, California commercial finfish and shellfish landings totaled approximately 343 million pounds, valued at $159 million.[18]

The commercial fishing industry is second to tourism in its annual contributions to the local economy.[19] In 1993, the landing value of commercial fish caught from the Bay totalled $6.9 million.[20] More than 70 fish species use Morro Bay.[21] Many of these species, including rockfish, thornyhead, Dover sole, and salmon are valuable to the commercial fishery of the area.

Clams and oysters are among the 19 different shellfish which have been collected in Morro Bay.[22] Mudflats along the southern and central portion of the Bay are being groomed for increased oyster production.[23] The most commonly caught species are Washington, gaper, and geoduck clams.

Wildlife

The diverse habitats of the Morro Bay area support a wide variety of resident and migratory wildlife. Many endangered and threatened species depend on the Bay and its surrounding environment for habitat. Among the federally-listed species which live in the Bay watershed are the southern sea otter, peregrine falcon and marbled murrelet.[24] As coastal wetlands continue to be destroyed in other portions of the State, animal species increasingly depend upon the wetlands of Morro Bay for survival. California has already lost 91 percent of its historical wetlands base.[25]

Migratory birds use Morro Bay for critical wintering habitat or stopover areas along the Pacific Flyway. The United States Fish and Wildlife Service counts over 270 migratory bird species which use Morro Bay.[26] The rich eelgrass beds of Morro Bay attract wintering brant. Seventy-six percent of the brant which winter along California's coast choose Morro Bay for wintering grounds.[27]

Threats to the Bay

Studies conducted by the California Coastal Commission, individual scientists, and local task forces have identified several threats to the health of Morro Bay. Priority problems that will be addressed by the Morro Bay Program will likely include sedimentation, pathogen contamination, and nutrient loadings.

Sedimentation

Erosion of lands within the watershed and the increase of sediment deposits into the Bay are recognized as the leading problems in this estuary.[28] Changes in land use, alterations from levees and dredging activities, and wildfires in the upper portion of the watershed have increased the rate of sedimentation in the Bay.[29] A 1989 United States Department of Agriculture study estimated that the rate of sediment production in the Bay's watershed is 50 percent greater today than in the 1700s. An estimated 45,500 tons of sediment are deposited in the Bay each year.[30]

Sedimentation disrupts the growth of eelgrass in the estuary by increasing turbidity of the water. Greater turbidity blocks valuable sunlight from reaching the eelgrass beds. Some of the suggested actions to reduce the rate of sedimentation include fire control, gully controls, best management practices for rangeland and small pastures, and creek bed restoration.[31]

VOL 12

3811

VOL 12

Pathogen Contamination

Pathogens are disease-causing microorganisms found in human and animal wastes which enter estuaries through sewage treatment plant discharges, septic systems, polluted urban stormwater, agricultural runoff, and boating waste. Pathogens in coastal waters pose risks to humans who eat contaminated shellfish or who recreate in beach waters. Gastroenteritis, hepatitis, and other diseases can result from incidental ingestion of pathogen contaminated water. For this reason, beaches and shellfish beds are closed or restricted when water monitoring indicates high levels of fecal coliform bacteria or total coliform (indicators of pathogen contamination) are present in coastal waters.

The principal sources of pathogens in Morro Bay are malfunctioning individual septic systems in the Los Osos Creek area, boaters dumping human waste overboard (the Morro Bay State Park does not have pump-out stations), and livestock waste along Chorro Creek.[32]

Unhealthy levels of pathogen contamination have caused shellfish harvesting restrictions in Morro Bay. Before the 1970s, Morro Bay was one of California's leading producers of Pacific oyster; however, because of increasing sewage-related contamination, landings of Pacific oyster in the Bay began to decline during the 1970s. In 1979, 179,000 pounds of oysters were harvested from the Bay. The landings dropped to 12,000 pounds by 1985 and to zero by 1990.[33] Today, following heavy rainfalls, many acres of recreational shellfish beds are restricted from harvest due to increased bacterial contamination.[34]

Nutrient Loadings

Nutrients, such as nitrogen and phosphorus, are introduced to the estuary by runoff from agricultural land, animal waste, stormwater, septic systems, and sewage treatment plant discharges. Excessive levels of these nutrients stimulate the growth of algae in the Bay. As the algae grow, they not only block sunlight needed by the submerged aquatic vegetation of the Bay, but also require a great amount of dissolved oxygen to decompose. The decomposition process reduces the levels of oxygen for other aquatic life. Low oxygen conditions (called hypoxia) can result in large fish kills.

Monitoring of the Bay has uncovered high levels of nitrate and phosphate in many areas of the Bay, Chorro Creek and Los Osos Creek.[35] In addition, the groundwater of the area is also being affected by nitrogen contamination.[36] Likely sources of groundwater contamination by nitrogen are septic systems and fertilizers which are applied to lawns. Septic systems are also being targeted as a primary source of nitrogen contamination in the portions of the estuary adjacent to Baywood Park.[37]

Toxic Contamination

In the upper portion of the watershed, abandoned mines are responsible for elevated levels of nickel and chromium in sediments. In fact, sediment samples from the Chorro Reservoir reveal levels of nickel in excess of hazardous waste standards.[38] The impact of the upper watershed's toxic contamination on the estuary has not been fully studied.

Samples of mussels taken from Morro Bay indicate that toxic chemicals are not a major threat to the health of the Bay. However, some samples have revealed higher-than-expected concentrations of cadmium, mercury, lindane, chlorbenside, and phosphorothoic acid.[39] In order to understand more about the current state of toxic chemicals on the Bay and to prevent worsening conditions, heavy metals and toxics are considered to be priority environmental problems for the Bay's future.

Additional Concerns

The potential increase in offshore oil development on the region's Outer Continental Shelf is another threat to the Bay. Located to the north of Morro Bay are four major marine terminals which are served by offshore oil activities in the Santa Maria Basin. Small spills have previously occurred in the area.

Trash accumulated on estuarine beaches also threatens the ecosystem. The amount found in just one day was staggering — on September 17, 1994, volunteers cleared 565,501 pounds of marine debris from 480 miles of California beaches. Of the total amount of marine debris collected, 54.1 percent was plastics, 18.5 percent was paper, 10.8 percent was metal, and 16.6 percent was from other materials.[40]

38/2

The Morro Bay National Estuary Program

With the Environmental Protection Agency's acceptance of Morro Bay into the National Estuary Program, it became one of the most recent group of seven estuaries added to the Program. On July 6, 1995 Morro Bay was officially designated an estuary of "national significance" under the National Estuary Program of the Clean Water Act. Shortly thereafter, the EPA convened a Management Conference responsible for coordinating the development of a Comprehensive Conservation and Management Plan (CCMP) to restore and protect the Bay. The CCMP is expected to be completed in three years.

VOL 12

Narragansett Bay
in Rhode Island

Narragansett Bay is a place where fresh water from the surrounding watershed meets the salt water of the Atlantic Ocean. Our Bay is one of the most biologically-productive ecosystems on earth - sustaining and embracing over 40,000 species of life, including people. Located primarily in Rhode Island, 60 percent of the Bay's watershed is in Massachusetts. Narragansett Bay is the heart of the region's environment and economy; draws visitors from all over the world; provides jobs and recreational opportunities for residents; and provides habitat for an incredible diversity of wildlife.

—Curt Spalding, Executive Director, Save the Bay

Portrait of the Bay

The Narragansett Bay Program is examining the water quality and habitat problems of the Narragansett Bay and the impact that the greater watershed area has on the estuarine system. Regarded as Rhode Island's most precious resource, Narragansett Bay consists of approximately 132 square miles of surface water.[1] The average depth of the Bay is 30 feet, a greater average depth than most of the estuaries located in the mid-Atlantic region.[2] The average salinity of Narragansett Bay is between 29 and 31 parts per thousand (the ocean has a 35

Narragansett Bay

Area of surface water	132 square miles
Area of watershed	1,853 square miles
Population	1.8 million people
Average depth	30 feet
Values	• Lobster catch generates $165 million* • Tourists spent $1.47 billion* • Habitat for the federally endangered bald eagle and piping plover
Threats	• Pathogen contamination • Nutrient loadings • Habitat loss and population growth • Toxic pollution • Floatable Debris
CCMP status	Approved in 1993

Designated as a "Nationally Significant" Estuary in 1987.

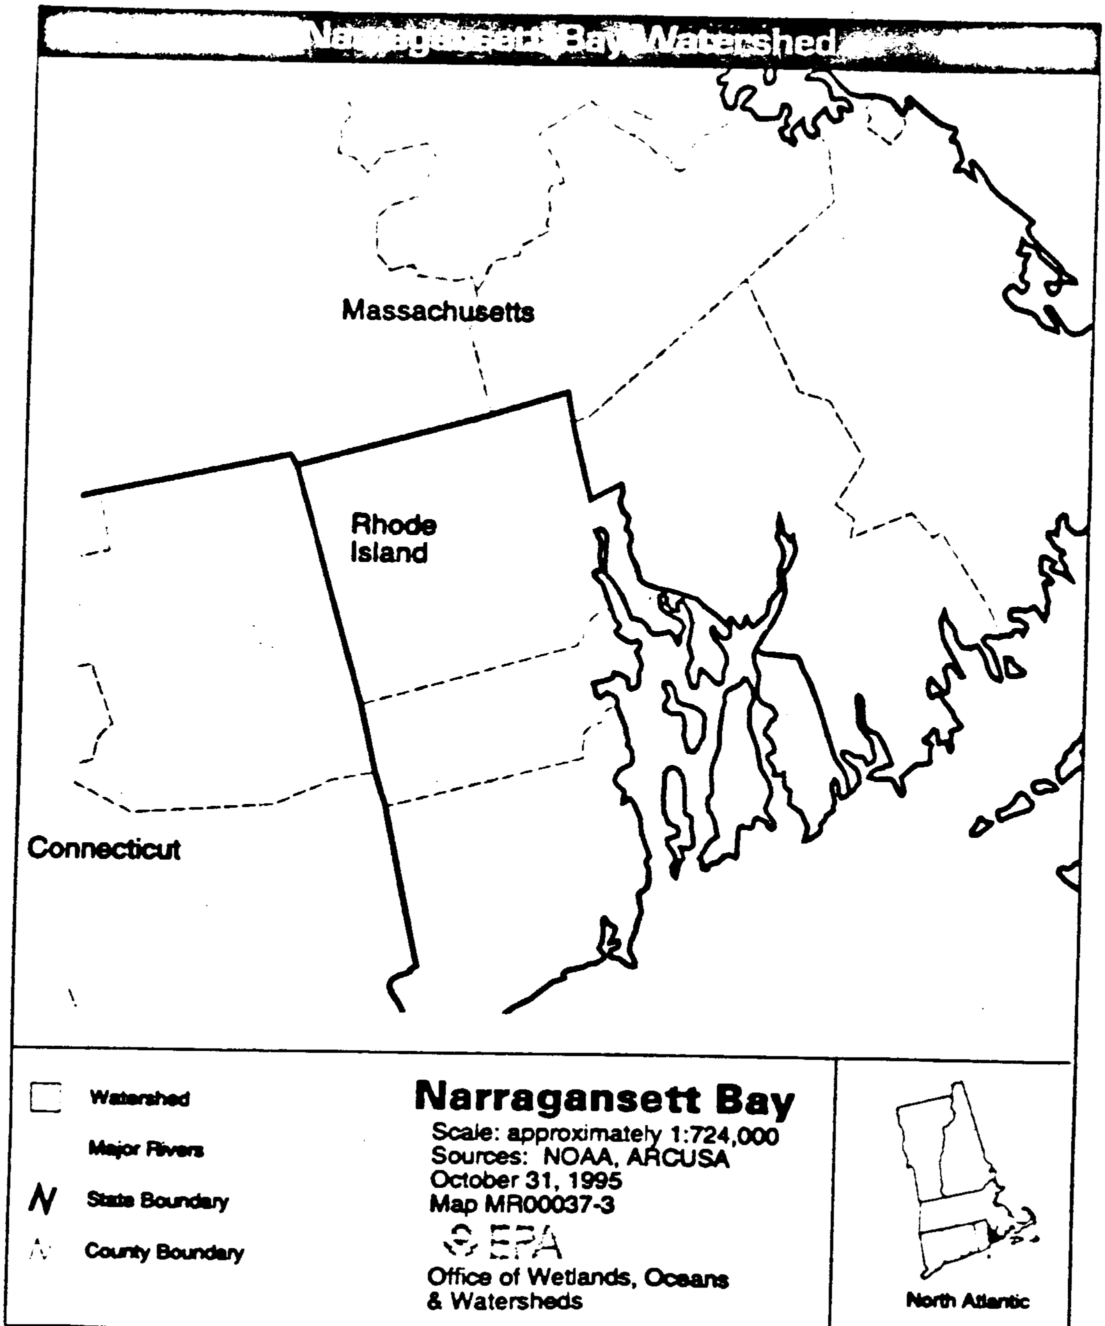
VOL 12



38-15

R0037123

parts per thousand salinity). This higher-than-average estuarine salinity is due to the minimal flow of freshwater into the Bay— less than 0.05 percent of the Bay's total volume is freshwater.[3]

The Narragansett Bay watershed area covers 1,853 square miles in Rhode Island and Massachusetts.[4] The Bay's watershed is one of the most densely populated in the nation. About 1.8 million individuals reside in the area, yielding a population density of over 1,100 persons per square mile.[5] Major municipalities in the watershed include Worcester and Fall River, Massachusetts; and Providence, Rhode Island.

The majority of the freshwater which flows into the Bay is delivered by three rivers—the Blackstone, Taunton, and Pawtuxet rivers. Smaller rivers and streams also carry freshwater to the Bay. Three drowned river valleys connect Narragansett Bay to Rhode Island Sound and eventually the Atlantic Ocean. These passages—East Passage, West Passage, and the Sakonnet River—are separated by the Aquidneck, Conanicut, and Prudence islands.

The Bay supports approximately 2,800 acres of salt marsh and 4,400 acres of tidal flats. Freshwater wetlands represent only six percent, or 63,000 acres, of the watershed.[6]

Values of the Bay

In 1989, the Bay contributed $2.5 billion to Rhode Island's economy through fisheries, tourism, marine industries, United States Navy-related activities, and marine education.[7] Popular recreational activities in the Bay include boating, camping, bird-watching, hiking, and fishing.

Recreation/Tourism

In 1994, tourists in Rhode Island spent $1.47 billion and supported over 25,000 tourist-related jobs.[8] Narragansett Bay and its shoreline attract many of these tourists to the state. It is estimated that annual Bay-related tourism is responsible for supporting over 15,000 jobs and generating over $390 million in revenue.[9]

Narragansett Bay is reputed as one of the best places in the world to sail. For this reason, recreational boating exceeds all other Bay activities in terms of total economic impact.[10] Other popular activities in the Bay are sunbathing, swimming, observing wildlife, and visiting historical sites. In 1991, an estimated 260,000 individuals observed wildlife; while 65,000 photographed wildlife in the State of Rhode Island.[11]

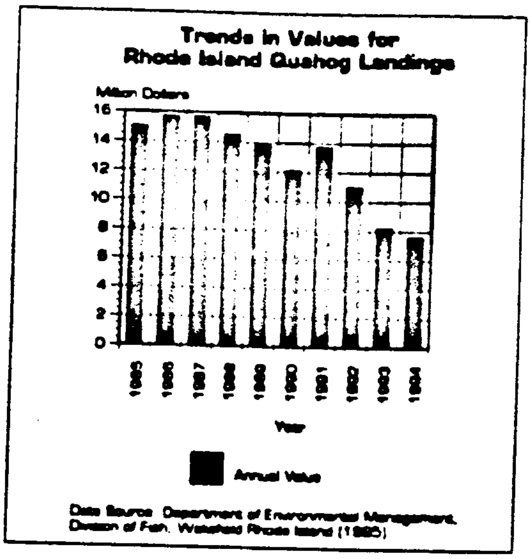
Recreational fishing provides another significant source of revenue for Rhode Island and the Narragansett Bay region. In 1991, an estimated 171,000 individuals spent over 2.1 million days fishing Rhode Island's fresh and salt waters.[12] Recreational fishing generated approximately $125 million in economic output and employed nearly 2,200 persons that year.[13] Saltwater fishing is a more popular pursuit for anglers than freshwater fishing. In 1991, more than 124,000 people enjoyed saltwater fishing in Rhode Island, spending $41.8 million.[14] Bluefish, striped bass, and flatfish are the most sought-after saltwater fish.

Fisheries/Seafood

The fisheries of Narragansett Bay are considered to be part of the New England fishery region. In 1994, the combined market value of commercial finfish and shellfish landings in the New England region totaled approximately $583 million. Many of the commercially valuable species in New England depend upon the health of Narragansett Bay for survival. In 1994, the State of Rhode Island's commercial finfish and shellfish landings totaled approximately 112 million pounds, valued at $77 million.[15] Commercial lobster landings alone generated $165 million for the State in 1993.[16]

Commercial fishing is a vital part of the Narragansett Bay area's economy. In 1993, the Bay's combined finfish, shellfish, and lobster landings generated $23.9 million in revenues.[17] The City of Newport is home to one of the largest lobster ports in the Northeastern United States.

Shellfish have historically provided substantial revenue for the Bay region; however, pollution, loss of habitat and overharvesting have decimated shellfish populations during this century. In the early 1900s, Narragansett Bay oyster production was a booming industry. However, in the 1930s and 1940s, the industry collapsed due to pollution, overharvesting, and a destructive hurricane. By 1957, the last Rhode Island oyster harvesting operation had closed.[18] Bay scallops, once plentiful, have also almost completely disappeared from the Bay.



The most profitable fishery of the Narragansett Bay is the quahog (hard clam), accounting for 84 percent of the Bay's total fishing revenue.[19] Yet, the quahog catch in Rhode Island has dropped from 4.2 million pounds (in weight of meats), valued at $15 million in 1985, to 1.6 million pounds (in weight of meats), valued at $7.6 million in 1994.[20] Landings have remained at historical lows due to extreme fishing pressure and continuing shellfish bed closures caused by bacterial contamination. In addition, the number of commercial shellfish licenses issued between 1991 and 1993 fell from 2,000 to 200 prompted by the closure of Greenwich Bay, a significant harvesting site in Narragansett Bay.[21]

Wildlife

A variety of wildlife depend upon the rich resources of the Bay for their survival. Migrating shorebirds use the Bay for foraging; while sea ducks depend upon the Bay for wintering grounds. The Bay's islands are used by harlequin ducks, tree swallows, herons, glossy ibis, snowy owls, purple sandpipers and over 200 other bird species at different times of the year.[22] In addition, large populations of osprey and other raptors nest in the area.[23]

Red foxes, weasels, minks, and harbor seals are also found in the areas surrounding Narragansett Bay. Rhode Island has 16 federally-listed threatened and endangered animal species.[24] Of these, the bald eagle and piping plover depend on the State's estuarine and marine wetlands for habitat.[25]

Threats to the Bay

Like other estuaries of the United States, Narragansett Bay and its resources are being affected by growth and urbanization throughout the watershed. Urban development compounds water quality problems by increasing the amount of contamination entering the Bay and by modifying and destroying important habitat. The Narragansett Bay Comprehensive Conservation and Management Plan (CCMP), approved in 1993, identifies pathogen contamination and excessive nutrient loadings as priority threats to the Bay's ecosystem. Additional threats to the health of Narragansett Bay include habitat loss, population growth, toxic pollution, and marine debris.[26]

Pathogen Contamination

Pathogen contamination is the most critical pollution problem for Narragansett Bay. Pathogens are disease-causing bacteria and viruses found in human and animal wastes that enter estuaries through sewage treatment plant discharges, combined sewer overflows (CSOs), polluted urban stormwater, agricultural runoff, boating waste, and septic systems. Pathogens in coastal waters pose risks to humans who eat contaminated shellfish or who recreate in polluted beach waters. Gastroenteritis, hepatitis, and other diseases can result from the ingestion of pathogens.

In Narragansett Bay, combined sewer overflows are the leading source of pathogen contamination. After periods of extensive rainfall or snow melt, the combined sewer systems often cannot handle the flow of stormwater and wastewater. As the system becomes overloaded, industrial wastewater and untreated or partially treated sewage combine with contaminated stormwater and then discharge into the Bay and its tributaries. Over 100 CSOs discharge four billion gallons of wastewater into Narragansett Bay and its tributaries annually.[27] Other sources of pathogens include wastewater treatment facility discharges, septic systems, cesspools, and boating discharges.

VOL 12

38/7

Bacterial contamination forces the closures of shellfish harvesting areas in the Bay. Currently, over 36,000 acres (almost one-third of the total) of the Bay's shellfish beds are permanently closed or harvest-restricted as a result of unsafe bacterial levels.[29] In 1992, valuable winter shellfish harvesting areas were closed in Warwick and East Greenwich due to bacterial contamination. These closures in Greenwich Bay, which normally contribute four million dollars annually to the Bay region, devastated the shellfish industry.[29]

Nutrient Loadings

Nitrogen and other nutrients that flow into the Bay can damage submerged aquatic vegetation and contribute to conditions that cause large fish kills. Nutrients enter the Bay from many sources, including atmospheric deposition, urban and rural polluted runoff, groundwater, septic systems, publicly-owned treatment works, and CSOs.[30] Municipal wastewater discharges are the principal source of nitrogen loading in upper Narragansett Bay.[31] In addition to the four billion gallons of wastewater per year discharged by CSOs, the Bay and its tributaries receive over 73 billion gallons of treated wastewater annually from publicly-owned sewage treatment plants.[32]

Excessive nutrients stimulate the growth of algae. When large algal blooms form, submerged aquatic vegetation can not receive the amount of sunlight needed for its growth. Nutrient loadings in Narragansett Bay have caused dramatic losses among eelgrass beds, important spawning and nursery habitat for fish and shellfish. Another consequence of nutrient overloading is the depletion of dissolved oxygen. As algae decompose, they require large amounts of oxygen, often creating hypoxic ("low oxygen") conditions which threaten the aquatic life of the Bay. Over the years, fish kills in Narragansett Bay and its tributaries have occurred as a result of depleted oxygen levels.

Habitat Loss and Population Growth

The effects of human settlement and development have led to many water quality problems in Narragansett Bay. Since the 1780s, Rhode Island has lost over 37 percent of its historic wetlands acreage.[33] In addition, Rhode Island has lost a substantial portion of its original forested lands; between 1982 and 1988, 15 percent of the State's forests were cleared.[34] In addition, all of the major rivers in Rhode Island are dammed. These changes in the watershed have had severely negative consequences — less nursery habitat for fish, less contaminant filtration, increased amounts of polluted runoff and stormwater, and diminished freshwater flow — for the Bay.

Towns along the Narragansett Bay have experienced great population growth during the past few decades. The town of Narragansett's population tripled between 1960 and 1990. The town of East Greenwich doubled its population during the same period.[35] Population pressures are expected to continue. By the year 2010, Rhode Island's population is anticipated to grow by another 10 percent.[36] The increasing population will likely cause additional declines in water quality because of the limited capacity of existing wastewater treatment systems and the further destruction of habitat. As natural vegetation is replaced by impervious surface areas such as pavement and roofs, the absorption of stormwater and the filtering of pollutants is reduced.

Toxic Pollution

Toxic pollution is a consistent threat to the Narragansett Bay region. As recently as January, 1996, the Rhode Island coast was plagued by toxic contamination when a cargo barge ran aground and spilled over 800,000 gallons of heating oil. In the first two days after the spill, at least 11,000 dead lobsters washed ashore along Rhode Island's southern coast.[37] The complete impact of the spill on other wildlife and natural resources in Rhode Island has yet to be determined.

Industrial pollution such as this has been a long-standing problem for Narragansett Bay. By 1860, Rhode Island was considered the most industrialized State in the nation.[38] The early industrialization in Rhode Island and Massachusetts, combined with more recent industrial activities, presents tremendous challenges to the restoration of Narragansett Bay.

Sediments from the bottom of the Blackstone River are laden with toxins from metal plating and textile activities from the nineteenth and early twentieth centuries. Historically, toxic metals entered

VOL 12

3/8/8

R0037126

the Bay from jewelry manufacturing and electroplating plants, textile mills, cement companies, and other industrial sites. Petroleum-derived contaminants, such as polychlorinated biphenyls (PCBs) were used in electrical transformers before they were banned in 1977; however, they can still be found in the Bay system. Other toxic pollutants found in the Bay include copper, cadmium, lead, zinc, chromium, silver, nickel, and mercury. Copper pipes with lead solder that were used to transport drinking water to Bay communities are another source of these toxics.[39]

The toxic contamination of the sediments and waters of Narragansett Bay jeopardizes the Bay's aquatic life and poses risks to human health. Toxins accumulate in the tissues of fish and shellfish causing potential reproductive or mutagenic problems. Bioaccumulation of the toxics in the tissues of aquatic animals has led to lobster, mussel and plankton kills in some portions of the Bay.[40] In addition, humans who eat large quantities of contaminated fish put themselves at increased risk of developing cancer.[41]

Floatable Debris

Trash accumulated on estuarine beaches threatens the Bay ecosystem. On September 17, 1994, volunteers cleared 20,000 pounds of marine debris from 49 miles of Rhode Island beaches. Of the total amount of marine debris collected, 62.1 percent was plastic, 10.8 percent was glass, 10 percent was metal, and 17.1 percent was from other materials.[42]

The Narragansett Bay Project

In 1985, the Narragansett Bay Project (NBP) was created to assess the water quality problems of the Bay and to make the necessary recommendations. In 1987, Narragansett Bay was chosen as one of the original six estuaries to be included in the National Estuary Program. The coordination of the project was to be carried out by the NBP. The first task of the NBP team was to bring together interested parties to examine the primary sources of pollution to the Bay and identify solutions. The project team worked with representatives from industry, the scientific community, marine trade groups, citizen organizations, and state agencies. Since its inception, the NBP has initiated over 100 studies on the environment and management of the Bay.[43]

In January of 1993, the EPA approved the Comprehensive Conservation and Management Plan (CCMP) for Narragansett Bay which identified five goals: prevention of further water quality degradation; protection of critical resource areas; management of living resources; rehabilitation of degraded waters; and coordination and implementation of the CCMP.[44]

After the CCMP was approved, the NBP became administered by the Rhode Island Department of Environmental Management (DEM) where a small staff has been assisting in the implementation of the plan. An Implementation Committee and an Implementation Advisory Committee were established to oversee the actions of the NBP. The effectiveness of the NBP is limited in part because its funding sources are so tenuous. Without the ongoing commitment of state and federal resources it is difficult to ensure proper monitoring and implementation of the CCMP. There is also a serious problem regarding the lack of integration of the CCMP recommendations into state and local policy plans and actions. For instance, although the CCMP was adopted as part of the State Agency Guide Plan, and the Coastal Resources Management Council is obliged to follow the guidelines in the CCMP, there is no enforcement mechanism, and therefore, no oversight to ensure compliance with the provisions in the CCMP.

Nevertheless, great strides have been made in improving the environmental quality of the Bay, and there have been some tremendous programmatic accomplishments. An example of a successful NBP effort is the establishment of the Greenwich Bay Watershed Restoration Initiative. Restoration of the water quality of Greenwich Bay, a 3,200-acre embayment within the Narragansett Bay system, was recently targeted as a top priority by both NBP and the Rhode Island DEM. Save The Bay, a non-profit membership organization, was tapped to join in the efforts to address a range of pollution sources, such as failed septic systems, polluted stormwater and discharges of sewage from boats.

For decades Greenwich Bay has been a glorious vacation spot and a thriving resource, supporting scallops, oysters, and winter flounder. Within these waters are some of the most productive quahog beds in the world. The Bay's popularity eventually aided in its transformation into one of the most congested areas in Rhode Island. The population in some areas was six times the State average. Finally, the day of reckoning came in December, 1992 when unacceptable levels of bacterial pollution resulted in the closure of the area to shellfishing, and the loss of $4 million in commercial shellfish revenues.[45]

The immediate goal of the Restoration Initiative was to reduce bacterial pollution so that Greenwich Bay could be re-opened for shellfishing. These efforts involved such varied activities as door-to-door surveying to identify failed septic systems, building support for a bond referendum for the City of Warwick to pay for stormwater mitigation work, and constructing a two-mile sewer line. Throughout the process, Save The Bay has been committed to community education and volunteer monitoring projects, always stressing the role of the individual in cleaning up the Bay. Save The Bay is also involved in helping to meet the longer-term goal of improving the water quality so that the Bay can support eelgrass beds, bay scallops and other native aquatic resources.

Other successful NBP efforts include the Field's Point wastewater treatment facility which has achieved a 90 percent reduction of metal contaminants in its effluent compared to 1981 levels.[46] CSO problems are also being addressed by a project which will create two deep tunnels and storage facilities to more effectively treat combined sewer discharges in the upper Narragansett Bay. A 99 percent reduction in fecal coliform loadings from the CSOs is expected for this area of the Bay.[47] New pumpout stations are also under construction at marinas throughout Rhode Island to meet a "no-discharge" designation for the Bay, making all boat sewage discharges illegal.[48]

Although these and other projects are clearly important, the CCMP failed to highlight which projects are most significant for the health of the Bay and which ones should be carried out first. The CCMP includes hundreds of recommendations for protecting the Bay, but they are not listed in any priority order. In some cases it is also difficult for citizen activists to determine if their input throughout the process was actually given due consideration in the writing of the plan. In addition, the stakeholders who were involved in developing the plan have become frustrated with the lack of clarity, direction, and commitment to its implementation. This, in part, may be due to a lack of ongoing citizen involvement and public input in refining the CCMP over time.

National Coastal Caucus

Since 1970, when Save The Bay was formed by a handful of volunteers and grassroots activists, it has grown into one of the largest and most effective, non-profit, membership-based environmental organizations in New England. Headquartered in Providence, Rhode Island, with 15,000 members, an annual budget of approximately $1 million, and a staff of over 20 full-time professionals, Save The Bay employs education and advocacy to promote environmental protection, restoration, and preservation of Narragansett Bay.

Save The Bay has been involved in the NBP since its earliest days. The staff, Board of Directors, and membership have been involved in numerous capacities. In particular, they have served on the original NBP Team, Steering Committee, Critical Habitat Subcommittee, and the Non-point Source Subcommittee.

During the past 25 years, Save The Bay has worked collaboratively with others in the community, as well as with government agencies, to cut certain forms of pollution in Narragansett Bay in half, but much work remains to be done. Currently, Save The Bay's Narragansett Bay protection programs provide the public with a greater understanding of, and appreciation for, their place in the Bay ecosystem. Save The Bay's volunteer-based Bay monitoring program (Narragansett Bay Watchers), on-the-water action and response program (Narragansett BayKeeper), outdoor school and workplace-based education program (Explore The Bay), and Bay Habitat Restoration and Protection Program, offer individuals many opportunities to learn more about the Bay and to participate directly in Bay protection efforts.

New Hampshire Estuaries
in New Hampshire

Portrait of the Estuaries

The New Hampshire Estuaries Project is examining the water quality and habitat problems of two New Hampshire estuaries, and the impact that their greater watershed areas have on these systems. The Great Bay Estuary and the Hampton Harbor Estuary, included in the New Hampshire Estuaries Project, are situated along New Hampshire's 150 miles of tidal shoreline.[1] The Great Bay Estuary and the Hampton Harbor Estuary are two distinct estuaries that will be jointly studied in order to address the problem of bacterial contamination and the resulting closure of shellfish beds currently at issue in both systems.

New Hampshire Estuaries

Area of watershed	• Great Bay 930 square miles
	• Hampton Harbor 47 square miles
Population Centers	• Great Bay (largest cities) 87,521 people
	• Town of Hampton 12,466 people
Values	• Fisheries generate $13 million*
	• Total economic output of recreational fishing — $178 million*
	• Support the largest wintering population of bald eagles in New Hampshire
Threats	• Pathogen contamination
	• Shellfish bed closures
CCMP status	Expected in 1998

Designated as a "Nationally Significant" Estuary in 1995.

*State figure

The Great Bay Estuary is a drowned river valley located along the New Hampshire-Maine border.[2] Seven rivers provide freshwater for the Great Bay Estuary: the Lamprey, Oyster, Cocheco, Salmon Falls, Squamscott, Winnicut, and Bellamy Rivers.[3] The watershed area of the Great Bay Estuary covers 930 square miles.[4] Two-thirds of the Great Bay watershed is in New Hampshire; one-third is located in southern Maine.[5] The largest cities within the Great Bay watershed are the New Hampshire cities of Rochester, Dover, Exeter and Portsmouth. In 1993, these four cities had a combined population of 87,521.[6]

Habitat types within the Great Bay Estuary are varied. About 1,000 acres of saltmarsh; 52 acres of oyster beds; 2,575 acres of clam flats; 5,000 acres of subtidal eelgrass; many acres of mudflats; and rocky outcroppings combine to provide habitat for an abundance of plants and wildlife.[7] Sixty-six percent of the watershed's land cover is forested; 10 percent consists of wetlands; another 10 percent consists of urbanized lands; and the remaining 14 percent consists of agricultural, disturbed, cleared and water habitats.[8]

At the southern end of the New Hampshire coast lies Hampton Harbor, a shallow estuary bordered by salt marsh. Mill Creek, and the Taylor, Hampton, Browns, and Blackwater Rivers are Hampton Harbor's primary sources of freshwater.[9] The watershed area of the Hampton Harbor Estuary is 47 square miles.[10] Eighty percent of the Harbor's watershed is in New Hampshire; the remaining 20 percent is located in Massachusetts.[11] The largest municipalities in the Hampton Harbor watershed include Hampton, Hampton Falls, and Seabrook, New Hampshire. The town of Hampton, with an estimated 1993 population of 12,466, is the largest population center of the watershed.[12]

38824

Hampton Harbor's land area is made up of 40 percent forested lands, 23 percent urbanized lands and 21 percent wetlands. The remaining 16 percent of land is a mixture of agricultural, disturbed, cleared and water habitats.[13] Hampton Harbor's developed areas consist primarily of residential areas and summer resorts which border the beaches. During the summer months, the town of Hampton's population climbs substantially. On some days, as many as 100,000 people (vacationers, permanent and summer residents) recreate along Hampton Harbor beaches.[14]

For both of the Estuaries, development is concentrated near the tidal waters and does not expand too far into the watershed.[15] Light industrial operations and low-to-moderate density residential areas comprise most of the urbanized use of land in the watersheds.[16]

Values of the Estuaries

The Hampton Harbor and Great Bay Estuaries are rich in recreational opportunities, fisheries, and wildlife. Natural resources and recreational activities generate significant amounts of revenue for local economies.

Tourism/Recreation

Tourism is the second largest industry along New Hampshire's coastline, supporting 15 percent of the regional work force.[17] Many residents and tourists sail, fish, water ski, swim, and dive in the Estuaries of New Hampshire. A number of parks and trails border the Estuaries. In 1991, recreational fishing in New Hampshire generated approximately $178 million in economic output and employed nearly 3,000 people.[18] In the same year, approximately 75,000 saltwater anglers spent over 293,000 days fishing off the coast of New Hampshire. Fifty percent of the anglers were non-residents of the State.[19]

The Hampton Harbor area is New Hampshire's primary summertime beach resort area. Sandy beaches of the Estuary are a major tourist attraction. One unique feature of the Hampton Harbor Estuary is the 5,000 acres of salt marsh it contains. This feature attracts a number of recreational softshell clam harvesters, distinguishing Hampton Harbor Estuary as the most popular location in coastal New Hampshire for softshell clamming.[20] The oyster, clam, and mussel shellfisheries are important recreational resources for the New Hampshire Estuaries and the State of New Hampshire. Recreational shellfishing generates an estimated $3 million per year for local and state economies.[21] In recent years, an average of 5,000 bushels of oysters, worth $300,000, have been harvested from Great Bay oyster beds each year.[22]

Recreational anglers fish for Atlantic silverside, rainbow smelt, killifish, white perch, and flounders in the Great Bay. Charters take a number of anglers out to fish for bluefish, striped bass, cod, and mackerel. In 1990, saltwater fishermen spent over $52 million on fishing-related activities.[23] Lobstering is another valuable recreational activity in the Estuaries. Portsmouth Harbor within the Great Bay Estuary is one of the most popular lobster trapping areas in New Hampshire.[24]

Fisheries/Seafood

The New Hampshire Estuaries contribute valuable fishery resources to the New England region of the United States. In 1994, the combined value of New England's commercial finfish and shellfish industries totaled approximately $583 million. During that same year, commercial finfish and shellfish landings for the State of New Hampshire totaled approximately 12 million pounds, valued at $13 million.[25]

A remarkable array of fish and shellfish depend on the New Hampshire Estuaries for breeding grounds, nursery areas, and principal habitat. The Estuaries support anadromous fish runs for sturgeon, smelt, shad, salmon and alewives. Lobsters, winter flounder, cod, and striped bass rely on the Estuaries for nursery habitat. Oysters, softshell clams, blue mussels, and razor clams also inhabit the Estuaries.[26] Major commercial fisheries of the Great Bay include eel, lamprey, and lobster. Current annual lobster catches for the Bay are estimated at over 880,000 pounds and $4 million.[27]

VOL 12

VOL 12

3826

Wildlife

New Hampshire is home to 10 federally-listed threatened or endangered species,[28] including the federally endangered shortnose sturgeon which relies on the Estuaries.[29] Over 110 bird species frequent the Estuaries.[30] Cormorants and gulls are common year-round seabirds. Black ducks and Canada geese can be observed during the fall and winter.[31] Wading birds which use the estuarine habitat of the area include great blue herons, snowy egrets, glossy ibis, and the common least tern, which is threatened in the State of New Hampshire. The Great Bay Estuary supports the largest wintering population of bald eagles in New Hampshire — up to fifteen eagles have been observed in recent winters.[32] Mammals common in the Estuaries include otters, minks, beavers and harbor seals.[33] The Great Bay National Wildlife Refuge recently opened 1,000 acres of wildlife habitat previously used by the Pease Air Force Base.

Threats to the Estuaries

As previously noted, the most crucial problem affecting the Great Bay and Hampton Harbor Estuaries is bacterial contamination and the subsequent closure of shellfish harvest areas. Prime shellfish beds and flats in the Great Bay Area (including most of Little Bay, the Piscataqua River, and smaller tidal rivers) are closed or limited to harvesting due to bacterial contamination. Soft shell clams are the predominant shellfish of the Hampton Harbor Estuary. Major clam flats in the Harbor were closed in 1988 as a result of high bacteria levels. In September of 1994, a few of the flats were reopened on a conditional basis.[34]

Over the years, Great Bay and Hampton Harbor Estuaries have been the focus of several studies conducted by the University of New Hampshire, Jackson Estuarine Laboratory, and several New Hampshire State agencies. These studies have identified polluted runoff as the underlying cause of bacterial contamination in the Estuaries.[35] Stormwater, on-site sewage disposal systems, agricultural runoff, and runoff from shoreline development are some of the primary sources of bacteria, nutrients, heavy metals, and sediments that threaten the Estuaries.

Significant declines among shellfish populations and approved shellfish harvesting beds have been widely noted in many harvest area assessments and are of major concern to government officials and local citizens in the area. The New Hampshire Estuaries Project proposes to emphasize shellfish bed closures as an indicator of the environmental quality and a measure of successful restoration in the Estuaries.[36] The Project will focus on polluted runoff controls as a way to limit the bacterial contamination responsible for closing shellfish beds. In areas around Hampton Harbor Estuary, individual septic systems are believed to be responsible for loadings of bacteria and nutrients in the Estuary.[37] In 1990, 72 percent of the shellfish beds in the Great Bay were harvest-limited.[38]

Floatable Debris

Trash accumulated on estuarine beaches also threatens the ecosystem. The amount collected in just one day of an organized clean-up was staggering. On October 1, 1994, volunteers cleared 14,300 pounds of marine debris from 20 miles of New Hampshire beach area. Of the total amount of marine debris collected, 53.7 percent was plastics, 14.1 percent was metal, 11.8 percent was paper, and 20.4 percent was from other materials.[39]

The New Hampshire Estuaries Project

With the Environmental Protection Agency's acceptance of the New Hampshire Estuaries into the National Estuary Program, it was included among the most recent group of seven estuaries added to the Program. In July, 1995, the New Hampshire Estuaries were officially designated as "nationally significant" under the National Estuary Program of the Clean Water Act. The Project has established a three-year schedule to complete its Comprehensive Conservation and Management Plan (CCMP). The Project is currently exploring the possibility of adding representatives of Maine and Massachusetts to the Management Conference. The Project has decided not to have a free-standing Citizens Advisory Committee and Science/Technology Advisory Committee. Instead, it will incorporate citizens and technical experts on all Project committees.

VOL 12

New York-New Jersey Harbor Estuary
in New York and New Jersey

The Estuary is like a family. Its' air, water, land, and communities of people and communities of wildlife, all related, all living together. It is a marvelous organism whose life and health depends on us all, and benefits us all. The Estuary is alive!

—Steve Barnes, Conservation Director
NY/NJ Baykeeper

Portrait of the Estuary

The New York-New Jersey Harbor Estuary Program is examining the environmental problems of the Harbor system and the impact that the greater watershed area has on the Estuary. The New York-New Jersey Harbor Estuary is comprised of the New York-New Jersey Harbor and a complex of tidal rivers and streams. Its core area, called the Hudson-

Raritan Estuary, extends from the Piermont Marsh in New York State to the Sandy Hook-Rockaway Point Transect. This region of the Harbor includes the bi-state waters of the Raritan Bay, Upper and Lower Bays, Hudson River, Kill Van Kull, Arthur Kill, and other tributaries.[1] The Estuary covers approximately 298 square miles of surface water.[2] The average depth of the Estuary is 21 feet.[3]

The watershed area of the Estuary extends into southwestern Vermont, northwestern Massachusetts, and portions of upstate New York. The watershed measures approximately 16,500 square miles.[4] New York City, Jersey City, and Newark are all part of the watershed. The Ports of Newark, Elizabeth, and New York lie at the heart of the Estuary. Together they comprise one of the largest port areas in the world.[5] This heavily urbanized Estuary is enjoyed by 20 million residents[6] and over 17 million annual visitors.[7] The Arthur Kill sub-watershed alone has 690,000 residents, a density of 5,300 people per square mile.[8]

More than two-thirds of the Estuary's freshwater is delivered by the Hudson River.[9] On average, the Estuary receives approximately 26,700 cubic feet of freshwater per second, a high rate compared to other estuaries of the middle Atlantic region.[10] The New York Bight is another special feature of the area. The Bight includes the ocean waters from the Sandy Hook-Rockaway Point Transect approximately 100 miles to the Outer Continental Shelf. Since there is a clear linkage between the Bight and the New York-New Jersey Harbor, efforts to restore both of these areas have been combined and are being addressed by the Estuary Program.

Tidal rivers, salt and fresh tidal marshes, woodlands, shallow bays, barrier beaches, and sand dunes can be found in the Estuary. Water is the predominant habitat type in the Estuary. Salt- and freshwater tidal marshes cover 180,000 acres in New Jersey and 25,000 acres in New York.[11] Approximately 75 percent of the salt and freshwater tidal marshes in New Jersey and New York have been lost to development. In addition, there are probably no more than 15-17,000 acres of tidal wetlands left within the core area of the Harbor Estuary.[12] The Estuary has approximately 481 miles of shoreline; however, human-developed structures, such as piers and bulkheads, make up 75 percent of this shoreline.[13]

Benefits of the Estuary

The New York-New Jersey Harbor Estuary provides a wealth of economic benefits and recreational opportunities. The Port of New York and New Jersey contributes $14 billion per year to the area's economy and employs approximately 200,000 people.[14] Estuarine-based attractions of the area include the Hackensack Meadowlands, the Manhattan skyline, Battery Park, the Statue of Liberty, Sandy Hook National Park, Liberty State Park, and Jamaica Bay National Wildlife Refuge.

Recreation/Tourism

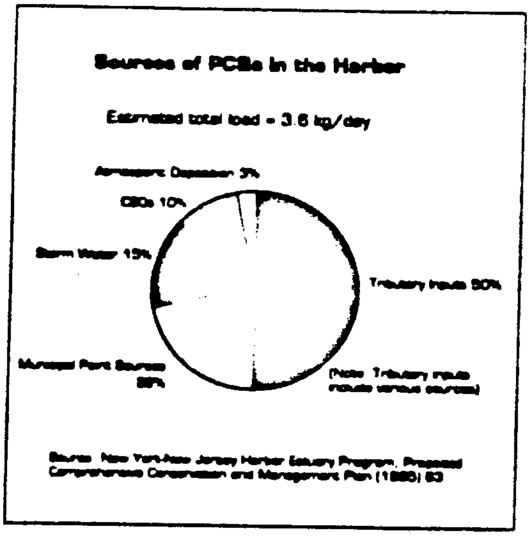
Millions of tourists and residents use the Harbor ecosystem each year and participate in a variety of recreational activities. Sailing, sport fishing, waterskiing and beach-going are some of the activities enjoyed by these visitors. This recreational value translates into tremendous economic benefits for the region. The State of New Jersey alone gains $4 billion annually from revenues generated by oceanfront tourism;[15] while New York's coast generates $2.9 billion from tourism.[16]

Pollution episodes and their effects on the living resources and habitat of the Estuary can devastate the coastal tourism industry of the area. During the summers of 1987 and 1988, medical waste and floatable debris washed ashore and resulted in severe economic losses from fewer tourist expenditures. It is estimated that New York lost between $900 million and $2 billion and that New Jersey lost between $900 million and $4 billion in revenues as a result of these pollution episodes.[17]

The New York-New Jersey Harbor provides important fishing grounds for sport fishermen. Striped bass, fluke, bluefish, and winter flounder are commonly caught by the recreational anglers. In 1991, recreational fishing in New Jersey generated approximately $1.3 billion in economic output and employed nearly 17,000 people. In the same year, recreational fishing in New York generated approxi-

VOL 12

3830



mately $1.4 billion in economic output and employed nearly 18,000 people.[18] In 1991, approximately 491,000 anglers spent over 3.5 million days saltwater fishing off the coast of New York. During the same year in New Jersey, approximately 746,000 saltwater anglers spent over 6 million total days fishing.[19]

Fisheries/Seafood

In 1994, the combined market value of commercial finfish and shellfish landings in the middle Atlantic region totaled approximately $149 million. Many of the commercially valuable species in the middle Atlantic region depend upon the health of the New York-New Jersey Harbor for survival. In 1994, the State of New York's commercial finfish and shellfish landings totaled approximately 45 million pounds, valued at $43 million. In the same year, New Jersey's commercial finfish and shellfish landings totaled approximately 202 million pounds, valued at $100 million.[20]

The waters of the New York-New Jersey Harbor Estuary have traditionally supported productive finfish and shellfish populations. However, over the past 100 years, there have been significant declines in these populations because of overfishing, habitat destruction, and declining water quality. In the past, oysters and American sturgeon were regularly harvested from the Estuary. However, pathogen contamination and habitat destruction have led to severe declines in oysters such that no commercial harvest exists today. In addition, only a small commercial harvest exists for American sturgeon.[21] A naturally-occurring disease has caused further declines among lobster, crab, and shrimp populations within the estuary.[22]

Today, the leading commercial fisheries in the Estuary are winter flounder, menhaden, bluefish, weakfish, and baitfish. A modest fishery exists for American shad.[23] Hard and soft-shell clams, ocean quahogs, sea scallops, and blue mussels are commercially valuable shellfish found in waters of the Harbor and Bight.[24]

Wildlife

Many wildlife species inhabit the areas surrounding the estuary and rely upon the various estuarine habitats for their survival. The loss and modification of coastal habitat to serve development interests have caused coastal bird and mammal populations to decline in the Estuary area.[25] The coastal habitat which does remain provides critical nesting and foraging habitat for birds and other wildlife species, including the federally threatened piping plover and federally endangered roseate tern. The Arthur Kill area supports nesting herons and egrets. Osprey and hawk populations are beginning to rebound in the area after an absence primarily caused by the use of now-banned pesticides.[26] The extensive riparian area of the Harbor watershed also forms vital habitat for aquatic species.

Although the New York-New Jersey Harbor is rich in aquatic and semi-aquatic species, human impacts, such as, urban growth and toxic pollution, threaten the future of wildlife populations and diversity. As more vegetated land within the Hudson-Raritan Estuary is destroyed by urban development, the preservation and restoration of the remaining natural areas in the Estuary will become increasingly essential to protect wildlife populations and diversity.

Threats to the Estuary

The urbanized nature of the New York-New Jersey Harbor Estuary contributes to many of the water quality and habitat problems of the system. The urban population's impact on the waters presents obstacles to the restoration of the Estuary. The proposed Comprehensive Conservation and Management Plan (CCMP) identifies seven areas where the health of the Estuary is seriously impaired: loss of habitat and living resources, toxic contamination, dredged material management, pathogenic contamination, floatable debris, nutrients and organic enrichment, and rainfall-induced discharges.[27] However, there is a growing belief that the way these problems are addressed should reflect their effects on habitat. Therefore, the threats listed below emphasize the impacts of population growth, and habitat loss, as well as the impacts to habitat from toxic pollution, contaminated sediments, pathogen contamination, floatable debris, and nutrient loadings.

Habitat Loss and Degradation

The shorelines, beaches, and tidal rivers in the Estuary are subject to pressures from urban and coastal development. Constructed piers, bulkheads, and rip-rap; the filling and dredging of wetlands; and the accumulation of floatable debris in marshlands are a few examples of the human activities which have altered the estuarine environment. These structures also disrupt spawning patterns of fresh and saltwater fish by altering natural erosion and accretion processes.

As natural areas diminish and are replaced by impervious surfaces, such as pavement and roofs, the biological integrity of the estuary is seriously impaired. It is estimated that at least 75 percent of the historic tidal wetlands in each of New York City's boroughs and in New Jersey counties surrounding the Harbor have been destroyed. Additional estimates indicate 99 percent of New York City's historic freshwater wetlands have been lost.[28] The cumulative consequences of these lost wetlands are significant as the valuable functions that they perform cannot be matched by human-made structures.

Habitat is also affected by the damming of rivers within the watershed and the diversion of the Harbor and Bight's freshwater to serve municipal and industrial uses. By changing the mixing ratios of fresh- and saltwater and altering the natural vegetation, the aquatic life that use the estuary are negatively impacted.[29] However, pressures to convert more natural areas within the Harbor Estuary into developed land are, unfortunately, likely to continue. Studying the full consequences of future coastal development projects is an essential part of the efforts to restore the New York-New Jersey Harbor Estuary.

Toxic Pollution and Contaminated Sediments

The New York-New Jersey Harbor has suffered from a long history of abuse initiated by industrial and urban development. In 1990, there were 582 industrial and 287 municipal point sources discharging pollution in the Harbor.[30] For decades, toxic contaminants have accumulated in the sediments of the Harbor, posing major threats to aquatic life and surrounding human populations. In the Port Newark-Port Elizabeth complex for example, sediments contaminated with dioxin from a site in the Passaic River continue to enter Newark Bay. Proposed dredging of these toxic sediments has sparked a public debate over the impact sediment disposal would have on the aquatic environment of the Harbor Estuary, on fishery resources, and on New Jersey's commercial and recreational fishing industries.[31]

Toxic chemicals can be found in the waters, sediments, and fish and shellfish tissues throughout the Harbor and Bight. Areas with the greatest concentration of toxic contamination include Newark Bay, the tributaries leading into Newark Bay, and the Kills. Chemicals of concern in the Harbor-Bight include mercury, copper, nickel, lead, cadmium, arsenic, polychlorinated biphenyls (PCBs), dioxin, PAHs, and pesticides.[32]

The bioaccumulation of toxics in the food chain threatens the health of wildlife populations and people throughout the watershed. Fish caught with tumors and other physical abnormalities and birds with reproductive problems are considered to be linked to the toxic pollution in the Harbor/Bight.[33] In addition, consumption advisories for certain fish exist throughout the entire New York - New Jersey Harbor Estuary system. Some examples include: advisories for bluefish, striped bass, American eel, white perch, and white catfish in Sandy Hook and Raritan

Bays; and advisories for all fish, shellfish and crustaceans in the Kill Van Kull.[34] Furthermore, New York has completely closed its striped bass commercial fishery in the Harbor and in portions of the Bight due to high PCB levels.[35] There is growing concern that subsistence fishers and their families' health is at risk because of their above-average consumption of fish and shellfish caught directly from the waters of the Harbor.

Municipal and industrial point sources, atmospheric deposition, stormwater, and combined sewer overflows (CSOs) are leading sources for the loadings of heavy metals into the Harbor. Trends indicate that metal loadings into the Harbor and Bight were reduced between 1985 and the early 1990s, when an industrial pretreatment program became effective and a corrosion control program was established for New York City's water supply.[36] The principal sources of PCBs into the Harbor are tributary flows, municipal point sources and stormwater. Finally, PAHs, which are found in petroleum and other products, are introduced into the Harbor by atmospheric deposition, stormwater, CSOs, and oil and gas spills.[37]

Pathogen Contamination

Pathogens are disease-causing bacteria and viruses found in human and animal wastes which enter estuaries through sewage treatment plant discharges, combined sewer overflows (CSOs), polluted urban stormwater, agricultural runoff, boating waste, and septic systems. Pathogens in coastal waters pose risks to humans who eat contaminated shellfish or who recreate in contaminated beach waters. Gastroenteritis, hepatitis, and other diseases can result from the ingestion of pathogens in water. For this reason, beaches and shellfish beds are closed or restricted when water monitoring indicates high levels of fecal coliform bacteria (an indicator of pathogen contamination) are present in coastal waters.

Pathogen contamination has been a problem in the New York-New Jersey Harbor area for decades. Before passage of the Clean Water Act in 1972, environmental conditions in the New York-New Jersey Harbor were poor. For instance, one-half billion gallons of raw sewage flowed into the Harbor per day; fifty percent of the wastewater treatment plants discharged effluent which had received only primary levels of treatment (the initial phase of sewage treatment which is designed only to remove solids and floatables); and CSOs sometimes occurred even in dry weather.[38] Under- or untreated sewage has caused widespread pathogen contamination in the Harbor and Bight and has devastated many fisheries and shellfish areas.

During the past two decades, wastewater technology upgrades have helped to stem pathogen contamination in the Estuary. Currently, only two treatment plants lack secondary treatment technology (a process which biologically removes much of the suspended solids and pathogen content).[39] Still, malfunctions and system overloads can occasionally lead to discharges of under-treated sewage.

Combined sewer overflows cause significant problems for the health of the Estuary, with estimates of the total number of documented combined sewer outfall pipes reaching 730.[40] CSOs in New Jersey contribute only seven percent of the freshwater input into the Estuary, yet they are the source of over 90 percent of the pathogens entering the system.[41]

Currently, shellfish areas are either closed or restricted in all portions of the Harbor's core area and in many back bay areas near the Bight.[42] In the Bight itself, most waters are approved for shellfish harvesting.[43] The States of New York and New Jersey regularly test their ocean waters for pathogens. However, New Jersey's program has more stringent monitoring and closure protocols that require mandatory closures when a bacteria standard is violated.[44] During 1994, New Jersey beaches in the Harbor area were closed on five occasions for a total of 25 days due to stormwater pollution and suspected sanitary sewer leaks.[45] In the same year, Harbor area beaches on Staten Island, Coney Island, and Rockaway in New York were closed for health reasons.[46]

Floatable Debris

In the late 1980s, national attention was focused on the beaches of New Jersey and New York and public concern was raised after beaches closed because of medical wastes and other trash washing ashore. Types of debris affecting the Harbor-Bight

VOL 12 3833

R0037141

include wood, street litter, vegetation, sewage-related waste, fishing gear, and medical waste. Principal sources of this debris are combined sewer overflows, urban stormwater, littering, land-fill operations, and vessels.[47]

The public's disinclination to recreate on littered beaches and extended beach closures can cause significant economic losses to the region. During the infamous summers of 1987 and 1988 when the medical waste and other debris that washed on the shores steered tourists away in droves, the States of New York and New Jersey lost between $1.8 and $6 billion in recreational and tourist revenues.[48] The Army Corps of Engineers data indicates that in 1987 floating garbage caused an estimated $48 million worth of damage to shipping vessels.[49] In 1989, the area extending from the Upper Bay to the Raritan Bay was afflicted with 164 garbage slicks.[50] These impacts also result in population declines in fish and wildlife species due to the entanglement in and ingestion of wastes.

On September 17 and 18, 1994, volunteers cleared 102,758 pounds of marine debris from 543.1 miles of New York's beaches. Of the total amount of marine debris collected, approximately 59.4 percent was plastic, 13.04 percent was glass, 10.2 percent was metal, and 17.36 percent was from other materials.[51] In the same year on October 15 and 22, volunteers cleared 73,782 pounds of marine debris from 171 miles of New Jersey's beaches. Of the total amount of marine debris collected, approximately 66.3 percent was plastic, 10.4 percent was paper, 8.2 percent was metal, and 15.1 percent was from other materials.[52] In New Jersey, a coordinated campaign to sweep beaches of debris is underway. This project, called Operation Clean Shores, collects 10 million pounds of debris each year.[53]

Nutrient Loadings

Excessive nutrient inputs, also called eutrophication, into the Harbor and Bight are a serious problem. Excessive levels of these nutrients, such as nitrogen and phosphorus, stimulate the growth of algae in the Bay. As the algae grow, they not only block sunlight needed by the submerged aquatic vegetation of the Bay, but also require a great amount of dissolved oxygen to decompose. The decomposition process reduces the levels of oxygen for other aquatic life. Low oxygen conditions (called hypoxia) can result in large fish kills. Hypoxic conditions often occur in portions of the Harbor and Bight. Throughout the Harbor this problem has resulted in the destruction of fish and shellfish populations and habitat.[54]

The leading sources of nutrients into the New York-New Jersey Harbor are municipal and private wastewater and sewage treatment facilities, atmospheric deposition, tributary inputs, urban stormwater, agricultural runoff, boater discharges, and combined sewer overflows. Every day, about 2.6 billion gallons of wastewater are discharged into the Estuary by New York and New Jersey sewage plants alone.[55] Reducing the nitrogen loadings from these discharges is key to eliminating the hypoxic conditions of the Estuary.

The New York-New Jersey Estuary Project

In 1987, the New York - New Jersey Harbor Estuary was designated by Congress as an estuary of "national significance," and was initiated into the National Estuary Program (NEP) under the Clean Water Act. The following year, the New York-New Jersey Harbor Estuary Project (HEP) was formed to coordinate the drafting of a Comprehensive Conservation and Management Plan (CCMP) to restore the Harbor Estuary and the adjacent New York Bight. The draft CCMP has been endorsed by the HEP Policy Committee and awaits approval by the EPA Administrator and State Governors in July, 1996.

The HEP has assumed a tremendous challenge, as compared to some of the other NEP projects. The study area includes one of the most complex estuarine areas and some of the most diverse user groups. In an attempt to provide a forum for all groups interested in the Estuary, the HEP has organized a partnership among federal, state and local agencies, scientists, fishing organizations, environmental groups, business, industry, civic groups and other members of the public to participate in the Manage-

VOL 12

3834

R0037142

ment Conference and the drafting of the CCMP. The proposed CCMP identifies seven areas where the health of the Estuary is seriously impaired: loss of habitat and living resources, toxic contamination, dredged material management, pathogenic contamination, floatable debris, nutrients and organic enrichment, and rainfall-induced discharges.[16]

To begin to address these concerns the HEP has taken on several initiatives. The HEP has established waste-load allocations to limit the influx of toxic discharges for heavy metals commonly found in the Harbor and its sediments. Models for toxics monitoring are being developed and bio-monitoring of sediment movements is being initiated to prevent the continued degradation of water quality.[17] To educate the residents within the watershed, a "Lifestyle Guide" was developed to encourage oil recycling, water conservation and boater pollution prevention.

The HEP has also developed a long-term strategy to address the floatable debris problem, including the Operation Clean Shores program in New Jersey which has removed 5,000 tons of debris from beaches.[18] In addition, the HEP will coordinate its efforts with the Hudson River Estuary Program which manages living resources from Troy to the Verrazano Narrows.[19] Most recently, the States of New York and New Jersey have prioritized the protection of coastal habitats in the watershed.

In late 1993, in an attempt to ensure that the CCMP would reflect public priorities for restoring the Estuary, the Citizens Advisory Committee, the Science and Technical Advisory Committee and 32 grassroots organizations co-sponsored eight regional pre-CCMP public meetings. Over 350 persons participated in these meetings and clearly reiterated several key priorities, including the need to: enhance public education and outreach and to make special efforts to ensure participation by all income, age and ethnic groups; increase the focus on habitat protection; place particular emphasis on beneficial re-use when determining dredged disposal options; use watershed planning as a means to limit waterfront development and to emphasize the cumulative environmental impacts of upriver actions; ensure better enforcement of the laws and stricter penalties; and to abate pollution in general.

Another round of public hearings took place after the release of the final CCMP in 1995. However, the end result of this process has been met with mixed reaction. Citizens groups still do not feel that these comments will be actively incorporated into the final plan.

Unfortunately, many citizens groups in the HEP believe that most of the actions proposed in the Draft CCMP will result in little more than maintenance of the 'status quo'. In addition, they believe that the proposed CCMP still does not adequately reflect their major concern expressed at public hearings: the loss of habitat. They believe that all the sections of the Draft CCMP that address specific impacts (Toxics, Pathogens, Floatables, etc.) should be related to the effects these problems have on habitat for both people and wildlife. In this way, the CCMP will reflect an ecological approach to managing the Harbor-Estuary that will benefit both human and wildlife communities, and sustain the economic benefits of the Estuary to the region and nation for many years to come.

In addition, public interest groups believe that it is essential to obtain a strong commitment from the States to undertake actions that will result in positive, measurable improvements to the Estuary if the goals of the Plan are to be attained.

National Coastal Caucus

The Baykeeper Program is devoted to protecting and preserving historic and environmentally significant areas of coastal land and waterways of the New York/New Jersey Harbor Estuary. The Baykeeper Program was established in 1990 as a program of the American Littoral Society, a national, non-profit public interest organization founded in 1961 to encourage a greater understanding of aquatic environments and to provide a unified voice advocating protection of the delicate fabric of life along this shore. The Society, and the Baykeeper Program are both headquartered at Sandy Hook, New Jersey.

Baykeeper is one of the "keeper" programs established throughout the country. The Baykeeper and his staff, along with dozens of concerned citizen volunteers, participate in varied activities designed to preserve and protect the Harbor Estuary's ecosystem.

VOL 12

3835

They work in cooperation with federal, state and local government agencies, and coordinate their efforts with those of other environmental and conservation organizations.

Members, staff and boardmembers of the Baykeeper and the ALS have been involved in numerous capacities in the development of the CCMP and in monitoring of the interim actions and other steps taken to implement the plan. Baykeeper has served as a member of the Habitat Work Group and the Citizens Advisory Committee, and ALS has served as host for public hearings on the Draft CCMP.

Efforts by grassroots groups, such as Baykeeper, focus on ensuring federal and state commitments to achieving the objectives and recommended actions in the CCMP. Baykeeper and other groups have also been successful in advocating an ecosystem-based habitat focus for the entire CCMP.

Baykeeper and ALS have recently begun work on a new grassroots habitat effort called the "Hudson-Raritan Habitat Initiative" (HRHI). HRHI is designed to help guide and coordinate public and private planning and resources for habitat preservation, restoration, and long-term management projects in the Estuary and its watersheds. While HRHI is not affiliated with the HEP, its work directly addresses the recommendations contained in seven of the twelve objectives of the CCMP.

Another Baykeeper initiative is called the Fisher's Information Network. The goal of the Network is to provide information to the citizens of Newark about the dangers and health concerns of eating fish and crabs from the Newark Bay and the Passaic River. The target audience is pregnant and nursing women and subsistence anglers of all ethnic groups and incomes, especially those who do not speak English or are of low income, who may not be aware of State issued advisories. This goal is achieved through the distribution of a fish advisory brochure; posting of multi-language, illustrated signs during the fishing season that state the reason one is not supposed to take, eat or sell fish or crabs from the targetted waterways; a survey aimed at anglers to determine whether they are fishing for subsistence or recreation; and working with health clinics and social services organizations to distribute a survey to determine their clientele's cooking, cleaning, and source of fish.

Other programs conducted by the Baykeeper include the Baykeeper Citizen Volunteer Water Monitoring Program and the Baykeeper Boat Auxiliary of volunteers that spot and report violations of environmental regulations.

Peconic Bays
in New York

In 1995, as the Brown Tide once again started inundating our beautiful bay system, discouragement crept in. Where had our courage gone? Our steady faith in the face of adversity? It's still there, it just seems to get clouded over at times, as do the Bays with Brown Tide. We must have faith that our positive actions are having a positive effect. Just remember how beautiful, clear, and clean the Bays were last year without the Brown Tide. And how these same crystal clear waters brought us the best scallop harvest since the Brown Tide decimated this economic mainstay of the East End in the mid-1980s. We ARE making a difference. Let us continue to do so!

—Gayle Marriner-Smith, President
Save the Peconic Bays

Portrait of the Bays

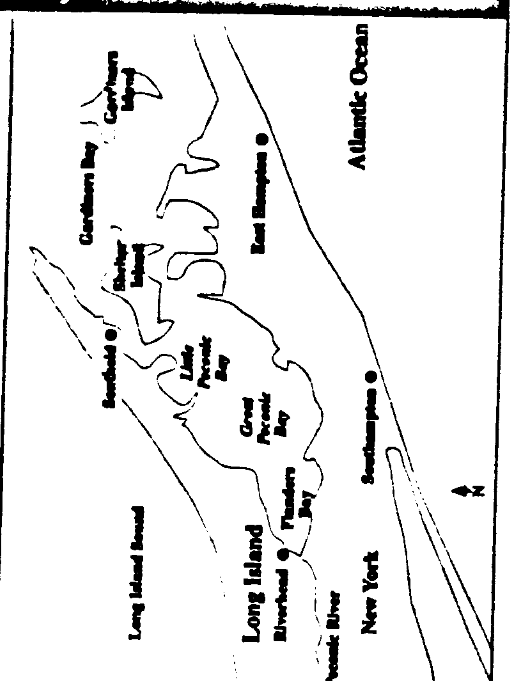
The Peconic Estuary Program is examining the water quality and habitat problems of the Peconic Bays and the impact that the greater watershed area has on the estuarine system. The Peconic Bays system is situated about 80 miles east of New York City, between the North and South Forks of eastern Long Island, New York. The system is comprised of over 100 distinct bays, harbors, embayments, and tributaries.[1] The four largest bays in the system are Great Peconic Bay, Flanders Bay, Little Peconic Bay, and Gardiners Bay. The system's surface water area measures approximately 100,000 acres.[2] The average

Peconic Bays

Area of surface water	100,000 acres
Area of watershed	110,000 acres
Average depth	5 to 21 feet
Shoreline	340 miles
Population	115,000 people
Values	• Fisheries generate $43 million*
	• Boating generates $200 million
	• 125 species of birds breed in the Peconic Bays
Threats	• Brown tide
	• Nutrient loadings
	• Pathogen contamination
	• Habitat loss and degradation
	• Floatable debris
CCMP status	Draft to be completed in 1996

Designated as a "Nationally Significant" Estuary in 1992.

*State figure



VOL 12

3839

VOL 12

3840

depth of the marine waters ranges from five feet in Flanders Bay to 21 feet in Little Peconic Bay.[3] The flushing time of the Bays (the time it takes to recycle the total amount of water in the estuary) varies from approximately three months in western Flanders Bay to three weeks in the far eastern portions of Gardiners Bay.[4]

The watershed area of the Bays covers 110,000 acres of land.[5] The watershed's western boundary is marked at the headwaters of the Peconic River. Montauk Point and Plum Island form the watershed's eastern boundary. A total of 340 miles of coastline border the estuarine system.[6]

Freshwater draining from land intermixes with saltwater from oceans to create productive estuaries such as the Peconic Bays. In the Peconic estuary system, freshwater is delivered by the Peconic River, other streams and creeks, and groundwater flows. A wide passage at the eastern end of the system connects the estuary with the ocean.

The Peconic Bays' watershed area is the year-round home to approximately 115,000 people and contains all or part of the six "East End" towns of Long Island — Brookhaven, East Hampton, Riverhead, Shelter Island, Southampton, and Southold.[7] The population is projected to increase by 21,000 people by the year 2000.[8] Unlike many Atlantic Coast estuaries, the watershed area of the Peconic Bays is lightly populated and undeveloped. Almost 24 percent of the land in the watershed is used for recreation and "open space;" 23 percent of the land is used for residential, commercial, and industrial purposes; and 11 percent is used for agricultural purposes.[9]

Most of the estuary's primary habitats — sandy beaches, cliffs, dunes, salt marshes, and freshwater wetlands — remain in a fairly natural condition. Over 3,600 acres of tidal wetlands are located in the estuary system.[10]

Values of the Bays

The Peconic estuary system is esteemed for both its rarity and diversity of habitats and wildlife. The Nature Conservancy designated the estuary system as one of the "Last Great Places" in the Western Hemisphere. The system includes the internationally rare dwarf pine plains and 14 other ecosystems noted for their rare occurrences on Long Island.[11] Also, over 40 areas in the system have been chosen by the New York State Coastal Management Program as significant coastal fish and wildlife habitat.[12]

The natural resources of the Bays are not just renowned for their ecological importance, they are also economically significant. A community survey conducted by the Suffolk Community College showed that 81 percent of the area's residents believe the Peconic Bays are "very to extremely important" to the local economy.[13] Maintaining a healthy and productive estuary is a clear objective in ensuring a sound future for the coastal communities.

Recreation/Tourism

The Peconic estuary is an important recreational resource for the residents and visitors of the area. Over 5,000 acres of the watershed are publicly-owned parklands, recreational areas, and wildlife refuges.[14] In addition, there are 30 public beaches, 69 marinas, and 14 public boating launch sites along the coasts.[15] Boating, hiking, sport fishing, camping, scuba diving, and biking are some of the more popular recreational activities to enjoy in the Peconic Bays area.

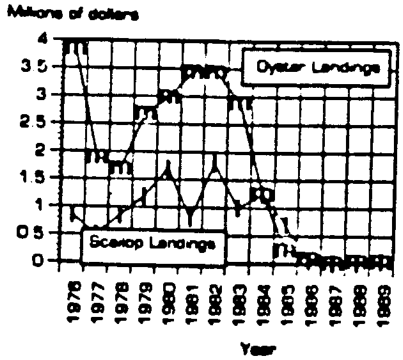
Tourism is one of the leading industries in the area. During the summer months, the area population exceeds 280,000 people — a 143 percent increase from the year-round population.[16] By the year 2000, the area's summer seasonal population is projected to reach 365,000 people.[17] The estimated value of tourism throughout Long Island is $7-9 billion.[18]

Recreational fishing and boating are other important components of the local economy. Direct boating revenues in the Peconic Bays area exceed $200 million annually.[19] In addition to the open estuary water, anglers fish along the rivers, creeks, and shore areas of the Bays. According to recreational use surveys, over 348,000 anglers fish on Long Island.[20] Over 80 fish species, including winter flounder, striped bass, bluefish, snapper, weakfish, porgy, and hard clams are commonly caught in the Peconic system by sport anglers and recreational clammers.

VOL 12

3841

Oyster and Scallop Landing Declines in Peconic Estuary



Source: Suffolk County Department of Health Services, Brown Tide Comprehensive Assessment and Management Program 1992 (Volume I) 2-50,2-53.

In 1991, 491,000 saltwater anglers spent approximately 3.6 million days fishing in waters off the New York coast.[21] The Peconic Bays are important to the State's saltwater fishing industry for their critical role in providing habitat for juvenile fish. Also in 1991, the State of New York's fresh- and saltwater recreational fishing industries generated approximately $1.4 billion in economic output and employed nearly 18,000 people.[22]

Fisheries/Seafood

In 1994, the combined market value of finfish and shellfish landings in the Middle Atlantic region totaled approximately $149 million.[23] Many of the most valuable species in the region, such as bay scallops and hard clams, depend upon the health of the Peconic Bays for survival. In 1994, the State of New York's commercial finfish and shellfish landings totaled approximately 45 million pounds, valued at $43 million.[24]

The Peconic Bays have an extensive fishing and maritime heritage. Historically, bay scallops, oysters, hard clams, and blue mussels have been the leading fisheries of the estuary. In 1982, bay scallops caught from the estuary comprised almost 28 percent of the nation's total bay scallop landings.[25] The dockside value of the estuary's bay scallop fishery in the early 1980s was as high as $1.8 million.[26] Since 1985, an unpredictable and recurring Brown Tide has decimated bay scallop populations. Landings of bay scallops, which between 1966 and 1986 averaged 271,000 pounds annually, dropped to only 250 pounds in 1988.[27] The 1988 value of the bay scallop harvest was just $2,300.[28]

In the late 1800's, oyster harvesting began in Peconic Bays and became a productive fishery of the estuary. In 1982, almost 800,000 pounds of oysters with a value of approximately $3.4 million were harvested from the Peconic system.[29] After the Brown Tide bloom devastated oyster production, the value of the oyster harvest plunged to less than $10,000 in 1987—a 99.7 percent drop from 1982.[30] The scallop and fish populations are showing some signs of rebounding after the economically devastating Brown Tide blooms of the 1980s.

Wildlife

The variety of habitats found in the Bays system support a great diversity of wildlife, including migratory birds and a number of imperiled species. Birds migrating along the Atlantic Flyway use the Peconic estuary system for resting, feeding, and wintering grounds. Scoters, mergansers, black ducks, mallards and Canada geese can be found using the habitats of the system. A New York State inventory of breeding bird species found that 125 of the 245 bird species which breed in the State use the Peconic Bays area for breeding grounds.[31]

A number of nationally protected, endangered and threatened species inhabit the Bays system. Endangered species which use the Peconic Bays system include the Kemp's ridley turtle, loggerhead sea turtle, leatherback sea turtle, green sea turtle, and roseate tern. In addition, the threatened piping plover dwells in the area.[32]

Threats to the Bays

During the 18th and 19th centuries, numerous sailing vessels used in the whaling, fishing, and shipping industries were based on this area of Long Island. The maritime ports of Riverhead, Hampton Bays, and Southold prospered during these days.

VOL 12

3842

During the 20th century, scallop and oyster harvests added to the national reputation of the Peconic estuary. Today, the water-based economy of the East End is threatened by Brown Tide blooms and increasing pollution, especially in the western portion of the estuary.

The major threats to the estuary as identified by the Peconic Estuary Program are the Brown Tide, nutrient loading, and pathogen contamination. The adverse impacts of increased development and recreational use on habitats and wildlife are additional concerns.

Brown Tide

The most overwhelming problem of the Peconic Bays system is the Brown Tide, an algal bloom of the species *Aureococcus anophagefferens*. The microscopic algal bloom was first detected in the Peconic system in 1985 and was, at the time, an unknown alga species. Since then, it has reappeared in 1986, 1987, 1988, 1990, 1991, 1992, and 1995. The appearances and durations of the Brown Tide blooms are unpredictable. The suspected causes of the Brown Tide include organic nutrients, chelators such as citric acid, and certain metals such as iron, selenium, vanadate, arsenate, and boron.[33] The principal sources of the suspected causes vary. The chelator citric acid is a detergent additive; arsenate is used in fertilizer and is a by-product of fossil fuel combustion; boron is derived from soap products; and vanadate occurs from the burning of oil and coal.[34] Excessive inputs of nitrogen and phosphorus, which have been attributed to large, destructive algal blooms in other estuaries, have neither been identified nor eliminated as a cause of Peconic Bays' Brown Tide.

Although the alga itself is microscopic, past blooms have grown to cover large portions of the surface water of the Peconic estuary system. The most frequent locations of the Brown Tides in this area have been in the Peconic and Flanders Bays and the South Shores bays.[35] Flanders Bay and West Neck Bay, bordering Shelter Island, have experienced some of the most severe Brown Tides during the past decade.[36]

The Brown Tide inhibits the growth of plankton, the basis of the estuarine food chain. It is also responsible for virtually eliminating the bay scallop and oyster populations, depleting other shellfish and finfish populations, and decimating eelgrass beds of the estuary. The Brown Tide grows so thickly in the estuarine waters that it blocks the sunlight needed by eelgrass for growth. As the coverage and density of eelgrass decreases, juvenile aquatic species lose the vital spawning and nursery habitat that the submerged vegetation provides. The severe losses of scallops and oysters have devastated the local fishing industry. Following the Brown Tide blooms, the annual landings and dockside values of scallops and oysters fell to less than four percent of the total shellfish harvest for both weight and value. Scallops and oysters had accounted for over 80 percent of total pounds landed and over 90 percent of total value prior to the blooms.[37]

The occurrence of Brown Tide has secondary effects. After the bay scallop fishery collapsed, commercial fishermen began harvesting hard clams to such an extent that sustainable hard clam populations quickly became threatened. In addition, East End communities have suffered economic losses due to reduced recreational opportunities around the estuary.[38]

The Brown Tide problem has been the subject of numerous studies. The Peconic Estuary Program is continuing to fund extensive research and monitor the impacts on and restoration of eelgrass beds and bay scallop populations.

Nutrient Loadings

Nutrients, such as nitrogen and phosphorus, are introduced to estuaries by sewage treatment plants, polluted stormwater, agricultural runoff, atmospheric deposition, septic system operations, and boater discharges. Excessive levels of these nutrients stimulate the growth of algae in the Peconic estuary system. As the algal blooms grow, they not only block sunlight needed by the submerged aquatic vegetation of the estuary, but also require a great amount of dissolved oxygen for decomposition, which reduces the levels of oxygen needed by other aquatic life. Low oxygen conditions (called hypoxia) can cause large fish kills.

Nitrogen loading is a particular concern in the western portion of the system (Flanders Bay and the mouth of the Peconic River). In this portion of the estuary, flushing is poor, hence, it is more sensitive to pollution impacts than the eastern section, which consistently has good to excellent water quality.[39] Significant sources of nitrogen inputs to the western Bays system include Meetinghouse Creek, the Peconic River, and the Riverhead Sewage Treatment Plant.[40] Additional sources of nitrogen include sediment flux (the chemical exchange between sediments and the water column), sanitary systems' contributions to groundwater underflows, atmospheric deposition, and stormwater carrying fertilizers applied to residential and agricultural lands.[41]

Pathogen Contamination

Pathogens are disease-causing microorganisms found in human and animal wastes which enter estuaries through sewage treatment plant discharges, combined sewer overflows (CSOs), polluted stormwater, agricultural runoff, boating waste, and septic systems. Stormwater, which carries animal wastes from residential lawns and agricultural lands, is the principal source of pathogen contamination in the Peconic Bays system.[42] Pathogens in coastal waters pose risks to humans who eat contaminated shellfish or who recreate in beach waters. Gastroenteritis, hepatitis, and other diseases can result even from the incidental ingestion of pathogen-contaminated waters. For this reason, beaches and shellfish beds are closed or restricted when water monitoring indicates high levels of fecal coliform bacteria (an indicator of pathogen contamination) are present in coastal waters.

In the Peconic Bays, over 4,000 acres of the estuary's shellfish beds are closed or harvest-restricted because of excessive levels of fecal coliform bacteria.[43] Many of the impaired shellfish beds are situated in semi-enclosed embayments and near-shore areas. In addition to shellfish closures, the Bays are sometimes closed to recreational uses. The Suffolk County Health Department regularly tests the beaches along the Peconic Bays for the presence of bacteria and closes the beaches when State-established bacterial standards are exceeded.[44] After significant rainfalls, the County also posts bathing advisories to warn the public about impaired water quality.[45] During the summer of 1995, none of the beaches along the Peconic Bays system were closed due to bacterial contamination.[46]

Habitat Loss and Degradation

A 1988 survey of land uses in the Peconic Bays area indicated that 46 percent of the land was either vacant or serving agricultural purposes and available for development.[47] As both the year-round and seasonal populations of the Peconic Bays area expand, pressures to develop rural and vacant lands will mount, resulting in more pollution. Replacing natural lands with impervious surfaces, such as pavement and roofs, causes greater flows of stormwater carrying higher concentrations of nutrients, toxic metals, organic chemicals, and pathogens to discharge into the Bays.

Eelgrass, tidal wetlands, and freshwater wetlands will be affected by increased development in the watershed, putting further stresses on the valuable fish and shellfish resources of the estuary. Tidal wetlands and eelgrass beds provide important nursery and spawning grounds for commercial finfish and shellfish. The distribution of eelgrass beds within the Bays is already in serious decline due to the Brown Tide blooms.[48] The impact of greater nutrient inputs both from contaminated stormwater and groundwater underflow could cause nutrient-based algal blooms which destroy eelgrass beds.

Between 1976 and 1988, the Peconic Bays area only lost 21 acres of tidal wetlands and 26 acres of freshwater wetlands.[49] Avoiding losses of these important habitats is important to the communities of the East End. These wetlands provide countless benefits to coastal communities by reducing the impact of coastal storms, absorbing excess waters during heavy rains, filtering pollutants before they contaminate the Bays, serving as recreation sites, providing habitat for waterfowl, and performing other key functions.

Floatable Debris

Trash accumulated on estuarine beaches threatens the ecosystem and its wildlife inhabitants. The

VOL 12

3844

amount found in just two days was staggering — on September 17 and 18, 1994, volunteers cleared 102,758 pounds of marine debris from 543 miles of New York's beach areas. Of the total amount of marine debris collected, 59.4 percent was plastic, 13 percent was glass, 10.2 percent was metal, and 17.4 percent was from other materials.[9]

The Peconic Estuary Program

The Peconic Estuary Program (PEP) was formally accepted into the National Estuary Program on September 9, 1992 when it was officially designated as an estuary of "national significance" under the Clean Water Act. The Suffolk County Department of Health Services, Office of Ecology was established as the central program office to oversee the drafting of a Comprehensive Conservation and Management Plan (CCMP) for the Bays. Since the inception of the PEP in April, 1993, it has worked in cooperation with government agencies from federal, state, and local levels, technical experts, citizens, business interests, baymen, boaters, and civic groups. The PEP will be conducted during a four-year period rather than the five-year standard project period for other estuaries because of the work already performed by the Brown Tide Comprehensive Assessment and Management Program (BTCAMP). A draft of the CCMP is scheduled to be released during the summer of 1996 and the final plan is scheduled for completion in July, 1997.

The Peconic Estuary Program has developed an Early Action Plan, using the data gathered in the BTCAMP plan conducted by Suffolk County as its foundation. The Action Plan which was finalized in December, 1994, outlines recommendations for specific management actions that will be incorporated into the CCMP. One of the objectives of the Plan calls for a "no net increase of nitrogen" for the tidal Peconic River and Flanders Bay. In the eastern portions of the Estuary, a "no substantial degradation" policy has been established. The PEP also carried out other types of actions identified in the Plan, such as a program to plant bay scallops in Flanders Bay and to monitor and evaluate the repopulation process. To reduce coliform and nutrient loadings, the plan also called for the construction of a grass filter strip to control stormwater discharging into Gardiners Creek, and implementation of Open Marsh Water Management techniques at Long Beach in Southold.

The PEP is conducting a full range of other activities. For example, to address one of the Bays' most severe problems, the Brown Tide, the PEP is expanding and refining the water quality work of the BTCAMP. After the 1995 outbreak of Brown Tide, PEP organized a Brown Tide Summit attended by prominent algal experts. A result of this meeting was the formation of the Brown Tide Research and Management Initiative. Proposals to fund the Initiative have been sent to local, state, and federal governments and agencies. Suffolk County's monitoring program for Brown Tide outbreaks has expanded with the assistance of the NEP. Information gathered from over 30 locations and eight point sources is being used in a model to facilitate improvements in water quality in the main bays, peripheral creeks, and embayments. In addition, the PEP is adding an important natural resources component in an effort to preserve the Bays. The PEP is using Geographic Information Systems (GIS) technology to inventory and map wetlands, submerged aquatic vegetation, and hard clam beds. The data will be used to aid in integrating water quality and natural resource issues. Numerous other efforts are underway, including stormwater control projects at Southold and Shelter Island to limit nitrogen and fecal coliform pollution; the restoration of alewife runs along the Peconic River in Riverhead; and testing ultraviolet disinfection processes at the Shelter Island sewage treatment plant to replace chlorine.

The PEP has set forth an ambitious agenda for a four-year project. It will be a testament to the desire to protect the Bays if all of the stakeholders involved in the project are willing to take responsibility for ensuring that the plan is fully implemented. History has shown in some of the other NEPs that it may take substantially longer to reach agreement among all of the stakeholders on some of the more difficult

VOL 12

decisions. To date, however, there appears to be a high level of participation from both the environmental and business communities. There also seems to be a good mix of early action projects and steps toward longer term planning.

National Coastal Caucus

Save the Peconic Bays, Inc. is a non-profit organization dedicated to the protection, wise management and enjoyment of Long Island's coastal waters with special concern for the Peconic Bay Estuary. Founded in 1988 to enlist support to address the Peconic Estuary's problems, including the Brown Tide, Save the Bays is an educational organization working to raise public awareness of the problems and possible solutions concerning the system's waters. Save the Peconic Bays was the umbrella organization that spearheaded the effort to include the Peconic Bays into the National Estuary Program.

Members, board and staff of Save the Peconic Bays (SPB) have served in numerous capacities in the development of the CCMP and the implementation of the Action Plan. SPB has been involved in the NEP since its inception. In fact, between 1988 and 1992 the organization had two major goals: 1) to raise public awareness regarding the Bays' problems and to develop solutions to those problems; and 2) to include the Peconic/Gardiners system in the NEP. Today, the President of Save the Bays serves as the PEP Public Participation Coordinator, and the organization has representation on the Citizens Advisory Committee.

With help from private citizens, progress has been made on two priority natural resource issues: protecting scallops and restoring eelgrass beds. Major seeding and planting efforts are already underway. As a result of the reseeding efforts and wetlands restoration projects, the bay scallop returned to the Bays in 1994, yielding the best harvest since the Brown Tide blooms of the 1980s.

Puget Sound
in Washington

Puget Sound, a fjord-like estuary in Washington State, adjoining the inland marine waters of British Columbia, is home to orca whales, salmon runs, an internationally-significant shellfish industry, and 3.5 million people. The Sound's water quality is threatened by toxic chemicals accumulating in the sediments and poisoning the food chain; by polluted runoff that has closed nearly half of the commercial shellfish harvest areas; by sprawling growth that damages wetlands, streams and other habitat; and by the ever-present risk of oil spills. A landmark estuary management plan, developed in the 1980's by the Puget Sound Water Quality Authority, is at risk of never coming to fruition: in 199[illegible], the Legislature failed to reauthorize the Authority, cut back on water quality funding, and tried to destroy the State's oil spill prevention program.

—Kathy Fletcher, Executive Director
People for Puget Sound

Portrait of the Sound

The Puget Sound Water Quality Authority has worked since 1985 to protect and restore the water quality and habitat of Puget Sound and is examining

Puget Sound

Area of surface water	931 square miles
Area of watershed	16,000 square miles
Population	3.5 million people
Average depth	450 feet
Values	• Tourism generates over $4 billion • Fisheries generate $175 million* • Home to four National Wildlife Refuges
Threats	• Toxic Pollution • Oil spills • Pathogen contamination • Habitat loss • Land use and population growth • Floatable debris
CCMP status	Approved in 1991

Designated as a "Nationally Significant" Estuary in 1988.

the impact that the greater watershed area has on the estuarine system. Puget Sound is a protected inland sea in northwestern Washington. The Sound is a deep estuary which was formed by the retreat of glaciers 13,000 years ago. Averaging 450 feet deep, the Sound is deeper in the northern end than in the southern portion. At its deepest point, Puget Sound measures over 930 feet deep.[1] The water surface area of the Sound is 931 square miles.[2]

Puget Sound's watershed area is 16,000 square miles,[3] of which only 20 percent is actually water.[4] The eastern borders of the watershed are the Cascade Mountains and the western borders are the Olympic Mountains. Waters drain from the crests of these mountain ranges into the Sound. The watershed's population exceeds 3.5 million people — more than two-thirds of the entire State's population.[5] Over 120 cities and counties, as well as 16 tribes, are located within the Puget Sound watershed area.[6] Some of the largest cities in the watershed are Seattle, Tacoma, Olympia, and Bellingham. A similar mosaic of people and jurisdictions exists on the Canadian side of the shared marine waters of the Sound and Straits, where Vancouver and Victoria are the largest cities.

Freshwater draining from land intermixes with saltwater from oceans to create productive estuaries such as Puget Sound. Saltwater from the Pacific Ocean enters the Sound through the Strait of Juan de Fuca. Freshwater is delivered to the estuary by over 10,000 streams and rivers, groundwater underflow, and direct precipitation.[7] Approximately 39 million acre-feet of freshwater flows from the rivers in the watershed into Puget Sound each year.[8] Ten river systems — the Nooksack, Skagit, Snohomish, Stillaguamish, Cedar/Lake Washington Canal, Green/Duwamish, Puyallup, Nisqually, Skokomish, and Elwha Rivers — account for over 85 percent of the freshwater flowing into the Sound.[9]

The many islands, inlets, and narrow passages in the Sound actually inhibit circulation. As a result, it sometimes takes up to 300 days to replace or "flush" water in some parts of the Sound, making the estuary susceptible to the retention of harmful pollutants that settle out as sediments on the floor of Puget Sound.[10]

Predominant habitat types in the Puget Sound region include open water, islands, beaches, bluffs, deltas, mudflats, and wetlands. The shoreline of the greater Sound area stretches for over 2,250 miles.[11]

Values of the Sound

The global reputation of the Pacific Northwest is strongly tied to its legendary waters. Whether it's the Olympic Coast, the salmon runs, or Puget Sound itself, local residents take pride in their waters. Tourism and water-based recreational activities around the Sound provide substantial economic benefits for local communities. The estuary's fisheries and diverse wildlife are other important qualities which enhance the value of the Sound.

Recreation/Tourism

Puget Sound receives over three million visitors each year, many of whom come purely to enjoy the beautiful coastlines and participate in numerous recreational activities.[12] Tourism generates up to $4 billion and supports over 60,000 jobs in the Puget Sound region every year.[13]

Recreational attractions are plentiful in and along the Sound. Dozens of Washington State parks, recreational areas, natural areas, and wildlife refuges border the shore of the Sound, providing opportunities to camp, canoe, kayak, fish, sail, bird watch, and swim. The Puget Sound region boasts the highest per capita rate of boat ownership in the nation, with a total of over 300,000 pleasure boats.[14]

Recreational fishing is an especially popular activity for the residents and visitors of Washington. In 1991, freshwater and saltwater sport fishing generated approximately $1.9 billion in economic output and supported over 27,000 jobs.[15] In the same year, approximately 504,000 saltwater anglers fished a total of 3.5 million days off the Washington coast.[16] Puget Sound provides valuable recreational fishing areas for the State's sport fishers and serves as important nursery, spawning, and feeding grounds for many prized sport fish that could be caught outside of the Sound. Recreational harvesting of shellfish is also prevalent in the Sound. Recreational clammers harvest more than 3.3 million pounds of clams each year, generating over $11 million for the local economy.[17]

Fisheries/Seafood

In 1994, the combined market value of commercial finfish and shellfish landings in the Pacific region (excluding Alaska) was approximately $401 million. Many of the commercially valuable species found in the Pacific region depend upon the health of Puget Sound for survival. During the same year, the State of Washington's commercial finfish and shellfish landings totaled approximately 528 million pounds, valued at $175 million.[18]

In 1990, the most recent year for which Sound-specific data are available, the total value of the Sound's commercial fisheries was $73.5 million.[19] Although the 1990 harvest was substantial, its economic value was significantly lower than the 1987 harvest which was approximately $125 million.[20] In fact, commercial fishing harvests are at their lowest levels in 55 years. The populations of many of the Sound's fish are declining, and as a result, officials are closing or restricting many harvests. For instance, different types of harvest restrictions are in place for Pacific cod, Pacific herring, Pacific hake, pollack, lingcod, rockfish, English sole, and salmon.[21]

Water pollution, loss of habitat, overharvesting, and poor forest practices threaten shellfish, salmon and other finfish. The depleted salmon runs of the region are of special concern. It is estimated that some salmon runs have been reduced by as much as 90 percent.[22] Nine Puget Sound salmon stocks are now extinct.[23] In 1994, the State of Washington placed unprecedented emergency restrictions on the commercial and recreational salmon harvests in Puget Sound. Salmon are more than a prized commercial and recreational fish — they are a symbol of the bountiful and robust heritage of the Northwest. The severe decline of wild salmon populations in the Pacific Northwest has raised alarms about the potentially disastrous state of the region's ecosystems.

Oysters, clams, and mussels are among the principal shellfish found in the Sound. Over 200,000 oysters, clams and mussels are harvested each day off Whidbey Island alone.[24] Commercial shellfish harvesting in Puget Sound was worth $42 million in 1993, according to the Pacific Coast Oyster Growers Association.[25] Harvests in the Sound could be much greater, but failing septic systems, agricultural runoff, and other pollution problems have closed 40 percent of the commercial harvest areas. These restrictions cost an estimated $3 million in lost revenues each year.[26]

Wildlife

Puget Sound is also appreciated for its diversity of wildlife, including over 220 species of fish, 26 species of marine mammals, and 100 species of seabirds, shorebirds, and waterfowl.[27] Four National Wildlife Refuges (NWR) are located in the greater Puget Sound area. Dungeness Spit NWR, in the Strait of Juan de Fuca, is a coastal spit with marshes and lagoons which is frequented by loons, cormorants, grebes, bald eagles, ducks, and black brant. The Nisqually NWR protects part of the last unspoiled estuary in the Sound, the delta of the Nisqually River. The delta's mudflats, freshwater wetlands and salt marshes support migrating shorebirds, herons, beavers, otters, and black-tailed deer. In the San Juan Islands, the Jones Island National Wildlife and Migratory Bird Refuge and several units of the San Juan Islands NWR protect critical nesting habitat for puffins, pelagic cormorants, and auklets.[28]

Estuaries provide important habitat for a number of endangered, threatened, and rare species. Of Washington State's 22 federally protected, endangered and threatened species, the endangered American peregrine falcon and sockeye salmon, and the threatened bald eagle, stellar sea lion and Aleutian Canada goose rely on the State's estuarine wetlands for survival.[29] The San Juan Islands, in the northern part of the Sound, support one of the densest nesting populations of bald eagles in the lower 48 states. Between 1980 and 1994, the bald eagle population in the Sound increased by over 400 percent; however, it is feared that continued habitat degradation may result in a gradual decline in their numbers.[30] The imperiled marbled murrelet also lives in the Puget Sound region. The survival of this seabird is threatened by the loss of old-growth forest habitat, saltwater oil spills, and entanglement in fishing nets.

Some of the marine mammals that can be observed in the Sound include the harbor seal, orca

VOL 12
385/1

(killer whale), California sea lion, Stellar sea lion, and Dall's porpoise.[31] Harbor porpoises, once abundant in the area, are rarely observed in the southern and central portions of the Sound today.[32] The unique and fragile character of Puget Sound has led to proposals to establish a national marine sanctuary in the area of the northern Sound and Strait of Juan de Fuca.[33] The planning process for a sanctuary is currently underway.

Threats to the Sound

Rapid urbanization and development in the Puget Sound region have placed many of the estuary's resources in jeopardy. The loss of wetlands and salt marshes, the depletion of salmon populations, and the closure of shellfish harvest areas are a few of the more striking examples that have resulted from decades of unimpeded expansion. As the area's population continues to grow, the estuary system will experience even more environmental stresses. The Puget Sound Water Quality Authority has identified toxic contamination, pathogen contamination, habitat loss, diminishing living resources, and conventional water quality impairment as the priority environmental problems of Puget Sound.

Toxic Pollution

Toxic contamination is a growing concern in Puget Sound. Heavy metals and organic chemicals enter Puget Sound through industrial and municipal discharges, urban stormwater, atmospheric deposition, and agricultural land runoff. Particles of toxic metals and chemicals eventually settle out in the sediments of the Sound and its tributaries. Not only do many of these contaminants persist in the estuarine environment, but many also "bioaccumulate" through the food chain. Crabs, clams, oysters, bottomfish, and even gray whales depend on sediments of the Sound for food and habitat.[34] Bottom-dwelling organisms, fish, birds, and harbor seals in the Puget Sound region have exhibited reproductive and developmental problems associated with toxic contamination. Near urban areas of the Sound, fishing for bottom-dwelling species such as flounder and sole, is discouraged due to human health concerns about contaminated seafood.

Toxic pollution causes developmental, reproductive, and immune system problems in aquatic species and birds. About 40 percent of the English sole in Duwamish waterway and Eagle Harbor show signs of reproductive failure.[35] Other bottomfish in urban bays of the Sound have a higher incidence of cancerous liver tumors than fish in less urbanized areas of the Sound.[36] Recent studies have shown that juvenile chinook salmon in the Duwamish waterway exhibit a number of adverse effects due to PCBs and other toxins. Continual uptake of these chemicals during migration has altered immune system functions and reduced survival rates of the salmon.[37]

As a result of the high levels of toxic contamination, a large number of urbanized and industrial bays in the Sound contain "toxic hot spots," where toxic chemical concentrations in sediments far exceed federal and State standards. Special areas of concern are Sinclair and Dyes Inlets for consistently exceeding allowable State levels for mercury, and Elliott Bay for its high level of polycyclic aromatic hydrocarbons (PAHs).[38] Six Superfund sites are located in five urbanized portions of the Sound — Commencement Bay, Eagle Harbor, Elliott Bay, Sinclair Inlet, and Dyes Inlet.[39]

Oil Spills

Oil spills continue to threaten the Sound and its fish, bird, and marine mammal inhabitants. The 1991 spill of 100,000 gallons of diesel fuel, and the oils from the sunken fish processing vessel, the *Tenyo Maru*, cost nearly $9 million to clean up. Damages to natural resources cost from $5-13 million.[40] Although less spectacular and less publicized, the cumulative impact of countless smaller unreported spills may be even greater. Approximately two million gallons of used oil are dumped illegally down storm drains or improperly disposed of within the watershed each year.[41]

Pathogen Contamination

Pathogens are disease-causing microorganisms found in human and animal wastes which enter Puget Sound through improperly sited or malfunctioning septic systems, runoff from agricultural and urban lands, polluted urban stormwater, sewage treatment plant discharges, combined sewer overflows (CSOs) and boating wastes. One-third of the residents in the Puget Sound watershed use septic systems for waste disposal, up to 12 percent of these systems fail each year.[42] In some areas of the Sound, failure rates are as high as 40 percent.[43] About 28 major sewage treatment plant dischargers and 71 minor municipal dischargers dump wastewater into waterbodies that empty into the Sound.[44] Other wastes make their way to the Sound, including about 20 million gallons of minimally-treated wastewater that is dumped into the Strait of Juan de Fuca each day from Victoria, British Columbia.[45]

Pathogens in coastal waters pose risks to humans who eat contaminated shellfish or accidentally ingest contaminated waters while swimming. Gastroenteritis, hepatitis, and other diseases can result from this kind of contact with pathogens. For this reason, beaches and shellfish beds are closed or restricted when water monitoring indicates high levels of fecal coliform bacteria (an indicator of pathogen contamination) are present in coastal waters.

Pathogen contamination is the principal cause of shellfish bed closures in the Sound. Over 40 percent of the Sound's commercial shellfish beds are currently closed to harvest.[46] Since 1981, almost 41,000 acres of commercial shellfish beds have been closed in Puget Sound.[47] Increasing numbers of restrictions occur in portions of the estuary bordering rural areas. In fact, agricultural runoff was largely responsible for two of the most extensive shellfish bed closures in the past eight years.[48] In addition, four of the ten major rivers draining into the Sound — the Sammamish, Puyallup, Nooksack, and Green rivers — have levels of fecal coliform bacteria which exceed State standards. State monitoring indicates that pathogen contamination is a severe and chronic problem for the Sammamish and Puyallup rivers.[49]

In certain areas of the Sound, shellfish beds are being reopened due to improvements in sewage treatment plant operations. Since 1989, about 5,500 acres have been upgraded; but overall, pathogen contamination remains a serious problem for the Sound.[50] The State monitors and classifies approximately 70 recreational shellfish beaches. In 1994, 37 of these beaches were closed.[51] However, the State of Washington does not regularly test its bay and ocean beaches to ensure safe swimming waters.

Habitat Loss

The eelgrass beds, kelp beds, mudflats, salt marshes and beaches of Puget Sound provide important habitats for wildlife and perform a number of beneficial functions for coastal communities. As recreational and commercial development accelerates along the Puget Sound shore, these habitats become increasingly stressed.

According to a marine science advisory board established in 1994 by British Columbia and Washington, stemming the loss of these nearshore habitats is the single greatest priority to protect the future health of Puget Sound. Although minimal data exist on the types and amounts of nearshore habitats present in the area, studies do indicate that vast areas of valuable wetlands habitat in the Sound region have disappeared. It is estimated that 73 percent of the original salt marshes of the Sound have been destroyed, as have virtually all of the river delta marshes in urbanized areas.[52] Agricultural diking and draining are responsible for the reduction of up to 95 percent of the wetlands in the Skagit Valley.[53]

The loss of coastal wetlands has an adverse impact on the wildlife of the estuary. Shellfish, salmon, and other aquatic animals of commercial and recreational value in Puget Sound depend on wetlands for food, spawning and nursery habitat.[54] Chum and chinook salmon are heavily reliant on estuarine wetlands. In addition, juvenile coho, pink, and sockeye salmon use estuarine wetlands during at least one stage of their life cycles.[55] Habitat alterations and losses have been linked to up to 30 of the region's declining salmon stocks. In addition to supporting aquatic and terrestrial species, coastal wetlands filter pollutants carried in stormwater before they reach the Sound, absorb excess flood waters, recharge groundwater supplies, and protect shorelines from erosion. Wetlands also support a number of recreational activities.

There are many causes of habitat destruction. Dredging to build harbors and ports has destroyed great areas of eelgrass, essential habitat for numerous species, including herring, salmon, and Dungeness

VOL 12

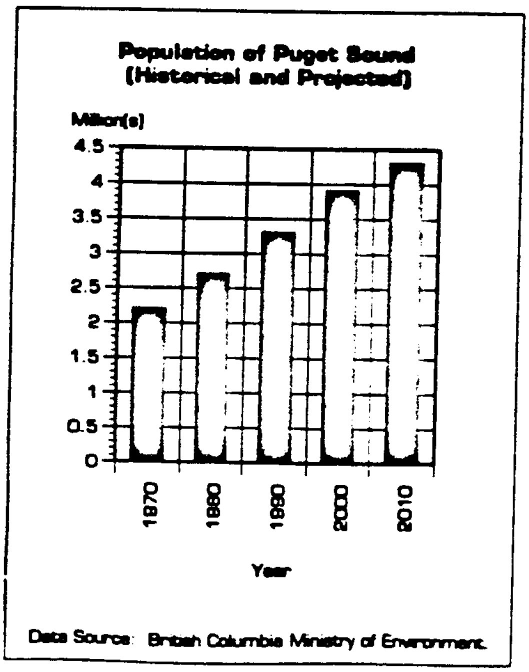
3853

R0037161

crab. Activities in upland areas are also leading to habitat loss, as forestry, agriculture, and development permanently alter the landscape. Logging and land clearing increase erosion and sedimentation, destroying in-stream salmon spawning habitat. Dams reduce flows and alter sedimentation patterns in river deltas, destroying coastal mud flat habitat. Buildings, roads, and other impervious surfaces replace natural lands in the watershed, resulting in increased stormwater flows that scour rivers and coastal areas.

Land Use and Population Growth

The population of the Puget Sound region is expected to increase by one-third between 1994 and 2010, growing from 3.4 million to 4.4 million people in 16 years.[56] The population boom is expected to have severely negative consequences for the health of the Sound. Land use projections forecast a 62 percent increase in urban development by the year 2000.[57] Unless carefully managed, this intensified land use will mean the further loss of wildlife habitat and severe increases in polluted runoff. Currently, about 900 million gallons of wastewater are discharged by municipal and industrial treatment plants each day.[58] As demands on the Sound's treatment plants intensify with a growing population, the estuary will be afflicted by more harmful contaminants.



Data Source: British Columbia Ministry of Environment.

Floatable Debris

Trash accumulated on estuarine beaches threatens the ecosystem and its wildlife inhabitants. The amount collected in just two days was staggering — on September 17 and 18, 1994, volunteers cleared 34,260 pounds of marine debris from 63 miles of beaches in Washington State. Of the total amount of marine debris collected, 67.3 percent was plastic, 12.4 percent was paper, 9 percent was metal, and 11.3 percent was from other materials.[59]

The Puget Sound Water Quality Authority

In 1985, prior to the establishment of the National Estuary Program (NEP), the State of Washington created the Puget Sound Water Quality Authority to develop a comprehensive plan for water quality protection in the Sound. First published in 1987, this plan, to be implemented by State and local governments, was the first comprehensive estuary plan in the nation. In 1988, the Environmental Protection Agency designated Puget Sound as an estuary of "national significance" and officially brought it into the NEP. In 1991, the Water Quality Authority's plan was approved as the Comprehensive Conservation and Management Plan (CCMP) for the Puget Sound Estuary Program.[60]

As one of the original NEPs and the first to complete its CCMP, Puget Sound has been considered a national and international model for dealing with complex estuary management challenges. Yet, since the approval of the CCMP, implementation of the different aspects of the Plan has been carried out with varying degrees of success.

For instance, although the State has developed sediment quality standards, some places in the Sound still have concentrations of toxic contaminants elevated 100 times or more over the levels in the cleanest rural bays. High concentrations of toxic contaminants in sediments have been associated with adverse biological effects in fish, including fin erosion, liver tumors and reproductive failures. Although some progress has been made toward limiting toxic pollutants, significant problems remain with regard to controlling the discharge of toxic substances. Without a tremendous commitment on the part of the State and federal governments in the form of financial assistance and pollution prevention, the contaminated sediment problem will remain largely unaddressed.

Participation by a full range of stakeholders, including cities, counties, tribes, storm water management utilities, and agricultural interests, has proven successful in the development and implementation of "watershed action plans." By December 1994, 101 of the more than 120 jurisdictions in the Sound had begun to implement stormwater control measures.[41] A 1995 survey by the Department of Ecology and the Authority show some local and nearshore improvements in water quality and habitat. Seventy-two percent of the jurisdictions have made progress in implementing stormwater programs and 20 percent have requested additional time to develop programs. In addition, nine cities are implementing programs to eliminate combined sewer overflows in order to reduce pathogenic pollution.

However, many of the CCMP's recommendations have gone unfunded and unrealized, including many of those related to habitat protection and other high priority programs. Implementation of the CCMP has also been hampered by political obstacles and the lack of political will to achieve its objectives. The political influence over the project could not have been more apparent than in the 1995 legislative session in Washington State. The Legislature declined to reauthorize the Puget Sound Water Quality Authority, thereby requiring that the Authority be dismantled on June 30, 1996. Because this result in 1995 flew in the face of public opinion, the 1996 Legislature enacted a "compromise" to avoid the criticism that it had abandoned Puget Sound. The Puget Sound program will be reconstituted as a new agency housed in the Governor's office and will be referred to as the Puget Sound Action Team.

The Authority which used to be governed by a board of 12 citizens appointed by the Governor, will be replaced by a board consisting of government agency representatives, advised by a citizen council. Citizens have clearly lost control in this turn of events. Once in a position to serve as a watchdog over government bureaucrats, now they have become powerless. While the staff of the Authority will carry on in this new structure, the very agencies that have resisted carrying out the Puget Sound Plan are now in charge of deciding which aspects of the Plan to fund, to delay, or to drop.

National Coastal Caucus

People for Puget Sound is a non-profit citizens group launched in 1991 to educate and involve people in protecting and restoring the land and waters of Puget Sound and the Northwest Straits. It seeks to eliminate contamination of our waters, to halt the destruction of natural habitats, and to sustain the Sound and Straits as a healthy source of people's livelihood, enjoyment and renewal. It plans to accomplish these goals by educating and involving communities in shared responsibility, by holding itself and its public officials accountable for carrying out commitments and enforcing laws and regulations, and by encouraging cooperation among diverse groups and interests throughout the region.

People for Puget Sound has served as a citizen watchdog over the agencies managing the Sound. Holding them accountable for implementation of the CCMP, the grassroots organization also lobbies the State Legislature for funding in order to achieve implementation of actions identified in the CCMP. Working together with local and regional groups, People for Puget Sound ensured that the Jobs and the Environment program was adequately funded in order to create jobs, such as restoring salmon stream habitats, for displaced timber workers.

People for Puget Sound has a very active educational program for children, an exciting and

VOL 12

unique Adopt-a-Politician program to involve citizens in legislative activities and to ensure that they stay engaged, and a habitat assessment and restoration program. People for Puget Sound is also working to establish the proposed Northwest Straits Marine Sanctuary.

San Francisco Estuary
in California

San Francisco Bay is perhaps the most highly modified major estuary in the world. If someone had sat down in 1849 and drawn up a plan to damage the Estuary as much as possible, s/he could hardly have done a better job. But the Bay area public understands the importance of a healthy Bay to the future of the region. In the next decade, we have a major opportunity to restore the health and biological diversity of the largest estuary on the West Coast.

—Barry Nelson, Executive Director
Save San Francisco Bay Association

Portrait of the Estuary

The San Francisco Estuary Program is examining the water quality and habitat problems of the Estuary, and the impact that the greater watershed area has on the system. The San Francisco Estuary is the largest estuary on the western seaboard of the Americas. It encompasses about 1,600 square miles of surface waters,[1] including the Sacramento-San Joaquin Delta and four embayments — the San Francisco, Suisun, and San Pablo Bays and the Carquinez Strait.

The watershed area covers 60,000 square miles —

San Francisco Estuary

Area of surface water	1,600 square miles
Area of watershed	60,000 square miles
Average depth	15 to 43 feet
Population	9.9 million people
Values	• Fisheries generate $159 million* • Tourists spend $3.9 billion • 20 million people rely on the Estuary system for drinking water
Threats	• Population growth and development • Freshwater diversion • Habitat loss and degradation • Pollutant loadings • Dredging
CCMP status	Approved in 1993

Designated as a "Nationally Significant" Estuary in 1987.

40 percent of the total area of California.[2] It stretches across 12 counties — Alameda, Contra Costa, Marin, Napa, Sacramento, San Francisco, San Joaquin, San Mateo, Santa Clara, Solano, Sonoma, and Yolo counties. It includes the cities of San Francisco, Oakland, Sacramento, Stockton, and San Jose, as well as the rich agricultural lands of the Central Valley. Approximately 9.9 million persons live within the watershed;[3] about 60 percent of this population resides in the San Francisco metropolitan area.[4]

The average depth of the San Francisco Estuary is 43 feet in the Central Bay and between 15 and 17 feet in the northern and southern portions of the Estuary. The Estuary's deepest point, located under the Golden Gate Bridge, is 360 feet.[5] The Bay-Delta system has a huge salinity range, from less than one part per thousand (ppt) in the Delta to 30 ppt in the Central Bay (the salinity of seawater is 35 ppt).[6] Consequently, different segments of the Estuary vary significantly in terms of the estuarine life they support.

The Sacramento-San Joaquin Delta is a triangular-shaped formation of land and water built by sediments at the confluence of the Sacramento and the San Joaquin Rivers. The Delta covers 1,150 square miles.[7] The Delta waters flow into the Suisun Bay, linking the Delta to the San Francisco Bay system. The Delta contains 57 low-lying islands and more than 700 miles of channels and sloughs, which feed the Estuary with freshwater from the Sacramento and San Joaquin Rivers.[8] Ninety percent of the freshwater entering the Bay-Delta drains from California's Central Valley; the remaining 10 percent originates from smaller rivers and streams flowing directly into San Francisco Bay.[9]

A diversity of habitats are found in the San Francisco Estuary and its watershed. These include open water habitats, intertidal mudflats, rocky shores, salt ponds, salt marshes, brackish marshes, freshwater marshes, riparian forests, and vernal pools.[10] Vernal pools are unique freshwater habitats which form when rain water pools in shallow depressions. They are home to more than 200 plant species, 91 percent of which are native only to California.[11]

Values of the Estuary

The San Francisco Estuary enriches the lives of millions of residents and tourists. Regional and State economies depend heavily upon the Estuary's aquatic resources for commercial fishing, boating, recreation, and tourism. Not only are the Estuary and its tributaries important for job creation, they also support drinking water supplies and agricultural production. Twenty million people, two-thirds of California's total population, rely on the Estuary system as a source of drinking water.[12] In addition, farmers use the area's freshwater to irrigate 4.5 million acres of agricultural land.[13] Finally, the San Francisco Estuary and its watershed area are invaluable to the many plant and animal species which have adapted to the estuarine ecosystem.

Recreation/Tourism

Sport fishing, bird watching, boating, swimming, hiking, and hunting are a few activities that attract Californians and tourists to the San Francisco Estuary. In 1990, visitors to the San Francisco area spent $3.9 billion on tourist-related activities, sustaining 66,000 jobs.[14] The region supports 290 shoreline parks, 200 duck clubs, 300 marinas, and about 500,000 recreational boaters.[15] Annual revenues generated by marina operations alone are estimated at $167 million.[16]

Recreational fishing in California, much of which is based in the San Francisco Estuary, provides a substantial revenue base for both State and local economies. In 1991, recreational fishing in California generated approximately $3.2 billion in economic output and employed nearly 40,000 people.[17] The average annual number of user-days devoted to recreational fishing in the San Francisco area is 4.4 million.[18] Recreational fish which are caught in the Estuary include chinook salmon, halibut, striped bass, starry flounder, sturgeon, brown rockfish, and surf perch. Other species which are caught in the rivers and streams of the Delta include American shad, steelhead trout, and bluegill.

Fisheries/Seafood

The San Francisco Estuary has historically provided valuable habitat for commercial fisheries in the Pacific region of the United States. In 1994, the combined market value of commercial finfish and

VOL 12

3860

R0037168

shellfish landings in the Pacific region (excluding Alaska) totaled approximately $401 million.[19] Many of the commercially valuable species in the State also depend upon the health of the San Francisco Estuary for survival. In 1994, California's commercial finfish and shellfish landings totaled approximately 343 million pounds, valued at $159 million.[20]

The San Francisco Estuary supports over 130 fish species, of which Pacific herring holds the only great commercial value.[21] Chinook salmon, caught commercially in the ocean waters off northern California, used to provide a significant revenue base for the region. However, landings have dropped from 825,000 pounds in 1988, to 350,000 pounds in 1990.[22] Habitat modifications along the rivers of the watershed have contributed to the decline of salmon in the Estuary and its tributaries. Today, only 300 miles of the original 6,000 miles of in-stream habitat in the Central Valley are able to support spawning salmon.[23]

Most of the shellfish found in the San Francisco Estuary were introduced to the Bay and have adapted over time to the Estuary. Examples of these species include the soft shell clam, Japanese littleneck clam and the eastern oyster.[24] In the late 1800s, for example, the commercial oyster harvest totaled approximately 15 million pounds annually; for the past several years, however, there has been no oyster harvest from the Estuary due to water quality and habitat declines.[25] Other commercially valuable shellfish in the Estuary include the Bay mussel and the Dungeness crab.

Wildlife

The Estuary provides important habitat for millions of migrating and resident birds, fish, and other wildlife. Approximately 255 bird species, 81 mammal species, 30 reptile species, and 14 amphibian species live in the watershed area.[26] Many of these species depend on the open water and wetland habitats of the Estuary for spawning, nursing, and feeding grounds.

Waterfowl and shorebirds can be found in huge numbers in the San Francisco Estuary. Over 70 percent of the migratory shorebirds along the Pacific Flyway use the San Francisco Estuary as resting or wintering habitat.[27] However, since 1900, wintering bird populations have decreased by approximately 75 percent due to habitat losses and excessive hunting.[28] During certain seasons the Estuary provides essential habitat for over one million shorebirds.[29] About 34 species of shorebirds, such as stilts, plovers, avocets, and sandpipers, feed on insects and crustaceans in the tidal mudflats, marshes and shorelines of the Estuary.

Twenty-two wildlife species in the watershed are listed by federal or State agencies as threatened or endangered.[30] Most of these species depend on the wetlands of the Estuary and Delta for critical habitat. The federally endangered species living in the Estuary area include the bald eagle, California clapper rail, California least tern, salt marsh harvest mouse, the San Joaquin kit fox, San Francisco garter snake, Lange's metalmark butterfly, mission blue butterfly, and the Bruno elfin butterfly.[31] In addition, the Sacramento River winter chinook salmon run is threatened and the southern sea otter can no longer be found in the Estuary.

Threats to the Estuary

The daily activities of nearly 10 million people within the San Francisco Estuary watershed take a great toll on the Estuary's water quality and natural resources. Polluted urban stormwater, industrial discharges, municipal discharges, agricultural runoff, and habitat losses are threatening the integrity of this rich ecosystem.

The San Francisco Estuary Project identifies the primary threats to the Estuary system as land use/ population growth; freshwater diversion; and declining biological resources due to habitat loss, increased pollution, and dredging activities.[32] Another threat is the marine debris within coastal areas of the Bay and Delta which affects human activities and the health of wildlife populations.

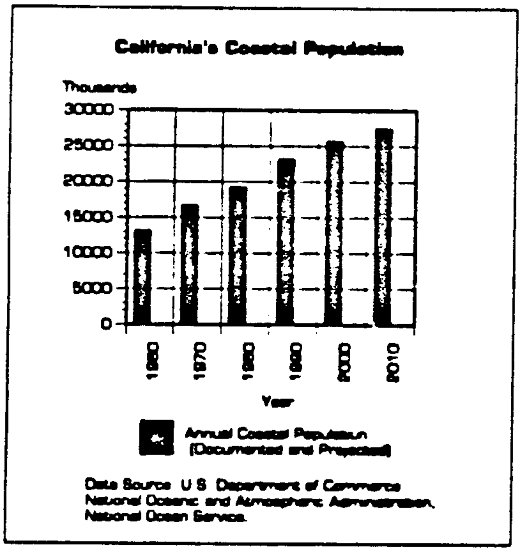
Population Growth and Development

Almost one-third of California's population lives in the watershed of the San Francisco Estuary. Population projections show that by the year 2005, an estimated 12 million people will live in the Central Valley and San Francisco Bay counties.[33]

As more people move to the watershed area of the San Francisco Estuary, development within the coastal area continues to increase. To date, approximately 30 percent of the land in the nine counties

VOL 12

3861



surrounding the San Francisco Estuary is urbanized.[34] Urbanization jeopardizes the salt marshes and freshwater wetlands which absorb stormwater, filter contaminants, and provide necessary spawning and nursery habitat for many of the fish and shellfish living in the Estuary. Replacing the natural soils, vegetation, and wetlands with impervious surfaces, such as pavement and roofs, allows greater concentrations of pollutants to enter the Estuary.

Freshwater Diversion

Over time, a number of water projects have occurred in the watershed, including the construction of flood control levees, water reservoirs, and dams, in order to provide freshwater for municipalities and agricultural producers. These projects divert approximately 16 million acre-feet of freshwater annually. In some years, this corresponds to a 50 percent reduction in the volume of freshwater reaching the Estuary.[35]

The two largest users of freshwater, the federal Central Valley Project and the State Water Project, extract 10 million acre-feet of water annually. Eighty-five percent of the water is diverted for agricultural uses and 15 percent is diverted for municipal, industrial and other uses, such as drinking water.[36] These water projects contribute to the economic growth of the region; but they also impair the estuarine ecosystem by increasing water salinity, changing water circulation patterns, altering habitat types, and affecting the survival rates of larval fish. During periods of drought in California, the negative environmental effects associated with water diversions are intensified.

