Delaware has fewer than 10 municipal or industrial point sources that discharge to nontidal waters. Nonpoint sources, including agriculture and urbanization activities, have the major impact on its nontidal streams. Delaware has the capacity to produce over 250 million chickens per year, has over 50% of its land area in crop production, and has an urban population that is increasing annually by 10%.

Delaware uses water quality monitoring to assess the condition of its surface waters for inclusion in its Section 305(b) report. Delaware designed the biological and habitat measures to assess the condition of nontidal streams and evaluate the impact of nonpoint source pollution. Biological and habitat assessments conducted by Delaware during the fall of 1991 and 1993 used a modified version of the EMAP-Estuaries probability-based statistical sampling design. The key to the modified approach involved selecting conveniently accessible sites adjacent to Delaware's roads as a cost-effective means of selecting sampling sites.

Results of these assessments impact decisions related to stormwater controls and the management of streams and ditches and their riparian areas. Stormwater controls are needed throughout the State, and existing sediment and stormwater control regulations must be aggressively adhered to in order to prevent further deterioration of habitat quality from urbanization. Data documenting the poor condition of ponds and the Inland Bays indicate the need for maintenance and restoration of streamside and riparian vegetation to attain the ecological and water quality potential of Delaware's surface waters.

Objectives

The primary objective of this monitoring approach was to provide an assessment of the biological and habitat condition of nontidal streams throughout Delaware. The data were intended for use in the 305(b) report and to support the establishment of biological criteria in the development of State Water Quality Standards. A secondary objective was to quantify the relationship between biological quality,

HIGHLIGHT HIGHLIGHT HIGHLIGHT

using aquatic macroinvertebrates, and habitat quality. This information will be used to evaluate habitat degradation as a biological stressor in nontidal streams and to assess the effect of nonpoint source pollution on stream ecological health.

Sampling Design

The probability-based statistical sampling design developed by EMAP-Estuaries was modified for nontidal streams and used for these assessments. This design allowed for the assessment of conditions over larger geographic areas by sampling a set of randomly selected sites.

The number of sites selected was based on the areal extent of the length of river and stream miles in each of 35 subbasins. The State took samples from a list of 3,311 randomly selected road crossings identified with a geographic information system (GIS).

The distance between road crossings in Delaware averages 1.1 miles. Assessments were made 100 to 150 meters (approximately 330-500 feet) upstream of the road crossing to ensure that the results were minimally affected by the cultural activities near the road.

Using road crossings as sample sites in Delaware is believed to be an acceptable approach because the road crossings occur frequently and are fairly evenly distributed, so they are representative of the nontidal streams; the conditions just upstream from Delaware's small country roads (as opposed to major interstate roads) are not significantly different from those between roads; and the stratification using 35 subbasins overcomes any patchiness in distribution. The statistical certainty of this approach is being further investigated by funding from EMAP-Surface Waters (SW) to compare the statistical validity of the road-crossing design with the standard EMAP-SW statistical sampling design.

The study design enabled the data collected from these sites to be extrapolated with confidence to the entire State. The results from the 189 sampling sites represent a database of sufficient size and statistical certainty to provide a comprehensive assessment of the biological and habitat conditions of nontidal streams throughout the State and in individual counties.

Biological Monitoring

Chemical monitoring is particularly complex and expensive when applied to diffuse and intermittent pollution sources, and criteria do not exist for such major nonpoint source pollutants as sediment and nutrients. Biological monitoring may provide, therefore, a cost-effective monitoring tool for identifying nonpoint source problems and tracking the progress of control programs.

Measurements associated with the aquatic macroinvertebrate community were used as the basis for determining the biological quality of the nontidal streams. There is considerable variability in the community of organisms found in the aquatic environment. This variability must be accounted for in order to detect differences among sites and among time periods. In this study, to minimize temporal variability, data were collected only during the fall of 2 years. Site variability was further reduced by defining groups of waterbodies with such similar characteristics as salinity, depth, width, and ecoregion. In Delaware nontidal streams, this categorization resulted in two distinct ecoregions: the Piedmont Ecoregion, characterized by gently rolling terrain, and the Coastal Plain Ecoregion, characterized by flat terrain. Biological monitoring was conducted solely in the Coastal Plain Ecoregion.

Standardization of collection and sample processing methods is also important to minimize biological and habitat data variability. The Mid Atlantic-Coastal Stream Workgroup, consisting of biologists from four States and two EPA Regions, developed and tested standard methods for collecting data. Delaware used the methods developed by this workgroup.

Habitat Measurements

Measurements to define the quality of the physical habitat were used to evaluate the relationship between habitat and biology in both ecoregions. The habitat parameters used to score the habitat quality of each site are as follows:

Northern Piedmont Ecoregion

- Channel modification
- Instream habitat
- Bank stability
- Bank vegetative type
- Shading
- Riparian zone width
- Velocity or depth ratio
- Sediment deposition
- Embeddedness (the percent of a rock "stuck" in the substrate)
- Riffle quality
- Riffle quantity

Coastal Plain Ecoregion

- Channel modification
- Instream habitat
- Bank stability
- Bank vegetative type
- Shading
- Riparian zone width
- Pools

Mid-Atlantic Highlands Assessment (MAHA)

In 1992, aquatic biologists in Pennsylvania, Maryland, Virginia, and West Virginia, EPA Region 3, and EPA's Office of Research and Development (ORD) began to explore the feasibility of developing biocriteria for the Mid-Atlantic Highlands and using ecoregions as a management tool. Three years later, this modest effort has evolved into a multistate, multiagency effort known as MAHA (Mid-Atlantic Highlands Assessment). The Mid-Atlantic Highlands, covering some 65,000 square miles, is comprised of many unique terrestrial and aquatic ecosystems, extending east to west from the Blue Ridge Mountains to Ohio and north to south from New York to North Carolina/Tennessee (Figure 1). It includes six major watersheds: West Susquehanna, Upper Susquehanna, Potomac, Kanawa, Monongahela, and Allegheny.

The natural features of this region illustrate both the complexity and the interconnection of ecological systems. The streams are inhabited by the greatest variety of freshwater mussels in the United States. The surrounding landscapes contain some of the most diverse deciduous forests in the world, as well as geographically restricted species that are on the edge of their range or are isolated genetically. The Shenandoah National Park is world renowned for its beauty and variety of animal and plant life. This region also includes extensive and unique cave ecosystems.

In 1995, nine Federal agencies formed the Mid-Atlantic Highlands Coordinating Council to foster and promote cooperation among these entities in carrying out their responsibilities in the Mid-Atlantic Highlands. An interagency Memorandum of Understanding (The Highlands Accord) was signed during the summer of 1995 in the Nation's Capital by and between the U.S. Department of the Interior's Office of Surface Mining, the National Park Service, the National Biological Service, the Fish and Wildlife Service, the U.S. Geological Survey, the U.S. Forest Service, the U.S. Department of Agriculture's Natural Resources Conservation Service, the Agricultural Research Service, and the U.S. Environmental Protection Agency.

The purpose of the Memorandum of Understanding is to establish a framework for regional cooperation and participation among the Federal cooperators and with the States and other parties toward a collective and more holistic approach to the management, conservation, and protection of the Mid-Atlantic Highlands' natural resources. It is anticipated that another three to five Federal agencies and relevant States will join the Council over the next year. The Council will conduct an ecological

VOL 12

5474

HIGHLIGHT HIGHLIGHT HIGHLIGHT

assessment of the condition of the aquatic resources in the Mid-Atlantic Highlands, their associated watersheds, and the factors that affect them. The protection and sustainability of these valuable natural resources can be enhanced through cooperation among the Federal, State, and local agencies and citizens groups involved in managing the area's ecosystems.

Field studies began during 1993. This was the first step toward building a joint monitoring and assessment effort that will ultimately be used to characterize the ecological condition of the Highlands. The field efforts in MAHA are an integration of the base EMAP-Surface Waters stream pilot, the Region 3 R-EMAP project (biological criteria in streams of the Ridge and Valley region), and the TIME project (assessment of streams sensitive to acidic deposition in response to the Clean Air Act Amendments).

First Survey

During the Spring of 1993, field crews from Pennsylvania, Maryland, Virginia, West Virginia, EPA Region 3, EPA's ORD, and the U.S. Fish and Wildlife Service visited 256 stream locations across the four-state area. Using common protocols, they sampled these sites for fish, benthic invertebrates, attached algae, physical habitat, riparian habitat, and water chemistry. Additionally, information from satellite images and aerial photography were collected for the watersheds sampled. Of these sites, 41 had been specifically selected as being representative of either minimally disturbed sites or sites known to be highly impacted. The remainder of the sites had been selected using a statistical process, similar to election

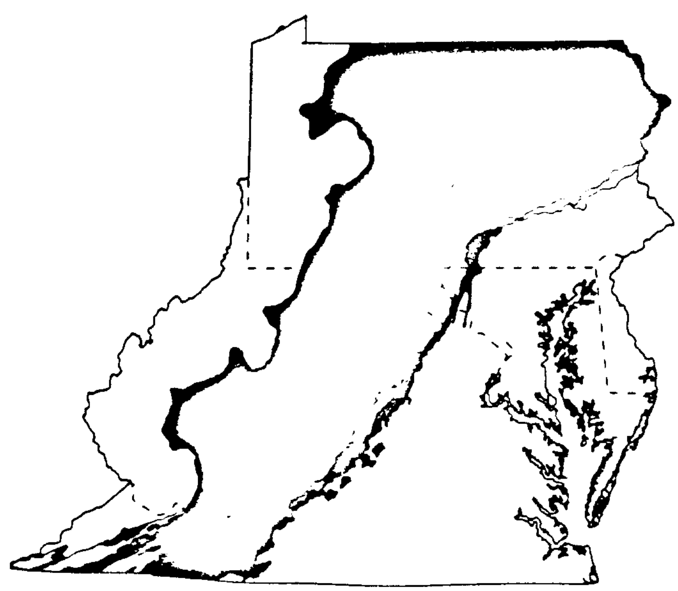

Figure 1. Ecological Regions of the Mid-Atlantic Highlands.

VOL 12

5475

R0038783

HIGHLIGHT HIGHLIGHT HIGHLIGHT

polls, so that information from these sites could be used to estimate the conditions found across all small streams within the region.

The information presented here represents just the initial findings of the first year's survey, yet significant information about the chemical, biological, and habitat conditions of streams in the mid-Atlantic was uncovered. Additional analyses are ongoing by the Region, States, ORD, and local universities to more fully describe the stream conditions in MAHA. This first survey only addressed small, "wadeable" streams (first- to third-order streams). Although small, these streams account for approximately 80% of the total stream length in the region. Thus, impacts or alterations in these systems can have a significant effect on the region's fisheries and a cumulative impact on the larger streams and rivers with which people are more familiar.

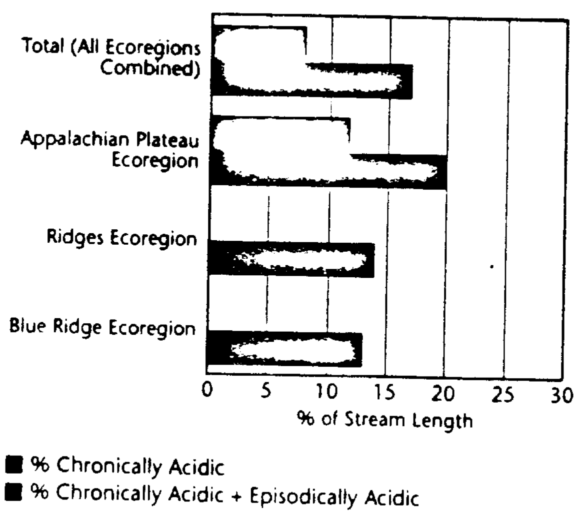

Figure 2. The Extent of Acidification of Streams in the Mid-Atlantic Highlands Regions.

Chemical Quality of MAHA Streams

Previous studies have identified streams in the Mid-Atlantic Highlands as very sensitive to acidification from sources such as acid rain or acid mine drainage. Previous 305(b) reports from States in the mid-Atlantic identified resource extraction, predominantly coal mining, as one of the major impacts on streams. This study looked at impacts from acidification in the Appalachian Plateau, the Ridges, and the Blue Ridge ecoregions. From measures of acid neutralizing capacity (ANC) in streams, it was estimated that 32% of the stream length in the Appalachian Plateau is either chronically acidic (12%) or chronically and episodically acidic (20%) (Figure 2). For this analysis, ANC ≤ 0 was the criterion for chronically acidic streams and ANC ≤ 50 was the criterion for episodically acidic systems.

Given the high impact in the Appalachian Plateau, there was interest in determining how much of the acidification impact was from deposition, mine drainage, or a mixture of impacts. Figure 3 shows the relative magnitude of different chemical impacts in streams of the Appalachian Plateau. Mixed impacts affect 29,000 km (18,021 miles) of stream while mine drainage impact

HIGHLIGHT HI HIGHLIGHT HIGHLIGHT

is seen in 11,000 km (6,835 miles) of stream. Acidic deposition appears to account for approximately 8,000 km (about 4,971 miles) of impacted streams in the Appalachian Plateau. Within this ecoregion, approximately 21,000 km (13,049 miles) of the small streams showed little or no chemical impact. The stream benthic community shows a response to these impacts, with the response being most severe in streams showing impacts from acid mine drainage (Figure 3).

Riparian Condition

Historically, alteration to the riparian system has not been of concern in water quality studies. But as our concern spread to encompass the protection of aquatic life, it became apparent that alterations to other facets of the riverine system, besides the water itself, could significantly impact the system. Alterations to the strip of land bordering the stream, the riparian corridor, have been shown to have potentially important implications to aquatic life. This riparian vegetation

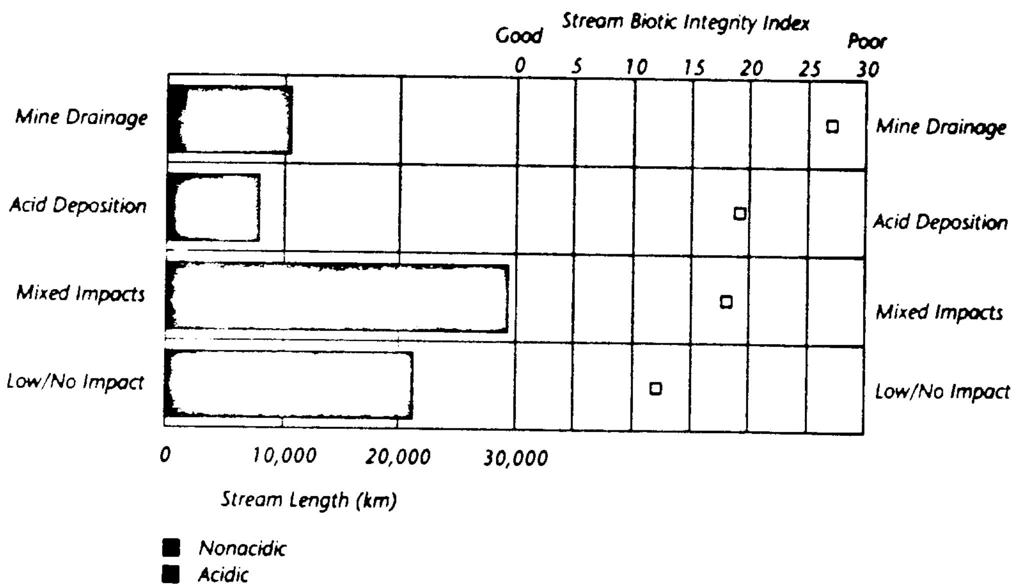

Figure 3. Extent of Chemical Impacts in Streams of the Appalachian Plateau Ecoregion and Resulting Condition of Aquatic Insects (Measured as Biotic Integrity).

VOL 12

5477

R0038785

HIGHLIGHT HIGHLIGHT HIGHLIGHT

provides shade, cover, and a constant supply of vegetative material for use by aquatic insects. Previous 305(b) reports for the region estimated that less than 1% of the assessed stream length was impacted by hydrologic or habitat alterations. The current study suggests that this number might be much higher, ranging from 73% of the stream length in the Western Allegheny Plateau to 17% in the Ridges of the Mid-Atlantic Region (Figure 4).

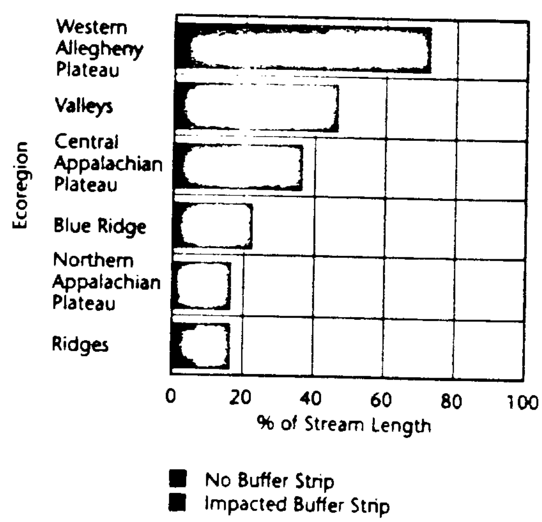

Figure 4. Percent of Riparian Buffer Impacted or Destroyed Along Streams in the Mid-Atlantic Highlands Region.

Biotic Integrity

The presence of healthy, diverse, and sustainable biological communities in streams reflects a strong biotic integrity. The State and Regional biologists continue to evaluate the best indicators of biotic integrity and establish biological criteria based on these indicators. Much was learned, however, during this first survey about the region's biological stream resources. In the smallest streams (first-order), 21% of the stream length (18,900 km or 11,744 miles) contained no fish (Figure 5). It is not known at present whether the absence of fish is due to natural causes or to anthropogenic alterations. However, the first-order streams contain as much stream length (26,000 km or 16,156 miles) with game fish as the second- and third-order streams combined (~25,000 km or 15,535 miles). Clearly this very small stream resource should be an important part of any management efforts to sustain sport fish. When this same information about fish presence is analyzed by ecoregion, the Ridge, Valley, and Western Allegheny ecoregions show significant portions of the stream resource with no fish present–39%, 18%, and 26%, respectively. It is uncertain whether the lack of fish is a natural condition or results from disturbances to the ecosystem.

VOL 12

5478

The Mid-Atlantic Highlands provide habitat for one of the most diverse fish communities in the country. Thus the introduction of exotic species, intentional or accidental, presents a significant threat to native fishes. Results from the first year of the MAHA survey provide an initial estimate of the extent of nonnative fish in the streams of the region. Overall, approximately 12% of the stream length in the mid-Atlantic contains nonnative (exotic) fish species. This is a result of both intentional introductions by fish stocking programs and accidental releases or invasions by nonnative fishes. The presence of exotic species is greatest in the third-order streams where approximately 49% of the stream length contains exotic fish species. In contrast, only 2% of the first-order stream length appears to contain nonnative fish species.

Future analyses of the MAHA data will refine the estimates provided here as well as present additional information on the condition and related causes of impacts to the stream resource of the Mid-Atlantic Highlands.

John Theilgard, Bynum, NC

Lakes, Reservoirs, and Ponds

Forty-four States, Puerto Rico, and the District of Columbia (hereafter collectively referred to as States), and two Tribes rated lake water quality in their 1994 Section 305(b) reports (see Appendix B, Table B-1, for individual State and Tribal data). These States and Tribes surveyed over 17.1 million acres of lakes, reservoirs, and ponds, which equals 42% of the 40.8 million acres of lakes in the Nation (Figure 3-1). The States and Tribes based 66% of their survey on monitored data and evaluated 18% of the surveyed lake acres with qualitative information (including best professional judgment by water quality managers). The States and governments did not specify whether 16% of the surveyed lake acres were monitored or evaluated.

The number of surveyed lake acres declined between 1992 and 1994 because several States chose not to use their fish tissue data to help determine overall use support. Some of these States, such as Minnesota, have established massive databases of fish tissue contamination information (which is used to establish fish consumption

THE STATES SURVEYED more than 17 million acres of lakes for 1994.

advisories) but lack other types of water quality data for many of their lakes. In 1994, these States chose not to assess overall use support entirely with fish tissue data alone, which is a very narrow indicator of water quality. In general, fish tissue data do not measure the health of a lake's aquatic community or swimming conditions although they do, of course, affect fish consumption. These States determined that it would be more useful to incorporate their fish tissue data into their discussions of public health concerns (see Chapter 7).

These changes are just one example of the numerous modifications the States made to their water quality survey methods between 1992 and 1994 as a result of many Federal, State, and Tribal partnerships implemented to improve monitoring in the Nation. Due to these changes, the summary data presented herein should not be compared with summary data presented in the 1992 Report to Congress.

Discrepancies in State survey methods also undermine comparisons of lake information submitted by individual States. Lake data should not be compared among States, which devote varying resources to monitoring biological integrity, water chemistry, and toxic pollutants in fish tissues. The discrepancies in State monitoring and survey methods, rather than actual differences in water quality, often account for the wide range in water quality ratings reported by individual States.