Increased salinity levels in the Estuary reduce the overall biological productivity of the aquatic environment.[37] As less freshwater is delivered to the Estuary, saltwater gradually intrudes into historical freshwater habitats. Saltwater intrusion threatens the drinking water supply[38] and impedes the flushing capacity of the Estuary, making the retention of pollutants more likely.[39] Due to reduced levels of freshwater flow, zooplankton in the northern portions of the Estuary have experienced substantial declines.[40] Striped bass and salmon populations have also experienced declines, partially due to altered freshwater flows and water diversions which often kill fish eggs and juveniles.[41]

Despite these and other concerns, additional water diversion projects are being proposed that are expected to divert an additional 1.1 million acre-feet of water per year.[42] Water conservation and management measures need to be implemented and enforced to ensure the future health of the Estuary and its economic contributions to the region.

Habitat Loss and Degradation

Of the approximately 550,000 acres of original tidal wetlands in the San Francisco Estuary, only 44,371 exist today — a 92 percent loss.[43] Urban development, dredging activities, and hydrological changes in the tributaries are the chief causes of the destruction of Bay area wetlands. The ability of the aquatic ecosystem to support thriving wildlife and fish populations is severely reduced by habitat losses. The decline of wildlife populations throughout the Estuary demonstrates the impact of wetlands losses. Of the 32 species listed as in decline, 23 are wetlands-dependent species.[44]

Riverine habitat that has been altered for dam and levee construction is contributing to declines among anadromous fish in the watershed. For instance, the number of chinook salmon returning to spawn in tributaries is approximately 70 percent lower than historic levels.[45] In fact, the present-day

VOL 12

3863

commercial salmon fishery of the northern California coast relies on fish hatcheries for most of its salmon harvests.[46] However, these fish are usually genetically weaker and less able than wild fish to withstand environmental stresses, such as disease and temperature changes. The loss of riverine habitat and wetlands is also largely responsible for declining populations of striped bass, Delta smelt, longfin smelt, Sacramento splittail and California Bay shrimp.[47] Currently, the striped bass population is at its lowest level since the turn of the century.[48]

Pollutant Loadings

Nutrients, toxic contaminants, pathogens, and heavy metals enter the Estuary through polluted urban stormwater, industrial discharges, municipal discharges, agricultural runoff, and atmospheric deposition. The effects of these pollutants range from shellfish bed closures to health defects among the area's wildlife.

Polluted runoff and stormwater are the major carriers of pollutants to the Estuary and its tributaries. During rain events, stormwater delivers more contaminants to the Estuary than municipal and industrial discharges combined. It is estimated that stormwater carries 20 times more lead than point sources, as well as significant amounts of copper, nitrogen, phosphorus, animal waste, oil and grease residues.[49]

Pesticides from agricultural lands in the Central Valley and polychlorinated biphenyls (PCBs) are harming populations of mussels, clams, herons, and starry flounders in the Estuary.[50] Tissues of clams, mussels, and several species of fish and birds, especially those found near harbors and industrial waterways, have exceeded the State Maximum Allowable Residue Levels for DDT, PCB, and other heavy metals.[51]

In 1990, there were over 175 industrial point sources and over 85 municipal wastewater treatment plants discharging into the San Francisco, San Pablo, and Suisun Bays.[52] In 1992, the average volume of wastewater discharged in estuarine waters from chemical, metal finishing, oil refining, paper and other industries was 81 million gallons per day. In the same year, approximately 750 million gallons of wastewater from publicly-owned treatment plants flowed into the Bay and Delta each day.[53]

The heavy metals of greatest concern in the Estuary are arsenic, cadmium, chromium, copper, lead, mercury, nickel, selenium, silver, tin, and zinc.[54] Unusually high levels of toxic contaminants have been found in some fish and shellfish, especially striped bass and mussels. In 1986, California's Fish and Game Service initiated studies which revealed levels of selenium high enough to kill and deform waterfowl in San Pablo Bay and Suisun Bay.[55] In addition, levels of copper, lead, mercury, and nickel exceed State water quality standards in many portions of the Estuary.[56] According to the San Francisco Baykeeper, 322 tons of lead shot have been deposited into San Francisco Bay from the activities of one gun club alone during the past 30 years.[57] Toxic "hot spots" identified by the San Francisco Bay Water Quality Control Board of Oakland include a 250-acre site in Suisun Bay, a 10- to 50-acre site in Oakland's Inner Harbor, and a 250-acre site in the Central Bay.[58]

Dredging

Each year, about seven million cubic yards of sediment are dredged from places like Oakland Harbor, the Port of San Francisco and local marinas in the Estuary. One dredging project, Richmond Harbor's John F. Baldwin Channel, removed 2.7 million cubic yards of sediment, enough to fill five Olympic-sized swimming pools every day for one year. Maintenance projects alone generate approximately eight million cubic yards of sediment each year, making disposal a serious concern.[59]

Dredged sediments are deposited at one of the five aquatic or four upland disposal sites. The dumping of dredged materials seriously threatens the estuarine ecosystem by reintroducing previously-buried toxics into the water column, smothering bottom-dwelling organisms such as clams and crabs, and causing turbidity or clouding of the water. Dumping is only part of the problem. Dredging itself can permanently alter the natural bottom habitat that aquatic species are dependent upon, and cause changes in the salinity of the Estuary waters.

Additional Concerns

Trash accumulated on estuarine beaches threatens the ecosystem and its wildlife inhabitants. On September

17, 1994, volunteers cleared 565,501 pounds of marine debris from 480 miles of California's beach areas. Of the total amount of marine debris collected, 54.1 percent was plastic, 10.8 percent was metal, 18.5 percent was paper, and 16.6 percent was from other materials.[60]

Standards and monitoring procedures to protect swimmer safety vary widely throughout California. There were 415 beach closures and advisories in the San Francisco area in 1994. Some examples of beaches that issued closures and advisories in that year are Keller Beach, Oyster Cove, Baker Beach, and Ocean Beach.[61] These beaches were closed after heavy rainfalls and sewer overflows in order to protect swimmers from the harmful effects of bacteria and other pathogens.

The San Francisco Estuary Project

The San Francisco Estuary Project (SFEP) joined the National Estuary Program (NEP) in 1987.[62] In 1993, the Comprehensive Conservation and Management Plan (CCMP) for the San Francisco Estuary was approved by the United States Environmental Protection Agency (EPA).[63] A short time later, the Friends of the San Francisco Estuary, a non-profit public benefit corporation, was established to help coordinate implementation of the CCMP.

The SFEP process stressed the connection between environmental protection and economic viability by including economic incentives in long-term plans.[64] Governmental agencies along with 100 participants representing diverse interests collaborated on the development of management options to protect and restore water quality. Due to the vast array of competing uses of the Estuary, a consensus-based approach was necessary to ensure community-wide support of the project. The SFEP developed an estuary-wide strategy to coordinate research, enhance consistency, and reduce duplication.[65]

The CCMP describes 144 actions necessary for restoring and protecting the Estuary. The pollution section of the CCMP sets out sixteen specific action plans ranging from pursuing a mass emissions reduction strategy to developing environmental audit procedures for major users of toxics. Some of the tangible benefits of the pollution prevention activities are worthy of note. For example, a local petroleum refinery recently improved the efficiency of one of its sites and eliminated 70-90 percent of the chromium and lead in its wastewater by changing one chemical used in its cooling towers.[66] Another refinery recently agreed to change its practices in order to reduce discharges of selenium, a toxic chemical, into San Francisco Bay and to pay $2.2 million to settle a lawsuit alleging violations of the Clean Water Act.[67]

In the agricultural arena, the SFEP assists ranchers in reducing water pollution through the use of Best Management Practices, such as the installation of pens, livestock barriers, and fences designed to prevent cattle from trampling on sensitive vegetation and to reduce erosion.[68]

Habitat destruction is another major concern identified in the CCMP. The massive wetlands losses in the Estuary region led the SFEP to focus to a large degree on wetlands restoration projects.[69] Funding provided by the SFEP is being used in an attempt to restore the beneficial flood control functions of existing wetlands, as well as other functions and values.[70] Goals for better wetlands management within the watershed include protecting existing wetlands, restoring the ecological productivity of impaired wetlands, expediting an increase in wetlands acreage, and educating the public about wetland values. Unfortunately, habitat declines continue despite these and other efforts. Clearly, the success of these goals is dependent upon an increase in funding, additional economic incentives, and enhanced public resolve.

In addition to these projects, more than 70 monitoring projects, ranging from fish surveys to the identification of pollutant loadings, are underway. Outreach and education have also played a huge part in efforts to restore the Estuary. The SFEP has sponsored public forums, presentations, and tours to inform citizens about the values and key threats to the Bay-Delta region. However, in order for these strategies to be successful in the long-term, State and/or federal agency leadership must be strengthened, and a new infusion of funds must occur in order to ensure adequate implementation of the CCMP.

National Coastal Caucus

Save San Francisco Bay Association (SSFBA) was founded in 1961 to protect open water, improve recreational opportunities, support wildlife conservation, beautify the shoreline, and promote resource planning. SSFBA has been actively involved in the SFEP serving on the Wetlands, Water Policy, Water Quality, and Management Committees.

SSFBA works with agencies like the Bay Conservation and Development Commission, the Army Corps of Engineers, and the Regional Water Quality Control Board that receive hundreds of applications each year for development projects that would irrevocably affect the Bay and the shoreline. As these applications are being processed, SSFBA works to ensure that the maximum public benefit is achieved and that the Bay's diminishing wetlands and other habitats are protected. It also serves as an important watchdog by reporting local Bay-related activities, protecting the Bay through legal means when necessary, educating the public, and encouraging citizen participation in Bay projects.

In 1994, the top priority of SSFBA's Restoring the Bay Campaign was protecting habitat in the reuse of closed federal military bases, acquiring habitat through the Land and Water Conservation Fund, and obtaining funds for restoration projects from the Regional Water Quality Control Board. Eight military facilities along the shoreline are expected to be closed in the next few years. Some of these bases were built partly on Bay fill and therefore displaced aquatic, tideland and/or wetlands habitat. The San Francisco Bay National Wildlife Refuge has identified important sites within these areas to be added to the refuge as protected areas, including the Alameda Naval Air Station and the Mare Island Naval Shipyard. However, opponents continue to argue that the sites should be reserved for economic development.

In 1995, SSFBA began to work on a project to enhance and restore 30,000 acres of wetlands that was funded through a grant from the Regional Water Quality Control Board. The San Pablo Baylands comprised one of the largest undeveloped tracts of former tidal wetlands in the entire state of California. The 30,000-acre Baylands were once extensive wetlands that were diked in the last century to create hay farms and salt ponds. The Partnership for the San Pablo Baylands is an entirely voluntary project that relies on the interest of landowners in the region to act as stewards of this valuable asset. The first phase involves a broad regional public education and outreach campaign. The outreach efforts will provide direct support for production and implementation of a wetlands enhancement plan. It will also develop a comprehensive inventory of educational materials and activities, including Baylands tours, videos and newsletters. The second element will employ an innovative approach known as Integrated Resource Management to create a plan that will enhance the management of multiple resources and attract the active support of landowners, citizens and government.

Another important victory for SSFBA was the recent agreement reached with environmental, agricultural and urban interests, and State and federal agencies, establishing new standards to protect the Bay from the effects of water diversion. This historic agreement which was the culmination of more than fifteen years of work by SSFBA, would strengthen environmental standards, protect endangered species, and create a $180 million Delta restoration fund. SSFBA also worked to find a solution to the dredging needs of the Port of Oakland in a project to use clean dredged mud to help restore 300 acres of tidal wetlands.

Through its Seafood Consumption Information Project, SSFBA has worked to persuade the State to conduct monitoring studies and post multi-lingual health advisories at Bay piers. As a result of this pressure, the State in December, 1994 found in the most comprehensive study to date, that sport fish in San Francisco Bay are so contaminated with PCBs, mercury, dioxin and pesticides that State health officials have warned against eating them more than twice a month. They have also advised that children under age six and pregnant or nursing women should not eat anything caught from the Bay."[1] SSFBA conducted their own survey of 93 pier fishers between the San Mateo and San Rafael bridges, and found that none of them had heard about the striped bass consumption advisory.

San Juan Bay
in Puerto Rico

Portrait of the Bay

The San Juan Bay Estuary Program is examining the water quality and habitat problems of the San Juan Bay system and the impact that the greater watershed has on the estuary. San Juan Bay is located along the northeastern coast of the Commonwealth of Puerto Rico, approximately 1,000 miles southeast of Florida. The estuary system includes San Juan Bay proper and a number of smaller channels and lagoons, including San Antonio Canal, Condado Lagoon, Martin Pena Canal, San Jose Lagoon, Los Corozos Lagoon, Suarez Canal, Torrecilla Lagoon, and Pinones Lagoon.[1]

The greater watershed area of San Juan Bay encompasses 60 square miles (38,682 acres) and has an estimated population of 461,000 people.[2] The San Juan Bay watershed is the most populated area of Puerto Rico, which itself, has the greatest population density of any U.S. State or Trust Territory.[1] The major municipalities of the watershed are San Juan, Catano, Guaynabo, Carolina, Bayamon, and Loiza.

Freshwater draining from land intermixes with saltwater from oceans to create productive estuaries such as the San Juan Bay. The Bay receives its freshwater from the Puerto Nuevo, Rio Piedras Rivers and the Juan Mendez, San Anton, and Blasina

San Juan Bay

Area of watershed	60 square miles
Population	461,000 people
Values	• Fisheries generate $4.3 million*
	• Tourism generates over $1 billion*
	• Tropical ecosystem with "Critical Coastal Wildlife Areas"
Threats	• Pathogen contamination
	• Toxic contamination
	• Nutrient loadings
	• Habitat loss and degradation
	• Population growth and development
CCMP status	Final expected in 1998

Designated as a "Nationally Significant" Estuary in 1992.

Creeks.[4] The Estuary system has three connections to the Atlantic Ocean — Condado Lagoon and the northern portion of Torrecilla Lagoon on the eastern edge of the system, and San Juan Bay at the western edge of the system.[5] The limited flushing capacity and low tidal range characteristic of this estuary make it susceptible to the retention of harmful pollutants in the Bay.

The San Juan Bay system contains a variety of productive habitats. The predominant habitat types within the system include mangrove forests, coral reefs, seagrass beds, mudflats, marshes, sand dunes, and open water.

Values of the Bay

The San Juan Bay system is an irreplaceable natural, recreational, and commercial resource for Puerto Rico's residents and visitors. The lush habitats of the system provide year-round and wintering grounds for an abundance of birds, fish, and wildlife. The system's mangroves and coral reefs offer especially important breeding, nursery, and sheltering habitats for fish and shellfish. Tourism and water-based recreational industries generate significant revenue for the local communities of the Bay.

Recreation/Tourism

Puerto Rico promotes itself as "The Shining Star of the Caribbean" and is reputed for its beaches, boating, sailing, snorkeling, SCUBA diving, and sport fishing. According to the Puerto Rican Tourism Company, over one billion dollars in tourism-related revenues were generated from over two million visitors to the island in 1987.[6] The San Juan area was visited by an estimated 1.7 million visitors in 1992.[7]

Clean waters and a healthy environment are the foundations of San Juan's tourist economy. The coastal areas known to have the best water quality typically generate the greatest amount of tourism revenues.[8] The coastal waters just beyond San Juan Bay support a prosperous sport fishing industry. Saltwater anglers from across the world travel to San Juan in order to fish these marine waters, which have been dubbed "Blue Marlin Alley" because of the numerous world fishing records broken in them. Prized sport fish in these coastal waters include blue marlin, white marlin, dolphinfish, wahoo, Allison tuna, and oceanic bonito. Although these fish do not inhabit San Juan Bay, they do feed on smaller fish which use the estuary for spawning and nursery grounds.[9]

Fisheries/Seafood

The ocean waters surrounding Puerto Rico are too deep to attract large pools of commercially valuable fish. As a result, commercial fishing operations are conducted by small boats in the coastal waters and along beaches. In 1992, there were only 300 registered commercial fishermen in Puerto Rico.[10]

Despite the limited number of commercial fishermen in Puerto Rico, landings of commercial fish provide significant revenue for the local economies. In 1994, the landings for Puerto Rico's commercial fishery (including shellfish) totaled approximately 2.4 million pounds, and were valued at $4.3 million.[11] The most prominent species landed include silk snappers, yellowtail snappers, mackerel, lobsters, and conch.[12]

Wildlife/Habitat

As a tropical island ecosystem, the San Juan Bay system supports a greater diversity of habitat and living species than estuaries of the continental United States. A substantial number of bird species inhabit the estuarine area, including the yellow-shouldered blackbird, orange-fronted parakeet, black-whiskered vireo, bananaquit, herons, osprey and gulls.[13] Beaches and sand dunes in the area are used by leatherback, green, and hawksbill sea turtles for nesting grounds. In addition, manatees, dolphins, and whales can be found in the estuary.[14]

The Puerto Rican Department of Natural Resources has classified three areas within the San Juan Bay system as "Critical Coastal Wildlife Areas." The Constitution Bridge Mudflats, Torrecilla-Pinones-Vacia Talega Lagoon Complex, and Palo Seco Peninsula were designated as critical coastal wildlife areas based on the number of threatened and endangered species that rely on them.

VOL 12

3870

R0037178

The Torrecilla-Pinones-Vacia Talega Lagoon complex alone contains more than 10,000 acres dominated by mangrove forests. This area contains the Pinones State Forest Natural Reserve, an area which supports a wide array of flora and fauna, but is most threatened by development projects.[15] In addition, the Palo Seco Peninsula, which was created in 1963 by dredged sands from the Bay, now provides essential habitat for mangroves and other valuable plant life.[16]

The Constitution Bridge Mudflats support the richest diversity of birds on the entire island.[17] Seagrass beds of the estuary provide essential habitat for juvenile fish and shellfish and trap pollutants and sediments which can damage coral reefs. Coral reefs are considered one of the most productive and diverse marine ecosystems on the planet. They cover a fraction of one percent of the Earth's surface but are home to a large percentage of all marine fish species.[18] Many of the commercially valuable fish of the San Juan Bay area rely on the corals, which are principally located around the Isla de Cabras. The potential use of coral communities in biomedical research and application is yet another argument for their protection.[19] For instance, it has recently been discovered that skeletons from stony corals may be useful agents in human bone grafts.[20] These areas, however, still await a comprehensive plan to define suitable measures for their protection.

Species listed as federally (U.S.) endangered which depend upon the San Juan Bay system include the West Indian manatee, green sea turtle, leatherback sea turtle, hawksbill sea turtle, roseate tern, and yellow-shouldered blackbird.[21] Other species which are listed as endangered by the Commonwealth of Puerto Rico and are found in the Bay system include the least tern, white-crowned pigeon, West Indian whistling duck, and ruddy duck.[22]

Threats to the Bay

At a quick glance, the San Juan Bay system appears to be a tropical paradise, complete with gorgeous beach areas, exotic wildlife species, and recreational diversions. In reality, however, this estuarine system has serious environmental problems ranging from toxic contamination to habitat degradation. The priority problems of the estuary which have been identified as the principal threats to the system are pathogen contamination, toxic contamination, and excessive nutrient loadings. Habitat destruction, population growth, and floatable debris also stress the Bay system.

Pathogen Contamination

Despite the availability of advanced (secondary) treatment technology for sewage treatment plants and federal grants during the 1970's and 1980's, to help meet the costs of upgrades, San Juan's major municipal plants continue only to perform primary treatment (solids are removed by screening and sedimentation) of sewage. Before 1985, these plants discharged the wastewater effluent directly into the Bay. Since then, these plants have dumped undertreated sewage in ocean waters through an outfall pipe. The San Juan Bay still receives direct discharges of untreated human sewage from nonsewered areas of the watershed, illegal sewer connections, municipal treatment plant bypasses, and boating waste.[23] As a result, San Juan Bay, local canals, and nearby ocean waters are impaired by pathogens.

Pathogens are disease-causing bacteria and viruses found in human and animal wastes. Pathogens in coastal waters pose risks to humans who eat contaminated fish and shellfish or who recreate in beach waters. Gastroenteritis, hepatitis, and other diseases can result from the ingestion of pathogen-contaminated waters or fish. For this reason, many beaches and shellfish beds are closed or restricted when water monitoring indicates that high levels of fecal coliform bacteria (an indicator of pathogen contamination) are present in coastal waters.

Direct discharges of sewage and illegal sewage connections to storm drains are some of most significant pollution problems in the San Juan Bay system. In some of the poorer neighborhoods of metropolitan San Juan, sanitary sewage disposal service is not provided. Along the Martin Pena Canal and San Jose Lagoon, human waste and garbage are dumped into local waters and onto bordering land. High tides and heavy rainstorms carry this waste, and the pathogens it contains, to other portions of the estuary.[24]

Another source of pathogen contamination in the Bay system is the illegal connection of sewage pipes to stormwater drains. Eliminating these illicit connections is a challenge to local officials because the task of identifying the connection points is difficult.

Raw sewage is responsible for fish and shellfish kills as well as human disease in the Martin Pena Canal and San Jose Lagoon system.[25] Scientists have made a direct connection between high concentrations of raw sewage and the incidence of Cigatuera, a disease causing severe gastrointestinal and nervous system disorders in human populations. Cigatuera is a naturally-occurring biotoxin found in tropical fish which reproduces more rapidly in areas where raw sewage concentrations are high.[26] Currently, poor water quality causes between 20,000 and 30,000 cases of Cigatuera each year in Puerto Rico and the Virgin Islands.[27]

Toxic Contamination

Unlike municipalities of the area, industries discharge their wastewater directly into the Bay system. Heavy metals, organic chemicals, and heated effluent are commonly found in these industrial discharges. Toxic chemicals also enter the Bay via illegal sewer connections to storm drains and stormwater carrying pesticides which have been applied to lawns and agricultural lands. Toxic chemicals which have been found in the Bay in excess of standard allowable levels include copper, lead, mercury, selenium, and zinc.[28] The San Juan Harbor is affected by these five heavy metals plus other chemicals, which include arsenic, beryllium, cadmium, chromium, cyanide, pesticides, polychlorinated biphenyls (PCBs), aluminum, thallium, silver, and nickel.[29]

In addition to organic chemicals and heavy metals, oil spills in the Harbor area of the Bay are additional sources of toxic pollution in the estuary. The U.S. Coast Guard estimates that between 1987 and 1990, the San Juan Bay area suffered from an average of 50 oil spills per year, at times, resulting in millions of gallons of oil spilled annually.[30] The effects of toxic discharges and oil spills wreak havoc on human and estuarine life, water quality, and habitat. Toxic levels of chemicals have been found in commercially valuable fish and in wildlife. Eating contaminated fish threatens human health. For the many people in the San Juan area who fish for subsistence, this risk is intensified since a heavy reliance on fish caught near the Bay shore increases the exposure to harmful contaminants, causing subsequent health problems. Endangered sea turtles in the area are deceived into eating floating tar balls resulting from oil spills.[31] Oil and chemical spills have led to beach closures in the area and an overall reduction in the number of beachgoers to the San Juan area.

Nutrient Loadings

Nutrients, such as nitrogen and phosphorus, are introduced to the estuary by urban stormwater, sewage treatment plants, power plant emissions, and other sources. Excessive levels of these nutrients stimulate the growth of algae in the Bay. As the algae grow, they not only block sunlight needed by the submerged aquatic vegetation of the Bay, but also require a great amount of dissolved oxygen to decompose. Submerged aquatic vegetation is used as juvenile nursery grounds by fish and shellfish and hence, is vital to sustaining populations of these commercially valuable resources.

Habitat Loss and Degradation

Mangroves, seagrass beds, and coral reefs are the three prominent habitats of the San Juan Bay system. Mangroves are invaluable to the aquatic communities of the Bay — they provide shelter and nursery areas for young fish; guard shorelines against erosion and coastal storms; and filter harmful sediments and pollutants. The San Juan Bay area contains approximately 14,401 acres of mangrove forests, nearly 25 percent of the total mangrove coverage in all of Puerto Rico.[32]

Ongoing development activities are destroying the sensitive tropical habitats of San Juan Bay. Mangrove forests which hug shorelines are particularly affected by development and non-permitted, dredging activities in the San Juan area.[33] Near the

VOL 12

3872

San Jose Lagoon, mangrove cutting and residential development projects reduced the acreage of mangroves by 41 percent between 1937 and 1987.[14] In addition to modifications of near-shore habitats, changes in upland habitats, such as land clearing for urban and agricultural uses, exposes mangroves to more harmful contaminants.

Increasing levels of sediments, toxic contaminants, and nutrients harm seagrass and coral habitats by clogging the respiratory systems of corals and blocking essential sunlight needed by both seagrasses and coral reefs.[15] In addition, both corals and seagrass beds suffer from physical abrasion from boat anchors and certain fishing gear.[16]

Population Growth and Development

Toxic pollution, polluted runoff, and habitat destruction in the San Juan Bay are all human-induced problems. Thus, the increase in human population and human activity in the region, further jeopardizes the health of the natural system. The population in San Juan has grown significantly since the 1970's. Between 1970 and 1980 the towns within the San Juan Bay watershed grew in population by approximately 22 percent. Residential development alone increased by 36 percent during this period.[17] Corresponding commercial development has also increased the stress on the system. As long as the San Juan Bay area continues to attract visitors and residents, the impact of human activity on the main island (particularly in the low, flat areas of San Juan) will continue to increase. Therefore, stronger measures must be taken to ensure compliance with water quality standards and the preservation and protection of valuable habitat as development projects ensue.

Floatable Debris

Trash accumulated on estuarine beaches threatens the ecosystem and its wildlife inhabitants. The amount found in just one day was staggering — on October 8, 1994, volunteers cleared 115,240 pounds of marine debris from 40 miles of Puerto Rico's beaches. Of the total amount of marine debris collected, 44.5 percent was plastic, 29.7 percent was glass, 14.8 percent was metal, and 11 percent was from other materials.[18] Garbage slicks and beach wash-ups, in addition to the approximately 50 oil spills that occur each year in the San Juan area, result in negative impacts on the tourist economy as is evidenced by declining occupancy at hotels along affected shorelines.[19]

The San Juan Bay Estuary Project

The San Juan Bay Estuarine System was nominated to participate in the National Estuary Program (NEP) on April 16, 1992. It was the first and remains the only tropical estuary system to be included in the NEP. Thus, its nomination is ground-breaking in its effort to manage and protect some of the Earth's most biologically diverse marine habitat. On October 22, 1992 EPA accepted the nomination and designated San Juan Bay a "nationally significant" estuary.

San Juan Bay is also the first NEP to be established outside of the continental United States. As a result, the development of the SJBEP's Comprehensive Conservation and Management Plan (CCMP) has presented more challenges than those faced by other NEPs. For instance, it took about two years to actually establish the SJBEP office which is now located in San Juan.

A two-day Estuary Planning workshop occurred in June, 1993 in Old San Juan that brought together the stakeholders in the area to discuss water quality issues facing the Bay, as well as the administrative issues necessary to move the Program forward. Unfortunately, participation of citizens and local government agencies at the workshop was lacking. As a result, the establishment of the Citizens Advisory Committee (CAC) had to be postponed. A much more intensive effort needs to be made to expand the participation and representation of different categories of user groups in the Program, particularly from the citizen and environmental communities.

Although, the Management Conference Agreement and the First Year Work Plan were approved by EPA in 1994, it was not until April, 1995 that the

CAC was officially established. The program is in the process of preparing a preliminary draft CCMP to highlight more critical concerns for the Estuary.

The Management Conference and the Scientific and Technical Advisory Committees have been meeting regularly and recommending interim actions to protect the Bay. The limited tidal flushing capacity and the low tidal range characteristic of the San Juan Bay system make it susceptible to a contaminated sediment problem. As a result, a water quality and sediment sampling initiative is underway. Other characterization studies are being conducted to help in the development of an appropriate monitoring system. For instance, an Ecosystem Assessment project was established in May, 1995 to identify impacted habitats and species. A Hydrodynamic/Water Quality Mathematical Model is also being developed to evaluate proposals which could impact water quality of the Bay system. Other projects in the works include the development of administrative procedures to process solid waste dumping enforcement cases, as well as the enforcement of appropriate stormwater and wastewater hookups.

VOL 12

Santa Monica Bay
in California

A healthy Santa Monica Bay is essential to the vitality and identity of Southern California. It is one of the most popular, but polluted coastal areas in the country. Between 50 million and 60 million visits are made to the Bay each year, and nine million people live within an hour's drive of the Bay. The population of Los Angeles County has increased by over 300 percent since 1940 and is predicted to grow another 30 percent by 2010. Our lifestyles have contaminated the Bay with DDT, PCBs, sewage, and toxic stormwater. Each of us must act individually and collectively now in order to save this precious resource

— Robert H. Sulnick, Executive Director
American Oceans Campaign

Portrait of the Bay

The Santa Monica Bay Restoration Project is examining the water quality and habitat problems of the Santa Monica Bay and the impact that the greater watershed area has on the estuarine system. Santa Monica Bay is located west of Los Angeles on the Pacific Coast of Southern California. It is bordered on the north by the Santa Monica mountains which, along with the Los Angeles coastal plain, dominate the physical terrain of the Bay region.[1] The Santa Monica Bay contains about 306 square miles of surface water, with depths reaching 1,640 feet, and a total water volume of about 6.8 trillion gallons.[2]

Santa Monica Bay

Area of surface water	306 square miles
Area of watershed	414 square miles
Maximum depth	1,640 feet
Population	3 million people
Values	• Fisheries generate $159 million* • Santa Monica Bay beaches generate $1.08 billion • Over 5,000 species inhabit the Bay area
Threats	• Habitat loss and degradation • Pathogen contamination • Conventional and toxic pollution • Floatable debris
CCMP status	Approved in 1995

Designated as a "Nationally Significant" Estuary in 1989.

Visitors and residents are attracted to the Mediterranean-like climate of the Santa Monica Bay: dry summer seasons and mild winter seasons. Rainfall averaged only 12 inches per year between 1983 and 1993.[3] The Bay offers a wide variety of natural habitats, ranging from rocky intertidal areas to coastal scrub (fire adapted, shrub-like plant communities).[4]

The Santa Monica Bay watershed encompasses a large number of highly populated communities including Beverly Hills, Calabasas, Culver City, El Segundo, Hermosa Beach, part of the City of Los Angeles, Malibu, Manhattan Beach, the Palos Verdes Peninsula, Redondo Beach, Santa Monica, and West Hollywood. About three million people live in the 414-square mile watershed area.[5] Griffith Park serves as the watershed's eastern border, with Point Fermin on the south and Ventura County on the west.

The Santa Monica Bay Restoration Project divides the study area of the Santa Monica Bay into three management regions: the wasteshed, the watershed, and the Bay. The wasteshed is the land area from which municipal wastes are collected before being treated and discharged into the Bay.[6] The 414-square-mile watershed receives water from 28 stream drainage basins, of which the Malibu Creek and Ballona Creek are the largest.[7] The combined area of the wasteshed and watershed is 1,380 square miles.[8]

The Bay's surface water is flushed relatively frequently, every three to four days.[9] Since it is an open embayment, the salinity of the Bay system ranges from 33.5 to 34.1 parts per thousand (ppt), close to the salinity of seawater (35 ppt).[10]

Values of the Bay

The Bay is the site of world-famous beaches, such as Malibu and Venice Beach, which draw great numbers of visitors to the Bay area each year. Santa Monica Bay provides a wealth of natural resources for residents and these visitors to enjoy. The Santa Monica Bay region includes a range of habitats including terrestrial, wetland intertidal, kelp bed, open water, and hard and soft bottom area.[11] Only a few thousand acres of wetlands remain in the watershed (riparian areas, lakes, ponds, coastal marshes, and lagoons). This area was once a vast, marshy system; but only a few hundred acres of coastal wetlands are found in the area today.[12] The few wetlands that remain trap nutrients and sediments that run off from the watershed before they reach Santa Monica Bay.

The shallow nearshore areas of Torrance and Redondo Beaches provide valuable nursery habitats for marine species such as California halibut and juvenile white sea bass. Hard bottom areas in the Bay provide habitat for giant kelp beds, fish and aquatic invertebrates.[13]

Recreation/Tourism

Tourism is the second largest industry in the Los Angeles Region, contributing $4.25 billion in payroll dollars per year to the regional economy, and supporting 437,000 full-time and part-time jobs.[14] A survey of visitors to Santa Monica Beach found that the daily recreational value per person was $18.36, using travel costs and parking fees as indicators.[15] The 1989 value, based on an attendance of 12.5 million visitors to Santa Monica Beach alone, is $229.7 million.[16] Visits to the various beaches in Santa Monica Bay total up to 60 million annually.[17] A calculation of $18 daily recreation value for 60 million individual visits results in a $1.08 billion annual recreation value for beaches of Santa Monica Bay.

Sport fishing is a booming industry throughout the Bay. Although statistics are not available specifically for the Bay, it is estimated that in 1989, sport fishermen made 5.5 million trips, worth about $536 million in gear and trip expenditures, to Southern California waters. Sport fisheries in the Bay include chub mackerel, barred sand bass, kelp bass, and California spiny lobster.[18] In addition, California grunion live in nearshore habitats and spawn along the shores of Southern California beaches in "grunion runs," attracting a wide number of spectators.

Santa Monica Bay is also a valuable educational resource. It is among the most frequented excursion sites for Los Angeles County school educational field trips, providing outdoor classrooms for students of all levels.[19]

VOL 12

3878

Fisheries/Seafood

In 1994, the combined market value of commercial finfish and shellfish landings in the Pacific Region (excluding Alaska) totaled approximately $401 million. In the same year, the State of California's commercial shellfish and finfish landings totaled about 343 million pounds, valued at $159 million.[20] Many commercially valuable species, notably California halibut and Northern anchovy, depend upon the health of Santa Monica Bay. Commercial fishing is prohibited in 62 percent of the Santa Monica Bay to protect local fish stocks which would otherwise be depleted by a combination of recreational and commercial fishing.[21]

Wildlife

The Bay's watershed is home to a diversity of species which use the Bay as spawning, nursery, and feeding grounds. To date, over 5,000 species have been identified, and more are still being discovered.[22] Wildlife found in the Bay's watershed include: invertebrates such as shrimp, crabs, clams, mussels, and sea urchins; birds such as egrets, herons, and sanderlings; and marine mammals such as seals and sea lions.[23]

Animals protected as rare, threatened, or endangered rely on habitats in the Santa Monica Bay watershed for survival. For instance, the California least tern and western snowy plover rely on beach areas in the Bay's watershed for nesting grounds; the California brown pelican relies on marine habitat in the area; the Belding's savannah sparrow relies on wetlands habitat in the Bay area; and the American peregrine falcon and California gnatcatcher rely on other watershed habitats for survival.[24]

Threats to the Bay

The water quality, habitat, and wildlife of Santa Monica Bay are under attack by many kinds of pollution, from a variety of sources. Some of the major threats to the Bay are: habitat loss and degradation, pathogen contamination, conventional and toxic pollutants, and floatable debris.[25]

Coastal pollution has contributed to the public's concerns about swimming in Santa Monica Bay. Although changes in weather may account for annual visitor fluctuations, beach attendance in Southern California declined by about 56 percent between 1983 and 1992.[26] Sewage spills and overflows from the Hyperion Sewage Treatment Plant in Los Angeles have resulted in beach closures and have raised public concern about beach pollution.[27] Pathogens carried to the oceans in storm drains are also a threat to human health.[28]

Habitat Loss and Degradation

The rapid urbanization and population growth in the Santa Monica Bay region have been key reasons for the impairment of Santa Monica Bay. The population of Los Angeles County has increased by over 300 percent since 1940,[29] to a 1990 estimate of nine million.[30] More people means an increased demand for land.

California has lost more than 91 percent of its wetlands, a higher percentage than any other State in the nation.[31] In the Santa Monica Bay region alone, 95 percent of the historic wetlands have been destroyed due to draining and filling activities for agriculture, flood control, port and oil development, and industrial and residential expansion.[32] With the destruction of these wetlands, many of the beneficial functions that wetlands provide are lost. Coastal wetlands serve as critical areas for spawning, nursing, and feeding of fish and shellfish. Many birds use these areas as nesting habitat. Coastal communities also benefit from wetlands. Wetlands filter pollutants carried in stormwater and urban runoff before they can reach waterbodies, absorb excess flood waters, and protect upland areas from coastal storms. In addition, wetlands are used by many people for recreational activities, such as bird watching and walking.

Historically, the Santa Monica Bay shoreline between the Pacific Palisades and Malaga Cove was composed of narrow beaches, rocky shores, sand dunes, and wetlands.[33] Destruction and development of these sensitive shoreline habitats over the last few decades has had serious financial consequences. Federal, State and local governments have constructed erosion control structures such as jetties and groins and have replenished beach sands at significant financial and environmental costs. These artificial structures also result in shoreline accretion and beach erosion at other points along the coast.

Pathogen Contamination

Pathogens are disease-causing microorganisms found in human and animal wastes which enter estuaries through sewage treatment plant discharges, polluted urban stormwater, agricultural runoff, boating waste, and individual septic systems. Pathogens in coastal waters pose risks to humans who eat contaminated shellfish or who ingest contaminated waters. Gastroenteritis, hepatitis, and other diseases can result from contact with pathogens. For this reason, beaches and shellfish beds are closed or restricted when coastal water monitoring shows that standards for fecal coliform, total coliform, or enterococcus (indicators of pathogens) are exceeded.

Two large municipal wastewater treatment plants currently discharge treated sewage into the Bay: the Hyperion Treatment Plant (HTP) run by the City of Los Angeles and the Joint Water Pollution Control Plant (JWPCP) run by the Los Angeles County Sanitation District. About 85 percent of the municipal wastes discharged to the Bay originate from residential use which averages 100 gallons per day per capita.[34] The HTP and JWPCP are being upgraded from primary to secondary treatment to comply with biological treatment requirements that destroy bacteria and viruses (and break down organic compounds such as oil, grease, and some pesticides).

Until the mid-1970s, 800 million gallons of sewage receiving only primary treatment were dumped into the Bay each day,[35] degrading benthic communities, bottom-dwelling plants and animals. In 1993, HTP had a total daily flow of 330 million gallons of sewage — 166 million gallons of which received secondary treatment; while JWPCP had a total daily flow of 328 million gallons of sewage — 133 million gallons of which received secondary treatment.[36] Due to recent improvements in the efficacy of sewage treatment, benthic communities are making significant recoveries.[37] The contaminants discharged to the Bay from HTP and JWPCP have improved significantly as a result of increased source control, land disposal of sludge, improved sludge and primary treatment, and increased secondary treatment.[38]

Recreational boaters also discharge raw and chemically treated sewage into the Bay, especially into the popular marinas of King Harbor and Marina del Rey,[39] which together have about 7,500 berths.[40] Discharges are unlawful unless boats are at least three miles beyond the shoreline. Nevertheless, boaters continue to discharge because on-shore pumpout facilities are grossly inadequate.[41] The Santa Monica Bay Restoration Project received a grant in 1996 to survey pump-out facilities in the Bay which should lead to recommendations for reducing the sewage attributable to boats.

Conventional and Toxic Pollutants

Industrial sources discharging directly into the Bay include three power generating stations and one oil refinery along the coast. The generating stations take in about 238 billion gallons of seawater per day for cooling,[42] grinding up millions of fish larvae in the process. They discharge heated water and treated wastewater that is non-hazardous according to State and federal regulations.[43] The Chevron refinery, California's largest, produces up to 405,000 barrels of petroleum products and discharges petroleum processing wastewater, boiler water and cooling water that receives secondary treatment.[44] In addition, over 160 smaller commercial and industrial facilities discharge non-process wastewaters to storm drain channels that flow into the Bay.[45]

Urban stormwater is the leading source of pollution in Santa Monica Bay.[46] Toxic pollutants are contained in the stormwater which is delivered to the Bay. On dry days, 25 million gallons of stormwater and urban runoff are carried into Santa Monica Bay through storm drain outlets.[47] During heavy rains, 10 billion gallons of stormwater flow into the Bay through storm drains. The 5,000-mile storm drain network transports 30 billion gallons of stormwater and urban runoff through more than 200 outlets, ranging from 370-feet wide to an almost undetectable size.[48] A 1993 study conducted by the University of California at Los Angeles and American Oceans Campaign identified over 160 toxic chemicals, including known human carcinogens and

VOL 12

3879

R0037187

mutagens. This pilot study included a review of five of the 64 major storm drains that empty into the Santa Monica Bay.[49] Stormwater is also a source of pathogens. The Santa Monica Bay Restoration Project has sponsored a health impact study to assess the risk of swimming near Bay storm drain outlets. The results will be released in the spring of 1996.[50]

Toxic pollutants are also contained in discharges from sewage treatment plants. Until the Clean Water Act's pretreatment program went into effect, many industries dumped untreated industrial wastes into sewer systems, which are not designed to treat such wastes. The pollutants passed through the sewer system into the ocean. Between 1940 and 1970, for example, sewer systems discharged 2,000 tons of DDT into the Santa Monica Bay near Palos Verdes.[51] As a result, 200 tons of DDT remain in the sediments of the Palos Verdes shelf. These historic discharges have accumulated in Bay sediments and contaminate aquatic species. In turn, they are ingested by organisms higher in the food chain, including humans.

Fisheries throughout the Bay are at risk from toxic contamination. The white croaker fishery was recently shut down due to concerns over possible toxic contamination.[52] As a result of DDT contamination in the Bay and its bioaccumulation in the food chain, Southern California's marine animals possess the highest levels of DDT poisoning in the world.[53] One meal of dover sole, Pacific sand dab, or white croaker caught by fishermen off the Bay's coast can expose the consumer to a dose of toxic chemicals equal to the amount a person would normally be exposed to in a lifetime.[54] Today, wastewater treatment facilities are required to enforce pretreatment standards for industrial facilities prior to discharge to the sewer system in order to remove toxic and conventional pollutants from the wastewater.

Marine vessels are a significant source of toxic pollutants given the 7,500 berths and hundreds of dry docks at Marina del Rey and King Harbor. Chemicals for the care of marine vessels contribute arsenic, chromium, copper, lead, mercury, PCBs, tributyl tin, and zinc.[55] Marine vessels are also a source of crude oil and refined petroleum products through tanker accidents, fueling, tank cleaning, bilge pumping, and improper disposal.[56] The U.S. Coast Guard estimated that an average of six petroleum product spills from recreational vessels and oil tankers occurred in Santa Monica Bay each year between 1973 and 1987, totaling almost 2,000 gallons of fossil fuels.[57]

Dredging contaminated materials presents other toxic pollution problems for the Bay. Dredging can stir up toxics and other contaminated materials and, when dumped at sea, can be carried back into the Bay by ocean currents. In the past, dredged materials were used for beach replenishment without testing for contaminant levels.[58]

No studies have been done of the Santa Monica Bay to determine the proportion of pollutants that fallout from air, but deposition is thought to be a significant source of lead, nickel, zinc, and PAHs.[59]

Floatable Debris

Trash and debris from beachgoers, marine vessels, and from urban runoff threaten estuaries and their wildlife inhabitants. Over 4,000 tons of trash are collected from Bay beaches annually.[60] The amount collected in just one day can be staggering — on September 17, 1994, volunteers cleaned 480 miles of California beaches. Of the 565,501 pounds of trash collected, 54.1 percent of plastic materials, 18.5 percent was paper, 10.8 percent was metal and the remaining 16.6 percent was other forms of trash.[61]

The Santa Monica Bay Restoration Project

The Santa Monica Bay Restoration Project joined the National Estuary Program in 1989. It seeks to address the following major problems: health risks associated with human contact with pathogen-contaminated water, seafood contamination, the loss of wetlands and living resources, and the impacts of pollution on the ecology and water quality of the Bay. The Project has encouraged cooperation among industry, the public sector, and environmental organizations.[62]

A draft action plan was developed in 1992. The final CCMP, with nearly 250 actions, was approved in March 1995. The Plan identified 74 priority actions costing about $67 million, 33 of which cost about $42 million and focus on the control of polluted urban runoff and stormwater.[63] The SMBRP initiated one of the nation's first permit programs to abate polluted stormwater into the Santa Monica Bay.[64] Current priority action items include: completing an epidemiological study of health risks to people swimming near storm drains; incorporating CCMP actions for stormwater control into a new county-wide NPDES permit for cities; improving the enforcement of water quality permits; reducing toxics from household and industrial sources; and restoring tidal influence of the Ballona Lagoon.

The Plan has a comprehensive monitoring framework to protect living resources. Recent steps have focused on making monitoring information more accessible to the public so that concerns over the health of the Bay can be more adequately addressed.[65]

Overall the SMBRP is renowned for respecting the public participation process and human health concerns that arise from multiple uses of the Bay. This has led to a comprehensive watershed approach to planning and implementation, engaging a wide range of stakeholders in efforts to protect and restore the Bay.[66]

California Senator Tom Hayden, Chairman of the California Senate Natural Resources Committee, although a participant on the Santa Monica Bay Restoration Project Oversight Committee, has also been a critic of the Plan. Thus far, the Project has spent almost $6.5 million in planning efforts; however, sources for the remainder of the $67 million needed for the priority actions have not been identified. Senator Hayden contends the $67 million would include the costs of further reports and studies when the findings of past research already make clear the kinds of actions that should be taken.[67]

Members of the environmental community believe that a significant part of the Bay's pollution problems result from the lack of enforcement by regulatory agencies, pointing out that in 1993-1994, the Los Angeles Regional Board cited only ten violations.[68] A stronger regulatory approach with fixed effluent limits and vigorous enforcement by regulatory agencies is needed. While 80 to 90 percent of the State's effluent flows to the ocean, only about five percent of the Water Resources Board's budget is allocated to ocean issues.[69] As is the case in several of the local NEPs, the Plan contains only those protective measures that all the stakeholders could agree upon, focusing on studies, planning, and education, rather than measurable pollution reduction goals and tough enforcement measures.

National Coastal Caucus

Environmental organizations focusing on the Santa Monica Bay have adopted different but complementary strategies. Heal the Bay is a non-profit coalition of people and organizations who are working to achieve swimmable and fishable coastal waters that meet the goals of the Federal Clean Water Act "to restore and maintain the chemical, physical, and biological integrity of the nation's waters." Founded in 1985, Heal the Bay informs publicly elected officials and the media about the Bay, the causes and effects of pollution, and the ways to deal with existing problems so that the Bay can begin the process of healing itself.

American Oceans Campaign (AOC) is a national non-profit organization dedicated to the protection and restoration of the world's oceans, estuaries, beaches and wetlands. AOC was founded in 1987 and is headquartered just a few blocks from Santa Monica Bay. AOC's approach to fulfilling its objective is to educate the public and decision-makers on the need to stop abusing the marine and coastal environments. AOC is committed to bring to the ocean debate diverse coalitions of local, regional, and national environmental organizations, elected officials, businesses, religious groups, labor, and other segments of society. American Oceans Campaign has a long history of working to ban oil and gas drilling off the nation's coast and to tighten restrictions on tankering. AOC has also joined with the City of Los Angeles and Unocal to establish a program for recycling used motor oil and to notify the public about this program. AOC also works to help disseminate information about products that can eliminate the need to change motor oil in cars, trucks, and boats and that may have a significant impact on the reduction of plastic debris entering the Bay.

Heal the Bay and American Oceans Campaign have a long tradition of working cooperatively with public entities and private businesses and industries to promote Bay restoration, as well as promoting educational efforts geared at the general public. Other groups, such as the Natural Resources Defense Council and Santa Monica Baykeeper have adopted a more litigious approach to Bay restoration. The permit to control stormwater and urban runoff illustrates how effectively the two strategies can work together.

Heal the Bay has worked intensively with many of the municipalities to bring about greater understanding and support for the NPDES stormwater permit for the L.A. region. It also launched a broad-based campaign to stencil storm drains to bring greater awareness to the public that what goes into the drains ends up in the Bay. AOC, along with scientists from UCLA, conducted a pilot study of five storm drains entering Santa Monica Bay that identified 160 toxic chemicals, including several known carcinogens and mutagens in the stormwater flow. AOC has also worked with the County of Los Angeles to develop the first-ever beach closure protocol which requires public notice about health risks posed by swimming in Santa Monica Bay due to toxic or bacterial contamination. NRDC has filed a number of lawsuits that have resulted in stringent court interpretations of existing stormwater controls and has, thereby, played a key role in shaping the new draft permit and in forcing the cities to focus on the issue of stormwater. The Baykeeper often serves as an investigative unit. With a 24-hour hotline, a cadre of volunteer inspectors, and a patrol boat, the Baykeeper gathers information about stormwater violations (along with other illegal discharges and activities such as unlawful fishing), and either deals with them directly, passes the information to the proper authority, or joins with lawyers to file a citizen suit.

American Oceans Campaign and Heal the Bay have been involved in the Santa Monica Bay Restoration Project since its inception. Members, Board Directors, and staff of both groups have served in numerous capacities in the development of the CCMP and in the monitoring of the interim actions and other steps taken to implement the plan. Currently, as part of the implementation phase, they serve on both the Santa Monica Bay Watershed Council and Oversight Committee.

Sarasota Bay
in Florida

Humans, largely responsible for problems plaguing the Bay, have the power to solve the most pressing ones — but do they have the political will? I fear not. The political pressures on the National Estuary Program are such that they restrict the progress of the well-intentioned, good people who want to utilize scientific data now available to resolve the real problems of the Bay.

—Gloria Rains, Chairperson
MansSota-88

Portrait of the Bay

The Sarasota Bay National Estuary Program is examining the water quality and habitat problems of Sarasota Bay and the impact that the greater watershed area has on the estuarine system. Sarasota Bay is one of many subtropical estuaries situated along Florida's southwestern coast. The Sarasota Bay system is an elongated coastal lagoon extending for 56 miles from Anna Maria Sound in the north to Venice Inlet in the south.[1] Its width ranges from less than 300 feet in several narrows to no more than four and one-half miles at its widest point. The Intracoastal Water-

3885

Sarasota Bay

Average depth	6 feet
Length	56 miles
Population	488,000 people
Values	• Sport fishing generates $3.5 billion in economic output* • Tourism generates $115 million • The federally threatened loggerhead sea turtle nests along the beaches
Threats	• Nutrient Loadings • Polluted urban stormwater • Toxic contamination • Habitat loss and degradation • Living resources declines
CCMP status	Approved in 1995

Designated as a "Nationally Significant" Estuary in 1988.

way (ICW), a navigational channel nine to 12 feet deep, runs the entire length of the Bay. The average depth of the Bay is less than six feet.[2]

The Sarasota Bay watershed includes Sarasota County and part of Manatee County. Interstate-75 provides a rough eastern boundary for the greater watershed. Anna Maria, Bradenton, Bradenton Beach, Holmes Beach, Longboat Key, and Sarasota are the largest municipalities of the watershed area. The Sarasota Bay watershed has been one of the fastest growing areas in the nation. Since 1980, approximately 32 people per day have moved into Manatee and Sarasota Counties.[3] Approximately 488,000 people lived in the Sarasota and Manatee Counties in 1990. By 2010, it is projected that 688,000 people will live in both counties — a 41 percent growth rate.[4]

In Sarasota Bay, freshwater is delivered through nine major creeks and other smaller waterways. Stormwater provides a significant source of the estuary's freshwater. At its northern end, the Sarasota Bay system opens into Tampa Bay through Anna Maria Sound. To the west, the Bay connects to the Gulf of Mexico through four passages — Longboat Pass, New Pass, Big Pass and Venice Inlet.

Distinctive habitats of the Bay area include salt marshes, mangroves, freshwater wetlands, barrier islands, seagrass beds, oyster reefs, soft bottoms, and spoil islands. During the past 50 years, the abundance of shoreline and seagrass habitats in the area has been significantly reduced, primarily as a result of development. In the Sarasota Bay watershed, 28 percent of the land is used for urban purposes and 26 percent is used for agricultural production.[5] Of the nation's estuaries along the Gulf of Mexico, the Sarasota Bay watershed has the greatest percentage of urban land use.

Values of the Bay

Sarasota Bay brings enjoyment to the many residents and visitors of the region. Commercial and sport fishing, swimming, boating, water skiing, and wildlife observation are some of the popular activities of the estuary. In 1988, Bay-front property was appraised at almost $2 billion, and its value is increasing.[6] Many businesses are being opened to support the nature-related activities of the area.

These businesses, along with the fishing industries of the estuary, provide significant economic benefits for local communities. The Bay is home to one of the oldest commercial fishery centers in Florida, the Village of Cortez. Sarasota Bay also serves important ecological functions for a great diversity of wildlife which use the estuary and its habitats.

Recreation/Tourism

Tourism, the largest industry of the Sarasota Bay area, is closely linked to the estuary and its living resources. Through tourist uses, property tax revenues, and water-related recreation, Sarasota Bay generates over $115 million annually.[7] Although tourism is economically beneficial to the area, the resulting pressures are actually harming the estuarine system. Since tourism and the ecology of the Bay are inextricably linked, ensuring the sustainability of both is a key objective of the restoration effort.

The Bay area has 85 public beach and Bay access points and over 40 public boating ramps.[8] Use of the Bay for windsurfing, water skiing, jet skiing, and boating is so intense that it has created traffic problems and conflicts with swimmers in several portions of the Bay. Palma Sola Bay, Longboat Pass, Venice Inlet, New Pass, Big Pass, and the ICW near Phillippi Creek and Sister Key all suffer weekend congestion.

Sport fishing is an integral component of the local and State economies. In 1991, recreational fresh- and saltwater fishing contributed $3.5 billion to Florida's economy and employed nearly 58,000 people.[9] In the same year, over 2 million saltwater anglers spent a total of 22.6 million days fishing off the coast of Florida. One-third of the anglers were non-residents of the State. In 1991, approximately 30 percent of the nation's total saltwater fishing days occurred off the coasts of Florida.[10]

With its shallow depth and easy accessibility, Sarasota Bay provides recreational anglers with substantial opportunities to fish for spotted seatrout, sand trout, pinfish, sheepshead, Gulf kingfish, snook, and other fish species. Although only limited economic data on the Bay's recreational fisheries has been compiled, they are considered to be of equal or greater value than commercial fisheries in terms of primary economic impact.[11]

Fisheries/Seafood

In 1994, the combined market value of finfish and shellfish landings in the Gulf region totaled approximately $806 million. Many of the commercially valuable species in the Gulf region depend upon the health of the Sarasota Bay for survival. In 1994, the State of Florida's Gulf of Mexico and Atlantic Coast commercial finfish and shellfish landings totaled approximately 177 million pounds, valued at $239 million.[12]

In 1985, "dockside revenues" for Sarasota Bay's commercial fishing industry equaled approximately $950,000 — the retail value was much greater.[13] In Sarasota Bay, black (striped) mullet and spotted seatrout are two of the most commercially significant fish. In 1990, commercial landings for black mullet in Sarasota and Manatee Counties exceeded 3.1 million pounds, making it the largest commercial fishery of the two counties.[14] However, over the past four decades, annual commercial landings of black mullet and spotted seatrout in the Bay have declined by almost 50 percent.[15]

Historically, Sarasota Bay supported commercial harvesting of oysters, quahogs (hard clam), blue crabs, and bay scallops. Although oysters, quahogs, and stone crabs can still be found in the Bay, commercial shellfish harvesting in the Bay is limited to one small "conditionally approved" area off Longboat Key. Pollution, red tides, and pass closures are responsible for the severe deterioration of the Bay's once productive shellfish beds. Efforts are presently underway to restore the bay scallop population by relocating juveniles to areas of the Bay where seagrass has returned.

Wildlife

Approximately 1,400 plant and animal species inhabit Sarasota Bay and its bordering lands.[16] The Bay has a great diversity of bird species, including herons, egrets, ibis, bald eagles, white and brown pelicans, and various shorebirds. Many species of ducks use the estuary for wintering habitat.

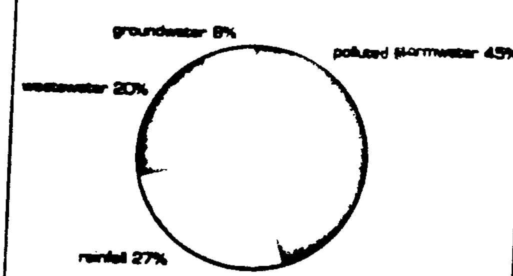
Sea turtles, manatees, and dolphins are some of the most celebrated wildlife inhabitants of the Bay. Sea turtles, including the federally-protected threatened loggerheads, nest on the beaches of the area. Endangered West Indian manatees populate the Bay from April to December and over 100 bottlenose dolphins are year-round residents of the Bay. The endangered wood stork and threatened piping plover, bald eagle, and green sea turtle also use Sarasota Bay and its neighboring habitats.

Threats to the Bay

Habitat modifications to meet the demands of a rapidly growing population and the resulting increases in pollution loadings have substantially altered the environment of Sarasota Bay. Many of the principal threats to Sarasota Bay are directly attributable to the population explosion in Florida. The area's population is expected to grow by 25 percent between 1992 and 1997.[17] Forty years ago, Sarasota Bay enjoyed a wide distribution of seagrass and its shores were thriving with thick mangrove forests. Bay scallops, finfish, and shellfish were abundant in the Bay and nearby Gulf of Mexico. Today, the Bay's fisheries, mangroves, and seagrasses are greatly reduced from 1950 levels. Recent restoration efforts and advancements in municipal and industrial wastewater technology are improving the health of the Bay. To continue the progress of restoring the Bay, the Sarasota Bay Project has developed initiatives to reduce nutrient loadings,

Sarasota Bay

Nitrogen Loading Sources for the Bay



Source: Sarasota Bay National Estuary Program.

stormwater pollution, habitat loss, wildlife declines, and to minimize the negative effects of population growth and increased development.

Nutrient Loadings

Nutrients, such as nitrogen and phosphorus, are introduced to Sarasota Bay by urban stormwater, wastewater treatment plants, septic system leachate, atmospheric deposition, and boater discharges. Excessive levels of these nutrients stimulate the growth of algae in the Bay. As the algae grow, they not only block sunlight needed by the submerged aquatic vegetation of the Bay, but also require a great amount of dissolved oxygen to decompose. The decomposition process reduces the levels of oxygen needed by other aquatic life.

Nitrogen is the nutrient of greatest concern in Sarasota Bay. Nitrogen loadings have increased by 300 percent since the early stages of urbanization in the 1950's.[18] If steps are not taken to reverse the rate at which nitrogen is discharged into the Bay system, another eight percent increase in nutrient loadings is anticipated by 2015.[19]

Presently, stormwater and atmospheric deposition are the two leading sources of nitrogen loadings into Sarasota Bay, contributing 45 and 27 percent of the total load, respectively.[20] Reducing nitrogen levels carried by stormwater requires cooperation from landowners to decrease usage of harmful fertilizers and to change landscape designs so that runoff from residential lawns is minimized. Automobile exhausts and power plants emit significant amounts of nitrogen into the air. As it rains, nitrogen from the air eventually makes its way into the Bay.

As advanced treatment technologies for wastewater plants are installed, nitrogen loadings contributed by wastewater systems are diminishing. Centralized sewer systems in some areas of the watershed are simultaneously reducing pollution discharges into waterways and providing more water for irrigation through wastewater reclamation. The regrowth of 125 acres of seagrass in the central portion of Sarasota Bay is likely due to nitrogen reductions.[21]

Most of Sarasota County is served by smaller sewage treatment plants and 45,000 individual septic systems. Many of the smaller sewage treatment plants do not directly discharge into the Bay; instead, they discharge into the area's groundwater and are thus subject to weaker discharge safeguards. Septic systems remain a significant problem for the Bay since they are only regulated with respect to human health and not environmental quality.

Septic systems in the Phillippi Creek area of the watershed are a special concern. These systems contribute four times more nitrogen to the Bay than the City of Sarasota's wastewater treatment plant.[22] A sewer expansion project under review by Sarasota County would replace 8,500 of the 32,000 septic systems which currently feed into Phillippi Creek, and six old sewage plants.[23] Expanding the service area of the City of Sarasota's treatment plant to include areas near Phillippi Creek would ultimately reduce nitrogen loadings in the Creek by an estimated 31 percent.[24]

Polluted Urban Stormwater

Stormwater pollution is a significant threat to the health of Sarasota Bay. Each year, the Sarasota area receives an average of 58 inches of rain from about 100 storms.[25] During frequent storm events, a substantial amount of nutrients, heavy metals, organic chemicals, sediments, pathogens, and litter is carried by stormwater to the Bay and its tributaries. As the Sarasota Bay watershed becomes more urbanized, the problems associated with heavy rainfall heighten. By replacing natural soils and vegetation with impervious surfaces, such as pavement and roofs, the flow of stormwater and the concentration of pollutants are increased. The beneficial functions that natural lands perform, such as filtering contaminants and absorbing excess waters, are lost as the area becomes more urbanized.

Due to poor management practices of the past, stormwater continues to be directed into the region's creeks and bayous without any form of filtration, detention, or retention. As a result, these tributaries are more polluted than the Bay as a whole because they are more directly affected by the pollutants. Without improved stormwater management measures, these tributaries will continue to deliver polluted stormwater into the Bay, and estuarine areas affected by nutrient enrichment and contaminated sediments will be at greater risk.

VOL 12

3889

R0037197

Toxic Contamination

The primary source of toxic chemicals in the Bay is stormwater, which picks up particles of heavy metals and organic chemicals and carries them to the Bay. The most commonly found heavy metals in the sediments of the Bay and its tributaries are lead, copper, zinc and cadmium.[26] Vehicle exhausts and brakes introduce lead and cadmium into the environment. Copper originates from anti-fouling paints used on boat bottoms and from some herbicides. The most prevalent pesticides which are found in the Bay include aldrin, DDT, dieldrin, heptachlor exopide, and chlorpyrifos.[27]

Five tributaries — Hudson Bayou, Cedar Hammock Creek, Bowlees Creek, Whitaker Bayou, and Phillippi Creek — have elevated levels of copper, lead, and zinc, that pose ecological risks to aquatic communities in the Bay.[28] Many toxins persist in the aquatic environment and over time, accumulate in the tissues of fish and shellfish. Shellfish sampled from Sarasota Bay contain levels of toxic contamination well above State averages.[29] Toxins are linked to reproductive and larval development problems in fish. Subsistence and recreational fishers put themselves at increased health risks from eating larger than average quantities of potentially contaminated fish and shellfish.[30]

Habitat Loss and Degradation

The loss of shorelines, seagrass, mangroves, and freshwater wetlands impairs the water quality and living resources of the Bay. Rapid development has significantly altered the habitats of the Bay. Bulkheads, seawalls, and rock revetments have been built along the coasts and natural shorelines have been artificially filled by spoils in the Sarasota Bay area. Only 22 percent of the Bay's shoreline remains in its natural state.[31]

Both tidal and freshwater wetlands serve critical functions for the estuary, its wildlife and coastal communities. Wetlands are important spawning and nursery areas for fish and shellfish, many of which are valuable commercial species. Wetlands also provide nesting and feeding grounds for waterfowl, shorebirds, mammals and reptiles. Mangroves and salt marshes prevent shoreline erosion and protect inland areas from coastal storms and tides. Finally, wetlands absorb flood waters, remove pollutants before the contaminants can reach the waters, provide places for recreation, and serve other beneficial purposes.

It is estimated that Florida lost over 9.2 million acres of its historic wetlands acreage between the 1780s and the 1980s — a 46 percent reduction. This represents the highest acreage loss of any state in the country.[32] Since the 1950s, significant amounts of Sarasota Bay's saltwater and freshwater wetlands have been destroyed.

Between 1950 and 1990, over 1,600 acres of the Bay's tidal wetlands were destroyed — a 39 percent loss.[33] An average of 40 acres of tidal wetlands were lost each year during this span. Mangroves are the predominant type of tidal wetland in Sarasota Bay; but, unlike the expansive stretches of mangroves which dominated the Bay shore in 1950, most of the remaining mangrove areas are small and fragmented. Dredge-and-fill activities, the construction of dikes in order to disrupt mosquito breeding, mangrove pruning and trimming, and the invasion of non-native plants (such as Brazilian pepper and Australian pine) are the chief causes of the significant loss of mangroves and salt marshes in the Sarasota Bay area.

Between 1975 and 1987, 1,900 acres of non-forested freshwater wetlands of the Sarasota Bay watershed were destroyed — a 35 percent reduction.[34] During these 12 years, 158 acres of non-forested wetlands were lost annually. In earlier years, most of the freshwater wetlands that were destroyed were converted to support agricultural uses. More recently, residential and commercial development are replacing once-existing, freshwater wetlands. The greatest freshwater wetland losses have occurred in the areas surrounding Hudson Bayou, Whitaker Bayou, Bowlees Creek, Cedar Hammock Creek, and Palma Sola Creek.[35]

Throughout the Bay, 30 percent of the historic coverage of seagrasses has been destroyed.[36] Dredge-and-fill activities to support waterside development; the construction of navigational channels; increased boater traffic, and pollution have all caused the declines of seagrasses in Sarasota Bay. Currently, seagrass beds account for 26 percent of the 33,000 acres of Bay bottom.[37] However, these remaining beds are not as productive as the seagrasses which covered the bottom prior to development activities. Restoring seagrass is important to the aquatic life of the estuary. Manatees and sea turtles feed on the seagrass, juvenile fish and shellfish use seagrass beds for nurseries and shelter, and dolphins rely on seagrass for nursery habitat. Reductions in nitrogen from wastewater discharges are helping to restore seagrasses in certain portions of the Bay. In Longboat Pass and New Pass, seagrass coverage is expanding.

Living Resources Declines

Human use of the estuary has disturbed the fragile balance of estuarine life. Human activities often come into direct conflict with animal life. Despite intense work to preserve the Bay's turtles, manatees, and dolphins and protect their habitats, heavy recreational use of the Bay and its beaches puts populations of these animals at risk. Colliding with boats is the leading cause of manatee deaths. Of the 19 manatees which died in the area between 1987 and 1991, nine were mutilated by boat propellers or died after colliding with boats. In addition, seven of the 19 were calves that researchers believe were separated from their mothers while fleeing from boats.[38] Only about 1,850 West Indian manatees remain in Florida waters.[39] During busy weekends, dolphins move to shallower waters to escape boating noise and reduce the risks of collisions. Seagrasses are important calving and nursery grounds for dolphins, just as beaches are vital habitat for turtle nesting. Losses or alterations of these habitats contribute to the decline of these animals.

Pollution is another major contributor to the losses among native plants and animals. Since the 1960s, pollution has contributed to drastic declines among scallop, hard-clam, and oyster populations, and to the closing of shellfish beds to harvest.[40] Declines in these shellfish populations alter the composition of aquatic life in the system. Some believe that this imbalance is triggering the increase in populations of stone crabs and other species.

Reduced fish stocks are a recent trend in Bay waters. Habitat losses are contributing to lower commercial landings in the area. For example, concrete seawalls have been built where mangroves once thrived and as a result, a large area of juvenile fish habitat no longer exists.

In Florida, the invasion of exotic plant species, which replace native species and destroy wildlife habitat, is a massive problem. Specifically, in Sarasota Bay, exotic species, such as Brazilian pepper and Australian pine, have doubled their coverage along the coastline since 1948.[41] Australian pines, which have a shallow root system and large canopy, frequently blow over during heavy storms and alter nearshore channel flow in the process. In addition, their roots often prevent turtles from nesting. Finally, carrotwood has also started to invade mangrove stands.

Additional Concerns

The accumulation of trash on estuarine beaches threatens the ecosystem and wildlife inhabitants. The amount found in just one day was staggering — on September 17, 1994, 1,267 miles of beach were cleared of 368,255 pounds of debris by volunteers in Florida. Of the total amount, 61.4 percent was plastic, 12.5 percent was metal, 11 percent was glass, and 15.1 was other materials.[42]

Florida does not have a state beach water quality monitoring program; however, the Department of Environmental Regulation has established bacteria standards for swimmer safety.[43] Sarasota County monitors 12 beaches quarterly for swimmer safety. In 1994, Sarasota County had two beach closures — both at Blind Pass Beach — which were caused by red tide. Manatee County has not adopted a water monitoring program for swimmer safety.[44]

The Sarasota Bay National Estuary Program

Sarasota Bay was formally designated as an estuary of "national significance" under the National Estuary Program (NEP) in 1988. A five-year workplan for developing a Comprehensive Conservation and Management Plan (CCMP) was approved by the Sarasota Bay National Estuary Program's

VOL 12

Policy Committee in 1989. The structure of the Sarasota Bay National Estuary Program (SBNEP) consists of the Policy Committee, the Elected Officials Forum, the Management Committee, the Technical Advisory Committee, and the Citizens Advisory Committee. The SBNEP completed its "State of the Bay" report in January, 1990. In November 1995, the Environmental Protection Agency and the Governor of Florida approved the CCMP for Sarasota Bay. The approved plan outlines water quality improvement initiatives through additional wastewater treatment, stormwater controls, increased wetlands restoration, and pollution prevention activities.

By 1993, a compilation of studies that were completed over the past several years, and some new scientific research on the health of the Bay had been gathered and made available. Unfortunately, some questions exist regarding the accuracy, thoroughness, and timeliness of the data and the modeling that was conducted. For instance, although nitrogen is a significant problem for the health of the Bay, no studies were conducted on the atmospheric deposition of nitrogen oxide. After receiving numerous complaints some modeling, although inadequate, was eventually conducted.[43] Other studies included an assessment of fish and shellfish contamination, modeling of water circulation and pollutant loads, and evaluations of wetlands losses. The data from the research was used as a guide for the SBNEP in developing its CCMP and has assisted in determining the type and scope of necessary interim action projects. Some believe, however, that enough information had already existed to begin to address some of the most serious concerns of the Bay and that too much emphasis was placed on research as opposed to action.

One of the main purposes of the SBNEP was to establish working, coordinated partnerships among the federal, State and local agencies to address the threat of pollution in Sarasota Bay. To this end, the SBNEP has been quite successful. The level of civic involvement, of both citizens and local officials, has raised awareness and acceptance of the goals of the CCMP, as well as support for immediate action to protect and restore the Bay. Yet, it must be remembered that the Plan relies on acceptance by a wide number of political entities whose priorities may not always coincide with that of the Plan and who are reluctant to relinquish power to any central authority for implementation. A simple, yet telling, example of the political pressure is the change of emphasis on action between the draft CCMP and the final version — all language stating that agencies "shall" take specific actions was changed to "should" in the final version.

Wastewater and stormwater issues provide a good example of interagency cooperation under the SBNEP. County objectives for these issues coincide quite well with the goals of the CCMP. It is generally believed that stormwater reduction efforts and upgrading wastewater treatment plants, have been somewhat successful at reducing nutrient loadings into the Bay. The CCMP recommends using the excess capacity of the City of Sarasota's Advanced Wastewater Treatment Plant to service the inefficient and overburdened treatment plants of nearby communities, and to connect up failed septic systems that run adjacent to Phillippi Creek. County stormwater plans include the development and use of retention basins, detention ponds and the like to hold back waters that would normally discharge directly into tributaries of the Bay. Unfortunately, however, the SBNEP has yet to accomplish substantial gains in reducing nitrogen loading from septic systems.

The SBNEP has set a wetlands restoration goal of 29 acres per year. By 1995, the SBNEP had restored 75 acres of saltwater wetlands.[44] It has provided for demonstration projects to transplant seagrasses, re-establish scallops, and provide signs to reduce boat propeller scarring of underwater habitats. In addition, the Program experimented with an inexpensive artificial reef system to be used along existing sea walls lining the Bay. However, this proposal has proven to be extremely controversial. Although it provides additional reef habitat for fish, it has negative consequences. These consequences include disposing rubble into marine habitats to create the reef, forcing aquatic life to depend on artificial habitat, and losing on-site opportunities for education on the values of natural reefs, which can not be artificially duplicated.

3892

A Florida Yards & Neighborhoods Program was recently adopted to reduce pollution from individual homes. The SBNEP is recommending a 20 year commitment to this program at a cost of $200,000 per year. Its public education objectives include native plant selection, lawn maintenance reduction, shoreline management, mangrove conservation, and landscaping to reduce residential runoff. The anticipated results are a reduction in nitrogen loadings from over-fertilization of residential landscapes, water conservation, and habitat protection. However, since this is a strictly voluntary program with a relatively small budget — considering the amount of public outreach it must conduct to be effective — there is concern that there will be little impact and no clear way to measure its effectiveness.

The SBNEP also engages in hands-on educational projects. For instance, children and adults educate other citizens about the impact of individual actions by painting blue dolphins on storm drains with the statement "Dumping Here Pollutes Our BAY."

National Coastal Caucus

ManaSota-88, A Project For Environmental Quality 1968-2088, is a non-profit organization comprising more than 2,500 concerned members, all dedicated to the health and preservation of the environment. ManaSota-88 serves as an environmental watchdog organization for the two-county area of Manatee and Sarasota. It is actively engaged in a full range of advocacy and public education issues affecting both Sarasota and Tampa Bay.

Created in 1968, ManaSota-88 evolved from a major environmental health study sponsored by the U.S. Public Health Service, Florida State University, the University of Florida and the Sarasota and Manatee County Commissions. Manasota-88 functions primarily through working committees composed of citizen volunteers and public officials. A steering committee provides overall leadership and direction. The organization operates entirely through volunteer support and receives no contributions from the government or "special interest" groups.

Members, volunteers and staff of ManaSota-88 have served in numerous capacities in attempting to strengthen the development of the CCMP and in monitoring the interim actions and other steps taken to implement the Plan. In particular, they have served on the Citizens Advisory Committee and have served in an advisory capacity on other local government boards and commissions, such as the Southwest Florida Water Management District Board, Environmental Advisory Committee and Manasota Basin Board.

Spokespersons for ManaSota-88 present testimony on behalf of the organization in countless forums. ManaSota-88 educates its members, the general public and policymakers by promoting legislative initiatives, commenting on regulations, using the judicial process to enforce the law, initiating studies, and conducting research to help protect the Bay. For example, the organization works on federal legislation such as the Clean Water Act; State legislation such as the Mangrove Trimming & Preservation Act; local zoning decisions on such issues as protecting public resource lands and endangered species; and public right-to-know issues such as obtaining public records from the Port Authority on levels of airborne particulates in excess of State standards generated at their facility. In addition, ManaSota-88 has worked with the State Legislature to find economically viable solutions to dredging and port expansion projects. They have worked to assist the Legislature in coming up with a plan to determine and prioritize which ports merit allocation of funding. They have effectively argued that port expansion should not occur near aquatic preserves.

One of the most recent and important initiatives that ManaSota-88 has been involved with has been its outspoken opposition to the alternative fuel, Orimulsion. Orimulsion is a manufactured fuel that rapidly disperses in estuarine waters when spilled. The use of Orimulsion will cause other problems for the health of the Bay. It will increase nitrogen oxide emissions in the area by 10,000 tons or more per year. Emissions of other pollutants, including

VOL 12

3893

vanadium will also increase. ManaSota-88's efforts pulled the review process in the right direction and preserved its right to seek appellate court review.

The American Littoral Society (ALS) is a non-profit organization, founded in 1961 to encourage a better understanding of the marine environment and to provide a unified voice advocating for the protection of the delicate web of life along our coasts. The shore, its adjacent wetlands, estuaries, and coral reefs — the littoral zone — is the special area of interest and concern for the organization. ALS works to protect these resources by promoting marine education, accessing media coverage, and giving testimony at the local, state and national levels for legislation that furthers a cleaner marine environment.

The activities of ALS, as they relate to Sarasota Bay, include lectures, beachwalks, snorkeling trips, and Bay boat trips that emphasize the natural history and need for restoration of the Bay. The ALS has played a key role in the development of the CCMP. Specifically, the regional director of the Gulf/South Atlantic chapter serves on the Sarasota Bay National Estuary Project Citizens Advisory Committee and is a member of the Southwest Florida Water Management District Board, Environmental Advisory Committee.

ALS provides plenty of opportunities for activism. The organization runs a volunteer restoration project at Palmer Point, a 30 acre publicly-owned strip of barrier island located on north Casey Key and Siesta Key. Australian pine and Brazilian pepper are removed and replaced with native species grown by volunteers. ALS also conducts coastal cleanups, coastal strand and dune restoration, volunteer monitoring, seagrass planting, fish tagging and more. They organize outdoor field trips, such as seining, canoeing, camping, hiking, and diving, along the coastal strand. They also go whale watching, shark tagging, and otter trawling for marine specimens. ALS runs the nation's largest fish tag-and-release program. Over 10,000 fish are tagged annually. Tag and return data is sent to a computer at the National Marine Fisheries Center, Woods Hole Oceanographic Institution, Massachusetts. Those records help marine biologists learn more about fish migration and growth rates, among other things.

3895

Tampa Bay
in Florida

Once the State's most diverse and productive estuarine system, rapid urban and industrial development have significantly changed the character and ecology of Tampa Bay over the past 100 years, with habitat destruction and water quality degradation escalating during the last 30 of those 100 years. This profound loss of habitat has resulted in the complete collapse of our scallop and oyster fisheries, as well as major declines in bait and food shrimp, spotted sea trout and red fish.

—Peter Clark, President
Tampa BayWatch

Portrait of the Bay

The Tampa Bay National Estuary Program is examining the water quality and habitat problems of Tampa Bay and the impact that the greater watershed area has on the estuarine system. Tampa Bay, located on Florida's Gulf coast, is the largest open-water estuary in the State. The Bay's water surface area measures approximately 400 square miles. The average depth of Tampa Bay is about 12 feet; however, this includes the depths of dredged shipping channels which are 43 feet deep.[1] Most of the Bay is relatively shallow.

Tampa Bay

Area of surface water	400 square miles
Area of watershed	2,200 square miles
Average depth	12 feet
Population	2 million people
Values	• Fisheries generate $239 million* • Sport fishing generates $3.5 billion in economic output* • Mangrove islands support 40,000 nesting pairs of birds
Threats	• Nutrient loadings • Toxic pollution • Habitat loss and degradation • Pathogen contamination • Floatable debris
CCMP status	Expected in 1996

Designated as a "Nationally Significant" Estuary in 1991.

*State figures

Office of Wetlands, Oceans
& Watersheds
Florida

The watershed of Tampa Bay covers approximately 2,200 square miles and extends into most of Pinellas, Hillsborough, and Manatee Counties and portions of Pasco, Polk, and Sarasota Counties.[2] In 1991, 40 percent of the land in the watershed was classified as agricultural land and 17 percent was classified as urban land.[3] The largest municipalities within the watershed are Tampa, St. Petersburg, Bradenton, and Clearwater. The population of the Tampa Bay area has increased 24 percent since 1970.[4] Currently, more than two million persons live in the watershed.[5] The combined population of Pinellas, Hillsborough, and Manatee Counties is projected to grow to 2.4 million by 2010 — a 20 percent increase from the current population.[6]

The Hillsborough, Alafia, Little Manatee, and Manatee Rivers are the major sources of freshwater for Tampa Bay. A number of smaller rivers and creeks also drain into the Bay. The estuary's major connection with the Gulf of Mexico is at the mouth of Lower Tampa Bay. Several passes and inlets also join the waters of the Gulf and the Bay.

Distinctive habitat types in the Bay system include submerged seagrasses, hard-bottom growth, soft-bottom habitat, salt marshes, mud flats, forested uplands, and open water. As a combined system, these habitats support a great diversity and abundance of wildlife. However, human-induced pressures, such as habitat alterations and pollution loadings, continue to jeopardize the living resources of the estuary.

Values of the Bay

With its inherent physical beauty, and economic and recreational values, Tampa Bay enhances the quality of life of its residents and visitors. Rich in natural resources, Tampa Bay is among the most productive estuarine ecosystems in the country. The estuary's mangroves sustain large nesting populations of sea and shorebirds; and its aquatic vegetation supports a diversity of benthic organisms.

The coastal communities of the Bay derive a number of benefits from the estuary. Four major tributaries within the watershed — the Hillsborough, Palm, Manatee, and Braden Rivers — provide drinking water for more than 750,000 residents in the estuary region.[7] The Bay and its surroundings, especially the ocean beaches, offer numerous tourist destinations. The Bay's three ports — Tampa, St. Petersburg, and Manatee — form an international trading hub. The Port of Tampa alone, contributes approximately $5.5 billion to the regional economy and supports an estimated 68,000 jobs.[8] Nonetheless, shipping operations in the Bay threaten the area's water quality and habitat. Thus, maintaining a proper balance between human usage and the health of the Bay's natural resources is the key to the estuary's future productivity.

Fisheries/Seafood

In 1994, the combined market value of commercial finfish and shellfish landings in the Gulf of Mexico region totaled approximately $806 million.[9] Many of the commercially-valuable species in the Gulf region depend upon the health of Tampa Bay for their survival. In 1994, the State of Florida's commercial finfish and shellfish landings totaled 177 million pounds, valued at $239 million.[10]

Important commercial fisheries of Tampa Bay include black mullet and spotted seatrout. Tampa Bay fisheries have historically contributed to the economy of the region. In 1986, for instance, commercial fishermen landed about 35 million pounds of finfish and shellfish worth about $24 million in dockside revenues. Recently, however, the fishing industry has suffered from fish population declines. For example, between 1964 and 1990, finfish harvested at Tampa Bay Ports dropped by nearly 38 percent, from 17.6 million pounds to 11 million pounds.[12] Currently, there are bans prohibiting commercial fishing for red drum, menhaden, and herring in the Bay;[13] in addition, there is presently no approved commercial shellfish harvesting in Tampa Bay. The only shellfish which is approved for recreational harvest from Tampa Bay is the clam.[14] Water quality declines, overfishing, and habitat loss are the principal reasons for the Bay's decreased commercial fisheries production.

Recreation/Tourism

Tampa Bay and its surroundings are popular destinations for vacationers and residents in search of sunbathing, fishing, sailing, water skiing, diving,

VOL 12 3898

R0037206

camping, and many other recreational opportunities. It is estimated that 50 million people visit Florida's beaches, spending up to $25 million each year.[15] In 1991, recreational fishing in Florida generated approximately $3.5 billion in economic output and employed over 58,000 people.[16] In 1991, over 2 million saltwater anglers fished off the coast of Florida.[17] One-third of the anglers were non-residents of Florida.[18]

More than 100,000 boats are registered in Pinellas, Hillsborough, and Manatee counties.[19] State parks and preserves are found along the Bay. In addition, the Egmont Key, Pinellas, and Passage Key National Wildlife Refuges are located at the mouth of the Bay. In addition to the residents that frequent these natural areas in their local region, approximately eight million tourists visit the Tampa Bay area each year.[20]

Wildlife

The variety of habitats found in Tampa Bay provide shelter and food for hundreds of animal species. Shrimp, bay scallops, seatrout, sea horses, manatees, and sea turtles are among the many species that rely on the Bay's seagrasses. Invertebrates thrive in the soft mud and sand along the Bay's bottom. In fact, each square meter of the Bay's soft-bottom contains an estimated one million invertebrates.[21] Oysters, fish, and invertebrates can be found using the Bay's oyster reefs and other hard-bottom grounds. Mangrove islands in the Bay provide nesting grounds for brown pelicans, roseate spoonbills, white ibis, reddish egrets, and other birds. These islands contain some of the most diverse and productive nesting colonies in North America, supporting approximately 40,000 nesting pairs of at least 25 bird species each season. Other animals found in Tampa Bay include Atlantic bottle-nose dolphins, sandpipers, and loggerhead, green, and Kemp's ridley sea turtles. Up to 200 West Indian manatees are residents of the Bay.[22]

Many of the species that inhabit the coastal areas of Florida are threatened and endangered. More than 25 percent of Florida's federally-protected endangered and threatened animal species depend on the State's wetlands.[23] The endangered green sea turtle, hawksbill sea turtle, Kemp's ridley sea turtle, shortnose sturgeon, bald eagle, American woodstork, Florida salt marsh vole, rice rat, and West Indian manatee rely upon Florida's estuarine wetlands. Florida's loggerhead sea turtles and piping plovers are threatened species which depend upon estuarine wetlands in Tampa Bay and other parts of Florida.[24]

Threats to the Bay

During the past decade, efforts to restore natural habitats and upgrade wastewater treatment plants throughout the Bay have been extremely successful. However, many water quality problems remain. Stormwater and pollution running off urban and agricultural lands discharge a mixture of nutrients, bacteria, toxic chemicals, and trash into the Bay and its tributaries. Development in the region is replacing natural soils with impervious surfaces such as pavement and roofs, eliminating the filtering and absorbing capabilities of natural areas. Therefore, greater flows of water carrying higher concentrations of contaminants are reaching the Bay's waters. Fish and wildlife populations of the area are threatened by a combination of water quality impairments, habitat loss, and overfishing.

As the area's population continues to grow, the estuary's vitality will continue to be threatened. Thus, building upon recent environmental successes will be a challenge. The Tampa Bay Natural Estuary Program has identified nutrient loadings, toxic pollution, and habitat loss as among the priority problems facing the Tampa Bay system.

Nutrient Loadings

Nutrients such as nitrogen and phosphorus are introduced to the estuary by urban stormwater, agricultural runoff, leachate from septic tanks, sewage treatment plants, and atmospheric deposition from power plants and cars. Excessive levels of these nutrients stimulate the growth of algae in the Bay. As algae grow, they block sunlight needed by the submerged aquatic vegetation of the Bay. Thus, algal blooms cause declines among seagrass beds and subsequently bay scallop populations, which use seagrass as their primary source of habitat. In addition, as algal decomposition requires a great amount of dissolved oxygen, the process depletes oxygen levels — much-needed by other aquatic life — from the system. Low oxygen conditions (called hypoxia) can cause large fish kills.

Nitrogen is the nutrient of greatest concern to Tampa Bay. Stormwater is responsible for depositing almost one-half of the Bay's nitrogen loadings — urban stormwater alone accounts for 16 percent of the total nitrogen loadings. Twenty-eight percent of the nitrogen loadings come from atmospheric deposition; while 14 percent come from municipal and industrial point sources entering the Bay.[27] Previous deficiencies in wastewater treatment facilities have accounted for a large portion of past nitrogen loadings into the Bay system. The implementation of advanced wastewater treatment processes in the Bay's nine major public wastewater treatment facilities has effectively reduced nitrogen concentrations by as much as 90 percent. However, these facilities still dump approximately 28 billion gallons of effluent into the Bay yearly (including 440 tons of nitrogen).[26]

Toxic Pollution

When the Tampa Bay National Estuary Program began in 1991, toxic pollution was not considered one of the most pressing problems facing the Bay. However, subsequent research has found that toxic contaminants, such as heavy metals and pesticides, are a significant ecological concern for Tampa Bay. Of the nation's estuaries that border the Gulf of Mexico, Tampa Bay ranks among the highest in toxic chemical and pesticide concentrations.[27] Heavy metals found in elevated levels in Tampa Bay include cadmium, chromium, copper, lead, mercury, and zinc. Currently, due to high levels of mercury, fish consumption advisories exist for spanish mackerel and bluefish caught in Tampa Bay. The pesticides of greatest concern in Tampa Bay are DDT, mirex, dieldrin, endosulfan, and chlordane. Finally, polychlorinated biphenyls (PCBs) and polynuclear aromatic hydrocarbons (PAHs) are also present in the Bay.[28] All of these toxins can harm aquatic life in the Bay.

Particles of toxic metals and organic chemicals settle in the sediments of the Bay and its tributaries. These chemical contaminants persist in the system and are eventually consumed by aquatic organisms. Once consumed, these toxins accumulate in animal tissues and are passed throughout the food chain. Because of the persistent nature of these contaminants, chemicals and metals introduced to the system decades ago can have present-day effects on water quality, and wildlife and human populations. This is particularly problematic for subsistence fishers in urbanized waters.

The areas of the Bay system with the most significant concentrations of heavy metal contamination are found around urban centers, marinas, and ports, including Hillsborough Bay, the Port of Tampa, Boca Ciega Bay, and Bayboro Harbor.[29] Fish caught from the shipping channel have revealed cadmium, lead, and zinc levels high enough to cause biological impairments.[30] In addition, oysters in the Bay have revealed higher-than-average concentrations of lead, mercury, zinc, and arsenic when compared to oysters in other Gulf of Mexico estuaries. These contaminants are believed to be connected to reproductive and developmental deficiencies in Tampa Bay oysters.[31] Blue crabs, hardhead catfish, killifish, and red drum have also been found with biological impairments.

Pesticides are of particular concern in Cockroach Bay and Boca Ciega Bay. A survey of 200 nationwide sites revealed that oyster samples from Cockroach Bay had the third highest level of chlordane in 1988 and the fifteenth highest level of chlordane over a three-year period.[32]

Most toxic contaminants found in the Bay's sediments enter the Bay via stormwater discharges. In fact, stormwater carries an estimated 60 percent of the annual loadings of chromium, zinc, mercury and lead into the Bay.[33] Other sources of toxic contamination include atmospheric deposition and wastewater treatment plant discharges.

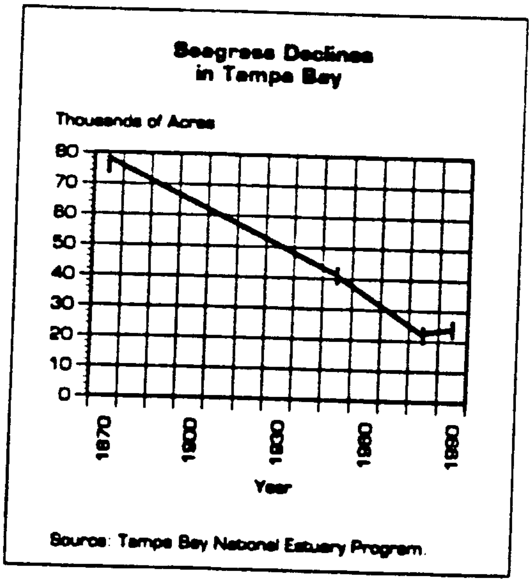
Habitat Loss and Degradation

According to the Tampa Bay Regional Planning Council, the Tampa Bay region is the third fastest growing urban area in the nation.[34] In an attempt to accommodate the growing population, development activities have escalated dramatically, causing significant habitat losses and water quality impairments in the Bay area. Shoreline, salt marsh, and

VOL 12

3900

R0037208



Source: Tampa Bay National Estuary Program.

seagrass habitats are the most severely affected by development activities.

Nearly 80 percent of the Bay's historical seagrasses have been destroyed.[35] In fact, between 1950 and 1982, seagrass coverage in the Bay decreased from 40,627 acres to 21,647 acres. However, aerial surveys show that seagrass coverage has been rebounding since 1982. For instance, about 4,000 acres of new seagrass beds sprouted between 1982 and 1992.[36] Stricter controls over pollution discharges and development activities are aiding in the restoration of seagrasses. In particular, nitrogen reductions in sewage treatment plant discharges have slowed the growth of algal blooms, which can prohibit sunlight needed for seagrass growth and productivity. Other causes of seagrass loss include dredging and filling seagrass beds for development projects, turbidity due to shipping channel dredging, and scarring of beds by boat propellers.

The area's mangroves and salt marshes are also at risk from development pressures. It is estimated that 9,700 acres, or 43 percent, of the original mangroves and salt marshes of the area were destroyed between 1950 and 1990.[37] Approximately 13,800 acres of mangrove forests and 4,600 acres of salt marsh remain in Tampa Bay.[38] Shoreline development projects, such as dredge-and-fill activities and seawall construction, plus the invasion of non-native vegetation, Brazilian pepper and Australian pine, are responsible for losses among these valuable wetlands.

Marshes and mangroves provide important habitat for birds, fish, and shellfish. In addition, these wetlands improve water quality by filtering pollutants, nutrients, and sediments before water carrying these contaminants is discharged into the estuary. Wetlands protect coastal communities from storms by collecting flood waters and providing buffers from strong tides.

Losses among life-sustaining habitats of the Bay threaten the productivity of the area's valuable wildlife resources. For example, declines in fish and shellfish populations are linked to diminishing spawning, feeding, nursing, and nesting habitats. As previously mentioned, bay scallop populations in the estuary are directly affected by the loss of seagrass beds, their primary source of habitat. The loss of seagrass habitat is also a chief reason for population and landing declines among spotted seatrout. Landings of one of the Bay's most popular sport fish, spotted seatrout plummeted from 487,000 pounds in 1950 to 67,000 pounds in 1990.[39]

Pathogen Contamination

Pathogens are disease-causing microorganisms found in human and animal wastes which enter estuaries through sewage treatment plant discharges, septic system failures, polluted urban stormwater, sanitary sewer overflows, agricultural runoff, and boating waste. Pathogens in coastal waters pose health risks to humans who eat contaminated shellfish or who recreate in beach waters. Gastroenteritis, hepatitis, and other diseases can result from the ingestion of pathogens. For this reason, beaches and shellfish beds are closed or restricted when water monitoring indicates high levels of fecal coliform and total coliform bacteria (indicators of pathogen contamination) are present in coastal waters.

During and immediately after heavy rain events, several of Tampa Bay's beaches and shellfish beds are routinely closed due to the threat of pathogen

VOL 12

3901

contamination. Not only does stormwater carry animal waste from lawns and pastures, but also it occasionally overloads municipal wastewater treatment plants, causing malfunctions that lead to the dumping of raw sewage into the Bay. During a severe rain event in August 1995, for instance, 15.6 million gallons of raw sewage were discharged into St. Petersburg canals that drain into the Bay.[40]

The local governments surrounding Tampa Bay use independent criteria to decide when swimming should be restricted. Many local health officials decide to close beaches when rainfall exceeds a certain limit, instead of actually monitoring for the presence of fecal coliform. The City of St. Petersburg's beach testing program is one of the most extensive in the State. St. Petersburg monitors its beach waters weekly and preemptively closes beaches following excessive rainfalls. In 1994, Maximo and North Shore beaches were closed 77 times, mostly due to the threat of pathogens following heavy rains. Hillsborough and Pinellas Counties test their beaches at least once a month.[41]

The monitoring of shellfish beds is conducted at least once a month and closures are determined by State standards. Currently, shellfish harvesting acres in Cockroach Bay are closed due to persistent pathogen contamination[42] and lack of funds for monitoring.

Floatable Debris

Trash accumulated on the beaches bordering Tampa Bay threatens the ecosystem and its wildlife inhabitants. On September 17, 1994, volunteers cleared 368,255 pounds of debris from an estimated 1,267 miles of Florida beaches. Of the total amount of debris collected, 61.4 percent was plastic, 12.5 percent was metal, 11 percent was glass, and 15.1 percent was other materials.[43]

Monofilament fishing line is a hazardous form of "debris" that has been harming the Bay's bird populations. Even a single piece of monofilament fishing line can claim the lives of multiple birds. In 1995, Tampa BayWatch surveyed 40 islands and gathered 45 pounds of monofilament fishing line and other entangling debris. Thirty dead birds were discovered in connection with the debris.[44] The elimination of this debris is critical to the recovery of the many threatened and endangered bird species which use Tampa Bay.

The Tampa Bay National Estuary Program

In 1991, the Tampa Bay National Estuary Program was established and charged with the responsibility of drafting a Comprehensive Conservation and Management Plan for the Bay. Congress designated Tampa Bay an estuary of "national significance," thereby incorporating it into the Clean Water Act's National Estuary Program. Since its inception, the Tampa Bay National Estuary Program (TBNEP) has been guided by a nine-member Policy Committee which is responsible for establishing the long-term plan to restore and protect the Bay. To accomplish this goal, the TBNEP brought together local, county, State and federal governments, as well as concerned citizens, to identify and address their concerns about Bay issues. The Tampa Bay Regional Planning Council, representing 43 local governments in the region, assists with the administration of the TBNEP.

Preliminary Action Plans were developed in January of 1995 as the framework for the Comprehensive Conservation and Management Plan (CCMP). To further enlist public comment, the draft CCMP — *Charting The Course* — was presented during four town meetings held in February and March of 1996. The TBNEP expects that the final CCMP will be approved by the Governor and the Administrator of the EPA by the end of summer, 1996. Once the plan is approved, the TBNEP will work to attain the consent of the Policy Committee for an inter-governmental "implementation agreement," which they hope to have signed by November, 1996.

To date, the TBNEP has raised more than one million dollars in grants for wetland restoration projects, habitat-enhanced shoreline demonstration projects, and atmospheric deposition research. The Program has also awarded more than $50,000 to community partners to advance smaller Bay restoration and improvement projects.

The decision to give local government officials high profile roles on the Management and Policy

VOL 12

3902

R0037210

Committees of the Management Conference has been instrumental in ensuring their active participation in the planning process. The TBNEP also realized, from the outset, that close coordination with the Surface Water Improvement and Management (SWIM) Program, a program devoted to the restoration of waterways throughout Florida, would be critical to avoid duplication and ensure that there would be a single, unified management plan for the estuary. As a result, local government support for the TBNEP has been significant, especially compared to participation from other segments of the "stakeholder" population. Agricultural interests were slow to become involved in the early stages, while participation of the industrial groups has been mixed. Ongoing participation by broad based citizen groups and environmentalists has played a significant role in developing priorities for the TBNEP to begin implementation of the CCMP.

One of the lessons learned from the early stages of the Program is that the TBNEP tried to take on more issues than they were capable of coordinating. As a result, they were unable to address all the issues with the focus and resources necessary to adequately deal with the severity of the problems. Setting narrow priorities and limiting the overall number of issues is critical to the success of this type of broad-based watershed management initiative. However, in the process of narrowing priorities, it is critical that key information not get lost. The closure of the entire commercial shellfish industry in the Bay, does not appear in the draft CCMP until the 139th page in the document. The severity of this type of problem should not only be clearly highlighted as a major priority, but by so doing an issue like this would provide a tremendous opportunity to educate the public and motivate them into action.

Having learned from these lessons, the Program moved forward with some tremendous accomplishments. The TBNEP conducted extensive research on Bay water quality and habitat conditions. The results indicated that certain areas within the Bay have improved enough that they may now support the reintroduction of bay scallops.[45] As part of this effort, the TBNEP and Tampa BayWatch sponsor the "Great Bay Scallop Search" (in which volunteers snorkel the Bay's seagrass meadows searching for scallops) to assist in tracking long-term recovery trends. This data will provide a baseline for annual scallop surveys to record population trends. Homeowners along the Bay have also assisted in giving the scallops a head start. About 50 waterfront homeowners have agreed to allow the TBNEP to attach "scallop condos" to their docks to help them grow and survive in protective cages before they are released into the waters, where they are vulnerable to predators.

The TBNEP has had many other successes. Working with the Southwest Florida Water Management District, the Estuary Program has established preliminary nitrogen load reduction goals for the Bay. The Florida Yards & Neighborhoods Program was initiated by the TBNEP and has been applied throughout the region to educate landowners about preventing pollution in their communities. This program has encouraged residents, residential developers, and retailers to reduce fertilizer, pesticides, and water use by promoting and implementing environmental landscaping concepts.

Linking the commitments for action in the CCMP with appropriate regulatory programs also provides a strong incentive for TBNEP participants to follow through on implementation actions agreed to in the CCMP. Contaminated urban stormwater provides a good example because the permitting of discharges from municipal stormwater management systems is critical to protecting the future health of the Bay. Finally, to supplement the water quality and fisheries monitoring programs already being conducted by the local and state governments, the Tampa Bay NEP initiated two new monitoring programs in 1993. These two programs consisted of a benthic monitoring program to provide information on the health of bottom communities and the Great Bay Scallop Search monitoring program that uses citizen volunteers as mentioned above.

Tampa Bay's story shows a community rich in practical restoration experience with documented improvements in the Bay's resources due to habitat restoration action. However, capricious political trends have placed environmental restoration activities in serious jeopardy on a state-wide basis. Additionally, without federal and state support many local government programs and non-profit efforts will be rendered ineffective due to the lack of matching funds and other collateral support. Among the programs currently threatened by lack of State funding and political will is the SWIM program.

National Coastal Caucus

Tampa BayWatch is a non-profit environmental stewardship program devoted exclusively to the charitable and scientific purpose of restoring and protecting the marine and wetland environment of the Tampa Bay estuary. Tampa BayWatch employs trained professional staff to monitor and protect the Bay, and to coordinate public restoration and protection activities. The organization is currently operating under a grant to expand the TBNEP into the community via the Conservation Corps Network, which organizes citizens into a network to take on restoration projects. To date, Tampa BayWatch has recruited thousands of people from community groups, scout troops, and high schools to participate in monitoring and restoration activities, including: salt marsh plantings, shorebird nest site protection, storm drain marking, wildlife rescue, marine debris cleanups, and resource monitoring.

Members, staff, and the Board of Directors of Tampa BayWatch have played a key role in the development of the CCMP for the TBNEP. Specifically, it is the organization responsible for forwarding the nomination of Tampa Bay to the Governor for inclusion in the NEP process. In so doing, Tampa BayWatch helped develop the Nomination Package upon which the CCMP is based. In addition, the organization currently acts as co-chair of the Citizens Advisory Committee and sits on the Technical Advisory and Management Committees.

Tampa Bay is one of the few estuaries in the nation to have the benefit of actively managed water quality during the last 20 years, and restored natural habitat communities for the past 15 years. Because of this commitment, Tampa BayWatch is able to use this experience to document resource improvements resulting from management efforts, such as those of the TBNEP. Water quality has improved throughout the estuary to levels not seen since the 1960s. One example of how these improvements have translated into tangible benefits for the Bay is the natural recolonization of over 4,000 acres of subtidal seagrass beds, allowing the reintroduction of sensitive scallops in the Bay waters.

Tampa BayWatch is pleased with these successes but realizes much more work needs to be done. The organization and its committed public are a first line of defense against negative impacts to the Bay. Time and again, violations of environmental law are identified and reported by individuals who are routinely on the water. Tampa BayWatch provides a central clearing house for this information, passing it along to the appropriate authorities. The organization also ensures that environmental scientists are available to evaluate the information and follow up on enforcement actions.

Tillamook Bay
in Oregon

Tillamook Bay is one of the really critical areas on the Oregon coast for salmon and a wide variety of migratory birds. It has experienced massive ecological changes over the past century, and still has some serious problems today. The National Estuary Program gives us an opportunity to work with the community to address those problems before they get worse and to begin taking steps to restore some key pieces of the natural system.

—Bruce Taylor, Executive Director
Oregon Wetlands Joint Venture

Portrait of the Bay

The Tillamook Bay National Estuary Project is examining the water quality and habitat problems of the Tillamook Bay system and the impact that the larger watershed area has on the estuary. Tillamook Bay is located in northwestern Oregon, about sixty miles west of Portland. The Bay's water surface area measures 11 square miles.[1] The Bay is approximately six miles long. Its maximum width is three miles;[2] and its average depth is a shallow six feet.[3]

The watershed area of Tillamook Bay covers approximately 570 square miles, extending from the mountains of the Coastal Range to the Pacific Ocean.[4]

Tillamook Bay

Area of surface water	11 square miles
Area of watershed	570 square miles
Length	6 miles
Average depth	6 feet
Values	• Fisheries generate $86 million* • Sport fishing generates $940 million in economic output* • Important habitat for a variety of waterfowl, shorebirds and other wildlife
Threats	• Pathogen contamination • Sedimentation • Habitat loss and degradation
CCMP status	Final expected in 1998

Designated as a "Nationally Significant" Estuary in 1992.

Most of the watershed is located within Tillamook County; its largest municipalities are Garibaldi, Bay City and Tillamook. The combined 1994 population estimate for these three cities was 6,200 people.[5] Eighty-nine percent of the watershed is forested land, less than seven percent is agricultural, and less than two percent is urbanized.[6] With over 200 dairies in Tillamook County, milk and cheese production represent a significant portion of the local economy.[7] Unfortunately, the pollution caused by this industry is not currently compatible with the Bay's finfish, shellfish, and other natural resource-based industries.

Tillamook Bay's connection with the Pacific Ocean is limited to a narrow channel in the northwestern portion of the Bay. A four-mile long peninsula, called the Bayocean Spit, separates the Bay from the ocean and forms the western boundary of the Bay. Most of the freshwater entering the Bay is delivered by five rivers — the Miami, Kilchis, Tillamook, Wilson, and Trask Rivers.[8]

The Bay supports substantial acreage of intertidal flats. Up to 60 percent of the Bay's water surface area consists of these intertidal flats.[9] Salt marsh, mud flats, and seagrasses can be found in the estuary; eelgrass beds cover portions of the Bay's bottom.

Values of the Bay

Communities along the northern Oregon coast rely on the health and productivity of Tillamook Bay to help support their economies. Fishing, recreation, and tourism are key components of the local, natural resource-based economies. In addition, the wildlife, recreational opportunities, and natural appeal afforded by the Bay are attracting growing numbers of new residents to the area. Acknowledgment of the economic benefits derived from restoring the Bay and protecting its resources has increased the motivation of the community to develop a coordinated conservation strategy for this estuary.

Recreation/Tourism

The natural beauty of the Oregon coast and the variety of recreational pursuits it offers draw many visitors to Tillamook Bay each year. As the economies of Pacific Northwest communities diversify, the ecotourism sector is becoming more prominent in the Bay area. In Tillamook County, eight percent of the residents' personal earned income originates from the tourism industry.[10] Some of the most popular activities in the Bay area include sport fishing, hiking, camping, clam digging, bird watching, and boating.

In the State of Oregon, sport fishing is a particularly prominent and valuable recreational activity. In 1991, recreational fishing boosted Oregon's economy by approximately $940 million, and supported more than 15,000 jobs.[11] During the same year, 225,000 saltwater anglers spent over one million days fishing off the Oregon coast.[12] Thirty percent of the fishers were non-residents of the State.[13]

Each of the five major rivers within the watershed supports anadromous fish runs. Tillamook Bay and the Wilson and Trask Rivers are considered some of the State's best areas for salmon and trout fishing.[14] The widely reputed fall chinook runs and the summer steelhead catches lure significant numbers of sport fishers to the Bay each year. In addition to salmon and trout, surfperches, white sturgeon, green sturgeon, rockfish, and lingcod are caught in and near the Bay by anglers.[15] Also popular are the charter boat excursions from the Port of Garibaldi for salmon and groundfish fishing.

Fisheries/Seafood

In 1994, the combined market value of commercial finfish and shellfish landings in the Pacific region (excluding Alaska) totaled approximately $401 million.[16] Many of the commercially valuable species in the Pacific region depend upon the health of Tillamook Bay for survival. The State of Oregon's commercial finfish and shellfish landings in 1994 totaled approximately 246 million pounds, valued at $66 million.[17]

Tillamook Bay fisheries provide jobs for many residents in the area. The Bay's commercial fisheries are responsible for generating nine percent of the personal earned income in Tillamook County.[18] The Bay is reputed as the State's leading commercial shellfish producer, of which oysters and clams provide the greatest commercial landings.[19] In 1985, 300,000 pounds of oysters were caught from the Bay; the total State harvest was 424,000 pounds.[20] Between 1984 and 1994, 60 percent of Oregon's commercial clam harvest

VOL 12

3908

was caught in Tillamook Bay.[21] In 1994, over 150,000 pounds of clams were harvested from the estuary.[22]

Groundfish, coho salmon, chinook salmon, pink shrimp, and Dungeness crab are commercially caught in the nearby ocean waters. Since these species use the Bay and its tributaries for spawning and nursery habitat, the Bay's water quality and habitats are critical to the continued vitality of these fish and shellfish populations.

Wildlife

Overall, wildlife diversity in the Tillamook Bay watershed is typical of the Oregon Coastal Range, which ranks second in species diversity among the State's ten ecological provinces. Native species regularly using four selected habitat types (estuaries, coniferous forests, riparian, and marshes) include 256 bird species and 61 mammal species.[23] The salt marshes, mudflats, eelgrass beds, and open waters of Tillamook Bay provide some of the most important areas along northern Oregon's coastline for shorebirds and waterfowl. The Bay area contains over one-quarter of coastal Oregon's entire wintering waterfowl population.[24] It is one of three estuaries in Oregon where wintering brant can be found.[25] It is also among the six most important estuaries north of San Francisco Bay for migratory shorebirds along the Pacific Flyway.[26]

The Pacific Harbor seal is the most common marine mammal inhabitant of the estuary. California sea lions and orca whales can occasionally be observed in the Bay. Stellar sea lions can sometimes be observed on Seal Rock, which is part of the Three Arch Rocks National Wildlife Refuge, a few miles southwest of the Bay.

Tillamook Bay provides valuable habitat for a number of threatened and endangered animal species. For example, the endangered California brown pelican and the threatened bald eagle, Aleutian Canada goose, western snowy plover, and marbled murrelet use the estuary. The Bayocean Spit is one of the most populated breeding areas for the snowy plover in the State.[27] In addition, the marbled murrelet feeds at the mouth of the Bay and nests in at least one of the watershed's forests.[28]

Threats to the Bay

The rural character of Tillamook Bay's watershed has spared it from many of the pollution problems affecting other Pacific Coast estuaries. Nonetheless, fish and shellfish populations have been declining and habitat has been disappearing along the Bay. Communities near the Bay are planning to address three major threats to the future vitality of the estuary and its natural resources. These priority environmental problems are pathogen contamination, sedimentation, and loss of living resources/loss of habitat.

Pathogen Contamination

Pathogens are disease-causing microorganisms found in human and animal wastes which enter the Bay primarily through runoff from agricultural lands, sewage treatment plant discharges and raw sewage overflows, septic systems, and boating wastes. Pathogens in coastal waters pose risks to humans who eat contaminated shellfish or who recreate in beach waters. Gastroenteritis, hepatitis, and other diseases can result from the ingestion of pathogen-contaminated waters. For this reason, in some states, beaches and shellfish beds are closed or restricted to both recreational and commercial shellfish harvesting when water quality monitoring indicates elevated levels of fecal coliform bacteria (an indicator of pathogen contamination) are present in coastal waters.

The Oregon Health Department has the authority to post notices and close beaches if sewage spills pose public health risks. However, Oregon's bay and ocean beaches are not regularly monitored to ensure that water quality is safe for swimming and water contact sports,[29] and posting does not often, if ever, occur. Recently, the Oregon Department of Environmental Quality required the City of Garibaldi to post notices in an area subject to overflows of raw sewage. The Oregon Department of Environmental Quality does conduct monitoring for purposes of shellfish bed classification.[30] Tillamook Bay is sampled 10 times a year at 16 different stations for fecal coliform bacteria, salinity and temperature.[31]

High concentrations of bacteria frequently lead to shellfish harvest closures in the Bay. Currently, there are no "approved" commercial shellfish harvest areas in all of Tillamook Bay. Thus, all harvest areas have at least partial restrictions on harvesting. The Main Bay and Cape Meares portions of the Bay are "conditionally approved," meaning they are rou-

VOL 12 3909

R0037217

tinely closed following heavy rain events.[33] Shellfish harvesting is prohibited in the large southeastern and southern portions of the Bay known as Upper Bay, and for the area around Garibaldi.[35] These prohibited areas comprise over 20 percent of the Bay.[34] Typically, shellfish harvesting is prohibited 50 to 90 days a year due to suspected pathogen contamination.[35] Recreational harvesting for clams is allowed, but is subject to occasional red tide advisories.

Four small municipal wastewater treatment plants and extensive dairy production in the Tillamook Bay watershed are thought to be significant sources of the Bay's bacterial contamination. The area supports over 23,000 dairy cows which generate a cumulative 3 million tons of manure and urine annually.[36] Some dairy farmers are trying to minimize pollutant loading into the Bay by building structures, such as manure sheds and storage tanks. These facilities assist in restricting the concentrations of animal waste running off agricultural lands and into tributaries of the Bay. Unfortunately, many of these facilities also overflow, releasing waste into the Bay and its tributaries.

Most, if not all, dairy farms engage in the practice of spraying liquid manure on lands in amounts that exceed levels which plant life can uptake and use. Often the amounts are so great that they actually kill plants and trees. Due, in part, to the installation of tile drains in diked pastures which were formerly wetlands, this manure is carried quickly to waterways that drain into the Bay.[37] Since a study conducted by the Oregon Department of Environmental Quality identified animal waste as a major source of pollution for the Bay, local government agencies and the Tillamook County Creamery Association together have attempted to improve management practices.[38]

Sedimentation

As a result of the massive amount of sediment entering the estuary, the water volume of the Bay has decreased by 35 percent from historical levels.[39] Increased inputs of sediment also inhibit the productivity of the estuary's salt marshes, mud flats, and seagrasses. Sediments can smother aquatic plants and increase turbidity in the water, blocking sunlight needed for the growth of eelgrass beds.

Between 1918 and 1951, five major fires roared through the watershed area resulting in the destruction of forested habitat and the overall decline of the watershed's environmental health.[40] These fires caused massive shoreline erosion problems, and subsequently, greater loadings of sediments into the Bay and its tributaries. Since then, forestry and agricultural practices throughout the watershed have led to further erosion of stream and river banks. In addition, the natural flooding of rivers and the breaching of the Bayocean Spit have delivered more sediments to the estuary.

Mass wasting, a process in which landslides dump immense amounts of sediment into surrounding rivers and streams, is the leading cause of sedimentation in the Tillamook Bay system. The improper construction and inadequate maintenance of roads built to access lands for salvage logging practices is the primary cause of mass wasting. Another cause of sedimentation in Tillamook Bay is the high rate of erosion from steep slopes of cleared forest lands.[41] The reforestation of previously clear-cut areas is helping to lower the rates of sediment delivery into the Bay, but much more needs to be done to address this problem.

In 1952, the Bayocean Spit was breached by the Pacific Ocean. Gravel and sediments from the peninsula buried important tidal flats and altered the hydrology of the Bay.[42] The construction of jetties at the mouth of the Bayocean Spit is suspected to have altered the transport of sand needed to maintain the Spit and may have contributed to the breach.[43]

Habitat Loss and Degradation

As forests and pasture lands dominate the Tillamook Bay watershed, the problems faced by more urbanized lands are minimal in this estuary. To support agricultural production in the watershed, upland and freshwater wetlands have been converted to farm and pasture lands. In addition, tidal wetlands of the watershed have been diked. It is estimated that approximately 72 percent of the historical intertidal habitat has been lost to agriculture and other development activities.[44] These modifications have seriously harmed the ecology of the Bay and its watershed and are negatively impacting wildlife populations and diversity. Declining runs of salmon and trout are a particular concern.

VOL 12

3910

R0037218

The degradation of aquatic habitats in the Tillamook Bay watershed has harmed steelhead, chum, and coho salmon runs in the rivers. Today, Tillamook Bay's coho salmon stocks are declining at a faster rate than any other watershed's coho stocks in northern Oregon.[45]

Additional Concerns

Trash accumulated on estuarine beaches threatens the ecosystem and its wildlife inhabitants. On September 24, 1994, volunteers cleared 23,064 pounds of marine debris from 135 miles of beach area in Oregon. Of the total amount of marine debris collected, 66 percent was plastic, 14.5 percent was paper, 7.7 percent was metal, and 11.8 percent was from other materials.[46]

Toxic contamination and excessive loadings of nitrogen and phosphorus are other potential problems facing Tillamook Bay. However, more studies need to be conducted in order to reach any conclusions on their effect on the water quality of the Bay.

Tillamook Bay National Estuary Project

In the Spring of 1992, Tillamook Bay was designated as an estuary of "national significance" under the National Estuary Program of the Clean Water Act. Due to a lack of funding, the program suffered some initial delays in getting off the ground. However, by June, 1994 the Tillamook Bay National Estuary Project (TBNEP) had been established and the Management Conference Agreement and the start-up activities were completed. The TBNEP is a joint local, State and federal effort that is charged with coming up with a comprehensive plan to address the environmental problems of and to test possible solutions for Tillamook Bay and its watershed. The TBNEP has begun conducting research and gathering the data needed to produce its draft Comprehensive Conservation and Management Plan (CCMP) for the Bay. The target date for approval of the CCMP by the Governor and the Administrator of the EPA is July, 1998.

There are several committees responsible for feeding information into the Plan, including a Policy Committee, Management Committee, Scientific/Technical Advisory Committee, Finance Committee and Citizen Involvement Strategy Advisory Committee. Since it is a community-based initiative, all public and private agencies, organizations and individuals interested in the welfare of the Bay are involved in managing the Project. The TBNEP has encouraged many local residents to participate in the preservation of the estuary by sponsoring outreach and education programs, as well as training seminars, for area teachers. The Project has made strides in helping the public to understand that by preserving the watershed, the economies of the local communities which depend on the Bay are also protected. However, some citizens find participation in the Project difficult because the political power of the county is dominated by the dairy industry. There is growing concern about whether there will be a consensus to change the status quo.

In the early stages of the program, the TBNEP focused on providing the funding to research the many gaps of information regarding the Bay's ecology. Several projects conducted during the first year were interagency efforts focused on the technical characterization of the Bay and its watershed. Interagency coordination has been particularly effective in habitat inventory and watershed analyses.

One of the most recent projects is a Historical Reconstruction Study to focus on the physical changes in various characteristics of the watershed, such as: plant communities, stream flow patterns, and factors affecting the rate at which sediments reach the Bay.[47] The Study will provide information about how human activities and physical processes have changed the character and values of key resources in the Bay. In addition, a water circulation model has been developed to determine movements of sediments and bacteria throughout the watershed. Other projects include a watershed analysis and several fishery research projects including the development of a coho task force, salmonid habitat restoration maps, expanded coho spawning survey, and aquatic inventories. In October of 1995, over 50 percent of the stream miles in the Bay's watershed were surveyed by the Oregon Fish and Wildlife Service and Department of Forestry.[48] A Geographic Information System (GIS) computerized mapping program is also being utilized to document trends in land use and resource changes in the watershed.

VOL 12

391

National Coastal Caucus

Northwest Environmental Advocates (NWEA) is a 27-year old membership organization focused on water quality and wetlands protection in Oregon and Washington. NWEA is involved in litigation to force the States to perform Total Maximum Daily Loads (TMDLs) on waterbodies with unsafe levels of pollution. NWEA's interest in Tillamook Bay is primarily in developing regulatory controls on the disposal of manure and in establishing a program to restore former wetlands through dike breaching.

The Oregon Wetlands Joint Venture is a coalition of private conservation, waterfowl, and agricultural organizations and State and federal resource agencies. Direction is provided by the Steering Committee, made up of representatives of private, non-profit organizations. The coalition serves as a statewide umbrella for actions in Oregon under two larger, regional wetland habitat restoration initiatives — the Pacific Coast Joint Venture and the Intermountain West Joint Venture. Overall, the Joint Venture's mission is to create partnerships among agencies and organizations for projects to restore and enhance wetlands on public and private lands. Although Joint Venture has not previously been involved in projects in the Tillamook Bay region, its involvement in the NEP process demonstrates a commitment to wetlands habitat restoration in the watershed area of the Bay. The Joint Venture coalition encourages wetlands acquisition, or placing sensitive habitat into permanent protection to ensure long-term habitat protection. With a prospective project for 1996 involving continued wetlands restoration in the Tillamook Bay region, Oregon Wetlands Joint Venture intends to encourage the TBNEP to heighten its emphasis on wetlands restoration.

Oregon Wetlands Joint Venture has been a participant in the Tillamook Bay NEP since the project's inception. The Joint Venture's executive director serves as the "environmental interests" representative on the NEP's Management Committee and has participated on a number of subcommittees involved in developing NEP budgets and work plans, evaluating grant requests, and developing strategies for the draft CCMP.