The summary information presented in this chapter applies strictly to the portion of the Nation's lakes surveyed by the States and Tribes. EPA cannot make generalizations about the health of all of our Nation's lakes based on data extracted from the 305(b) reports because most States and Tribes rate their waters with information obtained from water monitoring programs designed to detect degraded waterbodies. Very few States or Tribes randomly select water sampling sites to represent a cross section of water quality conditions in their jurisdiction. Instead, many States and Tribes direct their limited monitoring resources toward waters with suspected problems. As a result, the surveyed lakes probably contain a higher percentage of polluted waters than all of the Nation's lakes.

General Water Quality

The States and Tribes rate whether their water quality is good enough to fully support a healthy community of aquatic organisms and human activities, such as swimming, fishing, and drinking water use. The States and Tribes designate individual lakes for specific activities, termed "individual designated uses." EPA and the States use the following terminology to rate their water quality:

- **Good/Fully Supporting**: Good water quality supports a diverse community of fish, plants, and aquatic insects, as well as the array of human activities assigned to a lake by the State.

- **Good/Threatened**: Good water quality currently supports aquatic life and human activities in and on the lake, but changes in such factors as land use threaten water quality, or data indicate a trend of increasing pollution in the lake.

■ **Fair/Partially Supporting**: Fair water quality supports aquatic communities with fewer species of fish, plants, and aquatic insects, and/or occasional pollution interferes with human activities. For example, runoff during severe thunderstorms may temporarily elevate fecal coliform bacteria densities and indicate that swimming is not safe immediately following summer storms.

■ **Poor/Not Supporting**: Poor water quality does not support a healthy aquatic community and/or prevents some human activities on the lake. For example, lake waters may be devoid of fish for more than a month each summer because excessive nutrients from runoff initiate algal blooms that deplete oxygen concentrations.

■ **Poor/Not Attainable**: The State has performed a use-attainability analysis and demonstrated that use support of one or more designated beneficial uses is not attainable due to one of six specific biological, chemical, physical, or economic/social conditions (see Chapter 1 for additional information).

Most States and Tribes rate how well a lake supports individual uses (such as swimming and aquatic life habitat) and then consolidate individual use ratings into an overall water quality rating. A lake receives a poor overall rating if water quality consistently fails to support any one human activity or a healthy aquatic community (see Chapter 1 for a complete discussion of use support).

Forty-one States, two Tribes, Puerto Rico, and the District of Columbia reported overall use support status for lakes in their 1994 Section 305(b) reports (see Appendix B, Table B-2, for individual State and Tribal information). Another three States reported individual use support status but did not report overall use support status. In such cases, EPA used aquatic life use support status to represent general water quality conditions in the State's lakes.

The States and Tribes reported that 63% of their surveyed 17.1 million lake acres have good water quality (Figure 3-2). Waters with good quality include 50% of the surveyed lake acres fully supporting uses and 13% of the surveyed lake acres that are threatened and might deteriorate if we fail to manage potential sources of pollution.

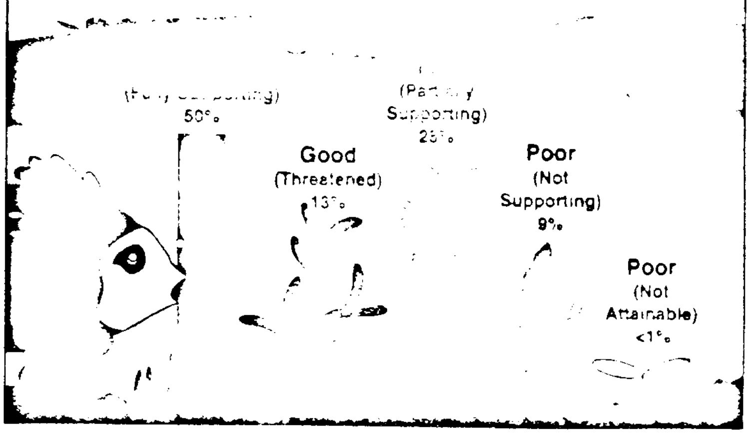
[a]Source: 1994 State and Tribal Section 305(b) reports.

Figure 3-2

Overall Use Support
in Surveyed Lakes, Reservoirs, and



Based on data contained in Appendix B, Table B-2 water quality.

Some form of pollution or habitat degradation impairs the remaining 37% of the surveyed lake acres. Twenty-eight percent of the surveyed lake acres have fair water quality that partially supports designated uses. Most of the time, these waters provide adequate habitat for aquatic organisms and support human activities, but periodic pollution interferes with these activities and/or stresses aquatic life. Nine percent of the surveyed lake acres suffer from poor water quality that consistently stresses aquatic life and/or prevents people from using the lake for activities such as swimming and fishing.

Individual Use Support

Individual use support information provides additional detail about water quality problems in our Nation's surface waters. The States and Tribes are responsible for designating their lakes for specific uses, but EPA requests that the States and Tribes rate how well their lakes support six standard uses so that EPA can summarize the State and Tribal data. The standard uses consist of aquatic life support, fish consumption, primary contact recreation (such as swimming and diving), secondary contact recreation (such as boating), drinking water supply, and agricultural use (see Chapter 1 for a description of each individual use).

Forty-one States, one Tribe, Puerto Rico, and the District of Columbia reported individual use support status of their lakes, reservoirs, and ponds (see Appendix B, Table B-3, for individual State and Tribal information). The reporting States and Tribes rated aquatic life use and swimming use in more lakes and identified more impacts on aquatic life use and swimming use than the other individual uses (Figure 3-3). These States and governments reported that fair or poor water quality impacts aquatic life in over 4.4 million lake acres (31% of the 14.5 million acres surveyed for aquatic life support), and swimming criteria violations impact 2.9 million lake acres (19% of the 14.8 million acres surveyed for swimming use support).

Many States and Tribes did not rate fish consumption use support because they have not codified fish consumption as a use in their standards. Some of these States consider fishing use as a component of aquatic life use—lakes that provide a healthy habitat for fish support fishing activities even though anglers may not be able to eat their catch in these States. EPA encourages the States to designate fish consumption as a use in their waterbodies to promote consistency in future reporting.

Water Quality Problems Identified in Lakes, Reservoirs, and Ponds

Figures 3-4 and 3-5 identify the pollutants and sources of pollutants that impair (i.e., prevent from fully supporting designated uses) the most acres of lakes, as reported by the States. The two figures are based on the same data (contained in Appendix B, Tables B-4 and B-5), but each figure provides a different perspective on the extent of impairment attributed to individual pollutants and sources. Figure 3-4 shows the relative impact of the leading pollutants and sources in surveyed lakes. Figure 3-5 presents the relative impact of the leading pollutants and sources in lakes with identified problems (i.e., impaired lakes), a subset of surveyed lakes.

The following sections describe the leading pollutants and sources of impairment identified in lakes. It is important to note that the information about pollutants and sources is incomplete because the States cannot identify the pollutant or source of pollutants impairing every impaired lake. In some cases, a State may recognize that water quality does not fully support a designated use, but the State may not have adequate data to document that a specific pollutant or process is responsible for the impairment. Sources are even more difficult to identify than pollutants and processes.

Pollutants Impacting Lakes, Reservoirs, and Ponds

Forty-one States, the District of Columbia, and Puerto Rico reported the number of lake acres impacted by individual pollutants and processes, such as invasions by noxious aquatic plants (see Appendix B, Table B-4, for individual State and Tribal information). EPA measures the impact of each pollutant or process by summing the total lake acres impaired (i.e., not fully supporting designated uses) by each pollutant or process. EPA ranks the pollutants and processes by the extent of their impacts on aquatic life and human activities rather than actual pollutant loads in lakes. This approach targets the pollutants and processes causing the most harm to aquatic life and public use of our waters, rather than the most abundant pollutants in our lakes, reservoirs, and ponds.

Figure 3-3

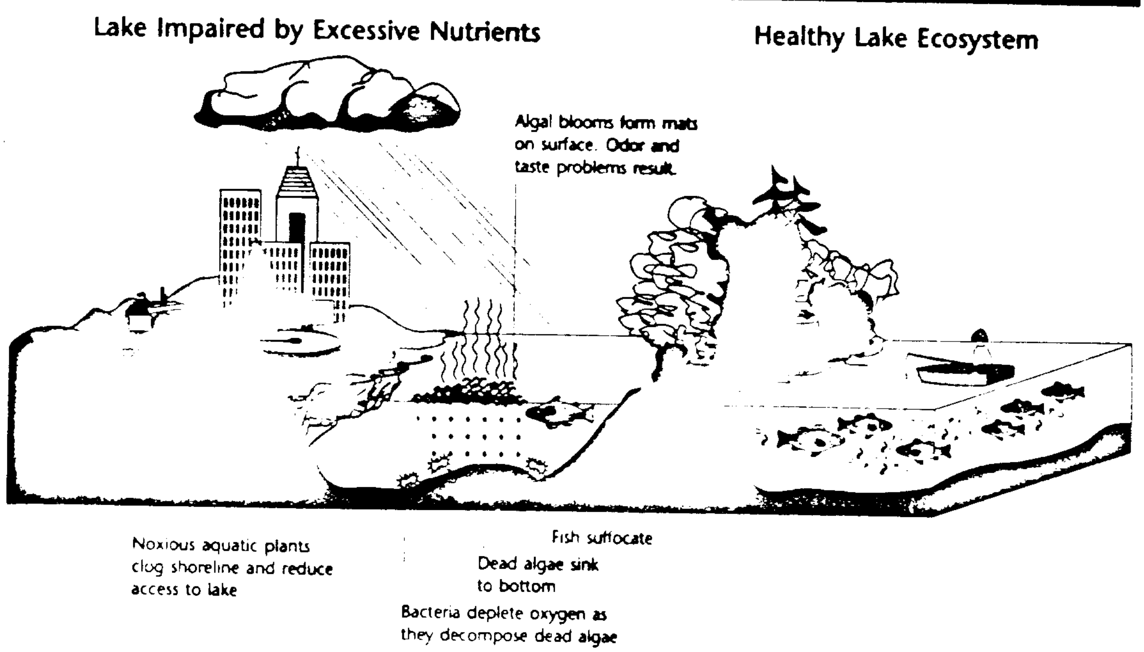
5487

R0038795

Thirty-seven States and Puerto Rico identified more lake acres polluted by nutrients than any other pollutant or process (Figures 3-4 and 3-5). The States and Puerto Rico reported that extra nutrients pollute 2.8 million lake acres (which equals 17% of the surveyed lake acres). Healthy lake ecosystems contain nutrients in small quantities, but extra inputs of nutrients (primarily nitrogen and phosphorus) from human activities unbalance lake ecosystems (Figure 3-6). When temperature and light conditions are favorable, excessive nutrients stimulate population explosions of undesirable algae and aquatic weeds. The algae sink to the lake bottom after they die, where bacteria consume the available dissolved oxygen as the bacteria decompose the algae. Fish kills and foul odors may result if the bacteria deplete the dissolved oxygen.

In addition to nutrients, the States, Puerto Rico, and the District of Columbia report that siltation pollutes 1.9 million lake acres (which equals 11% of the surveyed lake acres), enrichment by organic wastes that deplete oxygen impacts 1.6 million lake acres (which equals 9% of the surveyed lake acres), and

Figure 3-6



Nutrients cause nuisance overgrowth of algae as well as noxious aquatic plants, which leads to oxygen depletion via plant respiration and microbial decomposition of plant matter. If not properly managed and controlled, sources such as agriculture, industrial activities, municipal sewage, and atmospheric deposition can contribute to excessive nutrients in lakes.

metals pollute 1.4 million acres (which equals 8% of the surveyed lake acres).

Metals declined from the most widespread pollutant impairing lakes in the 1992 305(b) reporting cycle to the fourth leading pollutant impairing lakes in 1994. The decline is due to changes in State reporting and assessment methods rather than a measured decrease in metals contamination. In 1994, several States chose to no longer assess overall use support with fish contamination data alone. Much of that data consisted of measurements of metals in fish tissue. As a result of excluding these fish tissue data, the national estimate of lake acres impaired by metals fell by over 2 million acres in 1994.

Often, several pollutants and processes impact a single lake. For example, a process, such as removal of shoreline vegetation, may accelerate erosion of sediment and nutrients into a lake. In such cases, the States and Tribes count a single lake acre under each pollutant and process category that impacts the lake acre. Therefore, the lake acres impaired by each pollutant and process do not add up to 100%.

Most States and Tribes also rate pollutants and processes as major or moderate/minor contributors to impairment. A major pollutant or process is solely responsible for an impact or predominates over other pollutants and processes. A moderate/minor pollutant or process is one of multiple pollutants and processes that degrade aquatic life or interfere with human use of a lake. The States report that nutrients are the most widespread major cause of impairment in lakes.

Currently, EPA ranks pollutants and processes by the geographic extent of their impacts (i.e., the number of lake acres impaired by each pollutant or process). However, less abundant pollutants or processes may have more severe impacts than the leading pollutants listed above. For example, extreme acidity (also known as low pH) can eliminate fish in isolated lakes, but acid impacts on lakes are concentrated in northeastern lakes and mining States and are not widespread across the country as a whole. The individual State 305(b) reports provide more detailed information about the severity of pollution in specific locations.

Sources of Pollutants Impacting Lakes, Reservoirs, and Ponds

Forty-two States and Puerto Rico reported sources of pollution related to human activities that impact some of their lakes, reservoirs, and ponds (see Appendix B, Table B-5, for individual State information). These States and Puerto Rico reported that agriculture is the most widespread source of pollution in the Nation's surveyed lakes (Figures 3-4 and 3-5). Agriculture generates pollutants that degrade aquatic life or interfere with public use of 3.3 million lake acres (which equals 20% of the surveyed lake acres).

The States and Puerto Rico also reported that municipal sewage treatment plants pollute 1.3 million lake acres (7% of the surveyed lake acres), urban runoff and storm sewers pollute 1.2 million lake acres (7% of the surveyed lake acres),

VOL 12

5489

R0038797

unspecified nonpoint sources impair 989,000 lake acres (6% of the surveyed lake acres), hydrologic modifications and habitat alterations degrade 832,000 lake acres (5% of the surveyed lake acres), and industrial point sources pollute 759,000 lake acres (4% of the surveyed lake acres). Many States prohibit new point source discharges into lakes, but existing municipal sewage treatment plants remain a leading source of pollution entering lakes. Effluent from sewage treatment plants may include nutrients and ammonia, as well as oxygen-depleting wastes and chemicals from industrial facilities that discharge into the municipal plant.

The States and Puerto Rico listed numerous sources that impact several hundred thousand lake acres, including land disposal of wastes, construction, flow regulation, highway maintenance and runoff, contaminated sediments, atmospheric deposition of pollutants, and onsite wastewater systems (including septic tanks).

Tidal Estuaries and Ocean Shoreline Waters

Rivers meet the oceans, Gulf of Mexico, and the Great Lakes in coastal waters called estuaries. This chapter describes conditions in tidal estuaries, where tides mix fresh water from rivers with saline water from the oceans and the Gulf of Mexico. Fresh water estuaries around the Great Lakes are discussed in Chapter 12.

Estuarine waters include bays and tidal rivers that serve as nursery areas for many commercial fish and most shellfish populations, including shrimp, oysters, crabs, and scallops. Most of our Nation's fish and shellfish industry relies on productive estuarine waters and their adjacent wetlands to provide healthy habitat for some stage of fish and shellfish development. Recreational anglers also enjoy harvesting fish that reproduce or feed in estuaries, such as striped bass and flounder.

Estuaries

Twenty-three of the 27 coastal States and other government entities (hereafter collectively referred to as States) rated general water quality conditions in some of their

estuarine waters (Appendix C, Table C-2, contains individual State data). In addition, California and New Jersey reported individual use support status in estuarine waters but did not summarize general water quality conditions. The EPA used aquatic life use support status to represent general water quality conditions in California's estuarine waters and shellfish use support status to represent general water quality conditions in New Jersey's estuarine waters.

Altogether, these States surveyed 26,847 square miles of estuarine waters, which equals 78% of the 34,388 square miles of estuarine waters in the Nation (Figure 4-1). The States based 42% of their survey on monitored data and evaluated 31% of the surveyed estuarine waters with qualitative information (including best professional judgment by water quality managers). The States did not specify whether 27% of the surveyed estuarine waters were monitored or evaluated.

The States constantly revise their survey methods in an effort to improve their accuracy and precision. These changes limit the comparability of summary data presented herein and summary data presented in previous Reports to Congress. Similarly, discrepancies in State survey methods undermine comparisons of estuarine information submitted by individual States. Estuarine data should not be compared among States, which devote varying resources to monitoring biological integrity, water chemistry, and toxic pollutants in fish tissues. The discrepancies in State monitoring and survey methods, rather than actual differences in water quality, often account for the wide range in water quality ratings reported by individual States.

General Water Quality

EPA directs the States to rate whether their water quality is good enough to fully support a healthy community of aquatic organisms and human activities, such as swimming, fishing, and drinking. The States designate individual estuaries for specific activities, termed "individual designated uses." EPA and the States use the following terminology to rate their water quality:

- **Good/Fully Supporting**: Good water quality supports a diverse community of fish, plants, and aquatic insects, as well as the array of human activities assigned to an estuary by the State.

- **Good/Threatened**: Good water quality currently supports aquatic life and human activities on the estuary, but changes in such things as land use threaten water quality, or data indicate a trend of increasing pollution in the estuary.

- **Fair/Partially Supporting**: Fair water quality supports aquatic communities with fewer species of fish, plants, and aquatic insects, and/or occasional pollution interferes with human activities. For example, runoff during severe thunderstorms may temporarily elevate fecal coliform bacteria densities and indicate that shellfish are not safe to harvest and eat immediately after summer storms.

■ **Poor/Not Supporting**: Poor water quality does not support a healthy aquatic community and/or prevents some human activities on the estuary. For example, estuarine waters may be devoid of fish for more than a month each summer because excessive nutrients from runoff initiate algal blooms that deplete oxygen concentrations.

■ **Poor/Not Attainable**: The State has performed a use-attainability analysis and demonstrated that use support of one or more designated beneficial uses is not attainable due to one of six specific biological, chemical, physical, or economic/social conditions (see Chapter 1 for additional information).

Most States rate how well an estuary supports individual uses (such as swimming and aquatic life habitat) and then consolidate individual use ratings into an overall water quality rating. An estuary receives a poor overall rating if water quality consistently fails to support any one human activity or a healthy aquatic community (see Chapter 1 for a complete discussion of use support).

The States reported that 63% of the surveyed estuarine waters have good water quality that fully supports designated uses (Figure 4-2). Of these waters, 6% are threatened and might deteriorate if we fail to manage potential sources of pollution.

Some form of pollution or habitat degradation impairs the remaining 37% of the surveyed estuarine waters. Twenty-seven percent of the surveyed estuarine waters have fair water quality that partially supports designated uses. Most of the time these waters provide adequate habitat for aquatic organisms and support human activities, but periodic pollution

interferes with these activities and/or stresses aquatic life. Nine percent of the surveyed estuarine waters suffer from poor water quality that consistently stresses aquatic life and/or prevents people from using the estuarine waters for activities such as swimming and shellfishing.

Individual Use Support

Individual use support information provides additional detail about water quality problems in our Nation's surface waters. The States are responsible for designating their estuaries for State-specific uses, but EPA requests that the States rate how well their estuaries support five standard uses so that EPA can summarize the State data. The standard uses are aquatic life support, fish consumption, shellfish harvesting, primary contact recreation (such as swimming and diving), and secondary contact recreation (such as boating) (see Chapter 1 for a description of each individual use). Few States designate saline estuarine waters for drinking water supply use and agricultural use because of high treatment costs.

Twenty-one States reported the individual use support status of their estuarine waters (see Appendix C, Table C-3, for individual State information). Most often, these States examined aquatic life conditions and swimming use in their estuarine waters (Figure 4-3). The States reported that pollutants impact aquatic life in 6,945 square miles of estuarine waters (30% of the 23,117 square miles surveyed for aquatic life support) and violate shellfish harvesting criteria in 3,302 square miles of estuarine waters (26% of the 12,813 square miles surveyed for shellfishing use support). Pollutants also violate swimming criteria in 3,263 square miles of estuarine waters (15% of the 22,118 square miles surveyed for swimming use support).

Water Quality Problems Identified in Estuaries

Figures 4-4 and 4-5 identify the pollutants and sources of pollutants that impair (i.e., prevent from fully supporting designated uses) the most square miles of estuarine waters, as reported by the States. The two figures are based on the same data (contained in Appendix C, Tables C-4 and C-5), but each figure provides a different perspective on the extent of impairment attributed to individual pollutants and sources. Figure 4-4 shows the relative impact of the leading pollutants and sources in surveyed estuarine waters. Figure 4-5 presents the relative impact of the leading pollutants and sources in estuaries with identified problems (i.e., impaired estuaries), a subset of surveyed estuarine waters.

The following sections describe the leading pollutants and sources of impairment identified in estuaries. It is important to note that the information about pollutants and sources is incomplete because the States cannot identify the pollutant or source of pollutants impairing every estuarine waterbody. In some cases, a State may recognize that water quality does not fully support a designated use, but the State may not have adequate data to document that a specific pollutant or process is responsible for the impairment. Sources are even more difficult to identify than pollutants and processes.

Pollutants and Processes Impacting Estuaries

Twenty-five States reported the number of estuarine waters impacted by individual pollutants and processes, such as habitat alterations (see Appendix C, Table C-4, for individual State information). EPA ranks the pollutants and processes by the geographic extent of their impacts on aquatic life and human activities (measured as estuarine square miles impaired by each pollutant or process) rather than actual pollutant loads entering estuaries. This approach targets the pollutants and processes causing the most harm to aquatic life and public use of our waters, rather than the most abundant pollutants in our estuaries.

Often, more than one pollutant or process impacts a single estuarine waterbody. In such cases, the States and other jurisdictions count a single square mile of estuary under each pollutant or process category that impacts the estuary. Therefore, the percentages of estuarine waters impaired by all the pollutant and process categories do not add up to 100%.

The States identified more square miles of estuarine waters polluted by nutrients and bacteria than any other pollutant or process (Figures 4-4 and 4-5). Fifteen States reported that extra nutrients pollute 4,548 square miles of estuarine waters (which equals 17% of the surveyed estuarine waters). As in lakes, extra inputs of nutrients from human activities destabilize estuarine ecosystems. When temperature

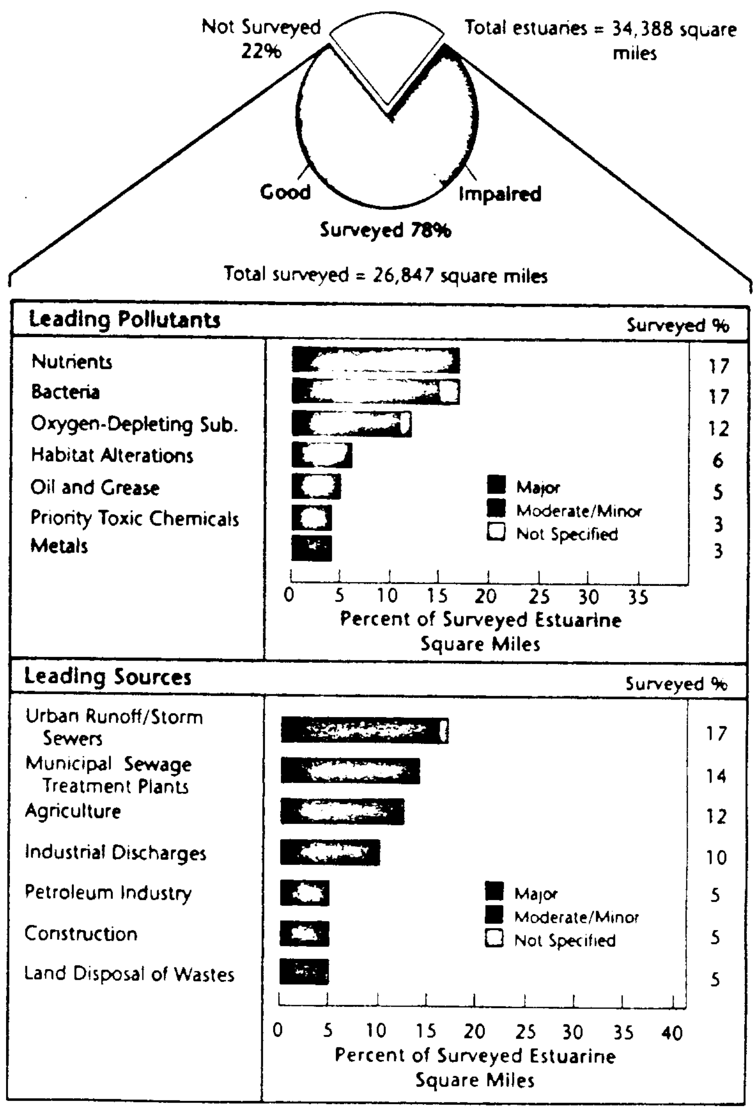
SURVEYED Estuaries: Pollutants and Sources



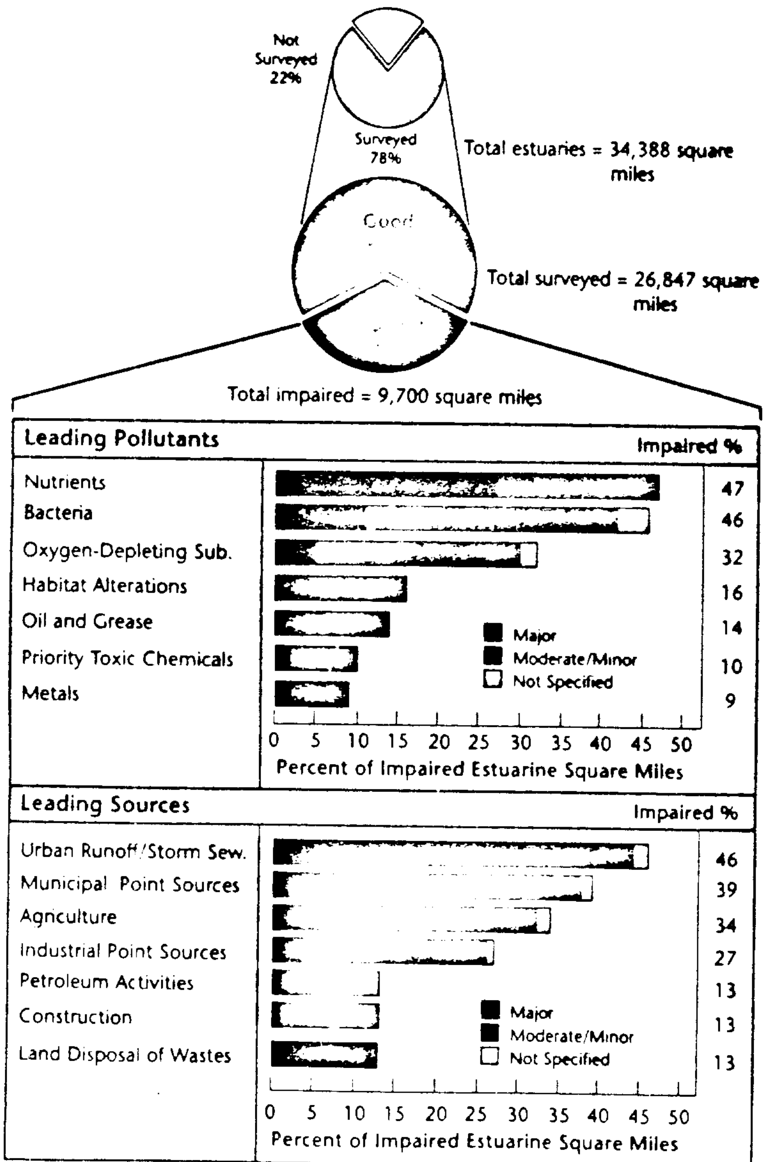
Based on data contained in Appendix C, Tables C-4 and C-5.

Note: Percentages do not add up to 100% because more than one pollutant or source may impair an estuary.

NUTRIENTS AND

Figure 4-5

IMPAIRED Estuaries: Pollutants and Sources



Based on data contained in Appendix C, Tables C-4 and C-5.

URBAN RUNOFF AND STORM SEWERS are the leading source of pollution in surveyed estuaries. According to the States, urban runoff and storm sewers

- affect 17% of all estuaries surveyed (see Figure 4-4), and
- constitute 46% of all water quality problems identified.

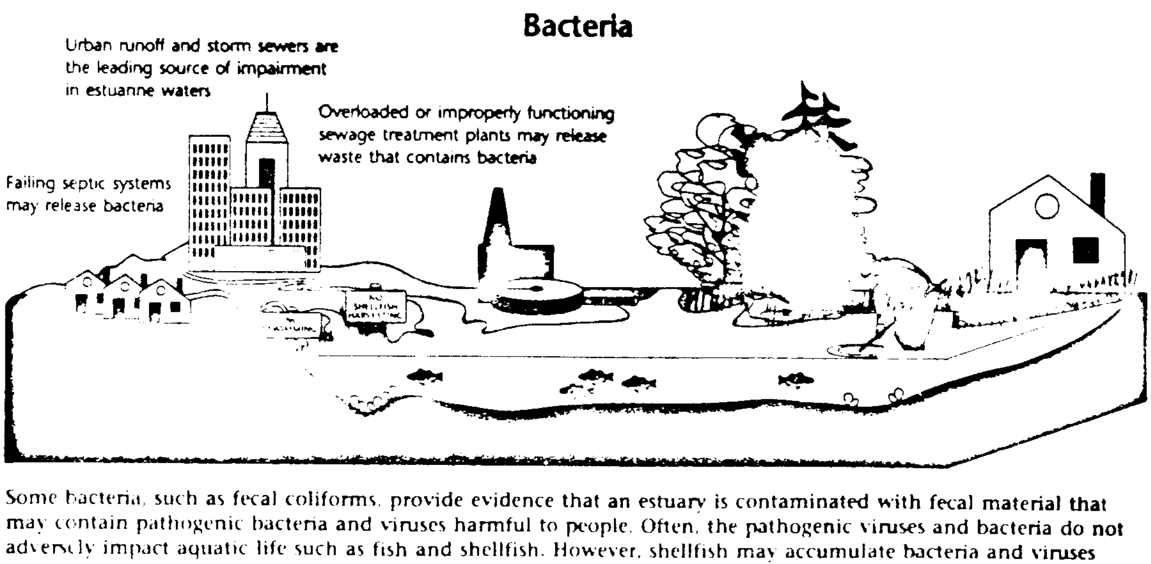
Note: Percentages do not add up to 100% because more than one pollutant or source may impair an estuary.

and light conditions are favorable, excessive nutrients stimulate population explosions of undesirable algae. Decomposition of dead algae depletes oxygen, which may trigger fish kills and foul odors. Explosive growth of algae populations can reduce light penetration and inhibit growth of beneficial aquatic plants. Submerged aquatic plants provide critical habitat for desirable shellfish, such as scallops.

Twenty-five States reported that bacteria pollute 4,479 square miles of estuarine waters (which equals 17% of the surveyed estuarine waters). Most States monitor harmless bacteria, such as *Escherichia coli*, that inhabit the digestive tracts of humans and other warm-blooded animals and populate sewage in high densities. Bacteria provide evidence that an estuary is contaminated with sewage that may contain numerous viruses and bacteria that cause illness in people. Most States monitor the indicator bacteria rather than run multiple tests to detect the numerous harmful viruses and bacteria in sewage.

Pathogenic viruses and bacteria seldom impact aquatic organisms such as fish and shellfish. However, shellfish can accumulate bacteria and viruses from contaminated water and cause illness when ingested. Therefore, the Food and Drug Administration and the States restrict the harvest and sale of shellfish grown in waters polluted with indicator bacteria. Bacteria also interfere with recreational activities because some pathogens can be transmitted by contact with

Figure 4-6



Some bacteria, such as fecal coliforms, provide evidence that an estuary is contaminated with fecal material that may contain pathogenic bacteria and viruses harmful to people. Often, the pathogenic viruses and bacteria do not adversely impact aquatic life such as fish and shellfish. However, shellfish may accumulate bacteria and viruses that cause human diseases when ingested. Therefore, officials restrict shellfish harvesting in contaminated waters to protect public health. Bacteria also impair swimming uses because some pathogenic bacteria and viruses can be transmitted by contact with contaminated water.

VOL 12

5500

R0038808

contaminated water or ingestion during swimming (Figure 4-6).

The States also report that oxygen depletion from organic wastes impacts 3,127 square miles (which equals 12% of the surveyed estuarine waters), habitat alterations impact 1,564 square miles (which equals 6% of the surveyed estuarine waters), and oil and grease pollute 1,344 square miles (which equals 5% of the surveyed estuarine waters). Dissolved oxygen depletion is a widespread problem reported by 21 States. In contrast, only one State (Maryland) reported extensive impacts from habitat alterations, and only one State (Louisiana) reported extensive impacts from oil and grease.

Most States rate pollutants and processes as major or moderate/minor contributors to impairment. A major pollutant or process is solely responsible for an impact or predominates over other pollutants and processes. A moderate/minor pollutant or process is one of multiple pollutants and processes that degrade aquatic life or interfere with human use of estuarine waters.

The States report that nutrients have a major impact on more estuarine waters than any other pollutant or process. The individual State 305(b) reports provide more detailed information about the severity of pollution in specific locations.

Sources of Pollutants Impacting Estuaries

Twenty-three States reported sources of pollution related to human activities that impact some of their estuarine waters (see Appendix C, Table C-5, for individual State information). These States reported that urban runoff and storm sewers are the most widespread source of pollution in the Nation's surveyed estuarine waters. Pollutants in urban runoff and storm sewer effluent degrade aquatic life or interfere with public use of 4,508 square miles of estuarine waters (which equals 17% of the surveyed estuarine waters) (Figure 4-4).

The States also reported that municipal sewage treatment plants pollute 3,827 square miles of estuarine waters (14% of the surveyed estuarine waters), agriculture pollutes 3,321 square miles of estuarine waters (12% of the surveyed estuarine waters), and industrial discharges pollute 2,609 square miles (10% of the surveyed estuarine waters). Urban sources contribute more to the degradation of estuarine waters than does agriculture because urban centers are located adjacent to most major estuaries.

Ocean Shoreline Waters

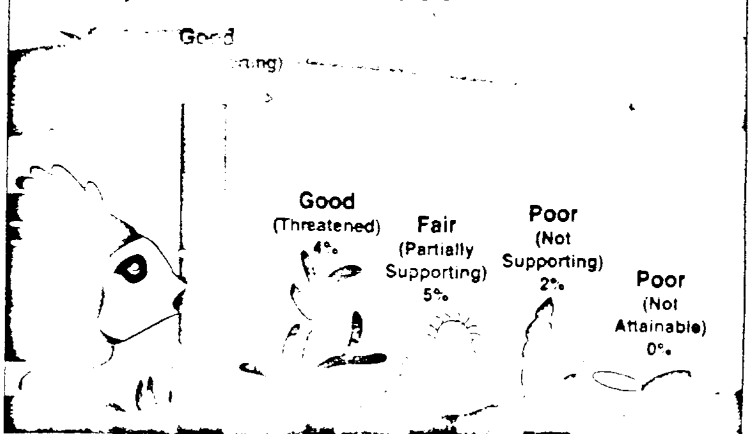
Thirteen of the 27 coastal States and Territories rated general water quality conditions in 5,208 miles of ocean shoreline. The surveyed waters represent 9% of the Nation's coastline (including Alaska's 36,000 miles of coastline), or 23% of the 22,421 miles of national coastline excluding Alaska (see Appendix C, Table C-6, for individual State information). Most of the surveyed waters (4,834 miles, or 93%) have good quality that supports a healthy aquatic community and public activities (Figure 4-7). Of these waters, 225 miles (4% of the surveyed shoreline) are threatened and may deteriorate in the future.

Some form of pollution or habitat degradation impairs the remaining 7% of the surveyed shoreline (374 miles). Five percent of the surveyed estuarine waters have fair water quality that partially supports designated uses. Most of the time, these waters provide adequate habitat for aquatic organisms and support human activities, but periodic pollution interferes with these activities and/or stresses aquatic life. Only 2% of the surveyed shoreline suffers from poor water quality that consistently stresses aquatic life and/or prevents people from using the shoreline for activities such as swimming and shellfishing.

Overall Surveyed Water Quality

Figure 4-7

Overall Use Support
in Surveyed Ocean Shoreline Waters



Based on data contained in Appendix C, Table C-6.

Individual Use Support

EPA requests that the States rate how well their ocean shoreline waters support five standard uses so that EPA can summarize the State data. The standard uses consist of aquatic life support, fish consumption, shellfish harvesting, primary contact recreation (such as swimming and diving), and secondary contact recreation (such as boating) (see Chapter 1 for a description of each individual use). Few States designate saline ocean waters for drinking water supply use and agricultural use because of high treatment costs.

The States provided limited information on individual use support in ocean shoreline waters (Appendix C, Table C-7, contains individual State information). Ten States rated aquatic life support and swimming use in their ocean shoreline waters, but fewer States rated their ocean waters for support of shellfishing, fish consumption, and secondary contact recreation. General conclusions cannot be drawn from information representing such a small fraction of the Nation's ocean shoreline waters (Figure 4-8).

Water Quality Problems Identified in Ocean Shoreline Waters

Only six of the 27 coastal States identified pollutants and sources of pollutants degrading ocean shoreline waters (Appendix C, Tables C-8 and C-9, contain individual State information). General conclusions cannot be drawn from the information supplied by these States because these States border less than 1% of the shoreline along the contiguous States. The six States identified impacts in their ocean shoreline waters from bacteria, metals, nutrients, turbidity, siltation, and pesticides (Figures 4-9 and 4-10). The six States reported that urban runoff and storm sewers, industrial discharges, land disposal of wastes, septic systems, agriculture, unspecified nonpoint sources, and combined sewer overflows (CSOs) pollute their coastal shoreline waters (Figures 4-9 and 4-10).

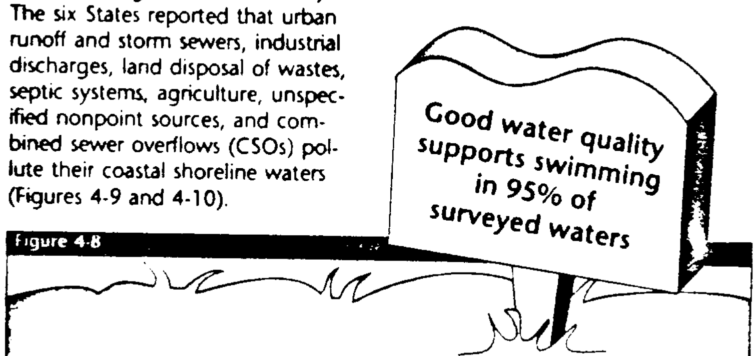


Figure 4-8

Individual Use Support in Ocean Shoreline Waters

Designated Use	Miles Surveyed	Good (Fully Supporting) %	Good (Threatened) %	Fair (Partially Supporting) %	Poor (Not Supporting) %	Poor (Not Attainable) %
Aquatic Life Support	4,125	93	2	4	1	0
Fish Consumption	2,367		0	4	0	0
Shellfishing	2,636		<1	4	1	0

EMAP Estuaries Summary

The Environmental Monitoring and Assessment Program (EMAP) has been developed jointly by EPA, the National Oceanic and Atmospheric Administration (NOAA), and the National Biological Survey (NBS) to provide the public, scientists, and Congress with information to evaluate the general health of the Nation's ecological resources. EMAP works with local, State, regional, and national resource managers to facilitate information transfer and to ensure that key questions are being addressed. Consequently, there is a growing interest in EMAP methods, indicators, data, and results among decision makers at all levels. The concepts used for specific EMAP studies are being investigated at various levels as a potential basis for monitoring and assessment guidance for States.

EMAP conducts annual surveys to assess the presence of pollution and its effect on "ecological health" indicators such as aquatic plants, animals, and the habitats that sustain them. At present, the program is developing the necessary tools to characterize the condition of the Nation's water resources with the goal of implementing long-term monitoring that will provide information on the overall health of the environment and the effectiveness of strategies implemented for pollution prevention and control. EMAP sampling was designed to yield statistically representative estimates of environmental condition.

EMAP Estuaries, 1990-1993

The present focus of EMAP's estuarine component (EMAP-E) is the development of a national monitoring design, and the studies currently being completed will help to provide a framework for that design. In addition, the current studies can be used to estimate the regional health of estuarine waters or resources. Ecological health is being assessed through the investigation of distributions of fish and bottom-dwelling organisms. EMAP is determining what portion of estuaries are healthy enough to sustain or support these plants and animals. In addition, EMAP studies will evaluate why certain areas are not able to maintain populations of these organisms.

Between 1990 and 1993, EMAP-E investigated the ecological condition of two estuarine regions or provinces that combined represent 55% of the Nation's estuarine acreage:

- **Virginian Province:** estuaries of the Middle Atlantic States from Cape Cod, Massachusetts, to Cape Henry, Virginia (sampling began in 1990)

- **Louisianan Province:** estuaries of the Gulf of Mexico from Anclote Anchorage, Florida, to the Rio Grande, Texas (sampling began in 1991).

HIGHLIGHT HI GHT HIGHLIGHT

Results will include estimates of the resources in these two provinces as well as national estimates based on this 55%.

Each summer since 1990, EMAP-E monitoring teams have collected bottom sediments to determine the number and types of organisms present and to see if these sediments contain harmful pollutants. Fish have been collected, identified, and examined for disease.

In addition, scientists have taken water quality measurements including dissolved oxygen, salinity, and temperature.

In General . . .

The EMAP-Estuary study design is based on a random site selection process so that monitored sites, as a whole, are statistically representative of the Nation's estuarine waters. Thus, information gained from the EMAP study, which assessed roughly 55% of our estuaries, can be used to estimate conditions of our estuarine resources on a national scale.

Based on the 1990-1993 pilot projects, about 74% of the Nation's estuaries are in good condition for supporting a diversity of plants, animals, and human uses. The remaining 23% to 29% have poor benthic (bottom-dwelling) and fish community conditions and unacceptable levels of pollution for human uses such as commercial shellfishing. Sediment contamination, affecting the diversity and abundance of pollution-sensitive benthic organisms, is a leading cause of poor conditions in both the Virginian and Louisianan Provinces.