CHAPTER 7

Recommendations to Strengthen National Estuary Program

Congress established the National Estuary Program (NEP) under section 320 of the Federal Water Pollution Control Act (commonly called the Clean Water Act) in its 1987 Amendments to the Act. The conference report for the 1987 Amendments stated that Congress was setting a "national policy to maintain and enhance the water quality in estuaries and provide for the biological integrity of these waters"[1] by creating the National Estuary Program. One of the main objectives of the NEP is to address the many complex issues — such as habitat destruction, pollution, resource management and land-use planning — that have contributed to the deterioration of the nation's estuaries.

As the NEP has expanded from six to 28 estuaries, several recommendations for improving the Program have been developed by representatives of citizens' groups who are active participants in their local estuary program. This coalition of grassroots activists, called the National Coastal Caucus (NCC), has suggested ways to improve the Program through legislative means. A collaborative effort has developed between the NCC and a number of dedicated members of Congress and their staff to propose legislative improvements to the National Estuary Program.

In recent years, several administrative actions to strengthen the Program have been taken by the Environmental Protection Agency. To reflect these changes, the legislative proposal has been regularly updated.

In each Congress since 1991, Representatives Rosa DeLauro (D-Connecticut) and Nita Lowey (D-New York), and Senators Joseph Lieberman (D-Connecticut) and Christopher Dodd (D-Connecticut) have introduced the Water Pollution Control and Estuary Restoration Act. This bill has incorporated legislative recommendations advocated by the National Coastal Caucus. In the 102nd Congress, H.R. 5070 was supported by 50 bi-partisan co-sponsors. The Senate counterpart to H.R. 5070 was S. 2831. During the 103rd Congress, H.R. 1720 was co-sponsored by over 60 Representatives. In addition, a significant portion of its Senate counterpart, S. 815, was accepted by the Senate Environment and Public Works Committee in its version of the bill to reauthorize the Clean Water Act, S. 2093. In the 104th Congress, H.R. 1917 was introduced on June 22, 1995. The Senate version will be introduced in 1996.

The National Coastal Caucus believes that adoption of these suggestions by Congress would improve the National Estuary Program and help to ensure the implementation of restoration plans, active citizen participation, and efficient coordination of all stakeholders during the planning process. Not only would these proposals enhance the environmental health of estuaries, they would also create jobs in coastal communities through expanded infrastructure investments.

Key recommendations for improving the National Estuary Program:

- ***Require implementation of approved Comprehensive Conservation and Management Plans (CCMPs).*** Section 320(f)(2) of the Clean Water Act explicitly states that approved CCMPs shall be implemented. However, in actuality, many approved estuary plans are not being sufficiently implemented due to funding constraints and a lack of political will among local, State, and federal elected officials. During the nomination and development of CCMPs, local and State officials are intensely involved in the planning process. In addition, the Governor must concur with the Plan before the EPA Administrator approves the CCMP. Due to their involvement throughout the development of the plan, elected officials should be supportive of the restoration efforts highlighted in the Plan and should

VOL 12

3914

R0037222

not be allowed to excessively delay the implementation phase. Further, citizens should be given a mechanism to ensure that officials are held accountable for the actual implementation of CCMPs. This will maximize the benefits of local citizens' investment of time and the nation's investment of resources that are expended during the planning process.

Local estuary restoration programs have been generally successful at identifying water quality problems and raising public awareness about the importance of protecting the estuary. However, it is essential that the National Estuary Program extend beyond identifying problems to implementing solutions. In order for this to occur, a stronger federal commitment must be made to the NEP. Section 320 of the Clean Water Act should be amended to clarify that implementation of approved estuary conservation and management plans is a non-discretionary duty of the Environmental Protection Agency, and a "set-aside" of federal financial assistance should be provided to aid in implementing plans.

• ***Assure funding to implement CCMPs.*** Due to State budget shortfalls and diminishing federal financial support, many States have been unable to implement their approved CCMPs. The Clean Water Act should include a funding mechanism to ensure that States are provided federal assistance to properly implement, monitor, and enforce CCMPs. Otherwise, the federal funds expended on crafting the plans will have been unwisely spent since actions to actually improve the estuary would not result. Approved estuary restoration plans represent the conclusions of a consensus-based process involving key stakeholders, and therefore should receive priority consideration for funding. Providing funds for implementation rewards the timely development of strong CCMPs that have garnered the full support of the community. Federal funding also provides incentives for states to undertake the more politically difficult task of putting the planning elements into practice. The most obvious source of federal monies for CCMP implementation funds is the Clean Water Act's State Revolving Loan Fund (SRF) program; however, current appropriation levels are severely inadequate to meet the growing demand for funding. The SRF should be increased to a minimum of $5 billion per year with a specific set-aside for implementation of Comprehensive Conservation and Management Plans.

• ***Increase citizen involvement.*** In many of the local programs, citizen participation in the development of CCMPs has been inadequate and inconsistent. The National Estuary Program would be strengthened by requiring citizen participation, and specifically representation by environmental organizations, in all aspects of the CCMP process. Rather than have citizens appointed primarily to the Citizens Advisory Committee, citizen representatives should also hold positions on other committees, including the Management and Policy Committees. In some cases, financial assistance to ensure full citizen participation on these committees might be necessary. In addition, public hearings should be held on a regular basis throughout the life of the program. The active recruitment of citizens to participate in the development of CCMPs will assist in building the public's commitment to take actions for restoration.

The Water Pollution Control and Estuary Restoration Act has been endorsed by over 150 local, regional, and national environmental organizations, labor organizations, and industry groups. The hopes of improving the National Estuary Program, restoring our productive coastal waters, creating jobs, and investing in clean water infrastructure projects are the major benefits which have brought this diverse coalition together.

Conclusion

American Oceans Campaign and the National Coastal Caucus are encouraged by federal, state, and local efforts to restore and protect the ecological integrity of the 28 "nationally significant" estuarine ecosystems around the nation. With the lessons learned and the accomplishments made by each local Estuary Program, a viable model has been created which can be used to assist future watershed planning efforts.

For the bounty of life they produce and nourish; the economies they boost and support; and the aesthetic qualities and recreational opportunities they offer; estuaries are a symbol of life and sustenance. It is not too late to halt the environmental abuse we have wrought on many of these priceless systems by way of pollution, habitat destruction, and coastal development. Nor is it too early to protect the more pristine estuaries from the levels of degradation faced by more urbanized ones. The situation is dire; yet with greater support to replenish these vital links between land and sea, the wealth and productivity of estuaries will be ensured for generations to come. The question that remains is whether or not we as a nation have the political will to fully fund and implement plans to revitalize our "nationally significant" estuaries and their living resources.

VOL 12

3916

National Coastal Caucus Contacts

The National Coastal Caucus ("NCC") was established by American Oceans Campaign in February of 1991 to provide an organized framework for like-minded groups to work together on issues of mutual concern. While recognizing that much of the important work of protecting our coasts, estuaries and oceans is best accomplished at the local and state levels, the NCC believes that the federal government's influence is also extremely important. Indeed, the concept of the NCC evolved out of the need to build and reinforce relationships among local, state and federal players.

Since its inception, the NCC has worked to strengthen the federal Clean Water Act ("CWA"). In doing so, it has supported other national coalition-building initiatives, such as the Clean Water Network. The NCC's work complements the work of the Network on a full range of CWA issues and has filled a void by focusing on the National Estuary Program, which previously lacked a major grassroots constituency. The following people and organizations participate in the NCC:

B

Glossary of Terms

Algae Simple rootless plants that grow in bodies of water.

Anadromous Fish Those fish, such as salmon, that spend part of their life cycle in the ocean and return to freshwater streams and rivers to spawn.

Anoxia The absence of oxygen.

Bayou A marshy or sluggish body of water that is a tributary to another body of water.

Bioaccumulation The process by which some persistent contaminants accumulate through the food chain and become biologically magnified. That is, contaminants concentrate as they travel via digestive processes up to higher levels of the food chain.

Biological Oxygen Demand The amount of oxygen used by organic matter in water. High levels of BOD can remove oxygen needed to support fish and other aquatic life.

Brackish A combination of saltwater and freshwater, common to coastal wetlands and estuaries.

Bycatch Fish and other marine life caught incidentally while fishing for something else.

Combined Sewer Overflow (CSO) A pipe that discharges untreated wastewater during storms from a sewer system that carries both sanitary wastewater and stormwater. The overflow occurs because the system does not have the capacity to transport, store, or treat the increased flow caused by stormwater.

Commercial Landing The quantity of fish or shellfish brought ashore by a commercial fishing operation.

Dredging The mechanical removal of sediment from the bottom of canals, rivers, or harbors.

Ecosystem A natural community of living organisms interacting with one another and with their physical environment, such as an estuary, rain forest or salt marsh. Damage to any part of a complex system may affect the whole. A system as complex as an estuary can also be thought of as the sum of many interconnected ecosystems such as the rivers, wetlands and bays.

Effluent The liquid waste that flows out of a facility or household into a waterbody or sewer system. For example, the treated liquid discharged by a wastewater treatment plant is the plant's effluent.

Estuary A partially enclosed, coastal water body where fresh water empties into and mixes with saltwater.

VOL 12

3920

VOL 12

Eutrophication
Inundation of a marine environment with nutrients, leading to excessive growth of phytoplankton, algae, or vascular plants, and often depletion of oxygen.

Floatable Debris
Garbage and trash which is dumped or is carried into the ocean. Also known as marine debris.

Habitat The environment on which an animal or plant depends for various stages of its life cycle.

Heavy Metals
Metallic elements, such as lead, mercury, silver, cadmium, copper, chromium and zinc, which have relatively high atomic weights and may be toxic at high concentrations.

Hypoxia A state of low oxygen concentration relative to the needs of aerobic species.

Inlet A short, narrow waterway connecting a bay or lagoon with the ocean.

Intertidal Area
The area between high and low tide levels. The alternate wetting and drying of this area makes it a transition between land and water and creates special environmental conditions.

Mangrove Forest
A community of salt-tolerant trees, with associated shrubs or vines and other organisms, that grows in a zone roughly coinciding with the intertidal zone along protected tropical and subtropical coasts.

Marine Debris
See Floatable Debris.

Marsh A wetland where the dominant vegetation is non-woody plants such as grasses and sedges, as opposed to a swamp where the dominant vegetation is woody plants like trees.

Nonpoint Source Pollution
Pollution that enters water from dispersed and uncontrolled sources (such as surface runoff) rather than through pipes. Nonpoint sources (e.g., forest practices, agricultural practices, on-site sewage disposal, and recreational boats) may contribute pathogens, suspended solids, and toxicants. While individual sources may seem insignificant, the cumulative effects of nonpoint source pollution can be significant. Also known as polluted runoff.

Pathogen An agent such as a virus, bacterium or fungus that can cause disease in humans.

Point Source
Any discernible, confined, and discrete conveyance, including but not limited to any pipe, ditch, channel, tunnel, conduit, well, discrete fissure, container, rolling stock, concentrated animal feeding operation, or vessel or other floating craft, from which pollutants are or may be discharged.

Pollutant A substance that adversely alters the physical, chemical, or biological properties of the environment. As defined in the federal Clean Water Act, pollutant means dredged spoil, solid waste, incinerator residue, sewage, garbage, sewage sludge, munitions, chemical wastes, biological materials, radioactive materials, heat, wrecked or discarded equipment, rock, sand, cellar dirt, and industrial, municipal, and agricultural waste discharged into water.

3921

Polycyclic or Polynuclear Aromatic Hydrocarbons (PAHs)
A class of complex organic compounds, some of which are persistent and cancer-causing. These compounds are formed from the combustion of organic material. PAHs are commonly formed by forest fires and by the combustion of gasoline and other petroleum products.

Primary Treatment
A wastewater treatment method that uses settling, skimming, and chlorination to remove solids, floating materials, and pathogens from wastewater. Primary treatment typically removes about 35 percent of biochemical oxygen demand and less than half of the metals and toxic organic substances.

Runoff Water that is not absorbed into the ground and hence which flows into streams or other bodies of water, or into a drain or sewer.

Seagrass A flowering plant that lives underwater and provides habitat for aquatic life.

Secondary Treatment
A wastewater treatment method that usually involves the addition of biological treatment to the settling, skimming, and disinfection provided by primary treatment. Secondary treatment may remove up to 90 percent of biochemical oxygen demand and significantly more metals and toxic organic material than primary treatment.

Sediment Material suspended in or settling to the bottom of a liquid, such as sand and mud.

Septic System
A system of tanks and porous pipes in which sewage is decomposed by anaerobic bacterial action and usually filtered by soil.

Submerged Aquatic Vegetation (SAV)
Plants that grow for the most part under water.

Tidal Flat Level, muddy surface bordering an estuary that is alternately submerged and exposed to the air by changing tidal levels.

Turbidity A cloudy condition in water caused by suspended silt or organic matter.

Watershed A geographic area in which water, sediments and dissolved materials drain to a common outlet — to a point on a larger stream, lake, underlying aquifer, estuary or ocean.

Wetlands Critical ecosystems, commonly called marshes, bogs, and swamps. Wetlands function naturally to preserve environmental quality by controlling floods and filtering contaminants from water. In addition, wetlands provide essential habitat for fish and wildlife.

FOREWORD

Today's rapidly developing and changing technologies and industrial products and practices frequently carry with them the increased generation of materials that, if improperly dealt with, can threaten both public health and the environment. The U.S. Environmental Protection Agency is charged by Congress with protecting the Nation's land, air, and water resources. Under a mandate of national environmental laws, the Agency strives to formulate and implement actions leading to a compatible balance between human activities and the ability of natural systems to support and nurture life. These laws direct the EPA to perform research to define our environmental problems, measure the impacts, and search for solutions.

The Risk Reduction Engineering Laboratory is responsible for planning, implementing, and managing research, development, and demonstration programs to provide an authoritative, defensive engineering basis in support of the policies, programs, and regulations of the EPA with respect to drinking water, wastewater, pesticides, toxic substances, solid and hazardous wastes, and Superfund-related activities. This publication is one of the products of that research and provides a vital communication link between the researcher and the user community.

The purpose of this User's Guide is to provide guidance to municipalities for investigating non-stormwater entries into storm drainage systems. Contaminated non-stormwater entries into storm drainage systems have been shown to contribute substantial levels of contaminants to the Nation's waterways. These entries may originate from many diverse sources including sanitary wastewaters from leaky or directly connected sanitary sewerage and from poorly operating septic tank systems, washwaters from laundries and vehicle service facilities, and many types of industrial wastewaters that are discharged to floor drains leading to the storm drainage or from direct industrial wastewater connections to the storm drainage system. Conventional pollution control programs may be ineffective if these pollutant sources are not identified and corrected.

This User's Guide will be useful to municipalities in conducting required studies as part of their stormwater discharge permit activities, in addition to other interested users. It will enable users to identify the type and to estimate the magnitude of non-stormwater pollutant entries into storm drainage systems and to design needed pollution control activities. An associated demonstration project (Pitt and Lalor publication pending) describes the development and testing of the procedures presented in this User's Guide.

E. Timothy Oppelt, Director
Risk Reduction Engineering Laboratory

ABSTRACT

This User's Guide is the result of a series of EPA sponsored research tasks to develop a procedure to investigate non-stormwater entries into storm drainage systems. A number of past projects have found that dry-weather flows discharging from storm drainage systems can contribute significant pollutant loadings to receiving waters. If these loadings are ignored (e.g., by only considering wet-weather stormwater runoff), little improvement in receiving water conditions may occur with many stormwater control programs. These dry-weather flows may originate from many sources, the most important sources may include sanitary wastewater or industrial and commercial pollutant entries, failing septic tank systems, and vehicle maintenance activities. After identification of the outfalls that contain polluted dry-weather flows, additional survey activities are needed to locate and correct the non-stormwater entries into the storm drainage systems.

This User's Guide contains information to allow the design and conduct of local investigations to identify the types and to estimate the magnitudes of these non-stormwater entries.

This report was submitted in partial fulfillment of contracts numbered 68-03-3255 and 68-C9-0033 and cooperative agreement CR-816862 under the sponsorship of the U.S. Environmental Protection Agency. This report covers a period from October 1, 1990 to September 30, 1992, and work was completed as of September 30, 1992. This report was prepared under subcontract to Foster-Wheeler Enviresponse, Inc. of Edison, New Jersey, and the Urban Waste Management and Research Center of the University of New Orleans.

ACKNOWLEDGMENT

This User's Guide contains information that has been developed and tested in a number of separate research reports investigating inappropriate pollutant entries into storm drainage systems. Many case studies were reviewed during early parts of this research to identify the most appropriate methods of investigation. Information that was obtained from these cities is gratefully acknowledged.

Valuable technical assistance concerning industrial dry-weather discharges was provided by Mark Miller and Tom Meinholtz (Triad Engineering, Inc.) who were supported by Kevin Weiss of the NPDES Branch, Permits Division, Office of Water, of the EPA through the Cadmus Group, Inc. Early report guidance was also provided by Gene Driscoll (Woodward Clyde Consultants), also supported by the Permits Division, Office of Water, of the EPA. Dan Murray, of the Center of Environmental Research Information, Cincinnati, Ohio, EPA, also provided support for the publication of this Guide.

Richard Field, Chief of the Storm and Combined Sewer Pollution Control Program, EPA, was the Project Officer for this project and provided much valued direction during this research. Michael Brown and Marie O'Shea of his staff, along with Ramjee Raghavan at Foster Wheeler Enviresponse, Inc., also provided important project assistance. Darwin Wright of the Office of Research and Development, EPA is gratefully acknowledged for his suggestion to work with the University of New Orleans, Urban Waste Management and Research Center to conduct EPA stormwater research activities. Helpful comments from the report reviewers are also gratefully acknowledged.

3933

SECTION 1

INTRODUCTION

Current interest in illicit or inappropriate connections to storm drainage systems is an outgrowth of investigations into the larger problem of determining the role urban stormwater runoff plays as a contributor to receiving water quality problems. Urban stormwater runoff is traditionally defined as that portion of precipitation which drains from city surfaces exposed to precipitation and flows via natural or man-made drainage systems into receiving waters. An urban stormwater drainage system also conveys waters and wastes from many other sources. For example, Montoya (1987) found that slightly less than half the water discharged from Sacramento's stormwater drainage system was not directly attributable to precipitation. Sources of some of this water can be identified and accounted for by examining current NPDES (National Pollutant Discharge Elimination System) permit records, for permitted industrial wastewaters that can be discharged to the storm drainage system. However, most of the water comes from other sources, including illicit and/or inappropriate entries to the storm drainage system. These entries can account for a significant amount of the pollutants discharged from storm drainage systems (Pitt and McLean 1986).

The U. S. Environmental Protection Agency's (EPA's) Office of Research and Development's Storm and Combined Sewer Pollution Control Program and the Office of Water's NPDES Program Branch have supported the development of this User's Guide for the investigation of inappropriate entries to storm drainage systems. This User's Guide is designed to provide information and guidance to local agencies by meeting the following objectives of:

1. Identifying and describing the most significant pronounced sources of non-stormwater pollutant entries into storm drainage systems.

2. Describing an investigative procedure that will allow for the determination of whether significant non-stormwater entries are present in a storm drainage system, and then to identify the particular source, as an aid to the ultimate location of the source.

The background study prepared in conjunction with this User's Guide (Pitt and Lalor publication pending) examined three categories of non-stormwater outfall discharges: pathogenic/toxicant, nuisance and aquatic life threatening, and clean water. The most important category is outfall discharges containing pathogenic or toxic pollutants. The most likely sources for this category are sanitary or industrial wastewaters. The outfall analysis procedure described in this User's Guide has a high probability of identifying all of the outfalls in this most critical category. High probabilities of detection of other contaminated outfalls are also likely when using these procedures. After identification of the contaminated outfalls, their associated drainage areas are then subjected to a detailed source identification investigation. The identified pollutant sources are then corrected.

ROLE OF DRY-WEATHER FLOWS IN URBAN STORMWATER RUNOFF ANALYSES

The EPA's Nationwide Urban Runoff Program (NURP) highlighted the significance of pollutants from illicit entries into urban storm drainage (EPA 1983). Such entries may be evidenced by flow from storm drain outfalls following and during substantial dry periods. Such flow, frequently referred to as "baseflow" or "dry-weather flow", could be the result of direct "illicit connections" as mentioned in the NURP final report (EPA 1983), or could result from indirect connections (e.g., leaky sanitary sewerage contributions through infiltration). Many of these dry-weather flows are continuous and would therefore also occur during rain induced runoff periods. Pollutant contributions from the dry-weather flows in some storm drains have been shown to be high enough to significantly degrade water quality because of their substantial contributions to the annual mass pollutant loadings to receiving waters.

Dry-weather flows and wet-weather flows have been monitored during several urban runoff studies. These studies have found that discharges observed at outfalls during dry weather were significantly different from wet-weather discharges. Data collected during the 1984 Toronto Area Watershed Management Strategy Study (TAWMSS) monitored and characterized both stormwater and baseflows (Pitt and McLean 1986). This project involved intensive monitoring in two test areas (one a mixed residential and commercial area, and the other an industrial area) during both warm and cold weather and during both wet and dry weather. The annual mass discharges of many pollutants were found to be dominated by dry-weather processes.

During the mid-1980s, several individual municipalities and urban counties initiated studies to identify and correct illicit connections to their storm drain systems. This action was usually taken in response to receiving water quality problems or information noted during individual NURP projects. Data from these studies indicate the magnitude of the cross-connection problem in many urban areas. From 1984 to 1986, Washtenaw County, Michigan dye-tested 160 businesses in an effort to locate direct illicit connections to the County stormwater drainage. Of the businesses tested, 61 (38 percent) were found to have improper storm drain connections (Schmidt and Spencer 1986). In 1987, the Huron River Pollution Abatement Program dye-tested 1067 commercial, industrial, and tax exempt businesses and buildings. A total of 154 (14 percent) were found to have improper connections to storm drainage (Washtenaw Co. 1988). Commercial car washes and other automobile related businesses were responsible for the majority of the illicit connections in both studies. Discharges from commercial laundries were also noted. An investigation of outfalls from the separate storm drain system in Toronto, Canada revealed 59 percent with dry-weather flows. Of these, 84 (14 percent of the total outfalls) were identified as grossly polluted based on the results of a battery of chemical tests (GLA 1983). In 1987, an inspection of the 90 urban stormwater outfalls draining into Inner Grays Harbor in Washington revealed 29 (32 percent) flowing during dry weather (Pelletier and Determan 1988). A total of 19 outfalls (21 percent) were described as suspect based on visual observation and/or anomalous pollutant levels as compared to those expected in typical urban stormwater runoff characterized by the EPA 1983 NURP report.

CURRENT LEGISLATION

With additional data now available, the Clean Water Act of 1987 contained provisions specifically addressing discharges from storm drainage systems. Section 402 (p) (3) (B) provides that permits for such discharges:

i. May be issued on a system or jurisdiction-wide basis.

ii. Shall include a requirement to effectively prohibit non-stormwater discharges into the storm drains, and

iii. Shall require controls to reduce the discharge of pollutants to the maximum extent practicable, including management practices, control techniques and system design and

VOL 12

3935

engineering methods, and such other provisions as the Administrator or the State determines appropriate for the control of such pollutants.

In response to these provisions, the EPA issued a final rule to begin implementation of section 402(p) of the Clean Water Act on November 16, 1990 (40 CFR parts 122, 123, and 124 National Pollutant Discharge Elimination System Permit Regulations for Storm Water Discharges, Federal Register, Vol. 55, No. 222). A screening approach which includes chemical testing of outfalls or storm drainage with dry-weather flow (defined by a 72-hour antecedent dry period), was adopted. The parameters to be tested are a combination of several pollutants of concern and "tracers" that may be used to help identify contaminated outfalls and predict the source of illicit discharges.

Section 122.26 (d) (1) (iv) (D) of the rule applies specifically to this User's Guide. The EPA requires an initial screening program to provide a means of detecting high levels of pollutants in storm sewerage. The protocol of this User's Guide seeks to determine whether or not non-stormwater flows are causing problems (e.g. pathogenic, toxic, aquatic life threatening, nuisance), and to provide additional detail with respect to the source. It accomplishes this by outlining an effective screening methodology to identify storm drainage system outfalls contaminated by illicit or inappropriate discharges and to determine specifically how the likely sources can be identified. This protocol is supported by a research report (Pitt and Lalor publication pending) containing the results of a demonstration project using these procedures and much more detailed information.

VOL 12

SECTION 2

OVERVIEW

POTENTIAL DRY-WEATHER DISCHARGE SOURCES

This User's Guide is directed to the identification and location of non-stormwater entries into storm drainage systems. It is important to note that for any effective investigation of pollution within a stormwater system, all pollutant sources must be included. Prior research has shown, that for many pollutants, stormwater may contribute the smaller portion of the total pollutant mass discharged from a storm drainage system. Significant pollutant sources may include dry-weather entries occurring during both warm and cold months and snowmelt runoff, in addition to conventional stormwater associated with rainfall. Consequently, much less pollution reduction benefit will occur if only stormwater is considered in a control plan for controlling storm drainage discharges. This User's Guide contains a protocol to identify sources of inappropriate entries to storm drainage systems. The investigations presented in this User's Guide may also identify illicit point source outfalls that do not carry stormwater. Obviously, these outfalls also need to be controlled and permitted.

Table 1 summarizes the potential sources of contaminated entries into storm drainage systems, along with their likely flow characteristics. The following subsections summarize these sources.

Residential and Commercial Sources

The most common potential non-stormwater entries, which have been identified by a review of documented case studies for commercial and residential areas are:

- Sanitary wastewater sources:
  - sanitary wastewater (usually untreated) from improper sewerage connections, exfiltration, or leakage
  - effluent from improperly operating, or improperly designed, nearby septic tanks
- Automobile maintenance and operation sources:
  - car wash wastewaters
  - radiator flushing wastewater
  - engine de-greasing wastes
  - improper oil disposal
  - leaky underground storage tanks
- Irrigation sources:
  - lawn runoff from over-watering
  - direct spraying of impervious surfaces
- Relatively clean sources:
  - infiltrating groundwater
  - water routed from pre-existing springs or streams
  - infiltrating potable water from leaking water mains

3937

TABLE 1. POTENTIAL INAPPROPRIATE ENTRIES INTO STORM DRAINAGE SYSTEMS

Potential Source:	Storm Drain Entry		Flow Characteristics		Contamination Category		
	Direct	Indirect	Conti-nous	Inter-mittent	Patho-genic/Toxic	Nuis-ance	Clear
Residential Areas:							
Sanitary Wastewater	X	x	X	x	X	x	
Septic tank effluent		X	X	x	X	x	
Household chemicals	x	X		X	X		
Laundry wastewater	X			X		X	
Excess landscaping watering		X		X	x	x	X
Leaking potable water pipes		X	X				X
Commercial Areas:							
Gasoline filling station	X	x		X	X		
Vehicle maintenance/repair	X	x		X	X		
Laundry wastewater	X		X	x	x	X	
Construction site de-watering		X	X	x		X	
Sanitary wastewater	X	x	X		X		
Industrial Areas:							
Leaking tanks and pipes	x	X	X	x	X		
Miscellaneous process waters[1]	X	x	X	x	X	x	x

Note: X: most likely condition
x: may occur
blank: not very likely

[1] see Table 2 for industrial examples

- Other sources:
  - laundry wastewaters
  - non-contact cooling water
  - metal plating baths
  - dewatering of construction sites
  - washing of concrete ready-mix trucks
  - sump pump discharges
  - improper disposal of household toxic substances
  - spills from roadway and other accidents
  - chemical, hazardous materials, garbage, sanitary sludge landfills and disposal sites

From the above list, sanitary wastewater is the most significant source of bacteria and oxygen demanding substances, while automobile maintenance and plating baths are the most significant sources of toxicants. Waste discharges associated with the improper disposal of oil and household toxicants tend to be intermittent and low volume. These wastes may therefore not reach the stormwater outfalls unless carried by higher flows from another source, or by stormwater during rains.

Industrial Sources

There are several types of industrial dry-weather entries to storm drainage systems. Common examples include the discharge of cooling water, rinse water, other process wastewater, and sanitary wastewater. Industrial pollutant sources tend to be related to the raw materials used, final product, and the waste or byproducts created. Guidance on typical discharge characteristics associated with common industries is given in Sections 4, 5, and 6.

There is also a high potential for unauthorized connections within older industries. One reason for this is that at the time of an industry's development, sanitary sewers may not have been in existence, since early storm drains preceded the development of many sanitary sewer systems. Also a lack of accurate maps of sanitary and storm drain lines may lead to confusion as to their proper identification. In addition, when the activities within an industry change or expand, there is a possibility for illicit or inadvertent connections, e.g., floor drains and other storm drain connections receiving industrial discharges which should be treated before disposal. Finally, industries processing large volumes of water may find sanitary sewer flow-carrying capacity inadequate or sanitary sewers located too far away, leading to improper removal of excess water through the storm drain system.

Continuous processes, e.g., industrial manufacturing, are important potential sources because any waste streams produced are likely to be constantly flowing. Detection of dry-weather discharges from these sources is therefore made easier, because the continuous and probably undiluted nature of these discharges is more discernable, e.g., odors produced will be stronger and colors more intense along with their tracer constituents being more concentrated and more readily detected by sampling.

Intermittent Sources

The presence of regular, but intermittent, flows will usually be a good indication of contaminated entries to the storm drains, and can usually be distinguished from groundwater infiltration flows. However, as drainage areas increase in size, many intermittent flows will combine to create a continuous composite flow. Examples of possible situations or activities that can produce intermittent dry-weather flows are:

- Wash-up operations at the end of a work shift, or job activity.
- Wash-down following irregular accidents and spills.
- Disposal of process batches or rinse water baths.

- Over-irrigation of lawns.
- Vehicle maintenance, e.g., washing, radiator flushing, and engine de-greasing.

Industries that operate on a seasonal basis, e.g., fruit canning and tourism can be a source of longer duration intermittent discharges.

Direct Connections to Storm Drains

Direct connections are defined in this Guide as physical connections of sanitary, commercial, or industrial piping (or channels) carrying untreated or partially treated wastewaters to a separate storm drainage system. These connections are usually unauthorized. They may be intentional or may be accidental due to mistaken identification of sanitary sewerlines. They represent the most common source of entries to storm drains by industry.

Direct connections can result in continual or intermittent dry-weather entries of contaminants into the storm drain. Some common situations are:

- Sanitary sewerlines that tie into a storm drain.
- Foundation drains or residential sump-pump discharges that are frequently connected to storm drains. While this practice may be quite appropriate in many cases, it can be a source of contamination when the local groundwater is contaminated, as for example by septic tank failures.
- Commercial laundries and car wash establishments that may route process wastewaters to storm drains rather than sanitary sewers.

Infiltration to Storm Drains

Infiltration into storm drains most commonly occurs through leaking pipe joints and poor connections to catch basins and manhole chimneys but can also be due to other causes, such as damaged pipes and subsidence.

Storm drains, as well as natural drainage channels, can therefore intercept and convey subsurface groundwater and percolating waters. In many cases, these waters will be uncontaminated and have variable flows due to fluctuations in the level of the water table and percolation from rainfall events.

Underground potable water main breaks are another potential clean water source to storm drains. While such occurrences are not a direct pollution source, they should obviously be corrected.

Groundwater may be contaminated, either in localized areas or on a relatively widespread basis. In cases where infiltration into the storm drains occurs, it can be a source of excessive contaminant levels in the storm drains. Potential sources of groundwater contamination include, but are not limited to:

- Failing or nearby septic tank systems.
- Exfiltration from sanitary sewers in poor repair.
- Leaking underground (and above-ground) storage tanks (LUST) and pipes.
- Landfill seepage.
- Hazardous waste disposal sites.
- Naturally occurring toxicants and pollutants due to surrounding geological or natural environment.

VOL 12

3940

Leaks from underground and above-ground storage tanks and pipes are a common source of soil and groundwater pollution and may lead to continuously contaminated dry-weather entries. These situations are usually found in commercial operations such as gasoline service stations, or industries involving the piped transfer of process liquids over long distances and the storage of large quantities of fuel, e.g., petroleum refineries.

INVESTIGATION METHODOLOGY

Applying the methodology presented in this User's Guide will determine if a storm drain outfall (and drainage system) is affected by pronounced non-stormwater entries. In many cases, the information to be collected by using this methodology will also result in a description of the most likely sources of these discharges.

Several aspects of this methodology were derived from the experience of many municipalities that have previously investigated inappropriate entries into storm drainage systems.

The methodology establishes priorities to identify the areas with the highest potential for causing problems. The investigative procedures then separate the storm drain outfalls into three general categories (with a known level of confidence) to identify which outfalls (and drainage areas) need further analyses and investigations. These categories are outfalls affected by non-stormwater entries from: (1) pathogenic or toxic pollutant sources, (2) nuisance and aquatic life threatening pollutant sources, and (3) unpolluted water sources.

The pathogenic and toxic pollutant source category should be considered the most severe because it can cause illness upon water contact or consumption and significant water treatment problems for downstream consumers, especially if the pollutants are solubla metal and organic toxicants. These pollutants may originate from sanitary, commercial, and industrial wastewater non-stormwater entries. Other residential area sources (besides sanitary wastewater), e.g., inappropriate household toxicant disposal, automobile engine de-greasing, and excessive use of chemicals (fertilizers and pesticides) may also be considered in this most critical category.

Nuisance and aquatic life threatening pollutant sources can originate from residential areas and aside from raw sanitary wastewaters may include laundry wastewaters, lawn irrigation runoff, automobile washwaters, construction site dewatering, and washing of concrete ready-mix trucks. These pollutants can cause excessive dissolved oxygen depletions, and algal growths, tastes and odors in downstream water supplies, offensive coarse solids and floatables, and noticeably colored, turbid or odorous waters.

Clean water discharged through stormwater outfalls can originate from natural springs feeding urban creeks that have been converted to storm drains, infiltrating groundwater, infiltration from potable waterline leaks, etc.

Figure 1 is an outline of the major topics presented in this User's Guide, and Figure 2 is a simplified flow chart for the detailed methodology. The initial phase of the investigative protocol includes the initial mapping and field surveys. These activities require minimal effort and result in little chance of missing a seriously contaminated outfall. The initial activities are followed by more detailed watershed surveys to locate and correct the sources of the contamination in the identified problem areas. After corrective action has been taken, repeated outfall field surveys are required to ensure that the outfalls remain uncontaminated. Receiving water monitoring should also be conducted to analyze water quality improvements. If expected improvements are not noted, then additional contaminant sources are likely present and additional outfall and watershed surveys are needed.

MAPPING & PRELIMINARY WATERSHED EVALUATION (SECTION 3)

1) Identify receiving waters.
2) Locate all outfalls and associated drainage areas.
3) Compile data on land uses within drainage areas.

SELECTION OF TRACER PARAMETERS (SECTION 4)

1) Select physical and chemical parameters to measure.
2) Determine suitable analysis techniques and number of samples required.
3) Develop library of potential local source flow characteristics.

INITIAL FIELD SCREENING SAMPLING ACTIVITIES (SECTION 5)

1) Conduct outfall screening survey for intermittent and continuous flows.

DATA ANALYSIS TO IDENTIFY PROBLEM OUTFALLS AND FLOW COMPONENTS (SECTION 6)

1) Simple procedures using checklists for typical major flow components.
2) More detailed analyses utilizing library of data on potential source flows will quantify flow components.

WATERSHED SURVEYS TO CONFIRM AND LOCATE INAPPROPRIATE POLLUTANT ENTRIES TO THE STORM DRAINAGE SYSTEM (SECTION 7)

1) Conduct drainage surveys using tracer parameters in critical watersheds.
2) Use flow mass balances, dye studies, smoke tests, and T.V. surveys in isolated drainage areas.

CORRECTIVE TECHNIQUES (SECTION 8)

1) Educate public/industry and enforce with ordinances, zoning, etc.
2) Disconnect illicit direct connections.
3) Wide spread entries may require regional solutions or designation of storm drainage system as a CSO.

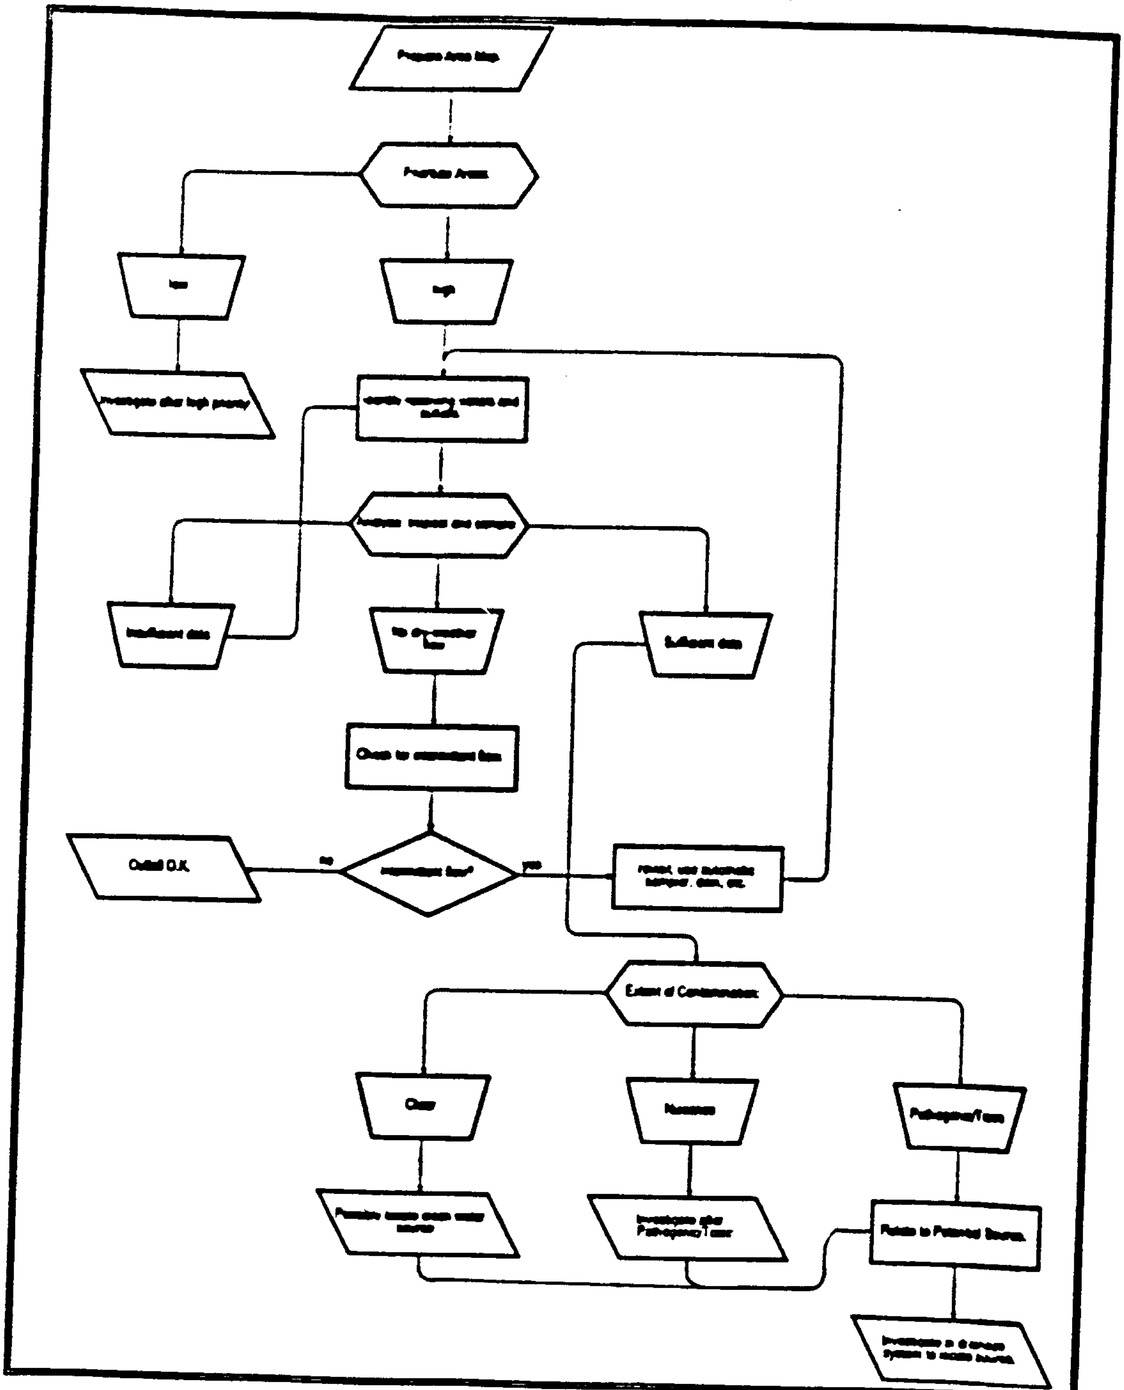

Figure 2. Flow chart for investigation procedures.

RECOMMENDATIONS

This User's Guide should be used as part of a comprehensive stormwater management plan which addresses all sources of stormwater pollution. Correction of pollutant entries identified by use of only this User's Guide is unlikely to achieve a significant improvement in the quality of stormwater discharges or receiving waters.

A municipality will need to plan their investigation of inappropriate entries to a storm drainage system to suit local conditions. This User's Guide describes the issues in sufficient depth and provides examples to enable the design of a local investigation. Greater detail and the results of a comprehensive demonstration of these procedures will be given in a supporting research report by Pitt and Lalor (publication pending).

The full use of all of the applicable procedures described in this User's Guide is likely to be required for successful identification of pollutant sources. Attempting to reduce costs, for example by only examining a certain class of outfalls, or using inappropriate testing procedures, will significantly reduce the utility of the testing program and result in inaccurate data. Also cursory data analyses is likely to result in inaccurate conclusions.

During investigations of non-stormwater entries to storm drainage systems, consideration should be given to any economic and practical advantages of designating the storm drainage system as a combined sewer systems and applying end-of-pipe combined sewer overflow (CSO) control-treatment.

It is also recommended that the methodology (appropriately modified) be applied to other types of sewerage systems, such as combined and separate sanitary sewerage systems, to locate inappropriate entries, e.g., untreated or toxic industrial wastewaters/wastes or infiltration/inflow (I/I) in separate sanitary sewers.

It is recommended that this User's Guide be updated and refined by incorporating experience gained in its application. Incorporation of information from a wide variety of test locations (e.g., lake and large river receiving waters, tidal receiving waters, areas experiencing long dry periods, areas having short summers, areas having unusual groundwater characteristics, etc.) will improve the testing and data analyses protocols described.

SECTION 3

MAPPING AND PRELIMINARY WATERSHED EVALUATION

PURPOSE

An investigation of non-stormwater entries into a storm drainage system needs to proceed along a systematic path of action, which investigates areas from high to low potential for causing problems, and focuses in from general outfall screening to pin-pointing pollutant sources.

A mapping and evaluation methodology, as detailed in this section, is required to identify the areas to investigate and to provide a basis to prioritize the areas by potential to contribute non-stormwater entries into the storm drainage system.

The data collected in this phase is important as it forms the basis for the rest of the more detailed investigations, described in the subsequent sections of this User's Guide.

MAPPING

To make this exercise as economical and productive as possible, full advantage should be taken of any existing and available information. Data gained from existing sources will need to be supplemented with information obtained by field investigations. The following summarizes the information required, likely data sources, and how to obtain the information.

Receiving Waters and Storm Sewer Outfalls

The receiving waters and stormwater drainage outfalls must be identified and accurately located on appropriate maps. However records of all outfalls are hard to locate, and even for those that can be found, the locations of the outfalls may not be accurate. It is therefore important that the field survey described in Section 5 be used to supplement the data collected during this initial stage. As noted in Section 5, it can take three visits to a drainage area to find all (or almost all) outfalls.

Possible sources of documented information include:

- City records, drainage maps, and storm drain maps.
- Previous surveys, e.g., sanitary sewer infiltration/inflow (I/I) and sewer system evaluation survey (SSES) studies.
- Topographic maps.
- Existing GIS (Geographic Information System) data.
- Pre-development stream locations.
- Drainage department personnel having knowledge of the area.
- Aerial surveys.

VOL 12

3946

Drainage Area for Each Outfall

The drainage area for each outfall must be determined and marked on the map. This will enable known potential pollutant source locations to be assigned to the correct outfall. Sources for this information are storm drain maps and topographical maps. These should be at least 1" = 200' scale and have no greater than 5 ft contour intervals (depending on the steepness of the area).

Land Uses for Each Outfall Drainage Area

Local planning departments should have detailed zoning maps of the area. These maps should designate residential, commercial, and industrial land uses in each of the outfall drainage areas. In addition, local revenue departments should have lists of business licenses for the entire municipality, but they may not be usefully sorted. The public health department should know where septic tanks are used. Aerial photographs can provide useful information to identify and or confirm land use areas. Historical land uses, especially landfills and industrial areas, should also be noted.

An effective way to obtain this information is to examine the municipality's zoning maps and to drive to the critical areas to conduct inspections. The land uses of most interest are all industrial, most commercial, and some municipal activities. The activities in the commercial areas of most concern include vehicle related activities (sales, parts, service, or repair), laundry or dry cleaning (including hospitals and hotels), and restaurants. The municipal activities of most concern include but are not limited to: landfills, bus barns, airports, and sanitary wastewater treatment facilities.

Table 2 can be used to identify the local industries in each drainage area most likely to contribute non-stormwater entries into the storm drainage system. The categories considered in this table include loading and unloading of dry bulk or liquid materials, outdoor storage or processing, water usage (cooling and process waters), dust or particulate generating processes, and illicit or inadvertent industrial connections. The likelihood of an industry producing dry-weather or wet-weather discharges in each of these categories was rated on the basis of high, moderate, or low potential and not applicable if there was no relationship evident.

The industrial categories listed in Table 2 were defined according to the 1987 Standard Industrial Classification Manual codes (SIC code). The industries were classified according to six main categories. The category for "Primary Industries" includes facilities involved in the production of food products and other basic goods. The category of "Material Manufacturing" includes those industries producing materials such as lumber, paper, glass, and leather. Similarly, the "Chemical Manufacturing" category includes those industries making products such as plastics, paints, detergents, fertilizers, pesticides, and other related substances. "Transportation and Construction" primarily concerns the discharge of contaminants from building or other types of outdoor development. The "Retail" category includes establishments engaged in the selling of merchandise or offering merchandise related services. Finally, all other industries which did not fit into any of the above classifications were placed into a "General" category. Those industries which are not specifically listed should have characteristics resembling the industries of the major groups with which they are classified by SIC code.

Investigators should take care to include any area where the land use has a potential to contribute pollutant sources to a storm drainage system. As stated above, these land uses may not be covered by Table 2. Some common examples of land use areas to be included are given below:

- Landfill areas can be a source of leachate and polluted runoff.
- Airports have a high potential for fuel spillage. Aircraft deicing agents, and other maintenance operations, produce wastewaters that may be discharged into the storm drainage system.

- Government facilities, such as military bases, may store or use polluting materials and have large vehicle maintenance facilities.
- Agricultural impacts are likely to be greater for wet-weather flows, but practices such as irrigation and drainage tiles may also produce dry-weather flows.

Finally, it is necessary to identify and locate existing permitted discharges to streams and storm drainage. The National Pollutant Discharge Elimination System (NPDES) permits, administered by most states or, if not, by the EPA Regional Offices, contain this information for the facilities currently having discharge permits. Only a small fraction of all industries have NPDES permits, as most have no direct wastewater discharges to waters of the United States. Pretreatment programs for municipal sewage treatment plants would also contain additional industrial information.

Other Relevant Information and Features

It is important that investigators be aware of any relevant features or information which may be specific to their drainage area and not included specifically in the above subsections of this User's Guide. Examples of some items that need to be included are discussed in this subsection.

Information on pre-development streams and springs, which may have been routed into the storm drainage system, will aid in the identification of natural uncontaminated or contaminated dry-weather flows.

Information regarding depth to the water table will be helpful. If the water table is well below the storm drain invert at all times, then groundwater infiltration may be less important as a potential source of dry-weather flow. However, the accumulation of percolating shallow groundwater will still occur in storm drainage fill material and be a potential source of some infiltration water. Groundwater conditions for the study area may be available from special studies conducted by the USGS (U.S. Geological Survey), the state water agency, or other sources. Utility construction and repair crews and earth moving companies should know of areas having shallow groundwater. Local I/I and SSES studies also include information concerning shallow groundwater. Well log data collected during drilling of water supply wells, and information from geotechnical investigations, may also be useful.

Areas serviced by sanitary sewerage and areas serviced by septic tanks should be determined in order to identify the areas most likely to have direct connections and infiltration sources, respectively. Either local health, sewerage, utility, environmental, or public works departments should have information on the location of these areas.

Older residential areas with failing infrastructure (especially sanitary sewerage in poor condition), and high density residential areas with septic tanks, should be designated as areas with a high potential for pollutant entries into the storm drainage system.

PRELIMINARY WATERSHED EVALUATION

The above activities should produce maps with complete descriptions of the drainage areas, including outfall locations, NPDES permittees, critical land uses, drainage boundaries for each outfall, city limits, major streets, streams, etc. The investigators need to classify drainage areas by their potential for causing non-stormwater entries. This mapping information, together with the information to be obtained as described in Sections 4 and 5 and analyzed as described in Section 6, will form the basis to rank the drainage areas in order of priority for further detailed drainage area investigations (Sections 7 and 8).

VOL 12

3949

The investigation of non-stormwater entries will have a cost associated with it, which will increase with the drainage system size and complexity, and with the number of sources being investigated. All pollutant sources, including both wet- and dry-weather pollutant entries, will need to be controlled to have an effective improvement in the quality of the stormwater system discharge. Pitt and McLean (1986) noted that even with the removal of directly connected non-stormwater entries, stormwater originating from industrial and commercial land uses has a high probability of having unacceptable pollutant loads. It would therefore be prudent, at an early stage in the investigation, to review the costs of the investigation and corrective action versus the cost for treatment of the stormwater system discharge. The classification of the storm drainage system as a combined sewer, and subsequent treatment of the flow, may prove to be a more economical and practical alternative. An appropriate time for such a review would be after the mapping and field screening activities to avoid complex, costly, and time consuming drainage system investigations into inappropriate non-stormwater entries, and instead direct resources to pollution control.

VOL 12

3950

SECTION 4

SELECTION OF TRACER PARAMETERS

INTRODUCTION

The detection and identification of inappropriate entries requires the quantification of specific characteristics of the observed outfall baseflow. The characteristics of most interest should be relatively unique for each potential flow source. This will enable the presence of each flow source to be noted, based on the presence (or absence) of these unique characteristics. The selected characteristics are termed tracers, because they have been selected to enable the identification of the sources of these waters.

One approach presented in this User's Guide is based on the identification and quantification of clean baseflow and contaminated components. If the relative amounts of potential components are known, then the importance of the baseflow can be determined. As an example, if a baseflow is mostly uncontaminated groundwater, but contains 5 percent raw sanitary wastewater, it would be a likely important source of pathogenic bacteria. Typical raw sanitary wastewater parameters (e.g., BOD$_5$ or suspended solids) would be in low concentrations and the sanitary wastewater source would be difficult to detect. Fecal coliform bacteria measurements would not help much because they originate from many possible sources. Expensive specific pathogen measurements would be needed to detect the problem directly.

The ideal tracer should have the following characteristics:

- Significant difference in concentrations between possible pollutant sources;
- Small variations in concentrations within each likely pollutant source category;
- A conservative behavior (i.e., no significant concentration change due to physical, chemical or biological processes); and,
- Ease of measurement with adequate detection limits, good sensitivity, and repeatability.

In order to identify tracers meeting the above criteria, literature characterizing potential inappropriate entries into storm drainage systems was examined. Several case studies which identified procedures used by individual municipalities or regional agencies were also examined. Though most of the investigations resorted to expensive and time consuming smoke or dye testing to locate individual illicit pollutant entries, a few provided information regarding test parameters or tracers. These screening tests were proven useful in identifying drainage systems with problems before the smoke and dye tests were used. The case studies also revealed the types of illicit pollutant entries most commonly found in storm drainage systems.

This list of potential illicit sources (see Section 2) led to a search for information regarding the chemical and physical characteristics of these specific flows. This search yielded typical characteristics for sanitary wastewater, septic tank effluent, coin-operated laundries and car wash effluents as well as potable water and "natural waters". This information, along with specifics obtained from case studies, provided the basis for selecting parameters for further study. Specific analyses will be needed to identify the characteristics of local potential inappropriate entries and uncontaminated water sources, as described in this section.

CANDIDATE PARAMETERS

Many different candidate parameters were evaluated before the suggested list was developed (Pitt and Lalor publication pending). It is recommended that the initial field screening effort (in the absence of known commercial and industrial activities in the watershed) include at least:

- Placement of outfall identification number.
- Outfall discharge flow estimate.
- Floatables, coarse solids, color, turbidity, oil sheen, and odor characteristics of discharge and/or receiving nearfield water.
- Other outfall area characteristics, e.g., stains, debris, damage to concrete, corrosion, unusual plant growth, or absence of plants.
- Water temperature.
- Specific conductivity.
- Fluoride and/or hardness concentrations.
- Ammonia and/or potassium concentrations.
- Surfactant concentration and/or fluorescence.
- Chlorine concentration and pH.

If commercial or industrial activities occur in the drainage area, then it is important to add additional parameters (e.g., a toxicity screening procedure and specific metallic and organic toxicant analyses) to the above list.

Most of the screening effort items listed above can be obtained at the outfall location using field procedures. It is much easier, more cost-effective, and much more accurate to collect samples in the field for later laboratory analyses. Analyzing multiple samples for the same parameter is much more efficient than trying to analyze a single sample for many parameters, especially under adverse field conditions.

The selection of the analysis procedures and equipment will depend on many conditions, most notably the expected concentrations in the uncontaminated baseflows and in the potential non-stormwater discharge flows, along with the needed probabilities of detection at the minimum contamination level. A description of the techniques developed as part of this study to help in the selection of the analytical procedures is given later in this section. Other factors affecting procedure selection include ease of use, analytical interferences, cost of equipment, training requirements, and time requirements to conduct the analyses.

Physical Inspection

Estimates of outfall flow rates, and noting the presence of oil sheens, floatables, coarse solids, color, odors, etc. will probably be the most useful indicators of outfall problems. Physical observations of outfall conditions have been noted in case studies to be very useful in determining the significance of contaminated dry-weather flows. There has been a good correlation between storm drains judged contaminated after physical inspection and those judged contaminated after chemical tests at several case studies (e.g., Inner Grays Harbor, Washington, Beyer, et al. 1979 and Pelletier and Determan 1988; Fort Worth, Texas, Falkenbury 1987 and 1988 and Moore and Hoffpauir 1988; and Toronto, Ontario, GLA 1983).

VOL 12

3952

Odor--

The odor of a discharge can vary widely and sometimes directly reflects the source of contamination. Industrial dry-weather discharges will often cause the flow to smell like a particular spoiled product, oil, gasoline, specific chemical, or solvent. As an example, for many industries, the decomposition of organic wastes in the discharge will release sulfide compounds into the air above the flow in the sewer, creating an intense smell of rotten eggs. In particular, industries involved in the production of meats, dairy products, and the preservation of vegetables or fruits, are commonly found to discharge organic materials into storm drains. As these organic materials spoil and decay, the sulfide production creates this highly apparent and unpleasant smell. Significant sanitary wastewater contributions to a dry-weather flow will also cause pronounced and distinctive odors.

Color--

Color is another important indicator of inappropriate discharges, especially from industrial sources. Industrial dry-weather discharges can have various colors. Dark colors, such as brown, gray, or black, are most common. For instance, the color contributed by meat processing industries is usually a deep reddish-brown. Paper mill wastes are also brown. In contrast, textile wastes are varied. Other intense colors, such as plating-mill wastes, are often yellow. Washing of work areas in cement and stone working plants can cause cloudy dry-weather discharges. Potential dry-weather sources causing various colored contaminated waters from industrial areas include process waters (slug or continuous discharges), equipment end work area cleaning water discharged to floor drains, and spills during loading operations (and subsequent washing of the material into the storm drains).

Turbidity--

Turbidity of water is often affected by the degree of gross contamination. Dry-weather industrial flows with moderate turbidity can be cloudy, while highly turbid flows can be opaque. High turbidity is often a characteristic of undiluted dry-weather industrial discharges, such as those coming from some continual flow sources, or some intermittent spills. Sanitary wastewater is also often cloudy in nature.

Temperature--

Temperature measurements may be useful in situations where the screening activities are conducted during cold months, or in areas having industrial activity. It may be possible to identify an outfall that is grossly contaminated with sanitary wastewater or cooling water during cold weather and possibly to conduct a rough heat balance. Both sanitary wastewater and cooling water could substantially increase outfall discharge temperatures. Elevated baseflow temperatures (compared to baseflows at other outfalls being screened) could be an indicator of substantial contamination by these warmer source flows.

Floatable Matter--

A contaminated flow may also contain floatables (floating solids or liquids). Evaluation of floatables often leads to the identity of the source of industrial or sanitary wastewater pollution, since these substances are usually direct products or byproducts of the manufacturing process, or distinctive of sanitary wastewater. Floatables of industrial origin may include substances such as animal fats, spoiled food products, oils, plant parts, solvents, sawdust, foams, packing materials, or fuel; whereas floatables in sanitary wastewater include fecal matter, sanitary napkins, and condoms.

Deposits and Stains--

Deposits and stains (residue) refer to any type of coating which remains after a non-stormwater discharge has ceased. They will cover the area surrounding the outfall and are usually of a dark color. Deposits and stains often will contain fragments of floatable substances and, at times, take the form of a crystalline or amorphous powder. These situations are illustrated by the grayish-black deposits that contain fragments of animal flesh and hair which often are produced by leather tanneries, or the white crystalline powder which commonly coats sewer outfalls due to nitrogenous fertilizer wastes.

Vegetation--

Vegetation surrounding an outfall may show the effects of intermittent or random non-stormwater discharges. Industrial pollutants will often cause a substantial alteration in the chemical composition and pH of the discharge. This alteration will affect plant growth, even when the source of contamination is intermittent. For example, decaying organic materials coming from various food product wastes could cause an increase in plant life. In contrast, the discharge of chemical dyes and inorganic pigments from textile mills could noticeably stunt plant growth, as these dry-weather discharges are often acidic. In either case, when the industrial pollution constituent in the flow ceases, the vegetation surrounding the outfall will continue to show the effects of the contamination.

In order to accurately judge if the vegetation surrounding an outfall is normal, the observer must take into account the current weather conditions, as well as the time of year in the area. Thus, flourishing or inhibited plant growth, as well as dead and decaying plant life, are all signs of pollution or scouring flows when the condition of the vegetation beyond the outfall contrasts with the plant conditions near the outfall. It is important not to confuse the adverse effects of high storm-induced flows on vegetation with highly toxic dry-weather intermittent flows. Poor plant growth could be associated with scouring flows occurring during storms.

Damage to Sewerage/Outfall Structure--

Sewerage structural damage is another readily visible indication of both continual and intermittent industrial dry-weather discharge contamination. Cracking, deterioration, and spalling of concrete or peeling of surface paint, occurring at an outfall are usually caused by severely contaminated discharges, usually of industrial origin. These contaminants are usually very acidic or basic in nature. For instance, primary metal industries have a strong potential for causing sewerage structural damage because their batch dumps are highly acidic. However confusion is possible due to the effects poor construction, hydraulic scour, and old age may have had on the condition of the outfall structure or sewerage system.

Chemical Parameters

Chemical tests are needed to supplement the above described physical inspection parameters. Chemical tests are needed to quantify the approximate components of a mixture at the outfall. In most cases, dry-weather discharges are made up of many separate source flows (e.g., potable water, groundwaters, sanitary wastewater, and automobile washwaters). Statistical analyses of the chemical test results can be used to estimate the relative magnitudes of the various flow sources (as described in Section 6 of this Guide).

Specific Conductivity--

Specific conductivity can be used as an indicator of dissolved solids. Specific conductivity measurements can be conducted with relative ease in the field, while dissolved solids measurements must be made in a laboratory.

The literature indicates that variation in specific conductivity measurements between water and wastewater sources could be substantial enough to indicate the source of dry-weather flow in the storm drainage system. Specific conductance was judged to be a reliable and quick field indicator of general outfall contamination in Toronto (GLA 1983). Observed levels ranged from 25 to 100,000 μS/cm (microSiemens per cm). Specific conductivity levels less than 1000 μS/cm indicated significant levels of rainwater in the drainage. Specific conductivity can be measured quickly, easily and cheaply. For these reasons, it was selected as a parameter for further study.

Fluoride--

Fluoride concentration should be a reliable indicator of potable water where fluoride levels in the raw water supply are adjusted to consistent levels and where groundwater has low to non-measurable natural fluoride levels. It is common practice for communities to add fluoride to municipal waters to improve dental health. Concentrations of total fluoride in fluoride treated potable waters are usually in the range of 1.0 to 2.5 mg/L.

Fluoride measurements have often been used to distinguish treated waters from natural waters. During the Allen Creek drainage study (Schmidt and Spencer 1986), the fluoride concentrations of dry-weather flows at outfalls were undetectable after most of the known improper connections to storm drains were eliminated. Very few of these improper connections were of sanitary wastewater to the storm drainage. Apparently, most of the non-stormwater discharges were treated potable water.

Hardness--

Hardness may also be useful in distinguishing between natural and treated waters (like fluoride), as well as between clean treated waters and waters that have been subjected to domestic use.

The hardness of waters varies considerably from place to place, with groundwaters generally being harder than surface waters. Natural sources of hardness are limestones which are dissolved by percolating rainwater made acid by dissolved carbon dioxide. Information regarding the average hardness of potable water as well as local groundwater and surface waters should be readily available wherever a public water supply system exists.

Ammonia/Ammonium--

As part of the nitrogen cycle, ammonia is produced by the decay of organic nitrogen compounds. Ammonia may then be broken down, forming nitrites and nitrates. The presence or absence of ammonia (NH_3), or ammonium ion (NH_4^+), has been commonly used as a chemical indicator for prioritizing sanitary wastewater cross-connection drainage problems. Correlations between elimination of improper sanitary wastewater cross-connections into storm drainage and reduced numbers of storm drainage outfalls with ammonia present were noted in Fort Worth (Falkenbury 1987 and 1988; Moore and Hoffpauir 1988). During studies in Toronto (GLA 1983), more "problem" storm drain outfalls had high ammonia concentrations (>1 mg/L) than any other single parameter, except TKN. During the Huron River (Michigan) study (Washtenaw Co. 1987 and 1988; Murray 1985), ammonia levels were found to be greater at all "problem" storm drain outfalls than at control locations. However, the Allen Creek (Michigan) Drainage study (Schmidt and Spencer 1986) reported that with 92 percent of the improper non-stormwater entries to storm drains eliminated, the ammonia concentrations did not change significantly (all were about 0.44 mg/L). However, very few of these cross-connection eliminations were for sanitary wastewater. Ammonia should be useful in identifying sanitary wastes and distinguishing them from commercial water usage.

Potassium--

Large increases of potassium concentrations have been noted for sanitary wastewater compared to potable water during studies in California (Evans 1968), Virginia (Hypes, et al. 1975), and Brussels, Belgium (Verbanck, et al. 1990). These potassium increases following domestic water usage suggest its potential as a tracer parameter.

Surfactants and Fluorescence--

Surfactants are discharged from household and industrial laundering and other cleaning operations. In the United States, anionic surfactants are commonly used in detergents and account for approximately two thirds of the total surfactants used. Anionic surfactants are commonly measured as Methylene Blue Active Substances (MBAS). In raw sanitary wastewaters, surfactants generally range from 1 to 20 mg/L, while natural waters usually have surfactant concentrations below 0.1 mg/L.

Large concentrations of surfactants are found in sanitary wastewater, but some researchers (Alhajjar, et al. 1989) have reported that they are not found in septic tank effluent. Surfactants can be totally degraded in the septic tanks. During the Allen Creek drainage study (Schmidt and Spencer 1986; Washtenaw County Drain Commissioner 1984; and Washtenaw County Statutory Drainage Board 1987), surfactants (as MBAS) decreased significantly after most of the improper non-stormwater entries to storm drains were eliminated. Surfactants can be used to identify sanitary or laundry wastewater cross-contamination in storm drainage systems. They may also be of use in distinguishing between infiltrating septic tank effluent and other washwaters from domestic or commercial cleaning operations.

Water fluorescence is also an indicator of detergent residue in waters. Most detergents contain fabric whiteners which cause substantial fluorescence. Fluorescent indicators remain after sanitary wastewater treatment in septic tanks. Fluorescence in contrast to MBAS may be useful in distinguishing between sanitary wastewater contamination and septic tank effluent.

pH--

The pH of most uncontaminated baseflows, as well as sanitary wastewater, is usually quite close to neutral (pH of 7). Therefore, Ph will probably not serve as an indicator of sanitary cross connections. However, pH values may be extreme in certain inappropriate commercial and industrial flows or where groundwaters contain dissolved minerals. If unusual pH values are observed, then the drainage system needs to be carefully evaluated. Very few of the stormwater outfalls tested during dry-weather in Fort Worth (Falkenbury 1987 and 1988; Moore and Hoffpauir 1988) had pH values either below 6 or above 9. None of the Toronto (GLA 1983) "problem" outfalls were reported to have extreme pH values.

Chemicals (acidic and alkaline) released into storm drains by chemically-oriented industries are frequently the cause of pH fluctuations which can range from 3 to 12.

Industries that commonly release low pH (acidic) dry-weather discharges include (but are not limited to) textile mills, pharmaceutical manufacturers, metal finishers/fabricators, as well as companies producing resins, fertilizers and pesticides. Wastes containing sulfuric, hydrochloric, or nitric acids are common industrial sources of low pH discharges.

Many industrial wastes contain high pH (alkaline) chemicals such as cyanide, sodium sulfide, and sodium hydroxide. High concentrations of these contaminants are found in discharges from soap manufacturers, textile mills, metal plating industries, steel mills, and producers of rubber or plastic.

Total Available Chlorine--

Chlorine can be present in water as free available chlorine and as combined available chlorine (usually as chloramines). Both types can exist in the same water and be determined together as the total available chlorine. Chlorine is not stable in water, especially in the presence of organic compounds. Tests of clean potable water during the demonstration project (Pitt and Lalor publication pending) found that total available chlorine only decreased by about 25 percent in 24-hours during an aerated bench-scale test. However, the chlorine demand of contaminated water can be very large, with chlorine concentrations decreasing to very small values after short periods of time. Chlorine therefore cannot be used to quantify flow sources because of its instability, but the presence of chlorine in baseflow waters (very unlikely) could indicate a significant and very close potable water flow source.

Other Chemicals Indicative of Manufacturing Industrial Activities--

Table 3 is a listing of various chemicals that may be associated with a variety of different industrial activities. If the industrial activities in an outfall watershed are known, it may be possible to examine the non-stormwater outfall flow for specific chemicals (e.g., listed in Table 3) to identify which industrial activities may be responsible for the dry-weather flow.

TABLE 3. SIGNIFICANT CHEMICALS IN INDUSTRIAL WASTEWATERS

Chemical:	Industry:
Acetic acid	Acetate rayon, pickle and beetroot manufacture.
Alkalies	Cotton and straw kiering, cotton manufacture, mercerizing, wool scouring, and laundries.
Ammonia	Gas, coke, and chemical manufacture.
Arsenic	Sheep-dipping, and felt mongering.
Chlorine	Laundries, paper mills, and textile bleaching.
Chromium	Plating, chrome tanning, and aluminum anodizing.
Cadmium	Plating.
Citric acid	Soft drinks and citrus fruit processing.
Copper	Plating, pickling, and rayon manufacture.
Cyanides	Plating, metal cleaning, case-hardening, and gas manufacture.
Fats, oils	Wool scouring, laundries, textiles,and oil refineries.
Fluorides	Gas, coke, and chemical manufacture, fertilizer plants, transistor manufacture, metal refining, ceramic plants, and glass etching.
Formalin	Manufacture of synthetic resins and penicillin.
Hydrocarbons	Petrochemical and rubber factories.
Hydrogen peroxide	Textile bleaching, and rocket motor testing.
Lead	Battery manufacture, lead mining, paint manufacture, and gasoline manufacture.
Mercaptans	Oil refining, and pulp mills.
Mineral acids	Chemical manufacture, mines, Fe and Cu pickling, brewing, textiles, photo-engraving, and battery manufacture.
Nickel	Plating.
Nitro compounds	Explosives and chemical works.
Organic acids	Distilleries and fermentation plants.
Phenols	Gas and coke manufacture, synthetic resin manufacture, textiles, tanneries, tar, chemical, and dye manufacture and sheep-dipping.
Silver	Plating, and photography.
Starch	Food, textile, and wallpaper manufacture.
Sugars	Dairies, foods, sugar refining, and preserves.
Sulfides	Textiles, tanneries, gas manufacture, and rayon manufacture.
Sulfites	Wood process, viscose manufacture, and bleaching.
Tannic acid	Tanning, and sawmills.
Tartaric acid	Dyeing, wine, leather, and chemical manufacture.
Zinc	Galvanizing, plating, viscose manufacture, and rubber process.

Toxicity Screening Tests

In addition to the parameters described above, relative toxicity can be an important outfall screening parameter. Short-term toxicity tests, such as the Microtox™ test (from Microbics) are valuable for quickly and cheaply assessing the relative toxicity (to a selected test organism) of different storm drain baseflows. These tests can be used to identify outfalls that contain flows in the most serious (toxic) category and that require immediate investigation. These tests are also very useful in identifying likely sources of toxicants to the drainage system by utilizing a toxicity reduction evaluation (TRE) procedure in the drainage system. If an outfall contains a highly toxic flow, then specific metallic and organic toxicants can be analyzed to support source identification.

TRACER CHARACTERISTICS OF SOURCE FLOWS

Table 4 summarizes the relative concentrations of tracer parameters in source flows. The unique "fingerprints" of each flow category shown can be used to identify the flow components, as shown in Section 6. This table also contains redundancies, (e.g., potassium and ammonia) to help identify sanitary wastewater and septic tank effluent. Fluoride and hardness are similarly used to identify treated potable water and surfactant (MBAS) and fluorescent measurements are used to identify washwaters.

Table 5 is a summary of the tracer parameter concentrations found in Birmingham, Alabama, from April 1991 to September 1992. This table is a summary of the "library" that describes the tracer conditions for each potential source category. The important information shown on this table includes the median and coefficient of variation (COV) values for each tracer parameter for each source category. The COV is the ratio of the standard deviation to the mean. A low COV value indicates a smaller spread of data compared to a data set having a large COV value. It is apparent that some of the abstracted and generalized relationships shown on Table 4 did not exist during the demonstration project. This stresses the need for obtaining local data describing likely source flows.

The fluorescence values shown on Table 5 are direct measurements from the Turner™ (Model 111) fluorometer having general purpose filters and lamps and at the least sensitive setting (number 1 aperture). The toxicity screening test results are expressed as the toxicity response noted after 25 minutes of exposure. The Microtox™ unit measures the light output from phosphorescent algae. The I_{25} value is the percentage light output decrease observed after 25 minutes of exposure to the sample. If an outfall sample has a very high light reduction value, it is typically subjected to additional organic and metallic toxicant tests. Fresh potable water has a relatively high response because of the chlorine levels present. Aged, or dechlorinated, potable water has much smaller toxicity responses.

Appropriate tracers are characterized by having significantly different concentrations in flow source categories requiring identification. In addition, effective tracers also need low COV values within each flow category. Table 4 indicates the expected changes in concentrations per category and Table 5 indicates how these expectations compared with the results of an extensive local sampling effort. The study indicated that the COV values were quite low for each category, with the exception of chlorine, which had much greater COV values. The high chlorine COV values reinforce what was previously indicated (under Total Available Chlorine), that chlorine is not recommended as a quantitative tracer to estimate the flow components. Similar data must be collected in each community where these procedures are to be used. The following subsection discusses how the number of samples needed per category can be estimated.

Determining Number of Observations Needed

It is very important to determine the number of observations needed for each tracer parameter for each source category in order to build a useful data library for analyzing the outfall data. This determination is a function of the tolerable error level in the data means and the standard deviations. The following paragraphs briefly describe a method that can be used to estimate the sampling effort needed to develop a useful library of source characteristic data.

Estimating Errors--

One equation that can be used to calculate the number of analyses needed, based on the allowable error is (Cochran 1963):

Number of samples = 4(standard deviation)^2/(allowable error)^2

With a 95 percent level of confidence, this relationship determines the number of samples needed to obtain a value within the range of the sample mean, plus and minus the error. Similarly, this equation can be used to predict the 95 percent confidence interval, based on the measured (or estimated) standard deviation and number of samples obtained:

Error = 2(standard deviation)/(number of samples)$^{0.5}$

where the confidence interval is the mean plus and minus the calculated error value.

Example of Log_{10} Transformation--

These equations assume a normal distribution of the data. However, most water quality data needs to be log_{10} transformed before a normal distribution is obtained. As an example, consider a tracer having a COV of 0.23 and a median value of 0.14. The resulting log_{10} transformed standard deviation would be about 0.12. For ten samples, the resulting 95 percent confidence range of the median observation (0.14 mg/L) is:

Error = 2(0.12)/(10)$^{0.5}$ = 0.076 in log_{10} space

The confidence interval is therefore log_{10}(0.14) +/- 0.076, which is -0.778 to -0.930 in log10 space. This results in a conventional 95 percent confidence range of $10^{-0.930}$ (= 0.12) to $10^{-0.778}$ (= 0.17). The error in the estimate of the median value is therefore between 14 and 21% for ten samples. If the original untransformed data were used, the error associated with 10 samples is 15%, within the range of the estimate after log transformations. These results are close because of the low COV value (0.23). If the COV value is large, the need for log transformations increases. Figure 3 (Pitt 1979) shows the approximate sample size needed to obtain different allowable errors for different COV values (using nontransformed data).

The COV value in the above example (0.23) was close to the median COV value for all of the source categories and tracer parameters shown on Table 5. Therefore, about 10 samples per source flow category should generally result in less than a 25 percent error for the median values obtained.

As shown in a later section, narrow confidence intervals are needed in order to estimate the relative mixes of the non-stormwater sources as measured at the outfall. Therefore, much care needs to be taken in order to estimate the characteristics of the potential non-stormwater flow sources, especially the COV values and medians.

Understanding the mechanisms affecting the non-stormwater sources (e.g., time of day, season, area of town, type and magnitude of land use activities, etc.) and obtaining a relatively large data base library for the source flow tracer concentrations is very important and should be a significant portion of a dry-weather flow source identification project.

VOL 12

SELECTION OF ANALYTICAL METHODS

The selection of the analytical procedure to be used is dependent on a number of factors, including (in order of importance):

- appropriate detection limits
- freedom from interferences
- good analytical precision (repeatability)
- low cost and good durability
- minimal operator training required

The following sub-sections discuss these requirements and present the recommended analytical procedures. Tracer characteristics in potential local source flows affect most of these requirements. Therefore, the suggested analytical procedures may not be the most cost-effective for all areas.

Detection Limit Requirements

In order to identify potential non-stormwater sources, it is necessary to have a basic knowledge about each potential source flow. As shown earlier, a significant sampling and analysis effort is needed to develop a library of source flow tracer concentrations. The COVs and means of the tracer concentrations are needed to estimate the detection limits required by the analytical procedures.

There are a number of different types of detection limits defined for laboratory use. Most instrument manufactures present a minimum readable value as the instrument detection limit (IDL) in their specifications for simple test kits. The usual definition of IDL, however, is a concentration that produces a signal to noise ratio of five. The method detection limit (MDL) is a more conservative value and is established for the complete preparation and analysis procedure. The practical quantification limit (PQL) is higher yet and is defined as a routinely achievable detection limit with a relatively good certainty that any reported value is reliable. Standard Methods (APHA, et al. 1989) estimates that the relationship between these detection limits is approximately: IDL:MDL:PQL = 1:4:20. Therefore, the detection limit shown in much of the manufacturer's literature is much less than what would be used by most analytical laboratories.

3953

Because of the screening nature of the outfall field surveys, the instrument detection capabilities are appropriate for the methodology described in this Users' Guide. The larger uncontrollable errors associated with obtaining representative outfall samples and in the variations of the tracer concentrations in the potential source flows would tend to diminish the significance of errors associated with reading concentration values from the instrument that are lower than the PQL.

A quick (and conservative) estimate of the needed detection limit can be made by only knowing the median concentration and the concentration variation of the tracer in the least contaminated component flow. Any amount of another component having a greater tracer concentration will increase the tracer concentration of the mixture. By ignoring this increase, minimum detection limits can be estimated based on the numerous probability calculations presented in the background demonstration project report (Pitt and Lalor publication pending):

COV value:	Multiplier for detection limit:
<0.5 (low)	0.8
0.5 to 1.25 (medium)	0.23
>1.25 (high)	0.12

As an example, if the baseflow tracer has a low COV (<0.5), then the estimated required detection limit is about 0.8 times the median tracer concentration.

More than 80 percent of the library categories (source flows and tracers) examined in Birmingham, Alabama during the demonstration of these procedures (shown on Table 5) had low COV values. About 15 percent had medium COV values, and about 5 percent had high COV values. Free available chlorine had medium or high COV values for almost all source categories. This is a major reason why chlorine is not used quantitatively to identify source flow components in outfall samples. Chlorine is used in a similar manner as an aesthetic parameter (e.g., turbidity or odor). If high chlorine concentrations are found at the outfall (greater than about 0.5 mg/L), then a major treated potable water leak is likely associated with the dry-weather flow.

Table 6 lists the detection limit requirements for the tracer parameter concentrations found during the Birmingham, Alabama, demonstration project. The recommended analytical methods satisfy most of the required detection limits, except for ammonia and surfactants in spring water and surfactants in potable water. The spring water ammonia concentrations were about equal to the detection limit, but because the variation in the ammonia concentrations were so large, a much lower detection limit would be preferable.

Figures 4 through 7 are probability plots showing the required analytical detection limits for mixtures of two source area flows both having low COV values (similar to the majority of expected conditions). Pitt and Lalor (publication pending) present similar plots for all possible combinations of COV values. These figures show four curves corresponding to four mixtures. PER100 is for a 100 percent solution of the flow having the higher tracer concentration, PER50 is for a solution having 50 percent each of two components, PER15 is for a solution of 15 percent of the component having the higher tracer concentration and 85 percent of the component having the lower tracer concentration, while PER0 is a solution only made of the component having the lower tracer concentration. Figure 4 is for two components that have mean concentrations differing by 1.33 times, Figure 5 is for a mixture where the component mean concentrations differ by five times, Figure 6 is for two components with mean concentrations differing by 20 times, and Figure 7 is for two components with mean concentrations differing by 75 times. Each figure shows the detection limits, relative to the lower base concentrations, for different probability of detection values. The detection limits required are reduced significantly as the means of the tracer components differ by greater amounts, especially for low probabilities of detection.

For example, if the two tracer mean concentrations vary by about five times (e.g., treated potable water and sanitary wastewater potassium concentrations from Table 5) and a mixture of 15 percent sanitary wastewater and 85 percent potable water needs to be identified with a 90 percent probability of detection, the required detection limit would be about:

1.4 [factor from Fig.5] x 1.6mg/l [potassium in treated potable water Table 5] = 2.2 mg/L

The more conservative approach stated above would result in a minimum detection limit of:

0.8 [factor for COV < 0.5] x 1.6mg/l = 1.2 mg/L.

VOL 12

3964

TABLE 6. DETECTION LIMIT REQUIREMENTS FOR TRACER CONCENTRATIONS FOUND IN BIRMINGHAM, ALABAMA WATERS

3967

Even with the above analytical requirements satisfied, it may still be difficult to precisely estimate the degree of contamination, especially for low contamination levels and for high COVs. The ratio of the tracer concentration in the contaminating source flow to the tracer concentration in the cleaner baseflow must increase as the desire to detect smaller contaminating source flows is required. Listed below, for 90 percent confidence levels and low COV values, are percentages of source flow in the baseflow and the corresponding minimum concentration ratios (source to clean baseflow tracer concentrations) required for the detection of the source flow contamination of the baseflow.

Percent of Source Flow Contamination in Baseflow:	Required concentration ratios (low COV values):
1%	50
5%	10
10%	7
25%	3
35%	1.5
50%	1.2

As an example, the median tracer concentration in the contaminating source flow must be about 10 times greater than the median tracer concentration in the cleaner baseflow to detect a five percent source flow contamination of the baseflow. If the tracer COV values are "medium" or "high", then the required concentration differences are much greater (up to 250 times difference in concentrations may be required).

Therefore, the differences in tracer concentrations must be quite large, and the COVs quite small, in order to have confident estimates of low levels (percentages) of contaminating source flows. Few tracers exhibit such a wide range in characteristics between source flow and baseflow categories. This is the main reason why the use of multiple tracers for source flow identification is important. Some tracers may not uniformly produce good estimates of contaminating source flow levels, but the use of redundant tracers for the same decision (e.g., ammonia and potassium to identify sanitary wastewater; fluorides and hardness to identify treated potable water; and surfactants and fluorescence to identify wash waters) and good estimates of local contaminant characteristics, will minimize these errors.

The actual minimum level of contaminating source flow that will be detectable will be dependent on the analytical precision, as discussed next.

<u>Required Sample Analytical Precision</u>

The repeatability of the analytical method is an important consideration in its selection. Precision, as defined in <u>Standard Methods</u> (APHA, <u>et al.</u> 1989), is a measure of the closeness with which multiple analyses of a given sample agree with each other. It is determined by repeated analyses of a stable standard, conducting replicate analyses on the samples, or by analyzing known standard additions to samples. Precision is expressed as the standard deviation of the multiple analysis results.

Figure 8 is a summary of the probability plots from Pitt and Lalor (publication pending) and indicates the needed analytical precision (repeatability) as a fraction of the median tracer concentration (i.e., the flow with the lower tracer concentration) to resolve one percent contamination of the baseflow by the source flow, at a 90 percent confidence level. This figure was developed for COV values of the tracer parameters in the contaminating flows ranging from 0.16 to 1.67.

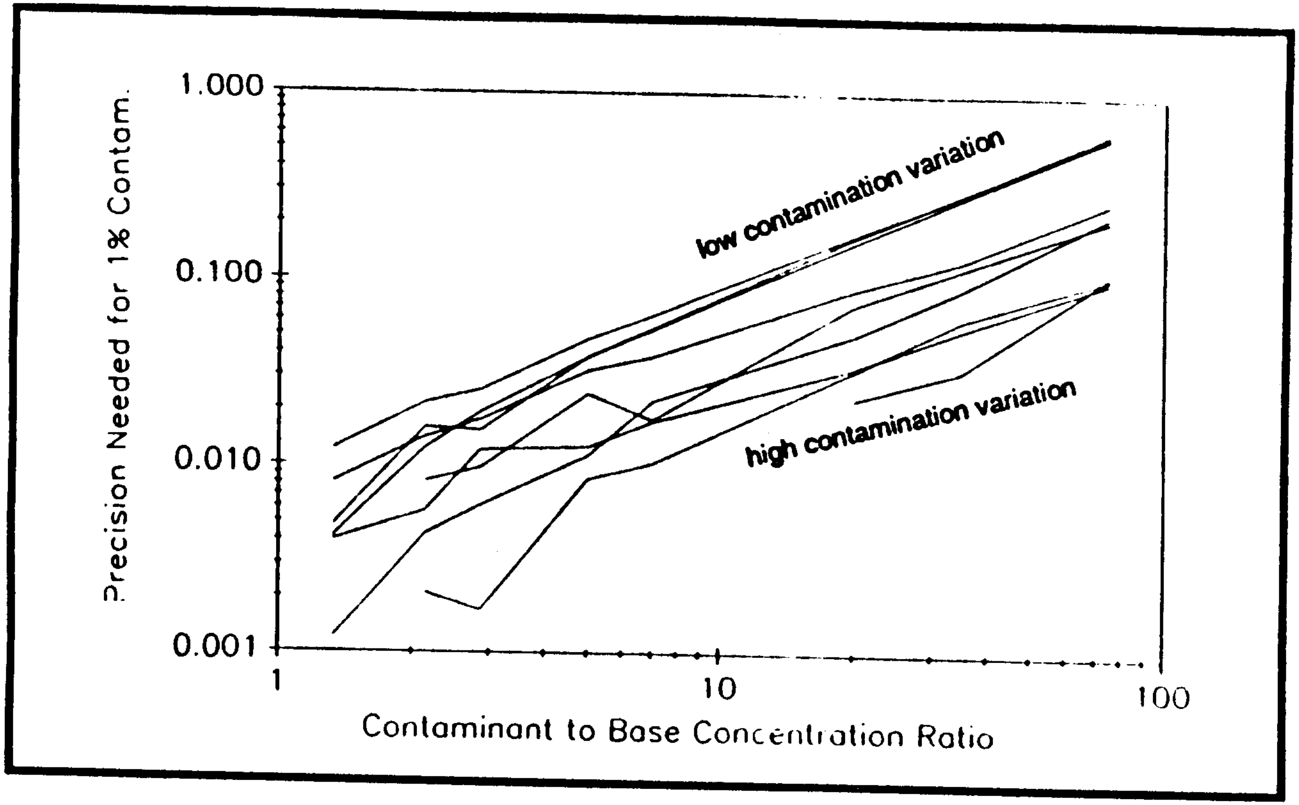

Figure 8. Analysis precision needed for detection of one percent contamination at ninety percent confidence.

If the available analytical precision is worse than these required values, then small contaminating flow levels may not be detected. Therefore, even with adequate analytical detection limits, poor analytical precision may not allow adequate identification of low levels of contaminating flow. In many cases, it is expected that a contaminating flow level of just a few percent can cause significant toxic and pathogenic problems. Examples include gasoline spills, direct connections of raw sanitary wastewater, and metal plating bath wastewaters.

If the tracer concentrations of the flow components are close in value and the variation of the concentrations are high, then it will be very difficult to adequately discern flow components. In contrast, if the tracer concentrations of the flow components are widely different and have low variabilities, then much smaller levels of contaminating flows could be detected. As an example, if the median contaminant tracer concentrations differ by a factor of 10 in two flow components, but have high concentration variations (high COV values), a precision of between 0.015 to 0.03 of the lower baseflow median tracer concentration is needed, for each percent of contaminating flow that needs to be detected. If the median tracer concentration in the cleaner baseflow is 0.15 mg/L (with a corresponding tracer median concentration of 10 times this amount, or 1.5 mg/L, in the contaminating source flow), then the required analytical precision is about 0.015 x 0.15 = 0.002 mg/L to 0.03 x 0.15 = 0.005 mg/L per one percent of contaminating flow to be detected. If at least five percent of contaminating flow is needed to be detected, then the minimum precision would have to be 5 x 0.002 = 0.01 mg/L.

The conservative method noted previously can be used to estimate the detection limit requirements for the above example:

low COV in the cleaner baseflow: 0.8 x 0.15 mg/L = 0.12 mg/L
medium COV in the cleaner baseflow: 0.23 x 0.15 mg/L = 0.035 mg/L
high COV in the cleaner baseflow: 0.12 x 0.15 mg/L = 0.018 mg/L.

The required analytical precision would therefore be about one-half of the lowest detection limit needed, and about 1/12 of the largest estimated required detection limit.

Recommended Analytical Methodology

An important part of the development of these investigation procedures and the demonstration project (Pitt and Lalor publication pending) was the laboratory and field testing of alternative analytical methods. Dry-weather outfall samples were subjected to different tests which compared several analytical methods for each of the major tracer parameters of interest. Tests were conducted to enable comparison of the results of alternative tests with standard procedures and to identify which methods had suitable detection limits, based on real samples. In addition, representative samples were further examined using standard addition methods (known amounts of standards added to the sample and results compared to unaltered samples) in order to identify matrix interferences. Matrix interferences are generally caused by contaminants in the samples interfering with the analysis of interest. Many of the analysis methods were also tested against a series of standard solutions to identify analytical precision (repeatability), linearity, and detection limits. The following paragraphs (and Table 7) summarize the recommended analytical procedures.

Most of the recommended analyses are conducted using small "field-type" instruments. However, despite their portability, the use of these instruments in the field can introduce many errors. Temperature and specific conductivity are the only analyses that are recommended for field analyses. For the other analyses, samples are collected at the site, iced, and taken back to the laboratory for analyses. The recommended analytical procedures can be easily conducted in a temporary laboratory; all that is needed is a work space and adequate ventilation. Access to power and water would be

helpful, but all of the equipment can be operated with batteries. At each outfall, a (2 L) sample of dry-weather discharge needs to be collected and stored in a polyethylene container. Another (500 mL) sample can also be collected in a glass container having a Teflon-lined lid for toxicity screening and selected toxicant analyses. All samples must be analyzed (or extracted) within accepted time limits.

Descriptions of the procedures and parameters recommended for the analysis and identification of dry-weather outfall samples are:

Water color--

Determine in the laboratory using a simple comparative colormetric (color wheel) field test kit from the HACH Company. Apparent color (unfiltered samples), expressed in HACH color units.

pH--

pH is measured in the laboratory using a standard laboratory pH meter after accurate calibration using at least two buffer solutions bracketing the expected sample pH value. (pH measurements using pH test paper have been found to be generally within one unit of the laboratory meter. However, this difference is too large and is not recommended. Small "pen" pH meters most suitable for field use can easily be off by a 0.5 pH unit and are relatively hard to calibrate. They accordingly must be used with care.)

Specific conductivity and temperature--

These parameters are quickly and easily measured in the field using a multi-parameter SCT meter from YSI model 33. Both specific conductivity and temperature must be calibrated against standard specific conductivity solutions and a standard thermometer. Specific conductivity should also be corrected to standard values obtained at 25°C (APHA, et al. 1989):

$$K = (K_m C)/[1 + 0.0191(t-25)]$$

where K = specific conductivity at 25°C

K_m = measured specific conductivity at temperature t°C

and C = cell constant

The cell constant is a correction factor determined by measuring a 0.01M KCl solution at 25°C, after three rinses, compared to 1413 µS/cm, the expected value. This equation results in about a 2% change in specific conductivity for every degree in temperature difference from 25°C. The International System of Units (Système International d' Unités, SI) specific conductivity unit of measurement is the µS/cm which is numerically equivalent to the U.S. Customary unit, µmhos/cm.

Fluoride--

Easily analyzed in the laboratory using a field spectrophotometer and evacuated reagent and sample vessels (HACH DR/2000™ and AccuVac™ ampules using SPADNS reagent, without distillation). The AccuVac™ procedure works well for sample concentrations less than 2.5 mg/L; however, in rare instances of higher concentrations, sample dilution is required because of non-linear instrument responses. The samples should be filtered through a 0.45 µ membrane filter (e.g., Millipore™ filter) before analysis to minimize color interference. (Specific-ion probes were also evaluated, but the technique proved to be too inconsistent, especially for personnel having little training.)

VOL 12 3972

R0037280

Ammonia--

Easily measured in the laboratory using a direct Nesslerization procedure and spectrophotometer (HACH DR/2000™ Nessler method, but without sample distillation). The samples should be filtered through a 0.45 μ membrane filter before analysis to minimize color interference. (The use of various indicator test papers and simple field test kits for ammonia determination gave poor results. Specific-ion probes were also tested. Typical problems encountered for these procedures, (except for the direct Nesslerization procedure), were color interferences, long analysis times, inconsistent results, and poor performance when standard solutions were analyzed.)

Potassium--

Measured in the laboratory either using a spectrophotometer (HACH DR/2000™ Tetraphenylborate method), or a flame atomic absorption spectrophotometer (if available). The samples should be filtered through a 0.45 μ membrane filter before spectrophotometric analysis to minimize color interference. (Specific-ion probes were also evaluated and indicated the same poor results found for fluorides and ammonia.)

Surfactants--

Measured in the laboratory using a simple comparative colormetric (color wheel) method (from the HACH Company). The samples should be filtered through a 0.45 μ membrane filter before analysis to minimize color interference. This procedure should be carried out under a laboratory fume hood. (Specific-ion probe titrations for surfactants were not successful because of poor detection limits.)

Fluorescence--

Analyzed using a laboratory fluorometer (Turner model 111). The fluorometer had general purpose filters and lamps and was operated at the most sensitive setting (number one aperture).

Hardness--

Determined in the laboratory using a field-titrimetric kit (HACH Digital Titrator Model 16900). The samples should be filtered through a 0.45 μ membrane filter before analysis to minimize color interference. (A number of simple field test kits were tested but the direct reading titration method proved most convenient and accurate. However, hardness test paper can be used to estimate the titration end point.)

Turbidity--

Determined using a HACH Naphelometer in the laboratory.

Chlorine--

Total available chlorine was determined with the DPD (N, N-diethyl-p-phenylenediamine) method using a HACH DR/2000™ spectrometer with AccuVac™ ampules.

Toxicity-screening--

Toxicity screening tests have been found to be very useful as indicators of contamination of storm drains. The Microtox™ (from Microbics) toxicity screening test can be used for relative toxicity values. The 100 percent screening test was most commonly used. If the light output decrease after 25 minutes (the I_{25} value) was greater than 50 percent, then the standard Microtox test was used to determine the sample dilution required for a 50 percent light decrease (the EC50 value). If a sample results in a large toxic response, then specific toxicant analyses (organics and metals) could be performed to better identify the toxicant source. In general, the Microtox™ screening test was found to be an efficient method for toxicity analysis, particularly for identifying samples requiring further analyses. (A number of simple test kits were used for specific heavy metal analyses, but with very poor results. High-detection limits and interferences make these methods impractical, unless an outfall is grossly contaminated with a concentrated source. such as raw plating bath wastewater.)

VOL 12

SECTION 5

INITIAL FIELD SCREENING SAMPLING ACTIVITIES

SAMPLING STRATEGY

The importance of sampling all outfalls, regardless of size, should be stressed. Figure 9 shows the distribution of outfalls for the Birmingham, Alabama area surveyed for the city's stormwater discharge permit application. The median equivalent diameter of the 566 outfalls that had drainage area estimates available was 36 in. About 20 percent of the outfalls were greater than 60 in. in diameter and about 20 percent were less than 20 in. in diameter. Most of the largest outfalls were actually drainage ditches. There was an average of about 70 acres draining to each outfall, but the drainage areas ranged from much less than one acre to over 1500 acres. About 40 percent of the outfalls were affected by either commercial or industrial land uses and would therefore be considered as critical drainage areas for both dry-weather flows and stormwater runoff.

The Birmingham, Alabama demonstration project that tested this protocol covered a residential and commercial drainage area having approx. 70 outfalls. The median outfall size of the outfalls in this study area was 16 in., and more than 75 percent of the outfalls were less than 36 in. in diameter. Examination of the outfalls during seven separate sampling occasions found that while some of the dry-weather flows occurred intermittently, most were continuous. About 25 percent of the outfalls were found to be consistently flowing during dry weather, with about two-thirds of the flows discharging from pipes that were less than 36 in. in diameter. About five percent of the outfalls exhibited dry-weather flows which were extremely toxic or were raw, undiluted, sanitary wastewater. Each of these contaminated outfalls were 20 in., or less, in diameter. Some of the worst dry-weather flow discharge problems were associated with very small (4 in. diameter) pipes draining automobile service areas adjacent to the receiving water. It was found that small outfalls can contribute significant pollutant loads to receiving waters and should not be neglected if receiving water improvement is a serious goal.

FIELD DATA COLLECTION

Before the field data can be collected, preliminary mapping and land use evaluation work is needed. Section 3 described the preliminary work and the likely data sources for the information that is needed before the field investigations can begin. The most important preliminary information required is:

- outfall locations,
- outfall drainage areas,
- commercial and industrial activities in each drainage area, and
- locations of septic tanks in the individual drainage areas.

3974

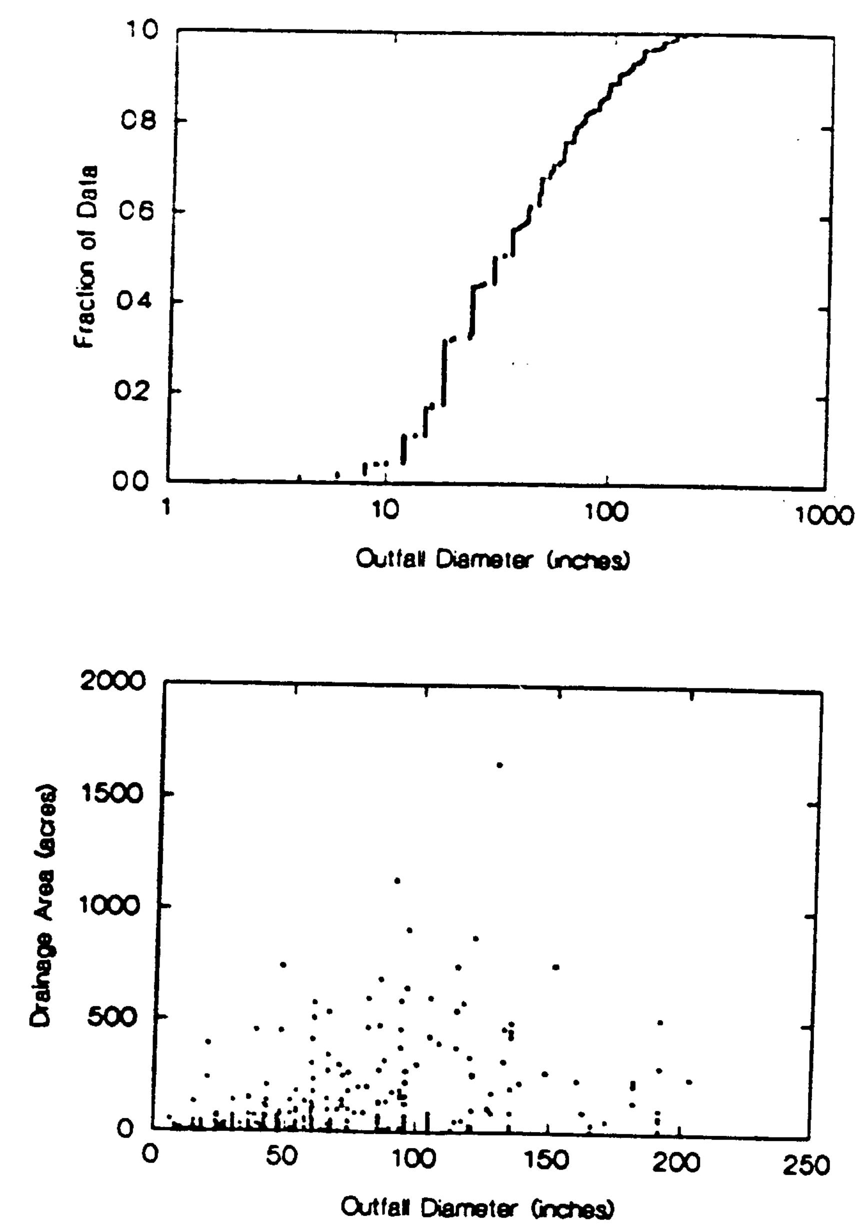

Figure 9. Outfall characteristics for Birmingham, Alabama demonstration project.

VOL 12

3976

Outfall Locations

Frequently, city maps of known outfall locations are inadequate. Many outfalls are not located on city drainage maps because of infrequent or improper updating, or unauthorized installations. Because it is very difficult for communities to maintain up-to-date maps of drainage facilities, actual stream surveys are needed to verify and update existing information. Illicit outfalls will not usually be shown on maps, and field surveys will be required to detect these as well. Most newer developments do have accurate drainage and outfall maps, but the outfall locations may not have been transferred to an overall city map. A few cities have Geographic Information Systems (GIS) in place and are including the storm drainage systems on appropriate data overlays. It is important to identify all outfalls because present data indicates no relationship between the most significant sources of non-stormwater discharges and the largest drainage areas, or the largest diameter outfalls.

Because of the likelihood of poor data concerning the outfall locations, it will probably be necessary to "walk" the creeks and actively look for outfalls. In most cases, it requires several trips (about three) to locate all outfalls. The initial outfall surveys should be conducted during times when riparian vegetation is minimal. Whenever an outfall is located, it needs to be marked (coded using spray paint or by other means).

If the receiving water is a small creek, it can be waded in a downstream direction. If the receiving water body cannot be waded, a small boat or canoe can be used to look for outfalls above the water. Submerged outfalls are more difficult to find and require more careful inspections for storm drain manholes along the shore. In flood or estuary tidal areas, surveys should be conducted during low tides when more outfalls are likely to be exposed. In many cities, streets parallel the banks of creeks or drainage canals that contain outfalls. It may be possible to carefully search the opposite bank from a moving automobile. It may also be cost-effective to use light aircraft (including helicopters) to search for outfalls. Submerged outfalls could be easier to identify from the air than from the water in cases where discharge plumes are visible.

Obviously, outfall characterizations should be conducted during these surveys, if possible. In all cases, at least two people are needed to look for outfalls, especially if wading a creek. Another person can drive a shuttle car to a convenient downstream location for crew rotation.

Field Survey

The main elements of the field sampling plan are the collection of necessary information and equipment, and preliminary screening of outfalls.

Collect necessary information and equipment--

Maps--Maps are the most important part of the field equipment. Adequate field maps can be prepared by enlarging standard USGS 7-1/2 minute quadrangle maps to appropriate scales. In addition, detailed street maps are also needed to locate specific street crossings and to identify locations of outfalls in the field.

Field sampling and analysis equipment--Table 8 lists the equipment that is needed for a field survey. In no case should personnel conduct the field surveys alone, wade streams without wearing waders, or be in boats without wearing life preservers. Heavy duty waders (heavy Cordura™ nylon) are preferred. Urban streams contain appreciable debris (broken bottles, etc.). In addition, urban

VOL 12

Temperature and specific conductivity meter.
Field notebook containing maps and non-stormwater flow evaluation field sheets.
Waterproof marker/pen.
Camera and film.
Spray paint.
Tape measures (both 3m and 30m).
Flashlight.
Watch (with second hand).
Glass sample containers with waterproof labels (500 mL).
Plastic sample containers with waterproof labels (1 to 2 L.).
Ice boxes with ice (left in vehicle).
Backpack.
Grab water sampler (dipper on long pole).
Hand operated vacuum pump sampler for shallow flows.
Waders and walking stick.
First aid kit and pocket knife.
Self protection pepper spray.
Two-way radios for communication between field crew and van driver.
Hand held GPS (global positioning satellite) system receiver (only capable of locating positions within about 100 to 350 feet).

3977

streams are isolated wildlife areas which tend to concentrate certain wildlife species that live in close proximity to man (including cottonmouths, water moccasins, copperheads, and rattlesnakes), plus contain lush growths of poison ivy or oak. The self protection pepper spray may be especially handy in case of harassing dogs.

This equipment would supplement needed boating equipment, if boats are used. Some of this equipment (ice coolers and ice, along with extra bottles) would be kept in the vehicle. In most cases, the vehicle should be moved in about 1/2 mile increments. This length would typically contain up to ten outfalls, with relatively few flowing outfalls to sample. The collected samples would therefore be iced within about 1/2 hour of collection. It is possible that the vehicle driver could conduct critical analyses (chlorine, pH and ammonia) while waiting. It is suggested that a three person crew rotate, with a new driver at each new shuttle location.

Arrange for lab testing and other support equipment--Before the field crew goes into the field to collect samples, the laboratory needs to be notified and ready to analyze the samples soon after they are available. As shown in the next section, the laboratory testing procedures for the basic tracer parameters are all simple and can be conducted in an unsophisticated laboratory. It may be feasible for the field crew to conduct the sample analyses in the afternoon of the day when they are collected.

Preliminary screening of outfalls--

Location of outfalls--Outfall locations need to be transferred to field maps and the daily activities planned. The number of outfalls that can be visited and sampled in a single day is highly dependent on outfall accessibility and mobility along the receiving water. The initial survey requires the longest time, after which repeated surveys require much less effort. In a small creek having shallow and slow water with numerous road crossings, about three miles of creek can be walked (with about 40 outfalls visited and ten outfall samples obtained) in a half-day of field activity with a crew of three people. Most other conditions would require additional labor for the same sampling effort. In all cases, careful planning, especially having an idea of where the outfalls are located, would greatly reduce the labor involved.

Scheduling field surveys--It is important to schedule the field surveys during low water levels (during low tides or low flows) because outfalls could be submerged and concealed during high water conditions. It is also best not to conduct the field surveys during periods of high flow in the receiving waters because of safety concerns.

Field surveys which are timed (diurnally, or seasonally) to coincide with periods with a greater potential for non-stormwater entries, are likely to reveal more dry-weather discharges. As examples, morning periods (or in areas of tourism, during the tourist season) usually experience the greatest sanitary wastewater flows. Scheduling sampling during these morning hours would be most successful in identifying sanitary wastewater contamination of the storm drainage system. Many inappropriate industrial entries to the storm drainage system also occur on a scheduled basis, e.g., cleaning up work areas between work shifts, or increased wastewater flows during periods of the year when the specific industry is especially busy. Again, investigating potentially affected storm drain outfalls during these critical periods would result in better data.

The field survey schedule will need to be flexible to avoid sampling during and immediately after a storm event, to ensure only dry-weather flows are recorded. In most urban areas storm runoff drainage flows will cease within 12 hours following the storm event, but this will need to be reviewed for each watershed area. The time to flow through the upstream drainage system and any detention and subsequent release of the storm water could extend this 12 hour period. This subject is discussed

VOL 12

3978

further under Section 5, Irregular Flows.

Sampling techniques--After an outfall is located, it is labeled with paint or marked by other means and the form shown on Table 9 is completed in the field. Table 10 describes the physical observation choices, previously discussed in Section 4. The use of field sheets and laboratory record keeping is very important because of the large number of outfalls that will likely be surveyed in each municipality.

Table 9 is a field sheet that can be used to record the observations and analytical results for the outfall survey. The top of the sheet includes basic outfall descriptive and weather information, a flow rate estimate, and an indication if industrial or commercial activities are known to occur in the area. The physical observation data section requires simple circling of the most appropriate value, or writing in another response. Samples should be obtained of floatable and staining materials for further laboratory microscopic analyses. If unusual vegetative conditions or damage to structures are found, then the extent and appearance of the damage should be described. In all cases, several photographs need to be taken of outfall conditions for each site visit. The analyses results are written on the form, along with a short descriptions of the equipment used.

Flows are estimated and visually characterized for each outfall visit. Field temperature and specific conductivity measurements are made in the field, and dry-weather discharge water samples are collected for later (same day) laboratory analyses. A single water sample (1 to 2 L) is sufficient for almost all analyses that may be conducted on the sample. This sample can be collected in a polyethylene collapsible container. In addition, another (500 mL) sample can be collected in a glass bottle (having a Teflon lined lid) if a toxicity screening procedure (like Microtox™) and selected organic tracers are to be analyzed. Specific sample volume requirements need to be determined in conjunction with the laboratory personnel. Excess samples should be placed in smaller polyethylene bottles and frozen for potenual future analyses (e.g., heavy metals and major ions).

Sample preservation--Usually icing of samples after collection and same-day laboratory analyses is adequate. Ammonia, chlorine, and pH are susceptible to change with time and special tests may be needed to determine the tolerable delay before laboratory analyses. As noted previously, it is not efficient to analyze the samples in the field, especially after each sample is collected.

Field tests--The only tests recommended for field analyses are temperature and specific conductivity. If a multi-purpose temperature/specific conductivity meter is being used for the temperature analyses, then both can be easily determined in the field.

Record keeping, sample preservation, and analyses--As noted above, the collected water samples need to be analyzed soon after collection. A central laboratory is much more effective than trying to analyze each sample in the field as it is collected. Section 4 presents the recommended laboratory procedures.

Data analyses--

Identification of contaminated outfalls--Section 6 describes several methods to identify the likely components in each flowing outfall. This information is then used to identify the contaminated dry-weather flows.

Isolation and correction of contaminating flow sources--After the problem outfalls are identified, drainage system surveys are used to find the sources of the contaminating flows. These procedures are briefly discussed later in this User's Guide.

TABLE 10. INTERPRETATIONS OF PHYSICAL OBSERVATION PARAMETERS AND LIKELY ASSOCIATED FLOW SOURCES

Odor - Most strong odors, especially gasoline, oils, and solvents, are likely associated with high responses to the toxicity screening test. Typical obvious odors include: gasoline, oil, sanitary wastewater, industrial chemicals, decomposing organic wastes, etc.

- sewage: smell associated with stale sanitary wastewater, especially in pools near outfall.
- sulfide ("rotten eggs"): industries, e.g., meat packers, canneries, dairies, etc; and stale sanitary wastewater.
- oil and gas: petroleum refineries or facilities associated with vehicle maintenance and operation or petroleum product storage.
- rancid-sour: food preparation facilities (restaurants, hotels, etc.).

Color - Important indicator of inappropriate industrial sources. Industrial dry-weather discharges may be of various colors, but dark colors, such as brown, gray, or black, are most common.

- yellow: chemical, textile, and tanning plants.
- brown: meat packers, printing plants, metal works, stone and concrete works, fertilizer application, and petroleum refining facilities.
- green: chemical plants, and textile facilities.
- red: meat packers.
- gray: dairies.

Turbidity - Often affected by the degree of gross contamination. Dry-weather industrial flows with moderate turbidity can be cloudy, while highly turbid flows can be opaque. High turbidity is often a characteristic of undiluted dry-weather industrial discharges.

- cloudy: sanitary wastewater, concrete or stone operations, fertilizer facilities, and automotive dealers.
- opaque: food processors, lumber mills, metal operations, and pigment plants.

Floatable Matter - A contaminated flow may contain floating solids or liquids directly related to industrial or sanitary wastewater pollution. Floatables of industrial origin may include animal fats, spoiled food, oils, solvents, sawdust, foams, packing materials, or fuel.

- oil sheen: petroleum refineries or storage facilities and vehicle service facilities.
- sewage: sanitary wastewater.

(continued)

VOL 12

3981

TABLE 10. (continued)

Deposits and Stains - Refer to any type of coating near the outfall and are usually of a dark color. Deposits and stains often will contain fragments of floatable substances. These situations are illustrated by the grayish-black deposits that contain fragments of animal flesh and hair which often are produced by leather tanneries, or the white crystalline powder which commonly coats outfalls due to nitrogenous fertilizer wastes.

sediment: construction site erosion.
oily: petroleum refineries or storage facilities and vehicle service facilities.

Vegetation - Vegetation surrounding an outfall may show the effects of industrial pollutants. Decaying organic materials coming from various food product wastes would cause an increase in plant life, while the discharge of chemical dyes and inorganic pigments from textile mills could noticeably decrease vegetation. It is important not to confuse the adverse scouring effects of high stormwater flows on vegetation with highly toxic dry-weather intermittent flows.

excessive growth: food product facilities.
inhibited growth: high stormwater flows, beverage facilities, printing plants, metal product facilities, drug manufacturing, petroleum facilities, vehicle service facilities and automobile dealers.

Damage to Outfall Structures - Another readily visible indication of industrial contamination. Cracking, deterioration, and spalling of concrete or peeling of surface paint, occurring at an outfall are usually caused by severely contaminated discharges, usually of industrial origin. These contaminants are usually very acidic or basic in nature. Primary metal industries have a strong potential for causing outfall structural damage because their batch dumps are highly acidic. Poor construction, hydraulic scour, and old age may also adversely affect the condition of the outfall structure which are not indications of upstream contaminating entries.

concrete cracking: industrial flows
concrete spalling: industrial flows
peeling paint: industrial flows
metal corrosion: industrial flows

VOL 12

3982

Irregular Flows

Irregular flows pose a special problem during the field surveys. Outfall apparent "dry-weather" flows can be intermittent in nature, only flowing soon after rains and then remaining dry, or may flow when inappropriate water sources enter the storm drainage system. If irregular flows are associated with rains, outfall surveys should be postponed until sufficient time has lapsed since the last major rain. For most urban areas, storm runoff drainage ends several hours (but usually less than 12) after the rain stops. Extended, but decreasing flows, after rains could be associated with high groundwater or percolating rain water infiltrating into the drainage system. In this case, most outfall surveys should be further delayed. However, some pollutant sources may be associated with these after storm flows, especially contaminated groundwaters (septic tank problems, leaky underground storage tanks, etc.). Therefore, it may be important to sample these flows, especially if these contaminant sources potentially exist.

Basic field indicators, such as the presence of residual stains or deposits, oil sheens, coarse solids, floatables, color, odors, etc., in the absence of a flow, indicate the likelihood of intermittent dry-weather flows. These observations will be enhanced by installing simple "tell-tale" devices, e.g., a terry-cloth (strain the discharge) or small caulk dam in the drain. Outfalls exhibiting these signs of non-continuous discharges should be visited several times to increase the probability of observing and sampling a dry-weather discharge. Analyzing pooled water immediately below the outfall or collected between visits in small, constructed dams within the storm drain can greatly assist in identifying non-continuous discharges. Coarse solids and/or floatables can be captured through the erection of coarse screens and/or booms at a manhole site, the mouth of the outfall, or in the receiving stream. It may be necessary to visit suspect outfalls frequently. However, it is virtually impossible to capture an isolated short-term intermittent flow (e.g., from the illegal dumping of wastes into the storm drainage system) from outfall visits.

Simple outfall area characteristics, noted above, are the most reliable indicator of a potential intermittent source at an outfall. In addition to using a dam, or other indicator device (e.g., a small screen to capture particulate debris), it may be desirable to use an automatic water sampler at especially important outfalls. Automatic samplers would be unreasonable and expensive to use at many outfalls in an area and test locations would need to be carefully selected. A sampler located in a close-by manhole and set to sample every fifteen minutes (with four samples placed in each bottle) can monitor for intermittent flows for a period of 24 hours. Automatic samplers can also be used to characterize variable quality flows. This information can be valuable in identifying possible discharge sources.

VOL 12

3983

SECTION 6

DATA ANALYSIS TO IDENTIFY PROBLEM OUTFALLS AND FLOW COMPONENTS

The field screening surveys are to be used as an initial effort to identify the outfalls needing more detailed drainage area investigations which would identify specific pollutant sources and control options. These field screening surveys, discussed in Sections 4 and 5, include physical, chemical, and relative toxicity evaluations of outfall and/or discharge conditions.

The purpose of the procedures presented in this User's Guide is to separate storm drain outfalls into general categories (with a known level of confidence) and to identify which outfalls (and drainage areas) need further analyses and investigations. The categories used in this Guide are outfalls affected by non-stormwater entries from: (1) pathogenic or toxic pollutant sources, (2) nuisance and aquatic life threatening pollutant sources, and (3) unpolluted water sources.

The pathogenic and toxic pollutant source category should be considered the most severe because it could cause disease upon water contact or consumption and cause significant impacts on receiving water organisms. They may also cause significant water treatment problems for downstream consumers, especially if they contain soluble metal and organic toxicants. These pollutants may originate from sanitary, commercial, and industrial wastewater non-stormwater entries. Other important residential area activities that may also be considered in this most critical category (in addition to sanitary wastewater) include inappropriate household toxicant disposal, automobile engine de-greasing, vehicle accident clean-up, and irrigation runoff from landscaped areas excessively treated with chemicals (fertilizers and pesticides).

Nuisance and aquatic life threatening pollutant sources can originate from residential areas and can include laundry wastewater, landscaped area irrigation runoff, automobile washing, construction site dewatering, and washing of concrete mixing trucks. These pollutants can cause excessive algal growths, depressed dissolved oxygen concentrations, tastes and odors in downstream water supplies, offensive coarse solids and floatables, and highly colored, turbid or odorous waters.

Relatively clean or unpolluted water discharged through stormwater outfalls can originate from natural springs feeding urban creeks that have been converted to storm drains, infiltrating groundwater, and infiltrating potable water from water line leaks.

A method must be used to compare data from individual outfall dry-weather samples to the library of dry-weather source flow data to identify which outfalls belong in which general category of contamination listed above. This comparison should result, at the very least, in the identification of the outfalls that are considered as major pollutant sources for immediate remediation. The degree of detail which can be identified for an outfall will depend on the extent of the local data collected to describe the likely source flows.

The procedures that can be used to identify outfall flow components may begin with simple yes/no checks. For example, if no surfactants are measured in an outfall sample, then sanitary wastewater is unlikely to be a contributor to the outfall flow. If no fluoride is measured, then fluoride

VOL 12

3984

treated potable water sources could be ruled out as contributors. The probability that remaining contenders are present alone or in a mixture may be determined using a combination of matrix algebra and the selecting of random values from within specified ranges using a Monte Carlo process and many iterations.

Most contaminated outfalls will require correction before the receiving water quality recovers to acceptable levels. However, ranking the outfalls allows the most serious outfalls to be recognized and enables corrective action to be initially concentrated in the most cost-effective manner. In some of the case studies investigated, correcting only problems at the most critical outfalls resulted in insufficient receiving water quality improvements. It may be important to eventually correct all non-stormwater discharge problems throughout a city, not just the most severe problems. The field screening program should therefore be considered as an initial effort that needs to be followed-up with more detailed watershed drainage surveys in most of the areas having observed dry-weather flows. The follow-up watershed surveys are to identify and correct inappropriate pollutant entries into storm drainage systems, as discussed in Sections 7 and 8.

The identification of flow components of the dry-weather storm drain flow can be used to determine which outfalls have the greatest pollution potential. As an example, if an outfall contains sanitary wastewater, it could be a significant source of pathogenic microorganisms. Similarly, if an outfall contains plating bath water from a metal finisher, it could be a significant source of toxicants. These outfalls would be grouped into the most critical category of toxicants/pathogens. If an outfall contains washwaters from a commercial laundry or car wash, the wastewater could be a major source of nutrients and foaming material. These outfalls would be grouped into an intermediate category of nuisance and aquatic life threatening. Finally, if an outfall only contains unpolluted groundwater or water from leaky potable water mains, the water would be non-polluting and the outfall would be grouped into the last category of unpolluted water sources.

The five methods of data analyses presented in the following discussions present a hierarchy of methods, ranging from relatively simple reviews of the outfall characteristics to more sophisticated methods requiring computer modeling for evaluation. It is suggested that as many of the procedures be used as possible in evaluating the data, as each method provides some unique insights into the problems. Pitt and Lalor (publication pending) contains a more through discussion of these analysis procedures, including evaluation of the Birmingham, Alabama, demonstration project data.

INDICATORS OF CONTAMINATION

Indicators of contamination (negative indicators) are clearly apparent visual or physical parameters indicating obvious problems and are readily observable at the outfall during the field screening activities. These observations are very important during the field survey because they are the simplest method of identifying grossly contaminated dry-weather outfall flows. The direct examination of outfall characteristics for unusual conditions of flow, odor, color, turbidity, floatables, deposits/stains, vegetation conditions, and damage to drainage structures is therefore an important part of these investigations. Table 10 in Section 5 presented a summary of these indicators, along with narratives of the descriptors to be selected in the field.

This method does not allow quantifiable estimates of the flow components and if used alone will likely result in many incorrect determinations (missing outfalls that have important levels of contamination). These simple characteristics, discussed further below, are most useful for identifying gross contamination. Only the most significant outfalls and drainage areas would therefore be recognized from this method. The other methods, requiring chemical determinations, can be used to quantify the flow contributions and to identify the less obviously contaminated outfalls.

Indications of intermittent flows (especially stains or damage to the structure of the outfall) could indicate serious illegal toxic pollutant entries into the storm drainage system that will be very difficult to detect and correct. Highly irregular dry-weather outfall flow rates or chemical characteristics could indicate industrial or commercial inappropriate entries into the storm drain system.

During the demonstration phase of this research project (Pitt and Lalor publication pending), odors and high turbidity were found to be the most useful physical indicators of severely contaminated outfall flows. High turbidity correlated well with high levels of surfactants and toxicity. Noticeable odors also correlated well with elevated toxicity. Color was not a very useful indicator of gross contamination and elevated toxicity, unless the color exceed 65 HACH color units.