Approximately 22% to 30% of the Nation's estuarine waters are categorized as degraded for some human use including swimming, boating, fishing, and walking along the shore. The factors contributing to this degradation are (1) water clarity, which affects recreational uses; (2) marine debris, which affects aesthetics and wildlife health; and (3) contaminants in the edible portions of fish and shellfish.

In the Virginian Province, marine debris is the most prevalent source of human-use degradation; water clarity and fish contamination are local rather than regional issues. In the Louisianan Province, marine debris and water clarity are the major contributors to human-use degradation.

Overall, contaminant concentrations in fish and shellfish are low, with the exception of some heavy metals. No fish or shellfish studied contain PCB residues greater than the health criteria set by the Food and Drug Administration (FDA). The overall incidence of fish contamination is low in both regions; however, elevated concentrations of contaminants might be expected in specific localities adjacent to contaminant sources. Periodic surveys will allow scientists to track potential changes in fish tissue residue levels

VOL 12

5507

HIGHLIGHT HIGHLIGHT HIGHLIGHT

and improvements or declines in the health of fish and shellfish.

Fish Diseases

Between 1990 and 1993, over 30,000 fish were examined for disease. Only 154 (<0.6%) had external abnormalities. The EMAP-E data provide the first evidence that the frequency of pathologies in estuarine fish is low. Bottom-dwelling fish (e.g., catfish) have the highest frequency of disease, 4 to 10 times more than other groups. The number of fish with external pathologies increases in areas with multiple contaminants in the sediments, regardless of the area of the country. Data indicate that pathologies are local in nature and appear to be associated with increased contaminant loadings.

Sediment Contamination and Toxicity

Most contaminants entering waterways (such as pesticides, PCBs, and heavy metals) end up in fish and bottom sediments; however, these substances are not always present at levels that are toxic to marine life. EMAP-E took more than 600 sediment samples during the pilot projects and examined them for 125 different contaminants. In general, the data show that about 34% of the Virginian Province and 6% of the Louisianan Province have a concentration of a contaminant above the ERM criterion. The ERM criterion is the level of a contaminant that will result in ecological effects approximately 50% of the time (based on scientific literature studies) and serves as a "red flag." For example, if a contaminant is found to be above the ERM criterion, then marine organisms will be affected about half the time.

There are distinct differences in the types of contaminants found in the two provinces. The Virginian Province is characterized by industrial contaminants and some urban pesticides; the Louisianan Province is characterized by agricultural contaminants. The presence of toxic sediments can have a direct effect on aquatic life. Sediments are actually considered toxic when there is greater than a 15% mortality rate in organisms exposed to the sediments. Through toxicity testing, approximately 19% of the Virginian Province sediments and 9% of the Louisianan Province sediments have been found to be toxic to estuarine organisms.

Water Quality

Dissolved oxygen (DO) is a fundamental requirement for all marine life. A threshold concentration of 4 to 5 ppm (parts per million) is defined by many States as a water quality standard. A concentration of 2 ppm is considered extremely stressful to most organisms. DO levels have natural daily and seasonal fluctuations and are usually higher during daylight hours due to photosynthesis, the production of oxygen by aquatic plants. Low levels occur mostly in bottom waters and have the greatest impact on organisms that live in the sediments such as oysters, crabs, and

VOL 12

5508

HIGHLIGHT HIGHLIGHT HIGHLIGHT

clams. Up to a quarter (9% to 25%) of the bottom water area in the Virginian Province has DO levels of below 5 ppm, whereas 4% to 8% has concentrations of less than 2 ppm. These depletions of oxygen occur primarily in the Chesapeake Bay. Less than 10% (2% to 8%) of the Louisianan Province's bottom waters have concentrations of less than 2 ppm. However, of these, about 50% are locations where daytime concentrations exceed 5 ppm. Approximately 15% to 21% of bottom waters in the Gulf of Mexico have DO levels below 5 ppm.

Marine debris has multiple negative effects, including entanglement and/or ingestion by animals and the economic cost of lost tourism and beach cleanups. EMAP-E estimates that 17% to 23% of the Virginian Province and 12% to 22% of the Louisianan Province have marine debris either floating on the water or lodged in the bottom sediments. This observed amount of debris would correspond to 3.8 million acres out of more than 23.6 million total acres nationally. About 80% of the debris observed is cans, glass, or paper; 15% appears to be plastics.

Clear water, another factor measured by EMAP-E, helps sustain healthy and productive ecosystems and is a trait that the public values. Water clarity was defined as the percentage of light reaching 1 meter depth. Less than 1% of the waters in the Virginian Province have clarity of less than 10% (primarily occurring in the upper portions of large tidal rivers), and 15% to 19% have clarity of less than 25%. In the Louisianan Province, 20% of waters have less than 10% clarity, while about half of the estuarine waters have clarity of less than 25%. The vast majority of waters with this low clarity are west of the Mississippi Delta.

A Program in Transition

In 1994, testing of ecological indicators and sampling design began in the Carolinian and Californian Provinces and was continued for a final year in the Louisianan Province. Also in 1994, EMAP-E began to expand its coverage to include additional coastal ecosystems, specifically coastal wetlands and offshore waters. A study to determine the best set of ecological indicators for coastal wetlands was completed, and monitoring programs were initiated for coastal waters in the Southern California Bight and the Gulf of Mexico through cooperative efforts with the State of California and NOAA.

The final year of province-wide monitoring and assessment was 1995 in the Carolinian Province (second year) and the West Indian Province (first year). For 1996, field sampling is continuing in the mid-Atlantic region (Delaware and Chesapeake Bays and coastal areas), and in regional EMAP programs begun in 1994. EMAP is continuing research on biological indicators of environmental condition and on the statistical elements of a national monitoring design.

VOL 12 5509

HIGHLIGHT HIGHLIGHT HIGHLIGHT

Recent Trends in Coastal Contamination*

Background

The National Oceanic and Atmospheric Administration (NOAA) created the National Status and Trends (NS&T) Program in 1984 to address national concerns over the quality of the coastal marine environment. One of its goals is to assess spatial distributions and temporal trends in chemical contamination. To meet that goal, the NS&T Mussel Watch Project was formed in 1986 to measure concentrations of a broad suite of trace metals and organic chemicals in surface sediments and whole soft-parts of mussels and oysters collected from about 300 coastal and estuarine sites. The mussels and oysters are collected every year, and the resulting time series indicates trends in chemical concentrations. The most important result to date is that contamination is decreasing for chemicals whose use has been banned, such as chlorinated hydrocarbons, or severely curtailed, such as cadmium. For other chemicals there is no evidence, on a national scale, for either an increasing or decreasing trend.

Chemicals and Species Monitored

The 14 elements and groups of organic compounds for which there are data on trends over the period 1986 to 1993 are: arsenic, cadmium, copper, mercury, nickel, lead, selenium, zinc, DDT (parent compound and metabolites), PCBs (18 congeners), PAHs (24 compounds), Chlordane (four compounds), Dieldrin (plus Aldrin), and butyltin (tri-,di-, and mono-butyltin).

Since no single species of mollusk is common to all coasts, it has been necessary to collect seven different ones: the blue mussel *Mytilus edulis* on the East Coast from Maine to Cape May, New Jersey; the American oyster *Crassostrea virginica* from Delaware Bay southward and throughout the Gulf of Mexico; the mussels *M. edulis* and *M. californianus* on the West Coast; the oyster Ostrea *sandvicensis* in Hawaii; the zebra mussel *Dreissena polymorpha* at sites in the Great Lakes; the mangrove oyster *Crassostrea rhizophorae* in Puerto Rico; and the smooth-edged jewel box *Chama sinuos* at the one site in the Florida Keys.

* The information contained in this highlight was extracted from *Recent Trends in Coastal Environmental Quality: Results from the Mussel Watch Project 1986 to 1993*, published by the National Oceanic and Atmospheric Administration, U.S. Department of Commerce, Silver Spring, Maryland, June 1995.

VOL 12

5510

HIGHLIGHT HIGHLIGHT HIGHLIGHT

VOL 12

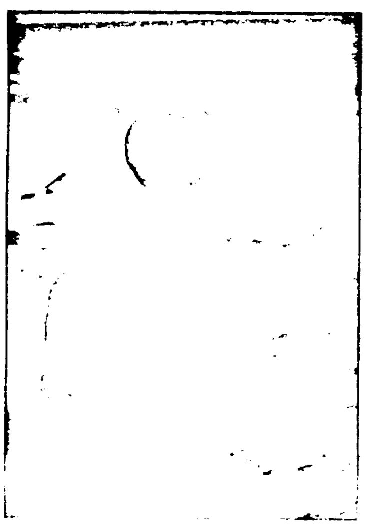
Temporal Trends

A trend is a correlation between concentration and time. There are 154 sites that have been sampled in at least 6 years. The data for those sites have been examined by a simple nonparametric statistical test to see if, with 95% confidence, concentrations are trending in a single direction, up or down.

The most common result is a lack of trends. Among the 2,156 combinations of 14 chemicals at 154 sites, there are only 41 increases and 217 decreases at the 95% level of confidence. On a per-chemical basis the trends are:

Chemical	Number of Increasing Trends	Number of Decreasing Trends
ΣChlordane	0	43
ΣDDT	0	24
ΣDieldrin	0	19
ΣPCB	0	26
ΣPAH	2	3
Σbutyltin	0	11
As	5	14
Cd	3	20
Cu	5	17
Hg	7	8
Ni	4	5
Pb	7	8
Se	2	12
Zn	6	7

Σ = sum



Julie Fountain, Youngsville, NC

Given a 5% probability of random data showing trends, there could be 54 increases and 54 decreases that are not real trends. Conceivably, none of the 41 increases are real. The important point, however, is that decreases greatly outnumber increases. Decreases exceed increases by a factor of three or more for all the chlorinated hydrocarbons, tributyltin, arsenic, cadmium, copper, and

5511

selenium. At a higher level of aggregation, as in Figure 1, there are decreasing trends in national geometric means for all of these chemicals except selenium.

Decreasing trends are not unexpected. All the monitored chlorinated hydrocarbons have been banned from use in the United States and tributyltin has been banned as a biocide on recreational boats. For cadmium and arsenic there have been decreases in their uses. There has been a 25% decrease in total annual cadmium consumption due to drops in uses for electroplating onto metal surfaces for rustproofing automobile parts, as a stabilizer in plastics, and for use in pigments. Annual consumption of arsenic in the United States has remained fairly steady since 1986, but there has been a decline in its agricultural uses. There has been no parallel decrease in use of copper within the United States. Possibly, its decreasing trend indicates increased success in control of copper emissions from many sources.

Although concentration data themselves do not indicate whether trace element levels in mollusks are affected by human activity, the existence of monotonic trends like those identified here are likely due to activities that are increasing or decreasing an element's concentration in the environment. All sorts of natural factors—either internal, such as mollusk growth or reproduction, or external, such as temperature or rainfall in the period preceding collection—can affect chemical concentrations. Such natural factors can make trends in chemical concentrations difficult to detect. However, it would be difficult to find a natural factor with year-to-year changes that would cause detection of a monotonic trend in chemical concentrations. The trace element trends, therefore, are most likely due to human actions.

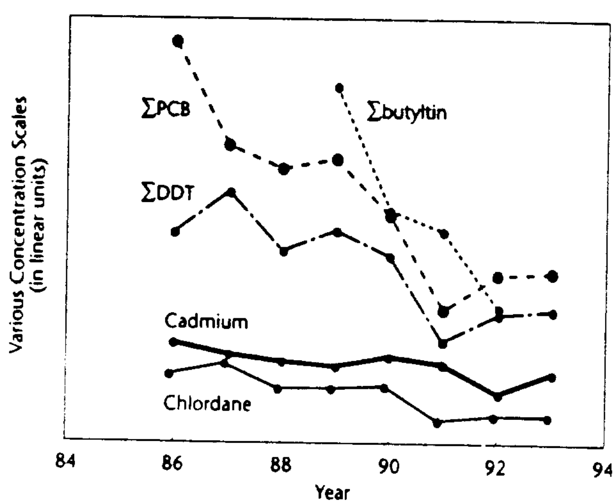


Figure 1. Decreasing National Geometric Mean Concentrations in Mollusks

Data Availability

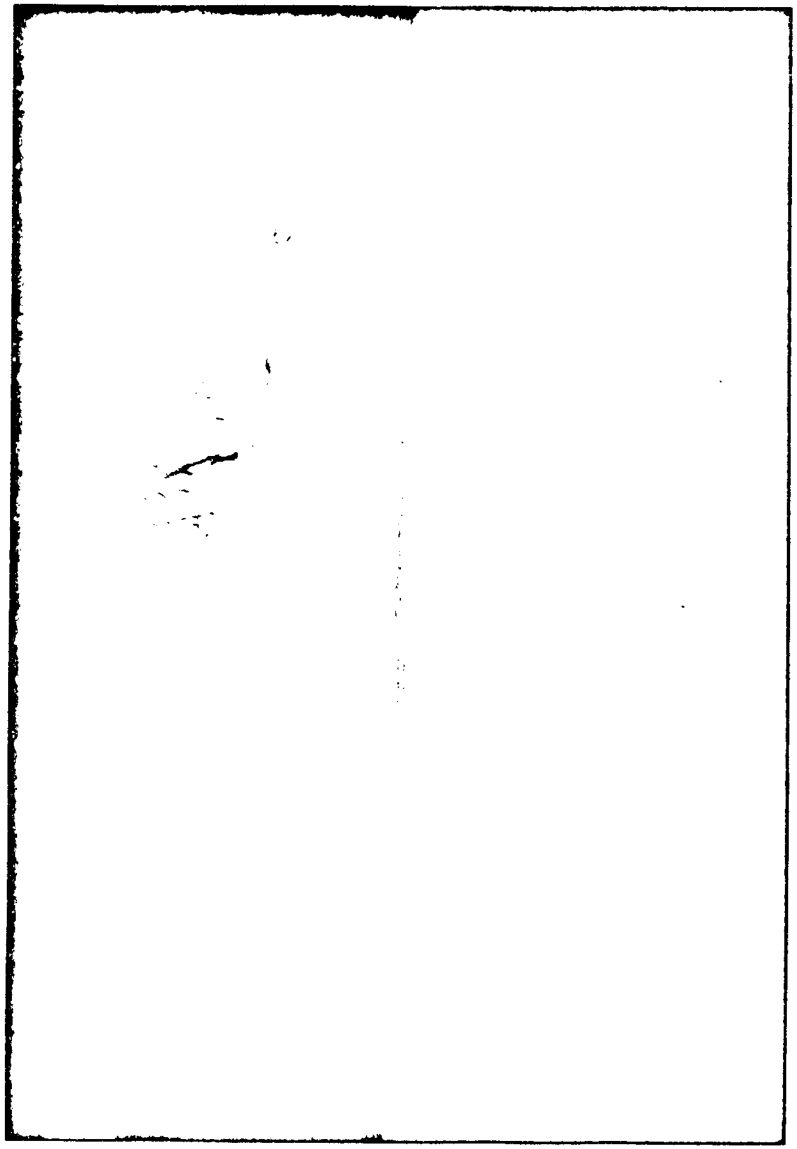
Audrey Moore, U.S. EPA Region 2



Wetlands

Introduction

Wetlands are areas that are inundated or saturated by surface or ground water at a frequency and duration sufficient to support (and that under normal circumstances do support) a prevalence of vegetation typically adapted for life in saturated soil conditions (Figure 5-1). Wetlands generally include swamps, marshes, bogs, and similar areas. This is the definition of wetlands as it appears in the regulations jointly issued by the Army Corps of Engineers (COE) and the U.S. EPA (33 CFR Part 328.3(b), 40 CFR Part 232.2 (r), and 40 CFR Part 230.3(t)).

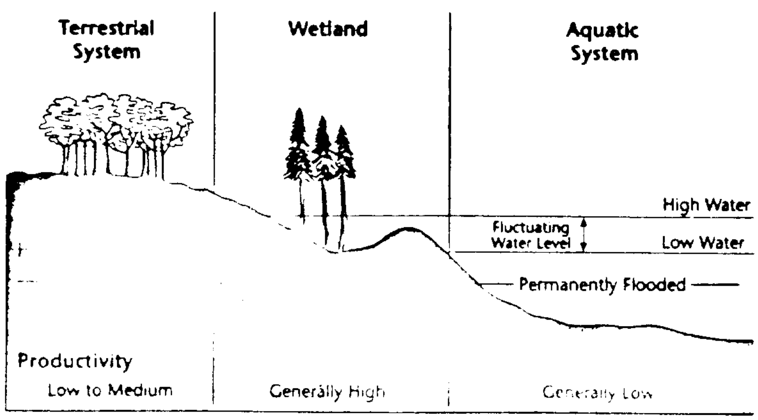
A wide variety of wetlands exist across the country as a result of regional and local differences in hydrology, vegetation, water chemistry, soils, topography, climate, and other factors. Wetlands type is determined primarily by local hydrology, the unique pattern of water flow through an area. In general, there are two broad categories of wetlands: coastal and inland wetlands.

With the exception of the Great Lakes coastal wetlands, coastal wetlands are closely linked to estuaries, where sea water mixes with fresh water to form an environment of varying salinity and fluctuating water levels due to tidal action. Coastal marshes dominated by grasses, sedges, and rushes and halophytic (salt-loving) plants are generally located along the Atlantic and Gulf coasts due to the gradual slope of the land. Mangrove swamps, which are dominated by halophytic shrubs and trees, are common in Hawaii, Puerto Rico, Louisiana, and southern Florida.

Inland wetlands are most common on floodplains along rivers and streams, in isolated depressions surrounded by dry land, and along the margins of lakes and ponds. Inland wetlands include marshes and wet meadows dominated by grasses, sedges, rushes, and herbs; shrub swamps; and wooded swamps dominated by trees, such as

Figure 5-1

Depiction of Wetlands Adjacent to Waterbody



Wetlands are often found at the interface between dry terrestrial ecosystems, such as upland forests and grasslands, and permanently wet aquatic ecosystems, such as lakes, rivers, bays, estuaries, and oceans.

hardwood forests along floodplains. Some regional wetlands types include the pocosins of North Carolina, bogs and fens of the northeastern and north central States and Alaska, inland saline and alkaline marshes and riparian wetlands of the arid and semiarid West, vernal pools of California, playa lakes of the Southwest, cypress-gum swamps of the South, wet tundra of Alaska, the South Florida Everglades, and prairie potholes of Minnesota, Iowa, and the Dakotas.

Functions and Values of Wetlands

In their natural condition, wetlands provide many benefits, including food and habitat for fish and wildlife, water quality improvement, flood protection, shoreline erosion control, ground water exchange, as well as natural products for human use and opportunities for recreation, education, and research.

Wetlands are critical to the survival of a wide variety of animals and plants, including numerous rare and endangered species. Wetlands are also primary habitats for many species, such as the wood duck, muskrat, and swamp rose. For others, wetlands provide important seasonal habitats where food, water, and cover are plentiful.

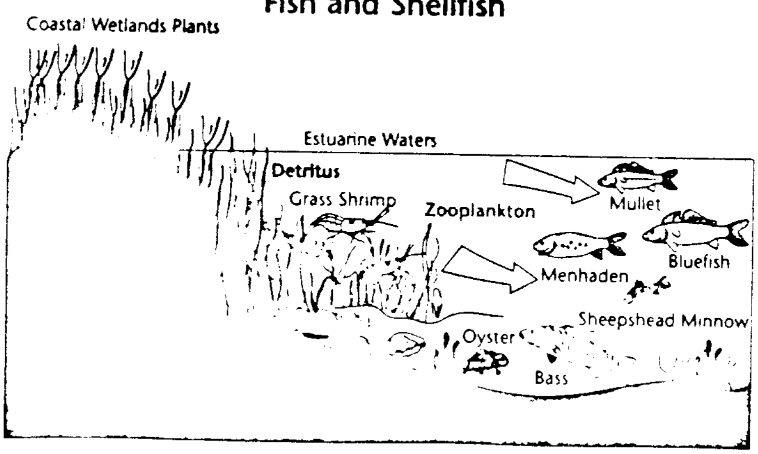
Wetlands are among the most productive natural ecosystems in the world. They produce great volumes of food, such as leaves and stems, that breaks down in the water to form detritus (Figure 5-2). This enriched material is the principal food for many aquatic invertebrates, various shellfish, and forage fish that are food for larger commercial and recreational fish species such as bluefish and striped bass.

Wetlands help maintain and improve water quality by intercepting surface water runoff before it reaches open water, removing or retaining nutrients, processing chemical and organic wastes, and reducing sediment loads to receiving waters (Figure 5-3). As water moves through a wetland, plants slow the water, allowing sediment and pollutants to settle out. Plant roots trap sediment and are then able to metabolize and detoxify pollutants and remove nutrients such as nitrogen and phosphorus.

Wetlands function like natural basins, storing either floodwater that overflows riverbanks or surface water that collects in isolated depressions. By doing so, wetlands help protect adjacent and

Figure 5-2

Coastal Wetlands Produce Detritus that Support Fish and Shellfish



downstream property from flood damage. Trees and other wetlands vegetation help slow the speed of flood waters. This action, combined with water storage, can lower flood heights and reduce the water's erosive potential (Figure 5-4). In agricultural areas, wetlands can help reduce the likelihood of flood damage to crops. Wetlands within and upstream of urban areas are especially valuable for flood protection, since urban development increases the rate and volume of surface water runoff, thereby increasing the risk of flood damage.

Wetlands are often located between rivers and high ground (called uplands) and are therefore able to store flood waters and reduce channel erosion. Wetlands bind soil, dampen wave action, and reduce current velocity through friction. These properties are very valuable for stabilizing shorelines (Figure 5-5).

Wetlands water storage capacity also allows recharge of ground water, which may be used as sources of water for drinking or agricultural uses (Figure 5-6). Elevated ground water tables and water stored in wetlands are also important for maintaining stream base-flows. Water entering wetlands during wet periods is released slowly through ground water or as runoff, moderating stream flow volumes

necessary for the survival of fish, wildlife, and plants that rely on the stream (Figure 5-7).

Wetlands produce a wealth of natural products, including fish and shellfish, timber, wildlife, and wild rice. Much of the Nation's fishing and shellfishing industry harvests wetlands-dependent species. A national survey conducted by the Fish and Wildlife Service in 1991 illustrates the economic value of some of the wetlands-dependent products. Over 9 billion pounds of fish and shellfish landed in the United States in 1991 had a direct, dockside value of $3.3 billion. This served as the basis of a seafood processing and sales industry that generated total expenditures of $26.8 billion. In addition, 35.6 million anglers spent $24 billion on freshwater and saltwater fishing. It is estimated that 71% of commercially valuable fish and shellfish depend directly or indirectly on coastal wetlands.

Consequences of Wetlands Loss and Degradation

The loss or degradation of wetlands can lead to serious consequences, including increased flooding; species decline, deformity, or extinction; and declines in water quality. The following discussion describes several examples of the consequences of wetlands loss and degradation.

Floods continue to seriously damage the property and livelihoods of thousands of Americans despite expenditures of billions of local, State, and Federal dollars spent over the years to reduce flooding. Loss or degradation of wetlands intensifies flooding by eliminating the wetlands' capacity to absorb peak flows and gradually release flood waters.

- In Massachusetts, the U.S. Army Corps of Engineers estimated that over $17 million of annual flood damage would result from the destruction of 8,422 acres of wetlands in the Charles River Basin. For this reason, the COE decided to preserve wetlands rather than construct extensive flood control facilities along a stretch of the Charles River near Boston. Annual benefits of the preservation project average $2.1 million while annual costs average $617,000.

- The Minnesota Department of Natural Resources estimates that it costs the public $300 to replace the water storage capacity lost by development of 1 acre of wetlands that holds 12 inches of water. The cost of replacing 5,000 acres of wetlands would be $1.5 million, which exceeds the State's annual appropriation for flood control.

Another consequence of wetlands loss or degradation is decline, deformity from toxic contamination, or extinction of wildlife and plant species. Forty-five percent of the threatened and endangered species listed by the U.S. Fish and Wildlife Service (FWS) rely directly or indirectly on wetlands for their survival.

- The destruction of wetlands around Merritt Island and St. John's Island in Florida has been identified as a major contributor to the extinction of the Dusky Seaside

Sparrow. The sparrow's habitat was diked and flooded in an attempt to control mosquitos, then drained and burned to promote ranching. The last Dusky Seaside Sparrow died in captivity on June 16, 1987.

■ Over-logging of mature bottomland hardwood forests is believed to have caused the extinction of the Ivory Billed Woodpecker in the United States. The clearing of bottomland hardwood forests has also affected the Louisiana Black Bear, or swamp bear, by destroying the bear's habitat. With its population plummeting from the thousands to several hundred, the FWS recently listed the Louisiana Black Bear as "threatened" under the Endangered Species Act.

■ Populations of Mallard Ducks and Northern Pintail Ducks in North America declined continually between 1955 and the early 1990s. In 1990, the number of Mallard Ducks in the prairies of the United States declined 60% from the number counted in 1989 to the lowest population figures on record, although recent data indicate that waterfowl populations are rebounding. The well-being of waterfowl populations is directly tied to the status and abundance of wetlands. As waterfowl populations are squeezed into the remaining wetlands, confined conditions favor outbreaks of avian cholera and other contagious diseases in waterfowl.

Wetlands loss and degradation also reduce water quality purification functions performed by wetlands.

■ The Congaree Bottomland Hardwood Swamp in South Carolina provides valuable water quality services, such as removing and stabilizing sediment, nutrients, and toxic contaminants. The total cost of constructing, operating, and maintaining a tertiary treatment plant to perform the same functions would be $5 million.

■ Forested riparian wetlands play an important role in reducing nutrient loads entering the Chesapeake Bay. In one study, a riparian forest in a predominantly agricultural watershed removed about 80% of the phosphorus and 89% of the nitrogen from the runoff water before it entered a tributary to the Bay. Destruction of such areas adversely affects the water quality of the Bay by increasing undesirable weed growth and algae blooms.

■ A study of two similar sites on the Hackensack River in New Jersey demonstrated the increase in erosion that results from the destruction of marshlands. In the study, marsh vegetation was cut at one site and left undisturbed at the other site. The bank at the cut site eroded nearly 2 meters (more than 6 feet) in 1 year while the uncut site exhibited negligible bank erosion.

These examples illustrate the integral role of wetlands in our ecosystems and how wetlands destruction and degradation can have expensive and permanent consequences. By preserving wetlands and their functions, wetlands will continue to provide many benefits to people and the environment.

STATES REPORT that residential development and urban growth are the leading sources of recent wetlands loss.

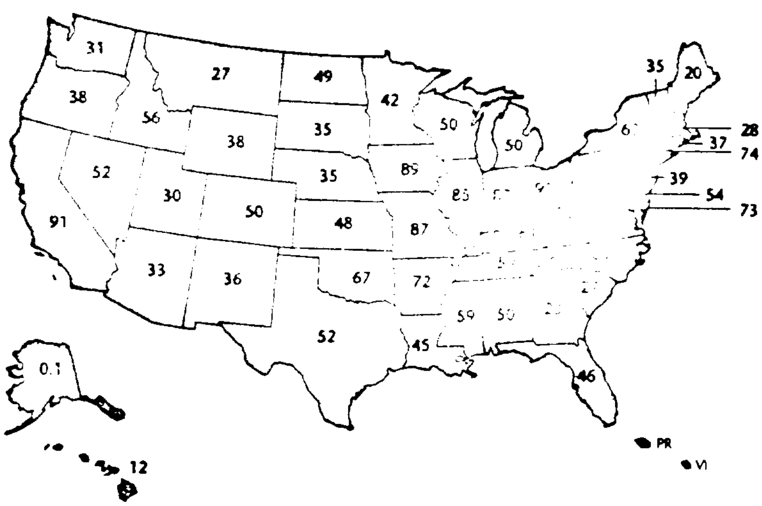
Extent of the Resource

Wetlands Loss in the United States

It is estimated that over 200 million acres of wetlands existed in the lower 48 States at the time of European settlement. Since then, extensive wetlands acreage has been lost, with many of the original wetlands drained and converted to farmland and urban development.

Figure 5-8

Percentage of Wetlands Acreage Lost, 1780s-1980s



Twenty-two States have lost at least 50% of their original wetlands. Seven of these 22 (California, Indiana, Illinois, Iowa, Missouri, Kentucky, and Ohio) have lost more than 80% of their original wetlands.

Source: Dahl, T.E., 1990, *Wetlands Losses in the United States 1780's to 1980's*, U.S. Department of the Interior, Fish and Wildlife Service.

Today, less than half of our original wetlands remain. The losses amount to an area equal to the size of California (see Figure 5-8). According to the U.S. Fish and Wildlife Service's *Wetlands Losses in the United States 1780's to 1980's*, the three States that have sustained the greatest percentage of wetlands loss are California (91%), Ohio (90%), and Iowa (89%).

According to FWS status and trends reports, the average annual loss of wetlands has decreased over the past 40 years. The average annual loss from the mid-1950s to the mid-1970s was 458,000 acres, and from the mid-1970s to mid-1980s it was 290,000 acres. Agriculture was responsible for 87% of the loss from the mid-1950s to the mid-1970s and 54% of the loss from the mid-1970s to the mid-1980s.

A more recent estimate of wetlands losses from the National Resources Inventory (NRI), conducted by the Natural Resources Conservation Service (NRCS), indicates that 792,000 acres of wetlands were lost on non-Federal lands between 1982 and 1992 for a yearly loss estimate of 70,000 to 90,000 acres. This net loss is the result of gross losses of 1,561,300 acres of wetlands and gross gains of 768,700 acres of wetlands over the 10-year period. The NRI estimates are consistent with the trend of declining wetlands losses reported by FWS. Although losses have decreased, we still have to make progress toward our interim goal of no overall net loss of the Nation's remaining wetlands and the long-term goal of increasing the quantity and quality of the Nation's wetlands resource base.

The decline in wetlands losses are a result of the combined effect of several trends: (1) the decline in profitability in converting wetlands for agricultural production; (2) passage of Swampbuster in the 1985 and 1990 Farm Bills; (3) presence of the CWA Section 404 permit programs as well as development of State management programs (see Chapter 17); (4) greater public interest and support for wetlands protection; and (5) implementation of wetlands restoration programs at the Federal, State, and local level.

Nineteen States listed sources of recent wetlands loss in their 1994 305(b) reports (Figure 5-9). Residential development and urban growth were cited as the leading sources of current losses (see Appendix D, Table D-1, for individual State information). Other losses were due to commercial development; construction of roads, highways, and bridges; agriculture; and industrial development.

Several States and the District of Columbia reported on efforts to inventory wetlands. Some of the programs are designed to augment the FWS's National Wetlands Inventory (NWI), while others are designed to produce independent status and trend information. Some of the programs have already been completed and others have been authorized but not funded.

- In 1994, the District of Columbia adopted a new estimate of total wetlands acreage generated by applying the Planogrid method to aerial NWI maps. The finer detail and resolution of the new methodology almost doubled previous estimates of wetlands acreage.

- New Hampshire recently completed a wetlands mapping project that translated LANDSAT digital imagery into a geographic information system (GIS) format. The project included extensive field verification. The GIS mapping system revealed many small wetlands that were overlooked by previous surveys. As a result, New Hampshire's estimate of total wetlands acreage climbed from 200,000 acres to almost 400,000 acres.

- In 1993, the North Carolina Division of Environmental Management (DEM) used hydric soils as a baseline to inventory wetlands in the Coastal Plain, rather than NWI maps used in previous inventories. DEM randomly selected 27 sample sites of 9,900 acres each, mapped published soils data for each site, and calculated the total area of hydric soils in each site with a video software analysis package.

VOL 12

5521

■ The Ohio Department of Natural Resources (DNR) is conducting a statewide inventory of wetlands as part of its Remote Sensing Program with cooperation from numerous agencies. The program utilizes digital data from the LANDSAT Thematic Mapper, digitized soils data, low-level aerial photographs, and USGS topographic maps to identify and map different types of wetlands, including farmed wetlands. DNR plans to update the maps every 5 years.

Monitoring Wetlands Functions and Values

Wetlands monitoring data are critical to the achievement of important national goals, such as no overall net loss of wetlands functions and values. With States and Tribes developing water quality standards for their wetlands, State and Tribal monitoring programs are critical for determining if wetlands are meeting their designated and existing uses. Monitoring data are also needed to prioritize wetlands for restoration and protection and to define successful mitigation.

Monitoring programs can provide the data needed to identify degradation of functions and values in wetlands and sources of that degradation, but specific wetlands monitoring programs are still in their infancy. Currently, no State is operating a statewide wetlands monitoring program.

However, several States include a few wetlands in their ambient monitoring programs, and a growing number of States are implementing monitoring projects at selected reference wetlands that are relatively free from impacts. The States will use the data collected at these reference wetlands to define baseline conditions in healthy wetlands and standards to protect wetlands.

■ Every 3 years, Kansas collects water quality samples from seven wetlands (covering 25,069 acres) owned by the State or the Federal government. The State monitors one station per wetland for nutrients, minerals, heavy metals, clarity, suspended solids, pesticides, bacteria, algae, temperature, and dissolved oxygen.

■ Kentucky added several wetlands to its reference reach monitoring program to characterize chemical water quality, sediment quality, fish tissue concentrations of contaminants, habitat conditions, and general biotic conditions in each physiographic region of the State. The information will be used to develop designated uses and biological criteria for wetlands.

■ Minnesota initiated the Reference Wetlands Project to develop a basis for assessing the biological and chemical health of wetlands. The project is characterizing invertebrate communities, vegetation, amphibians, land cover, and water and sediment chemistry at 32 relatively undisturbed wetlands and three impacted wetlands. The information will provide the basis for determining use support status and evaluating wetlands health and will help the State determine if restored wetlands can achieve a condition comparable to natural wetlands.

■ New Hampshire plans to monitor a variety of parameters at five wetlands throughout the State during 1994-1995 to provide baseline data for developing specific wetlands water quality standards.

Designated Use Support in Wetlands

The States,Tribes, and other jurisdictions are making progress in developing specific designated uses and water quality standards for wetlands, but many States and Tribes still lack specific water quality criteria and monitoring programs for wetlands. Without criteria and monitoring data, most States and Tribes cannot evaluate use support. To date, only nine States and Tribes reported the designated use support status for some of their wetlands (see Appendix D, Table D-1). Only Kansas used quantitative data as a basis for the use support decisions.

■ California reported that 12% of the 121,900 acres of surveyed wetlands fully supports aquatic life use and 88% partially supports aquatic life use due to metals, nutrients, oxygen depletion, and salinity. Sources impacting wetlands include municipal wastewater treatment plants, urban runoff and storm sewers, and hydrologic and habitat modifications.

■ The Coyote Valley Band of Pomo Indians in northern California classified all 1.6 acres of their wetlands as partially supporting uses for wildlife and use as a riparian buffer. The use support analysis was based on reconnaissance surveys rather than monitoring in the wetland. The wetland is impaired by exotic species, filling and draining, and other habitat alterations.

■ The Hoopa Valley Tribe in northern California reported that all of its 3,200 acres of wetlands partially support aquatic life use, religious use, wildlife habitat use, and use as a riparian buffer. Filling and draining, flow alterations, other habitat alterations, and exotic species impair the wetlands. Agriculture, forestry, construction, hydrologic modifications, and unknown sources have degraded wetlands on the Hoopa Valley Reservation.

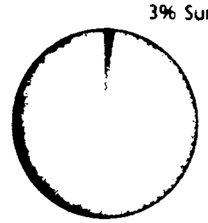
■ Iowa used best professional judgment to determine the designated use support status of 83 publicly owned wetlands covering 26,082 acres (about 69% of the State's total wetlands). Iowa reported that 3% of the surveyed wetlands acreage fully supports aquatic life use, 31% fully supports aquatic life use now but is threatened, 52% partially supports aquatic life use, and 14% does not support aquatic life use. Siltation, nutrients, habitat alteration, and pesticides have significant impacts on Iowa's wetlands. The leading sources of degradation are agricultural runoff and dewatering activities.

■ Kansas used monitoring data to determine use support in nine publicly owned wetlands (covering 25,069 acres) and qualitative information to assess one wetland (covering 70 acres). The State did not survey the remaining 25 publicly owned wetlands covering 10,388 acres. Kansas reported that 20% of

Wetlands Acres Surveyed by States and Tribes

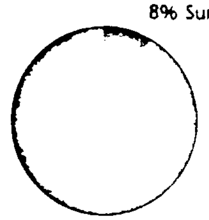
Including Alaska's wetlands

■ 8,822,472 acres = 3% surveyed
Total acres (including Alaska) = 277 million*



Excluding Alaska's wetlands

■ 8,822,472 acres = 8% surveyed
Total acres (excluding Alaska) = 107 million

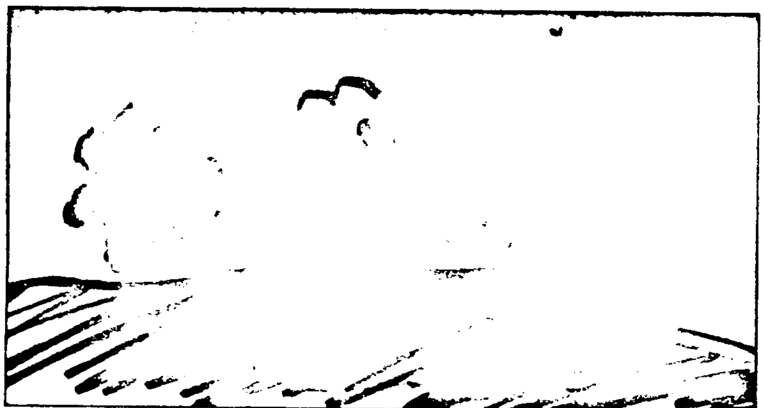


*From Dahl, T.E. 1990. *Wetlands Losses in the United States 1780's to 1980's.* U.S. Department of the Interior, Fish and Wildlife Service.

Source: 1994 Section 305(b) reports submitted by States, Tribes, Territories, and Commissions.

the surveyed wetlands acreage fully supports uses now but is threatened, 55% partially supports uses, and 25% does not support uses such as noncontact recreation and aquatic life support.

■ Louisiana assessed use support in almost 1 million acres of its 8.7 million total acres of wetlands. The State reported that 91% of the assessed wetland acres fully supports uses and 9% partially supports uses due to bacteria, siltation and suspended solids, and hydrologic modifications. Sources of impairment include channelization, dredging, flow regulation, drainage and filling, recreational activities, upstream sources, and natural sources.



Kings Park Elementary, 3rd Grade, Springfield, VA

■ Nevada surveyed use support in 36,169 acres (25%) of its 136,650 total acres of wetlands. Nevada reported that 28% of the surveyed wetlands partially supports uses, 67% does not support uses, and 6% cannot attain designated uses. The State reported that 100 acres are impaired by ammonia, pH, and organic enrichment and low dissolved oxygen concentrations.

■ North Carolina used aerial photographs and soil information to rate use support by current land use. North Carolina rated wetlands on hydric soils with natural tree cover as fully supporting uses. Partially supporting wetlands have modified cover and hydrology but still retain wetlands status and support most uses. For example, pine plantations still retain value for wildlife habitat, flood control, ground water recharge, nutrient removal, and aquatic habitat, although the modified wetlands support these uses less effectively than undisturbed wetlands. Wetlands converted to agriculture or urban land use are classified as not supporting original wetlands uses.

North Carolina used this methodology to survey use support in over 7 million acres of wetlands. The State reported that 66% of the surveyed wetlands fully supports uses, 13% partially supports uses, and 22% does not support uses.

- Oklahoma assessed one wetland covering 120 acres. The State classified all 120 acres of the wetland as threatened.

EPA cannot draw national conclusions about water quality conditions in all wetlands because the States used different methodologies to survey only 3% of the total wetlands in the Nation.

Summarizing State wetlands data would also produce misleading results because two States (North Carolina and Louisiana) contain 91% of the surveyed wetlands acreage.

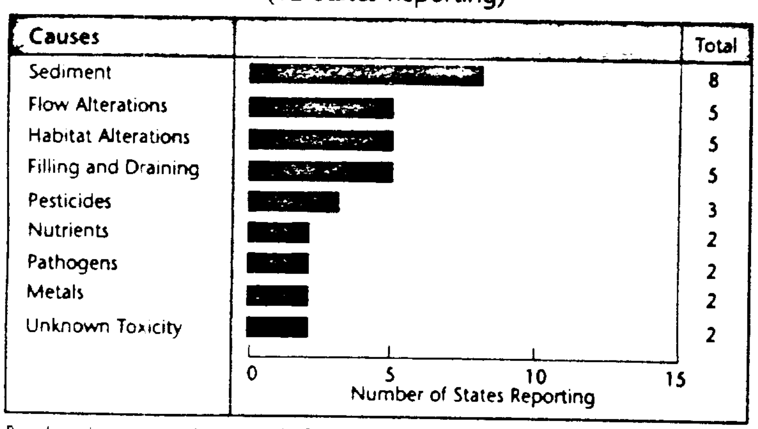
More States and Tribes will assess use support in wetlands as they develop standards for wetlands. Many States are still in the process of developing wetlands water quality standards, which provide the baseline for determining beneficial use support (see Chapter 13). Improved standards will also provide a firmer foundation for assessing impairments in wetlands in those States already reporting use support in wetlands.

More information on wetlands can be obtained from EPA's Wetlands Hotline at 1-800-832-7828, between 9 a.m. and 5 p.m. Eastern Standard Time.

Figure 5-10

Causes Degrading Wetlands Integrity

(12 States Reporting)



Based on data contained in Appendix D, Table D-2.

VOL 12

5525

R0038833

The States have even fewer data to quantify the extent of pollutants degrading wetlands and the sources of these pollutants. Although most States cannot quantify wetlands area impacted by individual causes and sources of degradation, 12 States identified causes and 13 States identified sources known to degrade wetlands integrity to some extent (Figures 5-10 and 5-11). These States listed sediment as the most widespread cause of degradation impacting wetlands, followed by flow alterations, habitat modifications, and draining. Agriculture topped the list of sources degrading wetlands, followed by urban runoff, hydrologic modification, and natural sources (see Appendix D, Tables D-3 and D-4, for individual State information).