Gross industrial wastewater contamination may be indicated by the presence and nature of floatable material and deposits near the outfall. Table 11 summarizes possible chemical and physical characteristics of non-stormwater discharges which could come from various industries. The properties considered are pH, total dissolved solids, odor, color, turbidity, floatable materials, vegetation, and damage to outfall structure. The descriptions in each of these categories contain the most likely conditions for a non-stormwater discharge coming from a particular industry. It should be noted that outfalls are likely to be affected by several industrial sources simultaneously, especially if draining industrial parks. The initial watershed analysis, discussed previously, which needs to describe the industrial and commercial facilities that are operating in each outfall's watershed, will be of great assistance in identifying which industries may be contributing dry-weather entries into the storm drainage system.

SIMPLE CHECKLIST FOR MAJOR FLOW COMPONENT IDENTIFICATION

Figure 10 is a flow chart describing the analysis strategy to identify the major non-stormwater discharge sources in residential areas. The first indicator is the presence or absence of flow. If no dry-weather flow exists at an outfall, then indications of intermittent flows must be investigated. Specifically, stains, deposits, odors, unusual stream-side vegetation conditions, and damage to outfall structures can all indicate intermittent non-stormwater flows. However, frequent visits to outfalls over long time periods are needed to confirm that only stormwater flows occur. The other points on the flow chart (Figure 10) serve to indicate if major contaminating sources are present, or if the water is uncontaminated water. The other methods discussed later are needed to quantify the component contributions.

Treated Potable Water

A number of tracer parameters may be useful for distinguishing treated potable water from natural waters:

- Major ions or other chemical/physical characteristics of the flow components can vary substantially depending upon whether the water supply sources are groundwater or surface water, and whether the sources are treated or not. Specific conductance may also serve as a rough indicator of the major water source.

- Fluoride can often be used to separate treated potable water from untreated water sources. Untreated water sources can include local springs, groundwater, regional surface flows or non-potable industrial waters. If the treated water has no fluoride added, or if the natural water has fluoride concentrations close to potable water fluoride concentrations, then fluoride may

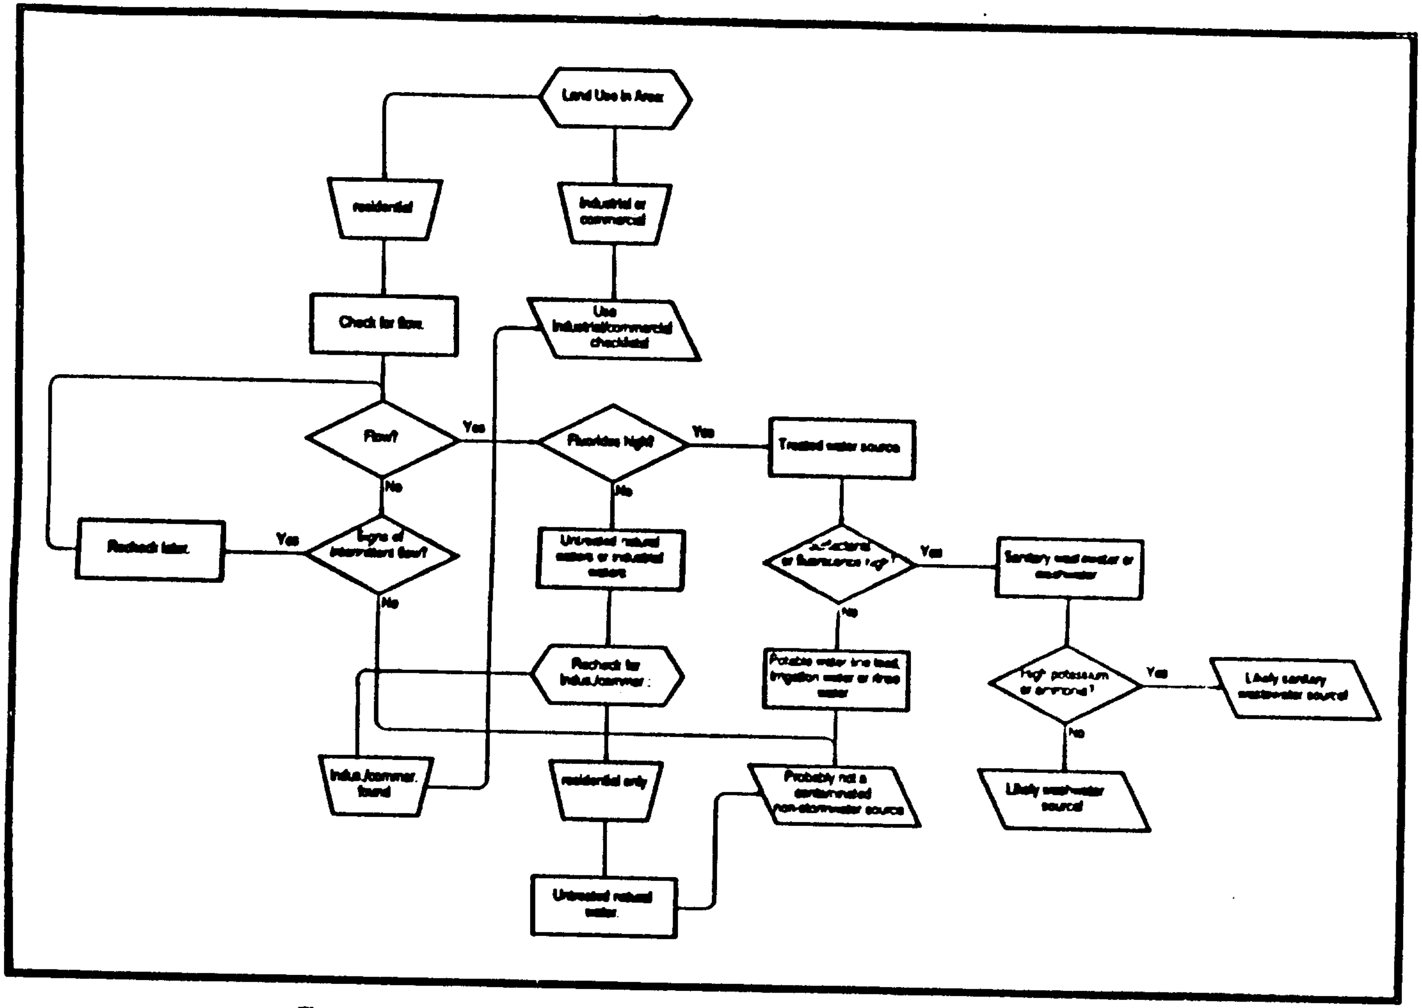

Figure 10. Flow chart to identify residential area non-stormwater flow sources.

not be an appropriate indicator.

- Hardness can also be used as an indicator if the potable water source and the baseflow are from different water sources. An example would be if the baseflow is from hard groundwater, and the potable water is from softer surface supplies.

- If the concentration of chlorine is high, then a major leak of disinfected potable water is likely to be close to the outfall. Because of the rapid dissipation of chlorine in water (especially if some organic contamination is present) it is not a good parameter for quantifying the amount of treated potable water observed at the outfall.

Water from potable water supplies (that test positive for fluorides, or other suitable tracers) can be relatively uncontaminated, e.g., potable waterline leakage or irrigation runoff, or heavily contaminated, e.g., sanitary wastewater.

<u>Sanitary Wastewaters</u>

In areas containing no industrial or commercial sources, sanitary wastewater is probably the most severe dry-weather contaminating source of storm drain flows. The following parameters can be used for quantifying the sanitary wastewater components of the treated potable water portion:

- Surfactant analyses may be useful in determining the presence of sanitary wastewaters. However, surfactants present in water originating from potable water sources could indicate sanitary wastewaters, laundry wastewaters, car washing wastewater, or any other waters containing surfactants. If surfactants (or fluorescence) are not present, then the potable water could be relatively uncontaminated (potable waterline leaks or irrigation runoff).

- The presence of fabric whiteners (as measured by fluorescence using a fluorometer in the laboratory or in the field) can also be used in distinguishing laundry and sanitary wastewaters.

- Sanitary wastewaters often exhibit predictable trends during the day in flow and quality. In order to maximize the ability to detect direct sanitary wastewater connections into the storm drainage system, it would be best to survey the outfalls during periods of highest sanitary wastewater flows (mid to late morning hours).

- The ratio of surfactants to ammonia or potassium concentrations may be an effective indicator of the presence of sanitary wastewaters or septic tank effluents. If the surfactant concentrations are high, but the ammonia and potassium concentrations are low, then the contaminated source may be laundry wastewaters. Conversely, if ammonia, potassium, and surfactant concentrations are all high, then sanitary wastewater is the likely source. Some researchers have reported low surfactants in septic tank effluents. Therefore, if surfactants are low, but potassium and ammonia are both high, septic tank effluent may be present. However, Pitt and Lalor (publication pending) found high surfactant concentrations in septic tank effluent during the Birmingham, Alabama demonstration project. This further stresses the need to obtain local site specific characterization data for potential contaminating sources.

- Obviously, odor and other physical characteristics, e.g., turbidity, coarse and floating "tell-tale" solids, foaming, color, and temperature would also be very useful in distinguishing sanitary wastewater from washwater or laundry wastewater sources. However, these indicators may not be very obvious for small levels of sanitary wastewater contamination.

FLOW-WEIGHTED MIXING CALCULATIONS

Before any flow-weighted mixing calculations can be made, the characteristics of potential contaminating sources must be identified. Table 12 summarizes hypothetical concentration medians and COVs for tracers that have been recommended to be used in the investigation of non-stormwater entries into storm drainage systems in residential areas. This method is an extension of the checklistmethod described above and attempts to quantify the likely source flow components at the outfall during dry weather.

Two general groupings of flow sources can usually be recognized for each of these tracers, a high concentration group and a low concentration group. Table 13 describes these groups, along with their composite tracer concentration ranges, variations, and medians. The outfall flow can be split between the two general groupings by simple algebra. This method can result in substantial errors if the tracer concentrations cannot be separated into distinct source groupings. The next two methods, using matrix algebra to solve simultaneous equations, do not require this simplifying assumption.

Example Calculations

The drainage area for a sampled outfall had no septic tanks or commercial and industrial land uses. The likely flow sources had source flow characteristics as described in Table 12. The required detection limits and precision for outfall characterizations must be determined, as previously described, for these source flow characteristics and desired study results. This outfall had the following tracer concentrations in a dry-weather sample:

Fluoride: 0.6 mg/L

Hardness: 200 mg/L as $CaCO_3$

Surfactants: 0.6 mg/L as MBAS

Potassium: 3 mg/L

Ammonia: 3 mg/L

The water had a slight septic odor, with some floatables of apparent sanitary wastewater origin. In addition, dry-weather flow was observed at the outfall during all visits.

It is apparent that this outfall has a direct connection(s) of raw sanitary wastewater. This method can determine the approximate mix of sanitary wastewater in the outfall flow and identify the other flow components. Table 14 summarizes the example calculations used in this analysis. The list below indicates the approximate expected source components at this outfall from this analysis:

Raw sanitary wastewater: 5%

Laundry wastewater: 5%

Groundwater: 70%

Remainder (most likely potable water, but may also contain irrigation water): 20%

This analysis did not consider the potential ranges in observed tracer concentrations and the

TABLE 14. MIXTURE CALCULATIONS TO IDENTIFY SOURCE FLOW COMPONENTS

Fluorides: 0.6 mg/L observed at outfall

x = fraction of surface & groundwater with concentration of 0.2 mg/L
y = fraction of treated water (all other sources) with concentration of 1.3 mg/L
(x & y fraction concentrations taken from Table 13)

x(0.2) + y(1.3) = 0.6 (for a unit volume of outfall water)
x + y = 1 (for no other sources of fluorides)

x = 0.63 (surface & groundwater)
y = 0.37 (all other sources)

Hardness 200 mg/L as $CaCO_3$ observed at outfall

x = fraction of groundwater with concentration of 250 mg/L as $CaCO_3$
y = fraction of all other sources with concentration of 39 mg/L as $CaCO_3$

x(250) + y(39) = 200

x = 0.76 (groundwater)
y = 0.24 (all other sources)

From Fluorides and Hardness Data:

Groundwater & Surface water = 0.63
Groundwater alone = 0.76
Surface water alone = -0.13→0

Therefore:
Groundwater fraction = (0.63 + 0.76)/2 = 0.7

Surfactants: 0.6 mg/L as MBAS observed at outfall

x = fraction of sanitary & laundry wastewater with a concentration of 4.6 mg/L as MBAS
y = fraction of all other sources with a concentration of 0.14 mg/L as MBAS

x(4.6) + y(0.14) = 0.6

x = 0.10 (sanitary & laundry wastewater)
y = 0.90 (all other sources)

VOL 12

3995

TABLE 14. (continued)

Potassium: 3 mg/L observed at outfall

x = fraction of sanitary wastewater
with a concentration of 21 mg/L
y = fraction of all other sources
with a concentration of 2.3 mg/L

$$x(21) + y(2.3) = 3$$

x = 0.04 (sanitary wastewater)
y = 0.96 (all other sources)

Ammonia: 3 mg/L observed at outfall

x = fraction of sanitary wastewater
with a concentration of 47 mg/L
y = fraction of all other sources
with a concentration of 0.44 mg/L

$$x(47) + y(0.44) = 3$$

x = 0.06 (sanitary wastewater)
y = 0.94 (all other sources)

From Surfactants, Potassium, and Ammonia Data:

Sanitary wastewater = (0.04 + 0.06)/2 = 0.05

Laundry wastewater = 0.1 - 0.05 = 0.05

resulting errors that may be associated with the above mixture portions. The following procedures are better suited for error analyses.

MATRIX ALGEBRA SOLUTION OF SIMULTANEOUS EQUATIONS

It is possible to estimate the outfall source flow components using a set of simultaneous equations. The number of unknowns should equal the number of equations available, resulting in a square matrix. If there are eleven likely source categories, then there should be eleven tracer parameters used. If there are only four possible sources, then only four tracer parameters should be used.

Further statistical analyses may therefore be needed to rank the usefulness of the tracers for distinguishing different flow sources. Pitt and Lalor (publication pending) show examples of how cluster and principal component analyses can be used to identify redundancy and other problems in the data library. As an example, chlorine is not useful for these analyses because the concentration variability within many source categories is high (it is also not a conservative parameter). Chlorine may still be a useful parameter, but only to identify possible large potable waterline leaks. It cannot be used to quantify the flow components. Another parameter having problems for most situations is pH. The variation of pH between sources is very low (they are all very similar). However, pH may still be useful to identify industrial wastewater problems, but it cannot be used to quantify flow components. pH is also not linearly affected by mass balance mixtures (a solution of 50 percent/50 percent of two components would not result in a pH value that is the average of the two individual pH values).

These equations are structured on a mass balance basis, like the previous procedure, but they can be used to distinguish all source categories simultaneously. A simplified example is shown in the following discussion considering just four possible flow components and four tracer parameters (P1, P2, P3, P4). This would result in the following set of equations for each outfall sample:

tracer parameter:	possible sources: 1		2		3		4		outfall quality
P1:	(A1)(C11)	+	(A2)(C21)	+	(A3)(C31)	+	(A4)(C41)	=	m1
P2:	(A1)(C12)	+	(A2)(C22)	+	(A3)(C32)	+	(A4)(C42)	=	m2
P3:	(A1)(C13)	+	(A2)(C23)	+	(A3)(C33)	+	(A4)(C43)	=	m3
P4:	(A1)(C14)	+	(A2)(C24)	+	(A3)(C34)	+	(A4)(C44)	=	m4

A1 through A4 represent the fraction of flow contributed from each possible flow source. The "C" terms represent concentrations from the source flow library for each particular parameter (P) within each flow source(1-4). The "m" terms represent the concentration of P actually measured in the outfall sample.

VOL 12

3997

The following is an example for an outfall dry-weather sample:

possible sources:

tracer parameter:	potable water	ground water	sanitary wastewater	laundry wastewater	outfall quality
fluoride:	(A1)(0.97 mg/L)	+ (A2)(0.031 mg/L)	+ (A3)(0.77 mg/L)	+ (A4)(33 mg/L)	= 3.8 mg/L
hardness:	(A1)(49 mg/L)	+ (A2)(240 mg/L)	+ (A3)(140 mg/L)	+ (A4)(14 mg/L)	= 126 mg/L
surfactants:	(A1)(0 mg/L)	+ (A2)(0 mg/L)	+ (A3)(1.5 mg/L)	+ (A4)(27 mg/L)	= 3.0 mg/L
potassium:	(A1)(1.6 mg/L)	+ (A2)(0.73 mg/L)	+ (A3)(6.0 mg/L)	+ (A4)(3.5 mg/L)	= 2.2 mg/L

This simple 4x4 matrix can be solved using available scientific calculators or math programs for personal computers, or by hand. For this example, the following are the approximate flow components (rounded to the nearest 5 percent):

- treated potable water (A1): 30%
- groundwater (A2): 35%
- sanitary wastewater (A3): 20%
- laundry wastewater (A4): 10%

These component contributions do not all add up to 100 percent. A number of errors, especially variations in source area characteristics and other sources present that were not considered, tend to result in component sums that are not 100 percent. The following method is similar, but considers uncertainty in source area characteristics and results in a range of likely component contributions.

MATRIX ALGEBRA CONSIDERING PROBABILITY DISTRIBUTIONS OF LIBRARY DATA

A stochastic version of the above procedure enables the variation in the library values to be considered. The matrix is set up in the same way, but instead of using a single value representing the parameter concentration for each likely source flow, a Monte Carlo simulation is used to randomly select values. A large number of analyses (from a few hundred to many thousands) are conducted and the percentage contributions for each component source are presented as a probability distribution instead of a single value.

It is therefore necessary to describe the distribution of source flow characteristics. In most cases, the tracer parameters can be represented using log-normal distributions. Some parameters, however, are adequately described with normal distributions. Again, local source flow monitoring is necessary to obtain this information. Pitt and Lalor (publication pending) contains examples using this method, including the code for the necessary computer program.

VOL 12

3999

SECTION 7

WATERSHED SURVEYS TO CONFIRM AND LOCATE INAPPROPRIATE POLLUTANT ENTRIES TO THE STORM DRAINAGE SYSTEM

After initial outfall surveys have indicated the presence of contamination, further detailed analyses are needed to identify and locate the specific contaminant source(s) (e.g., residential, commercial, and/or industrial) in the drainage area. For source identification and location, upstream survey techniques should be used in conjunction with an in-depth watershed evaluation. Information on watershed activities can be obtained from aerial photography and/or zoning maps, while upstream survey techniques will include the analysis of the dry-weather flow at several manhole points along the storm drainage system to narrow the location of the contaminating source; tests for specific pollutants or ions associated with known activities within the outfall catchment area; and the measurement of water flow rate and temperature, visual and T.V. inspections, and smoke and dye tests.

USING TRACER PARAMETERS IN THE DRAINAGE SYSTEM

In order to identify the specific contaminant sources in the drainage system, further detailed watershed analyses are needed. These may include:

- drainage system surveys (tests for specific pollutants, visual inspections, T.V. drainage pipe inspections, and smoke and dye tests),
- in-depth watershed evaluation (including aerial photographs), and
- industrial and commercial site studies.

Review Industrial User Surveys or Reports

This will require the submission of a questionnaire to industries to determine which industries or commercial locations are discharging to a storm drainage system. However site inspections will still be required because questionnaires may not be returned or may give incorrect details (either deliberately or unknowingly).

Follow-up Drainage Area and On-Site Investigations.

Further drainage area investigations upstream of identified problem outfalls would be conducted after the outfall studies have indicated dry-weather discharge problems. In order to be cost-effective, only a sub-sample of manholes located in a drainage area identified as having significant non-stormwater sources should be tested for the tracers. As an example, the main storm drain trunk sewer could be divided into tenths and the manholes closest to these subdivisions would be sampled. This would identify the upper limit of the drainage area above which the major sources are not located. A location may also be identified where the downstream manhole tracer mass yields (concentration times flow rate) are the same. This would mark the downstream limit of the contributing area for the tracers of concern. After the main trunk drainage reach is identified that contains the major non-stormwater sources, the branch storm drain lines can be similarly subdivided (but into fewer sections each, perhaps about three) and evaluated. Depending on the drainage area and complexity of the storm drainage system, this scheme could be suitably modified to enable the identification of relatively small areas responsible for the non-stormwater pollutant entries into the storm drainage system. These small areas would then be subject to the more intensive on-site investigations by smoke tests, dye studies, and T.V. inspections.

The above drainage system analysis procedure may find that the drainage system is contaminated by widespread sanitary wastewater entries, possibly due to sanitary and storm drainage systems in extremely poor condition. This situation may require that the drainage system undergo extensive and costly repairs. It may be more appropriate to consider the storm drainage system as a combined sewer and examine control alternatives that have been developed for combined sewer systems. This would also save further detailed drainage system analyses costs.

These drainage system surveys would be followed by industrial and commercial on-site investigations (e.g., dye and smoke studies and T.V. inspections) to locate specific sources of non-stormwater pollutant entries into the drainage system. Additionally, aerial photography can be very useful during later phases of non-stormwater discharge control projects. As an example, aerial photography can help identify areas having failing septic systems located in residential areas served by storm drainage systems. Aerial photography can also be used to identify continuous discharges to surface drainage systems, such as sump discharges, and to identify storage areas that may be contributing significant amounts of pollutants during rains. For example, the Tennessee Valley Authority (TVA), among other agencies, has extensively used aerial photography (stereo color infrared) to identify pollution sources, especially from failing septic tanks (Perchalski and Higgins 1988). The TVA's flights are made in early spring when investigating septic tank failures, to be able to identify unusual grass conditions, with minimal interference from trees. The flights are made at 6,000 feet, with resulting image scales of 1 inch to 1,000 feet. Their photography costs have been about $40 to $150 per square mile.

FLOW MASS BALANCES, DYE STUDIES, AND SMOKE TESTS

Industrial areas are known to contribute significantly polluted wet-weather stormwater discharges, along with contaminated dry-weather entries into the storm drainage system. Additional industrial site investigations are therefore needed to identify activities that apparently contribute these contaminants to the storm drainage system. Figure 11 is an industrial site survey form prepared by the Non-Point Source and Land Management Section of the Wisconsin Department of Natural Resources (R. Bannerman, personal communication). This form has been used to help identify industrial activities that contribute significantly polluted, indirectly connected dry- and wet-weather non-stormwater entries into the storm drainage system.

This form only considers outside sources that would affect the storm drainage system by entering through inlets or through sheetflow runoff into drainage channels. It does not include any information concerning indoor activities, or direct plumbing connections to the storm drainage system. However, the information included on this form can be very helpful in devising runoff control programs for industrial areas. This information most likely affects wet-weather discharges much more than dry-weather discharges. Obvious dry-weather leaching or spillage problems are also noted on the form.

Locating An Industrial Source

Hypothetical examples have been created to demonstrate how dry-weather discharges can be characterized so that their likely industrial sources can be identified. These examples show how observations of outfall conditions and simple chemical analyses, combined with a basic knowledge of wastewater characteristics of industrial and commercial operations located in the drainage area, can

be used to identify the possible pollutant sources. The initial activities include pollutant analyses of outfalls being investigated. This requires the characterization of the non-stormwater flows, the identification of the likely industries responsible for the observed discharges, and finally, locating the possible specific sources in the watershed.

Hypothetical Conditions--

The hypothetical industries which were identified as being located in a stormwater drainage area (from the watershed analysis) included a vegetable cannery, general food store, fast food restaurant, cheese factory, used car dealer, cardboard box producer, and a wood treatment company. The methods used to determine the most likely industrial source of the dry-weather discharges are considered for three hypothetical situations of outfall contamination.

Case Example One--The hypothetical results of the pollutant analysis for the first situation found constant dry-weather flow at the outfall. The measurements indicated a normal pH (6) and low total dissolved solids concentrations (300 mg/L). Other outfall characteristics included a strong odor of bleach, no distinguishing color, moderate turbidity, sawdust floatables, a small amount of structural corrosion, and normal vegetation.

The significant characteristic in this situation is the sawdust floatables (see Figure 12). The industries which could produce sawdust and have dry-weather flow drainage to this pipe are the cardboard box company and the wood treatment company. According to SIC code, the cardboard box company would fall under the category of "Paper Products" (SIC# 26) while the wood treatment company would be under that of "Lumber and Wood" products (SIC# 24). Looking up these two industries by their corresponding SIC group numbers in Table 11 and comparing the listed properties, indicates that the paper industry has a strong potential for the odor of bleach. Wood products does not indicate any particular smell.

Based upon this data, the most likely industrial source of the industrial non-stormwater discharge would be the cardboard box company. Table 2 under SIC# 26 indicates that there is a high potential for direct connections in paper industries under the categories of water usage and illicit or inadvertent connections. At this point, further testing should be conducted at the cardboard box company to find if the constant source of contamination is coming from cooling waters, process waters, or direct piping connections (process waters are the most likely source given the bleach and sawdust characteristics).

Case Example 2--The results of the pollutant analysis for the second situation found intermittent dry-weather discharges at the outfall. The test measurements indicated a low pH (3) and high total dissolved solids concentrations (approximately 6,000 mg/L). Other characteristics included a rancid-sour odor, grayish color, high turbidity, gray deposits containing white gelatin-like floatable material, structural damage in the form of spalling concrete, and an unusually large amount of plant life.

The rancid-sour smell and the presence of floatable substances at this outfall indicates that some type of food product is probably spoiling. This narrows the possible suspect industries to the fast food restaurant, cheese factory, vegetable cannery, and food store (see Figure 13). The corresponding SIC categories for each of these industries are "Eating and Drinking Places" (SIC# 58), "Dairy Products" (SIC# 202), "Canned and Preserved Fruits and Vegetables" (SIC# 203), and "Food Stores" (SIC# 54). Comparison of the properties listed in Table 11 for these SIC numbers indicates that elevated plant life is common to industrial wastes for the "Dairy Products" and "Food Stores" categories. However, the deciding factor is the low pH, which is only listed for "Dairy Products". Thus, the white gelatin-like floatables are most likely spoiled cheese byproducts which are also the probable cause of the sour-rancid smell.

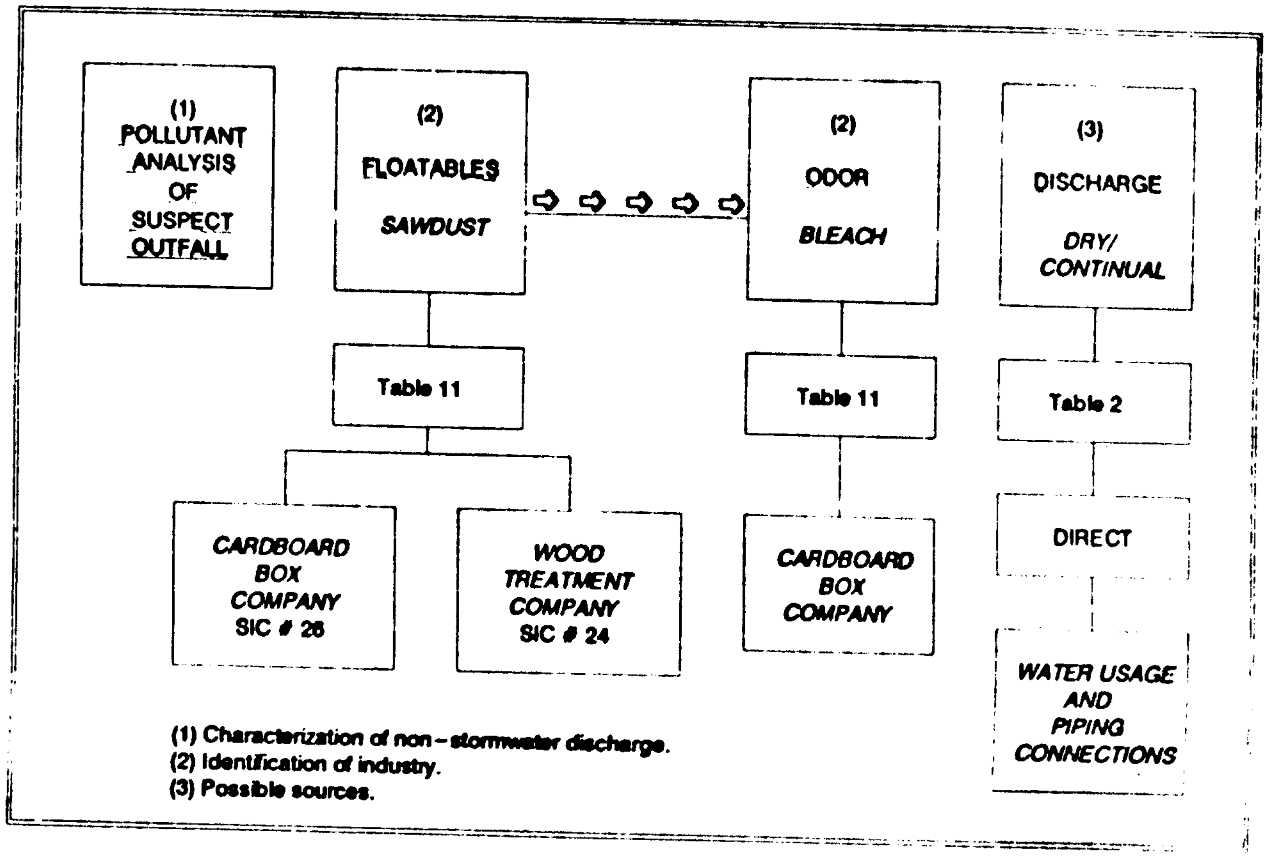

Figure 12. Flowsheet for Industrial Case 1.

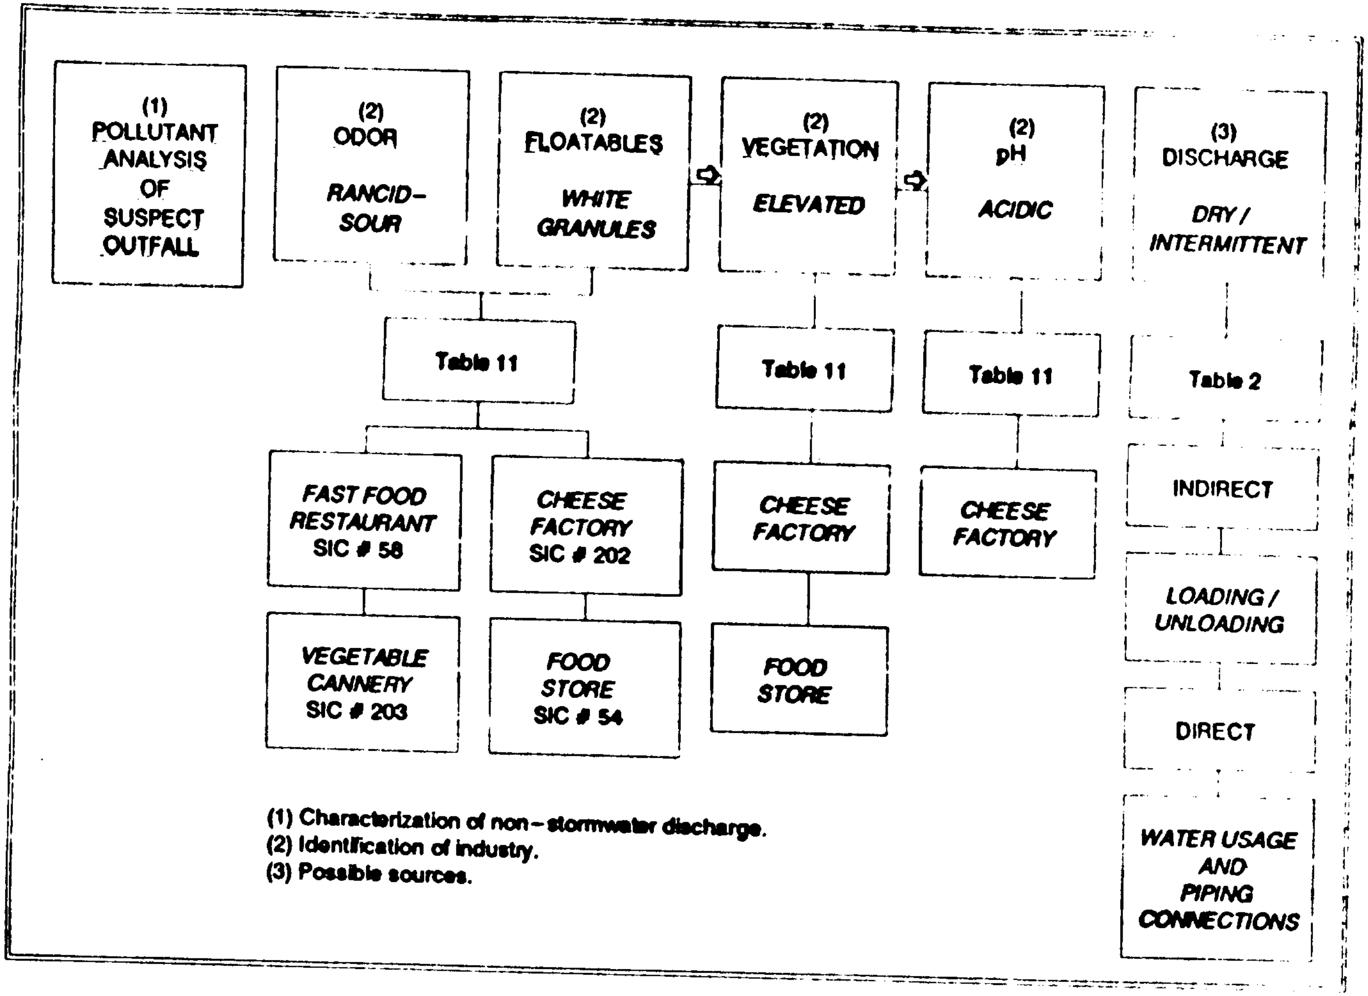

Figure 13. Flowsheet for Industrial Case Example 2.

Since the dry-weather entry to the storm drainage system occurs intermittently, the flow could be caused by either a direct or indirect connection. To locate the ultimate source of this discharge coming from the cheese factory, both direct and indirect industrial situations are considered under the category of "Dairy Products" in Table 2. Thus, further examination of the loading dock procedures, water usage, and direct piping connections should be conducted since these categories all exhibit high potential for pollution in dairy production.

Case Example 3-- The results of the test measurements for the final situation found a normal pH (6) and low total dissolved solids (about 500 mg/L). Signs of contaminated discharges were found at the outfall only during and immediately following rainfalls. Other outfall properties observed included an odor of oil, deep brown to black color, a floating oil film, no structural damage, and inhibited plant growth (see Figure 14).

According to Table 11, the fast food restaurant and the used car dealer are the only two industrial sources in this area with high potential for causing oily discharges. Their respective SIC categories are "Eating and Drinking Places" (SIC# 58) and "Automotive Dealers" (SIC# 55). Comparison of the properties shown on Table 11 indicates inhibited vegetation only for the second category. Thus, the most likely source of the discharge is the used car dealer.

Furthermore, the source of contamination must likely be indirect, since the discharge occurs only during wet weather. Reference to Table 2, under the category of "Automotive Dealers", indicates a high potential for contamination due to outdoor storage. This fact, plus the knowledge that most used cars are displayed outdoors, makes it fairly clear that surface runoff is probably carrying spilled car oil into the storm drain during rains.

SECTION 8

CORRECTIVE TECHNIQUES

In addition to identifying problems of unauthorized or inappropriate entries to stormwater systems, it is even more important to prevent problems from developing at all, and to provide an environment in which future problems will be avoided. Thus, a combined approach of identifying and correcting existing problems and avoiding future problems has considerable merit. In this section, the focus is on discussing ways in which future problems can be avoided. However it should be noted that this is not an in depth review, but has been included to provide the reader with suggestions that could be incorporated into a pollution prevention program.

There are also situations in which the sanitary system is so connected to the stormwater system that good intentions, vigilance, and reasonable remedial actions will not be sufficient to solve the problems. In an extreme case, it may be that while it was thought that a community had a separate sanitary sewer system and a separate storm drainage system, in reality the storm drainage system is acting as a combined sewer system. When recognized for what it really is, the alternatives for the future become clearer: undertake the considerable investment and commitment to rebuild the system as a truly separate system, or recognize the system as a combined sewer system, and operate it as such, without the disillusionment that it is a problem-plagued storm drainage system which can be rehabilitated.

Less extreme than designating a polluted stormwater drainage system a combined sewer system, is the action of focusing on pollution prevention by:

- public education,
- an organized systematic program of disconnecting commercial and industrial non-stormwater entries into the storm drainage system,
- tackling the problem of widespread septic system failure,
- disconnecting direct sanitary sewerage connections,
- rehabilitating storm or sanitary sewers to abate contaminated water infiltration, and
- developing zoning and ordinances.

In this section, the above items will be discussed, together with a section on treatment of wide spread sanitary sewerage failure.

PUBLIC EDUCATION

One can argue that an ill informed and apathetic public has condoned the past actions of private citizens, commercial entities, industrial concerns, and public officials which led to some of the past and present problems with unauthorized entries to storm drainage systems. One also knows the power of an aroused, concerned public in altering behavior at all levels. Thus, public education has a role to play. It can be effective in altering the behavior of an individual who had assumed that the inlet on the curb was the place to discharge used crankcase oil. It can be effective when organized groups lobby for the return of a stream or a reservoir to a clean and attractive condition.

Public education carries with it the implicit assumption that an educated public will make the "right" decisions, the educated public will be concerned about the "right" problems, and it will encourage private and public organizations to develop solutions to the "right" problems. Fortunately, most of the problems, issues, and corrective measures are clear cut with respect to unauthorized entries to the stormwater system. Public education is a communication art associated with significant changes when successful, and imperceptible change when unsuccessful. As with all education, it does not end, but is a continuing process. The following paragraphs describe some of the ways in which public officials can help to educate the public. The "public" has been subdivided into categories which are representative of the problem areas with respect to unauthorized entries to storm drainage systems. The subcategories of the public are:

- industrial
- commercial
- residential
- governmental

Industrial decision makers can be educated by public officials through direct contact when they seek information, by education of the consultants from whom industry seeks advice, and by education of trade associations. Indirect educational opportunities are provided by speaking to meetings of professional organizations and by writing in professional newsletters and journals. Industrial decision makers are a small group which is likely to respond as they recognize that they have to address the problem of unauthorized entries to the stormwater system.

Commercial storm drainage system users are a larger group to educate. The educational process will have to focus on both proprietors and their employees. It will have to recognize the state of both groups, new businesses opening; existing businesses moving, expanding, and closing; and employees entering the work force and changing jobs. Education will have to be focused in the local community. The role of trade and professional associations will be less than was the case with industrial groups. News announcements in the local press will play a role as well as mailed news items. Individual contact between a public official and the proprietor of a commercial establishment will play a larger role. Follow up and repeated contact may be necessary to answer questions and cope with employee turnover. Public education can also benefit from failures. For example, certain violations of discharge practices may be so serious, or flagrant, that a citation or fine results. The local press, if informed, may find such an incident newsworthy. The general public, or other potential offenders, may benefit from this educational procedure.

An informed public willing to act on their convictions is the product sought from public education. The public educator focuses on large groups, as one-on-one contact is unlikely to be either time or cost effective. Long range educational goals may be tackled through school programs, while shorter range educational goals may focus on community groups. Public education will have to focus on broader environmental issues than inappropriate entries to storm drains. Subgroups in the community may play important roles in public education. For example, scouts may undertake community improvement projects including placing signs on curbside storm drains informing the public that the drain is for stormwater only, and not for discharge of wastes. Thus, public education must take advantage of opportunities presented by groups looking for community improvement projects, the opportunities that are available in working with the school system, and opportunities arising from the news media being supplied with newsworthy items.

The final group that public officials should address in public education is other public officials and governmental institutions. Some small governmental units may not know about precautions to be taken with discharges to storm drainage systems unless they are properly informed. Such subgroups may include road departments, sanitation workers, and workers at public institutions such as hospitals and prisons. A multilevel, multitarget public education program can help to avoid problems.

COMMERCIAL AND INDUSTRIAL SITE DISCONNECTIONS OF NON-STORMWATER SOURCES

Out of convenience and out of ignorance, commercial and industrial sites may impose an increasing load on the storm drainage system. This may be through direct discharges to the storm drainage system, or it may be through diffuse and indirect sources in which the site grounds are contaminated by spills and discharges which are then washed off by storm runoff to the storm drain during rainfall events or by washwater during wash-down operations. The problem is compounded by the vast array of sizes of commercial and industrial enterprises. A single person enterprise has little opportunity to build expertise on the subject of stormwater pollution, while a large industrial enterprise may have an environmental division. To the uninformed person, any curb opening may be thought to be part of a comprehensive sanitary wastewater treatment system and the proper entrance point for polluted water discharges or other debris.

Corrective measures for improper uses of storm drains have to be developed recognizing the differences in knowledge and sophistication of the client. Industrial users are relatively few in number but are expected to have the most complex problems. If industrial users are aware, or made aware, of existing and or new federal, state, or local regulations to prevent pollution of stormwater drainage systems, they will usually comply with the regulation. If not, these regulations provide the authority and communication means to instigate corrective action.

Commercial groups are heterogeneous. An appropriate way of working with them to institute changes in their use of storm drainage systems, may be to work with one category of commercial groups at a time. For example, consider gasoline filling stations as a single category. It is possible to focus on correcting similar problems at many facilities that exist in this category. The flushing of radiators may be seasonally common. A typical practice is to let radiator flushing waters (including coolants) to drain to an inlet to the storm drainage system. Education followed by assurance that there will be strict enforcement of discharge regulations or ordinances may be effective. However, a group such as gasoline filling stations cannot be expected to have a long institutional memory as new operators take over and others drop out. Thus, vigilance and follow-up are important to insure that there is not a gradual diminution of appropriate practices.

For both small commercial and large industrial enterprises, willful and knowledgeable violation of the regulations limiting entries to storm drainage systems have to be dealt with firmly and promptly or the enforcement program runs the chance of becoming ineffective. Thus the governmental unit undertaking responsibility for improving the practices regarding entries to storm drainage systems must have an enforcement plan ready.

FAILING SEPTIC TANK SYSTEMS

Failing septic tank systems can have an impact on an otherwise well functioning storm drainage system. Before discussing corrective measures, it is important to identify the relationship that may develop between a septic tank system and a storm drainage system.

A septic tank system consists of two major components: a septic tank and a leaching field (a waste spreading or soil absorption system). In addition, of course, there is piping associated with the system. Sanitary wastewaters are piped directly to the septic tank. The septic tank typically is made of concrete, is rectangular in shape, is usually divided into two compartments, and has a capacity of one to several thousand gallons. The septic tank serves as an anaerobic digestion, floatation and settling unit in which biological action converts the biodegradable liquid and solid waste particles into stable end products. Gravity separates a significant portion of both biodegradable and non-biodegradable particulate matter to the tank bottom or top (depending on whether the particles sink or rise, respectively). Some of the products of this partial treatment process are carbon dioxide, methane, hydrogen sulfide and other odor producing gases, digested and refractory or relatively non-biodegradable sludge, and floating scum. Because the septic tank remains full, it must discharge a volume of wastewater each time a volume of wastewater is discharged into it. This discharged water enters a leaching field where some additional treatment occurs and the final effluent is discharged to the ground.

A septic tank may be a low maintenance treatment unit, but it is not entirely maintenance free. As the septic tank continues to be loaded, the scum and sludge layers build up so that the remaining volume available for treatment is reduced. Thus, some of the partially digested or undigested solids, scum, and sludge may be carried from the septic tank to the leaching field where the soil void space may become clogged. As the soil voids become clogged, the ability of the leaching field to handle the liquid portion of the waste is reduced, and surface ponding of the wastewater may result. Of course, ponding could have been prevented by having the septic tank serviced; that is, by having the septic tank pumped. Pumping removes the sludge, scum, and other contents of the septic tank so that its storage and treatment capacity is restored. Pumping frequency varies depending on the size of the septic tank and its loading rate. Residential septic tanks may need to be pumped every two to five years. Commercial and institutional septic tanks may need more frequent pumping.

Failed septic tank systems have the potential to pollute stormwater because the leaching field will saturate the ground, and possibly form ponded water on the ground surface. The ponded water may run off and enter a storm drain inlet or drainage ditch, or infiltrate the ground in another area which is intercepted by a storm drain through infiltration. When it rains, any remaining ponded water may be washed off with the runoff to the storm drainage system. Depending on the severity of the septic tank failure, the ponded water can have the characteristics of partially treated sanitary wastewater or nearly untreated sanitary wastewater. Thus, septic tank failures can contaminate the stormwater drainage system during both wet and dry weather.

Septic tank systems may fail even with good maintenance practices. Such failure can result when the soil is simply not permeable enough for the leaching field, or when the soil absorbance capacity is exceeded through long use. A tight clay soil may have such low permeability that the leaching capacity is very limited. If a number of homes are built in close proximity, their septic tank leaching fields may collectively exceed the soil's capacity, leading to a stormwater pollution problem. Even properly operating septic tank systems are a potential pollutant source. Because the basic function of the leaching field is to discharge partially treated effluent to the ground, this septic tank effluent can infiltrate into nearby stormwater drainage systems.

Various corrective methods exist for failing septic tank systems that pollute stormwater. These methods include: improve maintenance, institute preventative measures to avoid problems, and abandon the septic tank system with connections made to a sanitary sewerage system. In some cases, improved maintenance may be the answer. Some persons will not do any maintenance to their septic tank system until it fails (they note ponded water in the leaching field area). Then they call for the septic tank to be pumped. In many cases, this is not sufficient to correct the problem: it may be too little action too late. The preventative action of having the septic tank pumped should have taken place prior to failure of the system. Education may provide part of the remedy. The septic tank user may respond to exhortations to have the septic tank pumped on a regular basis, before failure. Coercion through ordinances may be another answer. Ordinances may require that the septic tank be pumped at a specified frequency, with a public body monitoring the program to ensure that maintenance has been carried out.

It sometimes happens that soil conditions and population density rule out both voluntary or involuntary maintenance. In this case, it may be necessary to consider abandoning the septic tank system and installing a system consisting of sanitary sewers leading to a treatment plant. Another option consists of abandoning the septic tank treatment method in favor of small package treatment units that provide aerobic treatment of the sanitary wastewater which is then discharged to a regional leaching field. This option may succeed where the septic tank system has failed, because wastes treated in an aerobic unit may not have the leaching field clogging potential of wastes treated in an anaerobic septic tank. However, experience has shown that these advantages are only obtained with proper control and maintenance. Aerobic systems are more sensitive than conventional septic tank systems to improper maintenance and may therefore not offer any real benefits.

DIRECT SANITARY SEWERAGE CONNECTIONS

Due to indifference, ignorance, poor enforcement of ordinances, or other reasons, a stormwater drainage system may have sanitary wastewater sewerage direct connections. Obviously, the sanitary wastewater entering the storm drain will not receive any treatment and will pollute a large flow of stormwater, in addition to the receiving water. If the storm drain has a low dry-weather flow rate, the presence of sanitary wastewater may be obvious due to toilet paper, feces, and odors. In cases of high dry-weather flows, it may be more difficult to obviously detect raw sanitary wastewaters due to the low percentage of sanitary wastewater in the mixture. Even though the sanitary wastewater fraction may be low, the previously discussed field testing procedures (e.g., testing for surfactants, ammonia, potassium, and fluorides) will assist in the detection and quantification of sanitary wastewater contamination in the storm drainage system. Flow monitoring may show the variations in the flow rate that are typical of sanitary wastewater.

Dye testing can be effective in finding specific sanitary wastewater connections between a house and a storm drainage system. Dye, such as diluted rhodamine or fluorescein, is flushed down the toilet of a house and the storm drain is monitored to determine whether the dye appears. Care has to be exercised when using this method, as these dyes may stain fixtures that are being tested, and any spillage in the house causes stains that are very difficult to remove.

Monitoring of the storm drainage system with television cameras can show the locations of breaks in the storm drain where a sanitary wastewater sewer or house lateral was attached. Television cameras may also show discharges taking place at these locations, demonstrating that the lines are in active use.

Corrective measures involve undertaking a program of disconnecting the sanitary sewer connections to the storm drainage system and reconnecting them to a proper sanitary wastewater sewerage system. The storm drainage system then has to be repaired so that the holes left by the disconnected sanitary sewer entrances do not become a location for dirt and groundwater to enter.

REHABILITATING STORM OR SANITARY SEWERS TO ABATE CONTAMINATED WATER INFILTRATION

Infiltration of contaminated water into a stormwater drainage system can cause substantial pollution of the system. This could occur where a sanitary sewer overlies and crosses (or parallels) a storm drain, with sanitary wastewater exfiltrating from the sanitary sewer and percolating the storm drain. Other instances would be in areas of polluted groundwater, where the storm drainage is below the water table or intercepts infiltrating groundwater, or in areas having septic tank systems, as discussed previously.

It would be best to correct the sanitary sewer if only one drainage system can be corrected. This would have the dual advantage of preventing infiltration of high or percolating groundwaters and preventing pollution of stormwater with exfiltrating sanitary wastewater. Rehabilitation of the drainage systems by use of inserted liners, or otherwise patching leaking areas, are possible corrective measures. It is important that all drains with infiltration problems be corrected for this corrective action to be effective. This would also include repairing house lateral sanitary wastewater lines, as well as the main drainage runs. However, these corrective measures are more likely to be cost effective when only a relatively small part of the complete drainage systems require rehabilitation.

ZONING AND ORDINANCES

Land use controls achieved by zoning have the potential to exacerbate problems or diminish them. For example, in an area with soils that are ill suited for septic tanks and leaching fields, the potential for future problems is increased if zoning allows small lots for single family residential development and allows septic tank systems. As the area develops, septic tank failures will become common, resulting in increased pollution of stormwater and groundwater. On the other hand, in areas having poor soils, zoning can require correspondingly larger lot sizes and larger leaching fields, resulting in fewer future problems. Ordinances may specify the results that have to be achieved by infiltration tests used to size leaching fields. Also, ordinances can require that a responsible public official be present when the infiltration test is run to decrease the likelihood of false or spurious results being reported. Certified septic tank installers, also checked by public official inspectors, should also be required to increase the likelihood of the system being installed correctly.

Zoning can also have a role to play in avoiding development of land that is subject to frequent flooding. In such land, flooding and high groundwater conditions can result in the sanitary sewerage system being gradually overloaded by infiltration so that cross flow to the storm drainage system can occur.

Ordinances can help to control problems by putting the force of law and public policy behind desirable practices. For example, ordinances can make mandatory practices such as septic tank maintenance that otherwise would be voluntary. By making the practice mandatory, desirable practices are performed on a regular schedule so that large problems have less opportunity to develop. Ordinances can also regulate the persons doing the pumping of septic tanks so that they discharge the septage to wastewater treatment plants where it can be properly treated rather than it being discharged improperly where the pollution problem is just transferred from one location to another.

Ordinances can also help prevent and or control pollution from many other sources by restrictions on: disposal of household toxic substances to storm drains, storage of chemicals by industry, disposal of industrial wash down water, etc.

Zoning and ordinances represent important means for governing bodies to anticipate problems, to avoid problems, and to manage problems, so that desirable ends are achieved and undesirable consequences are avoided. Enactment of zoning and ordinances occurs in the public arena where interested persons can participate and express their views and concerns. The public can become educated in this process, but zoning and ordinances have the desirable characteristic of being remembered and remaining enforceable long after an individual forgets, becomes disinterested, or becomes recalcitrant.

Another important step that municipalities can take is the development of policies and procedures for the management of spills from transportation (including both roadway and rail) and pipeline accidents. Spills should not be merely washed into the storm drainage system, but should be collected for proper treatment and disposal.

WIDESPREAD SANITARY SEWERAGE FAILURE

Connections (whether directly by piping or indirectly by exfiltration or infiltration) of sanitary sewers to the storm drainage system may be so widespread that the storm drainage system has to be recognized as a combined sewer system. This could also be the case when the prevalence of septic tank failures leads to widespread sanitary wastewater runoff to the storm drainage system. One usually thinks of a combined sewer system as having all of the sanitary sewer connections to the same sewers that carry stormwater, but the previous discussion suggests that there are degrees of a storm drainage system becoming a combined sewer system. Previously, the recommendations have been made that widespread failure of septic tank systems might necessitate the construction of a sanitary sewer to replace the septic tanks. Also recommended was a program of identifying and disconnecting sanitary sewers from the storm drainage system.

Prior to these actions taking place, the storm drainage system operates to some degree as a combined sewer system. It may be that the sanitary sewerage system is not capable of handling the load that would be imposed on it if a complete sewer separation program were undertaken. Or, in an extreme case, no sanitary sewer system may exist. By recognizing that a combined sewer system does in fact exist may help to focus attention on appropriate remedial measures. The resources may also not be available to undertake construction of a separate sanitary wastewater drainage system.

One should then focus on how to manage the combined sewer system that is in place. Management may require that end-of-pipe storage/treatment be investigated. Also, the combined sewer system may be tied into other combined sewers so that more centralized treatment and storage can be applied. Operation of a combined sewer system may be preferable to having the stormwater and the large number of sanitary entries receive no treatment.

An early identification and decision to designate a storm drainage system a combined sewer system, will prevent abortive time and costs being spent on further investigations. These resources can then be more effectively used to treat the newly designated combined sewer system.

In essence, recognition of a system as being a combined sewer system provides a focus in the regulatory community so that it may be possible to operate the system so as to minimize the damage to the environment.

VOL 12

4013

VOL 12

GLOSSARY

Accuracy - The combination of bias and precision of an analytical procedure which reflects the closeness of a measured value to a true value.

Baseflow - The dry-weather flow occurring in a drainage system, with no apparent source. Likely to be mostly infiltrating groundwaters in a sanitary or storm drainage system, but can also be contaminated with illicit wastewaters. See constant (or continual) dry-weather flow.

Batch dump - The disposal of a large volume of waste material during a short period of time. Usually an industrial waste.

Bias - A consistent deviation of measured values from the true value, caused by systematic errors in a procedure.

Coefficient of Variation (COV) - A measure of the spread of data (ratio of the standard deviation to the mean).

Combined Sewer - A sewer designed for receiving surface (dry- and wet-weather) runoff, municipal (sanitary and industrial) wastewater, and subsurface waters from infiltration. During dry weather, it acts as a sanitary sewer, but it also carries stormwater from wet-weather runoff.

Combined sewer overflow (CSO) - Flow from an outfall (discharge conduit) of a combined sewer collection system, in excess of the interceptor capacity or due to a malfunctioning or improperly set flow regulator, that is discharged into a receiving water and/or an auxiliary CSO control storage-treatment system.

Constant (or continual) dry-weather flow - Uninterrupted flow in a storm sewer or drainage ditch occurring in the absence of rain. See baseflow.

Deposits and stains - Any type of coating or discoloration that remains at an outfall as result of dry-weather discharges.

Detection limit - A number of different detection limits have been defined: IDL (instrument detection limit), is the constituent concentration that produces a signal greater than five times the signal to noise ratio of the instrument; MDL (method detection limit) is the constituent concentration that, when processed through a complete method, produces a signal with a 99 percent probability that it is different from a blank; PQL (practical quantification limit) is the lowest constituent concentration achievable among laboratories within specified limits during routine laboratory operations. The ratios of these limits are approximately: IDL:MDL:PQL = 1:4:20 (APHA, et al. 1989).

Direct (dry-weather) entries into the storm drainage system - Sources which enter a storm drainage system directly, usually by direct piping connections between the wastewater conduit and the storm drain.

Domestic sanitary wastewater - Sewage derived principally from human sources.

4014

Drainage area - The area of land from which a storm drainage system collects precipitation and storm runoff and then delivers the resulting stormwater to a specific point.

Dry-weather flow - Flow in a storm sewer or drainage ditch occurring in the absence of storm flow. But it is also a constituent of wet-weather flow. See baseflow.

Entries to storm drainage - Water (relatively clear or polluted) discharged into a stormwater drain from sources such as, but not limited to, direct industrial or sanitary wastewater connections, roof leaders, yard and area drains, cooling water connections, manhole covers, groundwater or subterraneous stormwater infiltration, etc.

Floatables - Floating materials, (plastic containers, condoms, sanitary napkins, tissues, corks, paper containers, wood, leaves, oil films, slimes, scum, etc.), that are either part of the inappropriate waste streams discharged to a stormwater system, or collected by flows which enter a stormwater drainage system.

Geographic Information System (GIS) - Computer software that maps land areas and produces images and information relating to the land area, e.g., topography, drainage, public utilities, roads, buildings, industry, land use, and demography.

Groundwater infiltration - Seepage of below water table groundwater and subterraneous stormwater into stormwater, sanitary wastewater, or combined sewer drainage systems, through such means as defective pipes, pipe joints, connections, or manhole walls.

Hardness - Caused by the presence of the divalent cations (principally calcium and magnesium) in water. Causes an increased amount of soap usage before producing a lather and scale to form in hot water pipes, boiler vessels, condensate return lines, cooling systems, kettles, etc.

House Lateral - A pipe connecting a house to a lateral or other sewerline. Also called a service connection.

Indirect dry-weather entries into the storm drainage system - Non-stormwater sources which enter a storm drainage system indirectly, usually by floor, areaway, and yard drains or inlets; and spills and dumping.

Industrial dry-weather entries into the storm drainage system - Any solid or liquid waste coming from industrial sources which enter storm drainage systems during periods of dry weather.

Infiltration - The process whereby water enters a drainage system underground through such means as defective pipes, pipe joints, connections, manhole walls, etc.

Inflow - The process whereby water enters a sanitary wastewater drainage system from surface locations, (e.g., through depressed manhole covers, yard and areaway inlets, roof leader setc.).

Intercepted stormwater/groundwater - The portion of surface runoff or groundwater moving through the soil that enters a storm drainage, combined sewer, or sanitary sewer system.

Interceptor - A sewer that receives flows from a number of wastewater trunk lines.

Intermittent dry-weather flow - Irregular flow in a storm drainage system occurring in the absence of storm flow.

Lateral - A drain or sewer that has no other drains or sewers discharging into it, except for service connections, or house laterals.

Leaching field - A system which facilitates the infiltration of a septic tank effluent into the soil. This is typically done by a pipe and infiltrating trench system which takes the effluent from a septic tank and distributes it through the leaching field, where additional treatment of the effluent occurs as it percolates through the ground or soil column.

Monte Carlo probabilistic simulation - A statistical modeling approach used to determine the expected frequency and magnitude of an output by running repetitive simulations using statistically selected inputs for the model parameters.

Municipal sewage/wastewater - Sewage/wastewater from a community which may be composed of domestic sewage/wastewater, industrial wastewater and/or commercial wastewater, together with subsurface infiltration.

National Pollution Discharge Elimination System (NPDES) - A national system of permits issued to industrial, commercial, and municipal dischargers to limit the amount of pollutants that can be discharged to waters of the USA.

Non-contact cooling water - Water that decreases the temperature of an object, without ever physically contacting the object.

Nonpoint pollution source- Any unconfined and nondiscrete conveyance from which pollutants are discharged, or sn urban drainage system not under the NPDES. These sources are usually from agricultural, silvicultural, and rural land areas..

Outfall - In this User's Guide, an outfall refers to a point at which a stormwater drainage system discharges to a receiving water. There is sometimes a concrete structure or retaining wall at this location to protect the end of the discharge pipe and prevent erosion of the receiving water bank.

Pathogen - A disease-causing microorganism.

Point source - Any discernible, confined, and discrete conveyance from which pollutants are, or may be, discharged. Under the NPDES it is an outfall discharge, or overflow of treated or untreated sanitary, industrial, combined sewage, or stormwater (from a municipality greater than 100,000 in population).

Pollutant - Any material in water or wastewater interfering with designated beneficial uses.

Potable water - Water that has been treated, or is naturally fit for drinking, i.e., the water has no harmful contents to make it unsuitable for human consumption.

Precision - The measure of the degree of agreement among replicate analyses of a sample, usually expressed as the standard deviation.

Pretreatment - The removal of material such as, gross solids, grit, grease, metals, toxicants. etc. or treatment such as aeration, pH adjustment, etc. to improve the quality of a wastewater prior to discharge to a municipal wastewater system. This is usually done by the industrial user of the water, but can also refer to the initial treatment processes of a sewage treatment plant.

Process line discharge - The disposal of anything used in, or resulting from, a manufacturing process.

Process water - Water used in industry to perform a variety of functions, or as an actual product ingredient.

Receiving waters - Natural or man-made water systems into which stormwaters, or wastewaters, are discharged.

Rinse water - Water that cleans or reduces the temperature of an object through actual physical contact with the object.

Sanitary sewer - A sanitary wastewater drainage system intended to carry wastewaters from residences, commercial buildings, industrial plants, and institutions together with minor quantities of groundwater, stormwater and surface water that are not admitted intentionally [40 CFR 35.2005 (b) (37)].

Sanitary wastewater - Wastewater of human origin.

Service Connection - See house lateral

Septic tank - A tank which receives sanitary wastewater direct from its source, (usually residential), and permits settling of the heavy solids and floatation of greases and fats along with anaerobic digestion. Septic tanks, typically need to meet minimum regulatory standards, e.g., minimum volume and detention time.

Sewage - In this text the term "sewage" refers to sanitary wastewater or wastewaters generated from commercial or industrial operations, it does not include stormwater.

Sewer - A pipe, conduit or drain generally closed, but normally not flowing full, for carrying sanitary, industrial and commercial wastewater and storm-induced (combined wastewater and stormwater) flows.

Sewerage - System of piping and appurtenances, with and without control-treatment facilities for collecting and conveying wastewaters with or without pollution abatement from source to discharge.

Specific Conductivity - Expressed in microSiemens/cm (or micromhos/cm). It is an indication of the dissolved solids (charged) concentration in a liquid.

Storm drainage discharge - Flow from a storm drain that is discharged to a receiving water.

Storm drain - A pipe, or natural or man-made channel, or ditch, that is designed to carry only stormwater, surface runoff, street washwaters, and drainage from source to point of discharge [40 CFR 35.2005 (b) (47)].

Stormwater - Water resulting from precipitation which either infiltrates into the ground, impounds/puddles, and/or runs freely from the surface, or is captured by storm drainage, a combined sewer, and to a limited degree, by sanitary sewer facilities. See urban runoff and urban stormwater runoff.

Surfactants - Surface-active agents and common components in detergents which affect the surface tension of water and can cause foaming.

SIC - Standard Industrial Classification, a code used to describe an industry.

Total solids - The entire quantity of solids in the liquid flow or volume including the dissolved and particulate (suspended, floatable, and settleable) fractions.

Toxicity - The degree to which a pollutant causes physiological harm to the health of an organism.

Tracer - In this User's Guide, a tracer is a distinct component, or combination of components ("fingerprint"), of a polluting source which is identified in order to confirm the entry of the polluting source to a storm drainage system.

Trace Metals - Metals present in small concentrations. From a regulatory standpoint, this usually refers to metal concentrations that can cause toxicity at trace concentrations.

Turbidity - The lack of clarity in the water usually caused by suspended particulate matter and measured by interference to light penetration.

Urban runoff - Any runoff stormwater from an urban drainage area that reaches a receiving water body or subsurface. During dry weather, it may be comprised of many baseflow components, both relatively uncontaminated and contaminated. See stormwater and urban stormwater runoff.

Urban stormwater runoff - Stormwater from an urban drainage area that reaches a receiving water body or subsurface caused by weather precipitation (rain, snow, etc.). See stormwater and urban runoff.

Watershed - A geographic region (area of land) within which precipitation drains into a particular river, drainage system or body of water that has one specific delivery point.

Wet-weather flow - Any flow resulting from precipitation (rain, snow, etc.) which may introduce contaminants into storm drainage combined sewerage, or sanitary sewerage systems.

THE ADMINISTRATOR

Honorable Albert Gore, Jr.
President of the Senate
Washington, D.C. 20510

Dear Mr. President:

I am pleased to present the Environmental Protection Agency's (EPA) "Report to Congress on Storm Water Discharges Potentially to be Addressed by Phase II of the National Pollutant Discharge Elimination System Storm Water Program." With this Report as a starting point, I believe, together with Congress and our other partners, we can make substantial progress in utilizing more cost-effective and resourceful ways to control storm water pollution and to protect public health and the environment.

This Report responds to Section 402(p)(5) of the Clean Water Act and provides data, analysis, and recommendations concerning the number and type of discharges potentially to be covered by a phase II storm water program. The Report also identifies the nature and extent of these discharges and discusses one possible approach to implementing a phase II storm water program.

Although this Report discusses only one possible approach for a phase II storm water program, EPA looks forward to working with Congress, States, Tribes, local governments, and other stakeholders to identify other options for a phase II program. Already, EPA is taking steps to explore additional possibilities by developing partnerships and seeking ideas from all groups that will be involved. We will draw on our experience with the phase I storm water program and collaborative efforts with our stakeholders to ensure a cost-effective storm water program.

As a first step, EPA is establishing an urban wet-weather advisory group composed of stakeholders from industry, States, municipalities, commercial and retail establishments, environmental groups and others, to address policy and technical issues related to urban wet weather. A storm water phase II subgroup will be formed to consider cost-effective ways of addressing pollution from phase II storm water discharges. We will share the results of these efforts with Congress as they develop.

VOL 12

4024

In addition to the phase II efforts, we plan to review and streamline the phase I storm water program. We will consider changes to existing monitoring and permitting requirements for regulated phase I municipal dischargers and will resolve questions regarding what cities must do under the Act's storm water control "maximum extent practicable" requirements.

I believe this Report responds fully to the mandates of Section 402(p)(5) of the Clean Water Act, and I hope Congress finds it useful in determining how to proceed with the storm water program.

Sincerely,

Carol M. Browner

EXECUTIVE SUMMARY

Introduction

Storm water discharges have been linked to one-third of all assessed surface water quality impairments nationwide by transporting large quantities of pollutants to our Nation's waterways.[1] Significant sources of contaminated storm water include urban runoff, industrial activities, construction, mining, other types of resource extraction, and different commercial activities. To address this problem, Congress amended the Clean Water Act (CWA) in 1987 to establish a phased approach for issuing National Pollutant Discharge Elimination System (NPDES) permits for storm water discharges.

Phase I of the storm water program, now underway, controls storm water discharges only from industrial activity and municipal separate storm sewer systems serving populations greater than 100,000. Many other sources of polluted storm water remain unaddressed. To deal with them, Congress required the United States Environmental Protection Agency (EPA) to prepare a study identifying additional sources of storm water contamination and establishing procedures and methods to control these discharges under a Phase II storm water program.

This report presents the results of the study to identify potential sources for consideration in a Phase II program and a discussion of the nature and extent of pollutants in their discharges. This report also contains recommendations for how to control Phase II storm water sources.

[1] This estimate is based on information contained in EPA's *National Water Quality Inventory, 1992 Report to Congress*, prepared pursuant to the Clean Water Act, Section 305(b), which is based on State reports of assessments of surface water impacts.

The storm water sources identified in this report and the recommendations for controlling these sources, represent one possible approach, developed by EPA, to a Phase II storm water program. Other approaches are also feasible and EPA plans to explore these through a broad inclusionary process with stakeholders from industry, municipalities, commercial and retail establishments, environmental groups and other interested parties. This will be done by establishing a Federal Advisory Committee Act (FACA) subcommittee on Phase II. This subcommittee will be tasked with examining the key issues for a Phase II storm water program and with recommending cost-effective ways of addressing pollution from Phase II sources. The outcome of this effort may be the formulation of a Phase II storm water program that will differ in scope and procedure from the approach discussed in this report.

This report includes an introduction to the study (Chapter 1), a description of the approach used (Chapter 2), an analysis of municipal sources to be included in Phase II (Chapter 3), and a review of individual sources to be addressed in Phase II (Chapter 4), as well as numerous appendices, which provide supporting data and information.

Summary of Key Findings

EPA has identified two major classes of potential Phase II storm water discharges that are described in this report: (1) discharges from municipal separate storm sewer systems not subject to Phase I and (2) discharges from individual (industrial, commercial, and institutional) facilities not subject to Phase I.

Based on the identification and analysis of potential Phase II sources and available information on impacts of storm water discharges, this report recommends that Phase II of the storm water program focus on the 405 urbanized areas identified by the Bureau of the Census. As described in *President's Clinton's Clean Water Initiative*, municipalities in these urbanized areas would be authorized to regulate industrial dischargers and to address, as necessary, commercial, institutional, and retail services within their jurisdiction using a flexible approach rather than EPA or the States permitting these sources directly.

Significant environmental benefit, including reduced pollutant loadings from urbanized areas, will be obtained by extension of the storm water program to these areas. As summarized below and explained in detail in this report, urbanized areas contain a large percentage of population and population growth, as well as industrial, commercial, and retail facilities, while constituting only 2 percent of the total land area. Focusing Phase II of the storm water program on urbanized areas thus targets the highest concentration of pollutant sources and maximizes the potential benefits.

Background

Water Quality Impacts

While rainfall and snow are natural events, the nature of runoff and its impact on water resources are highly dependent on human activities and the use of the land. Storm water runoff can affect surface water quality in two basic ways: (1) natural flow patterns can be radically altered; and (2) pollution concentrations and loadings can be highly elevated.

The National Water Quality Inventory, a report prepared every 2 years summarizing biennial State reports required by Section 305(b) of the CWA, provides a national assessment of surface water impacts associated with runoff from various land uses. The most recent report in this series, *The National Water Quality Inventory, 1992 Report to Congress*, concludes that storm water runoff from a number of diffuse sources, including agricultural areas, municipal separate storm sewers, urban runoff, and atmospheric deposition, are the leading cause of surface water quality impairment cited by States. Five leading contributors to use impairment are shown in Table ES-1.

Storm water runoff from urbanized areas and industrial and commercial activities can contain high levels of contaminants, such as sediment, suspended solids, nutrients, heavy metals, pathogens, toxics, oxygen-demanding substances, and floatables.[2] In urban areas,

[2] National Water Quality Inventory: *1992 Report to Congress*, EPA, 1994.

VOL 12

4039

Table ES-1. Five Leading Sources of Water Quality Impairment for Selected Classes of Waters

Rank	Rivers	Lakes	Estuaries
1	Agriculture	Agriculture	Municipal Point Sources
2	Municipal Point Sources	Urban Runoff / Storm Sewers	Urban Runoff / Storm Sewers
3	Urban Runoff / Storm Sewers	Hydrologic / Habitat Modification	Agriculture
4	Resource Extraction	Municipal Point Sources	Industrial Point Sources
5	Industrial Point Sources	Onsite Wastewater Disposal	Contaminated Sediments

Source: *National Water Quality Inventory, 1992 Report to Congress*, EPA, 1994.

the cumulative effect of widespread development will also change natural drainage patterns, causing much higher wet-weather peak flows and reduced dry-weather base flows in urban streams and wetlands. Increased peak flows can cause severe hydromodifications such as stream bank erosion, streambed scour, flooding, channelization, and alteration and/or elimination of habitat.[3] These flows will also accumulate and transport pollutants to receiving waters. These pollutants are generated from the numerous human activities within the urban area. Industrial and commercial operations, which are generally located in urban areas, can be significant sources of storm water contamination because of the nature of activities conducted, and materials stored, outdoors.

Appendix B provides an overview of the impacts associated with different pollutant classes and types of receiving waters and ground water. Pollutants associated with widespread urban development are discussed in Chapter 3. Pollutants associated with selected classes of industrial and commercial activities are discussed in Chapter 4.

Clean Water Act Framework

The 1972 amendments to the Federal Water Pollution Control Act (referred to as the Clean Water Act [CWA]) prohibit the discharge of any pollutant to navigable waters from a

[3] *Environmental Impacts of Storm Water Discharges—A National Profile*, EPA, June 1992, EPA 841-R-92-001.

VOL 12

4040

point source unless the discharge is authorized by a National Pollutant Discharge Elimination System (NPDES) permit issued under Section 402. In 1987, Section 402(p) was added to the CWA to modify the framework for addressing point source discharges composed entirely of storm water ("storm water discharges") under the NPDES program,[4] establishing a phased approach for issuing NPDES storm water permits. Phase I of the program addresses storm water from industrial facilities and discharges from municipal separate storm sewer systems serving populations of 100,000 or more. Section 402(p)(5) of the CWA directs EPA, in consultation with the States, to study additional storm water discharges not addressed by Phase I. Sections 402(p)(5)(A) and (B) direct EPA, in consultation with the States, to:

- Identify those storm water discharges or classes of storm water discharges for which National Pollutant Discharge Elimination System (NPDES) permits are not required under Phase I of the NPDES storm water program
- Determine, to the maximum extent practicable, the nature and extent of pollutants in such discharges.

Section 402(p)(5)(C) of the CWA requires EPA to establish procedures and methods to control Phase II storm water discharges necessary to mitigate impacts on water quality. Recommendations for procedures and methods to control Phase II storm water discharges are summarized in this report and described in detail in *President Clinton's Clean Water Initiative*, which is found in Appendix L. Together, this report, and *President Clinton's Clean Water Initiative*, fulfill the requirements of Section 402(P)(5) of the CWA.

Section 402(p)(6) of the CWA requires EPA, in consultation with State and local officials, to issue regulations for controlling designated Phase II storm water discharges necessary to protect water quality. The regulations must, at a minimum, establish priorities, requirements for State storm water management programs, and expeditious deadlines. The

[4] Storm water is defined in the NPDES regulations as "storm water runoff, snow melt runoff, and surface runoff and drainage." (40 *CFR* 122.26(b)(13))

program may include performance standards, guidelines, guidance, management practices, and treatment requirements, as appropriate.

Findings

Municipal Separate Storm Sewer Systems

The Bureau of the Census estimates that the population of the United States and associated territories was more than 252.2 million in 1990[5]. The concept of urbanized areas as defined by the Bureau of the Census served as an important tool for analyzing potential approaches to a Phase II program that addresses municipal separate storm sewer systems. More than 160 million people (63 percent of the total U.S. population) reside in the 405 urbanized areas, each with a population of 50,000 or more. The Bureau of the Census has defined an urbanized area as a central city (or cities) surrounded by a densely settled area. To meet the Bureau of the Census definition, the population of the entire urbanized area must be greater than 50,000 persons and the closely settled area outside of the city, the urban fringe, must have a population density generally greater than 1,000 persons per square mile (just over 1.5 persons per acre). These areas occupy less than 2 percent of the Nation's total land area and represent the largest, most widespread areas of dense urban development in the country.

The majority of new urban development also occurs in these urbanized areas. Construction activity related to new development is recognized as a significant source of pollution and impairment of waterbodies, providing some of the best opportunities for implementing storm water management controls in a highly cost-effective fashion. Between 1980 and 1990, the population of urbanized areas increased by 21.2 million.[6] Statistics on

[5] Population estimates based on the 50 States, the District of Columbia, Guam, the Commonwealth of Puerto Rico, the Virgin Islands, American Samoa, and the Commonwealth of the Northern Mariana Islands.

[6] About 7 percent of this increase, (1.5 million people) are associated with the net addition of 30 new urbanized areas between 1980 and 1990.

the population, number of urbanized areas, and estimated pollutant loads in runoff in urbanized areas are summarized in Table ES-2 and discussed below.

Phase I of the NPDES program for storm water discharges addresses 81.7 million people in portions of 136 urbanized areas.[7] EPA estimates that about 40 percent of the pollutant loads in storm water discharged from urbanized areas come from Phase I municipalities. The portions of these 136 urbanized areas that are not addressed by Phase I had a combined population of 35.8 million people in 1990. EPA estimates that 28 percent of the pollutant loads in storm water discharged from urbanized areas come from these Phase II portions of the 136 urbanized areas with a Phase I municipality.

Of the Census-designated urbanized areas, 269 do not have any municipalities subject to Phase I of the storm water program. EPA estimates that 32 percent of the pollutant loads in storm water discharged from urbanized areas come from these 269 urbanized areas.

In addition to populations within urbanized areas discussed above, the Bureau of the Census has identified an additional urban population of 29 million people that live outside urbanized areas, as well as 62.8 million people classified as rural. Although discharges from municipal separate storm sewers serving these populations are potential Phase II sources, they are not addressed in detail in this report.

Individual Phase II Facilities

The findings of this report are summarized in terms of the identification, nature, and extent of unregulated individual facilities. Due to very limited national data on which to base

[7] There are 621 incorporated places (cities) and portions of 77 counties within these 136 urbanized areas. Of these municipalities, 140 cities and 45 counties are specifically identified in the NPDES regulations that were published in November 1990. EPA and authorized NPDES States have designated an additional 481 cities and 32 counties as Phase I municipalities. In addition, approximately 30 municipalities (located in 21 urbanized areas) have received combined sewer exclusions where the total population served by separate storm sewers is less than 100,000 after subtracting the population served by combined sewers. The methodology used to classify municipalities as Phase I vs. Phase II for the purposes of this report is discussed in Chapter 2.

Table ES-2. Estimated Pollutant Loadings From Urban Runoff

Classification	Population Category	Number of Urbanized Areas*	Population* (millions)	Percentage of Urbanized Area Loading

	Over 250,000	14	16.0	9
	TOTAL	21	17.5	10
PHASE I MS4s OUTSIDE URBANIZED AREAS		NA	4.3	NA

* Totals are based upon 1990 Census, and include Puerto Rico, Guam, Virgin Islands, American Samoa, and the Commonwealth of the Northern Mariana Islands.
** Some municipalities identified in the November 1990 application regulations (55 *FR* 47990) as Phase I based on 1980 census data received combined sewer exclusions from Phase I where the total population served by separate storm sewers was less than 100,000 after subtracting the population served by combined sewers. (The 21 urbanized areas [with a population of 17.5 million] containing these municipalities are also contained in the above totals and are not in addition to those totals.)

VOL 12

4044

loadings estimates, the discussion of the extent of unregulated storm water discharges is limited to an analysis of the number and geographic distribution of the potential Phase II facilities. In general, the distribution of these facilities follows the distribution of population with a large percentage of facilities concentrated within urbanized areas.

EPA's efforts to identify sources and categories of storm water discharges for Phase II of the storm water program started with an examination of approximately 7.7 million commercial, retail, industrial, and institutional facilities for which permits are not required in Phase I. This examination resulted in the identification of two general classes of facilities with the potential for discharging pollutants to waters of the United States through storm water point sources. The first group (Group A) includes sources that are very similar, or identical, to Phase I activities but that were not included in Phase I due to the specific language of the statute or EPA's regulatory specificity in defining the universe of Phase I industrial activities. The second general class of facilities (Group B) were identified on the basis of potential activities and pollutants that may contribute to storm water contamination.

EPA estimates that there are approximately 100,000 facilities in Group A. Facilities in this group, which may be of high priority for Phase II due to their similarity to Phase I industrial facilities include: auxiliary facilities or secondary activities (i.e., maintenance of construction equipment and vehicles, local trucking for an unregulated facility such as a grocery store); facilities intentionally omitted from Phase I (i.e., treatment works with a design flow of less than 1 MGD, landfills that have not received industrial waste); and facilities exempted by the Intermodal Surface Transportation Efficiency Act of 1991 (most industrial activities owned or operated by municipalities of less than 100,000 people[a]).

Group B consists of nearly one million facilities. These have been organized into 18 Phase II sectors for the purposes of this report. Of these 18 sectors, the automobile service

[a] The Intermodal Surface Transportation Efficiency Act of 1991 exempted industrial activities owned or operated by municipalities of less than 100,000 population from Phase I permitting requirements with the exception of powerplants, airports, and uncontrolled sanitary landfills.

VOL 12

4045

sector (composed of gas/service stations, general automobile repair, car dealers, new and used, car and truck rental, etc.) makes up more than one-third of the total number of facilities identified in all 18 sectors. The 18 Phase II sectors are listed in Table ES-3.

EPA conducted a geographical analysis of these industrial and commercial facilities. The geographical analysis shows that the majority are located in urbanized areas, as presented in Table ES-3. In general, about 30 percent of potential Phase II facilities are found within the geographic jurisdiction of a Phase I municipality. Including the urbanized areas surrounding these Phase I municipalities adds another 12 to 13 percent of potential Phase II facilities. If all urbanized areas are included, an additional 16 percent of potential Phase II facilities are represented. Thus, nearly twice as many industrial facilities are found in all urbanized areas as are found in Phase I municipalities alone.[9]

President Clinton's Clean Water Initiative

President Clinton's Clean Water Initiative provides recommendations on how best to address the additional storm water sources identified by the study in a Phase II NPDES storm water program. The goal of *President Clinton's Clean Water Initiative* is to ensure that future storm water pollution prevention and management programs are focused where the maximum potential benefits can be obtained for the least cost, as well as to provide additional flexibility. A cost-benefit analysis was prepared for the *President's Initiative* and is summarized in Appendix L. No further cost-benefit analyses were conducted for this report.

The *President's Initiative* recommends that Phase II requirements focus on system-wide permits for municipal separate storm sewer systems in Census-designated urbanized areas. These areas consist of only 2 percent of the total land area, yet contain 63 percent of the

[9] Notable exceptions to this generalization include lawn/garden establishments, small currently unregulated feedlots, wholesale livestock, farm and garden machinery repair, bulk petroleum wholesale, farm supplies, lumber and building materials, agricultural chemical dealers, and petroleum pipelines, which can frequently be associated with smaller municipalities or rural areas.

Wholesale, Coal & Ores	1,384	23	31	48

* This figure is an approximation based on the total number of facilities in SIC codes 10 through 45 after subtracting an estimate of the number of facilities covered under Phase I. Geographical distribution information is based on all facilities in SIC codes 10 through 45, and may not be representative of all classes of facilities in this group. For the geographic distribution of specific SIC codes, refer to Appendix G.

** This number is based on SIC codes and does not reflect all feedlots potentially subject to Phase II. The United States Department of Agriculture has estimated that there are approximately 378,000 animal feeding operations between 20 and 1000 animal units. The facilities identified here should be representative of feedlots in general and allow estimation of the distribution of these facilities as a class.

4047

total population. Phase II areas account for nearly 60 percent of the loadings from urbanized areas, one and a half times the loadings from Phase I areas. In addition, 57 percent of the national population growth over the past decade has occurred in Phase II areas, compared to 30 percent in Phase I.

The *President's Initiative* contains flexibility in its recommendation that municipalities be authorized to regulate industrial discharges and to address commercial, institutional, and retail sources as necessary within their jurisdiction. This would allow municipalities to control Phase II sources using a flexible approach which would be less costly than having EPA or States permitting individual Phase II sources directly through individual or general permits. Facilities which could certify that there will be no exposure of contaminant sources to rain water and snow melt could be exempted from the storm water program altogether. This change would release low-risk facilities from NPDES requirements, allowing allocation of resources to more critical areas. This would also effectively create incentives for facilities to eliminate exposure of contaminants to rain and snow.

VOL 12

CHAPTER 1. INTRODUCTION

The 1972 amendments to the Federal Water Pollution Control Act (referred to as the Clean Water Act [CWA]) prohibited the discharge of any pollutant to navigable waters from a point source unless the discharge is authorized by a National Pollutant Discharge Elimination System (NPDES) permit. In 1987, Section 402(p) was added to the CWA to modify the framework for addressing point source discharges of storm water under the NPDES program. This provision established a phased approach for issuing NPDES permits for storm water discharges. Phase I of the program addresses storm water from industrial facilities and discharges from municipal separate storm sewer systems serving a population of 100,000 or more. Section 402(p)(5) of the CWA directs the United States Environmental Protection Agency (EPA), in consultation with the States, to study additional storm water discharges not addressed by Phase I of the program. Section 402(p)(5) requires a study for the purpose of:

(A) Identifying those storm water discharges or classes of discharges for which permits are not already required as part of the first phase of the NPDES storm water program, and

(B) Determining, to the maximum extent practicable, the nature and extent of pollutants in such discharges.

(C) Establishing procedures and methods to control storm water discharges to the extent necessary to mitigate impacts on water quality.

Section 402(p)(6) of the CWA provides for EPA to issue regulations that designate additional storm water discharges to be controlled to protect water quality under Phase II of the program and to establish a comprehensive program to regulate such designated sources. The program shall, at a minimum, establish priorities, requirements for State storm water management programs, and expeditious deadlines. The program may include performance standards, guidelines, guidance, and management practices and treatment requirements, as

4049

appropriate. This report presents the results of the study required under Section 402(p)(5) of the CWA.

1.1 BACKGROUND ON THE STORM WATER PROBLEM

While rainfall and snow are natural events, the nature of runoff and its impact on water resources is highly dependent on human activities and use of land. Runoff from lands modified by human activities can affect surface water resources in two ways: (1) natural flow patterns can be modified; and (2) pollution concentrations and loadings can be elevated.

Prior to development of land, a natural hydraulic cycle exists. Rainfall infiltrates to recharge ground water supplies and surface runoff drains through the natural streams which flow to form a watershed. Natural flow patterns can be modified by activities that make the land surfaces more impervious. Activities that alter the natural vegetation can change the natural infiltration characteristics of a watershed. This is particularly evident where widespread urban development occurs. Urban land use results in the removal of vegetation cover and the building of impervious structures such as roads, parking lots, sidewalks, and buildings. In urban areas, the cumulative effect of widespread development may bring dramatic changes to natural drainage patterns, which can cause much higher wet-weather peak flows and reduced dry-weather base flows in urban streams and wetlands. Increased peak flows can cause hydromodifications such as stream bank erosion, streambed scour, flooding, channelization, and elimination and/or alteration of habitat.[1] Additional hydromodifications result from engineered activities to accommodate higher peak flows, such as channel excavation, lining (retaining walls, rip-rap), realignment, underground culverts, and draining of wetlands.

Increased imperviousness and loss of wetlands and natural flow channels associated with urban development also decreases the amount of rainwater available for ground water

---

[1] *Environmental Impacts of Storm Water Discharges—A National Profile*, EPA, June 1992, EPA 841-R-92-001.

recharge. Reduced ground water levels lower base flows in streams during dry weather periods, which impairs the aquatic habitat, impairs riparian wetlands, and makes receiving streams more sensitive to other pollutant inputs and sedimentation.

Different activities and land uses can also contribute a wide variety of pollutants to runoff. Appendix B provides an overview of different types of impacts associated with different pollutant classes and types of receiving waters and ground water. Pollutants associated with widespread urban development are discussed in Chapter 3. Pollutants associated with selected classes of industrial and commercial activities are discussed in Chapter 4. Chapter 2 provides a description of the methodology and analysis used to develop Chapters 3 and 4.

1.1.1 National Summary of Impacts

The National Water Quality Inventory, a report prepared every 2 years summarizing biennial State reports, as required by Section 305(b) of the CWA, provides a national assessment of surface water impacts associated with runoff from various land uses. The most recent report in this series, *The National Water Quality Inventory, 1992 Report to Congress* provides a general assessment of water quality based on State reports indicating the portion of the States' waters that have been assessed that are not supporting designated uses. The report identifies the sources of use impairment for those waters (e.g., diffuse sources, point sources, and natural sources). Based on information from 51 States and Territories that reported on sources of pollution, the 1992 report indicates that roughly 40 to 60 percent of assessed rivers, lakes, and estuaries are not supporting the uses for which they are designated. In addition, 98 percent of the Great Lake shorelines assessed and 20 percent of the Ocean Coastal Waters were not fully supporting designated uses.

The National Water Quality Inventory, 1992 Report to Congress concludes that storm water runoff from a number of diffuse sources, including agricultural areas, separate storm sewers, urban runoff, and atmospheric deposition, is the leading cause of water quality

VOL 12

4051

impairment cited by States. Summaries of the major sources contributing to use impairment are provided in Tables 1-1 and 1-2.

The *National Water Quality Inventory* indicates that where impairment occurs, the type of land use (e.g., agriculture, urban, resource extraction) within a watershed is often related to the impairment. Urban land use, while only occupying a small fraction of the total land area of the country,[2] is responsible for a disproportionately high percentage of impairment. Urban land use is expected to be correlated to a number of major sources of impairment identified in the *National Water Quality Inventory*, including municipal point sources, separate storm sewers, urban runoff, combined sewer overflows, and many industrial point sources. At the same time, surface water resources in and near urban populations supply drinking water to 200 million U.S. citizens and provide recreational opportunities for millions more.[3]

The agricultural category listed in the *Inventory* comprises a number of activities, most of which are exempt from the definition of "point source" in Section 502(14) of the CWA which, in part, determines the jurisdiction of the NPDES program. One class of sources related to agriculture that is specifically identified in the statutory definition of point source is concentrated animal feeding operations (CAFOs). As discussed below, EPA has issued regulations to define the scope of the term "concentrated animal feeding operation." Although the contribution of various agricultural activities is difficult to evaluate independently, EPA has estimated that feedlots (which include both CAFOs identified as point sources under the NPDES regulations and other feedlots that are not addressed by the regulatory definition) contribute to 13 percent of impaired river miles, 7 percent of impaired

[2] For example, the 1990 Census indicates that 64 percent of the United States population lives in Census-designated urbanized areas of 50,000 or more. However, these urbanized areas are located on less than 2 percent of the total land area of the country. Other development, including smaller urban populations in areas of 10 acres or more and rural transportation, account for an additional 2 percent of land area. By comparison, agricultural activities, including cropland, pasture land and range land, account for 49 percent of the land in the United States. (See *Summary Report, 1987 National Resources Inventory*, Soil Conservation Service, December 1987).

<u>Explanation of Pollutant Sources</u>

Industrial Point Sources: Industrial process discharges and cooling water
Municipal Point Sources: Sewage treatment plants, including package plants
Combined Sewer Overflows: Discharges from sewage collection systems of sanitary sewage and runoff
Separate Storm Sewers/Urban Runoff: Discharges from separate storm sewers and other urban runoff
Agriculture: Crop production, pastures, rangeland, feedlots, animal holding/management areas, manure lagoons, aquaculture, and irrigation return flows
Silviculture: Forest management, harvesting, residue maintenance and road construction and maintenance
Resource Extraction: Mining and mine drainage
Hydrologic/Habitat Modification: Channelization, dredging, dam construction, flow regulation, bridge construction, streambank modification/destabilization, drainage/filling of wetlands
Land Disposal: Sludge, wastewater, landfills, industrial land treatment, septic systems, hazardous waste, sewage disposal

lake acres, 3 percent of impaired estuary square miles, and negligible amounts of impairment in the Great Lakes and Coastal areas.[4]

1.2 THE NPDES STORM WATER PERMIT PROGRAM

The appropriate means of regulating storm water point sources within the NPDES program has been debated since the establishment of the NPDES program in 1972. Each attempt to devise a workable program has been the focus of substantial controversy concerning the water quality impacts, large number of storm water sources, nature of storm water runoff, and constraints of program priorities and resources.

1.2.1 Early Regulatory Approaches

In 1973, EPA promulgated regulations that exempted a number of categories of point sources from NPDES permit requirements, including: silvicultural point sources; CAFOs below a certain size; irrigation return flows from areas of less than 3,000 contiguous acres or 3,000 noncontiguous acres that use the same drainage system; nonfeedlot, nonirrigation agricultural point sources; and separate storm sewers containing only storm runoff uncontaminated by any industrial or commercial activity (38 *FR* 13530 (May 22, 1973)). The Agency maintained that exemptions were appropriate to conserve the Agency's enforcement resources for more significant point sources of pollution. In addition, the Agency noted that the characteristics of runoff pollution make it difficult to promulgate numeric effluent limitations for most of the point sources exempted by the 1973 regulations.

The Natural Resources Defense Council (NRDC) brought suit in the U.S. District Court for the District of Columbia challenging the Agency's authority to selectively exempt categories of point sources from permit requirements, *NRDC v. Train*, 396 F.Supp. 1393 (D.D.C. 1975), *aff'd*, *NRDC v. Costle*, 568 F.2d 1369 (D.C. Cir. 1977). The District Court held that EPA could not exempt discharges identified as point sources from regulation under

[4] *The Report of the EPA/State Feedlot Workgroup*, EPA, September 1993.

the NPDES permit program. However, in acknowledging the administrative burden placed on the Agency by requiring individual permits, the court recognized EPA's discretion to use certain administrative devices, such as area or general permits, to help manage its workload. In addition, the court recognized some discretion on EPA's part to define what constitutes a point source.

In response to the District Court's decision in *NRDC v. Train*, EPA issued a series of regulations addressing discharges from separate storm sewers (March 18, 1976, (41 *FR* 11307)), CAFOs (March 18, 1976, (41 *FR* 11458)), agricultural activities (July 12, 1976 (41 *FR* 28493)), silviculture activities (June 18, 1976 (41 *FR* 24709)), and aquaculture projects (May 17, 1977 (42 *FR* 25478)). Each of these regulations defined classes of point source discharges that would be subject to the NPDES permit program and exempted other classes of discharges from NPDES jurisdiction.

The regulations addressing NPDES requirements for agricultural activities defined the term agricultural point source to include any discernible, confined, and discrete conveyance from which any irrigation return flow is discharged into navigable waters. In response to these regulations, Congress amended the CWA in 1977 to specifically exclude return flows from irrigated agriculture from the definition of agricultural point source.[5] In 1987, Congress further amended the CWA to exclude agricultural storm water from the definition of agricultural point source.

The regulations addressing NPDES requirements for silvicultural activities defined the term silvicultural point source to include any discernible, confined, and discrete conveyance related to rock crushing, gravel washing, log sorting or log storage facilities which are

[5] *President Clinton's Clean Water Initiative* (1994) recommends that EPA, with the concurrence of the Departments of Agriculture and the Interior, and after consultation with States and other Federal agencies, should submit a report to Congress within two years after reauthorization of the CWA that evaluates the nature and extent of water quality problems presented by irrigation return flows, identifies the most promising and cost-effective technical and programmatic solutions to these problems, and recommends appropriate actions, including programmatic improvements and necessary legislative changes.

operated in connection with silvicultural activities and from which pollutants are discharged into navigable waters. The regulation clarified that the term did not include nonpoint source activities inherent to silviculture such as nursery operations, site preparation, reforestation and subsequent cultural treatment, thinning, prescribed burning, pest and fire control, harvesting operations surface drainage, and road construction and maintenance from which there is runoff.

The regulations addressing NPDES requirements for CAFOs clarified that CAFOs are point sources. CAFOs are defined as animal feeding operations that discharge to waters of the United States at times other than during events greater than a 25-year, 24-hour storm and that (1) have more than 1,000 animal units; (2) have more than 300 animal units and pollutants are discharged into navigable waters through a man-made flushing system or other man-made device, or pollutants are discharged directly into waters of the United States which originate outside of and pass over, across or through the facility or otherwise come into direct contact with the animals confined in the operation; or (3) are designated by EPA or an authorized NPDES State upon determining that it is a significant contributor of pollution to waters of the United States.

The regulations addressing NPDES requirements for concentrated aquatic animal production facilities (CAAPFs) clarified that CAAPFs are point sources. CAAPFs are defined as a hatchery, fish farm or other facility which harvest fish over specified limits or which is otherwise designated by EPA or an authorized NPDES State upon determining that it is a significant contributor of pollution to waters of the United States.

The regulations addressing separate storm sewers established a comprehensive permit program. This rule substantially increased the number of storm water discharges subject to the NPDES program. Permits continued to be required for conveyances carrying contaminated storm water runoff from areas used for industrial or commercial activities, as well as storm water discharges designated by the permit-issuing authority as significant contributors of pollution. These sources were required to submit individual permit applications required of industrial and commercial process wastewater dischargers. In addition, the 1976 rule brought into the permitting program separate storm sewers defined as "a conveyance or system of conveyances . . . located in an urbanized area and primarily operated for the purpose of collecting and conveying storm water runoff." Channelized storm water runoff from rural areas that did not contain runoff from commercial or industrial activity was not defined as a point source unless designated otherwise by the permitting authority. Permit applications were not required for separate storm sewers at that time. EPA planned to study these discharges and issue general or area permits to address these sources because these discharges were expected to be less significant than runoff from industrial facilities. During this time, permitting efforts for storm water discharges focused on industrial facilities with effluent guideline limitations for their storm water discharges.[6]

On June 7, 1979, and May 19, 1980, EPA published comprehensive revisions to the NPDES regulations (44 *FR* 32854 (June 7, 1979); 45 *FR* 33290 (May 19, 1980)). These rules essentially retained the March 18, 1976, broad definition of storm water discharges subject to NPDES permit requirements but required more stringent application data for storm water point sources. Under these regulations, the same application information required of all industrial and commercial process wastewater dischargers would be required of all storm water point sources. The new requirements included testing under certain circumstances for a substantially greater number of pollutants identified in the 1977 amendments to the CWA.

This regulation brought suits in several Courts of Appeals and District Courts by numerous major trade associations, several of their member companies, NRDC, and Citizens for a Better Environment. The suits challenged many aspects of the NPDES regulations, including the storm water provisions. Eventually all petitions for review were consolidated

[6] The following effluent limitations guidelines address storm water or a combination of storm water and process water: cement manufacturing (40 *CFR* Part 411); concentrated animal feeding operations (40 *CFR* Part 412); fertilizer manufacturing (40 *CFR* Part 418); petroleum refining (40 *CFR* Part 419); phosphate manufacturing (40 *CFR* Part 422); steam electric (40 *CFR* Part 423); coal mining (40 *CFR* Part 434); mineral mining and processing (40 *CFR* Part 436); ore mining and dressing (40 *CFR* Part 440); and asphalt emulsions (40 *CFR* Part 443).

VOL 12

4057

in the U.S. Court of Appeals for the D.C. Circuit (*NRDC v. EPA*, 673 F.2d 392 (DC Cir. 1980)).

After 2 years of intensive settlement negotiations with representatives of most of the petitioners, the Agency and industry petitioners signed a settlement agreement on July 7, 1982, which addressed a number of issues relating to the NPDES program, including storm water. Under the terms of the agreement, EPA agreed to changes to the storm water regulations which were finalized on September 26, 1984 (49 *FR* 37998).

The 1984 final rule recognized two fundamental issues regarding the NPDES regulation of storm water: (1) which storm water discharges should be classified as pcint sources, and, therefore, within the NPDES program and (2) what is the best way to regulate these sources. On the first issue, data available to EPA, such as the Nationwide Urban Runoff Program (NURP) study, indicated that there are water quality problems associated with storm water runoff. The final rule retained the broad coverage of the 1980 rule in mandating the permitting of all storm water point sources that discharge pollutants into waters of the United States. The September 26, 1984, rule defined a storm water point source as a channelized conveyance of storm water runoff that (1) is located in an urbanized area, as defined by the Bureau of the Census, (2) discharges from lands or facilities used for industrial or commercial activities, or (3) is designated by the Director of the NPDES Program.

To address the second issue of how to regulate these sources administratively, the final rule set forth two categories of storm water point sources, each with different application requirements. Group I storm water point sources were defined as sources either subject to effluent limitations guidelines, located at an industrial plant, or plant-associated area, or designated by the Director. All other storm water point sources were classified as Group II. Group I dischargers were required to submit the NPDES application form for industrial and commercial process wastewater discharges, including certain sampling and testing data. The application requirements for Group II were significantly reduced. Group II sources were

VOL 12

4058

R0037366

required to submit only Form 1 and a narrative description of the drainage area, receiving water, and any treatment applied to the discharge.

These storm water regulations generated considerable controversy (through post-promulgation comment) and, once again, suits were filed. The 1984 rules deleted the term "contaminated" and relied instead on geographic criteria to define sources subject to permitting. Some commenters claimed that the new definitions would subject thousands of discharges to the program for the first time. However, in EPA's view, the scope of coverage of storm water point sources under the NPDES program was essentially unchanged by the September 26, 1984, rulemaking.

Upon consideration of post-promulgation comments, EPA concluded that it would be appropriate to obtain additional data on storm water discharges to assess their significance as an environmental problem and to identify the best means of control. Although the number of dischargers required to submit quantitative testing data had been reduced by the 1984 rule, tens of thousands of storm water point sources remained to be identified, tested, and analyzed. Despite the improvements made in the 1984 regulation, EPA realized it was appropriate to request comments on whether the collection of data from each individual Group I discharger was necessary and efficient. In addition, EPA realized that new deadlines would need to be established. EPA published proposed changes to the storm water regulations on March 7, 1985, at 50 *FR* 9362 and on August 12, 1985, at 50 *FR* 27354. These proposals were not finalized because of the passage of the Water Quality Act of 1987.

1.2.2 Water Quality Act of 1987

Section 402(p) was added to the CWA in 1987 to require implementation of a comprehensive two-phased approach for addressing storm water discharges under the NPDES program. Section 402(p)(1) prohibits EPA or NPDES States from requiring permits for discharges composed entirely of storm water ("storm water discharges") until October 1, 1992 (this deadline was later extended to October 1, 1994, by the Water Resources

Development Act of 1992), except for the following five classes of Phase I storm water discharges specifically listed under Section 402(p)(2):

- Storm water discharges issued a permit before February 4, 1987
- Storm water discharges associated with industrial activity
- Discharges from a municipal separate storm sewer system serving a population of 250,000 or more
- Discharges from a municipal separate storm sewer system serving a population of 100,000 or more but less than 250,000
- Storm water discharges that EPA or an NPDES State determine to be contributing to a violation of a water quality standard or a significant contributor of pollutants to the waters of the United States.

Section 402(p)(3)(A) of the CWA requires storm water associated with industrial activity to meet all applicable provisions of Sections 402 and 301 of the CWA, including technology-based requirements and any necessary water quality-based requirements. Section 402(p)(3)(B) makes significant changes to the permit standards for discharges from municipal separate storm sewer systems.[7] Permits for discharges from municipal separate storm sewers:

- May be issued on a system- or jurisdiction-wide basis
- Shall include a requirement to effectively prohibit non-storm water discharges into the storm sewers
- Shall require controls to reduce pollutant discharges to the maximum extent practicable, including management practices, control techniques and system, design and engineering methods, and such other provisions determined appropriate for the control of such pollutants.

[7] The 1987 amendments to the CWA did not specifically address requirements for water quality-based permit conditions in NPDES permits for discharges from municipal separate storm sewer systems. EPA interprets the Act to require that permits for discharges from municipal separate storm sewers include any requirements necessary to achieve compliance with water quality standards.

Section 402(p)(4) of the CWA establishes statutory deadlines for the initial steps in implementing the Phase I program. Deadlines are established for the development of permit application regulations, submission of permit applications, issuance of permits for Phase I sources, and compliance with permit conditions.

The 1987 amendments did not identify what sources would be subject to the NPDES program after the temporary moratorium on permit requirements of Section 402(p)(1) expired. Rather, the amendments established a process for EPA to evaluate potential Phase II sources and designate sources for regulation to protect water quality. Section 402(p)(5) of the CWA requires EPA, in consultation with the States, to conduct a study of storm water discharges other than Phase I sources (i.e., potential Phase II sources). The study is to identify storm water discharges not covered under Phase I and determine, to the maximum extent practicable, the nature and extent of pollutants in such discharges. The study is also to establish procedures and methods to control storm water discharges to the extent necessary to mitigate impacts on water quality.

Section 402(p)(6) of the CWA requires EPA, in consultation with State and local officials, to issue regulations designating additional Phase II storm water discharges to be regulated to protect water quality and to establish a comprehensive program to regulate such designated sources. The comprehensive program to regulate such designated sources must, at a minimum, establish priorities, requirements for State storm water management programs, and expeditious deadlines. The program may include performance standards, guidelines, guidance, management practices, and treatment requirements, as appropriate.

1.2.3 Phase I Regulatory Framework

EPA promulgated regulations for Phase I storm water discharges on November 16, 1990 (55 *FR* 47990). These regulations clarified the scope of the Phase I storm water program by providing regulatory definitions for the major classes of storm water discharges identified under Section 402(p)(2)(B), (C), and (D) of the CWA:

- Storm water discharges associated with industrial activity
- Discharges from municipal separate storm sewer systems serving a population of 100,000 or more.[8]

In addition, the November 16, 1990, regulations established permit application requirements, including submittal deadlines, for these classes of discharges.

The November 16, 1990, regulations define municipal separate storm sewer systems serving a population of 100,000 or more to include municipal separate storm sewers within the boundaries of 173 incorporated cities and within unincorporated portions of 47 counties with populations of 100,000 or more in their unincorporated areas.[9] The regulations allowed for additional municipal separate storm sewers to be designated by the NPDES permitting authority (EPA or an authorized NPDES State) as being part of a municipal separate storm sewer system subject to Phase I requirements. In addition, the regulations established comprehensive two-part permit applications for discharges from municipal separate storm sewer systems serving a population of 100,000 or more. Among other things, the permit applications require municipal applicants to propose municipal storm water management programs to control pollutants to the maximum extent practicable and to effectively prohibit non-storm water discharges to the municipal system.[10] Municipal storm water management programs are a combination of source controls and management practices that address targeted sources within the boundaries of the municipal system. Under this program, EPA has defined the role of municipalities in a flexible manner that allows local governments to assist in defining priority pollutant sources within the municipality and to develop and

[8] Consistent with Section 402(p)(2) of the CWA, the November 16, 1990, regulations address two subclasses of municipal separate storm sewer systems serving a population of 100,000 or more. Large municipal separate storm sewer systems are defined as systems serving a population of 250,000 or more (40 *CFR* 122.26(b)(4)). Medium municipal separate storm sewer systems are defined as systems serving a population of 100,000 or more, but less than 250,000 (40 *CFR* 122.26(b)(7)).

[9] See Appendices F, G, H, and I to 40 *CFR* 122.

[10] See 40 *CFR* 122.26(d)(2)(iv).

VOL 12

4062

implement appropriate controls for such discharges. Municipal programs can establish requirements for the control of discharges to the municipal system from privately owned lands (e.g., sediment and erosion control for construction sites) and can address municipal activities that affect storm water quality (e.g., maintenance of leaking sanitary sewers, road de-icing and maintenance, operation of municipal landfills, and some flood control efforts).

Moreover, the November 16, 1990, regulations defined the term "storm water discharges associated with industrial activity" to include 11 categories of industrial facilities (see 40 *CFR* 122.26(b)(14)) and established application requirements for such discharges.[11] In light of concerns raised by the industrial community about the complexity of the November 1990 storm water regulations, the difficulty in determining whether particular facilities were subject to the new rules, and administrative delays in permit issuance, EPA issued a series of extensions to permit application deadlines for discharges associated with industrial activity.[12] With these extensions, October 1, 1992, was established as the date by which any facility with a storm water discharge associated with industrial activity must submit either an individual or group application or obtain coverage under an applicable general permit.

Congress also has acted to grant extensions to the application deadlines for selected classes of discharges associated with industrial activity. In March 1991, Congress adopted Section 307 of the Dire Emergency Supplemental Appropriations Act of 1991, which ratified EPA's extension of Part I of the group applications to September 30, 1991. On December 18, 1991, the Intermodal Surface Transportation Efficiency Act of 1991 (or Transportation Act), extended NPDES permit application deadlines for storm water discharges associated with industrial activity from facilities that are owned or operated by municipalities. In addition, Section 1068(c) of the Transportation Act amended the Clean Water Act to provide

[11] As discussed below, on June 4, 1992, the U.S. Court of Appeals for the Ninth Circuit found EPA's rationale for exempting construction sites of less than 5 acres and certain uncontaminated storm water discharges from light industrial facilities from Phase I of the storm water program to be invalid and has remanded these exemptions for further proceedings (see *NRDC v. EPA*, 966 F.2d 1292 (9th Cir. 1992)).

[12] See 56 *FR* 12098 (March 21, 1991), 56 *FR* 56548 (November 5, 1991), 57 *FR* 11524 (April 2, 1992).

VOL 12 4063

that EPA shall not require any municipality with a population of less than 100,000 to apply for or obtain a permit for any storm water discharge associated with industrial activity other than an airport, power plant, or uncontrolled sanitary landfill owned or operated by such municipalities before October 1, 1992. In response to this provision, EPA has reserved application deadlines for these facilities.[13]

EPA also has modified the NPDES regulations to provide a greater degree of emphasis on site inspections as an alternative or supplement to discharge monitoring in permits for storm water discharges associated with industrial activity.[14]

On June 4, 1992, the United States Court of Appeals for the Ninth Circuit issued an opinion granting in part a petition for review of EPA's 1990 storm water regulations (*NRDC* v. *EPA*, 966 F.2d 1292 (9th Cir. 1992)). The court upheld several provisions of the regulations, including the definition of municipal separate storm sewer system, the standards for municipal storm water controls, the scope of the permit exemption for oil and gas operations, and EPA's decision not to provide public comment on Part 1 of the group applications for storm water discharges associated with industrial activity.

The Court did declare EPA's extension of the statutory deadlines for storm water permit applications to be unlawful, but declined to strike down the deadlines as the plaintiff had requested. In addition, the Court struck down and remanded two exemptions from the definition of storm water discharges associated with industrial activity.

One of the remanded exemptions addressed construction activities that result in the disturbance of less than 5 acres of total land area which are not part of a larger common plan of development or sale. EPA noted that State and local sediment and erosion controls may

[13] See 57 *FR* 11524 (April 2, 1992), 40 *CFR* 122.26(e)(1)(ii).

[14] See 57 *FR* 11524 (April 2, 1992), 40 *CFR* 122.44(i).

address construction activities of less than 5 acres and that the acreage limit reflected land disturbances that were industrial in magnitude because disturbances on large tracts of land will employ more heavy machinery and industrial equipment. The Court noted that EPA had proposed to exempt only sites for commercial and industrial construction smaller than 1 acre and sites for residential construction smaller than 5 acres. In the final rule, the exemption was increased to 5 acres for all construction sites, based on the Agency's determination that smaller sites would not have levels of activity similar to other industrial activities. The court ruled, however, that the record did not indicate "that construction sites on less than five acres are non-industrial in nature" (966 F.2d at 1306). The court rejected EPA's argument that the 5-acre cutoff constituted a *de minimis* exemption, because the record lacked information to suggest whether smaller discharges would be *de minimis*.

A second remanded exemption addressed light manufacturing facilities where material handling equipment or activities, raw material, intermediate products, final products, waste materials, byproducts, or industrial machinery are not exposed to storm water. With respect to the light industry category, EPA had adopted the exemption based on the belief that if (1) the activities in the selected facilities are undertaken in buildings; (2) emissions from stacks are minimal or nonexistent; (3) there is no unhoused manufacturing and heavy industrial equipment, outside storage, disposal, or handling of raw, finished, or waste materials; (4) and the activities being performed do not generate significant dust or particulates, the facility posed a much smaller risk of storm water contamination. Based on these factors, the Agency believed that these facilities were similar to commercial businesses, such as retail and service facilities.

The court noted, however, that the statutory term associated with industrial activity was very broad and concluded that Congress intended only to exempt discharges from non-industrial facility areas such as parking lots. The court rejected EPA's argument that industrial pollutant levels in storm water would be minimal at light industrial facilities, finding nothing in the record to support that conclusion. Therefore, the court found this exemption to be arbitrary and capricious (966 F.2d at 1304-05).

In response to the Ninth Circuit decision, EPA promulgated rules on December 18, 1992, specifying dates for permit approval or denial and permit compliance. In the December 18, 1992, notice, EPA also noted that it did not believe that the court's opinion had the effect of automatically subjecting small construction sites and light industries to the existing application requirements and deadlines for storm water discharges associated with industrial activity. The Agency also indicated that it believed that additional notice and comment rulemaking was necessary to clarify the status of these facilities under the storm water program.

1.2.4 Phase I Implementation Activities

The initial efforts to implement the Phase I storm water program have focused on reviewing group applications for industrial storm water, issuing general permits for industrial storm water, publishing draft general permits for storm water discharges from 29 industrial sectors, reviewing applications for municipal separate storm sewer systems, issuing permits for municipal separate storm sewer systems, and conducting outreach activities. In addition, the Agency, in conjunction with the Rensselaerville Institute, completed a study to develop recommendations for making Phase I of the program more effective.

1.2.4.1 General Permits

In September 1992 (April 1993 for Puerto Rico) EPA issued general permits for storm water discharges associated with industrial activity in the 11 States without NPDES authority, as well as for Territories, States where EPA issues permits for Federal facilities, and Federal Indian Reservations. Unlike traditional NPDES permits, these permits generally do not establish numeric effluent limitations for most discharges authorized by the permits.[15] Rather, the permits establish requirements for notices of intent, site inspections conducted by dischargers, and site-specific pollution prevention plans. The requirements for pollution prevention plans provide a framework for dischargers to identify sources of pollution and best management practices to prevent, reduce and/or control such pollutant sources. In addition, targeted facilities are required to sample and analyze their storm water discharges.

When the storm water application rules were issued in November 1990, only 17 out of the 39 authorized States authorized to administer the NPDES program were also approved to issue NPDES general permits. Since then, an additional 21 States have requested and received EPA approval to issue general permits, and one additional State has received NPDES authorization, including general permit authority. All but one of the States that now have general permit authority have issued general permits for storm water discharges.

1.2.4.2 Group Applications

EPA has received more than 1,200 Part I group applications representing more than 60,000 industrial facilities with storm water discharges. EPA has requested public comment on draft permits to address discharges identified in these applications that are in States without authorized NPDES programs.[16] The draft general permits contain requirements for 29 different industrial sectors.

1.2.4.3 Municipal Applications

Permit applications have been received for almost all municipal separate storm sewer systems serving a population of 100,000 or more. This represents a substantial initial

[15] The permits do establish numeric effluent limitations for some classes of storm water discharges. These limitations are either based on best available technology or established pursuant to State certifications under Section 401 of the CWA.

[16] See 58 *FR* 61146 (November 19, 1993).

VOL 12

4067

investment into Phase I of the storm water program by municipalities.[17] At the heart of these applications are proposed municipal storm water management programs, which will identify a variety of site-specific pollution prevention measures, source controls, and best management practices to control pollutants from targeted sources within the municipality.[18] EPA and authorized NPDES States have started to issue permits for these municipal separate storm sewer systems. The Agency estimates that 263 permits will be issued for Phase I municipal separate storm sewer systems; as of May 1994, 24 permits have been issued.

1.2.4.4 Rensselaerville Phase I Effort

In 1992 EPA completed a study, in conjunction with the Rensselaerville Institute, to obtain direct public input and develop recommendations for improving Phase I of the storm water program. These studies are discussed in more detail in Appendix I. The study raised five key issues relating to Phase I sources:

- Study participants thought that EPA has not been clear enough about the intended goals of the regulations and should communicate storm water risks, objectives, and requirements more clearly to the general public, as well as to the regulated community.
- Participants noted that the cost of program implementation is significantly higher than original EPA estimates and that there is great concern regarding the real costs of the program and of achieving compliance.
- Participants agreed that EPA and States must accelerate general permit issuance and focus on general permits to achieve efficient implementation of the program.

---

[17] The National Association of Flood and Stormwater Management Agencies estimates based on a 1992 survey that municipalities have spent more than $130 million on preparing NPDES permit applications for discharges from Phase I municipal separate storm sewer systems.

[18] A review of cost estimates for proposed municipal storm water management programs provided in 20 applications indicates that municipalities estimate the cost of program implementation (excluding permit application costs) to range from $23.91 to $37.00 per person. (See draft *Review of Program Costs in Part 2 NPDES Municipal Storm Water Permit Applications*, EPA, 1993.)

- Participants felt that technical outreach should be targeted at the State and local level rather than the national level and should provide better guidance on the regulations and their implementation.

- Participants noted that coverage under certain industrial storm water categories should be clarified.

EPA agreed with these recommendations and has taken steps to follow up in each area.

1.2.5 September 9, 1992 Notice—Phase II Issues

On September 9, 1992, EPA published a notice requesting information and public comment on the Phase II program. The notice is included in Appendix H of this report. The notice identified three sets of issues associated with developing Phase II regulations:

- How should sources that are to be subject to Phase II regulations be identified?
- What types of control strategies should be developed for these sources?
- What are appropriate deadlines for implementing Phase II requirements?

The September 9, 1992, notice presented a range of alternatives under each issue in an attempt to illustrate, and obtain input on, the full range of potential approaches for a Phase II strategy. The notice recognized that potential sources for coverage under Phase II fall into two main categories: municipalities; and individual sources (commercial and residential) activities. EPA recognized that a major distinction between most options for identifying Phase II commercial/residential sources was either to require targeted municipalities to develop source controls and management programs for storm water discharges within their jurisdictions or to require permits for discharges from individual facilities.

EPA received more than 130 comments on the September 9, 1992, notice. Approximately 43 percent of the comments were from municipalities, 29 percent from trade groups or industries, 24 percent from State or Federal agencies, and approximately 3 percent from other miscellaneous sources.[19] No comments were received from environmental groups. Appendix J contains a detailed summary of comments received as they relate to the specific issues raised in the notice.

1.2.6 Rensselaerville Phase II Effort

In early 1993, the Rensselaerville Institute and EPA held public and expert meetings to assist in developing and analyzing options for identifying Phase II sources and controls. These meetings and the resulting options are discussed in more detail in Appendix I of this report. The report on the effort indicates that the two options most favored by the various groups participating were:

- A program where States would select sources to be controlled in a manner that was consistent with criteria developed by EPA. The Phase II program would provide States with flexibility to either rely on NPDES requirements or other frameworks to control targeted sources.
- A tiered approach that would provide for EPA selection of high priority sources for control by NPDES permits and State selection of other sources for control under a State program other than the NPDES program.

1.2.7 President Clinton's Clean Water Initiative

On February 1, 1994, *President Clinton's Clean Water Initiative* was issued. The *President's Initiative* addresses a number of issues associated with NPDES requirements for storm water discharges, including:

- Compliance of discharges from municipal separate storm sewer systems with water quality standards
- Industrial facilities with no activities or significant materials exposed to storm water
- Deadline extensions for Phase II of the storm water program

[19] Percentages have been rounded off, and hence may not total 100 percent.

- Phase II storm water program requirements, including regulation of storm water from industrial facilities by municipalities
- Control of discharges from inactive and abandoned mines (IAMs) located on Federal lands.

To address municipal compliance with water quality standards, the *President's Initiative* recommends that the CWA be amended to establish a phased permit compliance approach that requires best management practices in first-round municipal storm water permits and improved best management practices in second-round permits, where necessary, to move towards compliance with water quality standards. In later permits, compliance with water quality standards will occur using water quality-based effluent limits, where necessary. This would give EPA and municipalities additional time to evaluate the technical feasibility of establishing numeric effluent limits to meet water quality standards and give States time to develop specific water quality standards appropriate for storm water discharges, if necessary. The *President's Initiative* further supports clarifying authority under section 402(p)(3)(B) concerning "maximum extent practicable" (MEP).

The *President's Initiative* recommends that EPA be authorized to exempt from individual storm water permitting requirements facilities that can certify that there is no—nor will there be—exposure of industrial or other activities or significant materials to rain water and snow melt. This change would ensure that several hundred thousand low-risk facilities are not subject to NPDES requirements, allowing allocation of resources to more critical areas. This would also effectively create incentives for facilities to eliminate contamination of storm water.

The *President's Initiative* recommends that the statutory deadline for EPA to issue Phase II regulations be extended. The *President's Initiative* also recommends that the deadline for Phase II sources to obtain a permit be extended. The *President's Initiative* indicated that extensions would allow EPA to work with States and municipalities in developing workable, effective regulations. A new deadline for permits would give municipalities an opportunity to begin to build institutional frameworks and provide the funding necessary to implement storm water management programs. It would also allow permits to be issued to Phase II municipalities at the same time Phase I permits are expiring. This would promote regional and watershed-wide permitting by allowing different municipalities to be co-applicants and to coordinate their storm water programs.

With respect to NPDES requirements for Phase II storm water discharges, the *President's Initiative* recommends[20] that NPDES Phase II requirements for storm water focus on system-wide permits for municipal separate storm sewer systems in Census-designated urbanized areas.[21] The *President's Initiative* recommends tiered permitting requirements. Storm water management programs would be developed for municipal separate storm sewer systems located within an urbanized area in which a municipal separate storm sewer system is already addressed under Phase I. The programs would, at a minimum, address non-storm water discharges into storm sewers and storm water runoff from growth and development and significant redevelopment. NPDES permitting authorities should be encouraged to implement watershed approaches which implement a more comprehensive municipal storm water management program where appropriate based on water quality impairments or other factors for municipal separate storm sewer systems in these urbanized areas. In the remaining Census-designated urbanized areas, municipal storm water management programs would be required which focus only on controlling non-storm water discharges into storm sewers and storm water runoff from growth, development, and significant redevelopment activities. The *President's Initiative* recommends that Phase II of the NPDES program not directly regulate Phase II light industrial, commercial, retail, and

[20] While the *President's Initiative* generally speaks to recommended statutory changes, EPA notes that under the existing CWA, with the exception of extending the deadline for permits for discharges from municipal separate storm sewer systems to comply with water quality-based requirements, EPA could issue Phase II regulations covering the same facilities to the same extent as suggested in the *President's Initiative*.

[21] The Bureau of the Census defines urbanized areas as a central city (or cities) with a surrounding area that is densely settled (i.e., urban fringe). The population of the entire urbanized area must be greater than 50,000 persons, and the urban fringe must have a population density generally greater than 1,000 persons per square mile (approximately 1.5 persons per acre). A complete description of the Bureau of the Census definition is provided in Chapter 3.

VOL 12

4072

institutional storm water discharges, and municipalities outside of Census-designated urbanized areas unless designated by the permitting authority for inclusion in the NPDES program under Section 402(p)(2)(E) of the CWA. Rather, such discharges, if a targeted source, should be addressed by Nonpoint Source programs.

The *President's Initiative* recommends authorizing municipalities to directly control Phase I industrial storm water facilities within their jurisdictions under the NPDES program. This recommendation is similar to the industrial pretreatment program currently authorized under the CWA. The *President's Initiative* recommends clarifying authority to issue permits on a statewide basis for IAMs, allowing Federal land managers to establish priorities and make the most effective use of available resources. Land managers would be allowed up to 10 years to meet appropriate water quality standards, while continuing to identify additional impacts from IAMs and implementing targeted controls once identified. A cost-benefit analysis was prepared for the *President's Initiative* and is summarized in Appendix L. No further cost-benefit analyses were conducted for this report.

1.2.8 NPDES Watershed Strategy

EPA issued the NPDES Watershed Strategy in March 1994. The Strategy discusses integration of NPDES program functions into a broader watershed protection approach and areas for coordination with stakeholders to promote implementation of the approach. The NPDES Watershed Strategy is based on the following principles:

- Watershed protection approaches may vary in terms of specific elements, timing, and resources, but all should share a common emphasis and insistence on integrated actions, specific action items, and measurable environmental and programmatic milestones.
- Related activities within a basin or watershed must be coordinated to achieve the greatest environmental benefit and most effective level of stakeholder involvement.

- Actions relating to restoration and protection of surface water, ground water, and habitat within a basin should be based upon an integrated decision-making process, a common information base, and a common understanding of the roles, priorities, and responsibilities of all stakeholders within a basin.
- Staff and financial resources are limited and must be allocated to address environmental priorities as effectively and efficiently as possible.
- Program requirements that interfere or conflict with environmental priorities should be identified and revised to the extent possible.
- Accurate information and high quality data are necessary for decision-making and should be collected on an incremental basis; interim decisions should be made based on available data to prevent further degradation and promote restoration of natural resources.

1.3 RELATED NONPOINT SOURCE PROGRAMS

1.3.1 Section 319 of the CWA

In 1987, Section 319 was added to the CWA to provide a framework for funding State and local efforts to address pollutant sources not addressed by the NPDES program (e.g., nonpoint sources). To obtain funding, States were required to submit Nonpoint Source Assessment Reports identifying State waters that, without additional control of nonpoint sources of pollution, could not reasonably be expected to attain or maintain applicable water quality standards or the goals and requirements of the CWA. States were also required to prepare and submit for EPA approval a statewide Nonpoint Source Management Program for controlling nonpoint source water pollution to navigable waters within the State and improving the quality of such waters. State program submittals were to identify specific best management practices (BMPs) and measures that the State proposes to implement in the first 4 years after program submission to reduce pollutant loadings from identified nonpoint sources to levels required to achieve the stated water quality objectives.

State programs funded under Section 319 can include both regulatory and nonregulatory State and local approaches. Section 319(b)(2)(B) specifies that a combination of "non-regulatory or regulatory programs for enforcement, technical assistance, financial assistance, education, training, technology transfer, and demonstration projects" may be used, as necessary, to achieve implementation of the BMPs or measures identified in the Section 319 submittals.

Although most States have generally emphasized the use of voluntary approaches in their 319 programs, some States and local governments have implemented regulations and policies to control pollution from urban runoff. States such as Delaware and Florida, as well as local jurisdictions such as the Lower Colorado River Authority, are pursuing storm water management goals through numerical treatment standards for new development. Many States and local governments have enforceable erosion and sediment control regulations. On a broader scale, nonpoint source pollution is being addressed at the watershed level by programs such as those being implemented by the State of Wisconsin, the Puget Sound Water Quality Authority, the States that are parties to the Great Lakes Water Quality Agreement, and other States. A number of individual States and local communities have adopted legislation or regulations similar to Maryland's Critical Areas Act, which limits development and/or requires special management practices in areas surrounding water resources of special concern.

1.3.2 Section 6217 of CZARA

Section 6217 of the Coastal Zone Act Reauthorization Amendments (CZARA) of 1990 provides that States with approved coastal zone management programs must develop and submit coastal nonpoint pollution control programs to EPA and the National Oceanic and Atmospheric Administration (NOAA) for approval. Failure to submit an approvable program will result in a reduction of Federal grants under both the Coastal Zone Management Act and Section 319 of the CWA.

State coastal nonpoint pollution control programs under CZARA must include enforceable policies and mechanisms that ensure implementation of the management measures throughout the coastal management area. Section 6217(g)(5) defines management measures as "economically achievable measures for the control of the addition of pollutants from existing and new categories and classes of nonpoint sources of pollution, which reflect the greatest degree of pollutant reduction achievable through the application of the best available nonpoint pollution control practices, technologies, processes, siting criteria, operating methods, or other alternatives." Congress mandated a technology-based approach based on technical and economic achievability under the rationale that neither States nor EPA have the money, time, or other resources to create and expeditiously implement a program that depends on establishing cause and effect linkages among particular land use activities and specific water quality problems. If this technology-based approach fails to achieve and maintain applicable water quality standards and to protect designated uses, CZARA Section 6217(b)(3) requires additional management measures.

EPA issued *Guidance Specifying Management Measures for Sources of Nonpoint Pollution in Coastal Waters* under Section 6217(g) in January 1993. The Guidance identifies management measures for five major categories of nonpoint source pollution: Agriculture, Forestry, Urban, Marinas and Recreational Boating, and Hydromodification. The management measures reflect the greatest degree of pollutant reduction that is economically achievable for each of the listed sources. These management measures provide reference standards for the States to use in developing or refining their coastal nonpoint programs. In general, the management measures were written to describe systems designed to reduce the generation of pollutants. A few management measures, however, contain quantitative standards that specify pollutant loading reductions.[22] The management measures approach was adopted to provide State officials flexibility in selecting strategies and management systems and practices that are appropriate for regional or local conditions, provided that equivalent or higher levels of pollutant control are achieved. Appendix K of this report summarizes the management measures for urban areas, animal feedlots, and marinas that were identified in the guidance.

[22] For example, the New Development Management Measure, which is applicable to construction in urban areas, requires: (1) that by design or performance that the average annual total suspended solid loadings be reduced by 80 percent; and (2) to the extent practicable, that the predevelopment peak runoff rate and average volume be maintained.

Storm water discharges regulated under Phase I of the NPDES program, such as discharges from municipal separate storm sewers serving a population of 100,000 or more and construction activities that disturb 5 or more acres, do not need to be addressed in Coastal Nonpoint Pollution Control Programs. However, potential Phase II sources, such as urban development adjacent to or surrounding Phase I municipal systems, smaller urbanized areas, and construction sites that disturb less than 5 acres, that are identified in management measures under Section 6217 guidance need to be addressed in Coastal Nonpoint Pollution Control Programs until such discharges are issued an NPDES permit. EPA and NOAA have worked, and continue to work, together in their activities to ensure that there is not an overlap of authorities between NPDES and CZARA.

EPA and NOAA published *Coastal Nonpoint Pollution Control Program: Program Development and Approval Guidance*, which addresses such issues as the basis and process for EPA/NOAA approval of State Coastal Nonpoint Pollution Control Programs; how EPA and NOAA expect State programs to implement management measures in conformity with EPA guidance; and procedures for reviewing and modifying State coastal boundaries to meet program requirements. The guidance clarifies that States generally must implement management measures for each source category identified in the guidance developed under Section 6217(g). This guidance sets quantitative performance standards for some measures. Coastal Nonpoint Pollution Control Programs are not required to address sources that are clearly regulated under the NPDES program as point source discharges. The guidance also clarifies that regulatory and nonregulatory mechanisms may be used to meet the requirement for enforceable policies and mechanisms, provided that nonregulatory approaches are backed by enforceable State authority ensuring that the management measures will be implemented. Backup authority can include sunset provisions for incentive programs. For example, a State may provide additional incentives if too few operators participate in a tax incentive program or develop mandatory requirements to achieve the necessary implementation of management measures.

1.3.3 President Clinton's Clean Water Initiative—Nonpoint Source Programs

President Clinton's Clean Water Initiative proposes a fundamental restructuring and strengthening of the nonpoint source pollution (NPS) control programs under Section 319 of the CWA. The *President's Initiative* proposes legislative changes that will result in upgraded and strengthened existing State NPS management programs within seven and one-half years of reauthorization of the CWA. These programs will implement best available management measures for nonpoint sources causing, contributing to, or threatening water quality impairments and for new nonpoint sources, except for new sources in States with an approved watershed management program. The *President's Initiative* recommends that the initial implementation period be followed by a second, five-year period to implement further measures where necessary (considering the actual and expected environmental benefits of the original management measures) to achieve water quality standards.

The *President's Initiative* recommends that strengthened Section 319 State programs rely on a mix of voluntary and regulatory approaches and that State programs include enforcement authorities to be used as needed to ensure implementation of management measures. Under the proposal, State authorities will be backed by Federal enforcement authorities to be exercised if a State should fail to implement the management measures. Where States do not develop an approvable program, Section 319 grants will be withheld from the State and EPA will be authorized to establish enforceable minimum NPS controls. The *President's Initiative* proposes that funding be increased for State implementation of NPS programs and that State revolving loan fund eligibility be clarified for NPS projects whose principal purpose is protecting and improving water quality. The *President's Initiative* also proposes that the CWA be clarified to require that Federal agencies comply with State or local requirements in nonpoint source programs to the same extent as non-Federal parties.

1.3.4 President Clinton's Clean Water Initiative—Watershed Management

President Clinton's Clean Water Initiative proposes that provisions for comprehensive watershed management be added to the CWA. Under the proposal, States can choose to implement comprehensive watershed programs which will be approved by EPA after conference with other Federal agencies. The States will determine the boundaries for all watersheds in the State and set a schedule for addressing them. States will oversee watershed management entities with appropriate representation of stakeholder interests and approve their watershed management plans. State watershed plans will include rankings based on environmental objectives as well as evidence of enforceable policies and mechanisms needed to implement the plans.

The *President's Initiative* proposes other changes to the CWA that: (1) provide guidelines for States wishing to adopt market-based approaches to point and NPS pollution controls within watersheds; (2) promote the development of wetland management plans that lead to increased flexibility and predictability of the wetlands permit process on a watershed basis; and (3) create comprehensive State inventories of waters that are threatened, impaired, or in need of special protection. The *President's Initiative* also recommends that States give urban watersheds a high level of priority in their State-wide ranking of watershed initiatives.

1.4 DEVELOPMENT OF THIS REPORT

A Draft of this report was circulated extensively in November 1993. Copies were distributed to States, EPA Regions, the Association of State and Interstate Water Pollution Control Administrators (ASIWPCA), and other interested parties. Comments received on that draft have been reviewed and appropriate changes to the Report have been made.

1.5 ORGANIZATION OF THIS REPORT

Chapter 2 of this report presents the approach and methodology for identifying categories of storm water sources and methods for estimating the distribution and content of these discharges. The next two chapters identify storm water discharges not regulated by the current program and discusses the nature of such discharges and the extent of pollutant loadings from these sources, as well as their geographic distribution for municipalities (Chapter 3) and industrial and commercial facilities (Chapter 4).

CHAPTER 2. APPROACH

This chapter describes the approach taken by the U.S. Environmental Protection Agency (EPA) to identify and characterize storm water discharges that are not subject to the first phase of the National Pollutant Discharge Elimination System storm water permit requirements under Section 402(p) of the Clean Water Act (CWA).

The study considered two major classes of storm water discharges: (1) discharges from municipal separate storm sewer systems (addressed in Section 2.2) and (2) industrial and commercial discharges (Section 2.3). EPA relied on existing information and data, particularly the 1990 U.S. census, and on a number of previous studies, as described in the literature review (Section 2.4). As a part of this study, EPA developed estimates of annual loadings for discharges from municipal separate storm sewer systems. Section 2.1 gives a brief overview of the approach.

2.1 OVERVIEW OF APPROACH

A main purpose of this report is to identify storm water discharges not addressed by Phase I of the NPDES program for storm water discharges and to determine the nature and extent of pollutants in these discharges. The analytical approach to this objective followed two separate paths—one for Phase II discharges from municipal separate storm sewer systems and another for individual Phase II sources. This section briefly summarizes both aspects of the approach. Sections 2.2 and 2.3 provide more detailed explanation.

In the analysis of municipal separate storm sewer systems, municipal systems addressed by Phase I of the NPDES program had to be identified to allow identification of the remaining potential Phase II municipal systems. EPA limited the analysis of potential Phase II municipal separate storm sewer systems to those municipalities that had populations that were classified as urban by the Bureau of the Census. Census information was used to identify the type of municipality, geographic location, and urban population. Selected geographic areas of potential concern, such as urbanized areas, coastal areas, and fast growing areas, were identified and evaluated following the procedures described below.

Pollutant loading estimates were developed for populations located in urbanized areas that were designated by the Bureau of the Census, including both Phase I and Phase II discharges. Pollutant loadings were estimated by using a simplified loadings model described in Section 2.2.2. Pollutant concentration data for seven pollutants, including conventional pollutants, nutrients, and metals, were taken from the results of the National Urban Runoff Program (NURP) (EPA, 1983). Runoff volume was estimated as the product of land area, the annual amount of precipitation, and the "runoff coefficient" (a fraction that indicates the proportion of precipitation that runs off the land and enters receiving waters). Land area for urbanized areas was provided by the 1990 U.S. census. Precipitation estimates were based on the rainfall zones established in the NPDES Permit Application Requirements for Storm Water Discharges (November 16, 1990). The runoff coefficient is a function of the imperviousness of the land surface, which is related to the density of roads, buildings, and other paved surfaces in an urban area. The amount of impervious area in urban settings can be estimated from population densities. The runoff coefficient used in this analysis was estimated by using a relationship based on population density (calculated from census data) that was published in the technical literature and in EPA documents (Heaney et al., 1977).

In the analysis of individual Phase II sources, identification of potential sources also proceeded in two steps. First, a review of the regulatory definition identified which types of facilities were clearly regulated under Phase I. This review aided the development of a list of facilities similar or identical to Phase I industrial facilities that were not covered under Phase I for a variety of statutory and regulatory reasons. Second, a literature review (see Section 2.4) identified, in general terms, additional commercial and retail sources of potential concern, based on the types of pollutants used or activities conducted. These potential Phase II sources were specified in detail using the Standard Industrial Classification (SIC) code system of the Office of Management and Budget. The use of SIC codes for identification of

VOL 12

4081

potential Phase II sources also facilitated the quantitative analysis performed in Chapter 4. Thus, the identification step covered the full range of industrial and commercial business activities that may be contributing to storm water pollution. A complete listing of industries classified within the SIC code system is provided later in this section.

The nature and extent of pollutants from individual Phase II sources were determined in two parts. The nature of pollutants was addressed qualitatively in two steps. First, pollutant sampling data from Phase I industrial sources was evaluated, summarized, and compared to previous studies of urban storm water content. This formed a basic reference on the nature of discharges from a wide variety of specific industrial categories. Second, potential Phase II sources were classified into groups and compared with Phase I sectors, where possible, to enable comparison to the pollutant concentration data from Phase I facilities and to determine the types and quantities of pollutants likely to be associated with unregulated discharges. This qualitative assessment of potential pollutant associations was supplemented with information documented in State and local nonpoint source programs, urban runoff programs, estuary programs, and technical articles identified through the literature review.

The extent of potential Phase II individual discharges was addressed by determining the geographic location and distribution of facilities that may contribute pollutants to storm water, rather than calculating pollutant loads as in the municipal analysis. The analysis focused on location rather than loadings because data on industrial and commercial pollutant discharges was insufficient to allow estimation of loadings on a national basis. Moreover, an attempt to estimate loads for industrial and commercial sources would lead to double counting, because many potential Phase II facilities are located in municipal or urban areas and the loading analysis for municipal sources already accounts for some of their contributions.

Using EPA's Facility and Company Tracking System (FACTS) computer file based on Dun & Bradstreet information about economic activity, the number of facilities in each SIC code was found for each county in the country.[1] From the 1990 census for each county, the proportion of population associated with geographic jurisdictions of interest was calculated. For each county and each SIC code, the number of facilities was multiplied by the proportion of population in each geographic area to yield an estimate of the number of facilities in that portion of the county. Summing over all counties provides an estimate of the proportion of facilities in each SIC code nationally that are located in the geographic jurisdictions of interest.

The two paths, municipal separate storm sewer systems and individual sources, were related through the geographical analysis of extent of discharges, which shows the proportion of pollutant loadings from municipal separate storm sewers and the proportion of individual facilities associated with various areas of concern. Although the effect cannot be quantified, the nature and extent of pollutants from industrial and commercial sources overlaps with the nature and extent of pollutant loadings calculated in the municipal analysis.

2.2 ANALYSIS OF MUNICIPAL SEPARATE STORM SEWER SYSTEMS

This section describes the procedure used to identify potential Phase II municipal separate storm sewer systems. The section also explains how the pollutant load estimates were developed for discharges from municipal separate storm sewer systems in urbanized areas.

2.2.1 Identifying Municipal Separate Storm Sewer Systems

Municipal separate storm sewer systems addressed by Phase I of the NPDES program had to be identified to allow identification of the remaining potential Phase II municipal systems. EPA limited the analysis of potential Phase II municipal separate storm sewer

[1] The FACTS data base is leased by EPA from Dun & Bradstreet Information Services, which created, maintains, and annually updates the information based on State and industry reports and on primary data collection in the business community, including detailed surveys and personal interviews. It has been estimated that this data base accounts for more than 96 percent of the U.S. Gross National Product (Caskins, 1992). FACTS was made available for this study through EPA's National Computer Center in North Carolina.

systems to populations that were classified as urban by the Bureau of the Census. The only other population classification available from the Bureau of the Census was rural populations. Rural populations and rural areas were generally excluded from this part of the analysis because the Agency was generally unable to tie these areas to development patterns and demographics that were thought to result in the installation of municipal separate storm sewer systems. Census information was used to identify the type of municipality, geographic location, and urban population.

2.2.1.1 Phase I Definitions

Section 402(p) of the CWA identifies discharges from municipal separate storm sewer systems serving a population of more than 100,000 people as requiring permit coverage under the first phase of the NPDES program. Phase I municipal systems are defined in the NPDES regulations at 40 *CFR* 122.26(b)(4) and (7) and explained in the preamble to include:

- Incorporated cities with populations greater than 100,000 served by separate storm sewers, according to the latest Decennial Census by the Bureau of the Census
- Counties with a population of 100,000 or more in unincorporated, urbanized areas, according to the latest Decennial Census by the Bureau of the Census (excluding the population of towns and townships)
- Municipalities that are designated by EPA or an authorized NPDES State.[2]

Phase I municipal systems also include systems that are designated by EPA or an authorized NPDES State under section 402(p) of the CWA as needing an NPDES permit because they are significant contributors of pollutants to waters of the United States or contribute to a violation of water quality standards.

[2] Designation of a Phase I municipal system is based on one of the following factors: physical interconnections with a municipal separate storm sewer system serving a population of 100,000 or more identified in the NPDES regulations, discharges from several municipal separate storm sewer systems, the quantity and nature of pollutants in the discharge, and the nature of the receiving waters.

VOL 12

4084

R0037392

For the purposes of determining Phase I populations, the NPDES regulations allow municipalities to reduce the population of the municipality to account for populations served by combined sewers.[3]

Census definitions data from the 1990 census was used to identify urban populations of potential Phase II municipal separate storm sewer systems. The Bureau of the Census organizes population information according to political and demographic factors. Political jurisdictions include entities with governmental structures, such as States, counties, incorporated places (e.g., cities, towns, villages), and minor civil divisions (MCDs), which include towns and townships in 20 States. Table 2-1 summarizes the definitions of these political entities.

Table 2-1. Bureau of the Census Definitions of Municipal Entities

Incorporated Places—Places incorporated under the laws of their States as cities, boroughs, towns, and villages, with the following exceptions: boroughs in Alaska and New York, and towns in the six New England States, New York, and Wisconsin.
Minor Civil Divisions—Minor civil divisions are primary divisions of counties established under State law in 20 States. Townships are minor civil divisions in 12 States (Illinois, Indiana, Kansas, Michigan, Minnesota, Missouri, Nebraska, New Jersey, North Dakota, Ohio, Pennsylvania, and South Dakota). Towns are recognized as minor civil divisions in eight States (Connecticut, Maine, Massachusetts, New Hampshire, New York, Rhode Island, Vermont, and Wisconsin).
Counties—In most States, the primary divisions are termed counties. In Louisiana, these divisions are known as parishes. In Alaska, which has no counties, the county equivalents are the organized boroughs. In four States (Maryland, Missouri, Nevada, and Virginia), there are one or more cities that are independent of any county organization and thus constitute primary divisions of their States.

Source: Census of Population and Housing, 1990.

[3] See 40 *CFR* 122.26(f)(3). Combined sewers are conveyances that are designed to collect and convey both storm water and sanitary sewage. Combined sewers are not regulated under the storm water permitting program because they are regulated as part of the total discharge from the combined system under the existing NPDES permit conditions for that system. Combined sewers are addressed in this report only as an adjustment factor used to estimate storm water flows from urban areas.

Two additional geographical classifications were evaluated in the report, urbanized areas designated by the Bureau of the Census and metropolitan areas (MAs) defined by the Office of Management and Budget (OMB). The definitions of these terms are summarized in Table 2-2. Census-designated urbanized areas are based primarily on demographics and represent densely settled areas of 50,000 or more people. OMB identifies metropolitan areas based on economics and social trends, in addition to population densities. Metropolitan areas are defined based on county boundaries and are significantly more inclusive than urbanized areas, which more closely follow population distributions.

Table 2-2. Population Classifications of Bureau of the Census

URBANIZED AREAS—An urbanized area (UA) comprises an incorporated place and adjacent densely settled surrounding area that together have a minimum population of 50,000. The densely settled surrounding areas consists of: 1. Contiguous incorporated places or census designated places having: a. A population of 2,500 or more; or b. A population of fewer than 2,500 but having either a population density of 1,000 persons per square mile, a closely settled area containing a minimum of 50 percent of the population, or a cluster of at least 100 housing units. 2. Contiguous unincorporated area which is connected by road and has a population density of at least 1,000 persons per square mile. 3. Other contiguous unincorporated area with a density of less than 1,000 per square mile, provided that it: a. Eliminates an enclave of less than 5 square miles which is surrounded by built-up area. b. Closes an indentation in the boundary of the densely settled area that is no more than 1 mile across the open end and encompasses no more than 5 square miles. c. Links an outlying area of qualifying density, provided that the outlying area is: (1) Connected by road to, and is not more than 1.5 miles from, the main body of the UA. (2) Separated from the main body of the UA by water or other undevelopable area, is connected by road to the main body of the UA, and is not more than 5 miles from the main body of the UA. 4. Large concentrations of nonresidential urban area (such as industrial parks, office area, and major airports) which have at least one-quarter of their boundary contiguous to a UA.
URBAN POPULATIONS—All persons living in urbanized areas and in places of 2,500 or more inhabitants outside of urbanized areas. The urban population consists of all persons living in (1) places of 2,500 or more inhabitants incorporated as cities, villages, boroughs (except in Alaska and New York), and towns (except in the New England States, New York, and Wisconsin), but excluding those persons living in the rural portions of extended cities; (2) census designated places of 2,500 or more inhabitants; and (3) other territory, incorporated or unincorporated, included in urbanized areas.
RURAL POPULATIONS—Population not classified as urban.

The following information was obtained from the 1990 census data (Summary Tape File-1A) for all parts of the United States[4]:

- State and County location
- Population
- Land Area
- Population Density
- Growth Projections.

Information on urbanized areas, urban populations, and metropolitan areas was obtained from documents published by the Census Bureau.

2.2.1.2 Identification of Phase I and Phase II Municipalities

The following steps were taken to identify municipalities with Phase I municipal separate storm sewer systems:

- **Cities Specifically Identified in Phase I Regulations:** Based on the 1980 census, 173 cities were originally identified as having populations exceeding 100,000. Of these, a survey of authorized NPDES States and EPA Regions indicated that 30 cities with populations of 100,000 or more have been exempted from Phase I storm water requirements due to populations served by combined sewers. An additional 5 cities' populations dropped below 100,000 based on the 1990 census. Permit applications have not been required from these cities unless they have been designated for inclusion in Phase I by EPA or a State. For the purposes of this report, 140 of the 173 cities identified in the Phase I regulations are considered to be Phase I.
- **Counties Specifically Identified in Phase I Regulations:** Based on the 1980 census, 47 counties were originally identified as having populations in urbanized, unincorporated areas that exceeded 100,000 after the population in the incorporated places, townships, or towns was excluded. Incorporated places with a population of less than 100,000 that were located in these counties were treated as potential Phase II municipalities unless they were identified as being designated into Phase I by an authorized NPDES State or EPA Region. The population of 2 of these counties had

[4] Information obtained for Guam, the Virgin Islands, American Samoa, and the Commonwealth of the Northern Mariana Islands was limited to population and growth projections. For the Commonwealth of Puerto Rico and the District of Columbia, all information described above was obtained and used in the analysis.

VOL 12

4087

dropped below 100,000 based on the 1990 census, leaving 45 Phase I counties specifically identified in Phase I regulations for the purposes of this report.

- Municipalities Designated by NPDES Authorities: Authorized NPDES States and EPA Regions have the authority to designate additional municipalities as subject to Phase I. A survey of authorized NPDES States and EPA Regions was used to identify designated municipalities. This report identifies designations that occurred before January 1994 and considers them to be Phase I sources for the purposes of this analysis.

All remaining municipalities with urban populations not identified as a part of Phase I of the NPDES storm water program were considered to be potential Phase II sources. Chapter 3 provides the specific numbers of municipal entities in various categories. Municipalities were differentiated based on characteristics such as size, density, or association with other levels and types of geographical and political jurisdictions. The designation of municipalities as Phase I vs. Phase II in this report is based on a "snapshot" of currently regulated municipalities as of January 1994.

2.2.2 Determining the Nature and Extent of Pollutants Associated With Municipal Separate Storm Sewer Systems

A review of the literature on urban runoff, including past studies conducted by EPA and the USGS, was used to develop a general descriptive profile of the nature of discharges from municipal separate storm sewer systems. Section 2.4 discusses this review.

Estimates of loads were developed for selected pollutants in runoff from urbanized areas. The approach used to estimate loadings of pollutants associated with discharges from municipal separate storm sewer systems was based on existing data and follows standard engineering practice (McCuen, 1989; American Society of Civil Engineers, 1969).

These estimates were developed to provide an overview of the extent of pollutant discharges associated with urban runoff and a relative ranking of the pollution potential from urbanized areas. The results can be used to compare potential Phase II municipal systems in urbanized areas with Phase I municipal systems. This approach was not designed to estimate actual loads for any specific locality.[5] Thus, it would not be appropriate to use load estimates generated as part of this study in assessing potential storm water impacts within a specific receiving water body.

To estimate pollutant loadings from municipal separate storm sewer systems, the following equation was used for each pollutant of concern and for each urbanized area:

Load = Pollutant Concentration × Land Area × Rainfall × Runoff Coefficient × Conversion Factor,

where:

Load = Storm water pollutant load in thousands of pounds per year[6]

Concentration = Mean pollutant concentrations determined from NURP (mg/l)

Area = Land area for the urban site or place from the U.S. census (square miles)

Rainfall = Average annual rainfall, based on rainfall zone (inches per year)

Runoff Coefficient = A fraction that represents the proportion of rainfall that runs off the land to surface waters. It is related to the amount of land covered by impervious surfaces, such as roads and buildings

Conversion Factor = Adjusts units into pounds per year.

2.2.2.1 Pollutant Concentrations

A review of the literature showed that data from NURP (EPA, 1983) are the most frequently cited and often used reference values for urban runoff pollutant concentrations. NURP data were used as the basis for loadings calculations for this study after evaluating the procedures used in NURP and comparing the results with other independent studies of urban runoff undertaken by USGS.

[5] In particular, rainfall and concentration data were not site-specific.

[6] The units of the final loading estimate were converted to thousands of pounds per year so that the results could be simplified.

NURP, which was conducted during the early 1980s, remains the most comprehensive assessment of pollutants in runoff from residential and commercial areas. The program was developed in the late 1970s, after EPA reviewed State 208 Water Quality Management Plan Reports and determined that additional and consistent data were needed to describe pollutants in urban runoff.

Under NURP, EPA provided direction and assistance to 28 planning projects located throughout the United States (Figure 2-1) that were selected from 93 area-wide agencies that had identified urban runoff as a potentially significant problem. (Table 2-3 lists the 28 NURP project locations according to EPA Regions.) Each project was separate and distinct but shared the common goal of conducting field monitoring to characterize pollutants in runoff from residential and commercial areas. The sampling locations within the 28 NURP projects included 81 specific sites and more than 2,300 separate storm events. The resulting data base represented a cross section of regional climatology, residential and commercial land use types, slopes, and soil conditions and, thereby, provided a basis for identifying patterns of similarities or differences and testing their significance.

Table 2-3. NURP Project Locations

EPA Region	NURP Code	Project Name/Location	EPA Region	NURP Code	Project Name/Location

Source: U.S. Environmental Protection Agency, 1983

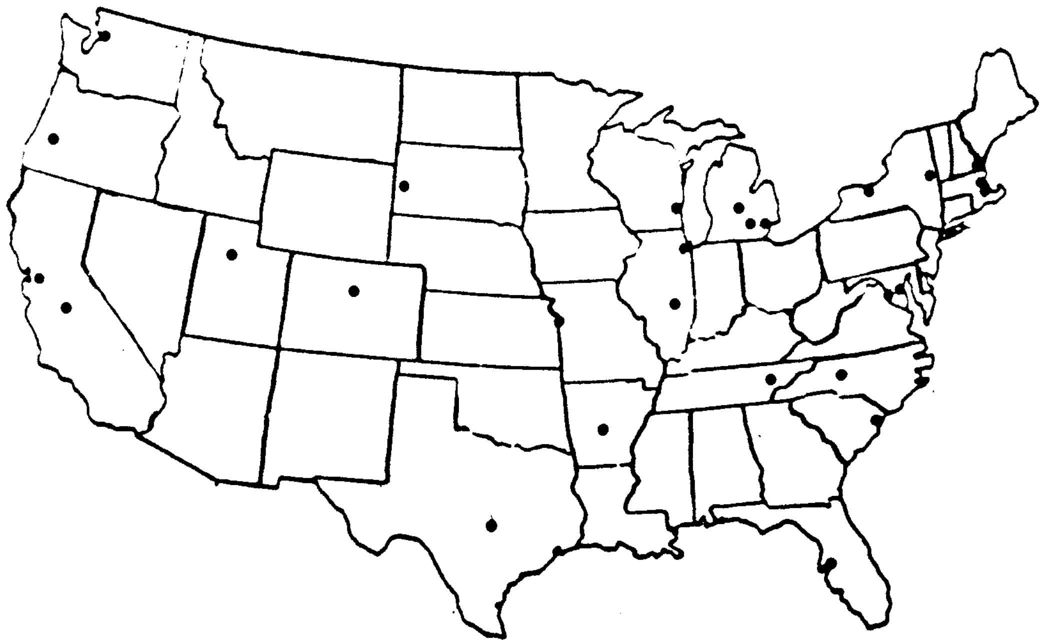

Figure 2-1. Location of NURP Sites

NURP focused on the following ten constituents, which were considered standard pollutants characterizing urban runoff:

- Total Suspended Solids (TSS)
- Biochemical Oxygen Demand (BOD)
- Chemical Oxygen Demand (COD)
- Total phosphorus (TP)
- Soluble phosphorus (SP)
- Total Kjeldahl Nitrogen (TKN)
- Nitrate + nitrite (N)
- Total copper (Cu)
- Total lead (Pb)
- Total zinc (Zn).

These pollutants are commonly associated with urban runoff and are often targets of point and nonpoint source studies. In addition, some of these pollutants can be surrogates for larger categories of pollutants such as oxygen consuming constituents and nutrients. NURP also examined coliform bacteria and priority pollutants (other than oil and grease). However, these parameters were only evaluated for a subset of sites and were not the primary focus of the NURP study. Moreover, they were not presented in a summary fashion suitable for estimating loadings. Soluble phosphorus is not discussed in this report because it was not addressed in USGS results or NPDES permit applications for industrial facilities (addressed later in this chapter).

NURP attempted to characterize the nature of storm water from residential and commercial areas. The data summaries excluded monitoring sites that were downstream of storm water controls. Sites were selected to focus on runoff from residential areas (primarily low density) and to avoid heavy industrial areas. NURP commercial site results did not include heavy industrial sites but in several cases reflected industrial park type use. Sites were also selected so that there were no extraneous sources of pollutants in the storm water discharge, such as illicit connections to the storm sewers. In addition, unusually high pollutant concentrations were eliminated from the data base as being atypical of storm water discharges.

Because of its site selection approach, NURP results represent normal or baseline urban runoff conditions from residential and commercial areas, not actual urban conditions which could include heavy industrial activities which were avoided by NURP. Because the NURP sites represent average runoff conditions from a mix of residential, commercial, and industrial park sites, loading estimates based on the NURP concentrations (described earlier in this Chapter and in Chapter 3) will be influenced by loadings from some of the sources considered in the industrial and commercial analysis (see Section 2.3 and Chapter 4) that were located in the catchments monitored.

VOL 12

4092

NURP showed that the concentrations of pollutants in urban runoff vary considerably from site to site. Concentrations at individual sites also varied through the course of a storm event and between events. This variability is the natural result of variations in rainfall intensity, occurrence, and site-specific factors (e.g., slope, land use) that affect runoff quantity and quality. NURP data were summarized using average values for storm events, with an event mean concentration (EMC, i.e., the total pollutant mass discharged divided by the total runoff volume). To determine typical storm water concentrations, NURP researchers examined the data in various ways using standard statistical procedures, each exploring the effects of different factors (e.g., slope, land use category) on final concentration values. Based on these statistical tests, NURP concluded that geographic location, land use categories, or other factors appear to be of little utility in explaining the overall site-to-site variability, and the best general characterization of urban runoff is obtained by pooling the site data for all sites (except the open/non-urban ones). NURP recommended the total pollutant mass discharged divided by the total runoff volume (i.e., the event mean concentration [EMC]) as the best single measure for characterizing overall storm water pollutant concentrations. The data summarized from NURP are recommended for planning purposes rather than site-specific characterization. Table 2-4 presents summary statistics from NURP for different sites and results from other USGS studies, discussed below.

Comparison to USGS Urban Storm Water Data Base

In addition to EPA's efforts to characterize urban runoff, USGS has collected urban rainfall, runoff, and water quality data nationally for several decades. In the mid-1980s, much of this information was compiled into a national data base. This data base contains information on 717 storms at 99 stations in 22 metropolitan areas throughout the United States (Driver et al., 1985). The USGS examined a set of constituents similar to those used in NURP. The USGS also reported its data in terms of flow-weighted samples so that concentration and loading values could be compared directly to NURP results.

Table 2-4. NURP and USGS Summary Statistics— Water Quality Characteristics of Urban Runoff

Pollutants	units/notes	NURP (1983) Median Urban Site (d) EMC Mean	NURP (1983) Median Urban Site (d) EMC Median	NURP (1983) Median Urban Site (d) 90th %-ile	NURP (1983) Commercial EMC Median	USGS (various years) Residential Mean	USGS Residential Median	USGS Commercial Sites Mean	USGS Commercial Sites Median	USGS Industrial Sites Mean	USGS Industrial Sites Median

a - EMC mean reported on page 6-60 of NURP report in the context of loading estimate comparisons. EMC should be used when comparing cumulative effects such as WQ impacts in lakes or when comparing loads on a long-term basis.

b - EMC median reported on 6-43 of NURP as the best description of urban runoff characteristics in terms of water assessing short-term water quality impacts in rivers and streams.

c - Simple mean and median calculated from raw data from USGS. Because the data were not normally distributed, the median is the best measure of central tendency.

d - NURP's "median urban site" is a composite of land use types.

NR - Not Reported.

To provide a comparison to the NURP data for this study, the USGS data were analyzed statistically to develop mean and median pollutant concentration values for 7 of the 10 NURP pollutants. (The USGS data did not include COD, TKN, or soluble P. As previously noted, soluble phosphorus is not discussed in this report because it is not addressed in USGS or NPDES permit applications for industrial facilities.) To provide some perspective on NURP, different land use categories (i.e., residential, commercial, and industrial park sites) were analyzed separately. Table 2-4 summarizes the results from the USGS data base next to the NURP results. Although NURP results (for the median) are higher for BOD, nitrate + nitrite, copper, lead, and zinc, most of the results differ by less than 50 percent, except for TSS results, which are highly variable. Both sets of results are in the same range,

VOL 12

4094

supporting the idea that these values are representative of the nature of urban runoff. This determination is consistent with the findings of Driver and Lystrom (1986), who also compared certain aspects of the two data sets.

As described in this chapter and in Chapter 3, this report uses historical data, generated by the Nationwide Urban Runoff Program (NURP) and by the U.S. Geological Survey (USGS), to generally and comparatively characterize metal contamination in storm water runoff from urban areas.

Recently, concerns have been raised regarding the validity and use of historical data for metals where adequate QA/QC cannot be properly documented (USGS, 1992). The quality of trace level metal data, especially at levels in the 1-5 part per billion (ppb) range, may be compromised due to contamination of samples during collection, preparation, storage, and analysis. These concerns have also been expressed as applying to the NURP metals data.

EPA believes that the metals data for urban runoff from USGS and NURP as used in this report are valid. Mean concentrations of copper, lead, and zinc observed under NURP and USGS were found to be in the range of 30 to 700 ppb (see Table 2-4), well above the 1-5 ppb range that has been identified as questionable. Furthermore, in dealing with the metals issue generally, EPA believes that most historical data for metals collected and analyzed with appropriate QA and QC at levels of 1 ppb or higher are reliable (EPA, 1993).

It should also be pointed out that the historical sampling data presented in this report is intended to provide a general, qualitative characterization of urban storm water runoff rather than a precise empirical relationship. The metals loadings estimated using NURP data are only used to illustrate relative loadings contributions from different geographical areas of the country. Quantitative loadings estimates, which could possibly be affected by suspect data, have not been presented in this report.

2.2.2.2 Land Area

Population and land area data (or population density) for all urbanized areas were obtained from the 1990 census. Phase I sources and potential Phase II sources were identified based on the procedure described in Section 2.2.1. An adjustment factor was developed to address combined sewer systems. Combined sewer systems are not considered to be part of the storm water regulatory program (although combined sewer overflows from combined sewer systems are addressed by the NPDES program). Therefore, storm water volume estimates in this report were adjusted to account for the flows entering combined sewers. Estimates of the land area served by combined sewer systems were based on data reported by the States for *The 1984 Needs Survey Report to Congress* (EPA, 1985).

2.2.2.3 Rainfall

Annual rainfall estimates were obtained from *Methodology for Analysis of Detention Basins for Control of Urban Runoff Quality* (Driscoll et al., 1986). This document identifies 9 rainfall zones in the United States (see Figure 2-2). Although these rainfall zones have been updated in *Analysis of Storm Event Characteristics for Selected Rainfall Gauges Throughout the United States* (Driscoll et al., 1989), (see Appendix B of this report) to include 15 more precisely defined rainfall zones, the 9 rainfall zones from the earlier report were used to simplify estimation procedures.

For each of the 3,141 counties in the country, the appropriate rainfall zone was identified, along with the average annual rainfall for that zone. This information was merged with the larger census data base at the county level to provide rainfall estimates for each municipality.

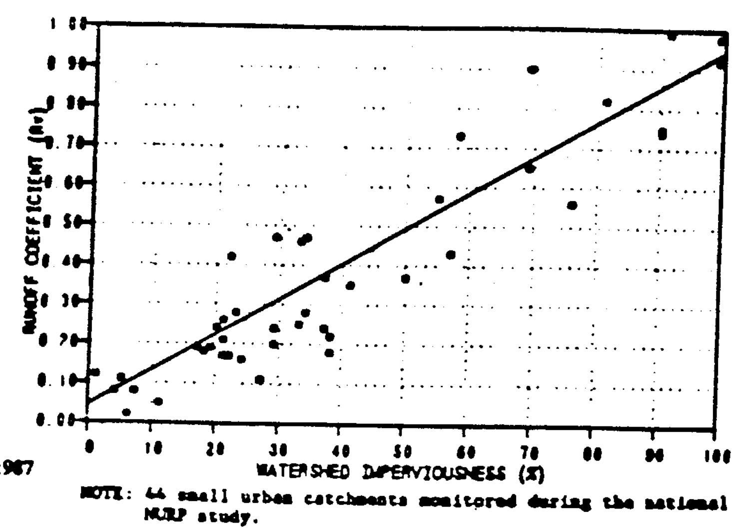
Figure 2-2. National Distribution of Rainfall Zones and Average Annual Precipitation (inches/year)

2.2.2.4 Runoff Coefficient

The runoff coefficient represents the portion (percentage) of total precipitation reaching the ground that becomes runoff to surface waters. A number of factors, such as the nature of the soils, topography, and amount or type of vegetative cover, can affect the runoff coefficient. However, the most important factor in determining the quantity of runoff from a given storm in a given area is the amount of impervious area (MWCOG, 1987). Impervious areas include all types of paved areas (e.g., streets, sidewalks, parking lots, driveways), buildings, roof tops, and other similar structures. The extent of impervious area is a function of many local considerations, such as the density and type of development. Generally, the runoff coefficient is directly related to watershed imperviousness, as illustrated in Figure 2-3, which contains data from 44 small urban catchments monitored during the national NURP study.



Source: MWCOG, 1987

Figure 2-3. Relationship of Watershed Imperviousness to Runoff Coefficient

The runoff coefficient used in the analysis of this report was estimated as a function of population density, based on equations that are widely used in the engineering literature, in previous studies by EPA's Office of Research and Development, and in the Corps of Engineers' Storage, Treatment, Overflow and Runoff Model (STORM) (which was designed for planning purposes and simulation of storm events [Heaney et al., 1977]). The two equations are:

$$\text{Impervious Proportion} = 0.096 \times \text{population density}^{(0.573 - 0.0391 \times \log(\text{Population Density}))}$$
$$\text{Runoff Coefficient} = 0.15\ (1 - \text{impervious proportion}) + 0.90\ (\text{impervious proportion}).$$

Combining the two equations yields:

$$\text{Runoff Coefficient} = 0.15 + 0.75 \times [0.096 \times \text{population density}^{(0.573 - 0.0391 \times \log(\text{Population Density}))}]$$
where population density is in persons per acre.

The first equation estimates the site-specific level of imperviousness from population density. This empirical equation is based on data from another study of hundreds of municipalities in New Jersey (Stankowski, 1974). The second equation estimates a runoff coefficient from an empirical equation that depends on the level of imperviousness. Using this model, an area with no impervious surfaces would be assigned a runoff coefficient of 0.15, while a completely impervious area would have a runoff coefficient of 0.90. These equations produce results that are similar to those presented in Figure 2-3.

The model can be used to estimate runoff coefficients when only population density is known. Figure 2-4 shows how the model predicts the relationship between population density, expressed in persons per acre and the runoff coefficient. For example, for an urban area with 10 people per acre (or 6,400 people per square mile), the model estimates a runoff coefficient of 0.4, meaning that, on average, 40 percent of the rainfall runs off to surface water. The model estimates that places with higher population densities will have higher runoff coefficients. Although limitations are associated with this relationship (e.g., the original equation is based on land use conditions in the 1960s and the estimates are limited by the uncertainty of the assumed variables), the model can make use of population density data from the 1990 census in estimating runoff coefficients for different municipalities for comparative purposes.

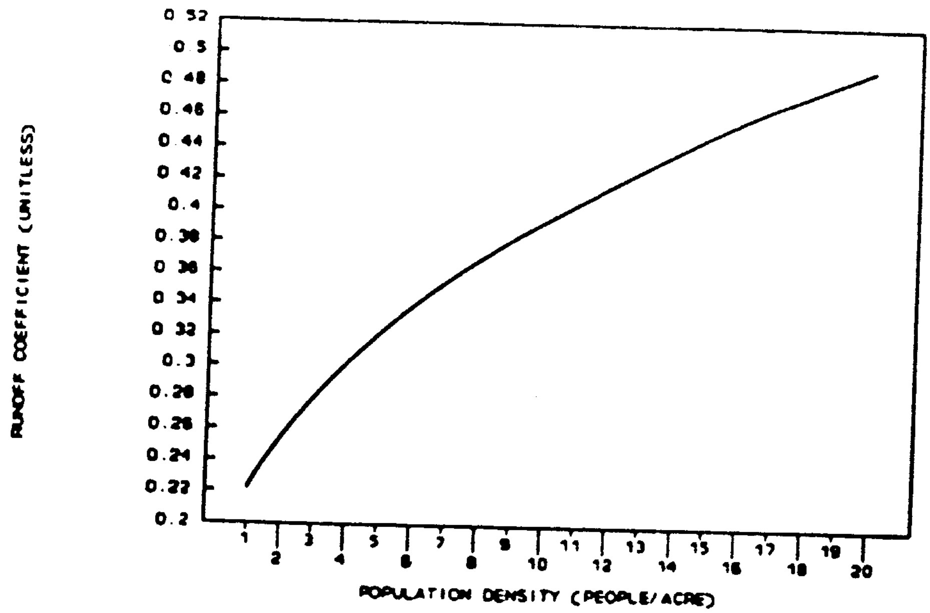


Figure 2-4. Runoff Coefficient Calculated as a Function of Population Density

2.3 ANALYSIS OF INDIVIDUAL PHASE II DISCHARGES

The second major focus of this study was to (1) identify types of industrial, commercial, and institutional storm water discharges for which permits are not already required as part of Phase I and (2) determine, to the maximum extent practical, the nature and extent of pollutants in such discharges. This section explains the approach used to select classes of facilities for study and the data analyses undertaken to develop the information presented in Chapter 4.

To develop information on remaining unregulated sources, sources regulated under Phase I were clearly defined and eliminated from consideration along with sources that have been statutorily exempted from both Phase I and Phase II. Then, from the remaining set of sources and facilities, classes of facilities with the potential to contribute pollutants to storm water discharges were identified. The analysis of the nature and extent of individual Phase II discharges addresses both pollutant concentrations and the geographic distribution of facilities. The geographical analysis was developed to determine the distribution and location of individual Phase II facilities in relation to Urbanized Areas and the Phase II municipalities identified in the first part of this study. Although there was not enough data available on a national basis to estimate pollutant loadings from individual Phase II sources, the approach taken could later be related to an assessment of water quality conditions at the local, regional, or State level.

2.3.1 Identifying Individual Phase II Storm Water Discharges

The storm water discharge regulations (Phase I) require permit applications from facilities with "storm water discharges associated with industrial activity," as defined in 40 *CFR* 122.26(b)(14) (55 *FR* 47990). This definition describes the 11 specific categories of industrial activities which are regulated. For the categories of industries identified, the term includes storm water discharges from:

> . . . industrial plant yards; immediate access roads and rail lines used or created by the facility; material handling sites; refuse sites; sites used for the application or disposal of process waste waters . . .; sites used for the storage and maintenance of material handling equipment; sites used for residual treatment, storage or disposal; shipping and receiving areas; manufacturing buildings; storage areas (including tank farms) for raw materials, and intermediate and finished products; and areas where industrial activity has taken place in the past and significant materials remain and are exposed to storm water [40 *CFR* 122.26(b)(14)].

The definitions of the 11 categories include both narrative descriptions of activities and specific designations of industrial operations based on Standard Industrial Classification (SIC) code.[7] For example, category (i) mentions facilities subject to effluent limitations guidelines

[7] The SIC code is the statistical classification standard underlying all Federal economic statistics classified by industry (OMB, 1987).

VOL 12

4101

developed by EPA, while category (xi) designates many specific SIC codes. Because of the comprehensiveness of the SIC system, even narrative descriptions can be correlated with SIC designations. For example, category (vii) covers steam electric power generating facilities, which are included primarily in SIC 4911, and category (ix) covers domestic treatment works, which are included primarily in SIC 4952. The practical effect of these narrative definitions and specific SIC code designations is that most of the industrial facilities subject to permit application requirements are represented by major SIC groupings 10 through 45.[8]

As a basis for identifying Phase II facilities and obtaining information about their distribution and abundance, this study focused on SIC codes. Major sectors of the economy are defined on the basis of the two-digit SIC code group. The two-digit code is a relatively general categorization of the Nation's economic activity; all industrial, commercial, and retail activities are organized into less than 100 two-digit SIC codes, which are listed in Table 2-5. The more specific four-digit SIC code provides a more detailed breakdown of these enterprises and is much more descriptive of the activities conducted at the establishment. The SIC code identifies facilities based on the "primary activity" in which a facility is engaged. Chapter 4 discusses selected advantages and disadvantages of using the SIC code system for identification of storm water sources. Focusing on SIC codes for the purposes of this study does not imply that EPA must regulate on a SIC code basis. Also, although some potential Phase II categories or concerns may be defined or discussed in terms of narrative descriptions, these can be evaluated in terms of SIC code designations.

Although all unregulated facilities which have point source discharges of storm water are potential Phase II sources, in practical terms, only a subset of four-digit SIC codes have real

[8] The NPDES regulations specifically exempt some categories of activity from the definition of point source, including storm water runoff from agricultural sources and silviculture activities (mostly in SIC codes 01 through 09) (40 *CFR* Part 122.3(e)), irrigation return flows (40 *CFR* Part 122.3(f)), and uncontaminated runoff from mining sites and oil and gas facilities (40 *CFR* 122.26(a)(2)). In addition, construction activities are regulated based on the site where activity is occurring, not based on the SIC code for contractors and builders that may participate in the construction (SIC 15 - 17).

potential to use, process, or store sources of pollutants, or engage in activities that could lead to contamination of storm water. In addition, there are many general sources of storm water contamination such as parking lots, trash dumpsters, and failing septic systems which could be associated with almost any commercial or residential activity. Some general information on these sources is presented in Chapter 4; however, the focus of this report is in identifying specific classes of facilities with greater than average potential for contribution of pollutants to storm water discharges based on their activities.

EPA identified two major groups of facilities for potential inclusion in Phase II. The first group of potential Phase II facilities identified (Group A) consists of facilities in the same SIC code groups as Phase I facilities (SICs 10-45) that are conducting activities that are essentially the same as Phase I industrial activities but that were not included in Phase I due to the specific language of the statute or EPA's regulatory specificity in defining the universe of Phase I industrial activities. The second major group (Group B) consists of facilities in all other SIC code groups where discharges of pollutants are suspected based on case studies, expert opinions, literature reviews, and other sources of information such as experience with Phase I of the storm water program.[9]

2.3.1.1 Group A Facilities

Group A is comprised of facilities which are generally identical to regulated Phase I industrial activities but that have been excluded from Phase I due to the specific language of the statute or EPA's regulatory specificity. While some of the facilities that make up Group A are obvious, (i.e., those with a specific statutory exemption from Phase I), others are more difficult to identify. Because these facilities may be described by SIC codes identical to Phase I regulated facilities, the FACTS data base was of little use in identifying these

[9] Although some sources similar to Phase I industrial activities were not identified in the 1990 application regulations (55 FR 47990) directly. EPA or an authorized NPDES State has the authority under Section 402(p)(2)(E) to designate individual facilities as needing an NPDES permit. Although some designations of this type have been made, this report bases the distinction of individual Phase I and Phase II facilities based on the regulatory definition and not on any individual designations which may have been made.

facilities. Instead, each of the 11 industrial categories that make up Phase I (see Chapter 4, Table 4-2) was examined for possible omissions and discrepancies. The result of this effort was a list of sources that are *not* covered under Phase I but that are closely related to one of the eleven categories of industrial activity. This list appears in Table 4-3. In order to help define these facilities, sources on the list were categorized into three major groups. Group A sources are described in Chapter 4.

2.3.1.2 Group B Facilities

The second general class of facilities were identified on the basis of potential activities and pollutants that may contribute to storm water contamination (Group B). Unlike Group A facilities which are generally represented by the same range of SIC code groups as Phase I facilities (SICs 10-45), Group B facilities have distinctly different SIC codes but may be performing similar activities or using similar materials as Phase I facilities. Based on the review and analysis of the types of industrial sources not covered under Phase I, several categories of Group B facilities were identified that have activities inherently similar to Phase I but are not currently regulated. Some SIC code groups were also identified using other criteria, described below.

Commercial facilities were specifically excluded from Phase I by Congress. However, many commercial sources represent an important environmental concern. These concerns are documented in State and local nonpoint source programs, urban runoff programs, and estuary programs identified through the literature review (see Section 2.4). The Rensselaerville Study (1992) reflected this view by identifying "gas, auto, service stations, transportation related activities, highway systems, land development, agricultural sources and related activities, commercial activities with industrial components, and large retail complexes" as sources of concern.[10]

[10] No SIC codes specifically identify all large retail complexes. However, these complexes are partially addressed through the loading analysis of storm water from urban/urbanized areas in the municipal section (Chapter 3).

Another class of facilities included in Group B is commercial agricultural-related activities. Categories that are specifically exempted from regulation under Section 402 of the CWA (or, in certain cases, under existing NPDES regulations) were eliminated from consideration in Group B as potential Phase II sources. (These include agriculture and most silviculture activities generally included in SIC code groups 01, 02, 07, 08, and 09.[11]) However, several specific SIC codes were retained on the list as potential Phase II sources because they are not specifically included under the agricultural exemption. These include nurseries, feedlots (the larger of which are already regulated under the NPDES permitting program),[12] some forestry operations, and miscellaneous others.[13]

A final review of other miscellaneous sources that have been identified as potential contributors to storm water pollution was conducted to reveal any sources not addressed by the criteria discussed above. The facilities identified use or handle materials containing pollutants of concern to publicly owned treatment works (POTWs). To the extent that these materials are used, stored, processed, or disposed of outdoors at Group B facilities, they may also represent a source of storm water contamination.

The procedure used to identify specific SIC codes with significant potential to discharge pollutants to storm water resulted in the identification of 90 categories of facilities. Table 4-4 lists the subset of 90 four-digit SIC codes identified from this analysis. The analysis was comprehensive and inclusive, while at the same time carefully determining whether a category had the potential to contribute pollution to storm water.

[11] The NPDES regulations at 40 *CFR* 122.27 cover discharges from certain types of silviculture activities but do not cover other discharges that are nonpoint in nature.

[12] Feedlots that are not contained within the regulatory definition of concentrated animal feeding operation (CAFO) are not point sources unless designated on a case-by-case basis under 40 *CFR* 122.23(c).

[13] Under 402(p)(6), EPA may establish regulations that could include sources that are not currently defined as point sources or examined as potential Phase II sources in this report, including some operations related to silviculture.

VOL 12

4106

The geographic distribution analysis was completed for all major two-digit SIC code groups and for the 90 specific four-digit SIC codes identified in Table 4-4. Information about the distribution of all facilities is presented in the report, even for categories that are not among the 90 potential Phase II categories, including all Phase I facilities, financial and service groups, and agricultural activities.

2.3.1.3 Service Sectors

Major SIC code groups in the service sectors, such as banking, finance, insurance firms, and food services were not considered to be potential Phase II sources. The activities of these enterprises are generally conducted indoors and do not inherently use or produce contaminants that may enter storm water. Although these facilities may have general sources such as parking lots or trash dumpsters which could contaminate storm water discharges, the municipal analysis considers pollutant loadings from these types of sources. All of the major SIC groups excluded on this basis are listed in Table 4-6. Regardless, the geographic and distributional analysis was conducted for these facilities at the major group (two-digit SIC) level. These results are presented in Appendix G.

2.3.2 Determining the Nature and Extent of Pollutants Associated With Industrial and Commercial Discharges

The nature and extent of discharges from potential Phase II industrial and commercial discharges were analyzed in a manner that allows comparison with the municipal analysis in terms of geographic distribution. The potential pollutant content of storm water from industrial and commercial sites was characterized and the locations of these potential discharges were analyzed with respect to urbanized areas. The nature of discharges was evaluated by comparison to existing studies (i.e., NURP and USGS), by analysis of discharge data from Phase I sources, and by compilation of qualitative information from a literature survey. The geographic extent of discharges was evaluated by analyzing the location of facilities using the FACTS data base in conjunction with information from the census, as explained below.

2.3.2.1 Identifying Pollutants Associated With Industrial and Commercial Discharges

Storm water discharged from industrial, commercial, and retail facilities has the potential to come into contact with raw materials, products, and waste streams, which can result in pollutant contamination of storm water discharges. A number of general categories of activities and conditions that have the potential to generate contaminants in storm water have been identified in both the proposed and final NPDES Permit Application Regulations for Storm Water Discharges (53 *FR* 49416; 55 *FR* 47990):

- Outside loading of dry bulk or liquid materials that may be spilled or accumulated and washed with rainfall into storm sewers or receiving waters
- Outside storage of raw materials, wastes, or products
- Outside processing of materials where rainfall may come into contact with materials in the process stream
- Practices with the potential for spills to the storm sewer or wash down of processing areas to floor drains
- High volume water use in material processing
- Direct application of wastes to the ground
- Dust and particulate generating processes
- Vehicle and equipment maintenance activities.

Most of these activities are specifically mentioned in the definition of discharges associated with industrial activity (40 *CFR* 122.26(b)(14)).

To characterize potential industrial and commercial storm water discharges, data on industrial and commercial sites and land uses were taken from the NURP and USGS studies and analyzed statistically and presented for comparison purposes. Chapter 4 provides further comparison and discussion. The results provide general insight into the nature of storm water runoff from light industrial areas.

The nature of industry-specific storm water quality data was characterized by analyzing sampling data submitted by group permit applicants under Phase I. These sampling results provide insight into the nature of storm water from these industrial sites and storm water from potential Phase II facilities which may have similar characteristics.

This analysis focused on the pollutants that were required to be analyzed for in the Part II NPDES storm water permit group application plus copper, lead, and zinc. For each pollutant and each industrial sector, the mean, median, and 95th percentile were calculated for both grab and composite samples, where the pollutant was identified. Where applicants reported none detected, the result was treated as zero, an approach consistent with the analysis of data from Phase I industrial facilities as presented in Appendix F. Chapter 4 summarizes these data. Appendix F contains detailed data summaries for each of 29 industrial sectors developed for the group application process.

To facilitate characterization of the nature of discharges from potential Phase II sources, similarities between Phase I and Phase II facilities were highlighted by comparing categories with similar activities, where possible. For facilities in Group A, comparison to Phase I sectors is generally straightforward and yields valuable information about these potential Phase II facilities. For Group B facilities, the corresponding Phase I activity may not be as similar. Comparisons were made only in general terms at the industrial sector level and not at the level of specific SIC codes or facilities. The resulting information presented in Chapter 4, therefore, can only be used as a guide to the general types and levels of pollutants that may be found at facilities of a given category, rather than a definitive determination of the degree of contamination at a particular site. These results are presented in Chapter 4.

To supplement the Phase I data analysis, a literature review was conducted to locate and summarize the available information on the nature of pollutants with emphasis on the groups of categories selected by the screening procedure outlined above. The literature review focused on identifying the types of pollutants that may be associated with particular categories of facilities. General qualitative information on storm water discharges and potential pollutants is available in the literature from a number of case studies and assessments of specific locations and types of facilities. Although providing useful background information, it is usually not comprehensive for any one category and may not be comparable across categories.

2.3.2.2 Determining the Extent of Individual Phase II Sources

The extent of storm water discharges from Phase II sources was determined by identifying the locations of the facilities in those categories, rather than the pollutant loads associated with them, as in the municipal analysis. Nation-wide information on the extent of pollutants from these facilities is limited. However, detailed quantitative information on the geographic extent and distribution of these facilities can be developed by combining two data sources[14]:

- FACTS provides data, including name and address, county affiliation, primary business activity (SIC), employment, and sales, on more than 7.7 million industrial, commercial, retail, and government facilities.
- The 1990 Census of Population and Housing, discussed previously, provides detailed information on population and area for most political subdivisions in the country. County-level information on population associated with urbanized areas was used in this analysis.

An analysis was conducted to determine the distribution of individual Phase II facilities and categories in relation to population patterns. To develop information comparable to the municipal analysis, the analysis of individual sources was conducted at the county level. This analysis was conducted to examine the distribution of industrial, commercial, and retail enterprises to determine how they are distributed relative to jurisdictions of potential interest in development of potential Phase II regulatory approaches.

[14] Information on number and location of facilities was limited to the 50 States and the District of Columbia. Analysis of these statistics in relation to urbanized areas was not performed for the facilities and urbanized areas in the Commonwealth of Puerto Rico.

The geographic analysis involved developing, for each county, population, and area, data for all the same political and geographic jurisdictions studied in the municipal analysis, based on the 1990 census data base. Jurisdictions of interest included urbanized areas and Phase I cities, as discussed in Section 2.2, for municipal discharges. For each county, then, the proportion of individual facilities within urbanized areas could be calculated, and the number of facilities located in Phase I and Phase II areas could be determined.

Because the facility location data was not available at the same level of detail as census data used in the municipal analysis, the next step of the procedure made use of the approximate correlation between the location of business and economic activity and the distribution of population. Specifically, the analysis relies on the premise that industrial and commercial facilities are distributed similarly to population within county jurisdictional boundaries. For example, the percentage of facilities estimated to be in the urbanized area of a county is allocated based on the percentage of population in the urbanized area of the county. The premise may be more valid for urban retail activities, such as automobile service activities, and less valid for agricultural activities, which are generally less likely to be associated with urban areas. However, when considering all counties together, as shown in Chapter 4, this procedure produces reasonable results, even for rural businesses, because they are more often located in counties with small urban populations.

Using FACTS, individual facilities were counted for each SIC code and for each county.[15] By basing the distribution of facilities on the distribution of population within a county, it was possible to allocate a portion of the facilities in each county to urbanized areas. The national total for each jurisdictional class was obtained by summing over all counties.

[15] A few facilities had incomplete records for county name and so could not be analyzed using this procedure. Given the intensive data collection activities of Dun & Bradstreet and the focus on economic activity for marketing purposes, the largest and most economically important facilities probably have the most complete records. Thus, the types of facilities with incomplete records are probably small and economically less significant.

2.4 LITERATURE REVIEW PROCESS

The literature review for information about storm water discharges, sources, and pollutants was fundamental to the approach. The following sections describe the activities conducted during the literature search.

2.4.1 Libraries

An extensive literature search was conducted at several libraries, including the University of Maryland and George Washington University, the Library of Congress, the USGS library, and the National Agricultural Library. The On-Line Computer Library Center (OCLC), a national bibliographic data base of 27 million records representing the holdings of more than 15,000 libraries worldwide, was accessed at the University of Maryland. Libraries that use OCLC primarily include public libraries, university libraries, and governmental agency libraries, such as the Department of Interior, Department of Agriculture, and the USGS. The system enables the user to search for periodicals, books, and other publications by using author, title, or subject key words. Numerous key words and phrases were searched, including key words associated with the activities of industries selected for the Phase II analysis. General terms such as storm water, industrial pollution, and names of products or contaminants thought to be associated with particular industries were also searched using OCLC.

At the Library of Congress, a data base search was conducted for information in trade association journals and other publications, environmental engineering journals and periodicals, environmental business journals and periodicals, and other publications that potentially have information related to the industrial analysis. Many of the trade association publications are only available to association members. For those publications found in library holdings, a search was conducted for articles that did not show up during the OCLC search. The data base used at the Library of Congress comprises numerous computerized disk files, each containing information on various subjects, such as science and engineering. The science and engineering disk (the most closely related topic area) was used to search for periodicals available through local libraries. Back-issues of many of the more topical publications were scanned for information relevant to the industrial analysis. The majority of periodicals searched are included in the list given in Table 2-6. At each library, library-specific data bases were searched for documents located in the individual library but not entered into the OCLC data base.

2.4.2 Additional Resources

Other resources used in the literature search included EPA documents and periodicals in the Pollution Prevention Information Clearinghouse and Toxic Release Information System, documents available through EPA, EPA's docket, topic-related development documents and effluent guidelines limitations, and publications from State offices related to potential Phase II industries. Additional organizations and individuals were contacted to obtain information on pollutant concentrations in storm water discharges from industrial facilities, especially potential Phase II sources. Only a few documents obtained contained industry-specific pollutant concentration data. The rest provided background information on potential Phase II sources. Organizations contacted specifically for information include the U.S. Department of Defense, the number and a list of military bases; the U.S. Department of Transportation, for an estimate on the acreage or miles of road disturbed per year; the Forest Service at the U.S. Department of Agriculture, for data on storm water discharges from the construction of roads for logging and related activities; and the National Estuary Program, to ascertain data on storm water impacts outlined in estuary management programs.

A list of the documents obtained from the various sources mentioned above is included in the bibliography at the end of this report. Other documents available in the EPA docket (Record For Proposed NPDES Storm Water Implementation Package) were also reviewed.

2.4.3 Potential for Obtaining Additional Information

Based on research efforts for the Report to Congress, quantitative information on pollutant concentrations (and loadings) from industrial activities, especially potential Phase II (unregulated) categories, is limited. EPA's literature search for information on industrial sources identified many major categories of information. Pursuing additional sources of information and extending the literature review effort would probably yield more qualitative information to enhance the existing information on industrial sources. In particular, information on the processes and activities associated with the facilities and a better idea of the types of pollutants involved could potentially be documented. By focusing on particular industry sectors, it may be possible to get more information on the number and size of facilities, as well as information on quantities of products mined, distributed, etc.

CHAPTER 3. MUNICIPAL SEPARATE STORM SEWER SYSTEMS

Section 402(p)(2) of the Clean Water Act (CWA) requires the control of discharges from municipal separate storm sewer systems serving a population of 100,000 or more under Phase I of the NPDES storm water program. This chapter identifies municipal separate storm sewer systems not identified in Phase I that potentially may be subject to requirements under Phase II of the NPDES storm water program. In addition, this chapter describes the nature and extent of pollutants associated with municipal separate storm sewer systems, with an emphasis on potential Phase II sources. To provide an appropriate context for the discussion of potential Phase II sources, this chapter also discusses Phase I municipal systems.

Municipal separate storm sewer systems are comprised of conveyances designed to collect and convey storm water (but not sanitary sewage[1]) that are owned or operated by a municipality. Section 402(p)(3) of the CWA authorizes EPA and NPDES States to issue system-wide or jurisdiction-wide permits for discharges from municipal separate storm sewer systems. NPDES permits for discharges from municipal separate storm sewer systems are to contain requirements to reduce the discharge of pollutants to the maximum extent practicable (MEP) and to effectively prohibit non-storm water discharges to the municipal system in order to meet water quality standards. These requirements can be implemented through municipal storm water management programs to control pollutants from targeted commercial, residential, industrial, and other sources that discharge storm water (or other non-storm water discharges) through the municipal system.

3.1 IDENTIFICATION OF MUNICIPAL SEPARATE STORM SEWER SYSTEMS

The Bureau of the Census estimates that the population of the United States and associated territories was more than 252.2 million in 1990.[2] There are 19,289 incorporated

[1] Combined sewers are conveyances designed to collect and convey both storm water and sanitary sewage. This report generally does not address combined sewers.

[2] Population estimates based on the 50 states, the District of Columbia, Guam, the Commonwealth of Puerto Rico, the Virgin Islands, American Samoa, and the Commonwealth of the Northern Mariana Islands.

VOL 12

4 / / 5

places and 17,796 minor civil divisions in the continental United States, Alaska, and Hawaii. These incorporated places and minor civil divisions are located in 3,141 counties or county equivalents. As discussed in Chapter 2, Table 2-2 provides the Bureau of the Census definitions for the major forms of municipal government.

3.1.1 Population Distributions

The Bureau of the Census defines two classes of population: urban and rural. The majority of the population in the United States is classified as urban (188 million or 75 percent of the total U.S. population), with only 25 percent of the population classified as rural.

3.1.1.1 Urbanized Areas

To provide a better separation of urban and rural population and housing in the vicinity of large cities, the Bureau of the Census defines an urbanized area as a central city (or cities) with a surrounding area that is densely settled (i.e., urban fringe). The population of the entire urbanized area must be greater than 50,000 persons, and the urban fringe must have a population density generally greater than 1,000 persons per square mile (just over 1.5 persons per acre). As discussed in Chapter 2, Table 2-2 provides the definitions of urban populations, rural populations, and urbanized areas used in the 1990 census.

The Bureau of the Census identified 405 urbanized areas of 50,000 or more people based on the 1990 census. The combined population of these areas was more than 160 million people (63 percent of the total U.S. population and 85 percent of the urban population). However, these areas occupy less than 2 percent of the Nation's total land area. Figure 3-1 shows the location of the 405 urbanized areas.

Table 3-1 gives the number of urbanized areas in different size classes. Table 3-2 provides the distribution of urbanized populations and municipalities by State.

Table 3-1. Size Distribution of Urbanized Areas in 1990

Urbanized Area Population Range	Number of Urbanized Areas	Total Population	Total Area (sq.mi.)	Average Area (sq.mi.)	Average Population Density (pop./sq.mi.)
Over 1,000,000	34	95,237,380	27,749	816	3,432
500,000 - 999,999	26	17,955,916	8,122	312	2,211
250,000 - 499,999	44	15,470,005	7,732	176	2,001
150,000 - 249,999	62	11,945,413	5,877	95	2,033
100,000 - 149,999	63	7,538,363	4,366	69	1,727
75,000 - 99,999	58	5,045,917	3,058	53	1,650

3.1.1.2 Metropolitan Areas

The Office of Management and Budget (OMB) identifies metropolitan areas based on economic and social trends, as well as population densities. The general concept of a metropolitan area is one of a large population nucleus, together with adjacent communities which have a high degree of economic and social integration. Metropolitan areas have a total population of 100,000 or more (75,000 in New England) and contain either a place with a population of 50,000 or more or an urbanized area of 50,000 or more. A metropolitan area is comprised of one or more central counties and outlying counties that have close economic and social relationships with the central county. Unlike a Census-designated urbanized area with boundaries that follow population patterns, the boundaries of a metropolitan area follow county boundaries[3] and can contain significant tracts of rural land.

[3] In New England, metropolitan areas follow town boundaries.

TOTAL	160,384,133	467*

*Urbanized areas which crossed state boundaries were counted more than once. There are 405 distinct urbanized areas nationwide.

Source: 1990 Census of Population and Housing, Bureau of the Census, U.S. Dept. of Commerce

OMB has defined 284 metropolitan areas based on the 1990 census. Figure 3-2 shows the location of the 284 metropolitan areas. These areas have a combined population of 192.7 million or 77 percent of the total U.S. population. This total includes rural populations of 26.5 million (14 percent of the metropolitan area population). Metropolitan areas occupy about 16.6 percent of the land area of the United States (about 88 percent of which is rural). There are 6,998 incorporated places (2,732 of which are rural) and 823 counties located in metropolitan areas. Table 3-3 provides a distribution of population inside and outside of metropolitan areas.

Table 3-3. Populations Inside and Outside of Metropolitan Areas in 1990

3.1.2 Identification of Phase I Municipal Systems

Section 402(p) of the CWA identifies discharges from municipal separate storm sewer systems serving a population of 100,000 or more as Phase I sources under the NPDES storm water program. Municipal separate storm sewer systems serving a population of 100,000 or more are defined in the NPDES regulations at 40 *CFR* 122.26(b)(4) and (7) to include:

- Incorporated cities with a population of 100,000 or more
- Counties with populations of 100,000 or more in unincorporated, urbanized areas (excluding the population of towns and townships)
- Municipalities designated by EPA or an authorized NPDES State as having Phase I municipal separate storm sewer systems.

VOL 12

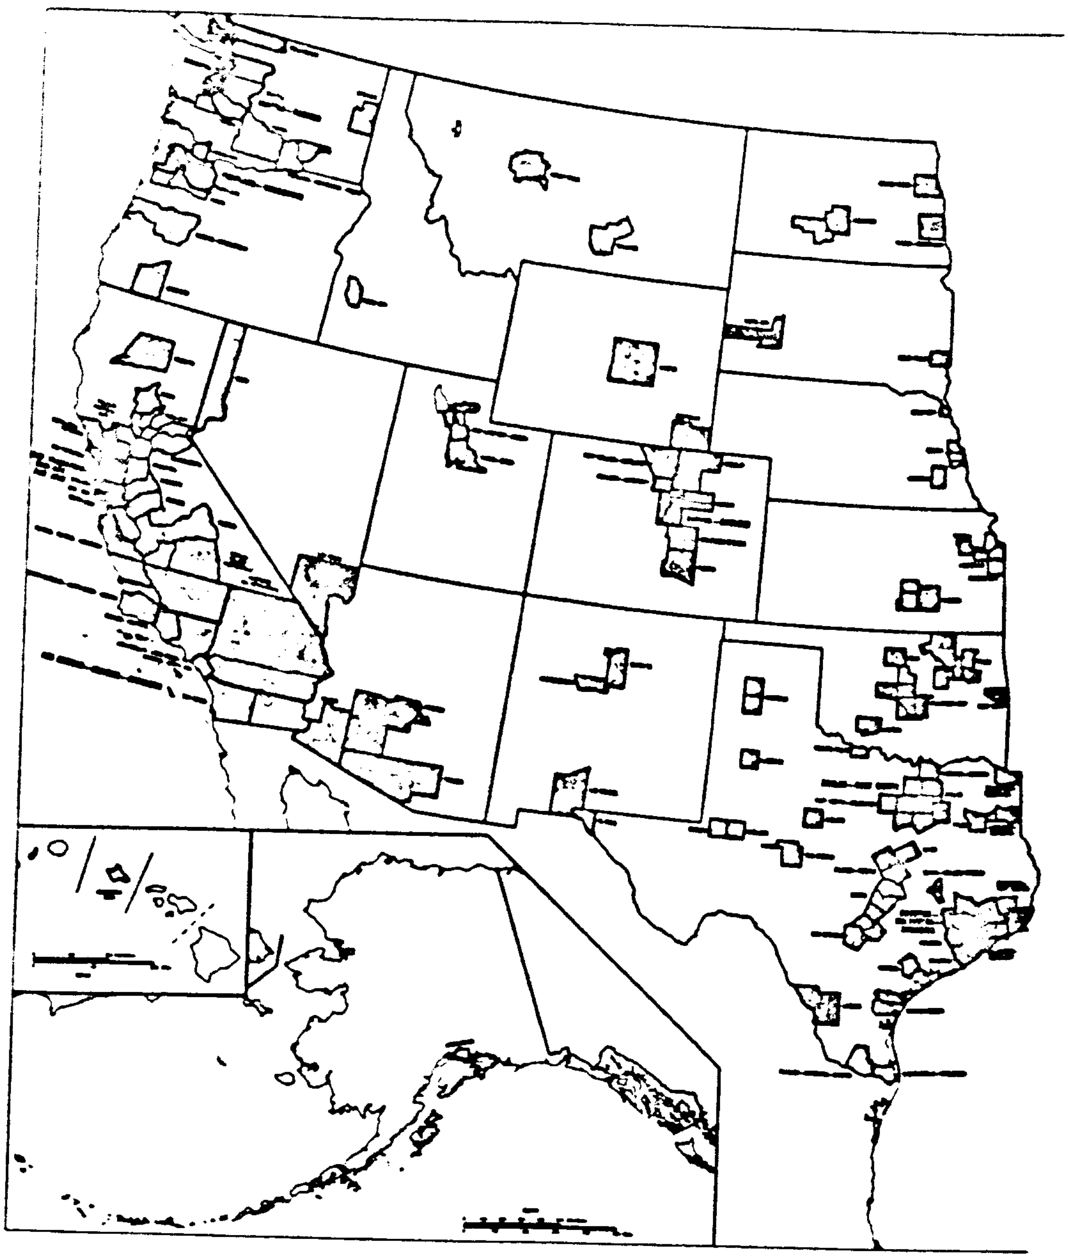

Figure 3-2. Metropolitan Areas of the United States

4122

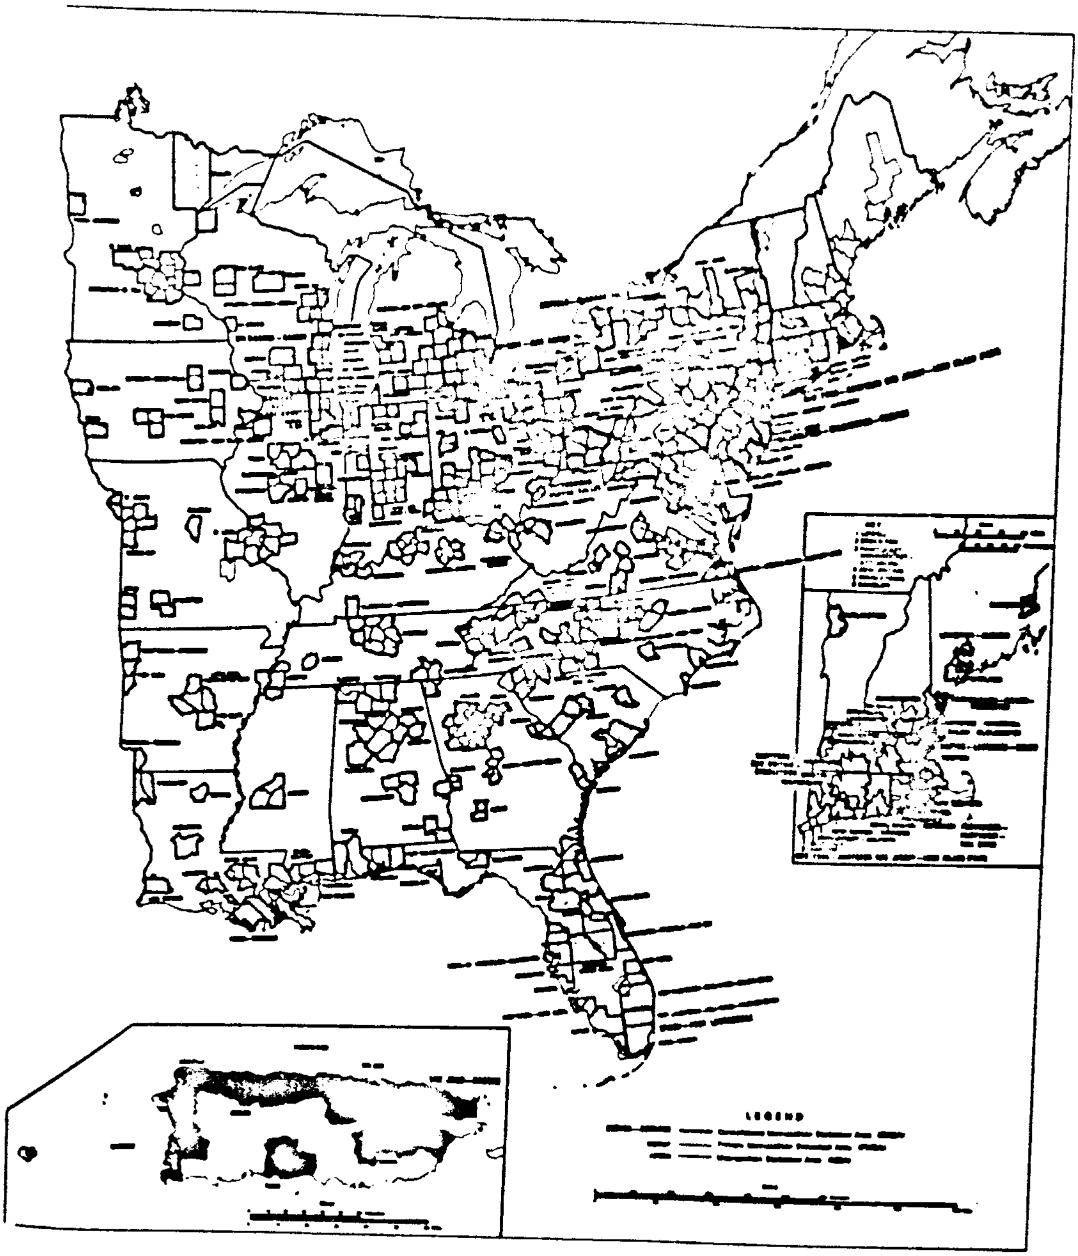

Figure 3-2. Metropolitan Areas of the United States (continued)

In addition, discharges from municipal separate storm sewer systems can be addressed under Phase I of the NPDES program if they are designated under Section 402(p)(2)(E) of the CWA as significant contributors of pollutants to waters of the United States or if they have contributed to a violation of a water quality standard.

Table 3-4 summarizes population and area estimates for municipalities with separate storm sewer systems subject to Phase I of the NPDES program. Appendix A lists Phase I municipal separate storm sewer systems. All but eight States (i.e., Maine, Montana, North Dakota, New Hampshire, New Jersey, Rhode Island, Vermont, and Wyoming) have one or more Phase I municipal separate storm sewer system. Table 3-5 summarizes Phase I municipal separate storm sewer systems by State.

Table 3-4. Municipalities Addressed by Phase I of the NPDES Storm Water Program

Phase I Municipalities		Number	Population (millions)	Area (sq.mi.)
Identified by Regulation*	Cities	140	50.9	17,634
	Counties	45	17.1 **	83,254 **
Designated by EPA/States	Cities	481	14.5	5,017
	Counties	32	3.5 **	27,862 **
	Other ***	60	NA	NA

* These counts exclude cities with a population of 100,000 or more that are exempted from Phase I of the water program due to populations served by combined sewers.

** Includes all of regulated counties. Of the 17.1 million people in counties identified by regulation, 14.6 are in urbanized unincorporated areas. Of the 3.5 million people in designated counties, 2.1 million are in urbanized unincorporated areas.

*** "Other" pertains to a municipality that is not defined by U.S. census political boundaries (i.e., State DOTs, drainage districts, universities, etc.).

3.1.2.1 Incorporated Cities With a Population of 100,000 or More

The Phase I NPDES storm water regulations initially specifically identified 173 incorporated places with a population of more than 100,000.[4] However, 30 of the 173 cities with a population of 100,000 or more have been excluded from Phase I of the NPDES storm water program because, after the population served by combined sewers is subtracted from the total city population, the population served by separate storm sewers is less than 100,000.[5] Table 3-6 lists the cities excluded from Phase I because of populations served by combined sewers.

The description of Phase I sources presented in this report includes available information on cities given exemptions from Phase I because of populations served by combined sewers.

3.1.2.2 Counties With Urbanized, Unincorporated Populations of 100,000 or More

Phase I of the NPDES storm water regulations specifically identify municipal separate storm sewer systems in unincorporated portions of 45 counties as needing an NPDES permit.[6] Counties specifically identified in the Phase I regulations were described as having 100,000 or more people (based on the 1980 census) who live in unincorporated areas and are part of an urbanized area designated by the Bureau of the Census. EPA identified counties with large unincorporated, urbanized populations for regulation under Phase I of the NPDES

4127

[4] The specific cities listed in the current NPDES storm water regulations were based on 1980 census data. Thirty-five cities had populations of less than 100,000 under the 1980 census but have populations of 100,000 or more based on the 1990 census. Five cities had populations of more than 100,000 under the 1980 census but have populations of less than 100,000 based on the 1990 census. For the purposes of this Report, these 40 cities are not addressed as Phase I municipalities, unless they have been designated by EPA or an authorized NPDES State as needing a permit as of January 1994.

[5] To account for populations served by combined sewers, 40 *CFR* 122.26(f)(3) allows municipalities to petition EPA or an authorized NPDES State to reduce their population for the purpose of Phase I population determinations.

[6] The specific counties listed in the current NPDES storm water regulations were based on 1980 census data. Thirteen counties had unincorporated, urbanized populations of less than 100,000 under the 1980 census but have unincorporated, urbanized populations of 100,000 or more based on the 1990 census. Two counties had unincorporated, urbanized populations of more than 100,000 under the 1980 census but have unincorporated, urbanized populations of less than 100,000 based on the 1990 census. For the purposes of this Report, these 15 counties are not addressed as Phase I municipalities, unless they have been designated by EPA or an authorized NPDES State as needing a permit.

VOL 12

4/28

storm water program because they were the primary municipal entity governing unincorporated areas. Because they are the primary municipal entity, these counties are the functional equivalent to an incorporated city for the purposes of a storm water program (i.e., the county generally performs many of the same functions and has the same legal and land use authority as incorporated cities). The 45 counties identified in this manner are located in 17 States, with the majority of the counties (33) being located in 6 States—Florida (9 counties), California (9 counties), Georgia (4 counties), Maryland (4 counties), Virginia (4 counties), and Washington (3 counties).

In 20 States, unincorporated portions of counties or county equivalents are divided into minor civil divisions. The criteria used to define Phase I municipal separate storm sewer systems did not address systems in counties with a population of 100,000 or more in these States, even where the unincorporated portions of the county were heavily urbanized. The Agency did not address such areas under Phase I of the program because of the complexities of the intergovernmental relationship between the county and incorporated places and minor civil divisions.

3.1.2.3 Designated Municipalities

The NPDES regulations authorize EPA or NPDES States to designate additional municipal systems as needing a permit under Phase I of the storm water program.[7] To date, 481 incorporated places and 32 counties have been designated by EPA and authorized NPDES States. These designated municipalities have a combined population of more than 18

[7] Designations can occur under two authorities. 40 *CFR* 122.26(b)(4) and (7) provide that additional municipal separate storm sewers may be designated as part of a system serving a population of 100,000 or more because of the interrelationship between the discharges of the designated storm sewers and the discharges from municipal separate storm sewers located in an incorporated place with a population of 100,000 or more or a county with an urbanized, unincorporated population of 100,000 or more. Additional municipal separate storm sewers within a region defined by a storm water management regional authority can be designated based on a jurisdictional, watershed, or other appropriate basis that includes an incorporated place with a population of 100,000 or more or a county with an urbanized, unincorporated population of 100,000 or more. Section 402(p)(2)(E) of the CWA provides that storm water discharges, including discharges from municipal separate storm sewer systems, that are a significant contributor of pollutants to waters of the United States or that have contributed to a violation of a water quality standard can be designated as needing a permit.

million. The majority of the designations (464 incorporated places and 28 counties) are in eight States (Alabama, California, Delaware, Florida, Georgia, Maryland, Oregon, and Tennessee). Municipalities have been designated as part of the Phase I NPDES storm water program in seven other States.

3.1.3 Identification of Potential Phase II Municipal Systems

Municipal separate storm sewer systems that are potentially subject to requirements under Phase II of the NPDES storm water program will be identified in terms of the following classes:

- Municipalities not addressed by Phase I, but located in an urbanized area with one or more Phase I municipalities
- Municipalities associated with an urbanized area without a Phase I municipality
- Urban populations outside of urbanized areas
- Rural populations
- Populations not addressed in the census.

3.1.3.1 Potential Phase II Municipalities Associated With Urbanized Areas With One or More Phase I Municipalities

Of the 405 urbanized areas designated by the Bureau of the Census, 136 have one or more municipalities with a separate storm sewer system addressed by Phase I of the NPDES storm water program. In most of these 136 urbanized areas, municipalities not addressed under Phase I are also found in the urbanized area. Table 3-7 lists the 136 urbanized areas with one or more Phase I municipalities. Table 3-8 summarizes the number of municipalities associated with different sizes of urbanized areas with a municipality with separate storm sewers subject to Phase I of the storm water program. Note that some urbanized areas cross state lines and are listed in the table in multiple states. In those cases, the portion of the urbanized area in each state is listed, rather than the total population within the urbanized area.

VOL 12

The 136 urbanized areas with one or more municipality with a separate storm sewer system addressed by Phase I have a total population of 117.5 million (47 percent of the total U.S. population). The portions of these urbanized areas currently not addressed by Phase I of the NPDES storm water program have a combined population of 35.7 million people. Of the 35.7 million people, 32.9 million people live in 1,587 incorporated places and 634 minor civil divisions. The remaining 2.9 million people live in unincorporated areas. EPA estimates that 305 counties currently not addressed by Phase I of the NPDES storm water program are part of an urbanized area in which one or more municipalities are in Phase I.

Two general patterns of municipal governments can be used to describe the 136 urbanized areas that have one or more Phase I municipalities. Most of the 136 urbanized areas can be described as having a large core city with a population of 100,000 that is addressed by Phase I of the program, with a large number of smaller potential Phase II incorporated places and minor civil divisions surrounding the core city. Figure 3-3 provides an example of this pattern, which illustrates the Milwaukee, Wisconsin, urbanized area.

4135

The second pattern of municipal government for the 136 urbanized areas consists of counties that do not have minor civil divisions. Urbanized areas that follow this pattern are comprised of a core city (which is usually addressed by Phase I) surrounded by a combination of unincorporated portions of counties and incorporated places. In urbanized areas that follow this pattern, unincorporated portions of one or more of the counties surrounding the core city may be in Phase I, while the smaller incorporated places surrounding the core city are generally not addressed by Phase I. Figure 3-4 gives an example of this pattern, which illustrates the Washington, D.C., urbanized area. Figure 3-4 also shows that Phase I jurisdiction for this urbanized area generally extends beyond the 1990 boundaries of the urbanized area. In this manner, Phase I addresses much of the new development associated with the expanding urbanized population, even though it occurs outside of the 1990 urbanized area boundary.

VOL 12

VOL 12

3.1.3.2 Potential Phase II Municipalities Associated With Urbanized Areas Without a Phase I Municipality

A total of 269 of the Census-designated urbanized areas currently do not have any municipalities with separate storm sewers subject to Phase I of the storm water program. Table 3-9 lists these urbanized areas. As in Table 3-7, note that some urbanized areas cross state lines and are listed in the table in multiple states along with the portion of the population in that state. Table 3-10 summarizes the population and number of municipalities associated with different classes of urbanized areas without a municipality with separate storm sewers subject to Phase I of the storm water program. Of the 269 urbanized areas, 101 (more than a third) have a population of more than 100,000 and 23 have a population of more than 250,000. These 269 urbanized areas without a Phase I municipal separate storm sewer system have a combined population of 42.9 million people (16 percent of the total U.S. population). Of the 42.9 million people, 37.1 million people live in 1,470 incorporated places and 966 minor civil divisions. The remaining 5.8 million people live in unincorporated areas. EPA estimates that 380 counties that are part of an urbanized area do not have a municipality addressed by Phase I of the NPDES storm water program.

Twenty-one urbanized areas have an incorporated city with a population of 100,000 or more that are not subject to Phase I of the NPDES storm water program because of populations served by combined sewers. Table 3-11 lists these urbanized areas. The 21 urbanized areas have a combined population of 17.5 million people, of which an estimated 11.7 million people are served by separate storm sewers. Three of these urbanized areas (i.e., Chicago, St. Louis, and Pittsburgh) have populations of more than a million people that are served by separate storm sewers. Of the remaining urbanized areas, 10 have a population of more than 250,000 and 7 have a population of more than 175,000, but less than 250,000. Of the 17.5 million people that live in the 21 urbanized areas, 6.0 million people live in cities with a population of 100,000 or more.

3.1.3.3 Urban Populations Outside of Urbanized Areas

The Bureau of the Census defines urban populations to consist of persons living in any densely settled place of 2,500 or more inhabitants. Urban populations outside of urbanized areas are comprised of distinct population centers of more than 2,500 but less than 50,000 people. The total urban population outside of urbanized areas is 29.0 million people. Of this total, 25.1 million people live in 3,689 incorporated places. The remaining 3.9 million people live in either minor civil divisions or unincorporated portions of counties. The urban population outside of urbanized areas but inside a metropolitan areas as defined by OMB is 10.8 million.

3.1.3.4 Rural Populations

The census population data base classifies any population other than urban populations as rural populations. In 1990, the rural population totalled 61.5 million people. Of this total, 8.8 million live in 13,044 incorporated places; the remaining 52.7 million people live in either minor civil divisions or unincorporated portions of counties.

3.1.3.5 Populations Not Addressed in Census

The census data does not address certain classes of development, including resort towns and second home development. The census population data base generally does not reflect seasonal populations, such as people that only live in a resort town during peak seasons, second home development, people staying in rental units, or tourists. For example, on some peak weekends, more than 250,000 people may visit Ocean City, Maryland. According to the census, however, the permanent population of Ocean City, Maryland, is only 5,146. It has been estimated that more than two-thirds of recreational subdivisions are situated near water, often on artificially constructed lakes (Reilly, *The Use of Land*, 1973).

3.1.4 Development Trends

New development is widely recognized as providing some of the best opportunities for implementing cost-effective storm water management controls. This section identifies major trends of new development.

During the twentieth century, the U.S. population has become increasingly urbanized. The rate of growth occurring over the last four decades is exemplified by Bureau of the Census data on urbanized areas with a population of 50,000 or more. Table 3-12 shows two important trends that have occurred since 1950:

- The total populations in urbanized areas have been rapidly increasing.
- Most of this growth has been occurring outside larger central cities in urban fringe areas.

Table 3-12. Growth of Urbanized Areas in the United States Between 1950 and 1990

Year	Number of Urbanized Areas	Population in Urbanized Areas (millions)			Land Area (sq.mi.)
		Total	Central Cities	Urban Fringe	
1950	157	69.2	48.4	20.9	19,728
1960	213	95.8	57.9	37.8	25,544
1970	273	120.7	65.1	55.6	35,081
1980	366	139.2	67.0	72.1	52,017
1990	405	160.4	79.7	80.7	61,520

Source: Bureau of the Census, U.S. Dept. of Commerce

Between 1980 and 1990, the population of Census-designated urbanized areas increased by 21.2 million[8] and the cumulative size increased by 9,000 square miles. During the same period, the rural population of the United States increased by 2.2 million, and the urban population that lived outside of urbanized areas increased by 0.9 million.

[8] About 7 percent of this increase (1.5 million people) is associated with the net addition of 30 new urbanized areas between 1950 and 1990. Another part of this increase which has not been estimated here is associated with the increase in land area of pre-existing urbanized areas.

Cities with a population of 100,000 or more with municipal systems already addressed by Phase I of the NPDES storm water program increased in population by about 4.9 million people (or an increase of 9 percent) between 1980 and 1990.[9] Between 1980 and 1990, the population of urbanized areas with one or more municipal systems addressed by Phase I of the NPDES storm water program increased by 16.4 million (or 67 percent of the total national growth). This represented a 25 percent increase in the population of these areas. The population of urbanized areas without a Phase I municipal system increased by 4.8 million. This represents 20 percent of the total national growth and an 11 percent increase in the population of these areas.

Population increase is only one indicator of new development. Significant development can occur, particular in some of the larger urbanized areas experiencing migration from core cities to suburban areas. For example, between 1970 and 1990, the total population of the Chicago urbanized area was relatively stable, increasing by only 77,509 people. However, during this time significant migration was occurring from the core city to surrounding suburban areas. The population of the city of Chicago decreased by 583,257 while the population of suburban areas increased by 660,766. The Chicago urbanized area increased in land area by 307 square miles, or by 25 percent of its 1970 size.

The migration away from central business districts to the suburbs has been occurring at high rates since the late 1970s. By the mid-1980s, approximately 57 percent of the office space in the country was located in the suburbs; before that time, central business districts within the urban core contained the majority of office space (Cooper, 1986).

Growth is concentrated in certain geographic regions of the country. For example, the most growth in urbanized areas is occurring mainly in the south and west. High rates of growth are occurring in coastal and estuarine areas. Population in these areas has increased

[9] The 4.9-million increase does not include increases associated with unincorporated, urbanized portions of Phase I counties and designated municipalities.

VOL 12

4149

by about 30 million people during the last 3 decades (almost half the total U.S. population increase) and is expected to increase, although at reduced levels (Culliton et al., 1990). The Bureau of the Census projects that most growth by 2010 will occur on the Pacific, Atlantic, and Gulf Coasts (Figure 3-5). High growth areas include California and Washington State in the West, all of the coastal States south of New Jersey in the East, and Florida and Texas in the Gulf Coast region.

A comparison of 1990 census data to 1980 data supports these projections (Table 3-13). Twenty-five of 30 coastal States have seen dramatic population increases since 1980 (Bureau of the Census, 1991). The largest increases occurred in California (6.1 million people), Florida (3.2 million people), and Texas (2.7 million people). While the major population corridors extend from New York to Washington, DC, Los Angeles to San Diego, and within the San Francisco Bay metropolitan area, estuaries in the Middle Atlantic contain the greatest percentage of urban land and is the most densely populated among regions (NOAA, 1990).

3.2 NATURE OF DISCHARGES FROM MUNICIPAL SYSTEMS

A number of features of the urban environment affect the manner in which discharges from municipal separate storm sewers may affect surface water resources, including:

- Urban activities and sources that generate or contribute to pollutants
- Increased levels of imperviousness
- Modifications and destruction of natural drainage features, including removal of riparian vegetation
- Design objectives of drainage system.

The degree of impact on a receiving water can also depend on other factors, including the frequency and duration of the storm water discharges, the quality and quantity of storm water discharges, the occurrence of other wet weather discharges (e.g., combined sewer

overflow discharges), and the quantity and quality of the base flow (dry weather flow) of the stream. Appendix B further discusses the potential impacts from storm water discharges to different classes of receiving waters.

3.2.1 Major Pollutant Sources

Pollutants in discharges from municipal separate storm sewer systems originate from a variety of diffuse sources. This subsection discusses both runoff-related and non-storm water sources of pollutants.

3.2.1.1 Runoff-Related Pollutant Sources

The urban environment has many sources that can contribute pollutants to storm water. Table 3-14 provides selected examples of the major common sources of pollutants in the urban environment. Many of these sources, such as those related to vehicles, building materials, and road maintenance, are ubiquitous in the urban environment. The complex interactions of the various pollutant sources in the urban environment have limited efforts to quantify the contribution of pollutants from specific sources. Rather, most studies of the quality of urban runoff have characterized pollutant concentrations in runoff from general land use categories (e.g., residential, commercial, open land). However, several recent studies have begun to look at smaller segments of the urban environment that may generate runoff with elevated levels of pollutants.[10] At least one recent study has attempted to evaluate the contribution of pollutants from different formulations of a commercial product (brake pads) to urban runoff.[11] Another recent study addressing deposition of air pollutants to waters identified fossil fuel combustion in industrial, commercial, and residential units;

[10] For example, see Bannerman, R., et al., 1993 *Sources of Pollutants in Wisconsin Stormwater*, Water Science & Technology (28): 3-5, pp. 241, which indicates that streets and roads may be the most significant source of pollutants associated with residential, commercial and industrial land use. Pitt, R., et al. *The Treatability of Urban Stormwater Toxicants*, International Congress on Integrated Stormwater Management, 1991, which reported that runoff from vehicle service areas and parking lots generally had higher concentrations of polynuclear aromatic hydrocarbons and metal than runoff from street surfaces. In addition, a higher frequency of runoff from vehicle service areas and parking lots exhibited toxicity.

[11] See Public Review Draft of *Contribution of Heavy Metals to Storm Water from Automotive Disc Brake Pad Wear*, Santa Clara Valley Nonpoint Source Pollution Control Program, 1994.

VOL 12

Table 3-14. Common Pollutants and Non-Industrial Pollutant Sources Associated With Urban Runoff

Pollutant	Source (Category: Components)
Lead	Vehicles: exhaust, tire wear (filler material), lubricating oil and grease Structures and roads: paint
Zinc	Vehicles: tire wear (filler material), oil and grease (stabilizing additive), brake pads, metal corrosion Paved surfaces: deicing salts Structures: paint, metal corrosion, wood preservatives
Copper	Vehicles: parts wear (brakes, metal plating, bearings and bushings), diesel fuel Structures: paint, metal corrosion, wood preservative Other: pesticides
Cadmium	Vehicles: tire wear (filler material) Other: pesticides
Chromium	Vehicles: parts wear (brakes, metal plating, engine parts)
Nickel	Vehicles: diesel fuel, lubricating oil, parts wear (brakes, metal plating, and bushings) Paved surfaces: asphalt
Manganese	Vehicles: parts wear (engine parts)
Bromide	Vehicles: exhaust
Mercury	Other: coal combustion Vehicles: fuel combustion Structures: paint
Iron	Vehicles: body rust, engine wear Structures: rust
Cyanide	Paved surfaces: deicing salts Structures: wood preservatives
PAHs	Vehicles: exhaust Other: incomplete combustion
Chloride	Paved surfaces: deicing salts
Sulphates	Other: combustion product Vehicles: exhaust Paved surfaces: road beds, deicing salts
Nitrogen, Phosphorus	Vehicles: exhaust Other: combustion product Landscape maintenance: fertilizers Soil erosion: land disturbance, exposed soils Sewage: leaking sanitary systems, septic systems

Sources: EPA, 1992, 1990, 1983; Kobriger et al., 1984.

Table 3-14. Common Pollutants and Non-Industrial Pollutant Sources Associated With Urban Runoff (continued)

Pollutant	Source (Category: Components)
Sediments, Particulates	Soil erosion: land disturbance, exposed soils Streambank erosion: high flows Vehicles: body rust, tire wear, other wear
Pesticides	General outdoor application Structures: wood preservatives, paint
Floatables	Litter: residential, commercial, industrial, recreation Waste disposal: residential, commercial, industrial recreation Vegetation: leaves, branches, trunks
Bacteria	Sewage: leaking sanitary systems, septic systems Other: animal droppings Soil erosion: exposed soils
Oil and grease	Vehicles: drippings, leaks Paved surfaces: asphalt Equipment maintenance: exposed surfaces Other: wood preservatives, wood/coal combustion
PCBs	Vehicles: catalyst in synthetic tires Other: electrical, insulation
Benzene	Vehicles: fuel Other: solvent use
Toluene	Vehicles: fuel and asphalt Other: solvent use
Chloroform	Vehicles: form by mixing salt, gasoline and asphalt
Oxygen Demand	Vegetation: leaves Litter: various sources Soil erosion: land disturbance, exposed soils
Phthalate, bis(2-eth.)	Structures: plasticizer Other: plasticizer

Sources: EPA, 1992, 1990, 1983; Kobriger et al., 1984.

municipal waste combustion and hazardous waste and sewage sludge incineration; and various manufacturing processes, such as cement production as major local sources of metals. The report also identified fossil fuel and biomass combustion in petroleum refineries, motor vehicles, and industrial commercial and residential units as major local sources of polycyclic organic matter.

A number of the sources provided in Table 3-14 are related to materials exposed to precipitation. Examples of these sources include zinc from galvanized gutters and roofs and lead from certain exterior paints. Other sources are generally released to the environment, such as metals and polynuclear aromatic hydrocarbons (PAHs) in automobile emissions, zinc in tire wear, and emissions from industrial sites. Pollutants from these sources can be carried away from their original point of generation and accumulate on other impervious surfaces where they are eventually washed off. In addition, erosion of land and streambanks can contribute sediments and other pollutants.

Pollutant concentrations in runoff from different land uses are discussed below.

3.2.1.2 Non-Storm Water Sources

Although separate storm sewers are primarily designed to remove runoff from storm events, materials other than storm water end up in and are ultimately discharged from separate storm sewers. For example, in Sacramento, California, it is estimated that less than half of the water discharged from the storm water drainage system is directly attributed to precipitation.[12] Non-storm water discharges to storm sewers come from a variety of sources,[13] including:

- Illicit connections and cross connections from industrial, commercial, and sanitary sewage sources
- Leaking sanitary sewage systems
- Malfunctioning onsite disposal systems (septic systems)
- Improper disposal of wastes such as used oil, wastewaters, and litter

[12] *Urban Runoff Discharge from Sacramento, CA*, Montoya, B., CA Regional Water Control Board, Central Valley Region, 1987, Report Number 87-1SPSS.

[13] A more complete description of non-storm water discharges to storm sewers is given in *Investigation of Inappropriate Pollutant Entries into Storm Drainage Systems: A User's Guide*, EPA, January 1993, EPA/600/R-92/238.

- Spills
- Infiltration of ground water contaminated by a variety of sources, including leaking underground storage tanks
- Wash waters, lawn irrigation, and other drainage sources.

Appendix C provides a more complete description of these sources of non-storm water. Table 3-15 summarizes numerous studies involving problems with non-storm water discharges. These case studies illustrate the wide range of pollutants (e.g., pathogens, metals, nutrients, oil and grease, phenols, and solvents) that can be contributed to storm sewers from non-storm water discharges. Removal of these non-storm water sources of pollutants often provides opportunities for dramatically improving the quality of discharges from separate storm sewers and is required by Section 402(p)(3)(B)(ii).

Table 3-15. Summary of Non-Storm Water Discharge Problems

Study Site	Comments
Jones Falls Watershed Baltimore City and County, MD	During the NURP study of the Jones Falls Watershed, 15 illicit connections were discovered in portions of the watershed. The illicit connections were grouped into four types: direct discharges from residences, leakage from cracked or broken sewer lines, decades-old overflows from the sanitary sewer, and sanitary sewage pumping station malfunctions. Elevated levels of pathogens, TSS, ammonia, TKN, total nitrogen, COD, and TOC were identified.
Tulsa, Oklahoma	A physical inspection was conducted on 120,000 feet of storm sewer 48 inches and larger serving a drainage area of approximately 12 square miles. 35 potential non-storm water discharges were observed. 23 of these were observed and/or suspected sanitary sewer connections, 4 were potable water discharges, and 8 were of an unknown source. In addition, 12,900 feet of sanitary sewer were laid within the storm sewer where the storm sewer served as a conduit. Most illicit connections were associated with development that occurred before 1970. Other documented observations were structural defects (900 feet of pipe showed signs of structural defects), pipe cross through (176 total), and debris buildup.

VOL 12

Table 3-15. Summary of Non-Storm Water Discharge Problems (continued)

Study Site	Comments
Washtenaw County, MI	Of the 1,067 businesses, homes, and other buildings inspected, 154 of the buildings inspected (14%) had illicit connections, including connections in restaurants, dormitories, car washes, and auto repair facilities. About 60% of the automobile-related businesses inspected had illicit discharges. A majority of the illicit connections discovered had been approved connections when installed. Pollutants that were detected include heavy metals, nutrients, TSS, oil and grease, radiator fluids, and solvents.
Fort Worth, TX	24 outfalls in a 10-mile radius were targeted for end-of-pipe observations. The success of the program was judged by a decline in the number of undesirable features at the target outfalls, from an average of 44 undesirable observations per month in 1986 (522 total) to an average of 21 undesirable observations per month in 1988. The Fort Worth investigation indicated problems associated with allowing septic systems, self-management of liquid waste by industry, and construction of municipal overflow bypasses from the sanitary sewer to the storm drains. These problems were attributed to the inability of the POTW to expand as rapidly as urban growth occurred. During a 30-month period, problems detected include 133 hazardous spills, 125 incidents related to industrial activity, 265 sanitary sewer line breaks, and 21 bypass connections of the sanitary sewer to the storm sewer. Highlighted cases include a 20 gallon-per-minute flow from a cracked sanitary sewer from a bean processing plant to a storm drain and an illicit connection of a sanitary sewer line from a 12-story office building to a storm sewer. Most industrial pollution enters the storm sewer system from illegal dumping, storm runoff, accidental spills, and direct discharges. Metals were not detected in dry-weather discharges but were found in significant levels in receiving water sediment. City officials state that the high metal concentrations in sediment are consistent with otherwise unexplained serious reported fish kills.
Seattle, WA	The city of Seattle has detected improper disposal and illicit connections from industrial sites by investigating sediment in storm sewers. One storm drain outfall that represented a major source of lead to the Duwamish River was traced back to a former smelter that crushed batteries to recover lead. Lead concentrations in the sediment were high enough to allow the city to send it to an operating smelter to be refined. Another storm drain contained high levels of creosote, pentachlorophenol, copper, arsenic, and PCBs, which (except for the PCBs) were traced back to a wood treatment facility. Thirty cubic yards of contaminated sediments removed from the storm drain contained 145 pounds of contaminants. Sediments removed from storm drains in another industrial area contained very high levels of PCBs (about 1 pound of PCBs in 70 cubic yards of sediment).
Upper Mystic Lake, NY	The NURP study for the Upper Mystic Lake Watershed project identified contamination of storm water runoff and, subsequently, surface water contamination of surface waters by sanitary discharges as a major problem in the watershed that contributed large quantities of phosphorus, certain metals, and bacteria. Interactions at 19 manholes serving both sanitary and storm sewer lines were identified as the major contributor of pollutants.

4158

Table 3-15. Summary of Non-Storm Water Discharge Problems (continued)

Study Site	Comments
Bellevue, WA	The NURP report for Bellevue, WA, recorded 50 voluntary citizen reports of illegal dumping and other non-storm water discharges during a 27-month period. The incidents reported were varied and resulted in at least two significant fish kills. 25 percent of the citizen reports involved improper disposal of used oil to the storm sewer. Other reports involved spills, illicit connections of floor drains, septic system pipes, and a car wash, as well as chemical dumping and concrete trucks rinsing out into catchbasins or streams.
Ann Arbor, MI	Studies in 19[illegible], 1978, and 1979 found that discharges from the Allen Creek storm drain contained significant quantities of fecal coliform, fecal streptococci, solids, nitrates, and metals. Of the 160 businesses dye-tested, 61 (38%) were found to have improper storm drain connections. Chemical pollutants, including detergents, oil, grease, radiator wastes, and solvents, were causing water quality problems. Monitoring of the storm drainage system during storm events indicated a decrease in the concentration of 32 of 37 chemicals monitored after the improper connections were removed.
Medford, OR	Fecal coliform tests at storm drain outfalls in city parks were used to detect 4 leaking sanitary sewer lines that were either located above the storm lines or saturated the ground with effluent, which entered the nearby storm drains; an agricultural equipment wash rack; and a house with sanitary lines plumbed to the storm drain. In addition, in one of the oldest sections of town, a large storm drain bored in the early 1900s also contained the sanitary sewer line. Under manholes, the sanitary line was only a trough. Even minor clogs or breaks resulted in a spillover of effluent into the storm drain below.
Toronto, Ontario*	Dry weather samples of discharges were taken from 625 storm drains in the Humber River watershed. About 10 percent of the outfalls were considered significant sources of nutrients, phenols, and/or metals, while 30 of the outfalls had fecal coliform levels of greater than 10,000 per 100 ml. Investigations identified 93 industrial and sanitary sewage illicit connections. Problems included residential connections of sanitary sewage to the storm sewers and yard runoff from a meat packing plant to a storm drain.
Grays Harbor, WA	Dry weather sampling of 29 outfalls of separate storm drains indicated that discharges from 6 of the outfalls had abnormally high pollutant levels with suspected illicit connections. The area under consideration had originally been served by combined sewers. Earlier efforts to separate the system had been incomplete, with some residences discharging sanitary sewage to the storm drain.
Seward, NY	Sewage from septic systems with clogged drainfields in clay soils flowed into open storm sewers. The open storm sewers posed health risks to neighborhood children and lowered property values.

VOL 12

4159

Table 3-15. Summary of Non-Storm Water Discharge Problems (continued)

Study Site	Comments
Norfolk Naval Station, VA	The Norfolk Naval Shipyard was originally built in 1767 and has had numerous additions since. It has an extensive network of underground pipes, including both separate storm sewers and sanitary/industrial sewers. In response to a lawsuit, officials at the Shipyard conducted dye-testing of sanitary facilities throughout the shipyard, which led to the identification and elimination of 25 cross-connections of sanitary and industrial waste to the separate storm sewer system.
Sacramento, CA	The city of Sacramento is currently undertaking a project to identify pollutant discharges and illegal connections to the storm water drainage systems. Recent studies identified acute toxicity in storm water and determined that less than half of the water discharged from the drainage system was not directly attributable to precipitation. Mass loading estimates of copper, lead, and zinc discharged by the drainage system were several times higher than the estimated pollutant loads of these metals from the Sacramento Regional Treatment Plant secondary effluent.
Hazardous Waste Case Studies	These case studies determined that onsite waste disposal where pollutants were added to runoff, eventually ending up in drainage systems, and other situations where a generator dumped wastes directly down a drain were common. Of the 36 cases of illegal dumping investigated in a GAO report, 14 cases investigated involved disposal of hazardous wastes directly to, or with drainage to, a storm sewer, flood control structure, or the side of a road. An additional 10 sites involved disposal to the ground, to landfills (other than those receiving hazardous wastes), or to trash bins, which can ultimately result in additional pollutants to subsequent storm water discharges.

* Information from cities outside of the United States included for informational purposes only.

3.2.2 Imperviousness

The level of watershed imperviousness can be linked to impacts to streams and other surface water resources (Schueler et al.). Urbanization and development increase the imperviousness of land, which alters the natural vegetation and infiltration characteristics of watersheds. These increases in imperviousness can dramatically alter natural flow patterns of streams, wetlands, and other surface water resources. Increased levels of imperviousness replace natural vegetation and decrease the natural infiltration characteristics of a watershed, increasing the amount of runoff during wet weather events. Schueler estimates that in undeveloped watersheds, 5 to 15 percent of the annual stream flow is delivered during storm events. As a general rule, the amount of runoff occurring during storm events is directly proportional to the amount of watershed imperviousness. For example, runoff from storm events will typically comprise half the annual stream flow in a watershed that is 50 percent impervious (Schueler, 1987). Figure 3-6 illustrates how storm water peak flows increase as population (and, consequently, imperviousness) increases based on data from the United States Geological Survey (USGS) and the Bellevue Planning Department (1977). In addition to causing increased flooding, changes in the hydrology of a stream can result in accelerated stream bank or stream bed erosion. Such erosion can cause or contribute to a number of generally detrimental effects on stream hydrology and morphology. For example, erosion can widen or deepen the stream channel, eliminate pools and other structures in the stream, and shift gravel or sand bars (Schueler, 1992).

Increased levels of imperviousness also cause less infiltration of rainfall to recharge ground water supplies, thereby lowering the water table. One result of lowered water tables is that baseline stream flows can be significantly decreased during dry weather. Reduced flows between storms may significantly affect the aquatic habitat and the ability of a stream to dilute toxic spills or other dry weather pollutants within the stream system (Bellevue NURP project). In some cases, the installation of storm sewers in a watershed results in previously perennial streams running dry several times a year (Long Island NURP project).

The level of watershed imperviousness is probably the most significant factor affecting pollutant loadings in runoff from many land uses, including residential and commercial areas (NURP, EPA 1984). Increasing imperviousness increases runoff volumes, which, in turn, increase pollutant loads. Increased imperviousness can also increase stream temperatures, resulting in adverse effects on cold water habitats. Moreover, increased imperviousness can result in decreases in fish diversity (Schueler and Galli, 1992).[14]

[14] For more information on the relationship of watershed imperviousness and biological quality see Jones and Clark, 1987; Klein, 1979; Limburg and Schmidt, 1990; Pedersen and Perkins, 1986; and Booth and Jackson, 1994.

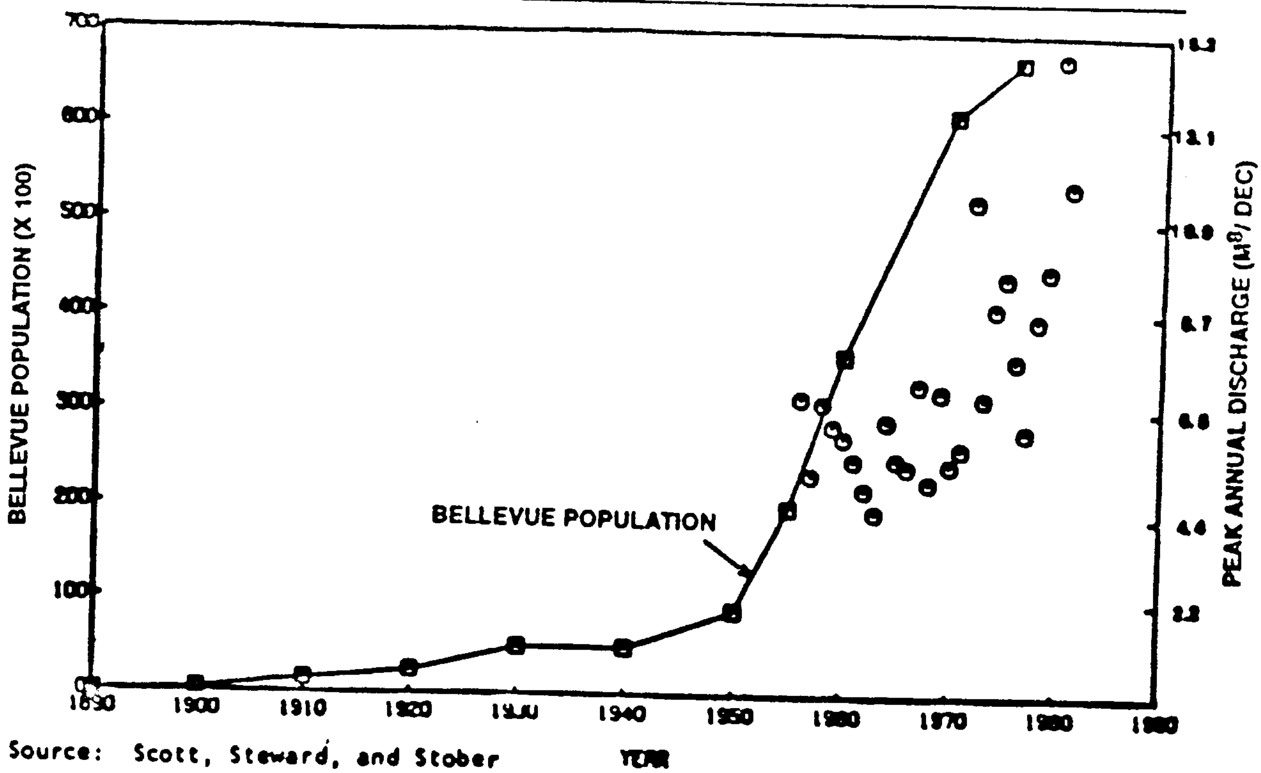

Figure 3-6. Population of Bellevue and Peak Annual Discharge in Kelsey Creek. Data From USGS and Bellevue Planning Dept., 1977

3.2.3 Modification of Natural Stream Channels and Riparian Vegetation

During the process of development, the natural drainage system (e.g., streams, wetlands, and other receiving waters) and surrounding vegetation is often modified. Streams can be diverted through underground culverts or channelized. Wetlands can be drained or filled, reducing the natural capacity of the drainage systems to dampen peak flows associated with storm events. After development has occurred, the natural drainage system is often unable to handle the higher volume of flows. The higher volume of flows can result in high stream bank and stream bed erosion rates or flooding. Drainage systems that have undergone these changes often need additional engineered modifications downstream, such as channelization or lining projects or direction of streams through underground culverts.