Summary

Currently, most States are not equipped to report on the integrity of their wetlands. Only nine States and Tribes reported attainment of designated uses for wetlands in 1994. National trends cannot be drawn from this limited information. This is expected to change, however, as States adopt wetlands water quality standards and enhance their existing monitoring programs to more accurately assess designated use support in their wetlands.

Ground Water Quality

Ground water is a vital national resource that is used for a myriad of purposes. It is used for public and domestic water supply systems, for irrigation and livestock watering, and for industrial, commercial, mining, and thermoelectric power production purposes. In many parts of the Nation, ground water serves as the only reliable source of drinking and irrigation water. Unfortunately, this vital resource is vulnerable to contamination, and ground water contaminant problems are being reported throughout the country. In their 1994 305(b) reports, States, Tribes, and Territories identified contaminant sources and the associated contaminants that threaten the integrity of their ground water resources. Controlling these sources of contamination and preventing further contamination of the resource have become the focus of numerous local, State, and Federal programs.

This chapter contains information provided by 48 States, 2 Territories, and 5 Tribes in their 1994 305(b) reports. The 1994 305(b) reports are based on guidelines, developed by EPA, requesting that each reporting agency characterize the quality of its ground water resources. Because few States and Tribes possess the capability to characterize ground water quality using ambient monitoring data, EPA asked them to provide available information on specific contaminant sources and associated contaminants degrading ground water quality. And, for the first time, EPA asked States and Tribes to provide information on selected parameters that will be used in the future to provide an indication of spatial and temporal trends in ground water quality.

This chapter presents an overview of ground water use in the United States as well as a discussion detailing State-identified sources of contamination and contaminants that are adversely impacting our Nation's ground water quality. State progress in the development of ambient ground water monitoring networks is highlighted. The progress made in developing ground water indicators is also described.

GROUND WATER is a source of drinking water for 51% of the population.

Ground Water Use in the United States

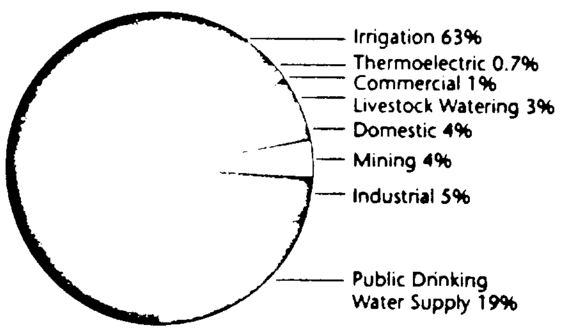
In 1990, ground water supplied 51% of the Nation's population with drinking water—the highest-priority use of water. Overall, ground water supplied approximately 20% (80.6 billion gallons per day [bgd] out of a total 408.4 bgd) of all water uses in the United States. These water uses include public and domestic water supply, irrigation, livestock watering, mining, and commercial, industrial, and thermoelectric cooling applications. Figure 6-1 illustrates the distribution of ground water use among these categories. As shown, irrigation

VOL 12

5529

Figure 6-1

National Ground Water Use as a Percentage of Total Withdrawals



Source: Open-File Report 92-63, U.S. Geological Survey.

Figure 6-2

Withdrawal and Discharge of Ground Water as a Percentage of Contribution

(63%) and public water supply (19%) are the largest uses of ground water withdrawals.

One of the largest and most important contributions of ground water is not presented in Figure 6-1. The volume of ground water that is naturally discharged to streams and other surface waterbodies, thereby maintaining streamflow during periods of low flow or drought conditions, was previously unrecognized and unquantified. This volume, 492 bgd, is measured using special instruments or estimated using stream gaging and hydraulic gradient data. The importance of ground water flow into streams and other surface waters cannot be underestimated. Ground water can transport contaminants to streams and affect surface water quality and quantity, which may impact drinking water supplies drawn from surface waters, fish and wildlife habitats, swimming, boating, fishing, and commercial navigation. Modifications to the quantity or quality of ground water discharged into surface water ecosystems can also have major economic repercussions as a result of adverse impacts on recreation, public health, fisheries, tourism, and general ecosystem integrity.

The importance of ground water to stream baseflow maintenance is illustrated in Figure 6-2, which shows all of the major uses of ground water in relation to stream baseflow maintenance. Stream baseflow maintenance accounts for 54% of ground water discharges. The next highest use of ground water is irrigation, which accounts for 29% of national ground water use. Figure 6-3 shows that ground water use for drinking water supply, agricultural supply, industrial/

VOL 12

5530

commercial supply, and mining and thermoelectric supplies varies in different regions of the country. For example, ground water is more heavily used for drinking water and industrial/commercial supplies in eastern States and for drinking water and agricultural supplies in western States.

Despite the variation in usage across the Nation, ground water used for drinking water supply is one of the most critical uses. Data reported by the U.S. Geological Survey were used to estimate ground water statistics related to public water supply (PWS) and private wells on a State-by-State basis. Specifically, the data were used to determine whether there was an increase or a decrease in the volume of ground water used for PWS from 1970 to 1990; the percent change in volume during the same period; the ratio of the change in ground water use from 1980 to 1990 to the change in surface water use during the same period for PWS; the percent of population dependent upon ground water for drinking water the

HIGHLIGHT HIGHLIGHT HIGHLIGHT

Vulnerability

Virtually all aquifers have some inherent susceptibility to contamination. To determine the susceptibility of aquifers to contamination from shallow (Class V) injection wells, EPA performed a nationwide assessment.* The purpose of the assessment was to determine ground water vulnerability and aquifer sensitivity for each of the 48 conterminous States.

Ground water vulnerability is dependent upon the geology of the physical system. However, population density and distribution are also important as the greatest number of shallow injection wells occur in areas of high population density. Aquifer sensitivity is related to the potential for contamination to occur. Aquifers that have a high degree of vulnerability and occur in areas of high population density are considered to be the most sensitive. The assessment determined that 44% of the shallow unconfined aquifers in the continental United States are highly susceptible to contamination, and that 60% have some degree of susceptibility.

Estimates of inherent susceptibility can be obtained through a variety of assessment methods that consider different characteristics of the aquifer and/or overlying materials. The assessment method selected depends on the goal of the assessment. Because the goal of, and method for, each assessment may be different, multiple assessments may yield different results. Such a seeming discrepancy in results does not detract from the benefits of susceptibility assessments for ground water management purposes, because results are goal-specific.

Several States have performed their own statewide aquifer susceptibility assessments to address a high-priority management concern. For example, Georgia performed a "DRASTIC" assessment of susceptibility and determined that approximately 65% of the State was either moderately or highly susceptible to surface-applied sources of contamination. These results are similar to those obtained by Pettyjohn et al. (1991)* in which it was estimated

* Pettyjohn, W.A., M. Savoca, and Dale Self, 1991, *Regional Assessment of Aquifer Vulnerability and Sensitivity in the Conterminous United States*, Robert S. Kerr Environmental Research Laboratory, Office of Research and Development, U.S. Environmental Protection Agency, Ada, Oklahoma, 319 pages.

HIGHLIGHTS

that 62% of Georgia is susceptible to shallow subsurface sources of contamination.

Although high-priority concerns differ among States, the results of the nationwide assessment show that a significant part of the Nation is highly susceptible to at least some type of contamination. That such a significant portion of the Nation's ground water is susceptible attests to the need for contaminant prevention.

Examples of Surface Water Contaminated by Contaminated Ground Water

EPA's Chesapeake Bay Office estimates that 30% to 40% of the nitrates entering the Bay, the major pollutant in the Bay, comes from ground water discharge. Agriculture is the primary source of these nitrates because farming is common in the huge watershed draining into the Bay. Along with nitrates, pesticides also enter the Bay. Pesticides are used to control pests on land and may be destroying beneficial organisms in ground water as well. Thus, the benefit that these organisms provide in cleaning ground water before it enters the Bay is lost. To further exacerbate the problem, the forests that surround the shoreline continue to be cleared as development spreads. Research shows that trees are effective in removing nitrates and other pollutants from ground water before it discharges to surface water, and thus another water cleaning mechanism is lost. In addition, the development that removes the trees adds yet more pollutant load to the watershed. This general model, with minor variations, is common throughout the country.

EPA recently published *A Review of Methods for Assessing Nonpoint Source Contaminated Ground Water Discharge to Surface Water,** which identified seven methods commonly used to estimate the quantity of ground water discharging to surface water. Although these methods are well established, published research that describes loadings from ground water for specific locations is not abundant. Nevertheless, a review of the scientific literature identified more than 100 studies nationwide in which contaminated ground water was discharged into and contaminated surface water. For example,

- In the Missouri Valley watershed, ground water accounts for 84% to 95% of the nitrate loading to surface water.

- On the St. John's River, Florida, about 20% of chloride loading comes from ground water seeping into canals that drain into the river.

- At the Mahantango Creek watershed in Pennsylvania, a link was observed between the intensity of corn production and concentrations of atrazine in ground water. As corn production and the use of atrazine increased, higher concentrations of atrazine were observed in more wells. Specifically, atrazine was

*U.S. EPA, 1991, Office of Water, EPA 570/9-91-010.

detected at concentrations less than EPA standards in 74% of all sampled wells.

- In Rehoboth Bay, Indian River Bay, and Little Assawoman Bay, Delaware, over 75% of nitrogen loading comes from ground water discharge.
- In Key Largo Marine Sanctuary, Florida, ground water discharge showed numerous pesticide peaks and heavy metal concentrations 100 to 10,000 times above sea water levels.
- In Cedar River, Iowa, the pesticides atrazine and deethylatrazine were found in the river and 75% was contributed from ground water.
- In the Indian River estuary in Florida, dissolved reactive phosphate was found and 99% came from ground water discharge.

Microbial Paths of Contamination

Various pathogenic microorganisms are also introduced into ground water and surface water as a result of various human activities. These activities include malfunctioning septic systems, back-siphonage of water systems, and maintenance deficiencies. The most relevant diseases spread by these pathogens are those related to consumption of contaminated drinking water, including gastroenteritis, campylobacteriosis, and hepatitis A. The protozoan *Cryptosporidium* has recently been recognized as a significant human pathogen. Floods and other natural disasters can also cause pathogens to enter ground water and surface water used for drinking water supplies.

In the summer of 1994, State agencies in Illinois, Iowa, Kansas, Minnesota, Missouri, Nebraska, North Dakota, South Dakota, and Wisconsin and the Centers for Disease Control and Prevention coordinated a survey of the contamination of well water. Samples were taken from 5,530 private wells evenly spaced across these States. Preliminary results of the survey indicated that coliform bacteria were present in 41% of these wells. The presence of coliform bacteria may indicate contamination by harmful bacteria and viruses. In the sampled wells, Federal drinking water standards established for nitrates and atrazine in public water systems were exceeded in 14% and 0.4% of these wells, respectively. The results are being analyzed for associations between well contamination and well construction practices and health effects.

supplies in 1990; and the percent of ground water used for private drinking water supplies. Ground water statistics are provided in Appendix I-1. Figure 6-4 illustrates the percentage of population dependent upon ground water for drinking water in 1990. As shown, New Mexico, Mississippi, and Florida rely on ground water for 90% or more of their drinking water supply. Following is a brief summary of significant trends.

For the period 1970 to 1990,

- Twenty-one States and one Territory increased ground water use for public water systems at a rate greater than overall public water use.
- Alaska, Arizona, California, Florida, Kentucky, Missouri, and Puerto Rico more than doubled their use of ground water for public supply.
- Hawaii, Idaho, Louisiana, Maryland, Minnesota, Montana, Massachusetts, New Mexico, North Carolina, Pennsylvania, Texas, and Wyoming nearly doubled their use of ground water for public supply.

For the period 1980 to 1990,

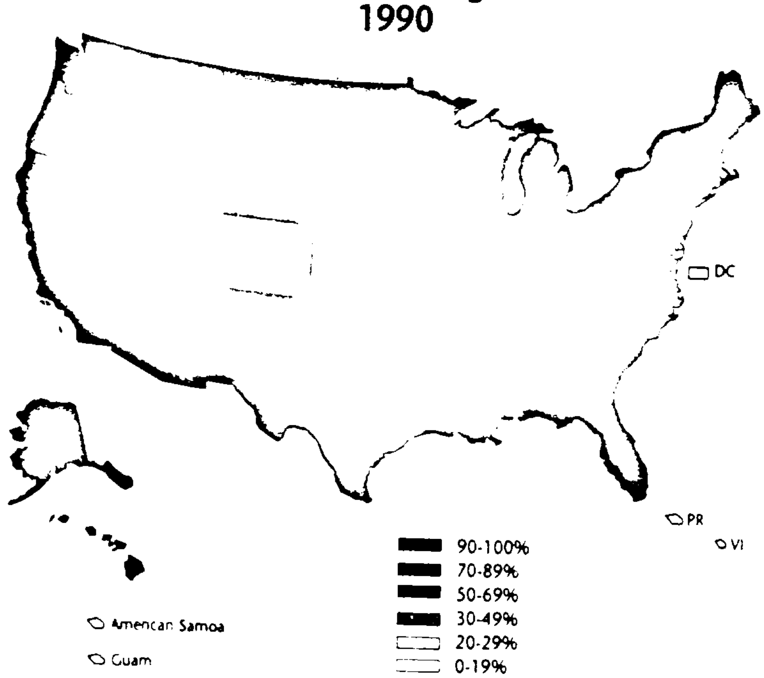
- For incremental drinking water use, ground water supplied two of every three additional gallons of water supplied by public water systems nationally.

In 1990,

- More than half of the national population was dependent upon ground water for drinking water.
- More than half of the population (51% to 93%) in 30 States relied on ground water for drinking water.
- Approximately 32% of the national population dependent upon ground water obtained their drinking water from private wells.
- Ninety-five percent of the population in rural areas relied on ground water for their water supply.
- In Kentucky, Maine, North Carolina, South Carolina, and West Virginia, 65% to 77% of the population relied on ground water from private wells.

Figure 6-4

Percent of Population Dependent on Ground Water for Drinking Water 1990



Source Open File Report 92-63, U.S. Geological Survey.

■ At least 40% of the population in 23 States and 1 Territory relied on ground water from private wells.

Ground Water Quality

Ground water moves slowly, on the order of less than an inch to tens of feet per day. Consequently, contaminants introduced into the subsurface are less likely to be diluted than those introduced into more rapidly moving surface water. The slow movement of ground water often results in a delay in the detection of ground water contamination. In some cases, contaminants introduced into the subsurface more than 10 years ago are only now being detected and affecting ground water uses.

While the larger ground water resource is of good quality, localized areas of high demand and chemical use can be affected by contamination. This situation exists because locations of more productive ground water yields are often places that allow more infiltration and recharge of aquifers, carrying contaminants more easily to ground water. This vast resource remains exceedingly vulnerable to contamination by toxic compounds, bacteria, viruses, and inorganic contaminants. In one study of five midwestern States, the Ground Water Protection Council* estimated that between 15% and 48% of the land area is underlain by highly vulnerable aquifers.

Contamination of ground water typically occurs in localized areas. These incidents are frequently serious and often pose threats to human health or result in increased costs to consumers. Many locations within every State have shown water quality degradation that constrains the use of ground water resources. As ground water quality is degraded, Americans are becoming increasingly aware that contaminated ground water is both difficult and expensive to clean up.

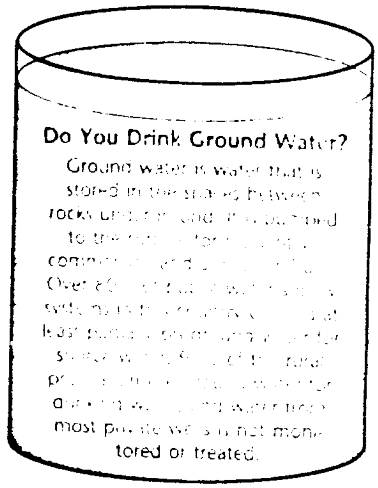
The following statistics help to illustrate the prevalence of localized ground water contamination incidents:

■ More than 85% of abandoned hazardous waste disposal sites (Superfund sites) have some degree of ground water contamination. Most of these sites impact aquifers that are currently used or could potentially be used for drinking water.

■ Of the contaminated aquifers at Superfund sites, 62% discharge into surface waters. Of these aquifers, 38% are used to supply drinking water. Nineteen percent of these contaminated aquifers discharge to sensitive ecological environments.

■ At 49% of the Superfund sites where cleanup costs are expected to exceed $20 million, dealing with large volumes of contaminated ground water is a key factor contributing to that cost.

■ Currently, 418 land disposal facilities are subject to ground water monitoring requirements under the Resource Conservation and Recovery Act (RCRA). Of these, an estimated 37% are undertaking measures to clean up existing ground water contamination. The EPA estimates



* Wayne A. Pettyjohn, *Aquifer Vulnerability, Sensitivity, and Ground Water Quality in Selected States*, Ground Water Protection Council, 1994, 94 pages.

that another 10% of the land disposal facilities will detect ground water contaminants in the next 2 years.

- EPA estimates that 1.2 million federally regulated underground storage tanks (USTs) are buried at over 500,000 sites nationwide. An estimated 139,000 USTs have leaked and impacted ground water quality.

- EPA estimates that the total number of leaking USTs could reach 400,000 in the next several years.

The EPA requested that States provide information on the degradation of ground water resources used for public drinking water supply. As a result, 21 States reported on the quality of ground water supplied by a total of 20,294 public water systems that serve approximately 52 million people. Among these States:

- Nineteen reported incidents of public water systems that use ground water exceeding the Maximum Contaminant Level (MCL) for at least one contaminant. These exceedances occurred in 3% of the ground-water-supplied public water systems and affected drinking water quality for 1.4 million Americans.

- Eleven reported incidents in which ground water supplied by public water systems exceeded the MCL for nitrate. Barium, arsenic, and fluoride were cited most frequently among the other 12 inorganic contaminants reported to have exceeded MCLs.

- Fifteen volatile organic compounds (VOCs) and eight pesticides were noted to have exceeded MCLs in ground-water-supplied public water systems. Among the most frequently cited of these compounds were trichloroethylene, tetrachloroethylene, and benzene.* Atrazine, alachlor, and lindane were the most frequently cited pesticides.

Sixteen States also reported on the occurrence of ground water contaminants at levels that are approaching the MCL. The concentrations of these contaminants in ground water do not yet present human health hazards. Nonetheless, they provide a clear indication that future uses of ground water may be impaired. Of the 16 States reporting:

- Fourteen States detected nitrate at a level between 50% and 100% of the MCL in ground water supplied by public water systems. Among the 12 other inorganic contaminants reported to be approaching the MCL, the most frequently cited were cadmium, nickel, selenium, and thallium.

- Fourteen VOCs and 13 pesticides were reported at levels that approached MCLs. The most frequently cited of these compounds were benzene, carbon tetrachloride, and vinyl chloride.* Lindane, simazine, and aldicarb were the most frequently cited pesticides.

* Trichloroethylene is a carcinogen (i.e., cancer-causing substance) used in textiles, adhesives, and metal degreasers. Tetrachloroethylene is a carcinogen used in dry cleaning and other solvents. Benzene is a widely used carcinogenic component of gasoline, pesticides, paints, and plastics.

* Carbon tetrachloride is a carcinogenic component of solvents and their degradation products. Vinyl chloride is a carcinogen that may leach from polyvinyl chloride pipe or be formed by the breakdown of other solvents.

Ground Water Contaminant Sources

Ground water quality may be adversely impacted by a variety of potential contaminant sources. EPA presented a list of potential contaminant sources in the 1994 305(b) guidelines and requested each State to identify and rank the specific sources that threaten their ground water resources. Ranking was based on the best professional judgment of the State ground water officials and took into account the number of each type of source in the State, the location of the various sources relative to ground water used for drinking water purposes, the size of the population at risk from contaminated drinking water, the risk posed to human health and/or the environment from releases, hydrogeologic sensitivity (the ease with which contaminants enter and travel through soil and reach aquifers), and the findings of the State's ground water protection strategy and/or related studies.

Figure 6-5 lists potential ground water contaminant sources ranked according to the number of States that identified each source as a high, medium, low, or unspecified priority. As shown, the greatest number of States reported that leaking underground storage tanks (USTs) are a source of ground water contamination with 41 States rating USTs as a high-priority source of ground water contamination in their 1994 305(b) reports. Montana indicated that there have been 963 confirmed releases from USTs and that half of these releases impacted ground water resources. Leaking USTs have also caused serious ground water pollution problems in Rhode Island with more than 511 leaking USTs identified in the State since 1985. Many of these sites have required active remediation of contaminated ground water. In several cases, restoration of contaminated ground water was deemed infeasible, and alternative measures had to be taken to supply affected areas with drinking water.

The primary causes of leakage in USTs are faulty installation and corrosion of tanks and pipelines. It is estimated that, on a national basis, 139,000 tanks have leaked and impacted ground water quality, and reports of leaking USTs continue to increase. Rhode Island indicated that new reports of leaking UST sites requiring investigation for potential ground water contamination numbered 50 to 70 per year during 1992-1993. Montana indicates that new reports of leaking USTs come in at a rate of 20 to 30 per month. This rise in the number of reports of leaking USTs most likely reflects increased awareness, stricter requirements on site assessments upon closure of tanks, and monetary aid to assist responsible parties to clean up the contaminated sites. In addition, increased reporting of UST leaks may reflect an increase in leaks as older tanks corrode.