VOL 12

4162

Removal of riparian vegetation, coupled with increased watershed imperviousness, can result in significant increases in water temperatures. Such changes can reduce or eliminate sensitive stream insects and fish species. Modification of riparian vegetation can also have significant impacts on stream habitat value.[15]

3.2.4 Design Objectives of Drainage System

The manner in which a storm sewer system is installed, and its design objectives, affect the quality and quantity of the storm water discharge, as well as the potential presence of non-storm water discharges. The historical development of storm sewers can be characterized in terms of four overlapping time periods. A description of storm water management during these periods shows how some of the water quality problems associated with storm sewer discharges have come about.[16]

1800-1850	The first storm sewers were installed primarily to reduce flooding and ponding. Sanitary sewage connections resulted when adequate sanitary sewers were not provided.
1850-1950	In some municipalities, combined sewers designed to carry both storm water and sanitary sewage were installed.
1900-Present	In other municipalities, separate systems were installed for sanitary and storm sewers. Storm sewers were designed to provide for the rapid removal of storm water runoff from a site.
1970-Present	Some communities begin to address storm water as a resource to be used to recharge ground water and to supply fresh water to surface waters. In addition, properly managed storm water avoids problems with erosion, flooding and adversely impacting natural drainage features such as streams, wetlands and lakes. The multiple goals of water quality and water quantity are addressed when managing storm water.

[15] For a more detailed discussion of the relationship between streams and the hyporheic zone, the area that is biologically and hydrologically connected to the surface water of a system, see *Entering the Watershed, A New Approach to Save America's River Ecosystem*, Doppet, B. et al., 1993.

[16] NURP - Ann Arbor, MI Report, 1984, and *Water and the City: The Next Century*, Rosen and Keating, American Public Works Association, 1991.

VOL 12

4163

3.2.4.1 Early Sewers (1800-1850)

The oldest urban storm sewers in the United States date back to the early 1800s. Ponding of surface waters, coupled with poor sanitary conditions in urban areas, led to the installation of these early storm sewers to provide drainage. Little is known of the early storm sewers, as they were constructed by individuals or small districts at their own expense with little or no engineering or public supervision. Early storm sewers preceded the development of sanitary sewers. Once these early storm sewers were in place, they received wastes from other sources, some from direct connections of ditches and pipes to the storm sewers and others from materials dumped into the streets or storm sewers. Wastes which ended up in storm sewers included house wastes (most buildings lacked indoor plumbing), cesspool overflows, garbage, and excrement from horses and livestock. These practices created health and aesthetic problems, as storm sewers were often oversized on a flat grade, resulting in accumulation of sewage in storm sewers during dry weather. Wastes which accumulated during dry weather were then discharged into receiving streams during rain events. Many cities prohibited the discharge of domestic sewage to storm sewers but failed to provide public sanitary sewers, resulting in secret connections built without public supervision. Other illegal connections to the storm sewer were often overlooked by municipal officials because of the lack of proper sanitary sewers (NURP, 1984) (APWA, 1991).

3.2.4.2 Combined Sewers (1850-1950)

By the second half of the 19th century, combined sewer systems, designed to carry both sanitary sewage and storm runoff, were being installed to limit the costs associated with separate systems. At the time, these systems were chosen over separate systems because of their lower costs, even though it was known that separate systems were preferred on the basis of sanitary conditions. By 1875, although 67 cities in the United States with populations of greater than 100,000 had combined sewer systems, none treated waste before discharging it to the nearest receiving water body. In many cities, streams were covered to minimize the resulting nuisance. Pollution and health problems forced the expensive installation of interceptors to collect dry weather flows from hundreds of combined sewer outlets for conveyance or pumping to treatment plants prior to discharge.

As cities expanded, storm runoff and sewage flows increased. Combined interceptors which had been installed prior to expansion could not handle increases in flow to the point that even modest rain events could cause flooding of streets and basements. Combined sewer overflows (CSOs) that discharged storm water and sewage directly to surface waters were installed to minimize flooding problems, including sewage backing up into the basements of commercial and residential buildings. These systems bypassed treatment and the general sanitary quality of receiving waters again deteriorated (NURP, 1984) (APWA, 1991).

3.2.4.3 Separate Sewers for Water Removal (1900-Present)

The first large scale sewer system to provide separate collection of storm runoff and sanitary sewage was built in 1880 in Memphis, TN, although the construction of combined systems was continued and extended in most major cities. As early as 1900, many State regulatory agencies would not permit further construction of combined sewers. Where water quality impacts from CSOs were extreme, some cities implemented programs to separate portions of the older combined system.

Problems arose with separate storm water and sewage systems. As city populations increased, the demand for sewer service increased. However, sewer mains, interceptors, pumping stations and treatment plants were slow to grow. The post-World War II boom for sewer service into fast growing suburban areas was often associated with high infiltration rates and many illegal rain water connections which overloaded the system during rain events. To limit raw sewage backups in basements, hundreds of connections were made to bleed sewage from the sanitary sewers to the storm drains to limit flows in the sanitary sewers. Improper connections of grey waters such as automobile repair shop floor drains were either encouraged or implicitly allowed to discharge to storm drains.

Other problems arise with separate storm sewers, as storm water management often focuses on the rapid removal of storm water runoff from a site. The assumption is that problems will disappear after storm water leaves the site. Under this approach, which usually involves concrete channels and underground piping networks, storm drains are constructed without regard for the control and slow release of storm water or for possible downstream effects. This approach to storm water management has been characterized by simplistic goals, rigid design standards (such as requiring piping for drainage instead of relying on natural drainage features), low engineering review costs, and high construction and maintenance costs. In some cases, flood problems are only shifted to downstream sites (NURP, 1984) (APWA, 1991).

3.2.4.4 Storm Water Management for Water Quantity and Water Quality Purposes (1970-Present)

A few communities have developed programs where storm water is managed for multiple purposes including controlling water quantity (to avoid flooding and stream scour and to maintain stream flows during dry weather by recharging ground water during storms) and improving water quality. A range of alternative storm water control measures and facilities can be implemented to serve multiple purposes effectively. The natural cycles and processes which occur prior to the development of the land are used as a guide for managing storm water after development has occurred. Natural flow patterns and rates of discharge are retained through special storm water control facilities and measures. Natural processes are incorporated into the design of many "soft" engineered systems, including vegetated buffers, greenways, revegetation of storm water systems, wetland creation or retention for storm water management, and onsite retention, detention or infiltration systems. Policies emerging from these programs include:

- Reducing peak flows and improving storm water quality by onsite retention
- Reducing the volume of storm water leaving the site by natural infiltration

- Releasing storm water from onsite facilities at a rate similar to the pre-development runoff rate
- Managing for smaller storm events as well as those larger storm events that can cause major floods
- Protecting wetlands and floodplains as natural storm water storage areas
- Making storm water facilities amenities of the development (such as retaining natural drainage channels or providing attractive landscaping for storm water management ponds) and encouraging open space and recreational uses
- Developing programs that relate erosion and sediment controls during construction with storm water management after construction is completed.

The implementation of this approach typically involves somewhat higher costs for development plan review by local governments, but lower costs for storm water facility construction, and results in reduced social costs (NURP, 1984) (APWA, 1991).

3.3 THE EXTENT OF DISCHARGES FROM MUNICIPAL SYSTEMS

3.3.1 Pollutant Concentrations of Runoff From Residential and Commercial Areas

Many studies have examined the nature of pollutants in municipal storm water discharges on a local level, but few have attempted to do so on a national level. The two most extensive assessments of pollutants in urban runoff are the Nationwide Urban Runoff Program (NURP) and information compiled in the USGS data base. These two data bases primarily reflect pollutant concentrations associated with runoff from residential and commercial areas.

From 1978 to 1983, EPA provided funding and guidance to NURP to provide a better understanding of the nature of urban runoff from residential and commercial areas. NURP included 28 projects that were conducted separately at the local level but were centrally reviewed, coordinated, and guided by EPA. Project locations across the country were selected by EPA to provide a range of types of receiving waters and beneficial uses, hydrologic characteristics, and urban characteristics.

The major focus of NURP was to characterize the water quality of runoff from residential, commercial, and industrial park sites. The NURP program evaluated data from 81 sites in 22 cities covering more than 2,300 separate storm events. Of the 81 sites selected, 39 were completely or primarily residential, 10 were commercial, 20 were mixed commercial and residential, 4 were industrial parks, and 8 were open spaces in urban areas. Because the industrial park category did not represent heavy industrial activity, the data from industrial parks were merged with commercial land use data. Each project was separate and distinct but shared common field monitoring protocols.

The NURP study provides insight on what can be considered background levels of pollutants for runoff from residential and commercial land uses. Sites evaluated in NURP were carefully selected so that they were not influenced by pollutant contributions from construction sites, industrial activities, or illicit connections. Several sites were eliminated from the study because of elevated pollutant loads associated with these or other sources.

NURP showed that the concentrations of pollutants in runoff from residential and commercial areas vary considerably from site to site. NURP postulated that the best general characterization of runoff from commercial and residential areas for planning purposes, where local information is lacking, can be obtained by pooling data from many sites.

The majority of samples collected under NURP were analyzed for seven conventional pollutants (biochemical oxygen demand, chemical oxygen demand, total suspended solids, total Kjeldahl nitrogen, nitrate plus nitrite, total phosphorus, and soluble phosphorus) and three metals (total lead, total copper, total zinc). Table 3-16 presents average discharge concentrations for these pollutants in runoff from the residential and commercial sites studied in NURP.[17]

[17] Recently, concerns have been raised regarding the validity and use of historical data for metals. As discussed in Chapter 2, EPA believes that historical data on storm water runoff from NURP and USGS are suitable for the purposes of this report.

Table 3-16. Summary of Event Mean Concentrations From NURP for Selected Pollutants

Constituent	Mean	Median Site	90th Percentile Site	Coefficient of Variability for Events
TSS (mg/l)	239	100	300	1-2
BOD (mg/l)	12	9	15	0.5-1
COD (mg/l)	94	65	140	0.5-1
Total P (mg/l)	0.50	0.33	0.70	0.5-1
soluble P (mg/l)	0.15	0.12	0.21	0.5-1
TKN (mg/l)	2.3	1.5	3.3	0.5-1
Nitrate plus nitrite (mg/l)	0.86	0.68	1.75	0.5-1
Total Cu (mg/l)	0.05	0.03	0.09	0.5-1
Total Pb (mg/l)	0.24	0.14	0.04	0.5-1
Total Zinc (mg/l)	0.35	0.16	0.50	0.5-1

In addition, the Section 307(a) priority pollutants were measured at 20 of the sites. Of the 119 pollutants analyzed, 77 were detected. All 13 metals on the priority pollutant list were detected, and all but 3 of the metals were detected at frequencies greater than 10 percent of the samples. Copper, lead, and zinc, found in at least 91 percent of the samples, were the most frequently detected metals. Of the 106 organic pollutants measured, 63 were detected. A plasticizer (bis (2-ethylhexyl) phthalate) and a pesticide (alpha-hexachlorocyclohexane (alpha-BHC)) were found in at least 20 percent of the samples analyzed. An additional 11 organic pollutants were reported at frequencies between 10 and 20 percent, including 4 pesticides, 3 phenols, 4 polycyclic aromatics, and a single halogenated aliphatic compound. NURP data also showed that during warm weather conditions, fecal coliform counts in urban runoff are typically in the tens to hundreds of thousands per 100 milliliters of runoff. Table 3-17 lists pollutants that were detected in 10 percent or more of the NURP samples.

VOL 12

Fluoranthene	16
Phenanthrene	12
Pyrene	15

Source: EPA, 1983

The USGS has also collected urban rainfall, runoff, and water quality data nationally for several decades. In the mid-1980s, a data base containing information on 717 storms at 99 stations in 22 metropolitan areas throughout the United States (Driver et al., 1985) was compiled. The USGS examined a set of constituents similar to those compiled for NURP; the USGS also reported its data in terms of flow-weighted samples so that concentrations and loading values could be compared directly to NURP results. As described in Section 2.1.2.1 of this report, EPA compared information from the USGS data base to the findings from NURP.

In general, the findings between the two studies were very similar. Both data bases identified sediments and metals as the most significant pollutants measured. This determination is consistent with the findings of Driver and Lystrom (1986), who also compared the two data sets.

Two major trends related to automobiles that have occurred since the bulk of NURP data were collected are expected to affect urban runoff quality. The first trend involves the dramatic reductions in the levels of lead in gasoline. NURP data were generally collected during the time period when leaded gasoline was being phased out, and current concentrations of lead in runoff are expected to be generally lower than indicated by the NURP data.[18] Storm water monitoring data collected since that time tend to show a significant decrease in lead, but much less of a reduction then the percentage reductions of

[18] Tetraethyl lead has been extensively used as an inexpensive anti-knock, octane boosting gasoline additive since 1923. Aside from the Surgeon General temporarily suspending the production and sale of lead in gasoline in 1925, the use of lead in gasoline was largely unregulated until 1978. Decreases since that time are the result of two regulatory programs under the Clean Air Act (CAA): regulation of the amount of lead in leaded gasoline; and automobile emission standards resulting in new technology, catalytic converters, requiring the use of unleaded gasoline. Beginning in 1975, many automobile manufacturers began installing catalytic converters, which were poisoned by lead in gasoline, to meet emission standards. In 1978, EPA began to lower the level of lead in leaded gasoline under sections 211(c)(1) and (2) of the CAA to protect the public health and welfare and to safeguard the performance of emission control devices in general use. Most recently, EPA lowered the low-lead standard to 0.10 gplg, effective January 1, 1986, (March 7, 1985 (50 *FR* 9386)).

VOL 12

4171

lead in gasoline. Other remaining sources of lead include industrial sources, paint, background levels in soil, and soil contaminated after 65 years of using lead in gasoline.[19]

The second trend pertains to the prohibition of the use of asbestos in brake pads and clutch linings. This is expected to result in a decrease in asbestos in runoff, which was not monitored in NURP, and an increase in copper and zinc, which are a substitute for asbestos in some brake pads.

3.3.1.1 Comparison of Pollutant Concentrations in Runoff from Residential/Commercial Areas to Discharges From Publicly Owned Treatment Works

The concentration of pollutants in runoff from residential and commercial areas (based on NURP and USGS data bases) can be compared to the typical concentration of pollutants found in the discharges from publicly owned treatment works (POTWs) that provide secondary treatment[20] (see Table 3-18). The concentration of total suspended solids (TSS) in runoff from residential and commercial areas is about an order of magnitude greater than the concentrations from POTWs receiving secondary treatment. The concentrations of COD, total lead, and total copper were somewhat higher in runoff from residential and commercial areas. The concentration of phosphorus and nitrogen were about an order of magnitude greater in discharges from POTWs.

---

[19] This is consistent with the finding of *Deposition of Air Pollutants to the Great Waters, 1994 Report to Congress*, EPA, 1994, which indicates that the environment may act as an important reservoir or source of persistent contaminants that have been released previously.

[20] EPA estimates that 76 million people, or 42 percent of the population served by sanitary sewage treatment works, are served by systems that either provide greater than secondary treatment or have no discharge. *1992 Needs Survey Report to Congress*, EPA, 1993.

Table 3-18. Comparison of Mean Pollutant Concentrations in Runoff From Residential and Commercial Areas to Sewage Treatment Plant Receiving Secondary Treatment

Constituent	Runoff from Residential and Commercial Sites (NURP)	Sewage Plant With Secondary Treatment
TSS (mg/l)	239	20
BOD (mg/l)	12	20
COD (mg/l)	94	33
Total P (mg/l)	0.5	6
Soluble P (mg/l)	0.15	5
TKN (mg/l)	2.3	20
Nitrate plus nitrite (mg/l)	0.86	NA
Total Cu (mg/l)	0.05	0.05
Total Pb (mg/l)	0.24	0.03
Total Zn (mg/l)	0.35	0.14

Source: POTW discharge concentrations for lead, zinc, copper, BOD, COD, TSS, and oil and grease were based on data reported in *Fate of Priority Pollutants in Publicly Owned Treatment Works* (EPA, 1981). This report summarizes monitoring data from POTWs receiving secondary treatment in 50 cities. Pollutant concentrations for total phosphorus, soluble phosphorus, and total Kjeldahl nitrogen were based on personal communication with Dolloff Bishop or the EPA Wastewater Engineering Laboratory in Cincinnati, Ohio. Recently, concerns have been raised regarding the validity and use of historical data for metals. As discussed in Chapter 2, EPA believes that historical data on storm water runoff from NURP and USGS are suitable for the purposes of this report.

3.3.1.2 Comparison of Pollutant Concentrations in Runoff from Residential/Commercial Areas to Water Quality Criteria

NURP determined that toxic metals were the most prevalent priority pollutants in runoff from commercial and residential areas. All 14 inorganic priority pollutants (13 metals, plus cyanides, excluding asbestos) were detected in urban storm water. As shown in Table 3-19, a number of these constituents were detected at levels exceeding EPA water quality criteria. The table also identifies organic pollutants found that exceeded certain EPA water quality criteria. These exceedances were observed less frequently than exceedances for the inorganic constituents. Levels of coliform bacteria were also found to exceed EPA water quality criteria during and immediately after storm events in many surface waters (EPA, 1983).

VOL 12

4174

Table 3-19. Summary of Water Quality Criteria Exceedances for Pollutants Detected in at Least 10 Percent of NURP Samples—Percentage of Samples in Which Pollutant Concentrations Exceed Criteria[1]

Pollutant	Frequency of Detection(%)	Detection Samples[2]	Criteria Exceedances: None	FA	FC	OL	HH	HC[4]	DW

Pyrene	15	16/110						15,15,15	

*Indicates FTA or FTC value substituted where FA or FC criterion not available (see below).

[1] Based on 121 sample results received as of September 30, 1983, adjusted for quality control review. Where a value is reported for criteria exceedances, this value is a percentage of the number of samples where the pollutant was detected and blanks indicate no exceedances by any of the samples for which the pollutant was detected.

[2] Number of times detected/number of acceptable samples.

[3] FA = Freshwater ambient 24-hour instantaneous maximum criterion ("acute" criterion).
FC = Freshwater ambient 24-hour average criterion ("chronic" criterion).
FTA = Lowest reported freshwater acute toxic concentration. (Used only when FA is not available.)
FTC = Lowest reported freshwater chronic toxic concentration. (Used only when FC is not available.)
OL = Taste and odor (organoleptic) criterion.
HH = Non-carcinogenic human health criterion for ingestion of contaminated water and organisms.
HC = Protection of human health from carcinogenic effects for ingestion of contaminated water and organisms.
DW = Primary drinking water criterion.

[4] Entries in this column indicate exceedances of the human carcinogen value at the 10^{-5}, 10^{-6}, and 10^{-7} risk level, respectively. The numbers are cumulative (i.e., all 10^{-5} exceedances are included in 10^{-6} exceedances, and all 10^{-6} exceedances are included in 10^{-7} exceedances).

[5] Concerns have been raised regarding the validity and use of historical data for metals. As discussed in Chapter 2, EPA believes that historical data on storm water runoff from NURP and USGS are suitable for the purposes of this report.

[6] Where hardness dependent, hardness of 100 mg/l $CaCO_3$ equivalent assumed.

[7] Different criteria are written for the trivalent and hexavalent forms of chromium. For purposes of this analysis, all chromium is assumed to be in the less toxic trivalent form.

3.3.2 Pollutant Concentrations from Other Urban Land Uses

The NURP data base is limited to runoff from residential, commercial and industrial park land uses. These land uses typically comprise between 55 to 85 percent of the area of urban areas (EPA, 1990). Other major urban land uses which have the potential to contribute runoff with higher levels of pollutants include central business districts, industrial areas (typically 10 to 20 percent of the area of urban areas), and construction activities.

3.3.2.1 Central Business Districts

NURP noted that data describing runoff from central business districts are limited. However, NURP suggested that some central business districts may produce pollutant concentrations in runoff that are significantly higher than those from other sites in a given urban area. Pollutant loads from central business districts are thought to be significant because of the high pollutant concentrations coupled with the high degrees of imperviousness.

3.3.2.2 Industrial Land Uses

No truly industrial sites were included in any of the NURP projects. However, NURP suggested that runoff from industrial sites may have significantly higher contaminant levels than runoff from other urban land use sites. Several studies tend to support this suggestions, such as the Fresno, CA, NURP project which showed that industrial areas had the poorest storm water runoff quality of the four land-uses evaluated. Of the 62 non-pesticide constituents monitored, 52 were statistically highest in industrial site runoff. A study conducted in Spokane, WA, showed that industrial and commercial sites clearly contributed greater quantities of total dissolved solids, COD, total Kjeldahl nitrogen, lead and zinc (Oregon, 1986—Spokane Water Quality Management Program).

Given the range of different industrial activities in different urban areas, it would be difficult to characterize industrial runoff on a national basis. However, recent data collection efforts describing runoff from different types of industrial activities can be used to evaluate

VOL 12

4175

the potential for pollutants in runoff from specific industrial areas. Chapter 4 summarizes some of these efforts.

3.3.2.3 Construction Activities

The amount of sediment in storm water discharges from construction sites can vary considerably, depending on whether effective management practices are implemented at the construction site. Uncontrolled or inadequately controlled construction site sediment loads have been reported to be on the order of 35 to 45 tons/acre/year (Novotny and Chesters, 1981). Sediment runoff rates from construction sites are typically 10 to 20 times that of agricultural lands, with runoff rates as high as 100 times that of agricultural lands; the rates are typically 1,000 to 2,000 times those of forest lands. Over a short period of time, construction sites can contribute more sediment to streams than was previously deposited over several decades.[21]

3.3.3 Pollutant Loading Estimates

EPA has developed loading estimates for selected pollutants in discharges from municipal separate storm sewer systems associated with urbanized areas.[22] Chapter 2 describes the methods used for estimating pollutant loads.

Table 3-20 summarizes pollutant load estimates for different classes of municipalities currently addressed by Phase I of the NPDES storm water program and potentially addressed under Phase II. EPA estimates that in 1990, about 40 percent of the pollutant loads associated with runoff from urbanized areas came from Phase I municipalities. About one-quarter of the pollutant loads in runoff from urbanized areas came from potential Phase II

[21] Under current regulations, construction activities resulting in the disturbance of 5 or more acres are covered by the NPDES storm water program.

[22] The model used to estimate pollutant loads assumed constant concentrations for each of the seven pollutants. This assumption results in the ratio of loadings of different pollutants remaining constant for different classes of municipalities. Thus, where the percentage of pollutant loadings is presented, the percentage is the same for all seven pollutants.

VOL 12 4176

Table 3-20. Estimated Pollutant Loadings in Runoff From Urbanized Areas

Classification	Population Category	Number of Urbanized Areas*	Population* (millions)	Total Area** (sq. mi.)	Number of Incorporated Places*	Number of Minor Civil Divisions*	Number of Counties*	Percentage of Urbanized Area Loading

PHASE I MS4s OUTSIDE URBANIZED AREAS		NA	4.3	86,097	57	0	5	NA

* Totals are based upon 1990 Census, and include Puerto Rico, Guam, Virgin Islands, American Samoa, and the Commonwealth of the Northern Mariana Islands.
** Some municipalities identified in the November 1990 application regulations (55 *FR* 47990) as Phase I based on 1980 census data received combined sewer exclusions from Phase I where the total population served by separate storm sewers was less than 100,000 after subtracting the population served by combined sewers. (The 21 urbanized areas [with a population of 17.5 million] containing these municipalities are also contained in the above totals and are not in addition to those totals.)

portions of urbanized areas with a Phase I municipality. An additional one-third of the pollutant loadings associated with urbanized areas came from urbanized areas that do not have a Phase I municipality.

Table 3-21 compares annual pollutant loadings for three metals, zinc, lead, and copper, from urban runoff from the Metropolitan Washington urbanized area, with a sewage treatment plant that provides advanced treatment and that serves about 2 million people (the Blue Plains sewage treatment plant), and major industrial process wastewater discharges located in Maryland and Virginia. In general, the data in Table 3-21 indicates that the annual loadings of metals, nutrients, and oxygen demanding pollutants in urban runoff from the Washington, DC, area are higher than the loadings from the predominant sewage treatment plant for the area (the Blue Plains Sewage Treatment Plant provides advanced treatment and serves approximately two million people). The data also indicate that the annual loadings of zinc and lead in urban runoff from the Washington, DC, area are higher than the loadings from all industrial point source discharges from facilities in Maryland and Virginia that reported pollutant release information in 1987 to the Toxic Release Inventory established under the Emergency Planning and Community Right-to-Know Act.

Table 3-21. Annual Pollutant Loadings in Pounds for Selected Pollutant Sources

Pollutant	Urban Storm Water from Metropolitan Washington	Blue Plains Sewage Treatment Plant[1]	All MD and VA Direct Industrial Discharges in 1987 Toxic Release Inventory
Zinc	480,000	137,000	132,000
Lead	132,600	5,500	31,300
Copper	113,000	21,000	127,000
Nitrogen	30,000,000	12,000,000	not available
Phosphorus	1,200,000	113,000	not available
BOD5	9,500,000	1,400,000	not available

[1] Portions of collection system for Blue Plains are combined sewers carrying both runoff and sewage. The POTW loadings do not account for discharges from combined sewer overflows. The loadings estimate does account for urban storm water that is conveyed to Blue Plains, treated, and discharged. Recently, concerns have been raised regarding the validity and use of historical data for metals. As discussed in Chapter 2, EPA believes that historical data on storm water runoff are suitable for the purposes of this report.

A number of factors are expected to result in future changes to total loadings and the distribution of loadings between Phase I and Phase II municipalities. Factors that would generally increase loadings include increases in population and the area of urbanized areas. If recent development trends continue, most increases in loadings are expected to occur in urbanized areas with a Phase I municipality. The majority of the increase in loadings in these areas is expected to occur in suburban areas surrounding core cities.

The increased implementation of storm water management measures is expected to generally decrease pollutant loadings. Given the existing Federal mandate for storm water controls, such decreases are expected to occur in Phase I municipalities sooner than in potential Phase II municipalities.

Widespread product substitutions associated with activities that generate pollutants ultimately discharged in storm water may either increase or decrease pollutant loads, depending on the nature of such substitutions.

When analyzing annual loadings associated with urban runoff, it is important to recognize that discharges of urban runoff are highly intermittent and that the short-term loadings associated with individual events will be high and may have shockloading effects on receiving water.

3.3.4 Floatables/Litter/Plastics

Litter is common in urbanized areas. During storm events, litter can be washed into separate storm sewers or carried through other storm water conveyances to receiving waters. Litter is also commonly disposed of directly to storm sewer catchbasins. Discharges from separate storm sewers were identified as major sources of plastics to the surface waters in *Methods to Manage and Control Plastics Wastes—Report to Congress*, (EPA, 1989). Another study concluded that the majority of floating litter that washes up on New Jersey's beaches originates from discharges from separate storm sewers (New Jersey DEP, 1988).

Litter can cause significant aesthetics problems and impact the operating effectiveness of drainage systems and related management practices such as detention ponds.

3.3.5 Population Densities and Imperviousness

As discussed previously, the amount of imperviousness in urban watersheds can be linked to impacts to streams and other surface water resources. The population density of a municipality can be used as an indicator of the level of imperviousness. Figure 3-7 summarizes several studies that attempted to link population densities to percent imperviousness (Kobriger, 1984). However, using population density as an indicator of imperviousness does not account for high levels of day-time use associated with many commercial or industrial areas with high levels of imperviousness.

Population density is related to the total urban population in an area. Table 3-1, presented previously, indicates that as the total population of an urbanized area increases, so does the average population density. The average population density of urbanized areas with a total population of 1,000,000 or more (3,413 persons per square mile) is more than double the average population density of urbanized areas with a population of 50,000 to 100,000 (about 1,600 persons per square mile).

The population density varies within urbanized areas. Core cities generally have a higher population density than outlying suburban areas. However, other smaller cities that are part of larger urbanized areas can have high population densities. In 1990, the Bureau of the Census reported more than 600 incorporated places with populations under 100,000 but with a population density of at least 5,000 persons per square mile. Approximately 550 of the more than 600 incorporated places meeting this criterion were in an urbanized area. Approximately 415 of these incorporated places are in an urbanized area where at least one Phase I municipality is located.

3.4 SUMMARY

Bureau of the Census estimates that the population of the United States and associated territories was more than 252.2 million in 1990[23] and that there are 19,289 incorporated places and 17,796 minor civil divisions in the continental United States, Alaska and Hawaii. These incorporated places and minor civil divisions are located in 3,141 counties or county equivalents.

The concept of Bureau of the Census-designated urbanized areas served as an important tool for analyzing potential approaches to a Phase II program that addresses municipal separate storm sewer systems. More than 160 million people (63 percent of the total United States population) reside in the 405 urbanized areas with a population of 50,000 or more that have been designated by the Bureau of the Census. These areas occupy less than 2 percent of the Nation's total land area. These areas represent the largest, most widespread areas of dense urban development in the country.

The majority of new urban development also occurs in Census-designated urbanized areas. Construction activity related to new development is recognized as a significant source of pollution and impairment of waterbodies, providing some of the best opportunities for implementing storm water management controls in a highly cost-effective fashion. Between 1980 and 1990, the population of Census-designated urbanized areas increased by 21.2 million.[24] During the same time period, the rural population of the United States increased by 2.2 million, and the urban population that lived outside of urbanized areas increased by 0.9 million. Between 1980 and 1990, the population of urbanized areas with one or more municipal systems addressed by Phase I of the NPDES storm water program increased by 16.4 million (or 75 percent of the total National growth). This represents a 25 percent

[23] Population estimates based on the 50 States, the District of Columbia, Guam, the Commonwealth of Puerto Rico, the Virgin Islands, American Samoa, and the Commonwealth of the Northern Mariana Islands.

[24] About 7 percent of this increase, (1.5 million people) are associated with the net addition of 30 new urbanized areas between 1980 and 1990. Another part of this increase which has not been estimated here is associated with the increase in land area of pre-existing urbanized areas.

increase in the population of these areas. The population of urbanized areas without a Phase I municipal system increased by 2.6 million. This represents 12 percent of the total national growth and a 7 percent increase in the population of these areas.

The population and number of municipalities in urbanized areas, and estimated percentage of pollutant loads in runoff from urbanized areas are summarized in Table 3-20 and discussed below.

Phase I of the NPDES program for storm water discharges addresses 621 incorporated places (cities) and portions of 77 counties.[25] These municipalities had a combined population of 86 million people in 1990. Cities with a population of 100,000 or more whose municipal systems are already addressed by Phase I of the NPDES storm water program increased in population by about 4.9 million between 1980 and 1990.[26] The majority of the population of Phase I municipalities, 81.7 million people live in 136 of the 405 Census-designated urbanized ares. EPA estimates that about 40 percent of the pollutant loads in storm water discharged from urbanized areas come from Phase I municipalities.

The Phase II portions of the 136 urbanized areas with one or more Phase I municipal separate storm sewer system had a combined population of 35.8 million people. The population of those portions of these urbanized areas increased by 2.6 million between 1980 and 1990. EPA estimates that 1,587 incorporated places, 634 minor civil divisions, and parts of 305 counties are located in the Phase II portions of these urbanized areas. EPA estimates that 28 percent of the pollutant loads in storm water discharged from urbanized areas come from Phase II portions of the 136 urbanized areas with a Phase I municipality.

[25] Of these municipalities, 140 cities and 45 counties are specifically identified in the NPDES regulations that were published in November of 1990. EPA and authorized NPDES States have designated an additional 481 cities and 32 counties as Phase I municipalities. In addition, approximately 30 municipalities (located in 21 urbanized areas) have received combined sewer exclusions where the total population served by separate storm sewers is less than 100,000 after subtracting the population served by combined sewers. The methodology used to classify municipalities as Phase I vs. Phase II for the purposes of this report is explained in Chapter 2.

[26] The 4.9 million increase does not include increases associated with unincorporated, urbanized portions of Phase I counties and designated municipalities.

A total of 269 of the Census-designated urbanized areas do not have a municipality with separate storm sewers subject to Phase I of the storm water program. The 269 urbanized areas without a Phase I municipal separate storm system have a combined population of 42.9 million people. EPA estimates that 1,470 incorporated places, 966 minor civil divisions, and parts of 380 counties are located in these urbanized areas. EPA estimates that about one-third of the pollutant loads in storm water discharged from urbanized areas come from the 269 urbanized areas without a Phase I municipality. Of the 269 urbanized areas without a Phase I municipal system, 101, or over a third, have a population of more than 100,000, and 23 have a population of more than 250,000.

In addition to populations within urbanized areas discussed above, the Bureau of the Census has identified an additional urban population of 29 million people that live outside of urbanized areas, as well as 62.8 million people classified as rural. Of this total, 25.1 million people live in 3,689 incorporated places. The remaining 4 million people live in either minor civil divisions or unincorporated portion of counties. Although discharges from municipal separate storm sewer systems serving these populations are potential Phase II sources, they are not addressed in this report.

VOL 12

CHAPTER 4. INDIVIDUAL PHASE II DISCHARGES

This chapter identifies the discharges of storm water other than those from municipal separate storm sewer systems for which permits are not currently required and assesses, to the extent practicable, the nature and extent of pollutants in those discharges. To provide a context for this analysis, this chapter begins with an overview of the industrial categories that are addressed under Phase I of the storm water regulatory program. Using an approach described in Chapter 2 of this report, other categories of industrial, commercial, and retail facilities that may be sources of polluted storm water discharges are identified. For these potential Phase II sources, the type of their discharges and statistics on their geographic distribution are described. The nature of industrial storm water discharges is characterized using a summary of the sampling data reported by Phase I group permit applicants and comparing groups of Phase II sources to these Phase I industries. In an analysis patterned after that in Chapter 3, this chapter also explores the relationship between individual Phase II industrial, commercial, and retail facilities and urbanized areas of different configurations. The final section of this chapter summarizes the results of the analyses and offers some perspectives on individual Phase II storm water discharges. The results of these analyses are meant to be guideposts and are not intended to be an identification of specific industrial categories that must be regulated under Phase II.

4.1 OVERVIEW OF INDIVIDUAL PHASE II SOURCES

There are more than 7.7 million industrial, commercial, retail, and government facilities in the United States.[1] The Office of Management and Budget classifies businesses into categories based on similarity of economic activity. Some aspects of this discussion are

[1] This estimate is based on data from the FACTS data base, which is leased by EPA from Dun & Bradstreet Information Services, which created, maintains, and annually updates information based on a variety of sources. This estimate does not include inactive and abandoned mines which may constitute hundreds of thousands of additional sources.

based on this Standard Industrial Classification (SIC) code system.[2] Table 4-1 presents a breakdown of the major categories of industry and commerce. The current storm water regulatory program potentially applies to some types of individual facilities within the mining, construction, manufacturing, and transportation divisions. There are more than 850,000 enterprises in these divisions; however, only a portion of these are within the 11 categories of activities "associated with industrial activity" as defined by the November 1990 storm water permit application regulations.[3] As a result, from these 850,000 enterprises, EPA has estimated that approximately 150,000 facilities are currently subject to Phase I requirements.

Table 4-1. Summary of Major SIC Divisions of U.S. Commerce

Description	Total Facilities	SIC Codes Covered
Agriculture, Forestry, and Fishing	310,086	01 - 09
Mining	39,936	10 - 14
Construction	805,100	15 - 17
Manufacturing	511,831	20 - 39
Transportation and Public Utilities	306,894	40 - 49
Wholesale Trade	582,681	50 - 51
Retail Trade	1,850,121	52 - 59
Finance, Insurance, and Real Estate	672,693	60 - 67
Services	2,585,750	70 - 89
Public Administration	71,379	90 - 97
Total	7,736,471	

The remaining universe of facilities fall into two main groups, those that have a statutory or regulatory exemption, including agricultural and most silvicultural activities, and those that are considered to be potential Phase II activities. Many of these potential Phase II

[2] The Standard Industrial Classification (SIC) code system organizes industries into categories and subcategories. Major groups are designated by a two-digit code number between 01 and 99. Within major groups, facilities are further categorized at the industry group (3-digit) level and industry (4-digit) level.

[3] This figure excludes about 800,000 building, construction, and specialty contractors, which are regulated to the extent that they engage in construction activities disturbing 5 acres or more.

sources, however, are not expected to become subject to Phase II regulation. Sources that are not in Phase I and are not expected to become subject to NPDES storm water regulation in Phase II consist of sources that lack the potential to contribute significant levels of pollutants to storm water, including financial institutions, some governmental activities and many types of service organizations.

The remaining categories of light industrial, commercial, retail, governmental establishments, and residential activities represent the universe of facilities under consideration for potential inclusion in Phase II. These facilities fall into several general categories with respect to Phase II:

- Facilities with activities essentially identical or closely related to those "associated with industrial activity," that are not covered for a variety of statutory and regulatory reasons.
- Facilities with activities similar to those "associated with industrial activity," such as transportation activities, energy producers and distributors, and utilities.
- Commercial activities with industrial components, such as assembly and repair operations.
- Agriculture-related operations that include currently unregulated feedlots.[4]
- Non-agricultural operations with potential for use of pesticides and fertilizers.
- Facilities and households with failing septic systems.
- Other facilities with potential to use or produce toxic substances, including laboratories and some governmental facilities.

In general, the geographic distribution of industrial, commercial, and retail activity—in short, economic activity—tends to be closely associated with population and population

[4] To be subject to the NPDES program, sources must have point source discharges of pollutants to waters of the United States. EPA has defined concentrated animal feeding operations (CAFOs) as point sources currently subject to permitting under NPDES. This study looks at feedlots which do not meet the regulatory definition of CAFO to study their impacts on water quality and to identify them as potential sources to be covered under Phase II.

density. Through this relationship between population and economic activity, this industrial analysis can be compared with the municipal analysis undertaken in the previous chapter. The Phase I municipal approach is taken as the starting point for a locational analysis of industrial Phase I and potential Phase II sources in this chapter. The municipal component of Phase I of the storm water regulatory program focuses on the largest cities and counties, which contain about one-third of all the facilities in both regulated and nonregulated categories. There are a few notable exceptions to this relationship between economic activity and population, including agricultural and mining activity. These are discussed in more detail later in this chapter.

4.1.1 The Phase I Permitting Framework for Industrial Discharges

Section 402(p) of the CWA provides that EPA or NPDES-approved States cannot require a permit for storm water discharges from individual sources before October 1, 1994, except for discharges "associated with industrial activity" or those that had a permit prior to February 4, 1987, unless they are significant contributors of pollutants to waters of the United States or contribute to the violation of a water quality standard. The Act also clarifies that permits for discharges associated with industrial activity must meet all of the applicable provisions of CWA Sections 402 and 301, including both applicable technology-based requirements and water quality-based standards. All other storm water discharges that are potential candidates for coverage fall under Phase II of the program. The basic permitting framework for Phase I of the NPDES storm water program is established in 40 *CFR* 122, primarily Section 122.26.

The November 16, 1990, storm water regulations described 11 categories of industrial facilities that defined the term "discharges associated with industrial activity." The categories were derived from a combination of narrative descriptions and specific SIC code designations to define and identify Phase I sources (40 *CFR* 122.26(b)(14)). The types of industrial facilities covered by the definition are illustrated in Table 4-2.

VOL 12

4189

Table 4-2. Industrial Facilities That Must Submit Applications for Storm Water Permits (Phase I)

40 *CFR* 122.26(b)(14) Subpart	Description
(i)	Facilities subject to storm water effluent limitations guidelines, new source performance standards, or toxic pollutants effluent standards under 40 *CFR*, Subchapter N [except facilities which are exempt under category (xii)]
(ii)	Facilities classified as: SIC 24 (except 2434) ...... Lumber and Wood Products SIC 26 (except 265 and 267) . Paper and Allied Products SIC 28 (except 283 and 285) . Chemicals and Allied Products SIC 29 .... Petroleum and Coal Products SIC 311 .... Leather Tanning and Finishing SIC 32 (except 323) ...... Stone, Clay and Glass Products SIC 33 .... Primary Metal Industries SIC 3441 .... Fabricated Structural Metal SIC 373 .... Ship and Boat Building and Repairing
(iii)	Facilities classified as SIC 10 through 14, including active or inactive mining operations and oil and gas exploration, production, processing, or treatment operations, or transmission facilities that discharge storm water contaminated by contact with, or that has come into contact with, any overburden, raw material, intermediate products, finished products, byproducts, or waste products located on the site of such operations. SIC 10 .... Metal Mining SIC 11 .... Anthracite Mining SIC 12 .... Coal Mining SIC 13 .... Oil and Gas Extraction SIC 14 .... Nonmetallic Minerals, except Fuels
(iv)	Hazardous waste treatment, storage, or disposal facilities, including those that are operating under interim status or a permit under Subtitle C of the Resource Conservation and Recovery Act (RCRA).
(v)	Landfills, land application sites, and open dumps that receive or have received any industrial wastes including those that are subject to regulation under subtitle D or RCRA.
(vi)	Facilities involved in the recycling of material, including metal scrapyards, battery reclaimers, salvage yards, and automobile junkyards, including but not limited to those classified as: SIC 5015 .... Motor Vehicle Parts, Used SIC 5093 .... Scrap and Waste Materials
(vii)	Steam electric power generating facilities, including coal handling sites.
(viii)	Transportation facilities which have vehicle maintenance shops, equipment cleaning operations, or airport de-icing operations. Only those portions of the facility that are either involved in vehicle maintenance (including vehicle rehabilitation, mechanical repairs, painting, fueling, and lubrication), equipment cleaning operations, or airport de-icing operations, or which are otherwise listed in another category, are included. SIC 40 .... Railroad Transportation SIC 41 .... Local and Suburban Transit SIC 42 (except 4221-25) .... Motor Freight and Warehousing SIC 43 .... U.S. Postal Service SIC 44 .... Water Transportation SIC 45 .... Transportation by Air SIC 5171 .... Petroleum Bulk Stations and Terminals

Table 4-2. Industrial Facilities That Must Submit Applications for Storm Water Permits (Phase I) (continued)

40 *CFR* 122.26(b)(14) Subpart	Description
(ix)	Treatment works treating domestic sewage or any other sewage sludge or wastewater treatment device or system, used in the storage, treatment, recycling, and reclamation of municipal or domestic sewage, including lands dedicated to the disposal of the sewage sludge that are located within the confines of the facility, with a design flow of 1.0 million gallons per day or more, or required to have an approved pretreatment program under 40 *CFR* Part 403. Not included are farm lands, domestic gardens, or lands used for sludge management where sludge is beneficially reused and which are not physically located in the confines of the facility, or areas that are in compliance with Section 405 of the CWA.
(x)	Construction activity including clearing, grading, and excavation activities except operations that result in the disturbance of less than 5 acres of total land area and those that are not part of a larger common plan of development or sale.
(xi)	Facilities under the following SICs [which are not otherwise included in categories (ii)-(x)], including only storm water discharges where material handling equipment or activities, raw materials, intermediate products, final products, waste materials, byproducts, or industrial machinery are exposed to storm water. SIC 20 .... Food and Kindred Products SIC 21 .... Tobacco Products SIC 22 .... Textile Mill Products SIC 23 .... Apparel and Other Textile Products SIC 2434 .... Wood Kitchen Cabinets SIC 25 .... Furniture and Fixtures SIC 265 .... Paperboard Containers and Boxes SIC 267 .... Converted Paper and Paper Board Products (except containers and boxes) SIC 27 .... Printing and Publishing SIC 283 .... Drugs SIC 285 .... Paints, Varnishes, Lacquer, Enamels SIC 30 .... Rubber and Misc. Plastics Products SIC 31 (except 311) .... Leather and Leather Products SIC 323 .... Products of Purchased Glass SIC 34 (except 3441) .... Fabricated Metal Products SIC 35 .... Industrial Machinery and Equipment, except Electrical SIC 36 .... Electronic and Other Electric Equipment SIC 37 (except 373) .... Transportation Equipment SIC 38 .... Instruments and Related Products SIC 39 .... Miscellaneous Manufacturing Industries SIC 4221 .... Farm Products Warehousing and Storage SIC 4222 .... Refrigerated Warehousing and Storage SIC 4225 .... General Warehousing and Storage

Source: *Federal Register*, Vol. 55, No. 222, p. 48065, November 16, 1990.

Note: On June 4, 1992, the U.S. Court of Appeals for the Ninth Circuit remanded the exemption for construction sites of less than five acres and for manufacturing facilities in category (xi) which do not have materials or activities exposed to storm water to the EPA for further rulemaking. *NRDC* v. *EPA*, 966 F.2d 1292 (9th Cir. 1992). In response to the remands, the Agency intends to conduct further rulemakings on both the light manufacturing and the construction activities. In the December 18, 1992, *Federal Register*, EPA stated that it is not requiring permit applications from construction activity under five acres or light industry without exposure until this further rulemaking is completed.

For a more complete discussion of the interpretation of this definition, refer to the *NPDES Storm Water Program Question and Answer Document*, Parts I and II (EPA, 1992, 1993), which appear in Appendix D.

The original permitting framework of Phase I provided operators of industrial facilities with three options for applying for NPDES permit coverage. They could (1) submit individual applications, (2) participate in a group application, or (3) submit a notice of intent to be covered by a general permit.[5] For the first phase of the storm water program, EPA issued general permits to facilitate permitting the large number of facilities covered by the program on September 9, 1992 (57 *FR* 41176), September 25, 1992 (57 *FR* 44412), and April 14, 1993 (58 *FR* 19427). This Phase I framework is the result of a lengthy rulemaking process that included opportunities for, and response to, public comment. In addition, authorized NPDES States have issued numerous other general permits for facilities within their States.

Section 402(p)(2)(E) of the CWA allows EPA or States to require permits for any other discharges determined to be a contributor to a violation of a water quality standard or a significant contributor of pollutants to waters of the United States. Thus, the Phase I approach provides the foundation for extending regulation to additional sources and classes of discharges, as appropriate.

4.1.2 Industrial, Commercial, and Retail Sources *Not* Subject to Phase I Permit Requirements

This section responds to Congress' first mandate in CWA Section 402(p)(5): to identify the sources of storm water discharges for which permits are not currently required under Phase I. This chapter addresses individual Phase II sources; municipal separate storm sewer systems were discussed in Chapter 3. Based on a review of those facilities not subject to Phase I permitting requirements and a screening procedure based on information drawn from the literature review, activities were identified that may present opportunities for pollutant releases to storm water. The purpose of the source identification is to present the

[5] The group application permitting option is no longer available to permit applicants because the application deadlines have passed. EPA proposed an industry-specific multi-sector model general permit based on the information received through the group application process on November 19, 1993. EPA will be finalizing the multi-sector general permit in the near future.

full range of potential Phase II sources and to characterize them to the extent possible to facilitate decision making on the appropriate scope and approach of Phase II. The screening process was used to narrow consideration to a subset of facilities that may be appropriate for coverage under Phase II. Both the regulatory analysis and screening procedure are described below.

4.1.2.1 Phase I Regulatory Review

In defining "storm water discharges associated with industrial activity," the Phase I regulations identify 11 categories of facilities considered to be engaging in "industrial activity" (see Table 4-2). Only those facilities described in the 11 categories of the definition that have point source discharges of storm water are required to apply for storm water permit coverage under Phase I of the program. As shown in Table 4-2, regulated activities under Phase I were identified by SIC category, narrative descriptions of activities, or, in some cases, both. For example, Category viii regulated activities are defined as "only those portions of the facility that are either involved in vehicle maintenance . . ., equipment cleaning operations, or airport de-icing operations, or which are otherwise listed in another category . . . ." Seven separate SIC codes are then listed, including six two-digit codes and one four-digit code; several four-digit codes were specifically omitted from coverage.

There are a number of sources closely related to Phase I activities that are currently unregulated. One general class includes construction activities that disturb less than 5 acres (Category x) and light industrial activities that have no exposure of materials to storm water (Category xi). On June 4, 1992, the Court of Appeals for the Ninth Circuit remanded the exemption of both of these categories from the original storm water regulations.[6] The court found that EPA had not adequately established that light industrial facilities without exposure of materials or operations to storm water and construction sites disturbing less than 5 acres were non-industrial in nature.

[6] *Natural Resources Defense Council v. EPA*, 966 F.2d 1292 (9th Cir. 1992).

In response to the Ninth Circuit Court ruling, EPA issued a *Federal Register* notice on December 18, 1992, to explain the outcome of the ruling and to request comment and specific factual information to assist in the development of a new proposal to address light industry and small construction site categories. EPA noted that it did not believe that the court's decision has the effect of automatically subjecting small construction sites and light industries to the existing application requirements and deadlines. The Agency also indicated that it believed that additional notice and comment were necessary to clarify the status of these facilities. To the extent that some or all of these facilities may not be addressed by Phase I, they would be potential Phase II sources.

Additional categories of potential Phase II facilities have been identified based on the screening procedure described below.

4.1.2.2 Screening Procedure

Potential Phase II sources, categories, and activities were identified using previous information and additional screening based on the major sectors of the economy identified by SIC codes. Identifying potential Phase II sources based on SIC codes facilitates quantitative analysis of the numbers of facilities potentially subject to Phase II and provides a basis for a geographical location analysis that parallels the municipal analysis in Chapter 3. The geographical analysis (discussed in Section 4.2.2) was developed to show the distribution and "concentration" of non-domestic enterprises across the country and their association with various sizes and types of population centers. This geographical approach could later be related to a water quality or environmental assessment at a finer level of detail at the regional, state or local level.

As discussed in Chapter 2, major sectors of the economy are defined on the basis of the two-digit SIC code. This two-digit code is a relatively general categorization of the Nation's economic activity: all industrial, commercial, and retail activities are organized into 83 two-digit SIC codes. The four-digit SIC code provides a more detailed breakdown of these enterprises and is much more specific to the activities conducted at the establishment. Although all unregulated activities are potential Phase II sources, in practical terms, only a subset of four-digit SIC industry groups has real potential to use, process, or store pollutant-bearing materials or to engage in activities that could lead to contamination of storm water.

SIC codes are assigned by economic activity, not pollution potential. However, economic activities often correspond to physical activities or use of specific materials that can be assessed relative to the potential to generate storm water pollution. Thus, SIC codes can serve as an indicator of the underlying activities or materials of concern, even if they cannot be used to directly assess environmental effects.

The screening process described below focuses on two broad classes of facilities. The first (designated Group A) consists of facilities that fall within the same general range of SIC codes as Phase I industrial activities but that are not covered under Phase I. The second major group (designated Group B) consists of a specific subset of four-digit SIC codes of concern (outside SIC codes 10-45) where discharges of pollutants are suspected based on case studies, expert opinion, literature review, other EPA programs and concerns, and experience with Phase I of the storm water program.

This screening process does not establish negative environmental effects from storm water discharges. It does serve as a tool for focusing attention on those categories potentially contributing to storm water pollution. The geographical analysis reported in Section 4.2.2 allows EPA to determine how these specific categories of potential Phase II facilities are distributed nationally in geographic areas of concern (e.g., urbanized areas).

The following criteria were used to identify four-digit SIC codes of primary environmental concern. First, facilities highly similar to Phase I facilities are identified (Group A). Next, an additional 12 categories of potential Phase II sources are identified based on their similarity to Phase I activities or based on case studies and expert opinion

(Group B). These 12 Group B categories are then related to specific SIC code groupings for subsequent analysis in Section 4.2. The categories identified through this process represent the types of establishments or activities that may warrant further investigation and control under Phase II. This preliminary identification does not establish that water quality impacts are occurring.

As noted earlier, the SIC code system is a useful framework for identifying the numbers and locations of facilities. The SIC approach allows EPA to access information from many sources with a very precise level of detail, because of the efforts of many organizations (e.g., Commerce Department) to record and track economic activity by industrial category. Still, focusing on SIC codes for the purposes of this study does not imply that a regulatory strategy must proceed on this basis. The types of activities conducted at these facilities could be regulated through narrative descriptions, as was done for some categories in Phase I. Experience with the Phase I definition of "discharges associated with industrial activity" suggests that SIC designations alone may not be completely satisfactory because activities of concern may be conducted at a wide variety of facilities that do not happen to have the same primary SIC code. In addition, other potential Phase II sources that are not reflected by the SIC code system, including parking lots, large retail complexes, and facilities or residences with septic systems for septic wastewater disposal, can similarly be studied for impacts on water quality or regulated based on narrative description. Even within an SIC-based regulatory framework, additional factors, such as size, location, pollutant usage, or activity cutoffs or restrictions, can be used to identify specific facilities for regulation based on a potential correlation between facilities and water quality impacts.

The SIC system does not capture some types of facilities or activities that generate storm water discharges. SIC codes are designated based on the primary activity in which an establishment is engaged. A business that is involved in a number of different activities will be classified according to a single industrial code, which may not reflect activities associated with storm water discharges. In addition, some facilities carry out activities off-site, such as material storage and vehicle maintenance, that will not have independent business identities and, thus, no separate SIC designations. Similarly, the SIC system may not identify all facilities that are owned or operated from a remote central business location. The SIC system also does not individually identify industrial activities associated with municipalities. Although some municipal services (e.g., public ambulance services) are identified, other types of activities (e.g., municipal power generating facilities) are not captured within the SIC system. Even with these limitations, EPA analysis of potential Phase II sources in terms of SIC code assignments provides an extremely valuable analytical tool to assess the location and concentration of these activities at the national level.

Group A Sources

Although Phase I industrial activities generally fall within SIC codes 10-45, there are many omissions and exceptions within this range. While some of these omissions were intentional, others are the result of the specificity of the 1990 application regulations. Other facilities have been excluded from Phase I based on specific legislative changes. These classes of facilities are deserving of special attention due to their extreme similarity to Phase I industrial activities. For the purposes of discussion and analysis in this report, these facilities have been classified as Group A.

To clearly identify Phase II facilities that fall within the SIC range 10-45, a list of unregulated activities related to Phase I sources in each of the 11 industrial categories was developed. This list appears in Table 4-3. The similarity of many of the facilities on this list to Phase I facilities makes them difficult to distinguish from Phase I facilities for the purposes of the analyses in this report. In order to help characterize these sources, they have been categorized below according to three main criteria. The three groups identified together make up Group A. Although these groups do not encompass every one of the possible exceptions presented in Table 4-3, they represent the majority of facilities in SIC codes 10-45 that were not addressed under Phase I.

VOL 12

Table 4-3. Categories of Activities *Not* Regulated Under Phase I

Category	Activities and Facilities
i	• Facilities that were not considered for inclusion in the effluent guideline formulations
ii	• Offsite warehouses (unless auxiliary to a regulated facility) • Offsite salt storage piles • Chemical distributors that conduct incidental mixing and blending of products • Distributors of farm products and equipment with mixing and blending of fertilizers (not SIC 2875)
iii	• Pipelines • Petroleum product distribution, including SIC 49
iv	• Hazardous waste generation/storage sites subject to certain RCRA Subtitle C requirements but not permitting
v	• Landfills that have not received or do not receive industrial waste (Municipal Solid Waste Landfills (MSWLFs)) • Solid waste transfer stations with no vehicle maintenance or that are owned or operated by the entity that owns the final disposal site • Land application of sewage treatment plant effluent (exempted from RCRA requirements) • Incinerators (BIFs and municipal incinerators) (hazardous waste incinerators are permitted under RCRA Subtitle C and therefore are regulated under Phase I) • Temporary offsite waste storage sites
vi	• Interim recycling facilities (collection sites, satellite storage sites)
vi	• Facilities that generate electricity, but do not use steam electric generation
viii	• General equipment and vehicle storage/maintenance yards (municipal fire trucks, police cars, park maintenance; construction equipment yards) • Vehicle maintenance of garbage collection trucks owned by landfill operator • SIC 40-45 facilities without vehicle maintenance • Material handling/storage areas at SIC 40-45 facilities • School bus maintenance facilities owned or operated by school districts • Mining related equipment maintenance • Warehouses under SIC 4226 that do not have vehicle maintenance • Petroleum product wholesalers (SIC 5172) and bulk stations (SIC 5171) without vehicle maintenance
ix	• Treatment works with design flows less that 1 MGD (Transportation Act of 1991 exempted POTWs owned or operated by municipalities with population of less than 100,000) • Off-site non-domestic sewage treatment plants and sludge drying beds • Portable sanitary and septage service facilities • Water treatment plants
x	• Construction operations that result in the disturbance of less that five acres of total land area are under review due to the court opinion in *Natural Resources Defense Council* v. *EPA*, 966 F.2d 1292 (9th Cir. 1992)
xi	• Facilities where there is no exposure of material are under review due to the court opinion on *Natural Resources Defense Council* v. *EPA*, 966 F. 2d 1292 (9th Cir. 1992)

4/97

- **Auxiliary Facilities or Secondary Activities**—SIC codes are assigned on the basis of the primary activity from a financial standpoint that is taking place at a particular facility. Facilities with industrial activities that are in support of, or auxiliary to, a non-regulated activity would not be covered under Phase I. Examples include maintenance of construction equipment and vehicles and local trucking for an unregulated facility (grocery stores etc.).

- **Facilities Intentionally Omitted from Phase I**—Another class of facilities which are not addressed under Phase I are those that are related to, but were intentionally omitted from, one of the 11 industrial categories. For example, category ix does not cover treatment works with a design flow of less than 1 MGD, and category v does not address landfills that have not received industrial waste. While these activities may be slightly different from Phase I activities in size, scope, or specific materials present, there are many similarities which may make these facilities a potential concern in Phase II.

- **Facilities Exempted by the Transportation Act**—The Intermodal Surface Transportation Efficiency Act of 1991 (Transportation Act) exempted most industrial activities owned or operated by municipalities of less than 100,000 people from permit coverage under Phase I.[7] This exemption applies to approximately 19,000 incorporated places and 17,000 minor civil divisions in over 3000 counties. It is important to note that these activities are identical to Phase I facilities and are not located in municipalities which are covered under Phase I.

The overlap in SIC code assignments between Group A facilities and Phase I regulated activities make accurate estimation of the number of facilities in Group A very difficult. The estimates used are based on a process of elimination. Beginning with the total number of facilities in SIC codes 10-45 and subtracting the number of facilities accounted for under Phase I gives approximately 100,000 to 200,000 facilities. This is roughly equivalent to the size of Phase I. The difficulty in distinguishing these facilities from their closely related Phase I analogues also makes the geographic analysis conducted in section 4.2 difficult. Although the analysis has been conducted on a general basis for the entire group, this will only yield an overall approximation. Sub-classes of facilities within this group may be

---

[7] The Transportation Act exempted industrial activities owned or operated by municipalities of less than 100,000 population from Phase I permitting requirements with the exception of powerplants, airports, and uncontrolled sanitary landfills.

distributed quite differently. For information on the distribution of specific two-digit SIC codes within group A, see Appendix G.

Group B Sources

Based on the regulatory review and analysis of the types of industrial sources not covered under Phase I (discussed previously), several categories of facilities that are inherently similar or related to Phase I sources, but that fall into SIC code categories outside of SIC codes 10-45, were identified. A number of criteria were used to develop a comprehensive list of facilities which should be considered for inclusion in Phase II. This list constitutes Group B.

The first criteria used to identify Group B facilities were activities with industrial components or closely related activities. The main categories identified include:

- **Transportation Activities and Services**—SIC series 478x, which are similar to those identified in Category viii of the Phase I definition (see Table 4-2)
- **Energy Producers and Distributors**—Similar to Categories iii and vii, including pipelines (SIC 461x) and petroleum producers (SIC 4925)
- **Other Utilities**—Water supply, irrigation, and sanitation services that may often be municipally operated (SICs 494x, 495x, and 497x), which are related to Category ix
- **Municipal or Governmental Activities or Services**—In the 922x series that may have industrial components (Category ii) or activities related to transportation or vehicle maintenance (Category viii) (e.g., police stations, jails, and fire stations).

The next criterion used was commercial facilities with industrial components or similar operations. Commercial facilities were specifically excluded from Phase I by congressional intent. However, officials engaged in controlling urban runoff and nonpoint source pollution at the local, State, and national level believe that many commercial sources represent an important environmental concern. These concerns are documented in State and local nonpoint source programs, urban runoff programs, and estuary programs identified through the literature review. The Rensselaerville Study (1992) reflected potential areas of concern by identifying "gas, auto, service stations, transportation related activities, highway systems, land development, agricultural sources and related activities, commercial activities with industrial components, and large retail complexes."[8] Taking a broad view of these descriptions, facilities were identified in two main categories. The first category comprises commercial or retail establishments with industrial components or activities:

- Many types of establishments that provide automotive or transportation services, including car dealers and gas/service stations (SICs in the 55xx series) and other automobile-related services and maintenance with SIC codes from 751x to 754x, such as truck and car renters, various types of repair and body shops, parking structures, and car washes

- Commercial enterprises involved in fuel wholesaling and distribution, such as gas and petroleum storage and distribution (SICs 493x and 517x) and fuel oil and coal dealers (SIC 598x)

- Commercial or wholesale enterprises with manufacturing or assembly activities, mainly in the 50xx and 52xx series

- Commercial or wholesale facilities that include food processors or wholesalers that may have organic wastes (SIC 514x), photographic studios (SIC 7221) and photo finishing labs (SIC 7384), small repair shops that may have metal wastes (SIC 769x), including repair of communications devices, refrigeration units, other electrical or electronic devices, and welding; research and testing laboratories (SIC 873x) and laundries (SIC 721x)

- National security entities (SIC 9711); although industrial activities at military facilities are regulated in Phase I, potential Phase II activities may be located on these sites as well and would not show up individually in the analysis that follows.

The second category consists of commercial or retail facilities and other sources that are similar or related to agricultural activities or sources and includes:

[8] No SIC codes specifically identify all large retail complexes. However, these are partially addressed through the loading analysis of storm water from urban/urbanized areas in the municipal section (Chapter 3). If such items were to be addressed in a regulatory framework, it would likely be on the basis of a narrative description rather than a SIC designation.

- Agriculture-related operations in the SIC groups 021x and 025x because they may represent confined animal facilities or feedlots.[9] Wholesale livestock facilities (SIC 5154) were also included under this criterion as were animal husbandry operations aside from general farms, such as zoos (SIC 8422), racetracks and stables (SIC 7948), which may have operations that are similar to feedlots.

- Because of potential for use of pesticides and fertilizers, the following were included: nurseries and lawn and garden facilities (SIC 078x) and other facilities that may store, mix, or use agricultural chemicals or other pesticides, such as farm products and raw materials sellers (SIC 5159), wholesalers of chemicals and allied products (SIC 5169), farm suppliers (SIC 5191), lawn and garden suppliers (SIC 5261), and exterminators (SIC 7342).

- Other facilities that may use pesticides or fertilizers in substantial quantities, such as golf courses and other recreational establishments with large lawns (SIC 799x) and colleges and schools (SIC 822x), which may have lawns, gardens, nurseries, or experimental agricultural areas. (These may also operate power plants or treatment works or engage in other activities similar to regulated industrial categories.)

From the 12 categories of Group B Phase II sources identified above, the universe of facilities was screened to identify a specific subset for further analysis. Through this selection process, potential Phase II facilities were identified, including those associated with products or waste materials that contain pollutants, such as metals, pesticides, and nutrients, and those associated with processes, practices, or events that can lead to the discharge of those pollutants into storm water. The SIC manual identifies 83 major groups of SIC codes in 10 major divisions (identified in Table 4-1). These major groups are divided into 1,047 four-digit categories. Of these, 604 fall into Phase I regulated activities or closely related facilities which make up Group A (SIC 10-45). Of the 443 that remain in agricultural, commercial, and retail divisions, 168 fall into the excluded service sectors. Of the remaining 275 categories, the screening process and the 12 categories identified above correspond to 90 individual categories of facilities and activities for further study as potential Phase II sources.

[9] See footnote 4 regarding feedlots currently regulated under the NPDES program.

This subset of 90 four-digit SIC codes is listed in Table 4-4. More than a million facilities were identified for these SIC categories by searching EPA's Facility and Company Tracking System (FACTS) data base.[10]

To facilitate analysis, some additional grouping is necessary. These 90 individual categories could be grouped together based on the 12 criteria used to identify them. However, some of the criteria group together dissimilar activities. For example, "commercial wholesalers" include four dissimilar categories: wood, ore, metal, and machinery wholesalers. Based on these distinctions, the 12 groups were further subdivided, forming 18 potential Phase II sectors. The 18 sectors are listed in Table 4-5. The affiliation of each specific SIC code with a sector is shown in Table 4-4, along with the numbers of facilities in that SIC code. This grouping into sectors facilitates discussion of similarities and differences among categories later in the chapter.

The data on numbers of facilities in Table 4-4 reveal some interesting facts about individual categories. Of the 18 Group B sectors, the automobile service sector (comprised of gas/service stations (SIC 5541), general automobile repair (SIC 7538), top, body repair (SIC 7532), repair shops and services (SIC 7699), car dealers, new & used (SIC 5511), car dealers, used only (SIC 5521), car washes (SIC 7542), passenger car rental (SIC 7514), truck rental (SIC 7513), parking structures (SIC 7521), and miscellaneous auto services (SIC 7549)) make up more than one-third of the total number of facilities identified in all 18 sectors.

Table 4-5 also shows facility counts for the 18 Group B sectors, illustrating even more clearly the dominant categories. Facilities engaged in automotive service and vehicle maintenance are far more numerous than other groups of potential Phase II sources. Machinery and electrical repair facilities are the second largest group, and intensive users of agricultural chemicals, including lawn and garden establishments and nurseries, are the third largest group.

---

[10] As discussed in Chapter 2, the FACTS data base is leased by EPA from Dun & Bradstreet Information Services, which created, maintains, and annually updates information based on a variety of sources.

*Phase II sector is a grouping devised to facilitate discussion of similar facilities. The sectors are further described in the text and summarized in Table 4-5.

Table 4-5. Summary of Group B Phase II Sectors

Description of Phase II Sectors	No. of Facilities
Automotive Service	369,870
Machinery & Electrical Repair	135,744
Intensive Ag. Chemical Use (a)	121,861
Wholesale, Machinery	77,562
Laundries	51,376
Wholesale, Wood Products	48,593
Livestock, Feedlots	43,421
Petroleum Pipelines & Distributors	35,319
Photographic Activities	30,684
Various Utilities	22,242
Extensive Ag. Chemical Use (b)	18,992
Transport, Rail and other	14,808
Wholesale, Metal Products	14,303
Wholesale, Food	11,372
Laboratories	10,683
National Security	4,611
Municipal Services, Vehicle Maint.	2,414
Wholesale, Coal & Ores	1,384
Total	1,015,239

(a) e.g., nurseries, farm chemical suppliers & distributors
(b) e.g., large lawns, golf courses

Remaining Phase II Activities

The identification of all Phase I facilities together with facilities in Groups A and B only account for approximately 1.5 million of the estimated 7.7 million total facilities. This leaves over 6 million facilities "unaccounted for" in this analysis. These remaining facilities include a wide range of activities which fall into a number of general classifications.

General Sources—Widespread sources of potential storm water contamination which are not necessarily associated with any one particular activity are a large category of sources not addressed in this analysis. These include parking lots, trash dumpsters, leaking and failing septic systems, and activities related to individual residences such as fertilizer and pesticide application. The tremendous number of these sources would make individual permitting virtually impossible. Although the identification and analysis of individual Phase II sources does not focus on these sources, the municipal analysis does account for pollutant loadings from these types of sources which are related to the general process of urbanization.

Service Sectors—Major SIC groups in the service sectors, such as banking, finance, insurance firms, and all types of food services were not considered to be potential Phase II sources. The activities of these enterprises are generally conducted indoors and do not inherently use or produce contaminants that may enter storm water. However, these facilities may also have some of the general sources of storm water contamination discussed above, such as parking lots or trash dumpsters. All of the major SIC groups excluded on this basis are listed in Table 4-6. Although the analysis of this report does not focus on service sector facilities in detail at the four-digit SIC level, the geographic and distributional analysis was conducted for these facilities at the major group (two-digit SIC) level. These results are presented in Appendix G.

4.2 NATURE AND EXTENT OF POLLUTANTS ASSOCIATED WITH INDIVIDUAL PHASE II SOURCES

This section responds to the second congressional mandate in CWA Section 402(p)(5): to determine the nature and extent of pollutants in storm water discharges to the maximum extent practicable. EPA developed quantitative and qualitative information on the types of activities or materials associated with potential Phase II sources and their locations relative to various geographic jurisdictions.[11]

The nature of storm water discharges from industrial and commercial sources was addressed in two ways. First, sampling data on quality of runoff from Phase I industrial sources were analyzed and summarized to provide a basis of comparison for potential Phase II sources. The data submitted with group permit applications are among the most comprehensive sources of data on pollutant concentrations in industrial runoff. Second, descriptive information on the potential for storm water discharges from industrial and commercial activities was identified and summarized. This was based on the literature review, inference from descriptions of the activities associated with industrial and

[11] As discussed in Chapter 2, EPA was not able to identify adequate data to support the calculation of pollutant loadings on a national scale.

Table 4-6. SICs Not Considered as Potential Phase II Sectors

Transportation and Public Utilities Sector:	
SIC 48	Communication Facilities
Retail Trade Sector:	
SIC 53	General Merchandise Stores
54	Food Stores
56	Apparel and Accessory Stores
57	Home Furniture, Furnishings and Equipment Stores
58	Eating and Drinking Places
Finance, Insurance, and Real Estate Sector all facilities:	
SIC 60	Banking
61	Credit Agencies
62	Security Brokers
63	Insurance Carriers
64	Insurance agents
65	Real Estate
67	Investment Offices

96	Administration of Economic Programs

Source: OMB, 1987

commercial facilities, the documented experiences of municipalities operating storm water management programs, and EPA's experience in assisting the regulated community in meeting group application requirements under Phase I of the regulatory program.

Determining the extent of pollutants was addressed by identifying the geographic distribution of the sources that may contribute pollutants to storm water. Through a locational analysis, categories of facilities were analyzed to determine to what extent they are located in various sizes of cities, urban areas, and other political jurisdictions. This quantitative assessment of location is informative and useful for certain policy discussions but does not establish the presence of pollutants in storm water for any potential Phase II sources.

4.2.1 Nature of Pollutants Associated With Individual Phase II Sources

This section presents information on pollutants and activities associated with industrial, commercial, and retail categories that may contribute to storm water contamination.

4.2.1.1 Phase I Industrial Group Applicant (Part II) Data

Phase I Industrial Group Applicant (Part II) Data provides a basis for identifying the areas and activities that may be of concern when associated with nonregulated categories of facilities. This section presents analyses of storm water runoff quality data from Phase I (industrial) permit applicants. As part of the permitting process, 44,000 Phase I group applicants in 700 groups were organized into 29 sectors based on general similarity for purposes of writing a multisector general permit.[12] Part II of the permit application required approximately 10 percent of the members of each group to submit sampling results for pollutants in storm water discharges, including conventional, nutrients, and other toxic pollutants that might be present. Table 4-7 summarizes these results by reporting the composite sample mean concentration for each sector for nine of the basic pollutants studied in NURP plus oil and grease. Although the sources and methods of data collection differ, this industrial sector concentration data can be compared with summary data from NURP or USGS to provide some insight into storm water runoff quality. Comparisons can also be made among sectors to determine which are more likely to discharge higher concentrations of certain classes of pollutants. Appendix E provides a comprehensive summary of the industry sectors and sampling data from the group application process.

[12] The sectors were designed to group similar facilities together. Facilities were separated into 31 sectors for analysis of the Part II Group Application data for this report. Only 29 sector permits were developed in the multi-sector general permit. After some groups were combined, and others withdrew, only 700 groups representing 44,000 facilities remained from approximately 60,000 which began the group application process.

Table 4-7. Summary of Sampling Data from Phase I Group Permit Applications (with comparison to NURP and USGS studies[1])

		Pollutant Composite Mean (mg/l)									
		Conventionals				Nutrients			Metals

*Recently, concerns have been raised regarding the validity and use of historical data for metals. As discussed in chapter 2, EPA believes that historical data on storm water runoff from NURP and USGS are suitable for the purposes of this report.

Although it focuses on Phase I sources rather than Phase II, this analysis is an important contribution to the literature and this report because it may be the most comprehensive data available on sector-specific industrial discharges. This information can assist EPA and States in evaluating and targeting Phase II sources, at least those that may be similar to Phase I sources. The information can also be used to compare with other sources of information and to give some perspective on which Phase II sectors are of most concern (to the extent they are similar to Phase I activities). This exercise also demonstrates the usefulness of the data collection effort involved in the group application process. These summary data can also provide a baseline from which to measure future improvements in runoff quality and a basis for developing measurable indicators for performance evaluation of State, local, or industrial programs in the future.

An understanding of the group application sampling data is necessary. EPA approved facilities chosen for sampling within a group (ranging from 50 percent of small groups to 10 percent of large groups but no more than 100 facilities per group) only if they were representative, based on industrial activity, significant materials exposed, and geographic distribution. All data received from samplers were checked and double key punched and verified during entry.[13] At the same time, it is important to understand that the facilities submitting sampling data were not randomly selected but rather were identified by the group applicants. These facilities also chose the sampling locations at their sites and conducted monitoring in accordance with EPA guidance on the selection of suitable locations, storm events, and methodology.

In addition to the Phase I permit application data, historical data from past studies can provide some perspective on the nature of storm water from regulated and unregulated sources. Historical data on storm water quality from various types of sites from NURP and USGS were presented in Chapter 2. These data were collected from general urban, commercial, or industrial areas, not from specific industrial facilities. However, these data do provide useful historical reference points. In particular, the mean and median for the NURP urban site and USGS commercial sites were chosen for comparison with the new industry-specific data from permit applications. These levels provide a reference point based on past studies of the nature of storm water discharges. The pollutant concentrations observed in the NURP study should not be considered to be "acceptable" or normal levels of storm water contamination.

[13] Only those applications received before January 1993 are included in the data base used in this analysis.

VOL 12

4210

Permit application data were analyzed for 11 pollutants, including 9 pollutants studied in NURP—biochemical oxygen demand (BOD), chemical oxygen demand (COD), total suspended solids (TSS), nitrate plus nitrite nitrogen, total Kjeldahl nitrogen (TKN), total phosphorus, copper, lead, and zinc—plus oil and grease and pH. As discussed, Table 4-7 reports summary results for the composite mean from the permit application data for 31 Phase I sectors. Appendix F gives more detailed results for each pollutant and each industrial sector, including the mean, median, and 95th percentile, as well as the number of samples taken. To provide a basis for comparing across industrial categories, the mean of the composite sample results was chosen as an indicator of average storm water quality. Composite samples are preferable to grab samples for comparing average runoff conditions because grab sample results (also reported in the tables) may represent pollutant spikes, rather than more long term average storm conditions. The following paragraphs review these results.

Conventionals

Among the conventional pollutants, total suspended solids appears to be the pollutant with highest concentration. Half of the Phase I industrial sectors had concentrations higher than NURP and average results in the hundreds of parts per million are common. Composite mean concentrations were over 1,500 mg/l for mineral mining and for landfills. These data confirm the result in NURP and other literature that sediment is an important component of storm water runoff. It should be noted that sediments can also carry additional pollutants, such as metals and organics. As reported on Table 4-7, COD results for the composite mean are higher than NURP in about half of the sectors (14 sectors out of 31). The highest reported composite mean value for COD was 242 mg/l and five sectors had concentrations greater than 150 mg/l, including lumber and wood products, scrap and waste materials, metal mining, railroad transport, and wastewater treatment. All sectors had concentrations higher than the average of commercial sites found in USGS studies. Results for BOD indicate that average runoff quality is not appreciably higher than the secondary treatment standard for POTWs of 30 mg/l. Although 10 sectors have higher levels of BOD than reported in NURP and USGS, the highest composite mean value for BOD was 46 mg/l. Most results for pH (reported in Appendix F) are in the range of 6.8 to 8.5, indicating that acidity or alkalinity is not the greatest concern associated with runoff from these industrial sites. For oil and grease, composite results are highly variable, and neither NURP nor USGS provides a baseline for comparison. The highest concentrations, over 5 mg/l, are engaged in industrial sectors associated with transportation and vehicle and machinery maintenance, as might be expected.

Nutrients

Overall, storm water discharges from industrial sites do not appear to be contributing high concentrations of nutrients. Results reported in Table 4-7 indicate that concentrations for TKN exceed NURP results in 22 cases, including wastewater treatment plants, chemical manufacturers, scrap yards, mining sectors, transportation sectors, and leather manufacturers. However, most of the results were in the range of 2 to 5 mg/l. Concentrations (for the composite mean) over 16 mg/l were reported for the chemical and allied products sector and the air transport sector. Concentrations of nitrogen in the form of nitrates and nitrites for the industrial sites represented in the permit application data are generally in the range of 0.8 to 2.0 mg/l, but there are some important exceptions. The highest concentrations for the composite mean occurred in the wastewater treatment sector (20.5 mg/l) and the scrap and waste materials sector (5.9 mg/l). Phosphorus results also do not show generally high concentrations; only nine sectors had composite mean results over 1 mg/l. The highest concentrations occurred for chemical and allied products manufacturers (9.5 mg/l), military facilities (7.1 mg/l), lumber and wood products manufacturers (6.3 mg/l), and oil extractors (3.4 mg/l). In summary, nutrient concentrations exhibit a mixed pattern across industrial groups, with some very low and very high results. Results for the two forms of nitrogen and for phosphorus indicate that storm water discharges of nutrients tend to be site- and pollutant-specific. That is, discharge of one form of nutrient does not in general indicate that other forms are present or suspect, although the chemical and allied products sector is associated with all three.

VOL 12

4212

<u>Metals</u>

Because sampling for metals proceeded on the basis of whether individual facilities had reason to believe they were present in their discharge, not all sectors reported results for metals. Again, referring to Table 4-7, results for copper show that 13 sectors had composite mean concentrations higher than NURP. The highest of these included the primary metals sector (2.25 mg/l) and scrap and waste materials (0.63 mg/l). Eight sectors reported no sampling results for copper. For lead, the table shows that the majority of sectors (15 out of 23) had concentrations below the mean value reported in NURP (0.18 mg/l). However, two of those with higher concentrations had extremely high values: the highest concentrations of lead found in industrial runoff were associated with industrial landfills and dumps (20.6 mg/l) and metal mining (6.1 mg/l). The next highest values came from the scrap and waste materials sector (.88 mg/l) and the stone, clay, and glass products sector (.25 mg/l). Results for zinc show that most of the sectors (22 of 25) had composite mean concentrations higher than the 0.20 mg/l value reported in NURP for general urban runoff. Nineteen sectors had concentrations higher than the 0.31 mg/l value reported in USGS studies for commercial sites. The highest concentrations found were associated with the primary metals (6.6 mg/l), metal mining (3.9 mg/l), and scrap and waste materials (3.6 mg/l) sectors. Six sectors did not report results for zinc. In summary, higher concentrations of metals tended to be associated with the primary metals sector, metal mining, industrial landfills, scrapyards, and metal fabricators.

4.2.1.2 Qualitative Assessment of Potential Phase II Categories

The sampling data presented previously were used to assist in understanding the nature of storm water discharges in Phase II sectors. To facilitate comparison of potential Phase II sources with the sampling results reported above, where possible, categories of Phase II sources were compared to similar Phase I sectors. These comparisons were made qualitatively and are not meant to suggest that the sectors conduct exactly the same activities or operations. Similarities were identified for 12 of the 18 Phase II sectors, as summarized in Table 4-8. The remaining categories of potential Phase II sources were generally not

VOL 12

4213

classifiable based on similarities to Phase I sources. Using this correspondence to Phase I and information from the literature review, a summary table was developed showing the potential pollutants associated with each of the potential Phase II sectors. For some sectors, permit application data were used as the basis for determining which pollutants could be present. For other sectors, literature review information and other documents were used. This information is summarized in Table 4-8, which can be used as a guide to the possible presence of pollutants at Phase II facilities. This does not indicate that the pollutants will be found in substantial quantities or that water quality will be impaired. In particular, pollutants are associated with categories similar to Phase I facilities based on the fact that the Phase I sector had among the highest (top ten) concentrations of that pollutant. Thus, it is based on a relative ranking: an industrial category may be among the highest, even when overall concentrations are not very high.

Based on the literature review, assessments of SIC descriptions, the selection criteria outlined above, and the pollutant data summarized in Table 4-8, information about the 18 potential Phase II categories can be summarized into several major groups. The first major group includes facilities with activities similar to those regulated under Phase I, even though they may be small commercial or retail establishments, rather than industrial ones. This class includes about 80 percent of the potential Phase II sources. One of the chief activities of concern in this group is vehicle maintenance and related transport, storage, and machine repair activities. Other activities conducted at these facilities that are substantially similar to those already regulated include loading and unloading operations, which include pumping of gases or liquids, pneumatic transfer of dry materials, or transfer of containers to or from vehicles; outdoor storage, including storage of fuels, raw materials, byproducts, intermediates, final products, and process residuals or wastes; and other outdoor activities and land disturbing operations, such as small construction and landscape maintenance. The types of products or waste materials at facilities in this class could include a wide variety of materials that potentially contribute pollutants to storm water runoff. Although discharges could include the whole range of pollutants, these sources may be more likely to contribute

VOL 12

X - Indicates similar Phase I sector ranked in top ten of all sectors for this pollutant class
S - Indicates pollutant is suspected, based on literature review and expert opinion
NA - Not applicable: No clear correspondence with Phase I Sectors
• - Overall, nutrient levels were not high in Phase I application data. This indicates that the pollutant was found in the top ten, but actual concentration levels were not high.
Blanks indicate that such pollutants are not pollutants of concern for the Phase II sectors.

toxics, in addition to conventionals and nutrients. Pollutants of concern include organic and inorganic chemicals; fuels, such as coal and oil; paints; metals; solvents; and oil and grease. Although not specifically addressed in this analysis, off-site storage and maintenance activities, which may be owned and operated by Phase I facilities but are not currently regulated, could also fall into this class.

The second major classification of facilities includes categories of industrial, commercial, or retail activities and businesses with discharges that may be similar to those from agricultural sources (which are exempt from NPDES regulation under the CWA). For example, smaller feedlots that are not currently regulated and large users of pesticides and fertilizers may be similar to agricultural discharges but are not specifically exempted by statute. This class of facilities includes more than 180,000 facilities or about 20 percent of

VOL 12

4215

those selected for study. This group includes lawn and garden services (SIC 0782), farm supplies (SIC 5191), and lawn and garden supply (SIC 5283), which are among the largest SIC groups selected for study (see Table 4-4). Fertilizers and pesticides from these facilities have the potential to contaminate storm water from activities such as land application, spills and leaks, rinsing of containers and trucks, and improper disposal. Thus, the pollutants of concern include conventionals, pesticides, and nutrients that are associated with uses of open space that superficially resemble agricultural uses, such as lawn and landscape care or commercial/retail production, transport, or storage of nursery products.

The third major class of potential Phase II sources includes categories of facilities with the potential to use or produce toxic substances but about which there is little information. Research and development laboratories and some kinds of governmental activity (such as justice and public order facilities, SIC 92xx) fall into this category. Some of these facilities may be administrative centers with little potential to discharge pollutants. Others, such as police and fire protection services, however, may include vehicle maintenance activities with potential for discharges similar to those described above. This group includes about 20,000 facilities, representing only about 2 percent of those chosen for study.

This section described the categories of facilities and evaluated the nature of potential pollutant discharges qualitatively based on similarity to Phase I sources and information from storm water literature. However, from a national perspective, little quantitative information exists on discharge quality from these potential Phase II sources.

The majority of Group A facilities are so similar to Phase I activities that data collected from Phase I permit application data may be used to evaluate their pollution potential. There are also a very few classes of unregulated facilities for which some data is already available. One category of facilities for which substantial information is currently available is feedlots. Although feedlots which meet the definition of Concentrated Animal Feeding Operation (CAFO) are currently subject to NPDES permitting requirements, many smaller feedlots do

VOL 12

not meet the current regulatory definition of CAFO and hence are not subject to current NPDES regulations.[14]

The United States Department of Agriculture (USDA) has estimated that there are approximately 6,000 animal feeding operations with 1,000 or more animal units.[15] EPA's Permit Compliance System (PCS) data base indicates that, as of October of 1994, EPA and authorized States have individual permits covering 928 CAFOs and general permits covering at least another 2,130 facilities. The total number of NPDES permits for feedlots is significantly less than the approximately 6,000 facilities that have more than 1,000 animal units. The discrepancy between the number of facilities authorized to discharge by NPDES permits and the total number of feedlots over 1,000 animal units is believed to be due to a number of factors, including: (1) due to limited State and Federal resources, some feedlots that should have a permit have not been brought into the NPDES program; (2) some regulatory authorities misinterpret the Federal regulations for CAFOs and mistakenly exempt facilities that should have permits; and (3) permits are only required for facilities that discharge at times other than the event of a 25-year/24-hour storm. USDA estimates that there are approximately 378,000 animal feeding operations with less than 1,000 animal units but more than 20 animal units.

Animal feedlots contribute to a significant degree of water quality impairment. States report the scope and sources of water quality impairments under Sections 305(b) and 319 of the CWA. Information from these sources indicates that, nationally, feedlots cause 7 percent

4217

[14] As discussed in Chapter 1, CAFOs are defined as animal feeding operations that discharge to waters of the United States at times other than during events greater than a 25-year, 24-hour storm and that: (1) have more than 1,000 animal units; (2) have more than 300 animal units and pollutants are discharged into navigable waters through a man-made flushing system or other man-made device, or pollutants are discharged directly into waters of the United States which originate outside of and pass over, across or through the facility or otherwise come into direct contact with the animals confined in the operation; or (3) are designated by EPA or an authorized NPDES State upon determining that it is a significant contributor of pollution to the waters of the United States.

[15] U.S. Department of Agriculture, Office of Budget and Policy Analysis, Draft Report, 1992. *Progress and Status of Livestock and Poultry Waste Management to Protect the Nation's Waters.*

VOL 12

of impairment in lakes and 13 percent of impairments in rivers.[16] Feedlot impact is less significant, on average, in estuaries and ocean coasts, although there are estuaries, such as the Chesapeake Bay and Puget Sound, where animal waste is a significant water quality problem. In addition, the U.S. Fish and Wildlife Service estimated in 1984 that feedlots impair fisheries in nearly 60,000 miles of streams nationally. EPA is unable to identify the relative contributions to impairment of facilities currently subject to NPDES permits and those that are not; however, waterbodies have been identified in case studies where impairment is due to smaller feedlots not subject to permits, e.g., the Chesapeake Bay.

Feedlots produce an estimated 400 million tons of animal waste per year, twice as much waste as humans produce. These wastes contain ammonia, phosphorus, nitrogen, oxygen demanding materials, and high levels of pathogenic bacteria. When used properly, animal wastes are a valuable resource, but when such wastes are discharged into surface or ground water, they often cause impairment.

High pollutant concentrations can be associated with feedlot runoff. Nutrients, oxygen demanding materials, and bacteria in runoff from feedlots are often present in concentrations that are 10 to 100 times those of untreated sanitary sewage[17] or combined sewer overflows.[18] Fish kills may result from runoff, wastewater, or manure entering surface waters, due to ammonia and dissolved oxygen depletion. The decomposition of organic materials can deplete dissolved oxygen supplies in water, resulting in anoxic or anaerobic conditions. Methane, amines, and sulfide are produced in anaerobic waters causing the water to acquire an unpleasant odor, taste, and appearance. Such waters can be unsuitable for drinking, fishing, and other recreational uses. Solids deposited in water bodies can

4218

[17] *Report of the EPA/State Feedlot Workgroup*, EPA Feedlot Workgroup, September 1993.

[18] *Water Pollution from Feedlot Waste: An Analysis of its Magnitude and Geographic Distribution*, EPA Feedlot Workgroup, December 1992.

accelerate eutrophication through the release of nutrients over extended periods of time. Animal diseases can be transmitted to humans through contact with animal feces. Animal waste has been responsible for shellfish contamination in some coastal waters.[19] Animal wastes discharged to waterways perform the same nutritional function for aquatic plants as they do for field crops, with high levels of nitrogen and phosphorus promoting algae growth in receiving waters. Pathogens, nitrates, and salts in manure can impair ground water, with problems being reported in at least 17 States.

4.2.2 Geographic Extent of Facilities

This section addresses the extent of potential Phase II facilities through a geographic analysis of their location with respect to urbanized areas, regulated Phase I municipalities, and other population centers. The procedures used to generate this information were discussed in Chapter 2. This analysis does not provide any information on the quantity or quality of storm water discharged by these facilities. This is locational data only. Some facilities may have completely enclosed operations. Some may be connected to sanitary or combined sewers, rather than to separate storm sewer systems. Finally, some may have few pollutants of concern in use or in their discharges.

Even so, determining location and geographic distribution lends some valuable insights. The location of facilities is important for both environmental and for policy reasons. From an environmental perspective, facilities located in populous, urban, or dense areas may be larger and more heavily used, with the potential for larger amounts or concentrations of pollutants to be discharged. At the same time, however, runoff from these urban facilities may be more likely to discharge to storm or sanitary sewers, where it will mix with other storm water flows before ultimate discharge to receiving waters. Facilities located in more rural areas may be no different in terms of pollutant content but may have a greater potential for discharging directly into the Nation's waters.

[19] *Guidance Specifying Management Measures for Sources of Nonpoint Pollution in Coastal Waters*, EPA, January 1993.

From a policy perspective, urban and rural storm water discharges could also be treated differently. Industrial, commercial, and retail facilities in urban areas will more often fall within the boundaries of a municipal storm water control program. Thus, any control, detention, or sampling efforts by municipalities may help to locate and mitigate the impact of the storm water discharges within their jurisdictions, whether these discharges are federally regulated or not. The rural discharger, on the other hand, is more likely to be a direct discharger or to be located in a smaller municipality with no storm water program and, thus, may be relatively uncontrolled unless located in a high priority watershed that receives special State attention.

As discussed in Chapter 2, Phase II of the storm water program could cover additional commercial sources directly through permitting requirements for individual facilities or indirectly by requiring local governments to address commercial sources. With respect to the second approach, there are many ways of expanding control strategies to additional geographic areas and political jurisdictions, beyond those covered in Phase I. For example, EPA could expand regulatory or control requirements to:

- The urbanized fringe around existing Phase I cities
- All urbanized areas not covered in Phase I
- Additional cities (incorporated areas) based on size
- Growing areas, where both development pressures and opportunities for preventive measures are greatest
- Coastal areas, where storm water quality impacts have been identified.

Of course, a combination of options can also be considered, such as urbanized areas in coastal areas or cities of a certain size in fast growing counties. To evaluate alternatives, consideration must be given to how industrial, commercial, and retail establishments are distributed in different jurisdictions, such as cities or urbanized areas of a certain size. The analysis on the following pages demonstrates how these various options would affect

VOL 12

4220

industrial and commercial facilities (i.e., what portion of facilities in a given sector would be covered by a particular geographic approach). This analysis of location was completed for each of these perspectives. This section presents and discusses results for urbanized areas, primarily. Other relevant results are discussed in the text, but full numerical details are reported in Appendix G.

As discussed in Chapter 2, this presentation is based on the premise that individual commercial and retail activities are distributed similarly to the population at the county level. That is, if 40 percent of the people in a county live in urbanized areas, this analysis assumes that 40 percent of the industrial, commercial, and retail sources are located in urbanized areas. This premise may not hold true for activities that are usually located in rural areas, such as agricultural or silvicultural operations. However, because rural counties have a lower proportion of urbanized population, facilities that are commonly located in rural counties would be allocated to the non-urbanized portion of the county under this procedure. Thus, on average on a national scale,[30] the premise provides a useful estimation tool even for typically rural enterprises. This procedure is explained in more detail in Chapter 2.

The results of the distributional analysis of facilities and SIC-code activities are presented graphically in this section. Figure 4-1 shows the geographic distribution of facilities (by county) in the 90 selected four-digit SIC codes (potential Phase II) chosen for analysis. Counties are shaded in the map based on the number of facilities located in each. Counties with more than 1,000 facilities are shown in black, those with 500 to 999 facilities are shown in cross-hatch shading, and those with 250 to 499 facilities are shown in light shading. Counties with facility counts lower than 250 are shown in white but are not outlined.

Figure 4-2 shows similar information, except that counties are shaded on the basis of density of facilities (facilities per square mile) rather than straight facility counts. The

[30] The analysis does not address individual commercial and retail activities that are located in Territories other than the District of Columbus.

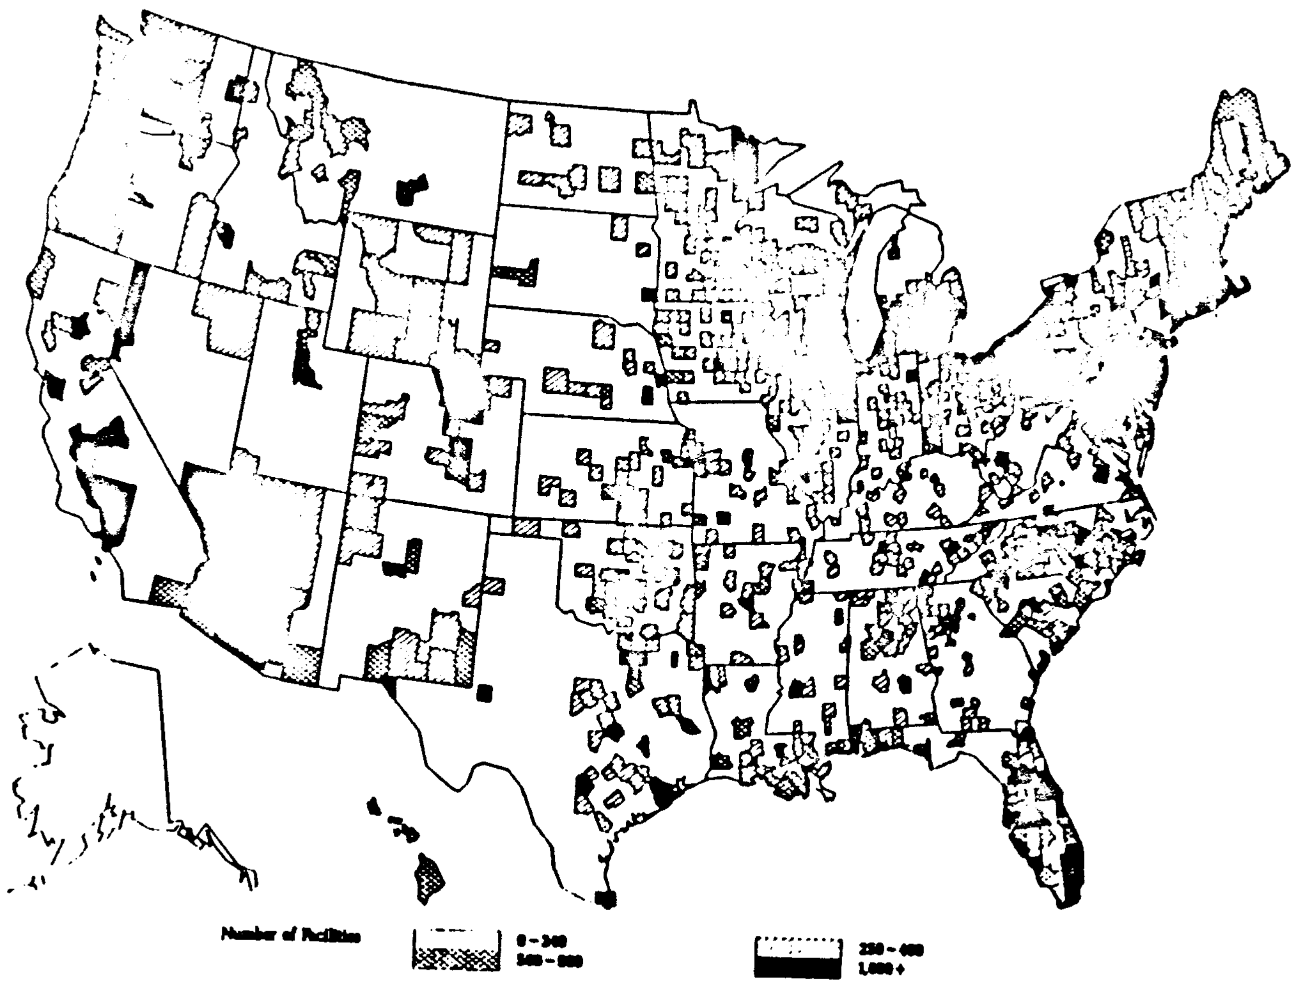

Figure 4-1. Geographic Distribution of Facilities With Selected 4-Digit SIC Codes (counties with less than 250 facilities are not shown)

VOL 12

4223

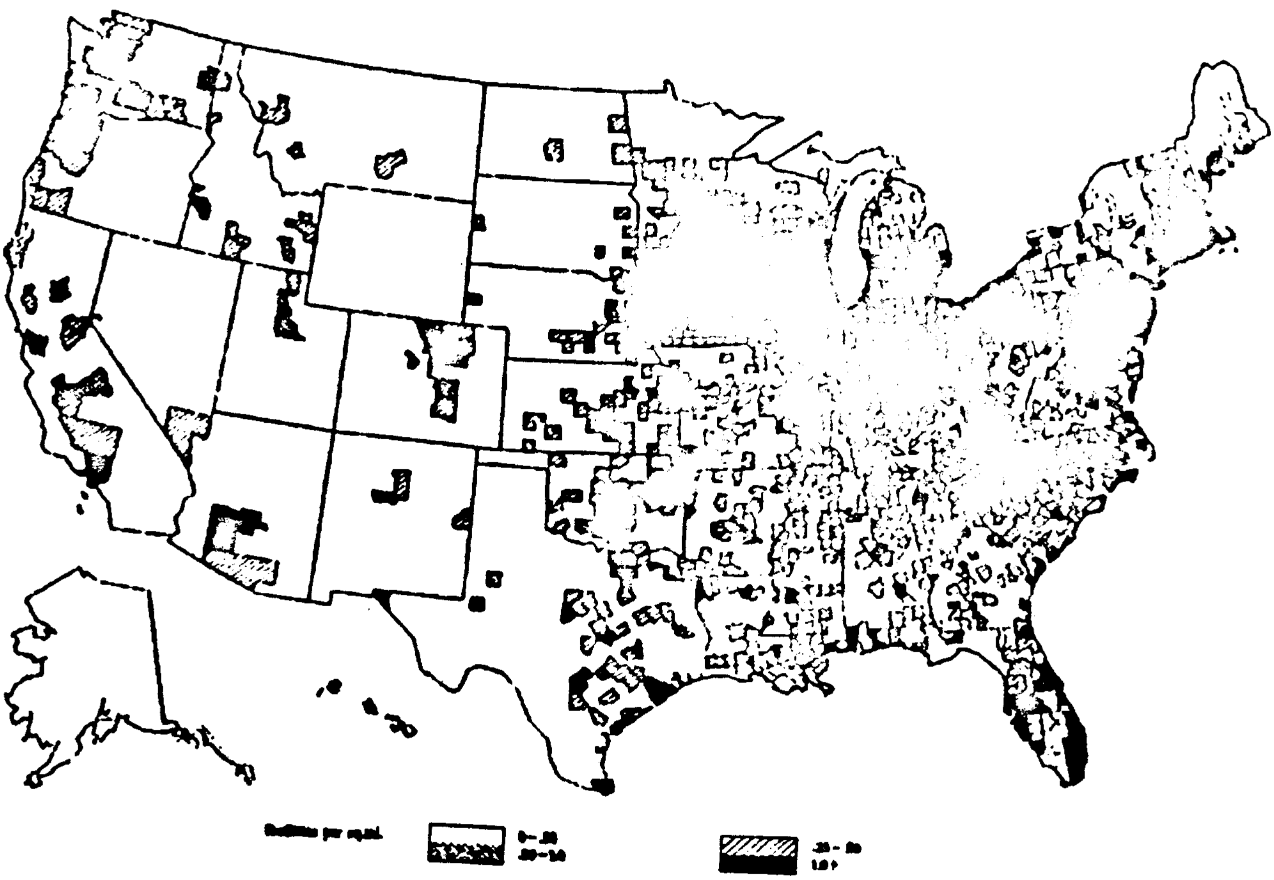

Figure 4-2. Geographic Distribution of Facilities With Selected 4-Digit SIC Codes by Density (counties with less than .25 facilities per square mile are not shown)

counties with the densest concentrations of facilities are shown in black, counties in the next density class are shown in cross-hatch shading, and the third density class is shown in light shading. Counties in the lowest density class are shown in white, but are not outlined.

As illustrated, the largest numbers and concentrations of facilities occur along the Eastern Seaboard; the industrialized southern Great Lakes Region; southern Florida; the Gulf Coast; and major cities of the southwest, California, and the Pacific Northwest. Although results for density show more focus around population centers, especially in the East and Midwest, both maps illustrate that potential Phase II facilities, which represent economic activity in industries, businesses, offices, and government services, are highly associated with population centers, in general. The same generalizations apply whether based on numbers of facilities or density of facilities, indicating that the most populous places tend also to have the greatest concentrations of potential Phase II facilities.

This geographic information on facility location is also presented quantitatively to lend additional insights. As described in the approach in Chapter 2, facility-specific information, including SIC code and county location, was combined with information from the 1990 census, which includes county population and area. These two sources of data were used to analyze the geographic distribution of all facilities in all two-digit SIC codes and of the 90 four-digit SIC codes selected as Group B Phase II categories. The results of this analysis are reported in detail in Appendix G. This section reviews some of the data and highlights important findings for the Group B sectors.

Table 4-9 presents information about the geographic distribution of industrial and commercial facilities in urbanized areas, based on the location with respect to Phase I cities. The columns of the table illustrate the locational relationships among jurisdictions when taking the perspective of expanding from current core (Phase I) cities out to the urbanized areas surrounding them, then on to remaining urbanized areas. Note that some urbanized areas encompass Phase I cities, while others are not contiguous with them.

Table 4-9. Geographic Distribution of Potential Phase II Facilities in Relation to Urbanized Areas

Potential Phase II Facilities Identified		Cumulative % of facilities located within:

[1] This figure is an approximation based on the total number of facilities in SIC codes 10 through 45 after subtracting an estimate of the number of facilities covered under Phase I. Geographical distribution information is based on all facilities in SIC codes 10 through 45 and may not be representative of all classes of facilities in this group. For the geographic distribution of specific SIC codes, refer to Appendix G.

[2] This number is based on SIC codes and does not reflect all feedlots potentially subject to Phase II. The United States Department of Agriculture has estimated that there are approximately 378,000 animal feeding operations between 20 and 1,000 animal units. The facilities identified here should be representative of feedlots in general and allow estimation of the distribution of these facilities as a class.

The rows of the table show each potential Phase II sector and the proportion of industrial facilities located in each of the geographic jurisdictions. Other major groups of industries—all facilities nationally, agricultural and silvicultural categories, manufacturing categories, and all commercial and retail categories—are included in the table to show by comparison how the potential Phase II categories are distributed relative to other major

VOL 12

4225

industrial and commercial sectors. As shown in the table, about one-third of the potential Phase II industrial and commercial facilities within the United States are located within municipalities already covered under Phase I of the storm water program. As a point of reference, agricultural and silvicultural activities (SIC Codes 01xx to 09xx) are less often associated with cities or urban areas. Only about 14 percent of the facilities in these agricultural sectors are associated with Phase I cities. Only about half of them are associated with urban areas, as compared to three-quarters for other more industrial sectors. This distribution holds also for the Phase II sector containing livestock and feedlot activities.

The table also shows the cumulative effect of expanding control of individual sources outward from central cities to encompass larger urbanized areas. In general, 30 percent of facilities are located in regulated Phase I municipalities, an additional 15 percent are located in the urbanized areas associated with Phase I cities, and an additional 15 percent are found in the remaining urbanized areas. Thus, about twice as many industrial facilities are found in all urbanized areas as are found in Phase I cities alone. This result holds for most of the potential Phase II categories. However, there are some exceptions. Petroleum pipelines and distributors show a weaker association with urban areas. It also is not surprising that feedlots are less closely associated with highly urbanized areas.

In another series of analyses, the distribution of industrial facilities was examined according to other geographic areas of potential interest. The results of these analyses are reviewed briefly here; Appendix F contains complete results. Urbanized areas of various population size classes were analyzed. This analysis shows that most facilities (about 45 to 50 percent) are located in the largest urbanized areas (over 250,000 people). An additional 7 percent are found in medium UAs (from 100,000 to 250,000 people). An additional 5 percent are found in UAs containing 50,000 to 100,000 people. These results show that the majority of facilities are located in the largest UAs and only a small increment is gained by including smaller UAs in the regulatory scenario.

For additional perspective on potential Phase II areas of concern, an analysis was conducted on the relationship between facility distribution and fast growing geographic areas. This analysis focused on counties expected to grow by more than 15 percent in the 15 years between 1990 and 2005 (based on Census Bureau projections).[21] The results show that about a quarter of Phase II facilities are located in these fast-growing counties. Of these, almost three-quarters are located in urbanized areas.[22]

Because coastal areas are also a potential concern, as reflected in the CZARA program, another analysis addressed the geographic distribution of industrial and commercial facilities in coastal counties. The definition used by the National Oceanic and Atmospheric Administration and the Bureau of the Census of the Department of Commerce is used in determining coastal counties. Of the 3,141 counties in the United States, 672 are defined as coastal by NOAA and have at least 15 percent of their land area in a coastal watershed or in a coastal cataloging unit (note that this is quite different from the "coastal zone" definition used in CZARA). The results reveal that coastal areas represent an important component of the industrial and commercial base in the country. As many as 44 percent of the potential Phase II facilities are located in coastal areas. Of these, about one-third are in areas that are already regulated in Phase I and almost three-quarters are located in urbanized areas.

The results in this section covered the 18 Group B sectors. The detailed results of this analysis for all two-digit and selected four-digit SIC codes are reported in Appendix G. The four-digit analysis provides a more detailed look at certain subsets within the two-digit groups. Generally, the four-digit breakdowns follow the pattern of the major (two-digit) groups: for the most part, the additional detail about selected four-digit SICs does not reveal much beyond that provided by the major group distribution.

[21] Note that this designation of "growing counties" differs from that used in Chapter 3.

[22] While this result holds in general, petroleum pipelines, wholesale coal and ores, and livestock feedlots appear to be less closely associated with fast growing areas.

4.3 SUMMARY

This section summarizes the findings on individual sources in terms of the main elements identified by Congress for discussion in this report: identification, nature and extent of unregulated discharges. Due to very limited national data on which to base loadings estimates, the discussion of the extent of unregulated storm water discharges is limited to an analysis of the number and geographic distribution of potential Phase II facilities.

4.3.1 Identification of Phase II Sources

The effort to identify sources and categories of storm water discharges for which permits are not required in Phase I of the program resulted in the identification of two general classes of facilities. The first group includes sources that are very similar or identical to Phase I activities but that were omitted from Phase I for a variety of statutory and regulatory reasons (Group A). The second general class of facilities were identified on the basis of potential activities and pollutants that may contribute to storm water contamination (Group B). The report also discussed general sources of storm water contamination which are widespread and not necessarily associated with specific activities or facilities.

Although the difficulty in differentiating Group A facilities from existing Phase I regulated activities makes quantitative analysis difficult, EPA estimates that there are approximately 100,000 facilities in this group. Facilities in Group A, which may be of high priority for Phase II due to their similarity to Phase I industrial facilities, are described and categorized in this report but are not included in the subsequent geographical analysis in the same level of detail as Group B facilities. Activities identified in Group A can be classified into three distinct categories: auxiliary or secondary activities such as vehicle maintenance in support of an unregulated activity; facilities which are related to Phase I facilities but that were intentionally omitted such as POTWs with a capacity of less than 1 MGD; and facilities which were specifically exempted from Phase I by the Transportation Act which include industrial activities owned or operated by municipalities of less than 100,000 population.

Group B consists of over one million facilities in 90 SICs. These 90 SIC categories have been organized into 18 Phase II sectors for the purposes of this report. Of these 18 sectors, the automobile service sector (comprised of gas/service stations (SIC 5541), general automobile repair (SIC 7538), top, body repair (SIC 7532), repair shops and services (SIC 7699), car dealers, new & used (SIC 5511), car dealers, used only (SIC 5521), car washes (SIC 7542), passenger car rental (SIC 7514), truck rental (SIC 7513), parking structures (SIC 7521), and miscellaneous auto services (SIC 7549)), make up more than one-third of the total number of facilities identified in all 18 sectors.

Other general sources of storm water discharges discussed but not clearly identified in the report include parking lots, trash dumpsters, leaking and failing septic systems, and activities related to individual residences such as fertilizer and pesticide application. Facilities in the service sectors, such as banking, finance, insurance firms, and all types of food services, were also discussed but not included in much of the analysis.

4.3.2 Nature of Phase II Sources

There is little quantitative or comprehensive data from a national perspective on the concentrations and loadings of storm water discharges from the industrial, commercial, and retail facilities selected for study as potential Phase II sources. As a result, it is not currently possible to estimate national concentrations or loadings from these sources. It is clear, however, that a significant number of facilities remain in unregulated Phase II categories that conduct operations that have the potential to discharge contaminated storm water. It is possible to classify the unregulated categories into three major groups:

- All of the potential Phase II facilities in Group A may have discharges similar or identical to discharges associated with industrial activity regulated under Phase I.
- Of the facilities in Group B, 80 percent may have discharges similar or identical to discharges associated with industrial activity regulated under Phase I. Facilities in this class have activities analogous to Phase I activities but are covered by different SIC codes. These facilities are also likely to employ substances that could result in

pollutants, such as toxics, metals, solvents and oil and grease, entering storm water.[23] This class includes wholesale operations and vehicle repair and maintenance categories.

- Almost 20 percent of the facilities in Group B had activities that resemble exempted agricultural sources but do not fall under the statutory exclusion of agriculture. These include smaller, currently unregulated feedlots, nurseries, and retailers of farm supply chemicals. Facilities in this class are likely to have activities that result in contributions of pesticides or fertilizers and nutrients to storm water.

In general, industries with large areas of industrial activity and significant materials exposed to storm water exhibited the highest concentrations of pollutants in their storm water discharges. Suspended solids, which can also carry metals and organic pollutants, appear to be the pollutant with the highest concentrations overall. Chemical oxygen demand appears at relatively high concentration levels in some industrial sectors. Oil and grease results were highly variable but highest in industrial sectors associated with transportation and vehicle and machinery maintenance. Results for metals varied across industrial sectors, but those that handle, process, manufacture, or mine metals, as well as landfills, had higher concentrations than other categories. Biochemical oxygen demand, and nutrients (nitrogen and phosphorus) were generally not found at high concentration levels in Phase I data, although results were variable for nutrients.

4.3.3 Geographic Distribution

The geographical analysis shows that the majority of industrial and commercial facilities are located in or near population centers (cities and other urban places). To the extent that they are located in populous, urbanized areas, they are more likely to be served by municipal storm sewers (either separate or combined) than to be discharging directly to streams.

[23] About 2 percent of these facilities conduct other activities that may use toxic pollutants but are not substantially similar to the other facilities in this group. These include research laboratories and some kinds of municipal or governmental entities, which may engage in a wide variety of activities. There is very little information available about the pollution potential of facilities in this class.

In general, about 30 percent of potential Phase II facilities are found within the geographic jurisdiction of a Phase I municipality. An additional 20 to 30 percent of Phase II facilities fall into Census-designated urbanized areas. Thus, nearly twice as many industrial facilities are found in all urbanized areas as are found in Phase I municipalities alone.

Notable exceptions to these generalizations include lawn/garden establishments, feedlots, wholesale livestock, farm and garden machinery repair, bulk petroleum wholesale, farm supplies, lumber and building materials, and petroleum pipelines, which are (relatively) more frequently associated with smaller municipalities or rural areas. Because a larger portion of these facilities are outside the confines of regulated municipalities, a larger portion of storm water discharges from these facilities may be going directly to receiving waters rather than into municipal separate storm sewer systems.

APPENDIX B

OVERVIEW OF IMPACTS FROM STORM WATER DISCHARGES

APPENDIX B - OVERVIEW OF IMPACTS FROM STORM WATER DISCHARGES

This appendix provides an overview of the types of impacts that storm water discharges have on receiving waters. Section B.1 describes the role of storm water discharges and the physical nature of storm water discharges. Section B.2 discusses the types of adverse impacts on receiving waters caused by storm water discharges. Section B.3 gives a general description of adverse impacts on various types of receiving waters that may be associated with storm water discharges.

B.1 THE PHYSICAL NATURE OF STORM WATER DISCHARGES

B.1.1 The Hydrologic Cycle

The hydrologic cycle is the continuous, unsteady circulation of water from the atmosphere to the Earth's surface and back to the atmosphere. Major features of the hydrologic cycle include precipitation, snow melt, surface runoff and drainage, infiltration, interflow, ground water recharge, and evapotranspiration. Each of these factors is discussed briefly below:

- **Precipitation**—Precipitation occurs as rain, sleet, hail, and snow. Precipitation is one of the key factors in analyzing storm water discharges because it is the initiating force in creating a discharge. Precipitation events are highly variable in nature and extent. As discussed in more detail below, the nature of precipitation patterns varies greatly in different parts of the country. Seasonal patterns also are usually important considerations.

- **Snow Melt**—When precipitation falls in the form of snow, surface runoff does not occur until the snow melts. In this case, the rate and volume of surface runoff discharges is controlled by the rate of snow melt.

- **Infiltration**—Infiltration occurs as rain water passes into the soil. The ability of soil to infiltrate water depends on a number of factors, including soil properties, soil

VOL 12

4261

R0037569

moisture content, vegetation cover, and the presence of impervious structures, such as pavement. Water that infiltrates into the soil can be subject to interflow, ground water recharge, and evapotranspiration.

- **Interflow**—Interflow (i.e., subsurface flow) occurs when water infiltrates into the soil and flows through the soil above the water table. Interflow can occur until water enters a drainage ditch, storm sewer, surface receiving water, or the ground water.

- **Ground Water Recharge**—Ground water recharge occurs when water infiltrates into the soil and enters the water table. Ground water then flows toward and into natural or artificial channels or other receiving waters. The flow of ground water to surface waters maintains flows in natural and manmade drainage ways and impoundments during dry weather conditions.

- **Evapotranspiration**—The term evapotranspiration describes two processes—evaporation and transpiration. Evaporation is the process where liquid water changes to a vapor. Transpiration occurs when water moves through vegetation and is then evaporated.

- **Surface Runoff and Natural Drainage**—Surface runoff (i.e., overland flow) occurs when water generated from precipitation or snow melt moves across the ground to a natural or constructed channel or some other receiving water. Natural drainage defines the flow of water through naturally occurring receiving waters and into the ocean. Because the natural drainage system contains a wide range of receiving waters, including wetlands and intermittent streams, it is often difficult to determine the point at which surface runoff ends and natural drainage begins. Although such distinctions may be important in our legal system, they have limited importance in the workings of the hydrologic cycle.

VOL 12

4263

B.1.2 Impacts of Land Use Activities on the Hydrology of Watersheds

Typically, a watershed is a geographic region in which surface waters flow towards a common receiving point such as a stream, river, lake, or estuary. The natural drainage system of a watershed may comprise many types of surface water features, including wetlands, intermittent streams, small perennial streams, and larger receiving waters. In other uses of the term, watersheds may also be defined based on ground water flows and aquifers.

As watersheds are developed for urban or agricultural uses, resource extraction, or other purposes, the natural drainage features of the water are often altered. Wetlands are dredged or filled, reducing the natural storage capacity of the drainage system, which, prior to its loss, damped peak flows associated with storm events. Smaller streams can be channelized, rip-rapped, or diverted into underground culverts, all of which allow the flow rates in the channel to increase.

The hydrology of the watershed also is changed by activities occurring on land. The natural drainage features of undeveloped land slow the flow of runoff by incorporating rainfall into the natural hydrologic cycle. Many types of development cause an increase in the volume of surface runoff and its rate of discharge. A given storm event will yield more runoff with a faster rate of discharge for a developed area than for an undeveloped area of the same size. These increases in the rate of flow and the total volume of flow often have a decided effect on pollutant loads, erosion rates, and flooding.

A number of factors can increase the volume and rate at which runoff flows from a developed site. Clearing land removes the vegetation cover that previously intercepted precipitation before it hit the earth. The thick humus layer associated with the vegetative cover is often removed or eroded away during grading activities, decreasing the ability of the surface to infiltrate and retain precipitation. The land is graded to make the surface smoother by removing natural depressions. Site slopes may be increased as part of terracing to improve site drainage. Wetlands, which may have previously soaked up water associated with peak flows, are drained or filled. Impervious structures, such as roads, parking lots, driveways, rooftops and sidewalks, are built. In other heavily used areas, soils become compacted and lose their ability to infiltrate precipitation.

After development has occurred, the natural drainage system (e.g., streams, wetlands, and other receiving waters) is often unable to handle the higher volume flows, resulting in high erosion rates or flooding. Drainage systems that have undergone these changes often need additional "improvement" from channelization or lining projects. In addition, streams are often directed through underground culverts.

The same characteristics of land development that cause higher peak flows also cause less infiltration of rainfall to recharge ground water supplies and a lowering of the water table. One result of lowered water tables is that surface stream flows during dry weather can be lowered significantly. Lower flows during periods between storms may significantly affect the aquatic habitat and the ability of a stream to dilute toxic spills or other dry weather pollutants within the stream system (Bellevue NURP). In some cases, the installation of storm sewers in a watershed results in small, previously perennial, streams running dry several times a year (Long Island NURP).

B.1.3 General Physical Characteristics of Storm Water Discharges

Storm water discharges are diffuse in nature; discharges in a watershed are generated by an extremely large number of points. Three characteristics of storm water discharges are particularly important when analyzing potential impacts of these diffuse sources within a watershed. Storm water discharges 1) may affect broad portions of a watershed, 2) can have high volumes, and 3) are generally of limited duration.

B.1.3.1 Effects on Broad Portions of a Watershed

Unlike many other major point source discharges that are directed to larger receiving water bodies or to relatively remote offshore locations, storm sewers discharge to essentially all of the portions of the drainage system within developed areas of the watershed. As a

VOL 12

4264

result, the impacts of storm water discharges, although more subtle, may be more widespread and potentially may affect a greater degree of the natural drainage system than traditional point source discharges.

Perhaps the widespread nature of storm water discharges is most evident when considering large urbanized areas.[1] Essentially all receiving waters in urbanized areas receive storm water discharges from some type of urban land, regardless of the sensitivity of the receiving water to potential impacts. This is because typical storm water management practices attempt to drain water from the land as soon as possible and discharge it to the nearest receiving water whether or not the receiving water has the ability to handle increased flows and pollutant loads.

In heavily developed areas, urbanization results in widespread alteration or destruction of much of the natural drainage system. Many of wetlands in these areas are drained or filled, while smaller streams can be heavily modified. These alterations to the natural drainage system decrease the system's ability to remove pollutants, function as habitat, and handle large flows. The cumulative impacts of these widespread effects can potentially affect larger downstream components of the watershed.

B.1.3.2 High Volumes/Velocities

A typical storm may generate a large number of storm water discharges within a watershed. The cumulative volume of these discharges may be high relative to the typical volume of flow of receiving waters. These high volume discharges may dramatically increase flow velocities in streams and drainage channels. High volume storm water discharges and resultant rapid stream velocities cause the combined effect of increasing:

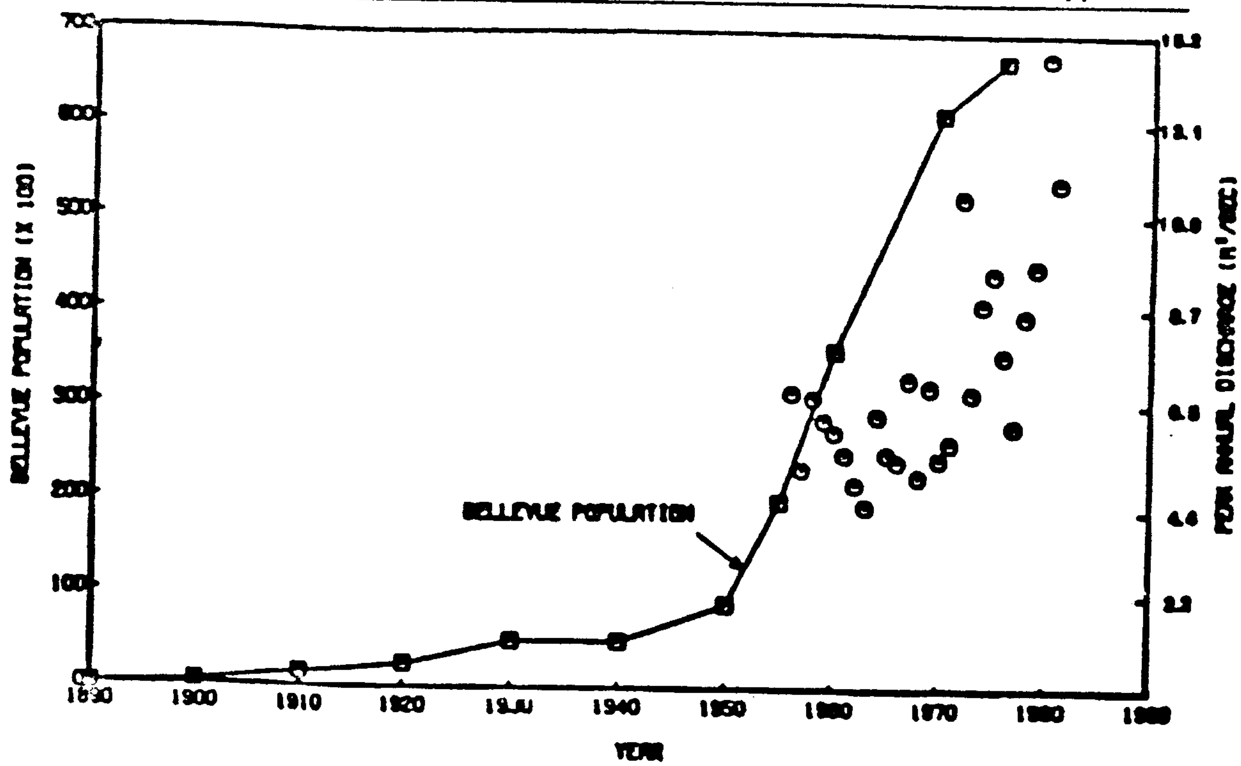
[1] As discussed in more detail in Chapter 3, the 366 urbanized areas designated by the Bureau of Census range in area from 17 square miles (Grand Forks, ND-MN) to more that 2,800 square miles (New York, NY-NJ).

- Pollutant loads
- The ability of discharges to erode the land and carry pollutants off the land
- The ability of streams to resuspend pollutants in bottom sediments and erode stream beds and stream banks
- The ability of streams to carry pollutants to slower flowing water bodies where pollutants may accumulate
- The need for stream channelization, installation of concrete walls, riprap, or other modification projects.

Figure B-1 shows the relationship between population and the volume of the peak annual flow in the Bellevue, Washington, watershed. The volume of the peak annual flow in the watershed almost doubled as the population in the city increased from 10,000 to 67,000. Peak flows that used to return every 10 years can now be expected to return at least every other year. Although the monthly average total volume of flows in the watershed increased only slightly over pre-urbanization years, the volume of flows during peak events increased two to three times as a result of urbanization. This increase in the volume of the peak annual watershed flow volumes increased stream bank erosion and stream bed scour, as well as the frequency of flooding. The increase in intensity of runoff has created unstable stream banks, which have eroded at a rapid rate. The stream channel is narrower and deeper than those of typical undisturbed streams serving similar watersheds. Pools and other sites along the stream bed that had slowed flows in the past have been removed by the higher flows.

B.1.3.3 Limited Duration

Although storm events and the resulting storm water discharges are of limited duration, pollutants in these discharges can cause both short- and long-term impacts on receiving waters. Short-term impacts generally occur during or shortly after a storm event. These impacts are usually caused by high levels of pollutants associated with the storm water discharges. Materials other than storm water, such as spills or dumped material, that discharge from a separate storm sewer may also cause short-term water quality impacts.



Source: Scott, Steward, and Stober

Figure B-1. Population of Bellevue and Peak Annual Discharge in Kelsey Creek (O). Data From U.S.G.S. and Bellevue Planning Dept. 1977

Long-term water quality impacts associated with storm water may be caused by pollutants accumulating in a watershed or by repeated exposures to pollutants from a large number of events. In addition, habitat destruction and other physical impacts, such as stream bed scour, can occur over a long period of time.

Although individual storm events are of relatively short duration, receiving waters may be affected by storm water discharges for time periods that are significantly longer than the storm event. The length of time that pollutants from storm water discharges remain in a receiving water will depend on four factors: 1) the duration of the storm event, 2) the size of the watershed, 3) flow rates in the receiving water, and 4) the tendency for pollutants to accumulate in bottom sediments.

VOL 12

4267

Small streams with small drainage basins respond immediately to the pollutants in storm water discharges, with pollutants passing through at relatively high velocities as a discrete pulse. High pollutant levels in large flowing rivers may occur at downstream locations for an extended period of time. Pollutant concentrations in large rivers initially rise with the onset of a storm event. After a storm is over, pollutants from storm water discharges to feeder streams draining upstream portions of a watershed can keep pollutant levels elevated at downstream locations of the river for an extended period of time. Pollutants in storm water discharges from upstream land uses may continue to impact a location for several days after the event.

Receiving waters with slower flows and longer resident times, such as impoundments, lakes, reservoirs and estuaries, may be affected for long time periods by pollutants from short-duration storms. Hence, the limited duration of individual storm water discharge events is of less importance when considering potential impacts on these receiving waters. In these receiving waters, slower velocities will result in many types of pollutants accumulating in bottom sediments where they may cause long-term impacts.

B.2 TYPES OF ADVERSE IMPACTS ASSOCIATED WITH STORM WATER DISCHARGES

Table B-1 summarizes the pollutant classes and pollutant sources identified in the 1992 National Water Quality Inventory as major causes of water quality impairment. The National Water Quality Inventory summarizes information regarding water quality impacts that is submitted by States in Section 305(b) reports. The summary generally identifies conventional pollutants, such as nutrients, sediment (siltation), oxygen demand, and pathogens, as the leading causes of surface water impairment reported by the States. Toxicity, caused by metals, priority organics, pesticides, oil and grease, and inorganic pollutants, is also identified as a major cause of impairment.

Table B-1. Top Five Pollution Sources and Contaminants

Five Leading Sources of Water Quality Impairment			
Rank	Rivers	Lakes	Estuaries
1	Agriculture	Agriculture	Municipal Point Sources
2	Municipal Point Sources	Urban Runoff/Storm Sewers	Urban Runoff/Storm Sewers
3	Urban Runoff/Storm Sewers	Hydrologic/Habitat Modification	Agriculture
4	Resource Extraction	Municipal Point Sources	Industrial Point Sources
5	Industrial Point Sources	Onsite Wastewater Disposal	Resource Extraction
Five Leading Causes of Water Quality Impairment			
Rank	**Rivers**	**Lakes**	**Estuaries**
1	Siltation	Metals	Nutrients
2	Nutrients	Nutrients	Pathogens
3	Pathogens	Organic Enrichment/Low DO	Organic Enrichment/Low DO
4	Pesticides	Siltation	Siltation
5	Organic Enrichment/Low DO	Priority Organic Chemicals	Suspended Solids

Source: National Water Quality Inventory, 1992 Report to Congress, EPA, 1994.

The National Water Quality Inventory primarily addresses larger receiving water bodies and does not address major portions of the natural drainage system of most watersheds, such as smaller feeder streams and wetlands.

This section briefly describes the major classes of pollutants associated with water quality impacts. For each class, special considerations regarding storm water discharges are discussed. Three additional pollutant classes, acidity, temperature, and floatables, that are of special concern when addressing storm water discharges are also discussed.

VOL 12

4269

B.2.1 Siltation/Sedimentation

Siltation from sediment pollutant loads can cause a broad range of interrelated impacts in receiving waters, including the following:

- **Loss of Benthic Habitat**—Increased stream flows and velocities produced by high volume storm water discharges may cause channel scour and bank erosion that result in habitat destruction. Suspended solids are deposited as sediment bars or sediment blankets in pools and other areas of reduced stream energy. These blankets can smother benthic organisms, including the eggs and immature forms of free-swimming organisms (Gupta, 1981; Novotny and Chesters, 1981).

- **Reduced Water Storage Capacity**—Increased sediment loads reduce water storage capacity in reservoirs (Novotny and Chesters, 1981). Nationwide, the average annual depletion rate of reservoir storage capacity caused by sedimentation is estimated at 0.2 percent (Tourbier, 1981). Sediment loads also decrease the depths of streams, which decreases the retention and conveyance capacity of streams and may result in increased flooding.

- **Impaired Oxygen Exchange**—Increased turbidity levels impair the ability of aquatic organisms to obtain dissolved oxygen from the water by interfering with the gill movements and associated water circulation (Novotny and Chesters, 1981).

- **Decreased Light Penetration**—The depth of light penetration into surface waters is sharply diminished by turbidity. As a result, photosynthetic activity and food sources are reduced. Loss of submerged aquatic vegetation may also remove habitat for juvenile fish and shellfish.

- **Impaired Navigation**—Accumulated sediments in river channels limit the passage of deeper draft boats, preventing navigational access or increasing the frequency of required channel maintenance dredging (Gupta et al., 1981; Novotny and Chesters, 1981). In some locations, sediments are so contaminated with pollutants that they should be handled as hazardous wastes, which dramatically increases disposal costs. Dredging activities result in re-suspension of pollutants in the sediment, causing additional water quality and aquatic habitat impacts (Novotny and Chesters, 1981).

- **Increased Water Treatment Costs**—Sediments can increase the costs of treating potable water supplies. Inadequate sediment removal may limit the germ-killing effects of chlorination.

- **Accumulation of Pollutants**—Many of the pollutants associated with many types of storm water discharges become chemically or physically bound with sediment particles. As these particles settle, the attached pollutants also sink (Brown et al., 1985; Novotny and Chesters, 1981). Sediments with attached pollutants can act as a source of contamination to the overlying water, to the benthic biota, and to the food chain. Over long periods of time, sediments may accumulate such high levels of toxics and other pollutants that exceedances of ambient water quality standards may occur in the water columns, increasing exposure of organisms to toxic chemicals (Harrington, 1986). Oxygen demanding pollutants in sediment deposits may also create oxygen deficits during and after storm water discharge events (Heaney and Huber, 1984; Mancini and Plummer, 1986; Novotny and Chesters, 1981).

- **Resuspension of Pollutants**—Highly variable flows in receiving waters can resuspend sediments, thereby increasing water column concentrations of those pollutants that had accumulated in bottom sediments. The repetitive process of deposition, re-suspension, and re-deposition of sediments may result in pollutants associated with sediments taking a long time to pass through a receiving stream (Novotny and Chesters, 1981).

B.2.2 Nutrients

Nutrients support and stimulate aquatic plant life. Natural nutrient cycles may be altered by land use activities within a watershed. Excessive nutrients overstimulate the growth of

VOL 12

4271

aquatic plants, which may result in low oxygen levels, accelerate eutrophication, cause unsightly conditions, interfere with navigation, interfere with treatment processes, and cause unpleasant and disagreeable tastes and odors. Eutrophic conditions are evidenced by surface algal scums, reduced water clarity, odors, and dense algal growth on shallow water substrates (Schueler, 1987). Algal blooms block light from submerged aquatic vegetation, which may remove habitat for juvenile fish and shellfish. After blooms or at the end of a growing season, the decomposition of dead vegetation may cause reduced oxygen levels. Reduced oxygen levels may, in turn, cause fish kills and mass mortality of benthic organisms.

Excessive nutrients may have more adverse effects in surface water bodies that have slow flushing rates, such as slow moving rivers, lakes, and estuaries. Nutrients delivered during storm events settle to sediments of such waters. Once in sediments, the nutrients can be solubilized or re-suspended by anaerobic conditions, currents, changes in concentration gradients, or the mixing effects of boat wakes (Field and Turkeltaub, 1981).

Aquatic vegetation requires both nitrogen and phosphorus to grow. Excess quantities of nitrogen are commonly present in fresh water, so plant growth is usually controlled by the levels of phosphorus input (Schueler, 1987). In marine waters, however, phosphorus is often in greater supply, and plant growth is controlled by nitrogen concentrations. In either case, when the controlling nutrient is added, greater plant growth is expected.

Several forms of phosphorus occur in the aquatic environment. Major forms of phosphorus include orthophosphorus (OP), dissolved or soluble phosphorus (DP), particulate phosphorus (PP), and total phosphorus. Orthophosphorus is the form immediately available for algal growth. Particulate phosphorus is considered to be potentially available after conversion to OP. During stream transport, OP is likely to become incorporated into the particulate fraction. A portion of the phosphorus bound to sediment particles can also be released as OP. Exchange between available and potentially available forms continues though processes of sediment and algal uptake and release. Transport distance from phosphorus sources to impacted receiving waters is recognized as a major factor in determining the availability and timing of load delivery. Strict control of phosphorus levels from direct and proximal discharges to affected receiving waters is recommended because of the high level of OP delivered from these discharges.[2]

Nutrient loading is directly related to the frequency of runoff events in developed watersheds and can vary by a factor of 3.5 between wet and dry years at the same location (Lung, 1986). High quantities of nitrogen and phosphorus may be transported in surface run-off in the dissolved form or attached to sediments; the relative significance of these two forms may vary seasonally, reflecting differing winter and summer runoff conditions (Jones, 1986; Urbonas and Roesner, 1986). Nitrogen and phosphorus concentrations in storm water from residential and commercial areas may occur at levels sufficient to stimulate excess growth of algae and aquatic macrophytes (i.e., eutrophication), partly because most of these nutrients occur in soluble forms that are readily assimilated by plants (Schueler, 1987).

Nitrate (generally the most stable form of nitrogen) at levels above the drinking water standard of 10 milligrams per liter can cause methemoglobinemia in infants under six months. This rare, but potentially fatal disease limits the oxygen carrying ability of the blood.

B.2.3 Organic Enrichment/Oxygen Demand

Aquatic organisms, such as fish and water-dwelling insects, require minimum levels of dissolved oxygen (DO). Excessive oxygen demanding pollutants can lead to periods of oxygen sag, which may cause fish kills and create anoxic conditions accompanied by foul-smelling odors. Oxygen levels in receiving waters can be lowered by the decomposition of organic matter by microorganisms, by the chemical oxidation of material, or by aquatic vegetation, which uses more oxygen at night than it produces.

Oxygen demand is the term applied to pollutant loads that result in reduced dissolved oxygen levels. The two parameters most commonly used to describe the oxygen demand of

[2] *Phosphorus: A Summary of Information Regarding Lake Water Quality*, IL EPA, August 1986.

pollutants are the 5-day biochemical oxygen demand (BOD5) and chemical oxygen demand (COD). BOD measures oxygen demanding substances that can be metabolized by bacteria and is an indicator of biodegradable organic matter. COD measures oxygen demanding substances that react with an oxidizing chemical in a heated acid bath. COD is an indicator of both organic matter and reduced inorganic chemicals. Of the two, COD is more accurate for the purpose of comparing the oxygen demand of storm water discharges to the oxygen demand of other types of discharges. The BOD5 test underestimates the true oxygen demand of storm water because the heavy metals in the storm water slow the bacterial action used in the test.

Storm water runoff may contain both organic and inorganic pollutants that consume oxygen in receiving waters. Storm water discharges generally occur on overcast days when the amount of sunlight available to oxygen producing plants in water is limited. Lower oxygen production rates increase the adverse impacts of oxygen demanding pollutant loads. Much of the oxygen demanding pollutant load of many types of storm water discharges is associated with suspended solids, which may form deposits in receiving waters. These deposits may result in long periods of low dissolved oxygen through gradual decomposition or may re-suspend during later runoff events. The impacts of oxygen demanding pollutants may be more dramatic in shallow, slow-moving waters due to limited aeration and the tendency of these pollutants to accumulate in bottom sediments of slow-moving waters.

Dissolved oxygen depletions may occur at times substantially different from the actual storm event, which originally discharged the oxygen demanding pollutants. Re-suspension of sediments with attached oxygen demanding pollutants during high flows worsen and delay the dissolved oxygen depletions.

B.2.4 <u>Pathogens</u>

Pathogens are disease-causing organisms, including viruses and some bacteria. Waterborne pathogens may be transmitted to humans or animals through direct recreational contact, drinking water supplies, or through eating contaminated shellfish. Major pathogen sources include human and animal wastes.

Separate storm sewers, unlike combined storm sewers, are not designed to carry sanitary sewage. However, pathogens may enter separate storm sewers from leaking sanitary sewers, illegal cross connections with sanitary sewers, and malfunctioning septic tanks. In addition, runoff can pick up pathogens from animal wastes on the land. Conditions inside a storm sewer system are often conducive to pathogen reproduction.

Due to difficulties and expenses associated with measuring pathogens directly, bacteria, including total coliform, fecal coliform, and fecal streptococci, are used as indicators of pathogens even though many of these bacteria are harmless. EPA studies indicate that although fecal coliforms are a good indicator of human pathogens for POTW discharges, they are inadequate indicators of human pathogens for many types of storm water discharges (51 *FR* 8012, March 7, 1986). However, most State and local health criteria for recreational contact and shellfish are based on fecal coliform levels, partially due to the low cost of testing procedures. As a result, storm water discharges are responsible for a significant number of restrictions placed on recreational uses and shellfishing.

B.2.5 Toxicity (metals, toxic organics, pesticides, inorganics, and oil and grease)

A wide range of chemicals may exhibit toxicity. Five major classes of chemicals that have toxic impacts recognized in the National Water Quality Inventory are metals, toxic organics, pesticides, inorganic pollutants, and oil and grease.

Toxic impacts may be classified in terms of acute and chronic effects. Acute toxicity refers to lethal concentrations or doses of toxic materials, which result in death of aquatic organisms in a relatively short time. Chronic toxicity refers to impacts, such as the formation of tumors, lowered reproductive, growth, or survival rates, that occur after a longer exposure to toxic substances. Bioaccumulation, or the accumulation of toxic chemicals in tissues of organisms, is another long-term effect of toxic substances that may affect the organism

VOL 12

4275

directly exposed to the chemical, or other animals, including humans, that consume contaminated organisms. For a given chemical constituent (or a mix of constituents) chronic toxicity occurs at lower concentrations than the concentrations that may cause acute effects. However, the exposure time necessary to trigger chronic effects is longer than the exposure times that cause acute effects.

Pollutants that are highly resistant to natural degradation processes are referred to as conservative pollutants. Conservative pollutants have a greater opportunity to cause chronic toxic effects or to bioaccumulate in organisms. Conservative pollutants also have the potential for wider dispersal in the environment through bioaccumulation and subsequent transfer in living organisms, such as fish, plankton, and fish eating birds and mammals. Toxic conservative pollutants include trace metals and some organic compounds, such as chlordane, polychlorinated biphenyls, and other halogenated hydrocarbons. Metals do not degrade, and some organic compounds degrade so slowly that they may remain in sediments for decades.

Many of the toxic metals and other toxic constituents in storm water discharges are attached to suspended solids in the discharge and settle out and accumulate in the bottom sediments of receiving waters where they may persist for long periods of time. Toxics concentrated in bottom sediments may cause adverse impacts on benthic organisms, may become resuspended during high flows resulting from other large storm events, or may dissolve into the water as parameters such as pH and dissolved oxygen change. Accumulated pollutants in bottom sediments may also adversely affect fish during periods of continuous low flow.

B.2.6 Flow Alterations

Activities on the land may cause dramatic changes to the natural hydrologic cycle. Changes in peak flow rates of receiving streams and associated increases in flow velocities cause changes in the stream shape and structure. Increased flow velocities have a greater ability to erode stream beds or stream banks. Stream channels may either be widened or made deeper, with large amounts of soils being swept downstream, forming shifting sandbars

VOL 12

4276

or other sediment deposits. Streams may widen to two to four times their pre-development width if storm water is uncontrolled from developed areas. High erosion rates adversely affect habitat by destroying benthic structures and habitat. High creek flows may also sweep poor swimming fish from the creeks and transport leaf material at higher rates, limiting the availability of food for macroinvertebrate organisms. Channelization projects that drain natural wetlands for development may dramatically alter natural flow patterns. These projects will greatly diminish or destroy the pollutant removal and flow attenuation abilities of the wetlands.

Increased flows associated with urbanization are often accompanied by the installation of extensive channelization projects to increase the flow capacity of the water course and limit erosion damage during storm conditions. Typical channelization projects include riprap, concrete retention walls or lining along stream banks, channel realignment, and diversion of streams through culverts.

After the initial construction of a channelization project is completed, both direct and indirect sources of pollution occur. Channelization projects reduce channel roughness to further increase flow velocities. Increased flow velocities that exceed the stability velocities of the bottom or bank materials cause erosion or scour. Such activity degrades the channel and furnishes sediment for stream transport, destroys natural habitats, and detracts from the aesthetics of the stream. In general, the more extensive the modification, the more damage caused to habitat areas. For example, concrete lining of channels eliminates habitat areas and aesthetic values for practical purposes. Increased channel dimensions may deprive the stream flow of shade from trees along streams banks, resulting in increased water temperatures. These types of projects may worsen downstream flood problems where storm flows are unable to spread out onto a flood plain and increased velocities increase erosion along unprotected banks downstream.

B.2.7 Acidity

Aquatic life may only be supported in a limited range of pHs. Receiving waters that are highly acidic (have a low pH) may be totally devoid of life. In other receiving waters, fish kills may be caused by periodic highly acidic conditions. Periodic episodes of acidity may be particularly harmful to juvenile fish, which tend to be more sensitive and reside in the smaller streams of a watershed, which are more likely to experience wider pH swings. In addition, acidic rain generally will have higher concentrations of heavy metals and other pollutants, which leach under acidic conditions.

Acidity in storm water may be caused by two sources—air pollutants and certain land use activities. Mining is the land use with the most well known acidic storm water discharges. Coal mining in the eastern United States generally involves coal that is high in sulfur and is historically associated with some of the most dramatic water quality impacts caused by acidity.

Nitrogen oxides (NO_x) and sulfur dioxide (SO_2) are the primary air pollutants that result in acid rain and, hence, highly acidic storm water. Acid rain occurs when SO_2, emitted primarily by electric utilities fired by eastern coal, and nitrogen oxides (NO_x), emitted primarily by transportation sources and utilities, are deposited in the form of wet or dry deposition. Rain in the western United States typically has a regional pH of 5.5 or above. Rain in the eastern United States is more acidic, with regional pH values below 4.2 in some regions. More than 80 percent of the SO_2 emissions in the United States originates in the 31 States bordering or east of the Mississippi River, with a heavy concentration from States in or adjacent to the Ohio River Valley. These airborne emissions are transported by prevailing winds to the east. Figure B-2 indicates regional acid rain patterns.

Several aspects of urbanization tend to create local conditions that may make receiving waters susceptible to impacts from acidity. High levels of airborne SO_2 and NO_x in large urbanized areas increases the acidity of the rainfall in the urbanized area to levels above those typically found for the region. Runoff from paved surfaces and other impervious surfaces

Data from four networks are plotted: Canada, CANSAP (circles) and AAPN (squares); United States, NADP (circles) and MAP3S (squares).

Source: Barrie and Hales, 1984.

Figure B-2. Spatial Distribution of the Precipitation-Amount-Weighted Annual Mean Hydrogen-Ion Concentration (expressed as pH) in North America in 1980

may have little or no opportunity to contact soils that may buffer the acidity of the rainfall. In urbanized areas with acidic rain, higher runoff volumes and rates associated with the urban development can increase the acidity of receiving streams rapidly and to high peak acidity levels. This results from more acid being deposited to receiving streams in a shorter amount of time.

B.2.8 Temperature

Increased temperature may have detrimental effects on fish and other aquatic life during various stages of their life cycle. Water holds less oxygen as it gets warmer, which may affect habitat and make the water more susceptible to oxygen demanding pollutants. Sustained water temperatures in excess of 70°F are considered stressful or lethal to many cold water fish species and stream insects. The availability of food, attendant life cycle chemistry, and water quality changes are all affected by water temperature.

During warm weather, the temperature of storm water discharges is generally higher than receiving water temperatures. High volumes of runoff from hot paved surfaces and rooftops may cause a rapid increase in surface water temperatures. Discharges from storm water management devices, which retain collected runoff in unshaded ponds for extended time periods, may also increase stream temperatures.

B.2.9 Floatables, Including Plastics

A large percentage of the litter and plastics that is found on land, if not removed, will eventually be flushed, swept, or blown down a storm sewer. Plastics, metals, and many other types of floatables degrade at extremely slow rates, increasing the time that they remain in receiving waters.

Litter and other floatables degrade aesthetic values, which play a role in the recreational uses of receiving waters, property values of nearby lands, and other broad community-level values. Economic losses caused by the aesthetic degradation of recreational areas, such as beaches, are significant. Plastic debris presents hazards to wildlife. Ingestion of plastic material by turtles and seabirds appears to present the biggest threat to wildlife. Floatables and plastics may also clog outlet structures of various types of storm water management devices, resulting in flooding or other system malfunctions.

B.3 ADVERSE IMPACTS BY TYPE OF RECEIVING WATER

Impacts on receiving waters associated with storm water discharges may be discussed in terms of three general classes: 1) short-term changes in water quality, 2) long-term water quality impacts, and 3) physical impacts.

Use impairment of receiving streams often is caused by a combination of all three types of impacts. Physical impacts and short-term water quality changes are generally more critical than long-term water quality impacts for receiving waters with relatively short residence times (such as smaller streams and rivers). Receiving waters with long residence times (lakes, estuaries) are generally more sensitive to long-term water quality changes, although certain physical changes, such as loss of reservoir capacity due to siltation, can be important.

Short-term changes in water quality occur during and shortly after storm events. Examples include periodic dissolved oxygen depressions due to oxidation of pollutants, short-term increases in the receiving water concentrations of one or more toxic pollutants, high bacteria levels, and high acidity. These conditions can result in fish kills, loss of submerged macrophytes, and other temporary use impairments.

Long-term water quality impacts are caused by the cumulative effects associated with repeated storm water discharges. These impacts often result from the cumulative effects of pollutants from a number of different types of sources. When evaluating long-term impacts, the cumulative and relative effects of seasonal and long-term pollutant loadings from all relevant sources (e.g., storm water, publicly owned treatment works, industrial discharges, nonpoint sources, atmospheric deposition, in-place pollutants) should be considered.

Examples of the long-term water quality impacts that storm water discharges may cause or contribute to include depressed dissolved oxygen caused by the oxygen demanding pollutants in bottom sediments, biological accumulation of toxics as a result of uptake by organisms in the food chain, chronic toxicity to organisms subject to repeated exposures of toxic pollutants, destruction of benthic habitat, loss of storage capacity in receiving waters, and increased lake eutrophication. Long-term water quality impacts are also caused by pollutants attached to suspended solids that settle in receiving waters and by nutrients that enter receiving water systems with long retention times. In both cases, long-term water quality impacts are caused by increased residence times of pollutants in receiving waters. Long-term water quality impacts of pollutants from storm water discharges may be manifested during critical periods other than during storm events (e.g., during low stream flow conditions and/or during sensitive life cycle stages of organisms).

Physical impacts may occur due to the erosional effects of high-volume flows and high-stream velocities that occur after the natural hydrologic cycle is altered. These changes are often accompanied by the installation of engineered structures, such as concrete walls or underground culverts, which may further degrade the habitat and aesthetic values of the receiving water. In addition, if ground water recharge is limited by the placement of impervious structures on the land, dry weather base flows may be lowered to the detriment of the receiving water.

B.3.1 Rivers and Streams

The *National Water Quality Inventory - 1992 Report to Congress* (EPA, 1992) indicates that the States identified the most extensive causes of impairment in the Nation's rivers as siltation (affecting 45 percent of impaired river miles), nutrients (affecting 37 percent), pathogen indicators (affecting 27 percent), pesticides (affecting 26 percent) organic enrichment/low dissolved oxygen (affecting 24 percent), and metals (affecting 19 percent). Discharges from storm sewers are identified as affecting 11 percent of the impaired river miles. The assessments focused primarily on larger streams and rivers and did not address many of the heavily degraded small streams found in urban areas and elsewhere.

The effect of human activities on the natural hydrologic system may be most evident on smaller streams. Development of a site may dramatically increase the volume and the maximum discharge rate of storm water discharges. Where a sufficient number of sites within the drainage basins of smaller rivers and streams occurs, the stream may experience increases in the magnitude and frequency of flooding, as well as extremely high-stream velocities associated with storm events.

Such changes in the hydrology of a stream may result in accelerated stream bank or stream bed erosion. Such erosion may cause or contribute to a number of generally detrimental effects, including widening or deepening of the stream channel, elimination of pools and other structures in the stream, and shifting of gravel or sand bars. In addition, base flows may be lowered during dry weather.

Streams that have experienced increased flooding or peak velocities often undergo a high degree of additional human flow modification, including channel excavation, lining, realignment, or diversion through underground culverts, which may have, for all practicable purposes, destroyed both fish and wildlife habitat and natural aesthetics. In many cases, highly modified streams are considered to be part of the storm sewer system.

Pollutant concentrations in smaller streams and rivers may experience relatively short-duration increases due to storm water discharges. However, in smaller streams, the concentration of pollutants may be almost as high as the concentrations found in discharges where dry weather base flows are significantly lower than wet weather flows and provide only limited dilution.

Larger rivers often respond slower to storm events than do smaller streams. After a storm event hits a large drainage basin, a given segment of the river may experience degraded water quality for several days because a single location on the river is sequentially affected by pollutants from different upstream sources caused by the same storm. For example, a segment may be influenced by urban runoff, only to then be influenced by agricultural runoff generated upstream of the storm water source, followed by silvicultural runoff from the river's headwaters.

In many streams, flow velocities slow substantially with increases in stream width or decreases in stream gradient. At these points, sedimentation of fine particles and associated pollutants result. The settled sediments can act as a reservoir for pollutants affecting the water column and the food chain long after the rain has ceased. In addition, disturbance of the deposited sediments by scouring from storm water discharges or combined sewer outfalls, navigation, construction, or dredging may re-introduce the sediments and their pollutants to the water column. The result can be a recurrence of adverse impacts originally associated with the storm water discharge.

The degree of impact on the river or stream depends on a number of factors, including the frequency and duration of the storm water discharges, the quality and quantity of storm water discharges, the occurrence of other wet weather discharges (combined sewer overflow discharges), and the quantity and quality of the base flow (dry weather flow) of the stream. Because larger rivers receive pollutants from a wide variety of sources in urbanized areas, the quality of the base flow may be marginal or poor, thereby increasing the sensitivity of the receiving stream to storm water discharges. In streams with very low base flows, on the other hand, the storm water discharge may be the major determinant of the water quality of the stream.

B.3.2 Lakes and Reservoirs

The most extensive causes of use impairment in lakes are metals (affecting 47 percent of impaired acres), nutrients (affecting 40 percent), organic enrichment/low dissolved oxygen (affecting 34 percent), siltation (affecting 42 percent of impaired acres), and priority organic chemicals (affecting 20 percent). The States reported that 63 percent of lake acres assessed were not fully supporting designated beneficial uses. In addition, the States reported that discharges from separate storm sewers affect 24 percent of the impaired acres of lakes excluding the Great Lakes. Onsite wastewater disposal impaired 16 percent of the impaired acres. For the Great Lakes, discharges from storm sewers were identified as affecting 11 percent of the impaired shore miles, and land disposal 31 percent of impaired shore miles.

Compared with rivers and streams, lakes and reservoirs have long residence times. The time scale of water quality impacts and recovery may be on the order of years, decades, or even centuries (Manning et al., 1977). The impacts that occur are more likely to be the result of seasonal or annual loadings of pollutants rather than loadings from individual events. Lakes and reservoirs, with longer residence times and slower flow rates, tend to become sinks for many pollutants that attach to the sediments typically carried by storm water. Longer residence time, coupled with poorer aeration, also increases the impacts of nutrients and other oxygen demanding pollutants. The peak concentrations of pollutants in storm water discharges are less important in determining the severity of adverse impacts than the total loading of pollutants delivered to the lake because of the larger capacitance of the system.

In lakes and reservoirs that are deep enough to become thermally stratified, the impacts of introduced pollutants vary seasonally. Pollutants that settled to the bottom attached to solids may become re-introduced into the water column during the strong currents and mixing that can accompany storms, particularly in autumn. This effect has been illustrated dramatically in the Great Lakes (Rosa, 1985; Eadie et al., 1984; Charlton and Lean, 1987).

B.3.3 Estuaries and Coastal Waters

The States reported that the most extensive causes of use impairment in estuaries are nutrients (affecting 55 percent of impaired square miles), pathogen indicators (affecting 42 percent) and organic enrichment/low dissolved oxygen (affecting 34 percent). Discharges from separate storm sewers affected 43 percent of the impaired estuarine area. The States reported that storm sewers affected 59 percent of ocean shore miles and land disposal affected 42 percent of ocean shore miles.

The pattern of water flow in a given estuary results from the effects of tides and density differences between surface and deeper waters. In most estuaries, fresh waters have an

VOL 12

4285

outward, seaward current. Pollutants are initially carried by the fresh water currents. As pollutants attach to sediment and as the flow rates in the estuary slow due to larger flow basins, the pollutants and sediment sink and their outward flow is reversed when they enter heavier, saltier bottom waters that have a net flow landward. As a result, many pollutants remain trapped in estuaries and never reach open waters. Once these sediments have been deposited, they exert long-term effects on water quality through toxicity, bioaccumulation, or nutrient release.

Much of the nutrient load that is present in surface waters can be incorporated into algae, which then settle. As the algae settle, nutrients are released back into the deeper, inflowing waters. As the inflowing waters mix with outflowing surface waters, the nutrients are once again incorporated into algae. This vertical cycling of nutrients in estuaries, referred to as the nutrient trap, allows the slow accumulation of nutrients in the water column. Contributions of nutrients from storm water discharges increase the rate of this nutrient accumulation, worsening the problems of estuarine eutrophication, which is increasingly one of the major focuses of many of the National Estuary Program projects.

B.3.4 Wetlands

Wetlands are generally located adjacent to the other kinds of surface waters. Wetlands buffer the ultimate receiving water by slowing and storing high, wet weather flows and by removing pollutants. In addition, the intensive levels of biological activity in wetlands play an important role in the ecology of the receiving water.

Wetlands are often dredged or filled when development occurs near surface water or near the floodplain. The destruction of wetlands without appropriate storm water management destroys the capability of wetlands to hold runoff and remove pollutants before discharging to other surface waters. This, in turn, results in higher runoff volumes, which discharge to receiving waters at a faster rate.

Wetlands that are used to receive storm water discharges from upland development may also experience impacts. In some cases, the large flow volumes, flow velocities, and pollutant loads delivered by storm water discharges can alter or destroy stable wetland ecosystems. Storm water discharges with high sediment levels from sources such as uncontrolled construction site runoff may fill or alter flow patterns in wetlands over a long time period. Persistent toxics may also accumulate in sediments, vegetation, and the food chain.

If the adverse physical impacts of the storm water discharges can be minimized, the organically rich, shallow, biologically productive wetlands may act as a buffer or treatment for nutrients in storm water, thereby mitigating the impacts of storm water discharges on the receiving waters.

B.3.5 Ground Water

Due to hydrological connections between surface water and ground water, storm water management may affect ground water in two major ways. First, human activities on the land may have dramatic impacts on the hydrologic cycle, increasing the amount of surface runoff and decreasing the amount of infiltration that recharges ground water supplies. Decreasing ground water recharge can lower the water table, which results in lower dry weather base flows in surface waters and may make the operation of wells more costly. Second, pollutants in precipitation and runoff that infiltrates into an aquifer may not be removed by the soil and may enter an aquifer. This may be a particular concern where storm water management techniques used to control flooding and to improve surface water quality infiltrate surface runoff generated by development to an aquifer.

The types of pollutants in the infiltrated precipitation and the subsurface geology determine the beneficial value of infiltrated precipitation for recharging an aquifer or the potential for polluting ground water. Pollutants that are highly soluble in water (e.g., chlorides, nitrates) pass through the overlying soils into the ground water without attenuation. For example, chlorides from highway runoff containing road salt are shown to have adverse impacts on ground water, as well as surface waters. Other chemical parameters that are less soluble in water tend to adsorb to the soils before reaching ground water supplies.

The potential for ground water contamination strongly depends on the types of land use activities occurring on the surface. Two NURP projects (Long Island, New York, and Fresno, California) addressed sole-source aquifers recharged by runoff from residential and commercial areas for more than two decades. These studies concluded that no change in the use of these practices was warranted. Both studies found that soil processes at the sites were efficient in retaining the pollutants in the runoff close to the land surface, and pollutant breakthrough of the upper soil had not occurred. The EPA report *Class V Injection Wells: Current Inventory; Effects on Ground Water; and Technical Recommendations* (1987), rated the ground water contamination potential of storm water and industrial drainage wells as moderate.

B.4 REGIONAL AND SEASONAL DIFFERENCES

Precipitation patterns vary dramatically in different parts of the United States. A number of parameters are important in characterizing these regional differences, including the duration, intensity, frequency, and annual number of storm events of a given region. Variations in the precipitation patterns of a given region also occur seasonally. These variations affect the volume of storm water discharges produced, can result in seasonal impacts, and may affect management practices. In addition, snow removal and management activities have a special impact on the quality of discharges.

Among the more dominant regional characteristics are the dry summers on the west coast, the abrupt changes in the desert States of the southwest, the peaks occurring in spring and winter in the central gulf and Ohio Valley States, the uniformity of monthly totals throughout the year in the New England States, and snowfall and melt runoff occurring in the northern States.

Seasonal differences may change the nature of storm water discharges and the characteristics of receiving waters. Many smaller rivers in areas with extended dry seasons do not flow all year. The dry seasons in areas like the west coast result in higher than normal pollutant loads associated with the first several storms of the wet season. These discharges may occur when rivers and receiving waters are at low flow levels. Areas with higher intensity storms are prone to flooding and high erosion. Accumulation of pollutants in snow and snow removal activities may adversely affect the quality of snowmelt. In areas were rainfall patterns are non-uniform, soils can become saturated during wet seasons, resulting in higher storm water discharge volumes and erosion rates, as well as overloading of storm water management controls, such as retention and infiltration basins.

Figure B-3 shows 15 rainfall zones for the continental United States that EPA has defined based on annual precipitation statistics.[3] These zones are defined to provide a guide for defining regional patterns, with the geographical area assigned to a zone made as large as possible. Table B-2 summarizes annual precipitation statistics for these zones. The annual precipitation statistics shown in the table only include storm events that were greater than 0.1 inches and consider multiple storms separated by less than a 6-hour period of dry weather as one event. It should be noted that, in general, site-specific data should be used for developing designs for a specific location and that local deviations could be significant, particularly in western parts of the country where mountains, deserts, and coastal patterns result in large differences over relatively small distances.

[3] EPA, *Analysis of Storm Event Characteristics for Selected Rainfall Gages Throughout the United States*, Draft, Driscoll, E.D., et al., November 1989. These 15 rainfall zones represent a refinement of the 10 rainfall zones which appeared in a 1986 draft of the Driscoll reference and which are used in 40 CFR Part 122 Appendix E for the purposes of group applications for storm water discharges associated with industrial activity.

APPENDIX C

NON-STORM WATER DISCHARGES TO STORM WATER CONVEYANCES

VOL 12

4292

APPENDIX C—NON-STORM WATER DISCHARGES TO STORM WATER CONVEYANCES

Although separate storm sewers are primarily designed to remove runoff from storm events, materials other than storm water find their way into and are ultimately discharged from separate storm sewers. Non-storm water discharges to storm sewers come from a variety of sources (EPA, 1990), including:

- Illicit connections and cross connections from industrial, commercial, and sanitary sewage sources
- Improper disposal of wastes, wastewaters, and litter
- Spills
- Leaking sanitary sewage systems
- Malfunctioning septic tanks
- Infiltration of ground water contaminated by a variety of sources, including leaking underground storage tanks.

One of the significant differences between storm water discharges and discharges from separate storm sewers affected by non-storm water is that non-storm water discharges may occur during dry weather when certain recreational uses of the receiving waters are more prevalent and stream flows are lower. In addition, pollutants from non-storm water discharges may accumulate in separate storm sewers until they are flushed out during a storm event, thereby contributing to higher pollutant concentrations and loads.

A wide range of pollutants may be contributed to storm sewers from non-storm water discharges, including pathogens, metals, nutrients, oil and grease, metals, phenols, and solvents. Removal of these non-storm water sources of pollutants often improves the quality of discharges from separate storm sewers dramatically.

The non-storm water discharges listed previously have a high potential for contributing pollutants to storm sewers (EPA, Pitt, 1992). Other non-storm water discharges may have less potential for contributing pollutants[1]:

- Water from street cleaning drainage
- Water from fire hydrant flushing
- Water from fire fighting activities
- Runoff from noncommercial residential activities, such as lawn watering, car washing, swimming pool discharges
- Water from water line breaks
- Certain cleaning water from commercial activities
- Condensate from residential and commercial air conditioning units
- Infiltration of uncontaminated ground water
- Industrial process wastewater, which has been issued a National Pollutant Discharge Elimination System (NPDES) permit.[2]

C.1 ILLICIT OR CROSS CONNECTIONS

Illicit connections, also referred to as cross connections, to separate storm water sewers are physically connected conveyances used to carry untreated wastewaters other than storm water. For many of these connections, there is a mistaken belief that materials are going to a sanitary sewer or some other type of treatment facility.

[1] See 55 *FR* 47990 (November 16, 1990) and "Investigations of Inappropriate Pollutant Entries Into Storm Drainage Systems", EPA, January 1993.

[2] EPA has clarified that it does not interpret the effective prohibition on non-storm water discharges to municipal separate storm sewers of Section 402(p)(3) of the CWA to prohibit non-storm water discharges in compliance with the conditions of an NPDES permit that discharge through a municipal separate storm sewer (see November 16, 1990, 55 *FR* 48037).

Illicit connections may take a variety of forms, including improper connections of residential sewer service lines or sumps, cross-connections with sanitary sewers, improper connections of industry sewer lines, and improper disposal of wastes to floor drains or outdoor drains connected to the separate storm sewer.

C.1.1 Improper Installation

In older sections of cities with separate storm sewers, the potential for improper connections to a separate storm sewer may be high. Problems with illicit connections in the oldest developed areas are often traced to the initial development of the storm sewer system (AWPA, 1990). Early storm sewers preceded the development of sanitary sewers. Once storm sewers were in place, however, they received other non-storm water sources of pollutants, some by direct connections and others from wastes dumped into the streets or storm sewers. Many cities prohibited the discharge of domestic sewage to storm sewers but failed to provide public sanitary sewers, resulting in secret illegal connections built without public supervision. Other illegal connections to the storm sewer were overlooked by municipal officials because of the lack of proper sanitary sewers or because the municipality did not have a program addressing the quality of discharges from the storm sewer system.

During redevelopment or infill development, illicit connections may arise when storm sewers are either mistaken for sanitary lines or the developer intentionally installs improper connections to a storm sewer that is more easily accessed than a sanitary sewer. Expanding or retrofitting large, older industrial complexes creates special problems if maps of the sanitary and storm sewer lines do not exist or are inaccurate and confusion arises regarding the appropriate function of the sewer lines. In addition, when the activities within an industrial facility change, floor drains and other discharge points, which are connected to the separate storm sewer, may begin to receive drainage and discharges that should be sent to a treatment plant. Such floor drains may receive a wide variety of discharges, including spills, rinse waters, cooling waters, and even process wastewaters.

Numerous factors may cause floor drains to be directed toward separate storm sewers. Many floor drains in commercial and industrial facilities are positioned so that they collect storm water running into a building, as well as cleaning water, spillage, and other non-storm water discharges generated within a building. Urbanized areas have experienced rapid growth since 1950. During much of that time, many municipalities did not provide adequate publicly owned treatment works (POTW) service; the development of POTW capacity often lagged far behind the rapid development of the urbanized area. When faced with limited POTW capacity or inadequate POTWs, which could not handle toxic materials (e.g., solvents and heavy greases), many municipalities encouraged developers to connect floor drains and other nonsanitary sewage lines from commercial and industrial facilities to separate storm sewers. Some municipal ordinances prohibited floor drains from being connected to the sanitary sewer system.[3] The operators of facilities with these types of improper connections usually do not know whether floor drains and other types of drains discharge to a separate storm sewer or to a sanitary sewer.

Recent studies in Michigan recognized that development that occurred while undersized POTWs were in operation can create wide-spread illicit connections. For example, the Huron River Pollution Abatement Program inspected 660 businesses, homes, and other buildings discharging storm water to the Allen Creek drain in Washtenaw County, Michigan. Of the buildings inspected, 14 percent were identified as having improper storm drain connections. Illicit discharges were detected at a higher rate of 60 percent for automobile-related businesses, including service stations, automobile dealerships, car washes, body shops, and light industrial facilities. While some of the problems discovered in this study were the result of improper plumbing or illegal connections, most connections were approved at the time they were built.

[3] Some municipalities have prohibited floor drain connections to sanitary sewers in overbroad efforts to comply with EPA regulations at 40 *CFR* 35.927-4, which require grant applicants to demonstrate that municipalities have sewer use ordinances prohibiting any new connections from inflow sources into the sanitary sewer portions of the sewer system.

VOL 12

4296

C.1.2 Sewer Maintenance/Restoration

As urban development grows, flows in the sanitary sewer system increase. In some systems where flows during dry or wet weather have grown to exceed the hydraulic capacity of sanitary sewers, the sanitary sewer has been intentionally cross connected to a storm sewer systems. In some cases, formal connections or overflow devices have been installed and, in others, holes are punched into the sanitary sewer to relieve the sanitary sewer of high flows. Some cross-connections result in wet weather combined sewer overflows; others discharge during dry weather events. Discharges from malfunctioning sanitary sewage pumping stations are often directed toward storm sewers.

Incomplete separation of combined sewers may result in significant numbers of cross-connections between the sanitary sewer system and the storm sewer system. Most municipalities separate sewers primarily to prevent basement and street floodings, with secondary consideration given to water quality concerns. Because separation operations are expensive and can cause significant disruptions to street usage, short cuts may be taken to satisfy flooding concerns at the lowest cost. EPA has recently issued a Combined Sewer Overflow (CSO) Control Policy.[4]

C.2 INTERACTIONS WITH SEWAGE SYSTEMS

As sanitary sewage collection systems age, the systems develop leaks and cracks. Municipalities have long recognized the problems of storm water infiltrating into sanitary sewers, because this type of infiltration disrupts the operation of a POTW. However, the reverse problem of sewage exfiltrating out of the sanitary sewer collection system can occur during dry weather periods. Many sanitary collection systems were initially built between the early 1900s and the mid-1950s. Sewer mains were constructed of asbestos cement, bituminous fiber, brick, cast iron, redwood, or vitrified clay. Manholes were prepared from brick and mortar or reinforced concrete. These aged materials, poorly constructed manholes and joints, and main breaks may permit exfiltration. Sewage from a leaky sanitary system

[4] Combined Sewer Overflow (CSO) Control Policy, EPA, 59 *FR* 18688 (April 19, 1994)

can flow to a storm sewer or contaminate ground water supplies. An EPA study on sewer exfiltration found significant ratios of the rate of exfiltration of raw sewage to the rate of infiltration of ground water or storm water into sanitary sewers. Field and laboratory results determined that this ratio varied between 1.5 to 1 and 14 to 1.[5] Not only are the ratio to rates high, but exfiltration can occur during dry periods, as well as wet weather periods; infiltration is more limited to wet weather periods or periods when the water table is high.

Separate storm sewers and sanitary sewers interactions can be caused by numerous conditions. For example, interaction may occur at manholes and where sanitary sewer laterals and storm sewer trenches cross. In addition, separate storm sewers and sanitary sewers may share the same trench, which is generally filled with very porous material, such as gravel.

C.3 IMPROPER DISPOSAL

Improper disposal of materials may result in contaminated discharges from separate storm sewers in two major ways. First, materials may be disposed of directly to a catchbasin or other storm water conveyance. Second, materials disposed of on the ground may either drain directly to a storm sewer or be washed into a storm sewer during a storm event.

Improper disposal to a separate storm sewer often occurs because many believe that disposal of materials to street catchbasins and other separate storm sewer inlets is an environmentally sound practice. Part of the confusion occurs because some areas are served by combined sewers, which are part of the sanitary sewer collection system, and people assume materials discharged to a catchbasin will reach an appropriate sewage treatment plant.

Materials that are commonly disposed of improperly include used oil; household toxic materials; radiator fluids; and litter, such as disposable cups, cans, and fast-food packages.

[5] U.S. EPA, "Results of the Evaluation of Groundwater Impacts of Sewer Exfiltration", Municipal Facilities Division, February 1989, Washington, DC.

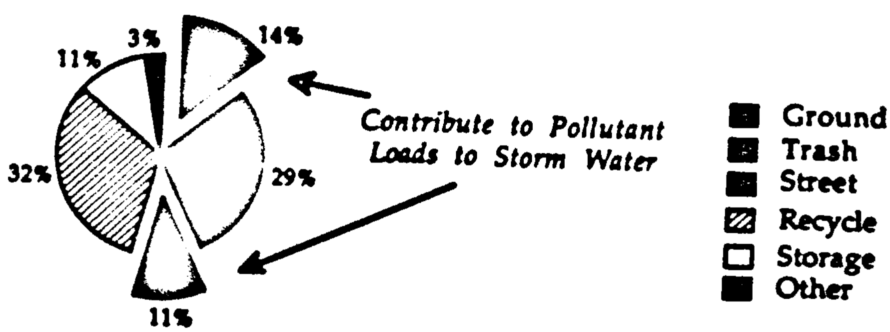
VOL 12

4298

A 1984 survey of household disposal practices estimated that the following percentages of households typically disposed of the materials listed directly to a storm sewer or a street:

- 3 percent of households—paints and thinners
- 11 percent of households—used motor oil
- 83 percent of households that flushed their own auto radiators—used radiator fluid (anti-freeze contaminated with metals).

In addition, although common practice may have changed since 1985, the study estimated that an additional 14 percent of households that changed their own motor oil disposed of the motor oil by pouring it on the ground. Figures C-1 through C-3 depict these data.



Source: Russell and Meiorin, 1985.

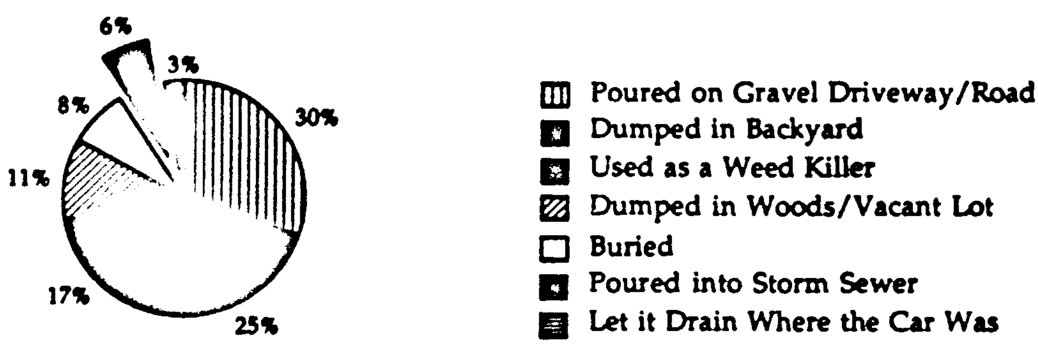
Figure C-3. Disposal Practices for Households Generating Waste Paints and Thinner

A Department of Energy study (Brinkman, 1981) addresses common disposal methods of used oil produced by do-it-yourself (DIY) oil changers. The study estimated that 342 million gallons of used oil were drained during DIY oil changes annually and that 40 percent of this used oil was poured on the ground. Figure C-4 shows the variety of types of oil disposal methods used for the 40 percent of DIY oil disposed of by pouring on the ground. EPA estimates that, 267 million gallons of used oil, including 135 million gallons of used oil from DIY automobile oil changes, are disposed of improperly each year.



Source: Brinkman, 1981.

Figure C-4. Disposal Practices of Households Pouring Used Oil on the Ground

The General Accounting Office (GAO) report, *Illegal Disposal of Hazardous Waste: Difficult to Detect or Deter* (1985) investigated illegal dumping of materials defined as hazardous wastes under the Resource Conservation and Recovery Act (RCRA). Although the report was unable to estimate the extent of illegal dumping of hazardous wastes, it reported that, based on surveyed officials in four States (i.e., Illinois, California, New Jersey, and Massachusetts), some officials believed that many cases of illegal disposal occurred. The report indicated that the Director of EPA's National Enforcement Investigation Center thinks that many cases of criminal disposal occur on a widespread basis, and that EPA receives more allegations than it can handle. The Director stated that the center received about 240 allegations that were judged as having good potential to involve violations during fiscal years 1982 through 1984.

The report indicated that cases of onsite waste disposal where pollutants were added to runoff, which eventually ended up in drainage systems, and cases where a generator dumped wastes directly down a drain, were common. Of the 36 cases of illegal dumping investigated in the GAO report, 14 cases involved disposal of hazardous material directly to or with drainage to a storm sewer, flood control structure, or side of a road. An additional 10 sites involved disposal to the ground, landfills (other than those receiving hazardous wastes), trash bins, which can then result in adding pollutants to subsequent storm water discharges. Disposal scenarios in several other cases could not be determined.

The GAO report concluded that because RCRA regulations and compliance inspections for generators and transporters were not designed to detect illegal disposal, local government agencies, including flood control agencies and departments of transportation were particularly important for detecting illegal dumping.

Businesses disposing of small amounts of hazardous waste may be of concern because they do not fully understand hazardous waste disposal regulations and employee training programs necessary to ensure proper disposal.

C.4 SPILLS

Spilled material may have a have a high potential for entering human-made drainage systems. Until recently, an accepted practice to responding to spills was to flush the spilled material away. These removal methods may often result in flushing the spilled material into a separate storm sewer.

A wide variety of materials, such as petroleum products, other liquid products, and waste chemicals, may spill during transportation, transfer, use, and storage. The U.S. Coast Guard's National Response Center (NRC) receives thousands of incident reports, involving hundreds of substances each year. Summary data, provided by the NRC, categorized spilled materials as either oil or hazardous substances defined under the CWA or the Comprehensive Environmental Response, Compensation, and Liability Act. The term oil is used to represent more than 90 different materials, including various grades of crude oil, naphtha, coal tar, creosote, refined oils, gasoline, and jet fuel.

Table C-1 summarizes the amounts of reported oil and hazardous substances discharged and the amounts reported in water during 1987 and 1988. As this table shows, significant quantities of pollutants are reported to the NRC as spilled or dumped each year. Cleanup activities are not initiated for each reported discharges. Where cleanup occurs, a significant portion of a spill is often not recoverable. Although no data are available to substantiate the number of unreported discharges, Merryman (1989) estimated that less than half of the reportable incidents occurring each year are reported to the NRC. Many of these incidents probably involve little cleanup activity because they were not reported to responsible authorities.

C.5 MALFUNCTIONING SEPTIC SYSTEMS

In rural and suburban areas served by septic systems, malfunctioning septic systems can contribute pollutants to separate storm sewers. Although septic systems work well in rural, low-density areas with suitable soil and a deep water table, septic systems are often installed in inappropriate areas, such as coastal areas, where rapid residential growth, particularly in second-home development areas, has outdistanced the ability of local governments to build sanitary sewers.

Table C-1. Summary of U.S. Coast Guard National Response Center Data on Discharges of Oil and CERCLA-Regulated Materials During 1987 and 1988

	1987 Gallons	1987 Pounds	1988 Gallons	1988 Pounds
Oil Spills Affecting Land	4,988,282	--	6,426,228	--
Oil Spills Affecting Water	3,613,555	--	4,637,600	--
Oil Spills Amount in Water	5,278,773	--	2,949,694	--
Hazardous Substances Spills Affecting Land	1,969,080	3,354,591	4,201,392	2,565,142
Hazardous Substances Spills Affecting Water	3,664,065	656,843	5,244,696	856,852
Hazardous Substances Spills Amount in Water	3,636,764	347,230	2,320,874	415,204

Oil is defined by the NRC to include 94 materials, including gasoline, crude and refined oils, creosote, jet fuel, diesel, naphtha, and coal tar.

Hazardous Substances include 494 materials either required by or containing substances regulated by CERCLA.

Surface malfunctions are caused by clogged or impermeable soils or when stopped up or collapsed pipes force untreated wastewater to the surface. Surface malfunctions can vary in degree from occasional damp patches on the surface to constant pooling or runoff of wastewater to a storm sewer. These discharges have high bacteria, nitrate, and nutrient levels and can contain a variety of household chemicals. One type of improper remedy to a surface malfunction is to install a pipe or trench over soil absorption systems to route untreated surface malfunction overflow away from the septic system, resulting in direct discharges to drainage ditches, empty lots, or surface waters.

Malfunctioning septic systems may be a more significant surface runoff pollution problem than a ground water problem. This is because a malfunctioning septic system is less likely to cause ground water contamination where a bacterial mat in the soil retards the downward movement of wastewater. (Poorly located septic systems that are operating properly are the greatest threat to ground water.)

In addition to surface malfunctions, insufficiently treated wastewater from a septic system may contaminate ground water, which may infiltrate into storm sewers, which serve as a conduit to surface waters. Also, seepage of sewage or effluent into underground portions of buildings can be pumped to separate storm sewers.

The 1992 Needs Survey estimates that approximately 30 percent of the population in the United States is served by septic systems[6].

C.6 INFILTRATION OF CONTAMINATED GROUND WATER

Many separate storm sewers discharge ground water that infiltrates into the storm sewer. Usually, these discharges are not contaminated and, in general, do not pose direct pollutant threats to surface waters. However, if ground water sources are contaminated by industrial or other sources, the separate storm sewer serves as a conduit for the contaminated ground water to surface waters. This process can greatly reduce pollutant removal associated with ground water migration through soils, as well as reduce the dilution processes associated with ground water plume migration. Conversely, observing contaminated discharges from separate storm sewers during dry weather may be used as a tool to detect sources of ground water contamination.

In addition to traditional industrial sources, ground water may be contaminated by a number of commercial activities. One leading cause of ground water contamination from commercial activities includes leaks from underground storage tanks (USTs) and underground pipes. Underground storage tanks are used to store large amounts of potential pollutants, such as petroleum products and chemicals. In 1987, EPA estimated that 676,000 UST systems stored retail motor fuel, 651,000 stored other petroleum products, and 54,000 stored hazardous chemicals in the United States. In addition, EPA estimated that potentially millions of other small UST systems, such as hydraulic lift tanks and power cable conduits, contain dielectric fluid. Pollutants leaking from these tanks may infiltrate through soil into either nearby ditches or storm water pipes (Fields, 1989). A draft EPA report (Kaschak and Hargrove, 1988) reviewed corrective action case histories of 50 leaking UST sites. The report indicated

[6] "1992 Needs Survey Report to Congress", EPA, September 1993.

VOL 12 4304

that surface water impacts were of concern at 14 percent of these sites, where fuels entered storm drains or flowed over the surface, or where the source was located close to a stream or surface waters.

C.7 ROAD OILING

EPA estimates that 70 million gallons of used oil, primarily supplied by service stations and repair shops, are used for road oiling.

A study of two rural roads in New Jersey treated with waste crankcase oil indicated that only 1 percent of the total oil applied to the road may remain on the road surface (Freestone "Runoff of oils from rural roads treated to suppress dust" NERC, EPA, Cincinnati, OH, 1972). The study concluded that oil could have left the road surface by several means such as volatilization, runoff, adhesion to vehicles, adhesion to dust particles with wind transport, and biodegradation.

INDUSTRIAL PERMIT APPLICATION QUESTIONS AND ANSWERS

Category I - Facilities subject to storm water effluent guidelines, new source performance standards, or toxic pollutant effluent standards.

1. **What kinds of facilities are included under category (i)?**

   Category (i) includes facilities subject to storm water effluent limitations guidelines, new source performance standards, or toxic pollutant effluent standards under Title 40 subchapter N of the Code of Federal Regulations (CFR) (except facilities with toxic pollutant effluent standards which are exempted under category (xi) of the definition of storm water discharge associated with industrial activity). The term "storm water" modifies only "effluent limitations guidelines." Facilities subject to subcategories with new source performance standards, toxic pollutant effluent standards, or storm water effluent limitation guidelines are required to submit a National Pollutant Discharge Elimination System (NPDES) permit application for storm water discharges associated with industrial activity.

2. **What kinds of facilities are subject to storm water effluent guidelines?**

   The following categories of facilities have storm water effluent guidelines for at least one of their subcategories: cement manufacturing (40 CFR 411); feedlots (40 CFR 412); fertilizer manufacturing (40 CFR 418); petroleum refining (40 CFR 419); phosphate manufacturing (40 CFR 422); steam electric power generation (40 CFR 423); coal mining (40 CFR 434); mineral mining and processing (40 CFR 436); ore mining and dressing (40 CFR 440); and asphalt (40 CFR 443). A facility that falls into one of these general categories should examine the effluent guideline to determine if it is categorized in one of the subcategories that have storm water effluent guidelines. If a facility is classified as one of those subcategories, that facility is subject to the standards listed in the CFR for that category, and as such, is required to submit a storm water discharge permit application.

3. **What kinds of facilities are subject to "toxic pollutant effluent standards"?**

   First, it is important to understand the term toxic pollutant. Toxic pollutants refers to the priority pollutants listed in Tables II and III of Appendix D to 40 CFR part 122 (not 40 CFR Part 129). If any of these toxic pollutants are limited in an effluent guideline to which the facility is subject (including pretreatment standards), then the facility must apply for a storm water permit.

The following categories of facilities have toxic pollutant effluent standards for at least one subcategory:

Textile mills (40 CFR 410)
Electroplating (40 CFR 413)
Organic chemicals, plastics, and synthetic fibers (40 CFR 414)
Inorganic chemicals (40 CFR 415)
Petroleum refining (40 CFR 419)
Iron and steel manufacturing (40 CFR 420)
Nonferrous metals manufacturing (40 CFR 421)
Steam electric power generating (40 CFR 423)
Ferroalloy manufacturing (40 CFR 424)
Leather tanning and finishing (40 CFR 425)
Glass manufacturing (40 CFR 426)
Rubber manufacturing (40 CFR 428)
Timber products processing (40 CFR 429)
Pulp, paper, and paperboard (40 CFR 430)
Metal finishing (40 CFR 433)
Pharmaceutical manufacturing (40 CFR 439)
Ore mining and dressing (40 CFR 440)
Pesticide chemicals (40 CFR 455)
Photographic processing (40 CFR 459)
Battery manufacturing (40 CFR 461)
Metal molding and casting (40 CFR 464)
Coil coating (40 CFR 465)
Porcelain enameling (40 CFR 466)
Aluminum forming (40 CFR 467)
Copper forming (40 CFR 468)
Electrical and electronic components (40 CFR 469)
Nonferrous metals forming and metal powders (40 CFR 471)

4. What kinds of facilities are subject to "new source performance standards"?

Most effluent guidelines listed in subchapter N contain New Source Performance Standards (NSPS). A facility that is subject to a NSPS as defined for that particular effluent guideline is required to submit a permit application for the storm water discharges associated with industrial activity at that site. The definition of a new source varies based on the publication date of the particular effluent guideline.

The following categories of 40 CFR Subchapter N facilities do not have new source performance standards. All other categories have at least one subcategory with new source performance standards.

VOL 12

4310

Oil and Gas Extraction (40 CFR 435)
Mineral Mining and Processing (40 CFR 436)
Gum and Wood Chemicals Manufacturing (40 CFR 454)
Pesticide Chemicals (40 CFR 455)
Explosives Manufacturing (40 CFR 457)
Photographic (40 CFR 459)
Hospital (40 CFR 460)

5. **If a facility is included under the description of both category (i) and category (xi), is that facility required to submit a storm water permit application if material handling equipment or activities, raw materials, intermediate products, final products, waste materials, by-products, or industrial machinery are not exposed to storm water?**

The answer depends on why the facility is included in category (i). If the facility is included in category (i) because it is subject to storm water effluent standards or new source performance standards, the facility is required to apply for a permit regardless of whether it has exposure or not. Facilities that are included in category (i) only because they have toxic pollutant effluent standards are not required to submit an application if they indeed have no exposure to material handling equipment or activities, raw materials, intermediate products, final products, waste materials, by-products, or industrial machinery.

Categories ii, iii, vi, viii, and xi

6. **What industrial groups are covered by Standard Industrial Classification (SIC) codes that are used in the definition of storm water discharge associated with industrial activity?**

The following SIC codes and associated industries are included in the indicated categories of the definition:

Category (ii)
24 (except 2434) - Lumber and Wood Products (except wood kitchen cabinets)
26 (except 265 and 267) - Paper and Allied Products (except paperboard containers and products)
28 (except 283 and 285) - Chemicals and Allied Products (except drugs and paints)
29 - Petroleum Refining Industries
311 - Leather Tanning and Finishing

32 (except 323) - Stone/Clay/Glass and Concrete Products (except glass products made of purchased glass)
33 - Primary Metal Industries
3441 - Fabricated Structural Metals
373 - Ship and Boat Building and Repairing

Category (iii)
10 - Metal Mining
12 - Coal Mining
13 - Oil and Gas Extraction
14 - Nonmetallic Minerals

Category (vi)
5015 - Motor Vehicles Parts, Used
5093 - Scrap and Waste Materials

Category (viii)
40 - Railroad Transportation
41 - Local Passenger Transportation
42 (except 4221-4225) - Trucking and Warehousing (except public warehousing and storage)
43 - U.S. Postal Service
44 - Water Transportation
45 - Transportation by Air
5171 - Petroleum Bulk Stations and Terminals

Category (xi)
20 - Food and Kindred Products
21 - Tobacco Products
22 - Textile Mill Products
23 - Apparel Related Products
2434 - Wood Kitchen Cabinets Manufacturing
25 - Furniture and Fixtures
265 - Paperboard Containers and Boxes
267 - Converted Paper and Paperboard Products
27 - Printing, Publishing, and Allied Industries
283 - Drugs
285 - Paints, Varnishes, Lacquer, Enamels, and Allied Products
30 - Rubber and Plastics
31 (except 311) - Leather and Leather Products (except leather tanning and finishing)
323 - Glass Products
34 (except 3441) - Fabricated Metal Products (except fabricated structural metal)

VOL 12

4311

VOL 12

35 - Industrial and Commercial Machinery and Computer Equipment
36 - Electronic and Other Electrical Equipment and Components
37 (except 373) - Transportation Equipment (except ship and boat building and repairing)
38 - Measuring, Analyzing, and Controlling Instruments
39 - Miscellaneous Manufacturing Industries
4221-4225 - Public Warehousing and Storage

Category III - Mining and Oil & Gas Operations

7. Are inactive mines included in the regulation?

Two conditions must be met for an inactive mine to be required to submit a storm water discharge permit application. First, the facility must have a discharge of storm water that has come into contact with any overburden, raw material, intermediate products, finished products, byproducts, or waste products located on the site of the facility. The second condition depends on the type of mining activity.

Inactive non-coal mining operations must apply until such sites are released from applicable State or Federal reclamation requirements after December 17, 1990. Non-coal mining operations released from applicable State or Federal requirements before December 17, 1990, must apply for an NPDES storm water discharge permit if the storm water discharges are contaminated as discussed above.

Inactive coal mining operations must apply unless the performance bond issued to the facility by the appropriate Surface Mining Control and Reclamation Act (SMCRA) authority has been released.

8. Are any oil & gas exploration, production, processing, or treatment operations, or transmission facilities classified under SIC code 13, exempt from having to apply for a storm water permit?

Yes, such facilities are exempt unless they have discharged storm water after November 16, 1987, containing a Reportable Quantity (RQ) of a pollutant for which notification is or was required pursuant to 40 CFR 117.21, 40 CFR 302.6, or 40 CFR 110.6; or if a storm water discharge from the facility contributes to a violation of a water quality standard, as set forth in 40 CFR 122.26(c)(1)(iii).

4312

9. **What is a reportable quantity for discharges from an oil or gas operations?**

As defined at 40 CFR 110.6, an RQ is the amount of oil that violates applicable water quality standards or causes a film or sheen upon or a discoloration of the surface of the water or adjoining shorelines or causes a sludge or emulsion to be deposited beneath the surface of the water or upon adjoining shorelines (40 CFR part 110.6). The RQs for other substances are listed in 40 CFR 117.3 and 302.4 in terms of pounds released over any 24-hour period.

10. **Are access roads for mining operations covered?**

Any construction that disturbs 5 acres or more of total land area must apply for a storm water discharge permit.

After construction, roads for mining operations would not be included unless storm water runoff from such roads mixes with storm water that is contaminated by contact with overburden, raw materials, intermediate products, finished products, byproducts, or waste products. When roads are constructed out of materials such as overburden or byproducts, an application for an NPDES storm water discharge permit would be required.

Category iv - Hazardous Waste Treatment, Storage, or Disposal Facilities

11. **Is a facility that stores hazardous waste less than 90 days required to submit an application?**

It is EPA's intent to cover those facilities that are operating under interim status or permit under the Resource Conservation and Recovery Act (RCRA) subtitle C. As such, only facilities meeting the definition of a hazardous waste treatment, storage, or disposal facility under RCRA are expressly included in this category. A facility that stores hazardous waste less than 90 days is not considered to be a treatment, storage, or disposal facility, and therefore is not required to submit a storm water permit application.

VOL 12

4313

VOL 12

Category v - Landfills, Land Application Sites and Open Dumps

12. Do closed or inactive landfills need to apply for a permit?

Yes. Any landfill, active, inactive or closed, must apply for a permit if it receives, or has received, wastes from the industrial facilities identified under 122.26(b)(14)(i)-(xi). To the extent that control measures and best management practices address storm water, the permit may incorporate those control measures.

13. Does a landfill that receives only the office waste and/or cafeteria waste from industrial facilities have to apply for an NPDES permit?

No. Only landfills that receive or have received waste from manufacturing portions of industrial facilities need to apply for a permit.

Category vi - Recycling Facilities

14. Are gas stations or repair shops that collect tires or batteries classified in the "recycling" category?

No. Only those facilities classified in SIC codes 5015 (used motor vehicle parts) and 5093 (scrap and waste materials) are in the "recycling" category. This includes facilities such as metal scrap yards, battery reclaimers, salvage yards, and automobile junk yards.

15. Are municipal waste collection sites included in category (vi)?

No. Municipal waste collection sites where bottles, cans, and newspapers are collected for recycling purposes are not classified as SIC codes 5015 or 5093.

4314

VOL 12

Category vii - Steam Electric Power Generating Facilities

16. Are offsite transformer areas regulated under the NPDES storm water rule?

No. Upon examination of the Toxic Substances Control Act, EPA determined that the regulation of storm water discharges from these facilities should be studied under Section 402(p)(5) of the Clean Water Act (CWA) (55 FR 48013). Future regulations may be developed to address these areas.

17. Are storm water discharges from electrical substations included in the definition of industrial activity?

No. Electrical substations are not covered by this regulation.

18. Are storm water discharges from coal piles that are located offsite from the power station included in the definition of industrial activity?

No. Offsite coal piles are not covered by this regulation. In order to be included, a coal pile must be located on the site of a facility defined by the regulation as being "engaged in an industrial activity."

19. Are storm water discharges from co-generation facilities included in the definition of industrial activity?

A heat capture co-generation facility is not covered under the definition of storm water discharge associated with industrial activity; however, a dual fuel co-generation facility is included and therefore must submit an application for the storm water discharges associated with industrial activity.

20. Are university power plants included in the definition of industrial activity?

Yes. A university steam electric power generating facility is required to apply for a storm water discharge permit.

4315

VOL 12

4316

Category viii - Transportation Facilities

21. Are gas stations and automotive repair shops required to apply for an NPDES storm water discharge permit?

No. These facilities are classified in SIC codes 5541 (gasoline filling stations) and 7538 (automotive repair shops). The storm water rule generally does not address facilities with SIC classifications pertaining to wholesale, retail, service or commercial activities. Additional regulations addressing these sources may be developed under Section 403(p)(6) of the CWA if studies required under Section 402(p)(5) indicate the need for regulation.

22. Does a vehicle maintenance shop or an equipment cleaning facility need to apply for a permit?

Yes, if the shop is categorized by the SIC codes listed in the transportation category of facilities engaged in industrial activity [i.e., SIC codes 40, 41, 42 (except 4221-25) 43, 44, 45 and 5171]. Only the vehicle maintenance (including vehicle rehabilitation, mechanical repairs, painting, fueling, and lubrication) and equipment cleaning areas (such as truck washing areas) must be addressed in the application.

As explained above, gas stations are classified in SIC code 5541 and automotive repair services are classified as SIC code 75, which are not included in the regulatory definition of industrial activity, and therefore are not required to submit NPDES storm water discharge permit applications.

23. Are municipally owned and/or operated school bus maintenance facilities required to apply for an NPDES permit?

No. The SIC Manual states that "school bus establishments operated by educational institutions should be treated as auxiliaries" to the educational institution. Since the SIC code assigned to educational institutions is 82, the municipally operated (i.e., by a school board, district, or other municipal entity) school bus establishments would not be required to apply for an NPDES permit for their storm water discharges. Private contract school bus services are required to apply for an NPDES permit for their storm water discharges.

24. Is SIC code 4212 always assigned to facilities with dump trucks?

No. The maintenance facility must be primarily engaged in maintaining the dump truck to be characterized as SIC code 4212. Dump trucks used for road maintenance and construction and facilities that maintain these trucks are classified under SIC code 16 (heavy construction other than building construction) and therefore would not be characterized as engaging in industrial activity.

25. How does a municipality determine what type of vehicle a particular maintenance facility is primarily engaged in servicing?

The SIC Manual recommends using a value of receipts or revenues approach to determine what is the primary activity of a facility. For example, if a maintenance facility services both school buses and intercity buses, the facility would total receipts for each type of vehicle and whichever generated the most revenue, would be the vehicle type that the facility is primarily engaged in servicing. If data on revenues and receipts are not available, the number of vehicles and frequency of service may be compared. If a facility services more than two types of vehicles, whichever type generates the most (not necessarily greater than half of the total) revenue, or is most frequently serviced, is the vehicle type the facility is primarily engaged in servicing.

26. Is a municipal maintenance facility that is <u>primarily</u> engaged in servicing garbage trucks required to apply for a permit?

The answer depends on the SIC code assigned to the establishment. If the municipality also owns the disposal facility (e.g., landfill, incinerator) that receives refuse transported by the trucks, then the maintenance facility would be classified as SIC code 4953 and thus would not be required to apply for a permit unless the maintenance facility was located at a facility covered under one of the other categories of industrial activity (e.g., a landfill that receives industrial waste). If, however, the municipality does not own the disposal facility, the truck maintenance facility would be classified as SIC code 4212 and thus would be required to apply for a permit. If other vehicles are serviced at the same maintenance facility, the facility may not be required to submit a permit application (see question #25 above).

27. Are fire trucks or police cars included in the transportation SIC codes?

No. The operation of fire trucks and police cars are classified under public order and safety (SIC code 92); therefore, the operator of a facility primarily engaged in servicing those vehicles would not be required to apply for a permit.

28. Do all airports need to apply for a storm water discharge permit?

No, only those airports classified as SIC code 45. Only those portions of the facility that are either involved in vehicle maintenance (including vehicle rehabilitation, mechanical repairs, painting, fueling, and lubrication), equipment cleaning, or airport deicing or which are otherwise identified under 122.26(b)(14)(i)-(vii) or (ix-xi) are required to be permitted. Airports that are not engaged in such activities do not require storm water discharge permits. Facilities primarily engaged in performing services that incidentally use airplanes (e.g., crop dusting and aerial photography) are classified according to the service performed.

29. Is the deicing of airplanes, runways, or both included in airport deicing operations?

Airports or airline companies must apply for a storm water discharge permit for locations where deicing chemicals are applied. This includes, but is not limited to, runways, taxiways, ramps, and areas used for the deicing of airplanes. The operator of the airport should apply for the storm water discharge permit with individual airline companies included as co-applicants.

30. Who is responsible for seeking permit coverage at an airport that has many companies using the facility and discharging storm water?

The operator is responsible for seeking coverage. EPA strongly encourages cooperation between the airport authority and all operating airlines at that airport. Each operator is responsible for coordinating with the others and they may act as co-applicants. Please note that under 122.26(a)(6) the Director has the discretion to issue individual permits to each discharger or to issue an individual permit to the airport operator and have other dischargers to the same system act as co-permittees to the permit issued to the airport operator.

VOL 12

4318

31. **Are railroad facilities included?**

Railroad facilities, classified as SIC code 40, which have vehicle maintenance activities, equipment cleaning operations or are otherwise identified under 122.26(b)(14)(i)-(vii) or (ix)-(xi) need to apply for a permit.

32. **Are repairs along a railroad system considered to be vehicle maintenance and thus regulated?**

No. Only nontransient vehicle maintenance shops are included in the transportation category.

33. **Are tank farms at petroleum bulk storage stations covered by the rule?**

No, unless the storm water discharge from the tank farm area commingles with storm water from any vehicle maintenance shops or equipment cleaning operations located onsite. However, tank farms located onsite with other industrial facilities, as defined in 122.26(b)(14), are included in the regulation.

34. **Is a parking lot associated with a vehicle maintenance shop included in the regulation?**

Yes. Under 122.26 (b)(14)(viii) vehicle maintenance and equipment cleaning operations are considered industrial activity. Parking lots used to store vehicles prior to maintenance are considered to be a component of the vehicle maintenance activity.

35. **Is the fueling operation of a transportation facility (SIC codes 40 through 45) covered if there are no other vehicle maintenance activities taking place at the facility?**

Yes. A nonretail fueling operation is considered vehicle maintenance [see 122.26(b)(14)(viii)] and requires an NPDES storm water discharge permit application.

36. **Is a manufacturing facility's offsite vehicle maintenance facility required to apply for a permit under the transportation category?**

No. An offsite vehicle maintenance facility supporting one company would not be required to apply for a permit if that company is not primarily engaged in providing transportation services and therefore would not be classified as SIC

VOL 12

code 42. The maintenance facility would be considered an auxiliary operation to the manufacturing facility. For a full discussion on auxiliary facilities see page 13 through 17 of the 1987 Standard Industrial Classification Manual. If the maintenance facility is located on the same site as the manufacturing operation, it would be included in the areas associated with industrial activity and must be addressed in an application.

37. **Is a marina required to apply for a storm water permit if it operates a retail fueling operation, but other vehicle maintenance or equipment cleaning activities are not conducted onsite?**

Facilities that are "primarily engaged" in operating marinas are best classified as SIC 4493 - marinas. These facilities rent boat slips, store boats, and generally perform a range of other marine services including boat cleaning and incidental boat repair. They frequently sell food, fuel, fishing supplies, and may sell boats. For facilities classified as 4493 that are involved in vehicle (boat) maintenance activities (including vehicle rehabilitation, mechanical repairs, painting, fueling, and lubrication) or equipment cleaning operations, those portions of the facility that are involved in such vehicle maintenance activities are considered to be associated with industrial activity and are covered under the storm water regulations.

Facilities classified as 4493 that are not involved in equipment cleaning or vehicle maintenance activities (including vehicle rehabilitation, mechanical repairs, painting, and lubrication) are not intended to be covered under 40 CFR Section 122.26(b)(14)(viii) of the storm water permit application regulations. The retail sale of fuel alone at marinas, without any other vehicle maintenance or equipment cleaning operations, is not considered to be grounds for coverage under the storm water regulations.

Marine facilities that are "primarily engaged" in the retail sale of fuel and lubricating oils are best classified as SIC code 5541 - marine service stations - and are not covered under 40 CFR Section 122.26(b)(14)(viii) of the storm water permit application regulations. These facilities may also sell other merchandise or perform minor repair work.

Facilities "primarily engaged" in the operation of sports and recreation services such as boat rental, canoe rental, and party fishing, are best classified under SIC code 7999 - miscellaneous recreational facilities - and are not covered under 40 CFR Section 122.26(b)(14)(viii).

4320

Category ix - Sewage Treatment Works

38. Are storm water permit applications required for offsite (i.e., physically separated from the main treatment works property) pumping stations?

No, storm water permit applications are not required for such sites.

39. Are separate permit applications required for vehicle maintenance/ washing facilities (located either onsite or offsite) associated with a wastewater treatment plant and owned/operated by the wastewater treatment agency?

Offsite vehicle maintenance facilities would not be required to submit applications unless they serve multiple clients since they do not fit the SIC codes listed in the transportation category of facilities engaged in industrial activity. Onsite vehicle maintenance/cleaning operations are associated with industrial activity and must be included in the application.

40. Do wastewater treatment facilities that collect their storm water runoff and treat the storm water as part of the normal inflow that is processed through the treatment plant have to apply for a permit?

No. If a facility discharges its storm water into the headworks of the treatment plant, it is essentially the same as discharging to a combined system or to a sanitary system and is therefore exempt from the requirements of 122.26(c).

41. The definition states that offsite areas where sludge is beneficially reused are not included as storm water discharges associated with industrial activity. How is beneficial reuse defined?

Beneficial sludge reuse is the application of sludge as a nutrient builder or soil conditioner. Examples include agricultural or domestic application.

VOL 12

4321

VOL 12

4322

Category x - Construction Activities

42. Is a construction site of five acres or more subject to the same deadline as other industrial facilities?

The individual application deadline for all storm water discharges associated with industrial activity is 10/1/92. If a construction activity is completed by 10/1/92, an application is not required.

43. What is the duration of an NPDES permit issued for a construction activity?

The permit will be effective as long the construction activity continues, but no longer than five years. If the construction continues beyond five years, the owner/operator must apply for a new permit.

44. Does the construction category only include construction of industrial buildings?

No. Any construction activity, including clearing, grading, and excavation, that results in the disturbance of five acres of land or more in total is covered by the rule. Such activities may include road building, construction of residential houses, office buildings, or industrial buildings, and demolition activity. However, this does not apply to agricultural or silvicultural activities, which are exempt from NPDES permit requirements under 40 CFR 122.4.

45. Does the rule require that storm water discharges after construction be addressed?

Yes. The individual application must describe proposed measures to control pollutants in storm water discharges that will occur after construction operations are complete, including a description of State and local erosion and sediment control specifications.

<u>Please Note</u>: EPA believes that construction activities should be covered under a storm water general permit wherever possible. 40 CFR 122.21(c)(1) allows the permitting authority to establish different and shorter submittal dates under the specific terms of a particular general permit.

VOL 12

4323

46. **The definition states that the operators of construction activity that disturb less than five acres are not required to apply for a permit unless that construction is part of a larger common plan of development or sale. What is meant by "part of a larger common plan of development or sale"?**

"Part of a larger common plan of development or sale" is a contiguous area where multiple separate and distinct construction activities may be taking place at different times on different schedules under one plan. Thus, if a distinct construction activity has been identified onsite by the time the application would be submitted, that distinct activity should be included as part of the larger plan.

47. **Who is responsible for applying for a storm water permit?**

The operator is responsible for applying for the permit as required by 122.21(b). In the case of construction, the owner may submit an application for a construction activity if the operators have not yet been identified. However, once the operators have been identified, they must become either sole permittees or co-permittees with the owner. The operator is determined by who has day to day supervision and control of activities occurring at a site. In some cases, the operator may be the owner or the developer, at other sites the operator may be the general contractor.

Category xi - Light Industrial Facilities

48. **If a category (xi) facility has determined that there is no exposure of certain activities or areas listed in the definition to storm water and the operator does not file a permit application, how does the operator prove, if asked, that he/she did not need to apply?**

There are no requirements set forth under the November 16, 1990, rule. However, the operator may want to document the facility evaluation which led to the conclusion that there is no exposure to storm water. This documentation should be retained onsite. Some States may have specific requirements. A facility is advised to check with its NPDES permitting authority for additional requirements.

VOL 12

49. Do those industries listed in 122.26(b)(14)(xi) that only have access roads and rail lines exposed to storm water need to apply for a permit?

No. As stated in 122.26 (b)(14), facilities in category (xi) do not have to apply for a permit if storm water only is exposed to access roads and rail lines.

50. If air pollution control equipment vents on the roof are exposed to storm water, does this constitute exposure and trigger a permit condition?

No. The exposure of air pollution control equipment vents does not in itself constitute exposure. It is possible, however, that even with the use of air pollution control equipment, significant pollutants may be exposed to storm water. For example, if a cyclone, a common particulate control device, is used alone, only about 80 percent of the potential pollutants would be removed. 20 percent of the pollutants may then come into contact with storm water. In this case, a permit application is required.

51. If there has been past exposure, can a facility change its operation to eliminate exposure, and thus become exempt?

Yes. If a category (xi) facility can change its operation and eliminate all exposure, the facility may be exempt from the regulation. It is important to note, however, that eliminating exposure may include clean up as well.

52. Is a covered dumpster containing waste material kept outside considered exposure?

No, as long as the container is completely covered and nothing can drain out holes in bottom, or is lost in loading onto a garbage truck, this would not be considered exposure.

4324

General Applicability

53. How is a storm water outfall from an industrial site defined for the purpose of sampling?

An industrial outfall is the point at which storm water associated with industrial activity discharges to waters of the United States or a separate storm sewer. Separate storm sewers may be roads with drainage systems, municipal streets, catch basins, curbs, gutters, ditches, man-made channels, or storm drains.

54. Are tank farms considered to be associated with industrial activity?

Yes, if they are located at a facility described in the definition of storm water discharge associated with industrial activity. Tank farms are used to store products and materials used or created by industrial facilities, and therefore are directly related to manufacturing processes. However, tank farms associated with petroleum bulk storage stations, classified as SIC code 5171, at which no vehicle maintenance or equipment cleaning operations occur, are exempt.

55. Is an offsite warehouse associated with a regulated industrial facility required to submit an application?

No. As stated on page 48011 of the preamble to the November 16, 1990, rule, warehouses of either preassembly parts or finished products that are not located at an industrial facility are not required to submit an application unless otherwise covered by the rule.

56. If a facility has more than one industrial activity, how many applications are required?

Only one application is required per facility. Permit conditions will address the various operations at the facility. The application must reflect all storm water discharges from areas associated with industrial activity as described in the definition at 122.26(b)(14). The activity in which a facility is primarily engaged determines what SIC code is assigned to that facility. To determine the activity in which a facility is primarily engaged, The SIC Manual recommends using a value of receipts or revenues approach. For example, if a facility manufactures both metal and plastic products, the facility would total receipts for each operation and the operation that generated the most revenue for the facility is the operation in which the facility is primarily engaged. If revenues and receipts are not available for a particular facility, the number of employees or production rate may be compared. If a facility performs more than two types of operations, whichever operation generates the most (not necessarily the majority) revenue or employs the most personnel, is the operation in which the facility is primarily engaged.

57. Are industrial facilities located in municipalities with fewer than 100,000 residents required to apply for a permit?

Yes. All industrial discharges of storm water through separate storm sewers or into waters of the United States must apply for an NPDES permit.

VOL 12

4326

58. If the SIC code for the activity in which a facility is primarily engaged is not included in the definition of storm water discharge associated with industrial activity, but the facility has a secondary SIC code that is included in the definition, is the facility required to submit an NPDES storm water permit application?

For purposes of this regulation, a facility's SIC code is determined based on the primary activity taking place at that facility. In the case described above, the facility is not required to apply for an NPDES storm water discharge permit. However, if the facility conducts an activity on the site identified in the narrative descriptions of categories (i), (iv), (v), (vii), or (x), then the facility would be required to submit an NPDES storm water permit application for portions of the facility used for the activities described in those categories.

59. Are military bases or other Federal facilities regulated under this rule?

Yes. Industrial activities identified under 122.26(b)(14)(i)-(xi) that Federal, State, or Municipal governments own or operate are subject to the regulation.

60. Does the regulation require a permit for storm water discharges to a publicly owned treatment works?

No. A discharge to a sanitary sewer or a combined sewer system is not regulated under the storm water regulation. Storm water discharges either to waters of the United States or separate storm sewer systems require a permit if associated with any of the industrial facilities listed in 122.26(b)(i) - (xi).

61. Are there any limits or size restrictions which narrow the scope of facilities requiring an application?

The only restrictions regarding size are for construction activities and sewage treatment works. All construction activities must apply for permit coverage except for operations that disturb less than five acres of total land which are not part of a larger common plan of development or sale. Sewage treatment works designed to treat one million gallons per day or more must submit an NPDES permit application.

62. **Do pilot plants or research and development facilities classified within one of the regulated SIC codes need to apply for a permit?**

A pilot plant or research facility classified by an SIC code which is specified under 122.26(b)(14)(i)-(xi) would be required to submit an application. A pilot plant or research facility's operations can be directly related to the manufacturing operations of the full-scale facility and therefore warrant a permit.

63. **Are stockpiles of a final product from an industrial site that are located away from the industrial plant site, included under the definition of storm water discharge associated with industrial activity?**

Such stockpiles would not be covered because they are not located at the site of the industrial facility.

64. **If a facility has a NPDES permit for its process wastewater and some, but not all, of its storm water discharges associated with industrial activity, does the operator need to apply?**

The operator must ensure that all storm water discharges associated with industrial activity are covered by an NPDES permit. The operator may wish to submit an individual application, participate in a group application, or seek coverage under a general permit for any remaining outfalls that are not covered by an existing NPDES permit. The permitting authority may also wish to modify the existing NPDES permit to cover the other storm water discharges.

65. **A facility holds a recently renewed NPDES permit which does not cover storm water discharges. Does that facility need to apply?**

Yes. If the facility is identified in paragraph 122.26(b)(14)(i) through (xi) of the rule, that facility may wish to submit an individual application, participate in a group application, or seek coverage under a general permit for any remaining outfalls that are not covered by an existing NPDES permit. The permitting authority may also wish to modify or reissue the existing NPDES permit to cover the other storm water discharges.

66. **If a regulated company owns and operates a subsidiary which is of a wholesale or commercial nature, would the subsidiary need to apply?**

VOL 12

4328

No. Since the subsidiary facility's operations are of a wholesale or commercial orientation, the operations are not considered to be industrial and therefore would not be covered by this rule unless they are specifically covered by one of the SIC codes or narrative descriptions in 122.26(b)(14).

67. Can an applicant claim confidentiality on information contained in an NPDES permit application?

No. Under 40 CFR 122.7(b), the permitting authority will deny claims of confidentiality for the name and address of any permit applicant or permittee, permit applications, permits, and effluent data.

68. Do the November 16, 1990, regulations modify the requirements of existing storm water effluent guidelines?

No. Existing storm water effluent guidelines are still applicable.

69. Which application forms are industries responsible for submitting?

- For discharges composed entirely of storm water, operators should submit Form 1 and Form 2F.
- For discharges of storm water combined with process wastewater, operators should submit Form 1, Form 2F, and Form 2C.
- For storm water discharged in combination with nonprocess wastewater, operators should submit Form 1, Form 2F, and Form 2E.
- For new sources or new discharges of storm water which will be combined with other non-storm water, operators should submit Form 1, Form 2F, and Form 2D.

70. Are Superfund sites regulated under this rule?

Yes, if the site is assigned an SIC code or fits the description of one of the categories listed in the definition of storm water discharge associated with industrial activity. Under the Superfund Amendment and Reauthorization Act (SARA) section 121(E), Superfund sites are required to "substantively comply" with all environmental regulations.

VOL 12

4329

VOL 12

4330

71. **Are areas used for the disposal of industrial wastewaters and sanitary wastewaters included in the definition of "associated with industrial activity"?**

Yes, the definition includes sites used for process water land application that are not used for agricultural activities.

72. **Do inactive industrial facilities need to apply?**

Yes, if the facility is included in the definition of storm water discharge associated with industrial activity and significant materials remain on site and are exposed to storm water runoff (p.48009 of 11/16/91 Federal Register). The regulation defines significant materials at 122.26 (b)(13) as including, but not limited to, raw materials; fuels; materials such as solvents, detergents, and plastic pellets; finished materials such as metallic products; raw materials used in food processing or production; hazardous substances designated under section 101(14) of the Comprehensive Environmental Response, Compensation, and Liability Act; any chemical the facility is required to report pursuant to section 313 of title III of SARA; fertilizers; pesticides; and waste products such as ashes, slag and sludge that have the potential to be released with storm water discharges.

73. **Can a facility apply for an individual permit after completing the group application or applying for coverage under a general permit?**

This option is available, but the operator is advised to discuss the matter directly with the permitting authority.

74. **If a facility is totally enclosed with no materials or activities exposed to storm water, but has a point source discharge of storm water, is a permit application required?**

If the facility is described in categories 122.26(b)(14)(i-x) a permit application is required regardless of the actual exposure of materials or activities to storm water. If the facility is described in 122.26(b)(14)(xi), a permit application is required only if there is exposure of materials or activities to storm water.

VOL 12

4331

75. **How does a municipally owned industrial facility apply for an NPDES permit?**

Such a facility must meet the same application requirements as any other industrial facility. The facility may submit an individual permit application (Forms 1 and 2F), participate in a group application, or seek coverage under an available general permit.

76. **Who is required to submit Form 1?**

Anyone submitting NPDES application Forms 2C, 2D, 2E, 2F, or a construction individual application is required to submit Form 1.

77. **Before the October 1, 1992, individual application deadline, which forms must a facility submit to renew its NPDES permit for a storm water discharge?**

Since the individual storm water application is not due until October 1, 1992, EPA is allowing such facilities to choose whether the storm water discharges are identified on a Form 2C or a Form 2F. After October 1, 1992, a facility must submit an application in accordance with 40 CFR 122.26(c) (i.e., Forms 1 and 2F).

78. **Are washwaters and/or noncontact cooling waters (e.g., air conditioner condensate) included in the definition of storm water?**

No. "Storm water" means storm water runoff, snow melt runoff, and surface runoff and drainage. Washwaters are usually considered to be process wastewater. Noncontact cooling waters are considered a nonprocess wastewater.

STORM WATER QUESTIONS AND ANSWERS PART II

I.	General Applicability

1. What kinds of storm water discharges are required to obtain an NPDES permit under Phase I of the storm water program?

A. The National Pollutant Discharge Elimination System (NPDES) storm water permit application regulations, promulgated by the U.S. Environmental Protection Agency (EPA), require that the following storm water discharges apply for an NPDES permit: (1) a discharge associated with industrial activity; (2) a discharge from a large or medium municipal separate storm sewer system; or (3) a discharge which EPA or the State determines to contribute to a violation of a water quality standard or is a significant contributor of pollutants to waters of the United States. The permit application deadlines are specified in EPA's regulations.

2. **What is a "storm water discharge associated with industrial activity?"**

A. The term "storm water discharge associated with industrial activity" means a storm water discharge from one of the eleven categories of industrial activity defined at 40 Code of Federal Regulations (CFR) 122.26(b)(14)(i) through (xi). Five of these categories are identified by Standard Industrial Classification (SIC) code and the other six categories provide narrative descriptions of the industrial activity. The complete definition is included in Section XIII of this document.

If any activity at a facility is covered by one of the five categories which provide narrative descriptions, storm water discharges from that activity of facility are subject to storm water permit application requirements. If the primary SIC code of the facility is identified in one of the remaining six categories, the facility is subject to the storm water permit application requirements. Note that only those facilities/activities described above having <u>point source</u> discharges of storm water to waters of the United States or to a municipal separate storm sewer system or other conveyance are required to submit a storm water permit application. The definition of "point source" is provided at 40 CFR 122.2. The definition is included in Section XIII of this document.

3. **What are SIC codes and how can a facility find out its proper SIC code?**

A. SIC codes are four-digit industry codes that were created by the Office of Management and Budget (OMB) for statistical purposes. Other governmental organizations sometimes use these codes when classifying business establishments. To find the correct SIC code, an applicant might check his or her unemployment insurance forms or contact the appropriate State unemployment services department. In addition, applicants may consult the Standard Industrial Classification Manual (SIC Manual), published by OMB in 1987. This manual is available in the resource section of most public libraries. Questions regarding assignment of particular codes can be addressed to your State permitting authority. A list of telephone numbers and addresses for State storm water contacts is provided as an attachment to this document.

4. What SIC code should a facility use when there are multiple activities occurring at the site?

A. For the purposes of the storm water program, a facility must determine its primary SIC code based on the primary activity occurring at the site. To determine the primary industrial activity, the SIC Manual recommends using the value of receipts or revenues. If such information is not available for a particular facility, the number of employees or production rate for each process may be compared. The operation that generates the most revenue or employs the most personnel is the operation in which the facility is primarily engaged. For case-specific determinations, contact the permitting authority for your State.

5. How is a facility regulated when multiple activities conducted by different operators are occurring on the same site (airports, for example)?

A. When multiple activities are conducted by different operators at a single location, each industrial activity is assigned its own SIC code. At an airport, for example, a passenger airline carrier will receive one SIC code, but an overnight courier located in the same hanger may receive another SIC code. Whereas the SIC codes may differ, if both are regulated industrial activities, EPA generally encourages these operators to become co-applicants (submit storm water permit application forms together) when they are located at the same site and when industrial areas/drainage basins are shared. When a permit is issued (or if the operators are filing for a general permit) the co-applicants will become co-permittees and share responsibility of permit compliance.

6. If a facility's primary SIC code is not listed in the regulations, but an activity that occurs on site is described in one of the narrative categories of industrial activity, does that facility have to apply for a permit?

A. If a facility conducts an activity on the site identified in the narrative descriptions of categories (i), (iv), (v), (vii), (ix) or (x), then the facility would be required to submit a storm water permit application for discharges from those portions of the facility where the activity occurs. Such narrative activities/facilities include: (i) activities subject to storm water effluent limitations guidelines, new source performance standards, or toxic pollutant effluent standards; (iv) hazardous waste treatment storage, or disposal facilities including those that are operating under interim status or a permit under subtitle C of the Resource Conservation and Recovery Act (RCRA); (v) landfills, land application sites and open dumps that receive or have received industrial wastes; (vii) steam electric power generating facilities; (ix) sewage treatment works with a design flow of 1.0 mgd or more; and (x) construction activity disturbing five or more acres of land.

7. Do storm water discharges from non-industrial areas at an industrial facility (employee parking lots, rental car operations at an airport) have to be addressed in an NPDES permit?

A. No. Only storm water discharges from those areas that are associated with industrial activity, as defined at 40 CFR 122.26(b)(14) must be addressed in the permit. However, if storm water runoff from a non-industrial area commingles with runoff from a regulated industrial area, the combined discharge would require permit coverage.

8. How are off site facilities (such as distribution centers, storage facilities, vehicle maintenance shops) regulated under the storm water program?

A. To determine the regulatory status of off site facilities, first the operator of a facility must determine if that off site operation can be classified according to its own SIC code. If there is no SIC code which describes the off site facility independently, then it would assume the SIC code of the parent facility it supports. However, certain off site facilities that fall within the categories of auxiliary facilities described in Section XIV of this document (or which are specifically described in the SIC code description) would, in most cases, be classified according to the parent facility they support. Such supporting establishments include central administrative offices, research and development laboratories, maintenance garages, and local trucking terminals.

EPA has determined that off site vehicle maintenance facilities that service trucks used for local transportation of goods or for local services are generally considered supporting establishments which would not be assigned a transportation SIC code; rather, such facilities are classified

VOL 12

4337

according to the SIC code of the facility they support. Please refer to Section II of this document for a discussion of off-site vehicle maintenance facilities.

9. **Can authorized NPDES States be more expansive in their use of the assignment of SIC codes? For example, can they make the rule applicable to secondary activities?**

A. Yes, State storm water regulations can be more expansive and cover more activities than the Federal regulations.

10. **Are all storm water discharges to sanitary sewers exempt from storm water permitting requirements? What about discharges to combined sewer systems?**

A. Any storm water discharge to a Publicly Owned Treatment Works (POTW) or to a sanitary sewer is exempt from storm water permit application requirements. However, it may be subject to EPA's pretreatment program under Section 307(b) of the CWA. Discharges to combined sewer systems are also exempt from NPDES permitting but may be subject to pretreatment requirements.

11. **Is a storm water permit application required for an industrial facility that has constructed a holding pond that usually does not discharge storm water, but could in the event of a large enough storm?**

A. All point source discharges of storm water associated with industrial activity that discharge to waters of the U.S. or through a municipal separate storm sewer system must be permitted. Therefore, if an industrial facility does not have a storm water discharge from its holding pond during typical storm events but has a storm water discharge in the event of a large storm, that discharge must be covered under an NPDES permit. In NPDES authorized States (a list is provided in Section XII of this document), facilities should consult their permitting authority for State-specific determinations on such "potential discharges."

12. **If a facility is <u>not</u> engaged in industrial activity as defined under 40 CFR 122.26(b)(14)(i)-(xi), but discharges contaminated flows comprised entirely of storm water into a nearby municipal separate storm sewer system, is the facility required to obtain a storm water permit?**

A. No, unless EPA or the State designates the discharge as contributing to a violation of a water quality standard or as significantly contributing pollutants to waters of the United States. However, industrial dischargers should note that large and medium municipalities (population 100,000 or more) are currently designing storm water management programs that will control contaminated storm water discharges from entering their separate storm sewer systems. Additional storm water discharges may be regulated under Phase II of the storm water program. EPA is currently in the process of developing Phase II.

13. **Are activities associated with industrial activity that occur on agricultural lands exempted from storm water permitting requirements?**

A. No. If a storm water discharge is associated with industrial activity as defined at 40 CFR 122.26(b)(14), it is subject to permit application requirements regardless of the location of the industrial activity. For example, if a gravel extraction activity occurred on land leased from a farm, the activity would be classified as mining under SIC code 1442 or 1446 and therefore would be considered a storm water discharge associated with industrial activity and require a permit.

14. **Are NPDES permits transferable from one facility owner to the next?**

A. Individual NPDES permits may be transferred to a new owner or operator if the permit is modified. These procedures are described at 40 CFR 122.61. Under the general permits for storm water discharges, issued by EPA in the September 9, 1992 and September 25, 1992, Federal Register notices (57 FR 41176 and 57 FR 44412), the new operator can submit an NOI two days prior to the change of ownership but must include the facility's existing general permit number on the NOI form. Many NPDES authorized States have similar provisions in their general permits.

15. **How does storm water permitting differ in States with approved State NPDES programs compared to States without NPDES State permit programs?**

A. While Federal storm water regulations (i.e., the November 16, 1990, storm water permit application regulations) establish minimum requirements nationwide. State permitting authorities may impose more stringent requirements or decide to expand the scope of its program to meet State priorities. EPA Regional offices are the permitting authorities for 12 States and most Territories; the remaining 38 States and the Virgin Islands administer their own storm water programs and issue permits to regulate municipalities and industries in their States. Regulated facilities in these States should contact the appropriate State permitting authority for guidance, application forms, general permits and other materials. Please note that some of the NPDES States do not issue permits for Federal facilities located in their States.

For regulated facilities in the 12 non-delegated States (MA, NH, ME, FL, TX, OK, LA, NM, SD, AZ, AK, ID), the Territories (all except the Virgin Islands), the District of Columbia, and for facilities located on Indian lands (in most, if not all, delegated States and in all non-delegated States), and for Federal facilities in the States of DE, CO, IA, KS, NH, NY, OH, SC, VT and WA, the storm water program is administered through EPA Regional offices. Such facilities may be eligible for coverage under the general permits issued by EPA in the September 9, 1992, and September 25, 1992, Federal Register notices (57 FR 41176 and 57 FR 44412).

VOL 12

II. Definition of Storm Water Discharge Associated With Industrial Activity

Category (i): Facilities subject to storm water effluent limitations guidelines, new source performance standards or toxic pollutant effluent standards under 40 CFR subchapter N.

16. What are toxic pollutant effluent standards?

A. 40 CFR 122.26(b)(14)(i) includes facilities that are subject to storm water effluent limitations guidelines, new source performance standards, or toxic pollutant effluent standards. The phrase "toxic pollutant effluent standards" refers to the standards established pursuant to CWA section 307(a)(2) and codified at 40 CFR Part 129. Part 129 applies only to manufacturers of six specific pesticide products which are defined as toxic pollutants. Please note that the phrase "facilities subject to toxic pollutant effluent standards" does not refer to those industries subject to effluent limitation guidelines for toxics under 40 CFR subchapter N.

4340

Category (iii): Mining and oil and gas operations classified as SIC codes 10-14.

17. What constitutes "contamination" at an oil and gas facility?

A. Oil and gas facilities classified as SIC code 13 are required to apply for a storm water permit if the facility has had a release of a Reportable Quantity (RQ) in storm water for which notification has been required any time since November 16, 1987, or if the discharge contributes to a violation of a water quality standard. RQs for which notification is required are defined at 40 CFR Parts 110, 117, and 302. An RQ for oil is defined at 40 CFR 110 as the amount of oil that violates applicable water quality standards or causes a film or sheen upon or a discoloration of the water surface or adjoining shorelines, or causes a sludge or emulsion to be deposited beneath the water surface or upon adjoining shorelines. For other substances, RQ levels are expressed in terms of pounds released over any 24 hour period and are listed at 40 CFR 117.3 and 40 CFR 302.4. A list of these RQ levels is available from the Storm Water Hotline at (703) 821-4823.

18. **Do EPA's industrial storm water general permits apply to discharges from mine sites that are subject to storm water effluent limitations guidelines, but which are not covered by an existing NPDES permit?**

A. No, storm water discharges from mine sites that are subject to storm water effluent limitation guidelines are not authorized by industrial storm water general permits issued by EPA in the September 9, 1992, and September 25, 1992, Federal Register notices (57 FR 41176 and 57 FR 44412). In States without NPDES permitting authority, the mine operators submit an individual application to address those storm water discharges, or could have participated in a group application prior to October 1, 1992 (note: any facility which did not submit an individual application prior to October 1, 1992 or participate in a timely group application missed EPA's regulatory deadline and may be subject to enforcement action). However, certain authorized States may issue general permits authorizing such storm water discharges from mine sites provided that those permits contain the applicable guideline requirements.

19. **Can point source discharges of contaminated ground water from mine adits and seeps at active or inactive mine sites be permitted under the storm water program?**

Point source discharges of non-storm water to waters of the United States must be authorized by an NPDES permit. Point source discharges of either contaminated ground water from a mine adit or seep that are not related to specific storm events would not be considered to be storm water. Discharges that are composed in whole or in part of non-storm water cannot be addressed solely by the permit applications for storm water (Forms 1 and 2F), and cannot be authorized by NPDES permits that only authorize discharges composed entirely of storm water. Rather, Forms 1 and 2C or 2D (and Form 2F if the discharge is mixed with storm water) must be used when applying for a NPDES permit for non-storm water.

VOL 12

4341

VOL 12

Category (iv): Hazardous waste treatment, storage or disposal facilities.

20. If the primary SIC code of a facility is not covered under the regulations, but there is a hazardous waste treatment, storage or disposal facility (TSDF) on site, is the TSDF subject to storm water permitting requirements?

A. Yes. If the hazardous waste TSDF is or should be operating under interim status or a permit under Subtitle C of the Resource Conservation and Recovery Act (RCRA), regardless of the facility's primary activity, the storm water discharges from that portion of the site are subject to the narrative definition of storm water discharges associated with industrial activity under category (iv). Even if a facility's SIC code is not included in the regulations, any activity described by one of the narrative categories of "industrial activity" that is occurring on the site would be regulated under the storm water program.

Category (v): Landfills, land application sites and open dumps that receive industrial waste.

21. At what point does an inactive, closed, or capped landfill cease being an industrial activity?

A. An inactive, closed or capped landfill is no longer subject to storm water permit application requirements when the permitting authority determines the land use has been altered such that there is no exposure of significant materials to storm water at the site. For example, if an impervious surface (such as a parking lot or shopping center) now covers the closed landfill, the permitting authority could determine that storm water discharges from the area are no longer associated with the previous landfill activity. These determinations must be made by the permitting authority on a case-by-case basis.

22. If construction of cells at a landfill disturbs greater than five acres of land, is coverage under EPA's construction general permits required?

A. No. EPA considers construction of new cells to be routine landfill operations that are covered by the landfill's industrial storm water general permit. However, the storm water pollution prevention plan for the landfill must incorporate best management practices (BMPs) that address sediment and erosion control. Where a new landfill is being constructed

4342

and five or more acres of land are being disturbed, such activity would need to be covered under EPA's construction general permit until the time that initial construction is completed and industrial waste is received. Please note that NPDES authorized States may address this situation differently.

Category (viii): Transportation facilities

23. **If all vehicle maintenance and equipment cleaning operations occur indoors at a transportation facility, as defined at 40 CFR 122.26(b)(14)(viii), is a permit application required for discharges from the roofs of these buildings?**

A. Yes. Storm water discharges from all areas that are "associated with industrial activity," described at 40 CFR 122.26(b)(14), are subject to the storm water permit application requirements. This would include discharges from roofs of buildings that are within areas associated with industrial activity. In addition, storage areas of materials used in vehicle maintenance or equipment cleaning operations and holding yards or parking lots used to store vehicles awaiting maintenance are also considered areas associated with industrial activity.

24. **For a facility classified as SIC code 5171 (bulk petroleum storage), is the transfer of petroleum product from the storage tanks to the distribution truck considered "fueling", and therefore an industrial activity as defined by the regulations?**

A. No. The transfer of petroleum product from the storage tanks to the tanker truck is not considered fueling and would not require a storm water permit. However, fueling of the tanker truck itself at the 5171 facility is considered to be part of routine vehicle maintenance, and storm water discharges from these areas must be covered under a storm water permit application.

25. **Is a retail fueling operation that occurs at an SIC code 5171 petroleum bulk storage facility regulated?**

A. No. The provisions of 40 CFR 122.26(b)(14)(viii) apply to fueling operations conducted at petroleum bulk storage facilities where the vehicles being fueled are involved with the petroleum bulk storage operation. Retail fueling of vehicles at such sites does not constitute "vehicle maintenance" (as defined in the November 16, 1990 Federal

VOL 12

4343

Register page 48066), and a storm water permit is not required for the discharges from that area. Only those portions of the SIC code 5171 facility where vehicle maintenance operations (including vehicle rehabilitation, mechanical repairs, painting, fueling, and lubrication) and equipment cleaning take place are required to be covered under a storm water permit application.

26. **Are off site vehicle maintenance areas required to submit permit applications for their storm water discharges?**

A. As discussed in Section I of this document, to determine the regulatory status of off site vehicle maintenance operations, the operator of a facility must first determine if that off site operation can be classified according to its own SIC code. If there is no SIC code which describes the off site facility independently, then it would assume the SIC code of the parent facility it supports. However, please note that off-site facilities that fall within the nine categories listed on page 17 of the SIC Manual (or which are specifically described in the SIC code description) would, in most cases, be classified according to the parent facility they support. See Section XIII of this document for the complete list. Such supporting establishments include central administrative offices, research and development laboratories, maintenance garages, and local trucking terminals. EPA has determined that off site vehicle maintenance facilities that primarily service trucks used for local transportation of goods or for local services are generally considered supporting establishments which do not assume a transportation SIC code; rather, such facilities are classified according to the SIC code of the facility they support. Long-distance trucking centers, on the other hand, are generally classified as SIC code 4213, and are subject to regulation under 40 CFR 122.26(b)(14)(viii)).

Category (x): Construction activity

27. **Who must apply for permit coverage for construction activities?**

A. Under the NPDES storm water program, the operator of a regulated activity or discharge must apply for a storm water permit. EPA clarified that the operator of a construction activity is the party or parties that either individually or taken together meet the following two criteria: (1) they have operational control over the site specifications (including the ability to make modifications in specifications); and (2) they have the day-to-day operational control of those activities at the site necessary to ensure compliance with plan requirements and permit conditions (9/9/92 Federal Register page 41190). If more than one party meets the above criteria,

VOL 12

4344

then each party involved must become a co-permittee with any other operator(s). For example, if the site owner has operational control over site specifications and a general contractor has day-to-day operational control of site activities, then both parties will be co-permittees.

When two or more parties meet EPA's definition of operator, each operator must submit an NOI, and either include a photocopy of the other operators' NOI(s) or the general permit number that was assigned for that project. Under EPA's storm water construction general permits, the co-permittees are expected to join in implementing a common pollution prevention plan prior to submittal of the NOI, and in the retention of all plans and reports required by the permit for a period of at least three years from the date that the site is finally stabilized.

For individual storm water discharge permits, applications must be filed 90 days prior to the commencement of construction. If a contractor has not been selected at the time of application, the owner of the project site would initially file the application and the contractor should sign on when selected. Under an individual storm water permit for construction, multiple operators would have to sign onto the permit, instead of submitting a new application. Please note that authorized NPDES States may have varying NOI and/or permit requirements and should be contacted on this issue.

28. What are the responsibilities of subcontractors at the construction site under EPA's storm water construction general permits?

A. EPA storm water construction general permits require subcontractors to implement the measures stated in the pollution prevention plan and to certify that he/she understands the terms and conditions of the permit requirements. Under EPA's general permits, subcontractors are not required to submit NOIs.

29. What is meant by a "larger common plan of development or sale?"

A. A "larger common plan of development or sale" is a contiguous area where multiple separate and distinct construction activities may be taking place at different times on different schedules under one plan. For example, if a developer buys a 20-acre lot and builds roads, installs pipes, and runs electricity with the intention of constructing homes or other structures sometime in the future, this would be considered a common plan of development or sale. If the land is parceled off or sold, and construction occurs on plots that are less than five acres by separate, independent builders, this activity still would be subject to storm water permitting requirements if the smaller plots were included on the original site plan.

VOL 12

4345

30. Does construction activity encompass repaving of roads?

A. Repaving is not regulated under the storm water program unless five or more acres of underlying and/or surrounding soil are cleared, graded or excavated as part of the repaving operation.

31. Is clearing of lands specifically for agricultural purposes regulated construction activity (40 CFR 122.26(b)(14)(x)) under the storm water program?

A. No. Although the clearing of land may be greater than five acres, any amount of clearing for agricultural purposes is not considered an industrial activity under the storm water regulations. Section 402(l)(1) of the 1987 Water Quality Act exempts agricultural storm water discharges from NPDES permitting requirements including storm water permitting. This exemption only applies, however, if the clearing of land is solely for agricultural purposes. (See Question 13).

32. If a construction activity that disturbs five or more acres commences on a site covered by an existing industrial storm water permit, are the storm water discharges from the construction area covered by the existing permit or is a separate permit required?

A. If the existing permit is an individual permit, than the operator must either request a modification of the existing permit to include the construction storm water discharges or apply for coverage under a separate permit that specifically addresses that construction activity. If the permittee decides to modify the existing individual permit, permit modifications must be approved prior to initiating any construction activity. If the existing permit is an EPA storm water industrial general permit, the operator should submit an NOI for coverage under EPA's storm water general permit for construction activities. States with NPDES permitting authority may have different requirements.

33. If a construction activity that disturbs less than five acres occurs on site of a regulated industrial activity currently covered by EPA's industrial storm water general permit, does the regulated industry have to modify its pollution prevention plan to include controls for the area of construction?

A. Yes. Regulated industrial activities covered by EPA's storm water industrial general permit must revise their pollution prevention plan to address all new sources of pollution and runoff including those from construction activities disturbing less than five acres, that occurred on the site of the regulated industry. However, if less than five acres, a separate storm water permit for the construction activity is not required (see Question 32).

34. For projects such as a 100-mile highway construction project, what location should be provided on the NOI?

A. The midpoint of a linear construction project should be used as the site location on EPA's NOI form. For construction projects that span across more than one State, the project must meet the application requirements of each State.

35. Are long-term maintenance programs for flood control channels (such as vegetation removal) or similar roadside maintenance programs subject to permitting if five or more acres are disturbed?

A. If grading, clearing or excavation activities disturb five or more acres of land either for an individual project or as part of a long-term maintenance plan, then the activity is subject to storm water permit application requirements.

36. **For a construction activity that uses off site "borrow pits" for excavation of fill material or sand and gravel, should the number of disturbed acres at the borrow pit be added to the number of acres at the construction site to determine the total number of disturbed acres?**

A. No, off site borrow pits are not considered part of the on site construction activity. If a borrow pit is specifically used for the removal of materials such as sand, gravel, and clay, the pit is considered a mine and is classified under SIC code 14. Such sites would be regulated as industrial activity as defined at 40 CFR 122.26(b)(14)(iii). However, if the borrow pit is utilized for the removal of general fill material (e.g. dirt) and disturbs five or more acres of land, the pit would be considered a construction activity as defined at 40 CFR 122.26(b)(14)(x).

37. **Would building demolition constitute a land disturbing activity and require a storm water construction permit application?**

A. The definition of land disturbing activity includes but is not limited to clearing, grading and excavation. At a demolition site, disturbed areas might include the site where building materials, demolition equipment, or disturbed soil are situated, which may alter the surface of the land. Therefore, demolition activities that disturb five or more acres of land would be subject to storm water construction permit application requirements.

38. What are the legal responsibilities and liabilities for construction activities disturbing less than five acres, pursuant to the Ninth Circuit U.S. Court of Appeals decision on June 4, 1992?

A. In NRDC v. EPA, 966 F.2d 1292, the Ninth Circuit U.S. Court of Appeals remanded for further rulemaking, EPA's exemption of construction sites less than five acres which are not part of a larger common plan of development or sale. The Agency intends to undergo further rulemaking proceedings for construction sites less than five acres. Until further rulemaking is completed, permit applications for such activities need not be submitted to EPA. However, States with NPDES permitting authority may have more stringent requirements.

39. **Do storm water construction general permits authorize non-storm water discharges?**

A. Under EPA's storm water construction general permits, issued on September 9, 1992, and September 25, 1992, the following non-storm water discharges are conditionally authorized (57 FR 41219) and (57 FR 44419): discharges from fire fighting activities; fire hydrant flushings; waters used to wash vehicles or control dust; potable water sources including waterline flushings; irrigation drainage; routine external building washdown which does not use detergents; pavement washwaters where spills or leaks of toxic or hazardous materials have not occurred (unless all spilled material has been removed) and where detergents are not used; air conditioning condensate; springs; uncontaminated ground water; and foundation or footing drains where flows are not contaminated with process materials such as solvents. These discharges, except for flows from fire fighting activities, must be identified in the pollution prevention plan and the plan must address the appropriate measures for controlling the identified non-storm water discharges. Other non-storm water discharges not listed above or not identified in the storm water pollution prevention plan, must be covered by a different NPDES permit.