In general, most USTs are found in the more heavily developed urban and suburban areas of a State. They are primarily used to hold petroleum products such as gasoline. Ninety-five percent of the USTs in Texas contain petroleum products. Rhode Island reports that, of 255 active sites, approximately 75% involve motor fuels (gasoline

VOL 12

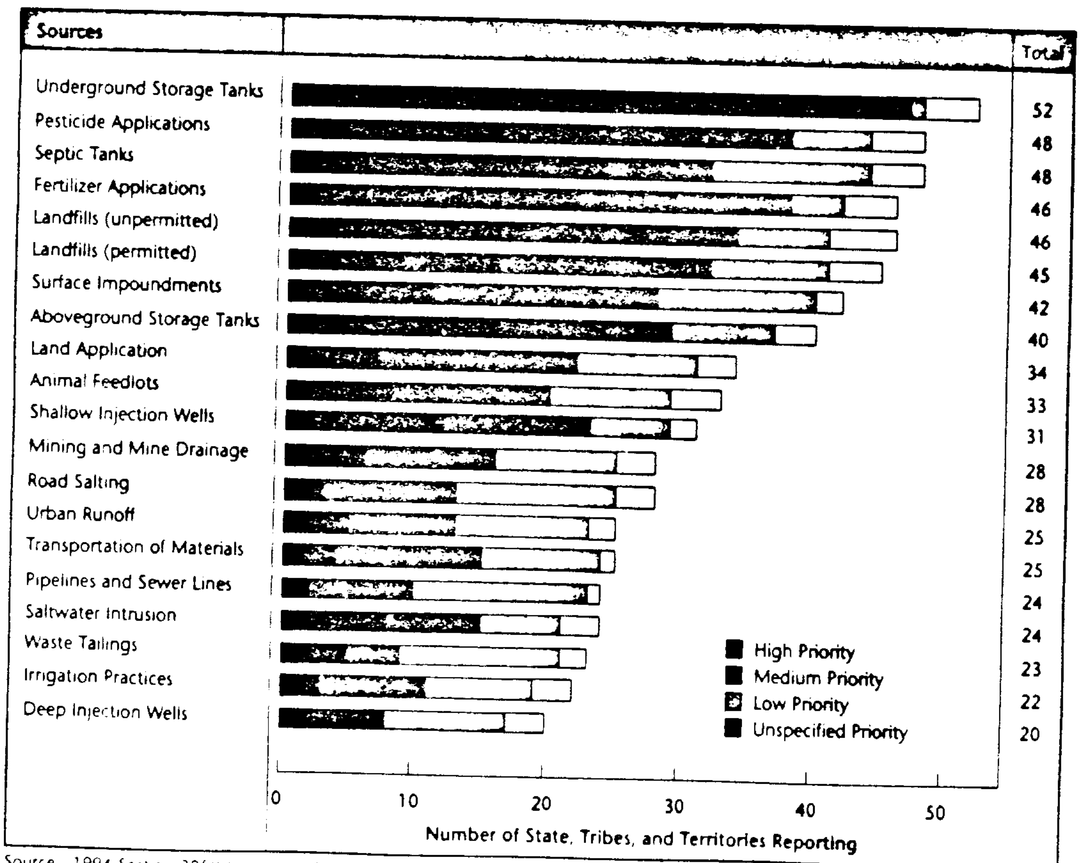
5539

and diesel fuel). The majority of these leaks at the active sites in Rhode Island occurred at gasoline service stations. North Carolina reported that leaking USTs accounted for 87% of the ground water contamination incidents occurring from October 1991 through September 1993. Of these incidents, 86% were related to the release of gasoline. Maine reports that petroleum leakage has contaminated over 200 private wells between 1990 and 1992.

Septic tanks and shallow injection wells were listed as the third and eleventh most common sources of ground water contamination, respectively. Shallow injection wells (classified as Class V wells in the Underground Injection Control Program) inject fluids into or above

Figure 6-5

Contaminant Sources Prioritized by States



Source: 1994 Section 305(b) reports submitted by States, Tribes, and Territories.

underground sources of drinking water. They include dry wells, septic systems, geothermal reinjection wells, industrial and utility disposal wells, and aquifer recharge wells. New Jersey reports that in a four-county study, including Passaic, Somerset, Camden, and Ocean Counties, subsurface discharges of wastewater from industrial septic systems, dry wells, and service station drains are a major source of drinking water contamination. One-hundred and twenty-four private wells and five municipal wells were contaminated—half by subsurface discharges.

Contamination of drinking water from shallow injection wells may take years to be detected in nearby wells. A chemical company in the Bethpage/Hicksville area of New York disposed of industrial wastewater containing a carcinogenic compound—vinyl chloride—into sumps. Two million gallons of wastes were discharged each year for 19 years. This led to extreme contamination of the Magothy aquifer. Fourteen wells, including five municipal supply wells, were contaminated with industrial organic wastes. An estimated 100,000 people were affected by the contaminated wells.

One obstacle in remediating ground water contaminated by shallow injection wells is determining the responsible parties. Three wells were closed in Burlington, Maine, due to trichloroethylene (TCE) and tetrachloroethylene (PCE) contamination. The closure of the wells affected 50% of the town's primary well field and approximately 20,000 people. Two nearby manufacturing plants are unconfirmed but suspected sources of contamination. Both facilities have dry wells and septic systems that contain TCE and PCE. The town continues to supply water to residents using a wellfield that previously served as a backup water supply.

In severe cases, even when responsible parties are required to remediate the contaminated area, costs are high—often too high for the responsible party or parties to afford. From the 1950s through 1981, a thermostat manufacturer in South Cairo, New York, poured wastes containing TCE and PCE sludges down drains connected to an abandoned septic system. As a result, high levels of TCE and PCE were detected in five privately owned wells in the vicinity. A 1983 Consent Order required the manufacturer to clean up the site, supply bottled water, and install, monitor, and maintain carbon filter systems for the five affected homes. In 1985, the manufacturer filed for bankruptcy, and EPA has assumed responsibility for maintaining the carbon filter systems and monitoring. EPA has also installed two new carbon filtration units and an air stripping system and drilled a new well in an effort to provide clean water. Future remedial action will include the provision of an alternate water supply through a pipeline at estimated capital costs of $2,270,000 and annual operation and management costs of $100,000.

A March 22, 1991, report prepared for EPA entitled *Drinking Water Contamination by Shallow Injection Wells* estimated that shallow injection wells contaminated the drinking water of approximately

VOL 12 [5541

1.3 million people at a cost ranging from $30,000 to $3.8 million.

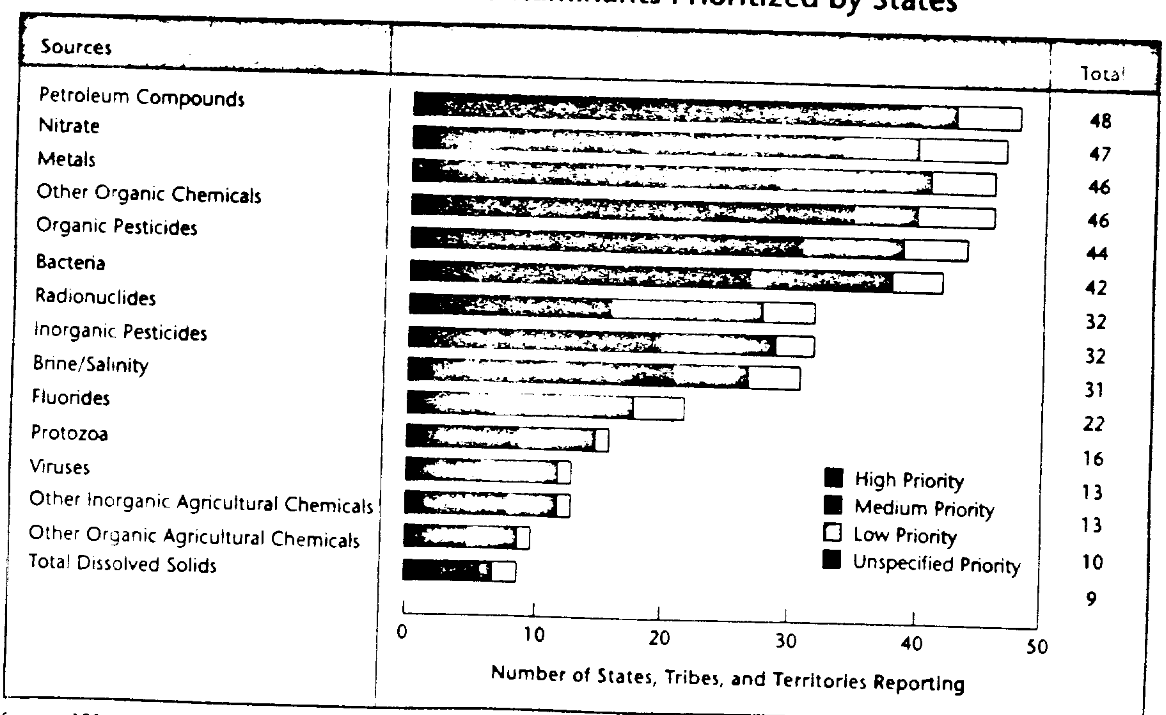
Ground Water Contaminants

EPA also requested that States identify and rank the contaminants impacting their ground water resources. This information was also based upon the best professional judgment of the State ground water experts. Factors that were considered include the areal extent of contamination, the location of contamination relative to ground water supplies used for drinking water purposes, the size of the population at risk from drinking water threatened by the contaminant, the risk posed to human health and/or the environment from this contaminant, hydrogeologic sensitivity, and findings of the State's ground water protection strategy or other reports.

As shown in Figure 6-6, the greatest number of States cited petroleum compounds as a high-priority contaminant in their ground water. Petroleum compounds are

Figure 6-6

Ground Water Contaminants Prioritized by States



Source 1994 Section 305(b) reports submitted by States, Tribes, and Territories.

generally associated with underground and aboveground storage tanks, and their frequent detection in ground water is consistent with the high priority assigned by the States to storage tanks as a contaminant source.

Petroleum is a complex mixture of more than 200 different compounds. Studies have found that four compounds (benzene, toluene, ethyl benzene, and xylenes) make up 95% of the compounds detected in ground water impacted by petroleum releases. It is generally these compounds that are most frequently detected in contaminated ground water. Using this information, Montana was able to relate five incidents of benzene contamination in public water supplies to leaking USTs.

Nitrate was the second most common ground water contaminant cited in State 305(b) reports. Twenty-four States indicated that nitrate was a major concern. Ten of these States indicated that nitrate was the prime contaminant of concern. High concentrations of nitrate in drinking water can cause serious human health problems, especially in babies. Exposure to high concentrations of nitrate (>10 mg/L) in drinking water causes methemoglobinemia, or blue baby syndrome, an inability to fix oxygen in the blood.

Nitrate is soluble in water, and, as a consequence, it is easily transported from the soil surface to ground water. Nitrate is applied extensively on agricultural fields, residential lawns, and golf courses to promote crop and lawn growth. Sources of nitrate include fertilizer, domestic wastewater and sludge, and septic tanks. Natural concentrations of nitrate in ground water vary, but a concentration of 3 mg/L is often considered to be typical outside of areas of naturally high nitrate levels. Concentrations measured above this level are typically considered to be the result of human activity. Elevated concentrations of nitrate in ground water are frequently considered to be an important indication of the degradation of ground water resources. The EPA drinking water standard for nitrate is 10 mg/L.

Following are highlights of several State programs focusing on nitrates.

Maine

The Maine Soil and Water Conservation Districts collected soil from the plow layer of 249 corn fields as part of a Manure Management Project. Soil nitrate was found to be twice the level needed to produce a normal corn crop, suggesting a threat that the excess nitrate could leach to ground water. In response, the Maine Cooperative Extension Service developed guidelines for manure utilization that include (1) the analysis of nitrate levels in soils and plants prior to fertilization, and (2) fertilization according to realistic crop uptake rates.

South Dakota

The Oakwood Lakes-Poinsett Rural Clean Water Program examined the impacts of agricultural chemical practices on ground water quality. A total of 114 monitoring wells were installed at seven study sites that represented both farmed and unfarmed areas. The study results showed that nitrate concentrations in ground water ranged from less than 0.1 mg/L to more

VOL 12

Frequently Detected Pesticide Residues in Ground Water

Ground water monitoring for agricultural chemicals during the past decade has shown that this vital resource is susceptible to contamination. The tabulated information on the following pages shows the results of recent monitoring for pesticides in the ground water of some States. These studies indicate that among the most frequently detected pesticides are those with active ingredients from the triazine (atrazine, cyanazine, simazine, and prometon) and amide (alachlor, metolachlor, and propachlor) herbicide families. While a number of pesticides have been detected in ground water, however, very few are found at levels that exceed health-based standards for drinking water.

Atrazine is the common name of an herbicide that is frequently used to control weeds in corn, sorghum, and other agricultural crops. Atrazine has a high potential to be transported to ground water, and is the seventh most frequently detected active ingredient tracked in the U.S. Environmental Protection Agency's Pesticides in Ground Water Database.* Atrazine residues were found in 1,512 (5.6%) of the 26,909 well samples that were collected for studies conducted across the United States from 1971 to 1991. Only 172 of the wells (0.6%) yielded samples in which atrazine levels exceeded the MCL.

Alachlor is the common name of an herbicide that is commonly applied to weeds in corn, cotton, soybeans, and peanuts. Alachlor has a moderate potential to be transported to ground water and is the ninth most frequently detected pesticide residue listed in the Pesticides in Ground Water Database. Of the 26,856 wells tested for alachlor residues in the past two decades, 543 (2%) contained detectable levels of this herbicide. Alachlor residues that exceeded the MCL for this compound were found in 101 wells (0.4%).

Simazine is the common name of an herbicide used primarily to control weeds in corn, vineyards, citrus orchards, and other agricultural crops. Simazine has a moderate potential to be transported to ground water. The Pesticides in Ground Water Database lists simazine as the tenth most frequently detected pesticide residual found in ground water over the past two decades. Simazine residues were found in 486 (2.2%) of the 22,374 well samples that were reported from 1971 to 1991. Only 89 of the wells (0.4%) yielded samples in which simazine levels exceeded the MCL.

HIGHLIGHT

Factors Affecting Pesticide Occurrence in Ground Water

In a study of the corn and soybean producing region of the midcontinental United States, researchers sought to understand the occurrence and distribution of selected agricultural chemicals and their degradation products in shallow aquifers.* The study region included parts of Illinois, Indiana, Iowa, Kansas, Michigan, Minnesota, Missouri, Nebraska, North Dakota, Ohio, South Dakota, and Wisconsin. Nearly 60% of the pesticides and nitrogen fertilizers used in the United States is applied to crops in these 12 States. A total of 303 wells were sampled during both the preplanting and postplanting seasons. Herbicides and metabolites were detected in 24% of the samples. None of the pesticides were detected at levels that exceeded the MCL.

Many of the studies summarized in the attached table sought to discern relationships between the occurrence of pesticides in shallow ground water and specific aquifer or land use conditions that rendered the cropland particularly susceptible to ground water contamination. In a recent study of agricultural chemicals in the ground water of Nebraska,* the authors concluded that the following factors may be related to pesticide occurrence in ground water:

- Nearly 70% of the atrazine detections occurred in highly vulnerable areas where nonpoint nitrate contamination has also been documented.

- The dispersed pattern of alachlor detections may suggest contamination that originated from misuse, overuse, back siphoning, or spills at mixing/loading areas, rather than through normal agricultural application.

- Some detections of propachlor in ground water may be related to use of the pesticide to control weeds around the wellhead of unsealed irrigation wells.

A National Look at Nitrates*

In addition to work being conducted by States, the U.S. Geological Survey evaluated nitrate concentrations on a national basis. The U.S. Geological Survey conducted an analysis of approximately 12,000 water samples collected from wells and springs in 18 of the 20 Study Units of the National Water Quality Assessment and five supplemental study areas.

The analysis indicated that about 50% of the wells were characterized by elevated levels of nitrate (levels that exceeded 3 mg/L, which is typically held as the threshold indicating human impacts). Nitrate concentrations exceeded the EPA maximum contaminant level (MCL) of 10 mg/L in approximately 21% of the samples. Samples collected from agricultural areas had significantly higher nitrate concentrations than other land use settings (for example, forest), with 16% of the samples exceeding the MCL. The nitrate concentrations were generally highest in the Northeastern, Northern Plains, and Pacific States. This reflects the fact that much of the agricultural land in these regions of the country is underlain by permeable, more well-drained materials, such as unconsolidated sand and gravel, or fractured carbonate bedrock. It was shown that nitrate concentrations were highest in areas of sandy soil.

The analysis indicated that nitrate concentrations exceeding the MCL were most frequently detected in irrigation and stock wells (16%) as opposed to private wells (9%) and public water supply wells (1%). However, EPA still urges well owners who know or suspect that their wells are affected by nitrates to have the water tested. Because of the many factors that may influence the contamination of drinking water wells, EPA recommends an approach that focuses on pollution prevention. Among the steps that should be considered to protect the Nation's ground water resources are appropriate applications of pesticides and fertilizers, site-specific assessments to accurately target and protect vulnerable ground water supplies, identification and protection of ground water recharge areas and wellhead areas, more careful use of flood irrigation, and continued efforts to identify problem areas.

than 70 mg/L. Fifteen percent of the 3,092 samples exceeded the EPA MCL of 10 mg/L. The highest nitrate concentrations were found in the top 20 feet of the aquifer, and nitrate concentrations were significantly higher at the farmed sites.

Arizona

Nitrate is one of the most common pollutants in Arizona's ground water. Large portions of aquifers within the Salt River Valley, including areas within Glendale, Mesa, Chandler, and Phoenix, contain ground water with nitrate concentrations high enough to render the water unfit for consumption. In addition, high nitrate levels occur in Marana, St. David, Quartzsite, Bullhead City, and other areas. Septic tank discharges are particularly prevalent sources of nitrate in rural areas and have often contaminated drinking water wells.

As a consequence, the following investigations are under way:

- Studies will be conducted in the Bullhead City/Riviera, Fort Valley, and Casa Grande areas to investigate the impacts of septic tanks and other nitrate contributions.
- Maps that reflect nitrate concentrations in Arizona's ground water are being produced to target prevention activities.

Georgia

The Georgia Environmental Protection Division (EPD) sampled over 5,000 shallow domestic drinking water wells for nitrate/nitrite. Results indicate that only 1% of the 5,000 wells is characterized by nitrate concentrations that exceed the MCL of 10 mg/L for nitrate in drinking water. Water from 97% of the wells is characterized by nitrate concentrations of less than 5 mg/L. Although it does not appear that nitrate is a widespread problem in Georgia, the EPD observed a very slight increase in average nitrate concentrations in the recharge areas of some Coastal Plain aquifers. These increases may indicate a future increase in nitrate in the down-dip confined portions of the aquifers. EPD will continue to monitor changes in the aquifers.

Iowa

Agriculture, Iowa's largest industry, is currently the primary source of ground water contamination in the State. One of the most significant impacts is related to the application of commercial fertilizers. An estimated 30% to 50% of the nitrogen applied as fertilizer to Iowa farm acres is volatilized and lost to the atmosphere or is lost through infiltration through the soil. Currently, approximately 18% of the State's rural population is served by water with nitrate concentrations in excess of the MCL (10 mg/L as nitrogen). However, only 10 out of 1,130 ground-water-based community public water supplies (PWSs) have levels of nitrate exceeding the MCL. High levels of nitrate affect a relatively low percentage of the population of Iowans served (0.3%).

Ground Water Monitoring

Section 106(e) of the Clean Water Act requests that each State monitor the quality of its ground water resources and report the status to Congress biennially. The most comprehensive approach to determining overall ground water quality is to use an ambient ground water monitoring network. However, the expense associated with installation and maintenance of such a network is often high and, depending upon State priorities, it may be prohibitive. Despite this, many States are taking the initiative to develop programs designed to evaluate the quality and vulnerability of their ground water resources, to identify potential threats to ground water quality, and to determine ways to protect their ground water resources from degradation. Thirty-three States indicated that they have implemented statewide ground water monitoring programs that focus on one or more contaminants. This is an increase of four States from what was reported in 1992. Additionally, six States indicated that they are in the process of developing similar programs. Following is a brief description of several State monitoring programs.

Pennsylvania – Fixed Station and Ambient Monitoring Programs

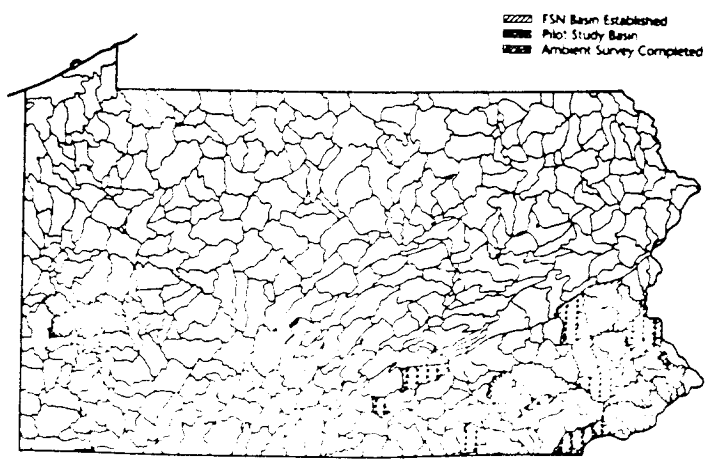
To improve the effectiveness of its ground water resource protection efforts, the Pennsylvania Bureau of Water Quality Management developed two ground water quality monitoring programs—the Fixed Station Monitoring Network and the Ambient Ground Water Quality Survey Programs. These joint programs enable Pennsylvania to (1) detect emerging ground water problems, (2) evaluate the impacts of unmonitored sources of pollution, and (3) assess the overall effectiveness of their regulatory program.