Category (xi): Light manufacturing facilities

40. **If oil drums or contained materials are exposed during loading or unloading at a category (xi) facility, are storm water discharges from this area subject to the storm water regulations?**

A. The storm water regulations require category (xi) facilities to apply for a storm water permit where material handling equipment or activities, raw materials, intermediate products, final products, waste materials, by-products, or industrial machinery are exposed to storm water. If there is a

VOL 12

4348

reasonable potential for leaks or spills from these drums which could be exposed to storm water, discharges from that area would be subject to storm water permitting requirements. Completely covering loading and unloading activities may eliminate exposure. Note that permitting authorities may have more stringent interpretations with respect to exposure on industrial sites and should be consulted for case-by-case determinations. For a discussion on the 9th Circuit Court of Appeals decision (June 1992) and future EPA rulemakings on category (xi) facilities, please refer to Section IX of this document.

41. Does the storage of materials under a roof at a category (xi) facility constitute exposure?

A. If materials or products at a light industrial facility are stored outside under a roof and there is no reasonable potential for wind blown rain, snow, or runoff coming into contact with the materials or product, then there may not be exposure at that area. However, if materials are stored under a structure without sides and storm water comes into contact with material handling equipment or activities, raw materials, intermediate products, final products, waste materials, by-products or industrial machinery, the discharge from that area must be permitted. The permitting authority should be contacted for specific issues related to exposure.

III. Individual Permits

42. Will individual permits include requirements for storm water pollution prevention plans and monitoring?

A. EPA anticipates that many individual permits will include storm water pollution prevention plans as a means of satisfying Best Available Technology (BAT)/Best Conventional Technology (BCT) requirements established in the Clean Water Act (CWA). With regard to monitoring requirements under individual permits, such requirements will be determined by the permit writer on a case-by-case basis. At a minimum, all facilities with storm water discharges associated with industrial activity must conduct an annual site inspection as prescribed at 40 CFR 122.44(i)(4)..

43. Do permitting authorities have the option of subjecting facilities that have submitted individual storm water permit applications to general permits?

A. Yes, permitting authorities may subject facilities that have submitted individual permit applications to general permits. Facilities that are covered

VOL 12

4349

by a general permit may petition the permitting authority to be covered under an individual permit by submitting an individual permit application with reasons supporting the request to the permitting authority, pursuant to 40 CFR 122.28(b)(2)(iii).

44. **What are the benefits/drawbacks of pursuing an individual storm water permit over a general permit?**

A. An individual storm water permit may be advantageous, as it is designed to reflect a facility's site-specific conditions, whereas general permits are much broader in scope, particularly in terms of monitoring requirements. However, the individual permit application is generally more difficult to prepare than submitting EPA's notice of intent (NOI) to be covered under a general permit (in part because the individual permit application requires sampling and EPA's NOI does not). General permits may be advantageous because regulated facilities know, in advance of submitting their NOI, the requirements of the permit. In addition, coverage under a general permit may be automatic (depending on how the permit is written), whereas the individual permitting process takes longer.

45. **When does EPA anticipate that individual permits will be issued?**

A. Issuance of individual permits may vary on a State by State basis, as permitting priorities and resources allow. The December 18, 1992, Federal Register (57 FR 60447) established October 1, 1993, as the deadline by which individual permits are to be issued. Many authorized States are already issuing individual permits.

46. **Can a facility that has submitted an individual permit application obtain general permit coverage upon issuance of a general permit in its State?**

A. Yes, an eligible facility may opt for coverage under a general permit (by submitting an NOI) up until the time that the permitting authority issues such facility its individual permit. Authorized States may require a written request for withdrawal from the individual permit application process. EPA recommends submitting such requests to the appropriate Regional office.

IV.	EPA General Permits (issued on 9/9/92 and 9/25/92)

47. What is the difference between EPA's construction and industrial general permits?

A. Because the nature of construction activity varies considerably from other industrial activities, EPA developed two separate general permits: one covering storm water discharges from construction activity and one for other storm water industrial discharges. Whereas the pollution prevention plan for the construction permit focuses on sediment and erosion controls and storm water management, the pollution prevention plan for industry emphasizes general site management. Note that some authorized States have industrial general permits that authorize storm water discharges from construction activity.

EPA's general permits for storm water discharges associated with industrial activity, issued on 9/9/92 (57 FR 41236) and 9/25/92 (57 FR 44438), authorize storm water discharges from all new and existing point source discharges of storm water associated with industrial activity, as defined at 40 CFR 122.26(b)(14), to waters of the U.S., except for ineligible storm water discharges that are listed at I.B.3. (9/9/92 Federal Register page 41305) and (9/25/92 Federal Register page 44444) in EPA's general permits.

EPA's general permits for storm water discharges associated with construction activity, which were issued on 9/9/92 (57 FR 41176) and 9/25/92 (57 FR 44412), authorize storm water discharges associated with construction activity, as defined at 40 CFR 122.26(b)(14)(x), except for ineligible discharges that are listed at I.B.3 (9/9/92 Federal Register page 41217) and (9/25/92 Federal Register page 44418) in EPA's general permits.

48. What is the procedure for applying for coverage under EPA's industrial or construction general permits?

A. Dischargers of storm water associated with industrial activity located in non-NPDES States must submit a Notice of Intent (NOI) to be authorized to discharge under the general permit. The NOI form is a one-page document requesting basic information about the nature of the facility and the particular storm water discharge under consideration. Under EPA's general permits, monitoring is not required for submittal of the NOI. States with NPDES authority may have different requirements for their NOI and should be contacted directly.

VOL 12

4351

49. **Will a facility automatically be covered by an EPA general permit upon submittal of an NOI or will it have to cease operations until the Agency provides notification of acceptance?**

A. Permit coverage begins two days after the postmark date on the NOI, provided the storm water discharges from the facility are eligible for coverage as established by the permit conditions (see 9/9/92 Federal Register page 41305 for limitations on coverage). The permitting authority can require the submittal of an individual application at any time. However, the facility may continue to discharge under the general permit until an individual permit is issued or denied.

50. **What are the deadlines for compliance with EPA's general permits?**

A. Individuals who intend to obtain coverage for a storm water discharge associated with industrial activity that commenced on or before October 1, 1992, were required to submit an NOI by October 1, 1992; however, EPA is accepting late NOIs. Regulated facilities wishing to obtain coverage under the general permit that have not yet submitted an NOI should do so immediately. EPA's storm water general permits require permittees to develop and implement a storm water pollution prevention plan. Deadlines for NOI submittal and development and implementation of plans are listed in the table below.

Facilities with salt storage or facilities that were not required to report under Emergency Planning Community Right to Know (EPCRA) Section 313 prior to July 1, 1992, (but must report after that date) must comply with the special requirements for section 313 facilities and salt storage (if applicable) within 3 years of the date on which the facility is required to first report under section 313. All other conditions in the permit must be met within the deadlines listed above. Plans do not have to be submitted to the Agency but must be kept on site and made available upon request.

Type of Discharge	NOI Deadline	Pollution Prevention Plan Development Deadline	Pollution Prevention Plan Implementation Deadline
Existing industrial activities (other than construction)	October 1, 1992	April 1, 1993	October 1, 1993

VOL 12

4352

R0037660

Type of Discharge	NOI Deadline	Pollution Prevention Plan Development Deadline	Pollution Prevention Plan Implementation Deadline
Industrial activities (other than construction) that begin between October 1, 1992 and January 1, 1993	2 days prior to the start of industrial activity	Within 60 days of commencement of operations	Within 60 days of commencement of operations
Industrial activities (other than construction) that begin on or after January 1, 1993	2 days prior to the start of industrial activity	Within 60 days of commencement of operations	Upon commencement of operations
Oil and gas facilities previously not required to be permitted that have an RQ after October 1, 1992	Within 14 days of first knowledge of the release	Within 60 days of first knowledge of the release	Within 60 days of first knowledge of the release
Municipally-owned or operated industrial activities that were rejected or denied from a group application	Within 180 days of the date of rejection or denial	Within 365 days of the date of rejection or denial	Within 545 days of the date of rejection or denial
Construction sites in operation on October 1, 1992	October 1, 1992	October 1, 1992	October 1, 1992
Construction sites that begin operation after October 1, 1992	2 days prior to the start of construction	Prior to the submittal of the NOI	With the initiation of construction activities

VOL 12

4353

51. Is there a fee for NOI applications?

A. EPA's general permits do not require fees at this time. However, authorized NPDES States may levy fees and should be contacted directly.

52. Where should NOIs be submitted?

A. Facilities in States and Territories where EPA is the permitting authority submit NOIs to the central processing center at the following address:

Storm Water Notice of Intent
P.O. Box 1215
Newington, VA 22122.

All permittees in States with NPDES authority submit the NOI to their State permitting authority except those in New York, who submit to the processing center at the above address. Note that authorized NPDES States may develop NOI forms that are different from EPA's NOI form. Under EPA's general permits, the operator of any industrial activity that discharges storm water through a municipal separate storm sewer system in a medium or large municipality must also submit a copy of the NOI to that municipality. In addition, operators of construction activities must provide a copy of all applicable NOIs for a site to the local agency approving sediment and erosion plans or storm water management plans.

53. Is an operating regulated industrial facility required to submit a separate NOI for each outfall that discharges storm water associated with industrial activity at the site?

A. Under EPA's general permits, one NOI is generally sufficient for the entire site, provided there is one operator. In this case, the pollution prevention plan must address all discharges of storm water associated with industrial activity from the site. If there are multiple operators at the site, each operator must submit an NOI. In addition, if a facility that is covered under EPA's industrial storm water general permit undertakes a construction activity disturbing more than five acres of land, then the facility must submit an NOI for those construction-related storm water discharges for coverage under EPA's construction general permit (or submit an individual permit application).

VOL 12

4354

54. **Will a facility receive any notification from EPA after submitting an NOI under EPA's general permit?**

A. Yes, EPA confirms the receipt of NOIs and will provide the applicant with a permit number and explains how to get a summary of the guidance on preparing storm water pollution prevention plans.

55. **Is an entire facility excluded from coverage under EPA's general permits if a single discharge at the site is excluded from coverage?**

A. No. Eligibility under EPA's general permits should be applied on a discharge-specific basis. Thus, a site with multiple discharges can be covered under two different permits: a general permit for some discharges and a separate NPDES permit for any discharges excluded from coverage under the general permit. NPDES States should be contacted for additional guidance on this issue.

56. **Does an industrial facility operating under an EPA industrial general permit have to apply for a separate permit for all on site construction activities that disturb more than five acres of land?**

A. Storm water discharges from construction activities that disturb five or more acres of land must be covered under a separate NPDES permit that specifically addresses storm water discharges from construction activity. EPA's industrial storm water general permits do not provide coverage for storm water discharges from regulated construction activities. Construction activities that disturb less than five acres of land do not require a storm water permit at this time. The pollution prevention plan for the industrial facility must be modified to address site changes due to that amount of construction activity.

57. **Can a facility submit one NOI for similar but separately located industrial facilities which are owned by the same corporation?**

A. No. One NOI must be submitted by the operator of each individual facility that intends to obtain coverage under a general permit, regardless of common ownership.

58. **Does an asphalt/concrete batch plant have to submit a new NOI each time it changes location?**

A. Under EPA's general permits, an NOI must be submitted each time the plant moves to a new site of operation. However, some authorized States may have different requirements with respect to asphalt/concrete batch plants and, therefore, facilities in such States should contact their permitting authorities.

59. **Who is required to monitor under the conditions of EPA's storm water general permits?**

A. EPA established tiered monitoring requirements in its final industrial storm water general permits based on the potential to contribute pollutants to storm water (4/2/92 Federal Register page 11394). Six classes of facilities are required to monitor semiannually and report annually, ten classes of facilities are required to monitor annually and keep the data on site, and all other classes of facilities are not required to monitor. All facilities authorized by general permits (including those facilities not otherwise required to monitor) must still conduct an annual site inspection, except for inactive mining sites where this may be impractical due to remote location and inaccessibility of sites (inspection no less than once in three years). The sixteen classes of facilities that are required to monitor are specified in EPA's industrial general permits (9/9/92 Federal Register page 41248), which are available from the Storm Water Hotline. EPA's construction storm water general permits require periodic inspections in lieu of monitoring.

60. **If an industrial facility that is required to monitor under EPA's industrial storm water general permits does not have any exposure of materials or activities to storm water, does it still have to conduct sampling?**

A. Under EPA's industrial storm water general permits, industrial facilities can provide a certification in lieu of monitoring results for a given outfall, that materials and activities are not presently exposed to storm water and will not be exposed during the certification period (see 9/9/92 Federal Register page 41314 for a more detailed description). This determination should be applied on outfall-by-outfall basis (e.g., permittees may elect to monitor certain outfalls while providing certification for others). The certification must be updated on an annual basis and retained in the pollution prevention plan. The six classes of facilities that are required to report monitoring results annually must submit this certification to the permitting authority in lieu of the Discharge Monitoring Report (DMR).

61. **Within one drainage area leading to a single outfall, if a facility conducts two separate industrial activities that are subject to both semiannual and annual monitoring requirements, which set of monitoring requirements will apply?**

A. If the discharges cannot be segregated, the combined discharge would be subject to both sets of monitoring requirements. In effect, a combined

VOL 12

4356

discharge could be subject to annual monitoring requirements for certain parameters and semi-annual monitoring for others. If a facility can segregate the discharges from the different activities, separate monitoring requirements would apply to each discharge.

62. **Is it possible to sample only one of several identical outfalls under the provisions of EPA's general permits?**

Yes. To reduce the monitoring burden on the facility, the permit allows an operator to sample one outfall where it is substantially identical to the other outfalls. Permittees that intend to use this provision must justify and document in writing why one outfall is substantially identical to the others. Criteria for making this determination are presented in the NPDES Storm Water Sampling Guidance Document. Facilities using this provision must include the written justification in their storm water pollution prevention plan. Facilities that are subject to semiannual monitoring requirements must submit the justification of why an outfall is substantially identical to the others with the Discharge Monitoring Report. Other facilities required to monitor under the permit are not required to submit the justification unless it is requested by the permitting authority.

63. **If a facility had to report under section 313 of the Emergency Planning and Community Right to Know Act (EPCRA) when its NOI was submitted but no longer uses the quantity of water priority chemicals that makes such reporting necessary, is that facility still subject to special requirements in EPA's industrial storm water general permits for facilities that handle EPCRA section 313 water priority chemicals?**

A. No. Such facilities are no longer subject to the special EPCRA requirements contained in EPA's industrial storm water general permit and should accordingly modify their pollution prevention plan to indicate the changes in industrial activity at the facility.

64. **Under EPA's general permits, when and where must Discharge Monitoring Reports (DMR) be submitted for semi-annual monitoring facilities?**

A. DMRs must be submitted to the permitting authority according to the following schedule: a) certain EPCRA section 313 facilities and wood treatment facilities monitor from January to June and July to December and report no later than January 28 following the second monitoring period; b) Primary metal facilities, facilities with coal pile runoff, and battery reclaimers monitor from March to August and September to February and report no later than April 28; and c) land disposal facilities monitor from October to March and from April to September and report no later than October 28. For facilities in non-NPDES States, DMRs must be

VOL 12

4357

submitted to the EPA Regional office (Section XI of this document includes storm water list of contacts for addresses). In States with approved NPDES permit programs, DMRs must be sent to the location specified in the State's general permit. The general permits in such States may also have different schedules for submitting DMRs than the one specified above.

65. Under the industrial general permit, coal-fired steam electric facilities have annual monitoring requirements for storm water discharges from coal handling sites (other than from coal pile runoff). Are access roads considered coal handling sites?

A. Coal handling sites include those areas of the facility where coal is either loaded or unloaded. Therefore, those portions of access roads where loading/unloading operations do not occur are not considered to be coal handling sites and, therefore, are not subject to annual monitoring requirements under EPA's general permits.

66. Are there specific numeric effluent limits in EPA's storm water general permits?

A. EPA's general permits establish pollutant discharge limits for total suspended solids (TSS) and pH in coal pile runoff. In most other situations, EPA's industrial storm water general permits focus on storm water management and the implementation of facility-specific pollution prevention plans; however, EPA's industrial general permits also include State-specific conditions that may include additional numeric effluent limits.

67. What is a storm water "best management practice" (BMP)?

A. A BMP (defined at 9/9/92 Federal Register page 41319) is a technique, process, activity or structure used to reduce the pollutant content of a storm water discharge. BMPs include simple, nonstructural methods such as good housekeeping and preventive maintenance. Additionally, BMPs may include sophisticated, structural modifications such as the installation of sediment basins. The focus of EPA's general permits is on preventative BMPs which limit the release of pollutants into storm water discharges. EPA has published guidance materials to assist in the selection of appropriate BMPs in the preparation of storm water pollution prevention plans, including: *Storm Water Management for Industrial Activities: Developing Pollution Prevention Plans and Best Management Practices (PB-92-235969)* and *Storm Water Management for Construction Activities: Developing Pollution Prevention Plans and Best Management Practices (PB-*

92-235951). These Manuals are available from NTIS at (703) 487-1650 and the Office of Water Resource Center at (202)260-7786.

68. **What should a facility do when the nature of its activities changes?**

A. When the nature of a facility's activities changes, the facility must modify the pollution prevention plan accordingly. If the facility is subject to new monitoring requirements as a result of the changes, sampling must begin at the start of the next monitoring period.

69. **Is there a procedure for notifying EPA when a storm water discharge associated with industrial activity covered by EPA's general permit has been eliminated?**

A. Yes. EPA's general permits include procedures for filing a Notice of Termination (NOT) form when there is no longer a potential for storm water discharges associated with industrial activity to occur. Operators of construction activities can submit an NOT once they have finally stabilized all areas that were disturbed. For construction activity, final stabilization means that all soil disturbing activities at the site have been completed, and that a uniform perennial vegetative cover has been established or equivalent permanent stabilization measures (such as the use of riprap, gabions, or geotextiles) have been employed with a density of 70% of the previously existing/background cover for unpaved areas and areas not covered by permanent structures. A copy of the NOT can be found in Federal Register notices dated September 9, 1992 (57 FR 41232 and 41341), and September 25, 1992 (57 FR 44434 and 44469).

70. **If a NPDES authorized State has general permitting authority but has not yet finalized an applicable general permit, can a facility still submit an NOI and assume general permit coverage?**

A. No, a facility cannot submit an NOI to obtain coverage under a general permit until that permit has been finalized. Furthermore, a facility located in an NPDES State cannot seek coverage under one of EPA's general permits.

71. **Will State general permit requirements vary and to what extent?**

A. General permit requirements for authorized NPDES States may vary considerably because these States develop and issue permits independently from EPA. However, all NPDES permits must meet minimum technical and water quality-based requirements of the Clean Water Act. Permittees in NPDES authorized States should consult with their permitting authorities regarding particular State conditions. Under EPA's storm water general permits, State-specific requirements vary

VOL 12

4359

because of different water quality concerns in different States. Each of the 12 non-authorized States and Territories provided certification that EPA's general permits comply with State water quality standards, and added permit requirements where necessary to achieve compliance with those standards in the final general permits.

72. **Can discharges from industrial areas at a construction site such as portable asphalt plants and/or concrete batch plants be covered under EPA's construction general permits?**

A. No. EPA's construction general permits only authorize discharges from the construction area; these permits do not authorize storm water discharges from industrial activities other than construction that are located on the construction site. Portable asphalt plants and/or concrete batch plants are considered to be "industrial activity," as defined 40 CFR 122.26(b)(14)(ii). Therefore, storm water discharges from such industrial activities must be in compliance with a general or individual storm water permit for industrial storm water discharges other than construction. At a construction site which disturbs less than 5 acres of land (and which is, therefore, not subject to storm water permit application requirements for the construction activity), the operator of the mobile asphalt or concrete plant still would be required to obtain storm water permit coverage for discharges from the plant. Please note that States with approved NPDES permit programs may allow portable asphalt plants and/or cement batch plants to be covered under the State's construction general permit.

V. Group Applications

73. **How will group applicants be permitted?**

A. EPA is currently developing a model permit using information from Part I and Part II group applications, and other sources. This model permit will have sections which address a particular type of industrial activity. When the model permit is completed, the permitting authority (EPA or NPDES States) then has the option to propose and issue final permits to cover group members within their state based upon the model permit.

VI. Sampling

74. **For what parameters does a facility have to sample under the individual or group application?**

A. Applicants are required to obtain quantitative data from samples collected during storm events from all outfalls that discharge storm water associated with industrial activity for the following parameters: (1) any pollutant limited in an effluent guideline to which the facility is subject; (2) Any pollutant listed in the facility's permit for its process wastewater (if the facility is operating under an existing NPDES permit); (3) Oil and grease, pH, BOD5, COD, TSS, total phosphorous, total Kjeldahl nitrogen, and nitrate plus nitrite nitrogen; (4) certain toxic pollutants listed in Tables II and III of the Appendix D to 40 CFR Part 122 (also listed as Tables 2F-2 and 2F-3 in the instructions for Form 2F) that are expected to be present in the storm water.

75. For an individual or group application, how many aliquots (portions) of storm water are needed to obtain a flow-weighted composite?

A. A flow-weighted composite may be taken as a combination of a minimum of 3 sample aliquots taken in each hour of discharge for the entire event or for the first three hours of the event, with each aliquot collection being separated by a minimum of 15 minutes. If the storm event lasts less than three hours, aliquots should be collected for as long as there is sufficient flow. Large and medium municipalities may use a different protocol with respect to time duration between collection of aliquots with approval of the permitting authority. EPA's *NPDES Storm Water Sampling Guidance Document* discusses several ways to estimate flows. [This manual is available from the Storm Water Hotline (703) 821-4823) and the Office of Water Resource Center (202)260-7786].

76. How does a facility measure flow if there are numerous small outfalls?

A. Applicants may provide either measurements or estimates of storm water flows. One possible method for estimating flow is to create a conveyance that would combine flows from many of the outfalls. Alternatively, where flows are similar, the flow at one outfall may be measured to calculate flows at the other outfalls, provided that the method of measurement is indicated to the permitting authority. EPA's *NPDES Storm Water Sampling Guidance Document* discusses several ways to estimate flows. [This manual is available from the Storm Water Hotline (703) 821-4823) and the Office of Water Resource Center (202)260-7786.]

77. For what parameters is only a grab sample appropriate?

A. When collecting storm water samples, grab samples are required for the following parameters: pH, temperature, cyanide, total phenols, residual

VOL 12

4361

chlorine, oil and grease, fecal coliform and fecal streptococcus. Both grab and composite samples are required for all other pollutants.

78. Do both a grab and a composite sample have to be taken from a 24-hour holding pond?

A. No. Only a minimum of one grab sample is required to be taken.for effluent from holding ponds or other impoundments with a retention period of greater than 24 hours for the representative event.

79. Can composite and grab samples be taken from separate events?

A. Grab and composite samples for a given outfall should be taken from the same storm event to provide a basis for comparing the data. If this is impossible, information describing each storm event used for sample collection should be recorded and submitted with sampling results. However, applicants are advised that the permitting authority may request data to be collected from only one storm event.

80. Is a facility required to sample all of its outfalls during a single storm event?

A. No. Unless otherwise specified by the permitting authority, a facility may sample outfalls during different events provided that the storms meet the criteria established in the application regulations or in the applicable permit language. Information describing each storm event used for sample collection should be recorded and submitted with sampling results.

81. If a facility has two conveyences that join and leave the site as one combined discharge, where should a sample be collected?

A. If the discharge is composed entirely of storm water, the sampling point should be at the outfall as it leaves the property. If the discharge is a combination of process wastewater and storm water, the storm water component of the discharge should be sampled before it commingles with the process waste water discharges. If sampling at an outfall at the property boundaries is impossible because of safety reasons, inaccessibility, or a poor conveyance, sampling may be done closer to the discharge source.

82. How long of a 'dry' period does a facility need before sampling?

A. A 'dry' period needs to be at least 72 hours. More specifically, all samples must be collected from the discharge resulting from a storm event that

VOL 12

4362

occurs at least 72 hours from the previously measurable (greater than 0.1 inches) storm event.

83. If two or more outfalls at a facility have identical discharges, does each outfall have to be sampled?

A. Where a facility has outfalls that discharge "substantially identical effluent," the permitting authority may allow the applicant to test only one outfall and report that the quantitative data are representative of the substantially identical outfalls. EPA's *NPDES Storm Water Sampling Guidance Document* (available from the Storm Water Hotline (703-821-4823)) provides information on how to prepare this petition, or the applicant should contact their permitting authority to determine what information is required.

84. Do analyses for storm water need to be done by a certified lab?

A. There is no Federal requirement to use a certified lab. However, certain States may require that a certified lab be used. Please note, analyses must comply with the analytical procedures set out in 40 CFR Part 136, as discussed below.

85. What analytical methods must be used for the pollutants for which sampling is required?

A. EPA-approved methods must be used where a method for a pollutant has been promulgated. 40 CFR Part 136 discusses required methods. If there is no approved method, the applicant may use any suitable method, but must provide a description of the method in its application. Additional information on general sampling issues can be obtained through the EPA's *NPDES Storm Water Sampling Guidance Document*. The manual is available from the Storm Water Hotline (703-821-4823).

VII. Municipal Permit Applications

86. Once a municipal separate storm sewer system (MS4) has submitted Part 2 of its storm water permit application, when does the term of the permit actually begin?

A. The term of the permit begins when a permit is issued by the permitting authority. Pursuant to 40 CFR 122.26(e)(7), storm water permits for discharges from MS4s are to be issued with in one year after submission of a complete application. Since applications for medium and large

VOL 12 4363

municipal separate storm sewer systems were due on May 17, 1993 and November 16, 1992, respectively, this results in permit issuance by November 16, 1993 for large municipalities and by May 17, 1994 for medium municipalities.

87. **How is EPA incorporating 1990 census data into the storm water program?**

A. Most of the municipalities that meet the definition of either a large or medium MS4 based on the results of the 1990 Census have already begun to seek an NPDES permit. Headquarters is working with the Regions and States to determine the best way to incorporate the remaining municipal entities into the program.

88. **How does EPA envision the relationship between large and medium MS4 operators and NPDES permitting authorities in terms of addressing industrial storm water discharges to MS4s?**

A. EPA envisions a partnership between NPDES permitting authorities and operators of large and medium municipal separate storm sewer systems in controlling pollutants in storm water discharges associated with industrial activity through MS4s. In addition, NPDES storm water permits provide a basis for enforcement actions directly against the owner or operator of the storm water discharge associated with industrial activity.

A second NPDES permit will be issued to the operator of the large and medium MS4. This permit will establish the responsibilities of the municipal operators in controlling pollutants from storm water associated with industrial activity which discharges through their municipal system. Under this approach, municipal operators will be able to:

- Assist EPA in identifying priority storm water discharges associated with industrial activity through their system;
- Assist EPA in reviewing and evaluating storm water pollution prevention plans that industrial facilities are required to develop; and
- Assist EPA in compliance efforts regarding storm water discharges associated with industrial activity to their municipal system.

A more complete description of this policy is provided in the August 16, 1991 Federal Register (56 FR 40973).

VOL 12

4364

VIII.	The Intermodal Surface Transportation Efficiency Act of 1991 (Transportation Act)

89. How did the Transportation Act affect permitting requirements for municipalities under 100,000?

A. Storm water discharges from certain industrial activities owned or operated by municipalities with a population of less than 100,000 people were granted a moratorium from the October 1, 1992 deadline for storm water permit applications. Exceptions to this moratorium include discharges from powerplants, airports and uncontrolled sanitary landfills.

90. How does the Transportation Act impact privately owned or operated industrial activities located in municipalities under 100,000?

A. The provisions of the Transportation Act specifically address publicly owned or operated industrial activities. Privately owned facilities that have storm water discharges associated with industrial activity, as defined at 40 CFR 122.26(b)(14), must submit a permit application regardless of the size of the population of the municipality in which they are located.

91. What is an "uncontrolled sanitary landfill?"

A. An uncontrolled sanitary landfill (discussed in the 4/2/92 Federal Register, page 11410) is a landfill or open dump, whether in operation or closed, that does not satisfy the runon/runoff requirements established pursuant to subtitle D of the Solid Waste Disposal Act. However, landfills closed prior to October 9, 1991 are not subject to RCRA runon/runoff requirements, and therefore need not submit storm water permit applications if they are located in municipalities of less than 100,000 population. Landfills closed after October 9, 1991 and others that meet the above definition would be subject to the storm water permit application requirements.

92. If a municipally-owned sewage treatment plant is located in a municipality with a population of less than 100,000 people, but the service population is greater than 100,000 people, is the facility subject to the permitting requirements?

A. Yes, because service populations are used in determining population for publicly-owned treatment works (POTWs) (April 2, 1992 Federal Register page 11394). Additionally, where one sewer district operates a number of POTWs, the entire service population of the district will be used to determine the applicable population classification of all the POTWs operated by the district. For example, if a district with a cumulative

VOL 12

4365

service population of 160,000 operates two sewage treatment plants, one of which serves 120,000 and the other which serves 40,000, both plants will be considered to be owned or operated by a municipality with a population of 100,000 or more.

93. If a construction operation disturbing five or more acres is owned by a small municipality (a population of less than 100,000 people)but operated by a private contractor, is the activity regulated?

A. No. If the construction activity is either owned or operated by a municipality with a population of less than 100,000 it would not be required to obtain a storm water permit during Phase I of the storm water program. Some States, however, may require that an application be submitted.

IX. 9th Circuit U.S. Court of Appeals Decision

94. What is the current status of light manufacturing facilities without exposure and construction activities under five acres, pursuant to the 9th Circuit Court decision?

A. The 9th Circuit Court decision remanded two "exemptions" provided in the NPDES storm water permit application regulations for light manufacturing facilities without exposure and construction activities under five acres (11/16/90 Federal Register page 48066). Both exemptions were remanded for further proceedings. In response to these two remands, the Agency intends to conduct further rulemakings on both the light manufacturing and construction activities under five acres. In the December 18, 1992, Federal Register, the Agency stated that it is not requiring permit applications from construction activity under five acres or light industry without exposure until this further rulemaking is completed.

X. Phase II of the Storm Water Program

95. What is the difference between Phase I and Phase II of the NPDES storm water program?

A. In the Water Quality Act of 1987, Congress mandated that EPA establish storm water control programs in two phases. While the first Phase I was defined on November 16, 1990, Phase II regulations were to be promulgated by October 1, 1992. However, the Water Resources Development Act (WRDA) of 1992 extended deadlines for Phase II of the

VOL 12

4366

storm water program as follows: 1) EPA must issue Phase II regulations by October 1, 1993; and 2) permits for Phase II sources may not be required by EPA or the State prior to October 1, 1994. EPA is currently developing regulations that will implement Phase II of the storm water program. (See Question #1 for more information on Phase I).

96. **Will all storm water discharges that are not regulated under Phase I be regulated under Phase II of the storm water program (e.g., service stations, retail and wholesale businesses, parking lots, municipalities with populations of less than 100,000)?**

A. Not necessarily. Statutory provisions require that EPA, in consultation with State and local officials, issue regulations that designate additional Phase II sources for regulation to protect water quality. EPA is currently developing approaches to identify and control high risk Phase II sources. EPA requested initial public comments on a variety of Phase II issues on September 9, 1992 (57 FR 41344). As part of this process, EPA is considering all sources of storm water not regulated under Phase I for potential coverage under Phase II.

APPENDIX E

GROUP APPLICATION PART 2 SAMPLING DATA AND INDUSTRY DESCRIPTIONS ORGANIZED BY INDUSTRY SECTOR

VOL 12

4369

APPENDIX E

GROUP APPLICATION PART 2 SAMPLING DATA AND INDUSTRY DESCRIPTIONS ORGANIZED BY INDUSTRY SECTOR

This appendix contains summary descriptions for the 31 industrial sectors that were identified in the group application portion of the Phase I permitting process (four of the sectors were consolidated into two sectors for permit development purposes). The summaries describe the industrial activities, significant materials, and pollutants of concern that were listed in the applications submitted by the industry groups. The descriptions also contain tables which summarize the sampling data submitted by the groups. The tables list the mean values, median values, 95th percentile values, for the grab and composite samples and the mean, median and 90th percentile values for NURP data for a portion of the pollutants sampled within each sector.

INDUSTRIAL SECTORS GROUP APPLICATIONS	
SECTOR	ACTIVITIES REPRESENTED
1	Lumber and Wood Products
2	Paper and Allied Products
3	Chemicals and Allied Products
4	Asphalt and Lubricant Manufacturers
5	Stone, Clay, Glass and Concrete Products
6	Primary Metal Industries
7	Metal Mining
8	Coal and Lignite Mining
9	Oil and Gas Extraction
10	Mining and Quarrying of Nonmetallic Minerals
11	Hazardous Waste Treatment Storage or Disposal Facilities
12	Industrial Landfills, Land Application Sites and Open Dumps
13	Used Motor Vehicle Parts
14	Scrap and Waste Materials
15	Steam Electric Power Generating Facilities
16	Railroad Transportation
17	Local and Suburban Transit and Interurban Highway Passenger Transportation Motor Freight Transportation United States Postal Service Petroleum Bulk Stations
18	Water Transportation
19	Ship Building and Repairing Boat Building and Repairing
20	Transportation By Air
22	Domestic Wastewater Treatment Plants
23	Food and Kindred Products Tobacco Products
24	Textile Mill Products Apparel and Other Finished Products Made From Fabrics and Similar Materials
25	Furniture and Fixtures Manufacturing
26	Printing Publishing and Allied Industries
27	Rubber and Misc. Plastic Products
28	Leather and Leather Products
29	Fabricated Metal Products, Except Machinery and Transportation Equipment Jewelry, Silverware, and Plated Ware
30	Industrial and Commercial Machinery (Except Computer and Office Equipment) Transportation Equipment
31	Electronic and other Electrical Equipment and Components Measuring, Analyzing, and Controlling Instruments; Photographic and Optical Goods; Watches and Clocks

Sector 1: Timber Products Facilities

The definition of storm water discharges associated with industrial activity includes point source discharges of storm water from eleven major categories of facilities, including: "... category (ii) facilities classified as Standard Industrial Classification (SIC) code 24 (except 2434)." Storm water discharges covered include those from establishments that cut timber and pulpwood, merchant sawmills, lath mills, shingle mills, cooperage stock mills, planing mills, and plywood and veneer mills that produce lumber and wood basic materials; and establishments that manufacture finished articles made entirely of wood or related materials. These facilities use wood as their primary raw material. Industrial activities include the following:

Log Storage and Handling activities include loading and unloading of logs onto trucks or railroad cars for transport to other facilities, log sorting, and storage of logs. In addition, some cutting may be performed, such as chopping off tree branches and sectioning of tree trunks for easier handling during transport. Chipping may be performed at facilities serving pulp industries. Residues generated at these sites may include bark, coarse sawdust, and wood chunks.

Untreated Wood Lumber and Residue Generation Activities occur at the following: saw and planing mills (SIC group 242); millwork, veneer, plywood and structural wood member manufacturing facilities (SIC group 243); wood container manufacturing facilities (SIC group 244); wood building and mobile home manufacturing facilities (SIC group 245); and miscellaneous wood product manufacturers (SIC group 249). These facilities may engage in one or more activities such as log washing, bark removal, milling, sawing, resawing edging, trimming, planing, machining, air drying, and kiln drying. Some facilities generate residue as a product, while other facilities may generate residues as a waste product. A summary of the residues generated include: bark, wood chips, planer shavings, and sawdust.

Wood Surface Protection Activities are accomplished by one of the following three methods: spraying, dipping, and green chain operations. Industrial activities at saw mills with the potential to contaminate storm water include spills from surface protection areas, storage and mixing tank areas, treated wood drippage, transport or storage areas, maintenance and shop areas, and areas used for treatment/disposal of wastes. Fugitive emissions from negative pressure spraying activities and hand spraying surface protection formulations may also result in the contamination of storm water.

Wood Preservation Activities are accomplished by two steps. First, the moisture content of wood is reduced to increase its permeability (this is referred to as conditioning). After conditioning, wood is impregnated with a preservative for fire retardency, insecticidal resistance, and/or fungicidal resistance. Then, the wood stock is often subject to cleaning in order to remove excess preservative prior to stacking treated lumber products outside.

Wood Assembly/Fabrication Activities such as the fabrication of fiberboard, insulation board, and hardboard may involve the use of wax emulsions, paraffin, aluminum sulfate, melamine formaldehyde, and miscellaneous thermosetting resins. These chemicals may be introduced as part of the board formation process or as a coating to maintain the board's integrity. In the formation of fiberboard/insulation board/hardboards, the digestion of pulp and fiber by mechanical, thermal, and sometimes chemical means takes place. Another operation which involves resinous agents is the formation of veneer. In this process, veneer is placed in hot ponds or vats to soften the wood. Veneer strips are removed and often bound by glue or a resinous agent. Glues are also used in the assembly of wood components. Other types of activities include the finishing of wood products. Stains, paints, lacquers, varnish, water repellents and sealants, etc. may be applied to some of the wood products.

Significant materials at timber products facilities which can contribute pollutants to storm water include: uncut logs, wood bark, wood chips wood shavings, sawdust, green lumber, rough and finished lumber, other waste wood material, non-hazardous wood ash, above and below ground fuel storage tanks, finishing chemicals, solvents and cleaners, petroleum, herbicides, pesticides, fertilizers, sawmill equipment, material handling equipment, boiler water treatment chemicals, scrap metals, scrap equipment and plastics, boiler blowdown water, and leachate from decaying organic matter.

Pollutants from timber products facilities generally include biological oxygen demand (BOD^5), total suspended solids (TSS), chemical oxygen demand (COD), leachate, wood wastes, chemicals, heavy metals, and pH.

Sector 2: Paper And Allied Products Manufacturing Facilities

The definition of storm water discharges associated with industrial activity includes point source discharges of storm water from eleven major categories of facilities, including: "...category (ii) facilities classified as Standard Industrial Classification (SIC) code 26 (except 265 and 267)." Storm water discharges covered include those from establishments primarily engaged in the manufacture of pulps from wood and other cellulose fibers, and from rags; manufacture paper and paperboard; and the manufacture of paper and paperboard into converted products, such as paper coated off the paper machine, paper bags, paper boxes, and envelopes. This major group also includes facilities which manufacture bags of plastics film and sheet.

Significant materials include fuels (diesel and gasoline), lumber, paper, and paperboard.

Pollutants of concern include total suspended solids (TSS), biochemical oxygen demand (BOD), and chemical oxygen demand (COD).

Sector 3: Chemical and Allied Products Manufacturing Facilities

The definition of storm water discharges associated with industrial activity includes point source discharges of storm water from eleven major categories of facilities, including: "... category (ii) facilities classified as Standard Industrial Classification (SIC) 28 (except 283 and 285)." Storm water discharges covered include those from establishments primarily engaged in manufacturing: industrial inorganic chemicals; plastic and synthetic materials; cleaning agents; paint products and varnishes; industrial organic chemicals; fertilizers; adhesives; explosives; and printing ink. Also covered are storm water discharges from facilities which manufacture inks and paints under SIC 3952. Storm water discharges from drug manufacturing facilities (SIC 283) are not covered.

Pollutants at chemical and allied product facilities include Biochemical Oxygen Demand (BOD), Chemical Oxygen Demand (COD), Copper, Manganese, and Zinc.

Sector 4: Asphalt Paving and Roofing Materials Manufacturers and Lubricant Manufacturers

The definition of storm water discharges associated with an industrial activity includes point source discharges of storm water from eleven major categories of facilities, including: "... category (ii) which identifies facilities classified as Standard Industrial Classification (SIC) code 29." This covers storm water discharges associated with industrial activities at facilities with a primary SIC code of 2951 (Asphalt Paving Mixtures and Blocks), 2952 (Asphalt Felts and Coatings), and 2992 (Lubricating Oils and Greases) including portable plants. Hereinafter, facilities with primary SIC codes 2951 or 2952 will be referred to as 'Asphalt Facilities,' and facilities with primary SIC code 2992 as 'Lubricant Manufacturers.'

Facilities manufacturing asphalt concrete, paving materials, or block, are classified as SIC code 2951. Facilities primarily engaged in manufacturing asphalt roofing products, such as asphalt felts, shingles, and other products including tars, pitch, and roofing cements, are identified as SIC 2952. Facilities primarily engaged in manufacturing oils and lubricants are identified as SIC 2992.

Manufacturers of Asphalt Paving Mixtures and Blocks: These facilities stockpile a variety of raw materials such as sand, gravel, crushed limestone, and recycled asphalt products (RAP). These facilities produce asphalt concrete, and may also mold and cure asphalt concrete products such as asphalt blocks. There are two types of facilities associated with these activities, batch plants and drum plants.

Manufacturers of Roofing Materials: Manufacturers classified in standard industrial code 2952 typically produce roofing felts, and impregnated roofing felts (shingles) and other products, such as tar papers, impregnated asphalt siding, expansion joints, roofing cements, tars and pitches. Many of the roofing products consist of materials coated with asphalt purchased from a vendor and then cured and stored out of doors until shipped.

Manufacturers of Lubricating Oils and Greases: Facilities primarily engaged in blending, compounding, and re-refining lubricating oils and greases from purchased mineral, animal, and vegetable materials are identified as SIC code 2992. SIC code 2992 includes manufacturers of metalworking fluids, cutting oils, gear oils, hydraulic brake fluid, transmission fluid, and other automotive and industrial oil and greases.

Significant materials at these facilities include additives, asphalt, asphalt cement, asphalt concrete, asphalt felt, asphalt release agents, asphalt shingles, crushed stone, fuel, granite, gravel, limestone, lubricants, mineral spirits, oil, quartzite rock, reclaimed asphalt pavement, sand, sandstone, and slag. The pollutants of concern at facilities which manufacture asphalt and lubricant include total, suspended solids (TSS), oil and grease, chemical oxygen demand (COD), and fuel wastes.

Zinc									0.20	0.16	0.50

Sector 5: Glass, Clay, Cement, Concrete, and Gypsum Product Manufacturing Facilities

The definition of storm water discharges associated with industrial activity includes point source discharges of storm water from eleven major categories of facilities, including: "...category (ii) which identifies facilities classified as Standard Industrial Classification (SIC) code 32."

Glass Product Manufacturing - Facilities primarily engaged in the manufacturing of glass and glassware, or manufacturing glass products from purchased glass are classified under standard industrial groups 321-323. Manufacturing processes include the storage of raw materials, weighing the materials, charging, melting and forming. Significant materials may include silica sand, limestones, feldspars, borates, soda ash, boric acid, potash and barium carbonate.

Cement Manufacturing - Facilities primarily engaged in manufacturing hydraulic cement (e.g., portland, natural, masonry, and pozzolana cements) are identified as SIC code 3241. The three basic steps in cement manufacturing are: 1) proportioning, grinding and blending raw materials; 2) heating raw materials to produce a hard, stony substance known as "clinker"; and 3) combining the clinker with other materials and grinding the mixture into a fine powdery form.

Clay Product Manufacturing - Facilities primarily engaged in manufacturing clay products, including brick, tile (clay or ceramic), or pottery products are classified as standard industrial groups 325 and 326. Although clay product manufacturing facilities produce a wide variety of final products, there are several similar processing steps shared by most facilities in this industry: 1) storage and preparation of raw materials; 2) forming; 3) drying; 4) firing; and 5) cooling. Manufacturers classified as standard industrial groups 325 and 326 typically use clay (common, silt, kaolin and/or phyllite) and shale (mud, red, blue and/or common) as their primary raw materials. Raw materials are generally stored outside.

Concrete Products - Facilities primarily engaged in manufacturing concrete products, including ready-mixed concrete, are identified as SIC group 327. Although concrete product facilities in SIC group 327 produce a variety of final products, they all have common raw materials and activities.

Concrete products manufacturers combine cement, aggregate, and water to form concrete. Aggregate generally consists of: sand, gravel, crushed stone, cinder, shale, slag, clay, slate, pumice, vermiculite, scoria, perlite, diatomite, barite, limonite, magnetite, or ilmenite. Admixtures including fly ash, calcium chloride, triethanolamine, calcium salt, lignosulfunic acid, vinosol, saponin, keratin, sulfonated hydrocarbon, fatty acid glyceride, vinyl acetate, and styrene copolymer of vinyl acetate may be added to obtain desired characteristics, such as slower or more rapid curing times.

VOL 12

4377

Gypsum Products Manufacturing - Facilities primarily engaged in manufacturing plaster, wallboard, and other products composed wholly or partially of gypsum (except plaster of paris and papier-mâché) are classified as SIC code 3275. The gypsum product manufacturing process begins with calcining the gypsum: finely ground raw gypsum (referred to as "land plaster") is fed into imp mills or calcining kettles where extreme heat removes 75 percent of the gypsum's molecular moisture. The result is a dry powder called stucco, which is cooled and conveyed to storage bins. To produce wallboard, stucco is fed into pin mixers where it is blended with water and other additives to produce a slurry. The slurry is then applied to continuous sheets of paper to form wallboard. In addition to producing wallboard, some facilities may combine stucco with additives (excluding water) to produce plaster.

As a result of the industrial activities such as materials handling and storage and other industry specific activities, pollutants of concern include: total suspended solids (TSS), chemical oxygen demand (COD), oil and grease, lead, aluminum, zinc, potassium and sulfate.

Sector 6: Primary Metals Facilities

The definition of storm water discharges associated with industrial activity includes point source discharges from eleven major categories of facilities, including: "(ii) facilities classified as Standard Industrial Classification (SIC) 33 [primary metals facilities]." Storm water discharges covered include those from the following types of activities: Steel works, blast furnaces, and rolling and finishing mills (SIC 331); Iron and steel foundries (SIC 332) Primary smelting and refining of nonferrous metals (SIC 333); Secondary smelting and refining of nonferrous metals (SIC 334); Rolling, drawing, and extruding of nonferrous metals (SIC 335); Nonferrous foundries (SIC 336); and Miscellaneous primary metal products, not elsewhere classified (SIC 339).

Facilities in the primary metals industry are typically involved in one or more of the following general operations: raw material storage and handling; furnace and oven related processes; preparation of molds, casts, or dies; metal cleaning, treating and finishing; and waste handling and disposal.

Pollutants at primary metals facilities include Aluminum, Copper, Iron, Manganese, Total Suspended Solids (TSS), and Zinc.

Sector 7: Metal Mining (Ore Mining and Dressing)

The definition of storm water discharges associated with industrial activity includes point source discharges of storm water from eleven major categories of facilities, including: "...category (iii) facilities classified by Standard Industrial Classification (SIC) codes 10 through 14 including active or inactive mining operations (except for areas coal mining operations no longer meeting the definition of reclamation area under 40 CFR 434.11(l) because the performance bond issued to the facility by the appropriate SMCRA authority has been released, or except for areas of non-coal mining operations which have been released from applicable State or Federal reclamation requirements after December 17, 1990) and oil and gas exploration production, processing or treatment operations, or transmission facilities that discharge storm water contaminated by contact with or that has come into contact with any overburden, raw material, intermediate products, finished products, byproducts or waste products located on the site of such operations." The following is a listing of the types of mining milling facilities that are covered under SIC code 10:

- Iron Ores (SIC 1011)
- Copper Ores (SIC 1021)
- Lead and Zinc Ores (SIC 1031)
- Gold Ores (SIC 1041)
- Silver Ores (SIC 1044)
- Ferroalloy Ores, Except Vanadium (SIC 1061)
- Metal Mining Services (SIC 1081)
- Uranium-Radium-Vanadium Ores (SIC 1094)
- Miscellaneous Metal Ores, Not Elsewhere Classified (SIC 1099)

The term "metal mining" includes all ore mining and/or dressing and beneficiating operations, whether performed at mills operated in conjunction with the mines served or at mills, such as custom mills, operated separately. The above establishments are primarily engaged in mining, developing mines, or exploring for metallic minerals (ores). This group also includes all ore dressing and beneficiating operations, whether performed at mills operated in conjunction with the mines served or at mills, such as custom mills, operated separately. These include mills which crush, grind, wash, dry, sinter, calcine, or leach ore, or perform gravity separation or flotation operations.

Pollutants of concern include total suspended solids (TSS), total dissolved solids (TDS), heavy metals, oil and grease, dust, and turbidity.

Sector 8: Coal Mines and Coal Mining-Related Facilities

The definition of storm water discharges associated with industrial activity includes point source discharges of storm water from eleven major categories of facilities, including: "...category (iii) facilities classified by Standard Industrial Classification (SIC) codes 10 through 14 including active or inactive mining operations (except for areas coal mining operations no longer meeting the definition of reclamation area under 40 CFR 434.11(l) because the performance bond issued to the facility by the appropriate SMCRA authority has been released, or except for areas of non-coal mining operations which have been released from applicable State or Federal reclamation requirements after December 17, 1990) and oil and gas exploration production, processing or treatment operations, or transmission facilities that discharge storm water contaminated by contact with or that has come into contact with any overburden, raw material, intermediate products, finished products, byproducts or waste products located on the site of such operations." Coal mining activities are classified as Standard Industrial Classification (SIC) code 12, and includes the following operations:

- Bituminous Coal and Lignite Surface Mining (SIC 1221)
- Bituminous Coal Underground Mining (SIC 1222)
- Anthracite Mining (SIC 1231)
- Coal Mining Services (SIC 1241)

Storm water discharges are covered at all inactive facilities and only from haul roads and rail lines at active facilities. Haul roads are non-public roads on which coal or coal refuse is conveyed. Access roads are non-public roads providing light vehicular traffic within the facility property and to public roadways. Railroad spurs, sidings, and internal haulage lines are rail lines used for hauling coal within the facility property and to off-site commercial railroad lines or loading areas. Inactive coal mines and related areas are abandoned and other inactive mines, refuse disposal sites and other mining-related areas.

Significant materials include coal, refuse coal, used equipment, and other equipment used to haul coal.

Pollutants of concern include total suspended solids (TSS), total dissolved solids (TDS), turbidity, oil and grease, dust, heavy metals, and acid/alkaline wastes.

Sector 9: Oil and Gas Extraction Facilities

The definition of storm water discharges associated with industrial activity includes point source discharges of storm water from eleven major categories of facilities, including: "...category (iii)...oil and gas exploration production, processing or treatment operations, or transmission facilities that discharge storm water contaminated by contact with or that has come into contact with any overburden, raw material, intermediate products, finished products, byproducts or waste products located on the site of such operations." Oil and gas extraction facilities are classified as Standard Industrial Classification (SIC) code 13. The activities subject to storm water regulations include the following types of operations:

- Crude Petroleum and Natural Gas (SIC 1311)
- Natural Gas Liquids (SIC 1321)
- Drilling Oil and Gas Wells (SIC 1321)
- Oil and Gas Field Exploration Services (SIC 1382)
- Oil and Gas Field Services, Not Elsewhere Classified (SIC 1389)

R0037692

Sector 10: Mineral Mining and Processing Facilities

The definition of storm water discharges associated with industrial activity includes point source discharges of storm water from eleven major categories of facilities, including: "...(iii) facilities classified as Standard Industrial Classifications 10 through 14 (mineral industry) including active or inactive mining operations (except for areas of coal mining operations no longer meeting the definition of a reclamation area under 40 CFR 434.11(l) because the performance bond issued to the facility by the appropriate SMCRA authority has been released, or except for areas of non-coal mining operations which have been released from applicable State or Federal reclamation requirements after December 17, 1990) and oil and gas exploration, production, processing, or treatment operations, or storm water contaminated by contact with, any overburden, raw material, intermediate products, finished products, by-products or waste products located on the site of such operations."

Mineral mining and processing facilities subject to storm water regulations include the following types of operations:

- Dimension Stone, (SIC Code 1411);
- Crushed and Broken Limestone, (SIC Code 1422);
- Crushed and Broken Granite, (SIC Code 1423);
- Crushed and Broken Stone, (SIC Code 1429);
- Construction Sand and Gravel, (SIC Code 1442);
- Industrial Sand and Gravel, (SIC Code 1446);
- Kaolin and Ball Clay, (SIC Code 1455);
- Clay, Ceramic, and Refractory Minerals, (SIC Code 1459);
- Potash, Soda, and Borate Minerals, (SIC Code 1474);
- Phosphate Rock, (SIC Code 1475);
- Chemical and Fertilizer Mineral Mining, (SIC Code 1479); and
- Miscellaneous Nonmetallic Minerals, Except Fuels, (SIC Code 1499).

There are typically three phases to a mining operation: the exploration and construction phase; the active phase; and the reclamation phase. The exploration and construction phase entails exploration and a certain amount of land disturbance to determine the financial viability of a site. Construction includes building of site access roads, and removal of overburden and waste rock to expose minable ore. These land-disturbing activities are significant potential sources of storm water contaminants. The active phase includes each step from extraction through production of a saleable product. The active phase may include periods of inactivity due to the seasonal nature of these mineral mining activities. The final phase of reclamation is intended to return the land to its pre-mining state. Non-metallic minerals are recovered using four basic forms of extraction techniques: open pit, open face or quarry mining; dredging; solution mining; and underground mining. Each type of extraction method may be followed by varying methods of beneficiation and processing.

Storm water discharges covered include all discharges where precipitation and run-on come into contact with significant materials commonly found at mining facilities which include:

overburden; waste rock; sub-ore piles; tailings; petroleum-based products; solvents and detergents; manufactured products; and other waste materials. This includes storm water discharges from haul roads, access roads, and rail lines used or traveled by carriers of raw materials, manufactured products, waste materials, or by-products created by the facility. In addition, overflows from facilities governed by effluent limitation guidelines with impoundments such as settling or sedimentation ponds, tailings ponds or piles, or other impoundments designed to contain a 10-year, 24-hour storm event are also covered.

Because of the land-disturbing nature of the mineral mining and processing industry, contaminants of concern generated by industrial activities in this industry include total suspended solids (TSS), total dissolved solids (TDS), turbidity, pH, dust, heavy metals, solvents, and oils.

Sector 11: Hazardous Waste, Treatment, Storage, or Disposal Facilities

The definition of storm water discharges associated with industrial activity includes point source discharges of storm water from eleven major categories of facilities, including: "...(iv) hazardous waste treatment, storage, or disposal facilities, including those that are operating under Subtitle C of RCRA [Resource Conservation and Recovery Act] ...." Industrial activities at treatment, storage, or disposal facilities (TSDF) can be described as follows:

At TSDFs, some wastes are disposed without any intervening storage or treatment, while other wastes are held in storage prior to treatment or disposal. Hazardous wastes are generally stored in containers and tanks, which are enclosed by a bermed area to prevent any releases to the environment from the storage units.

The processes for treating hazardous wastes can be divided into two major categories based on whether the waste is organic or inorganic in nature. Organic wastes are treated by destructive technologies, such as incineration, whereas inorganic wastes are treated using fixation technologies, such as stabilization, in which the hazardous constituents are immobilized in the residual matrix. Residuals from fixation processes are usually land-disposed.

Hazardous waste disposal units include landfills, surface impoundments, waste piles, and land treatment units. Wastes are also disposed of in incinerators. Some liquid hazardous wastes are underground-injected into deep wells regulated under the Underground Injection Control (UIC) program.

Hazardous wastes are also recycled at TSDFs. Recycling is considered a form of treatment, however, the recycling process itself is not generally regulated under RCRA. Recycling activities include reclamation, regeneration, reuse, burning for energy or materials recovery, and use in a manner constituting disposal (i.e., land application of hazardous waste or products containing hazardous waste).

Sector 12: Landfills/Land Application Sites

The definition of storm water discharge associated with industrial activity includes point source discharges of storm water from eleven major categories of facilities, including: "...category (v) landfills, land application sites and open dumps that receive industrial wastes." Special conditions apply to land disposal sites which meet the definition of a landfill under RCRA Subtitle D. Landfills are defined as areas of land or excavation in which wastes are placed for permanent disposal, and that are not land application units, surface impoundments, injection wells, or waste piles. Included in this definition are municipal solid waste landfills (MSWLFs) and industrial solid non-hazardous waste landfills. Land application sites are defined as facilities at which wastes are applied onto or incorporated into the soil surface for the purpose of beneficial use or waste treatment and disposal. Open dumps are defined as solid waste disposal units not in compliance with State/Federal criteria established under RCRA Subtitle D.

Municipal Solid Waste Landfills are constructed according to one of two generic designs, the trench method, area method, or a combination of both. The trench method requires the excavation of a trench into which wastes will be placed. In the area method, wastes are placed directly on the ground surface and disposal follows the natural contours of the land. Some landfills use combinations of the two methods at different times depending on the location of the active unit.

Most modern landfills contain one or more separate "units," which are final waste containment areas. Active units continue to receive wastes until they have reached disposal capacity. When capacity is reached, a unit is capped with a final cover, and additional wastes are placed in other active units. Within each unit, wastes are added in layers referred to as lifts. Received wastes are spread across the working face of the landfill to a depth of six to twenty feet and then compacted. At the end of each working day a thin layer of soil (daily cover) is spread on top of the added wastes and compacted. A large unit may consist of multiple lifts, depending on the planned final depth. When a landfill (or landfill unit) has reached disposal capacity, a final cover is applied. Final covers generally provide a relatively impermeable cap over which topsoil is placed and vegetation is established.

Industrial Landfills are similar to MSWLFs, but only receive wastes from industrial facilities such as factories, processing plants, and manufacturing sites. These facilities may also receive hazardous wastes from very small quantity hazardous waste generators (less than one hundred kilograms per month), as defined in RCRA Subtitle C.

Land Application Sites receive wastes (primarily wastewaters and sludges) from facilities in virtually every major industrial category. Typically, individual land application sites will only dispose of wastes with specific characteristics. However, the criteria for selection are site-specific, depending on type of process used and the soil characteristics.

The significant materials at land disposal sites consist of the wastes and the equipment used to handle the wastes. Examples of wastes disposed at these sites include household waste

VOL 12

4389

(including household hazardous waste which is excluded from RCRA hazardous waste regulation), non-hazardous incinerator ashes, commercial wastes, yard wastes, tires, white goods, construction wastes, municipal and industrial sludges, asbestos, and other industrial wastes from various industrial facilities.

Pollutants of concern at land disposal sites include total suspended solids (TSS), oil and grease, heavy metals, leachate, organics, and chemical oxygen demand (COD) and other toxic pollutants.

R0037699

Sector 13: Automobile Salvage Yards

The definition of storm water discharges associated with industrial activity includes point source discharges of storm water from eleven categories of facilities, including: "... category (vi) facilities classified as Standard Industrial Classification (SIC) code 5015." That SIC code includes battery reclaimers, salvage yards, and automobile junkyards.

Storm water discharges include discharges where precipitation and storm water runon come into contact with significant materials including, but are not limited to parts storage and cleaning, storage of junked vehicles, waste products, by-products, stored materials, fuels, and areas used for dismantling operations. Dismantlers are a major source for replacement parts for motor vehicles in service. The primary activity involves the dismantling or wrecking of used motor vehicles. Some facilities, however, perform vehicle maintenance and may rebuild vehicles for resale.

Typically, automobile dismantling facilities receive vehicles that are either uneconomical to run or wrecks that are uneconomical to repair. The nature of operations generally depends on the size and location of the facility. In urban areas where land is more valuable, vehicles are typically dismantled upon arrival, parts are segregated, cleaned, and stored. Remaining hulks are generally sold to scrap dealers rather than stored on site due to limited space. In more rural areas, discarded vehicles are typically stored on the lot and parts removed as necessary. Remaining hulks are sold to scrap dealers less frequently.

Once a used vehicle is brought to the site, fluids may be drained and the tires, gas tank, radiator, engine and seats may be removed. The dismantler may separate and clean parts. Such cleaning may include steam cleaning of the engine and transmission as well as the use of solvents to remove oil and grease and other residues. Usable parts are then inventoried and stored for resale. The remaining car and/or truck bodies are stored on site for future sale of the sheet metal and glass. Stripped vehicles and parts that have no resale value are typically crushed and sold to a steel scrapper. Some operations may, however, convert used vehicles and parts into steel scrap as a secondary operation. This is accomplished by incineration, shearing (bale shearer), shredding, or baling.

Significant materials include automobile parts (e.g., engine blocks, mufflers, batteries), solvents, oils, cleaning agents (e.g., detergents), used equipment, and junked automobiles. Due to the nature of the industrial activities at these facilities, pollutants of concern include: oil and grease, ethylene glycol, heavy metals, petroleum hydrocarbons, solvents, suspended solids, acid/alkaline wastes, detergents, phosphorus and salts.

Sector 14: Scrap and Waste Material Processing and Recycling Facilities

The definition of storm water discharge associated with industrial activity includes point source discharges from eleven major categories of facilities, including: ". . . category (vi) facilities involved in the recycling of materials, including metal scrapyards, battery reclaimers, salvage yards and automobile junk yards, including but limited to those classified as Standard Industrial Classification (SIC) 5093 and 5015." Automobile junk yards (SIC 5015) are addressed under Sector 13.

SIC 5093 includes establishments engaged in assembling, breaking up, sorting and the wholesale distribution of scrap and recyclable waste materials including bag, bottle and box wastes, fur cuttings, iron and steel scrap, metal and non-ferrous metal scrap, oil, plastics, rags, rubber, textiles, waste paper and rag wastes.

Table E-14.1
Materials and Sources of Pollutants of Concern

Significant Materials: White Goods (Appliances) Potential Sources: Leaking oil-filled capacitors, ballasts, leaking compressors, pumps, leaking pressure vessels, reservoirs, sealed electrical components and chipped or deteriorated painted surfaces Pollutants of Concern: PCBs, oil, lubricants, paint pigments or additives such as lead, and other heavy metals
Significant Materials: Ferrous and Non-ferrous turnings and cuttings Potential Sources: Cutting oil residue, metallic fines Pollutants of Concern: Oil, heavy metals
Significant Materials: Materials from Demolition projects Potential Source: Deteriorated/damaged insulation, chipped painted surfaces, lead, copper, and steel pipes Pollutants of Concern: asbestos fibers, lead, copper, zinc, cadmium, other metals

VOL 12

4393

Table E-14.1
Materials and Sources of Pollutants of Concern (continued)

Significant Materials: Electrical Components, transformers, switch gear, mercury float switches, sensors Potential Sources: Leaking oil-filled transformer casings, oil-filled switch, float switches, radioactive materials in gauges, sensors Pollutants of Concern: PCBs, oils, mercury, ionizing radioactive isotopes
Significant Materials: Fluorescent lights, light fixtures Potential Sources: Leaking ballasts Pollutants of Concern: PCBs, oil
Significant Materials: Food/Beverage Dispensing Equipment Potential Sources: Leaking fluorescent light ballasts, chipped painted surfaces Pollutants of Concern: PCBs, oil, heavy metals from paint pigments and additives
Significant Materials: Hospital and Dental Waste & Equipment Potential Sources: Drums/containers of hospital waste, shielding from diagnostic and other medical equipment, radioactive materials from gauges, sensors and diagnostic equipment Pollutants of Concern: Infectious/bacterial contamination, lead, ionizing radioactive isotopes
Significant Materials: Instruments Potential Sources: Radioactive material from thickness gages Pollutants of Concern: Ionizing radioactive isotopes
Significant Materials: Insulated wire Potential Sources: Insulation and other coatings, wire Pollutants of Concern: Lead, zinc, copper

VOL 12

Table E-14.1
Materials and Sources of Pollutants of Concern (continued)

Significant Materials: Lawnmowers, snowmobiles, motorcycles Potential Sources: Leaking engines, transmissions, fuel, oil reservoirs,leaking batteries Pollutants of Concern: Oils, transmission and brake fluids, fuel, grease, battery acid, lead acid
Significant Materials: Light gage materials Potential Sources: Deteriorating insulation, painted surfaces and other coatings Pollutants of Concern: Asbestos, lead, chromium
Significant Materials: Locomotives, rail cars Potential Sources: Leaking fuel reservoirs, fittings, hydraulic components, engines, bearings, compressors, oil reservoirs, worn brake pads, damaged insulation Pollutants of Concern: PCBs, diesel fuel, hydraulic oil, oil, brake fluid, grease from fittings, asbestos,
Significant Materials: Motor Vehicle Bodies, Engines, Transmissions, Exhaust systems Potential Sources: Leaking fuel tanks, oil reservoirs, transmission housings, brake fluid reservoir and lines, brake cylinders, shock absorber casing, engine coolant, wheel weights, leaking battery casings/housings and corroded terminals, painted surfaces and corrosion inhibitors, exhaust system, catalytic converters Pollutants of Concern: Fuel, benzene, oil, hydraulic oil, transmission fluids, brake fluids, ethylene glycol (antifreeze), lead, lead acid, lead oxides, cadmium, zinc, other heavy metals
Significant Materials: Misc. Machinery and obsolete equipment Potential Sources: Leaking reservoirs, damaged or chipped painted surfaces/coatings Pollutants of Concern: Fuel, oil, lubricants, lead, cadmium, zinc

VOL 12

4395

Table E-14.1
Materials and Sources of Pollutants of Concern (continued)

Significant Materials: Pipes/Materials from Chemical and Industrial Plants Potential Sources: Chemical residue, insulation, lead piping, chipped or damaged painted surfaces and protective coatings Pollutants of Concern: Chemical residue, oil, lubricants, damaged insulation (asbestos), lead, cadmium, zinc, copper
Significant Materials: Sealed containers, hydraulic cylinders Potential Sources: Leaking liquid reservoirs, containers, cylinders, misc. chemicals Pollutants of Concern: Oil, PCBs, solvents, chemical residue
Significant Materials: Salvaged Construction Materials Potential Sources: Chemical residues, oils, solvents, lubricants, damaged insulation, chipped painted surfaces and protective coatings Pollutants of Concern: Chemical residue, oily wastes, asbestos, lead, cadmium, zinc
Significant Materials: Tanks, containers, vessels, cans, drums Potential Sources: Leaking or damaged containers Pollutants of Concern: Chemical residue, oily wastes, petroleum products, heating oil
Significant Materials: Transformers (oil filled) Potential Sources: Leaking transformer housings Pollutants of Concern: PCBs, oil

[1] Institute of Scrap Recycling Industries, Inc.'s Environmental Operating Guidelines, (April 1992)

(2) Material Processing. The type of processes employed at a particular facility depends on the type of recyclable and waste material. Typical processes include; torch cutting, shredding, baling, briquetting, wire stripping and chopping, and compacting. Processes such as shredding and shearing reduce the bulk size of recyclable scrap and waste into a size that is more easily transportable and which allows separation into uniform grades based on

VOL 12

4396

manufacturer specifications. Processes such as shredding of automotive bodies include a means of segregating materials into their ferrous and non-ferrous fractions.

(3) Segregation of Processed Materials into Uniform Grades. Processing, e.g., shearing, shredding, baling, etc, of recyclable materials is followed by its segregation into uniform grades to meet a particular manufacturer's specifications. If segregated recyclable material remains exposed to precipitation, the potential still exists for storm water contamination.

(4) Disposal of Non-recyclable Waste Materials. During recycling of scrap and waste materials, a significant fraction is non-recyclable waste materials and must be disposed. The volume or quantity of material that remains un-recyclable may be too large to permit covered storage prior to shipment. Consequently, un-recyclable waste materials may be left exposed to both precipitation and runoff and, therefore, they are a likely source of storm water pollutants.

(5) Other Operations of Concern. There are a number of activities that frequently occur at scrap and waste recycling facilities including, heavy vehicle traffic over unstabilized areas, vehicle maintenance and fueling, and material handling operations. Operations associated with the receipt, handling, and processing of scrap and waste material frequently occur over areas that are not stabilized to prevent erosion. Erosion of unstabilized soils is potentially a significant source of suspended solids in storm water runoff. For example, sampling results for total suspended solids (TSS) concentrations provided in sampling data indicated a mean concentration of 466 mg/l. Unless specific measures or controls are provided to either prevent erosion or trap the sediment, this material will be carried away in storm water runoff and eventually exit the site. Suspended solids are of significant concern given the potential amount of unstabilized area and the significant amount of particulate matter that is often produced at these facilities. Both organic and inorganic pollutants can become bound up or absorbed to suspended solids in runoff.

Some scrap and waste recycling facilities may also conduct vehicle maintenance on-site. Although many of these activities frequently occur indoors, there are specific activities which could contribute pollutants to storm water. This includes washdown of vehicle maintenance areas, leaks or spills of fuel, hydraulic fluids and oil and outdoor storage of lubricants, fluids, oils and oily rags. Fueling stations are also frequently conducted outdoors without any roof cover. Activities such as topping off fuel tanks, or overfilling storage tanks (without high-level alarms) are also activities that can cause contamination of runoff. One last activity of concern is vehicle washing which can result in accumulated residue material being discharged to a storm sewer system.

The following table highlights activities associated with vehicle maintenance and material handling that are potential sources of storm water contamination.

Table E-14.2
Other Potential Pollutant Source Activities

Activity: Material Handling Systems (forklifts, cranes, conveyors) Potential Sources: Spills and/or leaks from fueling tanks, spills/leaks from oil/hydraulic fuel reservoirs, faulty/leaking hose connections/fittings, leaking gaskets Pollutants of Concern: Accumulated particulate matter (ferrous and non-ferrous metals, plastics, rubber, other), oil/lubricants, PCBs (electrical equipment), mercury (electrical controls), lead/battery acids
Activity: Vehicle Maintenance Potential Sources: Parts cleaning, waste disposal of rags, oil filters, air filters, batteries, hydraulic fluids, transmission fluids, brake fluids, coolants, lubricants, degreasers, spent solvents Pollutants of Concern: Fuel (gas/diesel), fuel additives, oil/lubricants, heavy metals, brake fluids, transmission fluids, chlorinated solvents, arsenic
Activity: Fueling stations Potential Sources: spills and leaks during fuel transfer, spills due to "topping off" tanks, runoff from fueling areas, washdown of fueling areas, leaking storage tanks, spills of oils, brake fluids, transmission fluids, engine coolants, Pollutants of Concern: gas/diesel fuel, fuel additives, oil, lubricants, heavy metals
Activity: Vehicle & Equipment cleaning & washing Potential Sources: Washing and steam cleaning Pollutants of Concern: solvent cleaners, oil/lubricants/additives, antifreeze (ethylene glycol)

b. Waste Recycling Facilities (SIC 5093) - (Liquid Recyclable Wastes)

This sub-section applies to those facilities engaged in the reclaiming and recycling of liquid wastes such as "spent solvents", "used oil", and "used ethylene glycol" typically identified under SIC 5093. This sub-section is particularly applicable to those facilities that participated in EPA group application number 195. EPA received a single group application in this category of waste recycling facilities. The following is a profile of industrial activities and the types of significant materials associated with facilities participating in this group activity.

Group application number 195 included 220 facilities of which 214 were classified as service centers. Service centers accumulate spent solvent, used oil and antifreeze, filter cartridges and still bottoms contaminated with dry cleaning solvents (typically perchloroethylene), and used lacquer thinner from paint gun cleaning machines. The typical service center has a total storage capacity limited to approximately 10,000 gallons in individual containers and tanks with a maximum storage capacity of 20,000 gallons each. Service centers are typically limited to a maximum of 6 tanks (a total of 120,000 gallons). Twenty (20) of the service centers also function as accumulation centers where they have a maximum storage capacity of 70,000 gallons of liquid materials in containers. None of the containers are opened except under conditions where a container begins to leak or is damaged.

The group application also included four (4) facilities that operated only as container transfer stations and do not operate storage tanks. These facilities are largely enclosed warehouses that provide secondarily-contained storage areas. Three (3) facilities were identified as used oil depots where only oily water and/or used oil are accumulated in storage tanks. Storage tanks are limited to a maximum capacity of 20,000 gallons each. Used oil is transported to the facility in tanker trucks (3,500 gallons) and shipped out in tanker trucks (7,500 gallons). The used oil is ultimately transported to a processing or re-refining facility (not covered under this permit). The following table summarizes the percentage of facilities with significant materials stored.

Table E-14.3
Significant Materials Reported in Group Application Number 195

Significant Materials	Percent of Facilities
Mineral Spirits	98%
Immersion Cleaner	98%
Dry Cleaner Solvents	98%
Paint Solvents	83%
Industrial Solvents	81%
Spent Antifreeze	59%
Used Oil	57%
Allied Products	98%

VOL 12 4399

The types of materials identified in Table E-14.3 are potential sources of storm water runoff contamination. Since these materials are stored and transported in individual drums and bulk storage tanks, the potential exists for spills and/or leaks during all phases of waste transport, waste transfer, container/drum handling and shipping.

There are a number of operations at these facilities that have significant potential to release pollutants to the environment if recyclable waste materials are not managed properly. However, in response to other Federal and State environmental regulations, such as RCRA and 40 CFR 112 (Oil Pollution Prevention), facilities in this group application currently employ a range of the best management practices and structural controls that also benefit storm water quality.

(1) Pollutants Found in Storm Water Discharges. Based on data provided in the group application number 195, pollutants that were most frequently reported included total suspended solids (TSS), BOD, COD, nitrite plus nitrate, oil & grease. The following table provides a statistical summary of data provided in group application number 195.

Table E-14.4
Summary Statistics for Waste Recycling Facilities in Group Application Number 195 (SIC 5093) - (Recyclable Liquid Wastes). All values in mg/l.

Paragraph	# of Samples		Mean		Min		Max		Median		99th Percentile	
Sample Type	Grab	Comp	Grab	Comp	Grab	Comp	Grab	Comp	Grab	Comp	Grab	Comp
BOD5	22	17	18	9	2	2	94	48	5	5	79	38
COD	22	17	133	83	12	5	660	400	45	45	449	320
TSS	21	16	51	28	5	5	500	84	28	20	68	59
Nitrite + Nitrate	22	17	0.90	0.78	0.05	0.05	3.70	3.50	0.61	0.38	3.45	3.29
TKN	22	17	3.1	2.0	1.0	1.0	11.0	6.0	1.5	1.0	9.9	5.7
Oil & Grease	22	17	1.8	1.5	1.0	1.0	5.0	3.0	1.5	1.0	4.0	3.0

Table E-14.4 indicates that, with the exception of BOD and COD, average concentrations in grab and composite samples were comparable with average values reported in the NURP study (NURP did not measure oil & grease). The data also indicates that pollutants such as industrial solvents were all below detection limits (without values). In the case of oil & grease, all concentration values were below the reportable concentration of 10 mg/l (see 40 CFR 110.10 and 117.21).

(2) Waste Material Handling and Storage. Given the nature and type of materials stored and handled at these facilities, the potential exists for accidental spills and leaks. Consequently, the types of activities that occur at these facilities which could potentially result in contamination of storm water runoff is also of concern to EPA. The following table is a list of activities which may result in a release of pollutants.

Table E-14.5
Types of Potential Pollutant-Causing Activities at Waste Recycling Facilities that Handle Liquid Recyclable Wastes

Activity: Drum/Individual Container Storage and Handling Potential Sources of Pollutants: Leaks or spills due to faulty container/drum integrity, e.g., leaking seals or ports. Container materials incompatible with waste material. Improper stacking and storage of containers. Pollutants of Concern: Mineral spirits, industrial solvents, immersion cleaners, dry cleaner solvents, paint solvents, spent antifreeze.
Activity: Return and Fill Stations Potential Sources of Pollutants: Leaks, spills, or overflows from tanker truck transfer of wastes and hose drainage. Leaking pipes, valves, pumps, worn or deteriorated gaskets or seals Pollutants of Concern: Mineral spirits, industrial solvents, immersion cleaners, dry cleaner solvents, paint solvents, spent antifreeze.
Activity: Individual Container/Drum Storage Potential Sources of Pollutants: Leaks or spills due to faulty container/drum integrity, e.g., leaking seals or ports. Improper stacking and storage of containers. Pollutants of Concern: Mineral spirits, industrial solvents, immersion cleaners, dry cleaner solvents, paint solvents, spent antifreeze.

Table E-14.5
Types of Potential Pollutant-Causing Activities at Waste Recycling Facilities that Handle Liquid Recyclable Wastes (continued)

Activity: Storage Tank Operations Potential Sources of Pollutants: Overfill of storage tanks, leaking pipes, valves, worn or deteriorated pumps seals. Leaking underground storage tanks Pollutants of Concern: Mineral spirits, industrial solvents, immersion cleaners, dry cleaner solvents, paint solvents, spent antifreeze.
Activity: Material Handling Equipment Potential Sources of Pollutants: Leaking fuel lines, worn gaskets, leaking hydraulic lines and connections. Pollutants of Concern: Fuel, hydraulic fluid, oil and grease.

3. **Other Activities of Concern:**

The following table highlights other types of activities that are potential sources of storm water contamination.

Table E-14.6
Other Potential Sources of Storm Water Contamination

Activity: Vehicle and Equipment Maintenance (if applicable) Potential Sources of Pollutants: Replacement of fluids such as transmission and brake fluids, antifreeze, oil and other lubricants, washdown of maintenance areas, dumping fluids down floor drains connected to storm sewer system, outside storage of fluids and oily rags and waste material. Pollutants of Concern: Oil and grease, fuel, accumulated particulate matter, antifreeze.
Activity: Vehicle or Equipment Washing (if applicable) Potential Sources of Pollutants: Wash water or steam cleaning Pollutants of Concern: Oil, detergents, chlorinated solvents, suspended solids and accumulated particulate matter.

Sector 15: Steam Electric Power Generating Facilities, Including Coal Handling Areas.

The definition of storm water discharges associated with industrial activity includes point source discharges of storm water from eleven major categories of facilities, including: "...category (vii) steam electric power generating facilities." The steam electric power generating category includes facilities which are coal, oil, gas, or nuclear fired. Heat captured co-generation facilities are not covered under the definition of storm water discharge associated with industrial activity, however, dual fuel co-generation facilities are included in the definition. Ancillary facilities such as fleet centers, gas turbine stations, and substations that are not contiguous to a steam electric power generation facility are not included in this classification.

Pollutants of concern include fuel, oil, heavy metals, ammonia, chlorine, sulfuric acid, sodium hydroxide, ethylene glycol, arsenic, and solvents.

Sector 16: Motor Freight Transportation Facilities, Passenger Transportation Facilities, Rail Transportation Facilities, and United States Postal Service Transportation Facilities

The definition of storm water discharges associated with industrial activity includes point source discharges of storm water from eleven major categories of facilities, including: "...category (viii) facilities classified as Standard Industrial Classification (SIC) codes 40, 41, 42 (except 4221-25), 43, 44, and 5171 that have vehicle and equipment maintenance shops, or equipment cleaning operations." The category further states that only those portions of the facility that are either involved in vehicle and equipment maintenance (including vehicle and equipment rehabilitation, mechanical repairs, painting, fueling, and lubrication) or equipment cleaning operations are associated with industrial activity.

Vehicle and equipment maintenance is a broad term used to include the following activities: vehicle and equipment fluid changes, mechanical repairs, parts cleaning, sanding, refinishing, painting, fueling, locomotive sanding (loading sand for traction), storage of vehicles and equipment waiting for repair or maintenance, and storage of the related materials and waste materials, such as oil, fuel, batteries, tires, or oil filters. Equipment cleaning operations include areas where the following types of activities take place: vehicle exterior wash down, interior trailer washouts, tank washouts, and rinsing of transfer equipment.

SIC code 40 includes facilities primarily engaged in furnishing transportation by line-haul railroad, and switching and terminal establishments. The following types of facilities are examples of those covered under SIC code 40: electric railroad line-haul operation, railroad line-haul operation, interurban railways, beltline railroads, logging railroads, railroad terminals, and stations operated by railroad terminal companies.

SIC code 41 includes facilities primarily engaged in furnishing local and suburban transportation, such as those providing transportation in and around a municipality by bus, rail, or subway. The following types of facilities are examples of those covered under SIC code 41: bus line operations, airport transportation services (road or rail), cable car operations, subway operations, ambulance services, sightseeing buses, van pool operations, limousine rental with drivers, taxicab operations, and school buses not operated by the educational institution.

SIC code 42 includes facilities providing local or long-distance trucking, transfer, and/or storage services. The following types of facilities are examples of those covered under SIC code 42: hauling by dump truck, trucking timber, contract mail carriers, furniture moving, garbage collection without disposal, over-the-road trucking, long distance trucking, and freight trucking terminal.

SIC code 43 includes all establishments of the United States Postal Service.

SIC code 5171 includes establishments engaged in the wholesale distribution of crude petroleum and petroleum products from bulk liquid storage facilities.

Significant materials include oily rags, air filters, batteries, hydraulic fluids, paints, and vehicles awaiting service.

Pollutants include fuel, oil, heavy metals, chlorinated solvents, acid/alkaline wastes, ethylene glycol, arsenic, heavy metals, organics, hydraulic fluids, dust, paint solids, sediment, detergents, phosphorus, salts, suspended solids, and biochemical oxygen demand (BOD).

Sector 17: Vehicle and Equipment Maintenance and Cleaning Operations

The definition of storm water discharge associated with industrial activity includes point source discharges of storm water from eleven major categories of facilities, including: "...category (viii) transportation facilities classified as Standard Industrial Classification (SIC) codes 40, 41, 42 (except 4221-25), 43, 44, 45, and 5171 that have vehicle and equipment maintenance shops, equipment cleaning operations, or airport deicing operations."

SIC code 41 includes facilities primarily engaged in furnishing local and suburban transportation, such as those providing transportation in and around a municipality by bus, rail, or subway. The following types of facilities are examples of those covered under SIC code 41: bus line operation, airport transportation service (road or rail), cable car operation, subway operation, ambulance service, sightseeing buses, van pool operation, limousine rental with drivers, taxicab operation, and school buses not operated by the educational institution.

SIC code 42 includes facilities providing local or long-distance trucking, transfer, and/or storage services. The following types of facilities are examples of those covered under SIC code 42: hauling by dump truck, trucking timber, contract mail carriers, furniture moving, garbage collection without disposal, over-the-road trucking, long distance trucking, and freight trucking terminal.

SIC code 43 includes all establishments of the United States Postal Service.

SIC code 5171 includes establishments engaged in the wholesale distribution of crude petroleum and petroleum products from bulk liquid storage facilities.

Vehicle and equipment maintenance is a broad term used to include the following activities: vehicle and equipment fluid changes, mechanical repairs, parts cleaning, sanding, refinishing, painting, fueling, storage of vehicles and equipment waiting for repair or maintenance, and storage of the related materials and waste materials, such as oil, fuel, batteries, or oil filters. Equipment cleaning operations include areas where the following types of activities take place: vehicle exterior wash down, interior trailer washouts, tank washouts, and rinsing of transfer equipment.

Significant materials include oils, washing equipment, used equipment, vehicle parts, vehicles, fuels, paint, waste rags, oil filters, storage tanks, and detergents. Pollutants from these facilities include fuel, oil, heavy metals, organics, solvents, suspended solids, phosphorus, salts, acid/alkaline wastes and arsenic.

Sector 18: Water Transportation Facilities, Vehicle Maintenance/Equipment Cleaning Operations

The definition of storm water discharges associated with industrial activity includes point source discharges of storm water from eleven major categories of facilities, including: ...category (viii) water transportation facilities classified as Standard Industrial Classification (SIC) code 44 that have vehicle maintenance shops and/or equipment cleaning operations. The category further states that only those portions of the facility that are either involved in vehicle and equipment maintenance (including vehicle and equipment rehabilitation, mechanical repairs, painting, fueling, and lubrication), or equipment cleaning operations are associated with industrial activity. Vehicle and equipment maintenance is a broad term used to include the following activities: vessel and equipment fluid changes, mechanical repairs, parts cleaning, sanding, blasting, welding, refinishing, painting, fueling, storage of the related materials and waste materials, such as oil, fuel, batteries, or oil filters. Equipment cleaning operations include areas where vessel and vehicle exterior washdown occurs.

SIC code 44 includes facilities primarily engaged in furnishing water transportation services. The following types of facilities are examples of those covered under SIC code 44:

- Deep Sea Foreign Transportation of Freight (SIC 4412)
- Deep Sea Domestic Transportation of Freight (SIC 4424)
- Freight Transportation on the Great Lakes - St. Lawrence Seaway (SIC 4432)
- Water Transportation of Freight, Not Elsewhere Classified (SIC 4449)
- Deep Sea Transportation of Passengers, Except by Ferry (SIC 4481)
- Ferries (SIC 4482)
- Marine Cargo Handling (SIC 4491)
- Towing and Tugboat Services (SIC 4492)
- Marinas (SIC 4493)
- Water Transportation Services, Not Elsewhere Classified (SIC 4499)

Pollutants of concern include paint solids, heavy metals, suspended solids, spent abrasives, solvents, dust, paint, paint thinner, spent solvents, dust, oil, ethylene glycol, acid/alkaline wastes, detergents, fuel, trash, petroleum products, sanitary waste bilge & ballast water, biochemical oxygen demand (BOD), and bacteria.

Sector 19: Ship Building & Repairing and Boat Building & Repairing Facilities

The definition of storm water discharges associated with industrial activity includes point source discharges of storm water from eleven major categories of facilities, including: "...category (ii) facilities classified as Standard Industrial Classification (SIC) code 373." SIC code 373 includes facilities primarily engaged in ship and boat building and repairing services, and include the following:

- **Ship Building and Repairing (SIC code 3731).** These are establishments primarily engaged in building and repairing ships, barges, and lighters, whether self-propelled or towed by other crafts. The industry also includes the conversion and alteration of ships and the manufacture of off-shore oil and gas well drilling and production platforms (whether of not self-propelled). Examples include building and repairing of barges, cargo vessels, combat ships, crew boats, dredges, ferryboats, fishing vessels, lighthouse tenders, naval ships, offshore supply boats, passenger-cargo vessels, patrol boats, sailing vessels, towboats, trawlers, and tugboats.

- **Boat Building and Repairing (SIC code 3732).** These facilities are primary engaged in building and repairing boats. Examples include building and repairing of fiberglass boats, motor-boats, sailboats, rowboats, canoes, dinghies, dories, small fishing boats, houseboats, kayaks, lifeboats, pontoons, and skiffs.

Pollutants of concern include spent abrasives, solvents, dust, oil, ethylene glycol, acid/alkaline wastes, detergents, paint solids, heavy metals, spent solvents, biochemical oxygen demand (BOD), bacteria, suspended solids.

VOL 12

4411

Sector 20: Vehicle Maintenance Areas, Equipment Cleaning Areas, or Deicing Areas Located at Air Transportation Facilities

The definition of storm water discharges associated with industrial activity includes point source discharges of storm water from eleven major categories of facilities, including: "... category (viii) facilities classified as Standard Industrial Classification (SIC) 45 that have vehicle and equipment maintenance shops, equipment cleaning operations, or airport deicing operations." Only those portions of the facility that are either involved in vehicle and equipment maintenance (including vehicle and equipment rehabilitation, mechanical repairs, painting, fueling, and lubrication), equipment cleaning operations, or airport deicing operations are considered associated with industrial activity. SIC code 45 generally applies to airports, airport terminals and flying fields. Industrial activities include the following:

Aircraft Deicing includes both deicing to remove frost, snow or ice, and anti-icing which prevents the accumulation of frost, snow or ice. Deicing of an airplane is accomplished through the application of a freezing point depressant fluid, commonly ethylene glycol or propylene glycol, to the exterior surface of an airplane. Both ethylene and propylene glycol have high biochemical oxygen demands (BOD) when discharged to receiving waters. Environmental impacts on surface waters due to glycol discharges includes glycol odors and glycol contaminated surface water and ground water systems, diminished dissolved oxygen levels and fish kills.

Runway Deicing/Anti-icing activities include deicing/anti-icing operations conducted on runways, taxiways and ramps. Runway deicing/anti-icing commonly involves either the application of chemical fluids such as ethylene glycol or propylene glycol, or solid constituents such as pelletized urea. Urea has a high nitrogen content, therefore degradation of urea in a receiving water causes an increase in nutrient loadings resulting in an accelerated growth of algae and eutrophic conditions. Under certain ambient conditions, the degradation of urea in receiving waters can also result in ammonia concentrations toxic to aquatic life.

Aircraft, Ground Vehicle and Equipment Maintenance and Washing. Maintenance activities included in this section include both minor and major operations conducted either on the apron adjacent to the passenger terminal, or at dedicated maintenance facilities. Potential pollutant sources from all types of maintenance activities includes spills and leaks of engine oils, hydraulic fluids, transmission oil, radiator fluids, and chemical solvents used for parts cleaning. In addition, the disposal of waste parts, batteries, oil and fuel filters, and oily rags also have a potential for contaminating storm water runoff from maintenance areas unless proper management practices and operating procedures are implemented. The spent wash water from aircraft and ground vehicle washing activities could potentially be contaminated with surface dirt, metals, and fluids (fuel, hydraulic fluid, oil, lavatory waste).

Runway Maintenance. Over time, materials such as tire rubber, oil and grease, paint chips, and jet fuel can buildup on the surface of a runway causing a reduction in the friction of the pavement surface. When the friction level of the runway falls below a specific level, then maintenance on the runway must be performed. The Federal Aviation Administration (FAA)

VOL 12

4412

recommends several methods for removing rubber deposits and other contaminants from a runway surface including high pressure water, chemical solvents, high velocity particle impact, and mechanical grinding. If not properly managed, the materials removed from the runway surface could be discharged into nearby surface waters. Similarly, if chemical solvents are used in the maintenance operation, improper management practices could result in discharges of the chemical solvents in the storm water runoff from runway areas to nearby surface waters.

Sector 22: Domestic Wastewater Treatment Plants

The definition of storm water discharge associated with industrial activity includes point source discharges from eleven major categories of facilities, including: "...category (ix) treatment works treating domestic sewage or any other sewage sludge or wastewater treatment device or system, used in the storage treatment, recycling, and reclamation of municipal or domestic sewage, including land dedicated to the disposal of sewage sludge that are located within the confines of the facility, with a design flow of 1.0 mgd or more or required to have an approved pretreatment program under 40 CFR part 403." This category does not includes farm lands, domestic gardens or lands used for sludge management where beneficially reused which are not physically located in the confines of the facility, or areas that are in compliance with section 405 of the CWA.

Pollutants of concern include diesel, gasoline, petroleum products other than fuels: numerous grades of motor oils, gear and chassis lubricants, turbine oils, grease and hydraulic fluids, acid/alkaline wastes, arsenic, organics, chlorinated ethylene glycol, acids and bases for pH adjustments, disinfectants, polymers and coagulants, alum, ferric chloride, soda ash, lime, methanol, sodium aluminate, sodium hypochlorite, sodium hydrochloride mineral spirits, acetone, paint thinner, and lacquer thinner, toluene, TCE, isopropandlamine, and methyl-ethyl-ketone, dust, paint solids, paint, spent chlorinated solvents, commercial brands of balance fertilizers (6-6-6, 8-8-8 or 12-12-12), commercial sludge based products, fuel, process chemicals, diazanon, malathion, amdro, dimethylphthalate, diethyl phthalate, dichlorvos, carbaryl, skeetal, batex, liquid copper, bacteria, biochemical oxygen demand (BOD), suspended solids, oil, heavy metals, chlorinated solvents, ethylene glycol, detergents, metals, phosphorous.

Sector 23: Food and Kindred Products Manufacturing Facilities

The definition of storm water discharges associated with industrial activity includes point source discharges of storm water from eleven major categories of facilities, including: "...category (xi) facilities under Standard Industrial Classification (SIC) codes 20, 21 ..."

- Meat Products (SIC Codes 2011, 2013, and 2015)
- Dairy Products (SIC Codes 2021, 2022, 2023, 2024, and 2026)
- Canned, Frozen, and Preserved Fruits, Vegetables, and Food Specialties (SIC Codes 2032, 2033, 2034, 2035, 2037, and 2038)
- Grain Mill Products (SIC Codes 2041, 2043, 2044, 2045, 2046, 2047, and 2048)
- Bakery Products (SIC Codes 2051, 2052, and 2053)
- Sugar and Confectionery Products (SIC Codes 2061, 2062, 2063, 2064, 2066, 2067, and 2068)
- Fats and Oils (SIC Codes 2074, 2075, 2076, 2077, and 2079)
- Beverages (SIC Codes 2082, 2083, 2084, 2085, 2086, and 2087)
- Miscellaneous Food Preparations and Kindred Products (SIC Codes 2091, 2092, 2095, 2096, 2097, 2098, and 2099)
- Tobacco Products (SIC Codes 2111, 2121, 2131, and 2141).

Meat Products (SIC Code 201X) - Production related activities include stockyards, slaughtering (killing, blood processing, viscera handling, and hide processing), cutting and deboning, meat processing, rendering, and materials recovery.

Dairy Products (SIC Code 202X) - Typical operations may include: culturing, churning, pressing, curing, blending, condensing, sweetening, drying, milling, and packaging.

Canned, Frozen, and Preserved Fruits, Vegetables, and Frozen Specialties (SIC Code 203X) -Fruits and vegetables are washed, cut, blanched, and cooked prior to being classified as finished product. Additional operations may include drying, dehydrating, and freezing.

Grain Mills (SIC Code 204X) - Process operations performed in the grain mill subsector include: washing, milling, debranning, heat treatment (i.e., steeping, parboiling, drying and cooking), screening, shaping (i.e., extruding, grinding, molding, and flaking), and vitamin and mineral supplementing.

Bakery Products (SIC Code 205X) - Process operations in this subsector include mixing, shaping of dough, cooling, and decorating.

Sugar and Confectionery (SIC Code 206X) - Typical processes include mixing, cooking, and then forming using various techniques. The manufacture of chocolate products requires shelling, roasting, and grinding of the cocoa beans followed by the typical processing operations.

Fats and Oils (SIC Code 207X) Typical process operations at an animal and marine fats and oils facility include cooking of inedible fats and oils. Operations at an edible oils manufacturer include refining, bleaching, hydrogenation, fractionation, emulsification, deodorization, filtration, and blending of the crude oils into edible products.

Beverages (SIC Code 208X) - Process operations may include brewing, distilling, fermentation, blending, and packaging (i.e., bottling, canning, or bulk packaging).

Miscellaneous Food Preparation and Kindred Products (SIC Code 209X) - Process operations may include shelling, washing, drying, shaping, baking, frying, and seasoning.

Tobacco Products (SIC Code 21XX) - Typical process operations may include drying, blending, shaping, cutting and rolling.

Significant materials exposed to storm water at food and kindred products manufacturing facilities consist mostly of food products or byproducts and include acids (phosphoric, sulfuric), activated carbon, ammonia, animal cages, bleach, blood, bone meal, brewing residuals, calcium oxide, carbon dioxide, caustic soda, chlorine, cheese, coke oven tar, detergent, eggs, ethyl alcohol, fats (greases, shortening, oils), feathers, feed, ferric chloride, fruits, vegetables, coffee beans, gel bone, grain (flour, oats, wheat), hides, lard, manure, milk, salts (brine), skim powder, starch, sugar (sweetener, honey, fructose, syrup), tallow, wastes (off-spec product, sludge), whey, and yeast.

The pollutants of concern are biological oxygen demand (BOD_5), total suspended solids (TSS), oil and grease, pH, and chemicals from applications of pesticides.

Sector 24: Textile Mills, Apparel and other Fabric Product Manufacturing Facilities

The definition of storm water discharges associated with industrial activity includes point source discharges of storm water from eleven major categories of facilities, including: "...category (xi) facilities under Standard Industrial Classification (SIC) code 22." Storm water discharges from the following activities are covered: Textile Mill Products, of and regarding facilities and establishments engaged in the preparation of fiber and subsequent manufacturing of yarn, thread, braids, twine, and cordage, the manufacturing of broadwoven fabrics, narrow woven fabrics, knit fabrics, and carpets and rugs from yarn; processes involved in the dyeing and finishing of fibers, yarn fabrics, and knit apparel; the integrated manufacturing of knit apparel and other finished articles of yarn; the manufacturing of felt goods (wool), lace goods, nonwoven fabrics, and miscellaneous textiles.

Pollutants of concern include biochemical oxygen demand (BOD5), total suspended solids (TSS), pH, total chromium, total aluminum, total copper, total lead, total zinc, COD, phenols, sulfides, oil and grease, and benzene.

Sector 25: Wood and Metal Furniture and Fixture Manufacturing Facilities

The definition of storm water discharges associated with an industrial activity includes point source discharges of storm water from eleven major categories of facilities, including: "...category (xi) facilities classified as Standard Industrial Classification (SIC) codes 2434 and 25." Furniture and fixture manufacturing facilities eligible for coverage include facilities identified by the following SIC codes:

- Wood Kitchen Cabinets (SIC Code 2434)
- Household Furniture (SIC Code 251)
- Office Furniture (SIC Code 252)
- Public Buildings and Related Furniture (SIC Code 253)
- Partitions, Shelving, Lockers, and Office and Store Fixtures (SIC Code 254)
- Miscellaneous Furniture and Fixtures (SIC Code 259).

The process of manufacturing wood furniture begins with the delivery and storage of wood. There are three different raw wood materials, lumber, veneer, and particle board. Once delivered, raw lumber is allowed to air dry up to one year. After the lumber is sufficiently air dried it is then transported to a dry kiln for further drying. Once the lumber has been dried to a desired moisture content, the dried lumber is taken to the processing area. The remaining furniture manufacturing processes are all completed indoors, including cutting, planing, sanding, finishing, and lathing.

Veneer is another raw material used in the production of furniture. In this process logs are placed in a steam vat to increase moisture content. The logs are turned on a lathe to peel off the veneer. The resulting veneer sheets are layered into stacks or "hacks." Moisture is removed from the hacks by kiln drying. After a desired moisture content has been achieved the hacks are disassembled.

Particle board is the third raw material incorporated into the manufacturing of wood furniture. The board is received, cut to size, and banded on all four edges with solid wood. The banding is accomplished in continuous, steam heated units utilizing adhesives. The panels are allowed to cool and then they are sanded.

The significant materials identified as exposed to storm water at wood furniture and fixture manufacturing facilities include raw wood, sawdust, coal, kiln ash, solvent-based finishing materials and waste products, used rags, raw glue and waste materials, and petroleum-based products.

Metal furniture manufacturing facilities may purchase wood pieces ready for assembly or they may have all the industrial activities of wood manufacturing facilities in addition to the metal manufacturing facilities. Facilities that manufacture metal household furniture maintain all operations including: machining and assembly, finishing, and temporary storage of finished products within an enclosed building. Cold roll steel is initially received and temporarily stored within the manufacturing building. However, steel may be stored outside

VOL 12

4418

prior to use. The steel is cut to size, bent, and welded to design specifications to fabricate raw metal household furniture. Final grinding, sanding, finishing, spot welding, and painting are then completed.

The significant materials identified as exposed to storm water at metal furniture and fixture facilities include metals, sawdust, solvent-based finishing materials and waste products, electroplating solutions and sludges, used rags, raw glue and waste materials, and petroleum-based products.

Pollutants at wood and metal furniture manufacturing facilities include TSS, pH, cadmium, arsenic, COD, BOD_5, lead, solvents, oil & grease, diesel fuel, and gasoline.

Sector 26: Printing and Publishing Facilities

The definition of storm water discharges associated with industrial activity includes point source discharges of storm water from eleven major categories of facilities, including: "...category (xi) facilities classified as Standard Industrial Classification (SIC) Code 27 which includes facilities primarily engaged in printing and publishing services. The following facilities are covered under SIC code 27:

- **Book Printing (SIC Code 2732)**: Establishments primarily engaged in printing, or in printing and binding, books and pamphlets, but not engaged in publishing.
- **Commercial Printing, Lithographic (SIC Code 2752)**: Establishments primarily engaged in printing by the lithographic process. Offset printing, photo-offset printing, and photolithographing are also included in this industry.
- **Commercial Printing, Gravure (SIC Code 2754)**: Establishments primarily engaged in gravure printing.
- **Commercial Printing, Not Elsewhere Classified (SIC Code 2759)**: Establishments primarily engaged in commercial or job printing. This industry includes general printing shops, as well as shops specializing in printing newspapers and periodicals for others.
- **Platemaking and Related Services (SIC Code 2796)**: Establishments primarily engaged in making plates for printing purposes and in related services. Also included are establishments primarily engaged in making positive or negatives from which offset lithographic plates are made.

Pollutants of concern include toxic waste ink with solvents chromium, lead, dust, sludge, ink - sludges with chromium or lead, solvents, photographic processing wastes, fuel, oil, heavy metals, trash, and petroleum products.

Sector 27: Rubber, Miscellaneous Plastic Products, and Miscellaneous Manufacturing Industries

The definition of storm water discharges associated with industrial activity includes point source discharges of storm water from eleven major categories of facilities, including: "... (xi) facilities classified as Standard Industrial Classification (SIC) major groups 30 and 39." Storm water discharges from category (xi) facilities are only regulated where precipitation and storm water runon come into contact with areas associated with industrial activities and significant materials. Sector 27 covers all storm water discharges from facilities classified as SIC 30 and 39, except for those facilities classified as SIC code 391 - Jeweler, Silverware, and Plated ware. Facilities classified as SIC code 391 are subject to Sector 29 permitting requirements.

Major SIC group 30 includes rubber and miscellaneous plastic products. Specifically, this SIC group includes manufacturers of tires and inner tubes, rubber and plastic footwear, rubber and plastic hose and belting, gaskets, packing and sealing devices, and miscellaneous fabricated rubber products. This SIC group also includes miscellaneous plastic products such as unsupported plastic film, sheet, rods and tubes, laminated plastic plate, sheet and profile shapes, plastic pipe and bottles, plastic foam products such as cups, ice chests and packaging materials, plastic plumbing fixtures, and miscellaneous plastic products.

Major SIC group 39 (except 391) includes miscellaneous manufacturing industries. Specifically, this group includes manufacturers of musical instruments, games, toys and athletic goods, pens, pencils and artists' supplies, buttons, and pins and needles.

Pollutants found in storm water discharges from rubber and miscellaneous plastic products manufacturers may include total suspended solids (TSS), oil and grease, zinc, and acids.

Sector 28: Leather Tanning and Finishing Facilities

The definition of storm water discharges associated with industrial activity includes point source discharges of storm water from eleven major categories of facilities, including: "...category (ii) facilities classified as Standard Industrial Classification (SIC) code 3111." Storm water discharges covered include those from leather tanning facilities and facilities which make fertilizer solely from leather scraps and leather dust where precipitation and storm water runon come into contact with significant materials including, but not limited to, raw materials, waste products, by-products, stored materials, and fuels.

Leather tanning or finishing is the conversion of animal hides or skins into leather. Leather is made from the inner layer of the animal skin, which consists primarily of the protein collagen. Tanning is the reaction of the collagen fibers with tannins, chromium, alum or other tanning agents. Tanning processes use sodium dichromate, sulfuric acid and detergents and a variety of raw and intermediate materials.

There are three major processes required to make finished leather. These are beamhouse operations, tanyard processes and retanning and finishing processes.

- Beamhouse Operations—These consist of four activities: side and trim; soak and wash; fleshing and unhairing. Side and trim is the cutting of the hide into two sides and trimming of areas which do not produce good leather. In soak and wash processes, the hides are soaked in water to restore moisture lost during curing. Washing removes dirt, salt, blood, manure, and nonfibrous proteins. Fleshing is a mechanical operation which removes excess flesh. The removed matter is normally recovered and sold for conversion to glue. Unhairing involves using calcium hydroxide, sodium sulfhydrate, and sodium sulfide to destroy the hair (hair pulp process) or remove hair roots.

- Tanyard Processes—These consist of bating, pickling, tanning, wringing, splitting, and shaving. Bating involves the addition of salts of ammonium sulfate or ammonium chloride used to convert the residual alkaline chemicals present from the unhairing process into soluble compounds which can be washed from the hides or skins. "Pickling" the hide with sulfuric acid provides the acid environment necessary for chromium tanning. In the tanning process, tanning agents such as trivalent chromium and vegetable tannins convert the hide into a stable product which resists decomposition. Wringing of the "blue hides" (hides tanned with chromium) removes excess moisture with a machine similar to a clothes wringer. Splitting adjusts the thickness of the tanned hide to the requirements of the finished product and produces a "split" from the flesh side of the hide. The hide is then shaved to remove any remaining fleshy matter.

- Retanning and Wet Finishing Processes—These include retanning, bleaching, coloring, fatliquoring, and finishing. The most common retanning agents are chromium, vegetable extracts and syntans (based upon naphthalene and phenol). Sodium bicarbonate and sulfuric acid are sometimes used to bleach leather. Coloring involves the use of dyes (usually aniline based) on the tanned skin. Animal or vegetable fatliquors are added to replace the natural oils lost in the beamhouse and tanyard processes. Finishing includes all operations performed on the hide after fatliquoring, and includes finishing to enhance color and resistance to stains and abrasions, smoothing and stretching of the skin, drying, conditioning, staking, dry milling, buffing and plating.

Significant materials include raw materials, brine or salt cured hides and skins, fuels, materials such as solvents, detergents, finished materials, fertilizers, pesticides, waste products, leather shavings and dust, leather scrap, blue hides and splits, empty chemical containers, spent solvents, and emissions from spray booths.

Pollutants include aluminum, manganese, Total Kjeldahl Nitrogen (TKN), nitrate + nitrite as N, and Biochemical Oxygen Demand (BOD_5).

Sector 29: Fabricated Metal Products Facilities

The definition of storm water discharges associated with industrial activity includes point source discharges of storm water from eleven major categories of facilities, including: "...category (xi) facilities classified as Standard Industrial Classification (SIC) codes 34 and 391." Storm water discharges from fabricated metal and processing facilities eligible for coverage include the following types of operations:

- Fabricated Metal Products, Except Machinery and Transportation Equipment, SIC code 34 (3429, 3441, 3442, 3443, 3444, 3451, 3452, 3462, 3465, 3471, 3479, 3494, 3496, 3499)

- Jewelry, Silverware, and Plated Ware, SIC code 391.

This section covers establishments engaged in fabricating ferrous and nonferrous metal products, such as metal cans, tinware, general hardware, automotive parts, tanks, road mesh, structural metal products, nonelectrical equipment, and a variety of metal and wire products made from purchased iron or steel rods, bars, or wire materials.

These facilities are engaged in the manufacturing of a variety of products that are constructed primarily by using metals. The operations performed usually begin with materials in the form of raw rods, bars, sheet, castings, forgings, and other related materials and can progress to the most sophisticated surface finishing operations. There are typically several operations that take place at a fabrication facility: machining operations, grinding, cleaning and stripping, surface treatment and plating, painting, and assembly. The machining operation involves turning, drilling, milling, reaming threading, broaching, grinding, polishing, cutting and shaping, and planing. Grinding is the process using abrasive grains such as aluminum oxide, silicon carbide, and diamond to remove stock from a workpiece. Cleaning and stripping is a preparatory process involving solvents for the removal of oil, grease and dirt. Both alkaline and acid cleaning are employed. Surface treatment and plating is a major component that involves batch operations to increase corrosion or abrasion resistance. This is generally in the form of galvanizing. Painting is generally practiced at most facilities to provide decoration and protection to the product. Assembly is the fitting together of previously manufactured parts into a complete unit or structure.

Areas with significant materials include those with waste storage, outside product storage, used for pickling acids, storage of cutoff scrap metal, aluminum scraps, hazardous materials, galvanized steel components, solvent storage, waste paper storage, and machinery storage.

Pollutants at these facilities include aluminum, copper, manganese, nitrate + nitrite as N, iron, and zinc.

Sector 30: Transportation Equipment, Industrial or Commercial Machinery Manufacturing Facilities

The definition of storm water discharge associated with industrial activity includes point source discharges of storm water from eleven categories of facilities, including: "...category (xi) facilities classified as Standard Industrial Classification (SIC) codes ... 34 (except 3441), 35, 37 (except 373),..." Under these SIC codes, the facilities subject to storm water regulations include:

- Fabricated Structural Metal Products, (SIC Code 344)
- Metal Forgings and Stampings, (SIC Code 346)
- Miscellaneous Fabricated Metal Products (SIC Code 349)
- Engines and Turbines (SIC Code 351)
- Farm and Garden Machinery and Equipment (SIC Code 352)
- Construction, Mining, and Materials Handling Machinery and Equipment (SIC Code 353)
- Metalworking Machinery and Equipment (SIC Code 354)
- Special Industry Machinery, Except Metalworking Machinery (SIC Code 355)
- General Industrial Machinery and Equipment (SIC Code 356)
- Refrigeration and Service Industry Machinery (SIC Code 358)
- Miscellaneous Industrial and Commercial Machinery and Equipment (SIC Code 359)
- Motor Vehicles and Motor Vehicle Equipment (SIC Code 371)
- Aircraft and Parts (SIC Code 372)
- Motorcycles, Bicycles, and Parts (SIC Code 375)
- Guided Missiles and Space Vehicles and Parts (SIC Code 376)
- Miscellaneous Transportation Equipment (SIC Code 379)

The general manufacturing process is conducted indoors, and includes activities such as cutting, shaping, grinding, cleaning, coating, forming, and finishing. Specific processes are referred to as "unit operations." These operations occur predominately indoors, so contamination of storm water discharges from manufacturing processes is unlikely.

Significant materials include ferrous and nonferrous metals, such as aluminum, copper, iron, steel and alloys of these metals; either in raw form or as intermediate products, paints, solvents (e.g., paint thinners, degreasers), chemicals (e.g., acids, bases, liquid gases), fuels (e.g., gasoline and diesel fuel), lubricating and cutting oils, and plastics.

Pollutants of concern at these facilities include total suspended solids (TSS), turbidity, fugitive dust, oil and grease, organics, heavy metals, and chemical oxygen demand (COD).

Sector 31: Electronic and Electrical Equipment and Components, Photographic and Optical Goods

The definition of storm water discharges associated with industrial activity includes point source discharges of storm water from eleven major categories of facilities, including: "... category (xi) facilities classified as Standard Industrial Classification (SIC) codes 36, 38, and 357."

Major SIC group 36 includes manufacturers of a broad range of electronic and electrical equipment and components, not including computer equipment. Specifically, this group includes manufacturers of electricity distribution equipment such as transformers and switch-gear, electrical industrial equipment such as motors and generators, household appliances, electric lighting and wiring equipment such as light bulbs and lighting fixtures, and audio and video equipment including phonograph records and audio tapes and disks. Also included are manufacturers of communication equipment including telephone and telegraph equipment, radio and television equipment, electronic components such as printed circuit boards and semiconductors and related devices, and miscellaneous electrical items such as batteries and electrical equipment for automobiles. Storm water discharges from facilities in this category are only regulated where precipitation and storm water runon come into contact with areas associated with industrial activities and significant materials.

Major SIC group 38 includes manufacturers of measuring, analyzing, and controlling instruments, photographic, medical and optical goods, and watches and clocks. Specifically, this group includes facilities which manufacture search, detection, navigation, or guidance systems such as radar and sonar equipment, measurement and control instruments and laboratory apparatus, surgical, medical and dental instruments and supplies, photographic equipment and supplies, and watches and clocks.

Computer and office equipment is included in industrial SIC group 357. This group includes manufacturers of computers, computer storage devices, and peripheral equipment for computers such as printers and plotters. Manufacturers of miscellaneous office machines are also included in this group.

Pollutants found in storm water discharges from Electronic and Electrical Equipment and Components, Photographic and Optical Goods manufacturers may include total suspended solids (TSS), heavy metals, organics, oil and grease, and acids.

APPENDIX F

GROUP APPLICATION PART 2 SAMPLING DATA

ORGANIZED BY POLLUTANT

This appendix contains tabular and graphical descriptions of the sampling data for the 31 industrial sectors that were identified in the group application portion of the Phase I permitting process (four of the sectors were consolidated into two sectors for permit development purposes, only tablular data is presented for copper, lead, and zinc). This appendix summarizes the sampling data on a pollutant by pollutant basis. The tables and figures display the mean values, median values, 95th percentile values, for the grab and composite samples and the mean, median and 90th percentile values for NURP data for a portion of the pollutants sampled within each sector.

INDUSTRIAL SECTORS GROUP APPLICATIONS (TABLE 1)	
SECTOR	ACTIVITIES REPRESENTED

[FRL-4202-9]

National Pollutant Discharge Elimination System, Request for Comment on Alternative Approaches for Phase II Storm Water Program

AGENCY: Environmental Protection Agency.

ACTION: Request for comment.

SUMMARY: In a memorandum dated January 28, 1992, the President asked regulatory agencies to review existing and proposed rules to improve cost effectiveness, minimize economic impact, and reduce regulatory burden. In response, today's notice requests information and public input on Phase II of the national storm water program mandated under section 402(p)(6) of the Clean Water Act (CWA). More specifically, EPA is today requesting public comment on a number of issues including scope of coverage under Phase II, identification of high risk Phase II discharges, alternative control strategies, and appropriate deadlines. With respect to each of these issues, the Agency is requesting input on how to meet environmental objectives and requirements set forth under section 402(p)(6) while at the same time identifying cost-effective control strategies that minimize the economic impact on the regulated community as well as the administrative burden on Federal, State and local government.

DATES: Comments on this notice must be received on or before November 9, 1992.

ADDRESSES: Respondents should send an original and two copies of their comments to Michael Plehn, Office of Wastewater Enforcement and Compliance (EN-336), United States Environmental Protection Agency, 401 M Street, SW., Washington, DC 20460, (202) 260-6929. The public record for this notice is located at EPA Headquarters, NE Mall room 220, 401 M Street, SW., Washington, DC 20460. Appointments to view the record can be made by contacting Michael Plehn at the above address. A reasonable fee may be charged for copying. The public record for previous rulemaking activity related to Phase I of the storm water program is located at EPA Headquarters, EPA Public Information Reference Unit, room 2402, 401 M Street, SW., Washington, DC 20460.

FOR FURTHER INFORMATION CONTACT: For further information on this notice, contact the NPDES Storm Water Hotline at (703) 821-4823, or Michael Plehn, Office of Wastewater Enforcement and Compliance (EN-336), United States Environmental Protection Agency, 401 M Street, SW., Washington, DC 20460, (202) 260-6929.

SUPPLEMENTARY INFORMATION:

I. Background

The 1972 amendments to the Federal Water Pollution Control Act (FWPCA, later referred to as the Clean Water Act or CWA) prohibit the discharge of any pollutant to the navigable waters of the United States from a point source unless the discharge is authorized by a National Pollutant Discharge Elimination System (NPDES) permit. Efforts to improve water quality under the NPDES program have focused traditionally on reducing pollutants in discharges of industrial process wastewater and discharges from municipal sewage treatment plants. This program emphasis developed because many industrial and municipal sources were not controlled at that time and were easily identified as contributing to water quality impairment. Over time, as pollution control measures were implemented for these discharges and as data collection efforts have provided additional information, it has become evident that more diffuse sources of water pollution, such as agricultural and urban runoff, are important contributors to water quality problems and use impairment. Some diffuse sources of water pollution, such as agricultural runoff and irrigation return flows, are exempted statutorily from the NPDES program. Controls for other point source discharge of storm water runoff, however, are addressed in this notice.

A. Environmental Impacts

Several national assessments have been conducted to evaluate the impacts of diffuse sources of storm water runoff on receiving water quality. The "National Water Quality Inventory, 1990 Report to Congress" provides a general assessment of water quality based on biennial reports submitted by the States under section 305(b) of the CWA. In section 305(b) Reports, States indicate the fraction of the States' waters that have been assessed, the fraction of those assessed waters that are not supporting designated uses, and the sources of use impairment for those waters (e.g., diffuse sources, point sources, and natural sources). The Report indicates that roughly 30 to 40 percent of assessed rivers, lakes and estuaries are not supporting the uses for which they are designated. Based on information from 51 States and Territories that reported on sources of pollution, the Report indicates that storm water runoff from a number of diffuse sources, including agricultural areas, urban areas, construction sites, land disposal activities, and resource extraction activities, is the leading cause of water quality impairment cited by States. For those States reporting in each category, diffuse sources were cited as causing use impairments in the following magnitudes: For rivers and streams, 11 percent of impaired river miles are caused by separate storm sewers, 6 percent are caused by construction activities, and 14 percent are caused by resource extraction. For lakes, 28 percent of impaired lake acres are caused by separate storm sewers and 25 percent are caused by land disposal. For the Great Lakes' shoreline, 6 percent of impaired shoreline miles are caused by separate storm sewers, and 41 percent are caused by land disposal. For estuaries, 30 percent of impaired acres are caused by separate storm sewers. For coastal areas, 36 percent of impairments are caused by separate

4481

storm sewers, and 37 percent are caused by land disposal.

In 1985, the States conducted a different study of diffuse pollution sources under the sponsorship of the Association of State and Interstate Water Pollution Control Administrators (ASIWPCA) and EPA. The study resulted in the report entitled "America's Clean Water—The States' Nonpoint Source Assessment, 1985." In that study, 38 States reported urban storm water runoff as a major cause of beneficial use impairment. In addition, 21 States reported construction site runoff as a major cause of use impairment.

Studies conducted by the National Oceanic and Atmospheric Administration (NOAA) indicate that urban storm water runoff is indeed a major pollutant source that adversely affects shellfish growing waters.[1] The NOAA studies concluded that urban runoff affects 39 percent of harvest-limited area on the East Coast, 59 percent in the Gulf of Mexico, and 52 percent on the West Coast.

B. Water Quality Act of 1987

In response to growing concerns with the environmental impact of storm water runoff, Congress addressed this issue as part of the Water Quality Act of 1987 (WQA) by adding section 402(p) to the CWA to require the establishment of a comprehensive two-phased approach for the control of storm water discharges. Section 402(p)(1) prohibits EPA or NPDES States from requiring permits for storm water discharges until October 1, 1992, except for 5 classes of storm water discharges specifically listed under section 402(p)(2) (see appendix A). These 5 classes of discharges make up Phase I of the existing national storm water program and include storm water discharges:

(A) Permitted before February 4, 1987;
(B) Associated with industrial activity;
(C) From a municipal separate storm sewer system serving a population of 250,000 or more;
(D) From a municipal separate storm sewer system serving a population of 100,000 or more, but less than 250,000;
(E) Which EPA or a NPDES State determines contributes to a violation of a water quality standard or is a significant contributor of pollutants to the waters of the United States.

Section 402(p)(3) confirms that, like all other point source discharges under the CWA, discharges of storm water associated with industrial activity must meet all applicable provisions of CWA sections 402 and 301, including technology-based requirements and any necessary water quality-based requirements. Permits for discharges from municipal separate storm sewer systems may be issued on a system- or jurisdiction-wide basis and must meet a new statutory standard requiring controls to reduce pollutant discharges to the maximum extent practicable (MEP).

Phase II of the storm water program covers all storm water discharges not addressed under the five Phase I classes described above. Under the current provisions of section 402(p), the existing statutory prohibition against permitting Phase II storm water discharges expires on October 1, 1992 (see appendix B).

Under CWA section 402(p)(5), EPA, in consultation with the States, is required to conduct two studies on Phase II storm water discharges for which permits cannot be required before October 1, 1992. The first study will identify those sources or classes of discharges that may be addressed in Phase II and determine the nature and extent of pollutants in such discharges. The second study is to establish procedures and methods to control Phase II storm water discharges to the extent necessary to mitigate impacts on water quality. These studies have not been completed.

Under section 402(p)(6), EPA, in consultation with State and local officials and based on the two studies, is required to issue regulations by October 1, 1992, which designate particular sources or classes of Phase II storm water discharges to be regulated to protect water quality and which establish a comprehensive program to regulate such designated sources. This program must establish priorities, requirements for State storm water management programs, and expeditious deadlines. The program may include performance standards, guidelines, guidance, and management practices and treatment requirements, as appropriate.