Pennsylvania's Fixed Station Monitoring Program was developed following division of the State into 478 ground water basins (Figure 6-7). These basins were then prioritized based on ground water use, land use (potential unmonitored sources of pollution), and environmental sensitivity. The 50 highest ranking basins were selected for inclusion in the Fixed Station Monitoring Network Program.

To date, 537 ground water monitoring stations have been established in 20 basins covering 2,318 square miles. The average ground water basin is 125 square miles in size and includes 25 monitoring locations, which are selected to represent the ambient ground water quality of a 4-square-mile area. Each ground water sample is analyzed for 27 parameters.

Figure 6-7

Ground Water Basin Map of Pennsylvania



Source: 1994 Water Quality Assessment, 305(b) Report, Commonwealth of Pennsylvania

VOL 12 5551

R0038859

Pennsylvania's Ambient Ground Water Quality Survey Program was initiated in 1988 to obtain ground water quality data in those basins not covered by the Fixed Station Program. Because these basins are considered to be less vulnerable, ground water samples are scheduled to be collected only two times.

Florida – Comprehensive Monitoring Networks

Florida's Water Quality Assurance Act required the establishment of a ground water monitoring network designed to (1) establish the baseline water quality of the major aquifer systems in the State, (2) detect and predict changes in ground water quality resulting from the effects of various land use activities and potential sources of contamination, and (3) disseminate to local governments and the public water quality data generated by the network. The Florida Network has three components: the Background Network, the Private Well Survey, and the Very Intense Study Area Network.

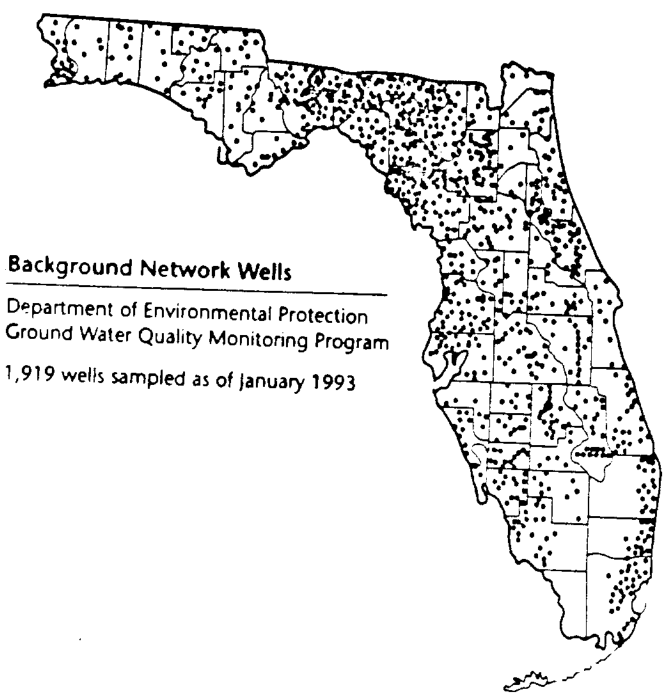
The Background Network was designed to help define background water quality using a statewide grid of wells that collectively tap all major aquifers, including the surficial, intermediate, Floridan, and Claiborne aquifers (Figure 6-8). One-third of the wells are sampled annually with a complete rotation of wells every 3 years. Approved data are available to the public on the Florida Ground Water Quality Monitoring Network Electronic Bulletin Board and in three State publications.

The Private Well Survey provides an evaluation of water quality in private drinking water wells serving families in 67 Florida counties. The survey calls for 50 private water wells to be sampled in each individual county. To date, sampling in 23 counties has been completed.

Twenty-three areas believed to be highly susceptible to ground water contamination based on predominant land use and hydrogeology are being studied as part of the Very Intense Study Area Network. A total of 461 wells make up this network, which is designed to monitor the effects of multiple

Figure 6-8

Location of Ground Water Quality Monitoring Program Background Network Wells in Florida



Source 1994 Florida Water Quality Assessment, 305(b) Report, Florida Department of Environmental Protection.

sources of contamination on water quality within a segment of an aquifer. The land uses represented are urban, suburban, industrial, agricultural, and mixed. Cumulative monitoring data will be compared to similar parameters in the Background Network representing the same aquifer segment to determine the effects of land use and site hydrogeology upon ground water quality.

Kansas – Assessing Temporal and Spatial Trends

Kansas established a Ground Water Quality Monitoring Network in 1976 to procure long-term, statewide ground water quality data for use in the identification of temporal and spatial trends related to (1) alterations in land use, (2) application of land treatment methods and other nonpoint source best management practices, (3) changes in ground water availability or withdrawal rates, and (4) variations in climatological conditions within the State. In addition, the network is intended to assist in the identification of ground water contamination problems.

The network currently consists of 242 wells (Figure 6-9), including public water supply wells (71%), irrigation wells (14%), private domestic wells (10%), multiple use wells (3%), livestock watering wells (1%), and industrial supply wells (1%). During the period 1990-1993, 599 samples were analyzed for common inorganic chemicals and heavy metals; 285 samples were analyzed for pesticides; 110 samples were analyzed for volatile organic chemicals; and 105 samples were analyzed for radionuclides. In evaluating the data, 103 instances were found in which the chemical quality of the raw ground water samples exceeded State drinking water standards. Of these, 71 were related to the presence of nitrate.

Wisconsin – Pesticide Monitoring Program

Wisconsin developed a pesticide monitoring program in response to the detection of aldicarb in 1980 in ground water near Stevens Point. Initially the monitoring program focused on aldicarb; however, it was expanded in 1983 to include additional pesticides (e.g., atrazine), and several studies were initiated to determine the potential impact of pesticide use on ground water quality. Following are the results of four studies:

Figure 6-9

Kansas Ground Water Quality Monitoring Network

VOL 12

5553

R0038861

- In 1985, the Wisconsin Department of Agriculture, Trade, and Consumer Protection installed monitoring wells at a number of farm fields in susceptible geologic environments. To date, atrazine was detected at 25 of the 35 study sites and alachlor was detected at 7 of the 23 study sites.

- During the period between August 1988 and February 1989, well water from 534 Grade A dairy farms was randomly collected by the Wisconsin Department of Agriculture, Trade, and Consumer Protection and analyzed for 44 pesticides. One or more pesticides were detected in 71 wells.

- Sixty-nine of the 71 Grade A dairy farm wells were resampled by the Wisconsin Department of Natural Resources along with 212 wells located in the areas of concern to determine the possible extent of the pesticide occurrences. One or more pesticides were detected in 57 of the 69 resampled wells and 63 of the other 212 wells.

- To better understand pesticides and nitrates in ground water, the Wisconsin Department of Agriculture, Trade, and Consumer Protection sampled nearly 2,200 rural wells for atrazine and triazine herbicides. Sixteen percent, or 351 of 2,187 wells, contained detectable concentrations of triazine-class compounds.

In response to concerns about pesticides in ground water, Wisconsin adopted an administrative rule to regulate atrazine use starting with the 1991 growing season. This rule has been revised in each subsequent year to account for additional atrazine data. Application rates are limited statewide based on soil texture and former use. The use of atrazine is prohibited in certain areas of the State. Throughout the rest of the State, a rate of application is required that is more stringent than Federal recommended limits.

Arkansas – Ambient Ground Water Monitoring

The Arkansas Department of Pollution Control and Ecology has established an ambient monitoring program at various locations statewide that enables the State to gather background ground water quality data from various aquifers in the State. Arkansas monitors water quality in 100 wells and 10 springs once every 3 years. The wells and springs are monitored for specific constituents likely to be found in the respective areas. Monitoring wells located at industrial or landfill sites regulated by the Resource Conservation and Recovery Act (RCRA) or the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) are monitored at least annually, but only for indicator parameters required by the regulations

Ohio – Tracking Ground Water Quality Using GIS

The Ohio Environmental Protection Agency Division of Drinking and Ground Waters is responsible for characterizing Ohio's ground water quality. The Division has collected an extensive amount of ground water quality data through three monitoring programs: the Ambient Network, the Pollution Source Network, and the Nonpoint Source Network. The Ambient Network currently includes approximately 200 well stations at nearly 150 sites. Of the total sites, roughly 110 (70%) are public water systems and roughly 40 (30%) are industrial/commercial water suppliers. Raw water samples are collected semiannually and are analyzed for a series of inorganic constituents. Organic constituents are analyzed at least annually.

Until recently, the ambient ground water data were kept solely in hard-copy files. However, during the past 2 years, the data were entered into a comprehensive database system, and locational information pertaining to each well station was entered into a GIS. In using the GIS program, the Ohio EPA has gained the ability to provide both graphical and numerical summaries of their monitoring data. Several preliminary plots are presented in Figures 6-10 and 6-11.

Indicators of Ground Water Quality

Developing the ability to characterize trends in ground water quality over space and time was one of the key recommendations of EPA's 1986 Ground-Water Strategy. However, data collection and organization varies among the States, and a single data source for

HIGHLIGHT HIGHLIGHT HIGHLIGHT

Ground Water Quality Indicators

EPA's 1986 Ground-Water Strategy recommended that States develop the ability to characterize trends in ground water quality over time. To support this goal, EPA's Ground Water Protection Division has been involved in the Intergovernmental Task Force for Monitoring Water Quality (ITFM), which has developed a set of environmental indicators that EPA and the States may use to target monitoring efforts and set priorities in ground water protection activities.

Selection of ground water indicators by the ITFM was based on their relevance to important water quality issues, such as human health protection, monitoring objectives, and the existence of appropriate analytical methodologies. The following criteria were considered in the selection of indicator parameters for ground water monitoring:

- Is the indicator parameter potentially toxic to human health and the environment, livestock, and/or beneficial plants?

- Does the presence of the parameter (e.g., hardness, iron, taste, odor, color) impair the suitability of the water for general use?

- Is the parameter of concern in surface water and is it easily transported from ground water to surface water?

- Is the parameter an important "support variable" for interpreting the results of physical and chemical measurements (e.g., temperature, specific conductance, major ion balance, depth to the water table)?

- Is analysis of the parameter affordable using well-established analytical methods at appropriate minimum detection and reporting levels necessary to achieve the objectives of the study?

Due to regional differences in the relative importance of water quality issues and the potential for significant differences in the objectives of monitoring programs, no one set of indicators is suitable or appropriate for all monitoring programs. However, the following table provides examples of ground water monitoring parameters that could be considered for monitoring in areas of differing land use and contaminant sources. The table focuses on classes of contaminants, including volatile organic compounds (VOCs), semivolatile organic compounds (SVOCs), petroleum hydrocarbon compounds, pesticides, and pathogens. The table does not include physical indicators such as color, odor, pH, specific conductance, temperature, or total dissolved solids because these six indicator compounds are suggested for each of the categories in the table.

HIGHLIGHT HIGHLIGHT HIGHLIGHT

The abbreviated table below provides a starting point for evaluating the relationship between land use patterns and likely contaminant loading to ground water. Monitoring agencies may tailor this list by reviewing existing data to determine what parameters are likely to be present in a given area. If documented occurrences of a particular parameter exist, that parameter should be included in the monitoring program.

If not, the likelihood that that parameter will be present in the ground water system must be determined. For example, whether potential sources of the contaminant exist in the area, whether the physical and chemical properties of the indicator parameter are likely to enhance mobility in the environment, and whether the aquifer system is susceptible to contamination must be considered.

Potential Indicator Parameters Based on Land Use

Land Use	Municipal		Domestic	Commercial	Agricultural
Parameters	Landfill	Sewer/ Pipeline	Storage Tanks	Property	Animal Feedlots
VOCs	●		●		
PCE	●				
TCE	●

Pathogens		●			●
Nitrate		●			●

characterizing ground water quality does not exist for purposes of this report. To amend this problem, the Office of Ground Water and Drinking Water developed a set of indicators to track progress and set priorities in ground water protection efforts. The initial (1992) set of ground water indicators included

- MCL violations in public drinking water systems supplied by ground water, and the population at risk from these violations
- Extent of ground water contamination resulting from hazardous waste sites, and the population at risk from exposure to this contamination
- Detections and levels of VOCs in ground water
- Detections and levels of nitrates in ground water
- Extent of leachable agricultural pesticide use.

In its guidelines for preparation of the 1992 State 305(b) reports, EPA encouraged States to use one or more of the above indicators to characterize ground water quality. As development of ground water indicators progressed, more explicit guidance was provided to the States for preparation of their 1994 State 305(b) reports.

The 1994 guidelines focused on four indicators specifically selected to provide a relative indication of the condition of ground water resources. The selected indicators were based on existing data and/or data that could readily be collected by the States over time. Where data were available, the States were encouraged to report the following:

- Number of MCL exceedances for ground-water-based or partially ground-water-supplied community water systems
- Number of ground-water-based or partially ground-water-supplied community water systems with reported MCL exceedances
- Number of ground-water-based or partially ground-water-supplied community water systems with detections between 50% and 100% of the MCLs
- Number of ground-water-based or partially ground-water-supplied community water systems that have local Wellhead Protection Programs in place.

Although this was the first time EPA had requested information specific to ground-water-based or partially ground-water-supplied public water systems, 21 States were able to provide quantitative data characterizing at least one of the above indicator parameters. States most frequently reported the total number of samples analyzed for metals, VOCs, pesticides, and nitrates, along with the number of exceedances in each category.

The above set of indicator parameters is being refined so that, over time, it can be used to detect and predict changes in ground water quality resulting from human effects and to assess the overall effectiveness of State ground water monitoring programs.

Ground Water: What We Still Need to Know

We are continuing to learn a great deal about the nature and quality of our Nation's ground water. Still, there is much we do not yet know about how to most effectively protect and preserve this vast and often vulnerable resource.

While the importance of ground water as a source of water in private wells is recognized, the quality of the water drawn from those wells is largely unknown. There are indications that private wells are vulnerable to contamination from microorganisms, nitrates, and pesticides. The occurrence of viruses in ground water and their impacts on private drinking water wells are poorly understood. Furthermore, the risks associated with redirecting surface water runoff into surface impoundments and infiltration ponds are frequently overlooked.

Whereas ground water protection measures are accepted as a "good idea," the performance of these measures in improving the quality of vulnerable ground water has not been tested. What are the differential impacts of nonpoint source best management practices on ground water and surface water? How effective are wellhead protection approaches in areas with fractured bedrock, sinkholes, or areas near surface water features? What are the indicators that should be used to track ground water quality and assess change over time?

We are only beginning to understand the capacity of the land to assimilate contaminants without adversely affecting the use of the ground water. Scientists have only begun to explore the effectiveness of natural ecosystems in processing and degrading contaminants. Many people are able to drink untreated ground water because natural processes improve water quality. Natural ground water systems may remove contaminants that conventional treatment does not address, such as pesticides, heavy metals, and a variety of toxic chemicals present at low concentrations. Ground water organisms are continually found and identified, yet their function in contaminant degradation and their impacts on ground water quality are only beginning to be understood. The interactions between ground water and surface water are known to be significant at the local level, but we do not often recognize the larger-scale implications on the quality of both resources.

Our continued quest for high quality and representative information about the status of our ground water resources will help to answer these questions. Through a greater understanding of how human activities have influenced the quality of our waters, we can better ensure the long-term availability of high-quality water for future generations.

Public Health and Aquatic Life Concerns

Water pollution threatens public health by contaminating seafood, drinking water supplies, and recreational waters with toxic substances as well as pathogenic viruses and bacteria, which cause disease. Aquatic organisms tolerate most bacteria and viruses pathogenic to humans, but many aquatic organisms are more sensitive to toxic substances than humans are. Aquatic organisms also suffer if chemical and physical conditions exceed an acceptable range. Important chemical and physical conditions include acidity (pH), dissolved oxygen concentration, and temperature.

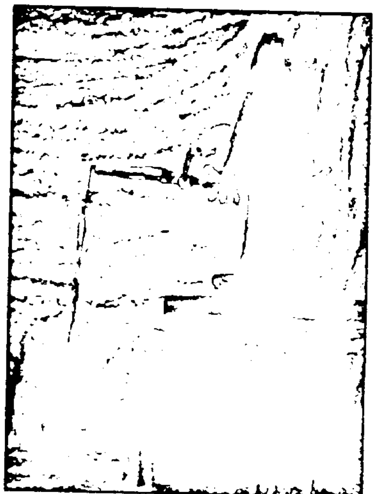
Public Health Concerns

Toxic Pollutants

Health officials link waterborne toxic pollutants, such as mercury, PCBs, and some pesticides with human birth defects, cancer, neurological disorders, and kidney ailments. Once discharged to surface waters, these toxicants persist in the sediments and contaminate the food chain and the overlying water. Waterborne toxicants can enter human systems via ingestion of contaminated fish, shellfish, or drinking water supplies. Swimmers may also swallow toxic substances or absorb toxic pollutants through skin exposure in contaminated recreational waters. Fish and shellfish contamination usually poses a greater human health risk than does contaminated drinking water or recreational waters because fish and shellfish concentrate many toxic substances in their tissues (see sidebar, page 128). As a result, the concentration of toxicants within fish and shellfish tissues may be from ten to one million times the concentration of toxicants in the surrounding waters.

Fish Consumption Advisories

States issue fish consumption advisories to protect the public from ingesting harmful quantities of toxic pollutants in contaminated fish and shellfish. In general, advisories recommend that the public limit the quantity and frequency of consumption of fish caught in specific waterbodies. The States tailor individual advisories to minimize health risks based on contaminant data collected in their fish tissue sampling programs. Advisories may completely ban fish consumption in severely polluted waters or limit fish consumption to several meals per month or year in cases of less severe contamination. Advisories may target a subpopulation at risk (such as



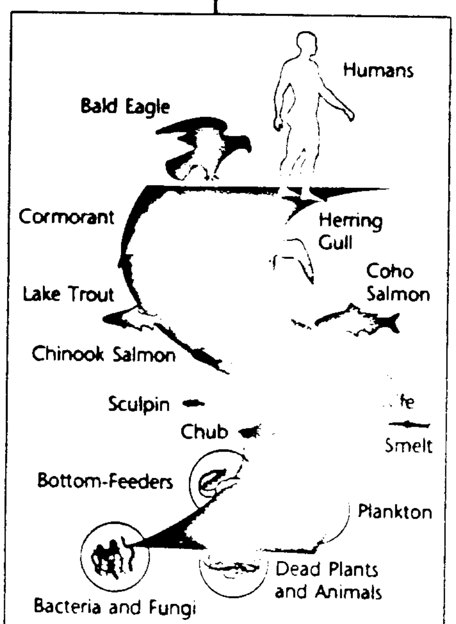
Michael Lira, age 8, Bruner Elementary, North Las Vegas, NV

Many toxic chemicals concentrate in fish and shellfish.

Bioaccumulation of Pollutants in the Food Chain

Certain organic pollutants (such as PCBs and DDT) have two properties that lead to high bioaccumulation rates. These pollutants are hydrophobic (i.e., do not have an affinity to water) and thus attach to the surface of particulates such as clay particles and small aquatic plants called phytoplankton. These organic pollutants are also lipophilic (i.e., have an affinity to lipids or fatty tissues) and readily dissolve in fatty tissues of plants and animals. As a result, these pollutants biologically accumulate (bioaccumulate) in phytoplankton at concentrations that greatly exceed the pollutant concentrations in surrounding waters, which may be so low that they cannot be measured even by very sensitive methods.

Small fish and zooplankton (microscopic grazers) consume vast quantities of phytoplankton. In doing so, any toxic chemicals accumulated by the phytoplankton are further concentrated in the fish, especially in their fatty tissues. These concentrations are increased at each level in the food chain. This process of increasing pollutant concentration through the food chain is called biomagnification.



The top predators in a food chain, such as lake trout, coho and chinook salmon, and fish-eating gulls, herons, and bald eagles, may accumulate concentrations of a toxic chemical high enough to cause serious deformities or death or to impair their ability to reproduce. The concentration of some chemicals in the fatty tissues of top predators can be millions of times higher than the concentration in the surrounding water.

Eggs of fish-eating birds often contain some of the highest concentrations of toxic chemicals. Thus, the first apparent effects of a toxic chemical in a waterbody may be unhatched eggs or dead or malformed chicks. Scientists monitor colonies of gulls and other aquatic birds because these effects can serve as early warning signs of a growing toxic chemical problem.

Biomagnification of pollutants in the food chain is also a significant concern for human health. To protect their residents from these risks, States issue fish consumption advisories or warnings about eating certain types of fish.

Source: Adapted from *The EPA Great Waters Program: An Introduction to the Issues and the Ecosystems*, 1994, EPA-453/B-94/030, Office of Air Quality Standards, Durham, North Carolina.

children, pregnant women, or nursing mothers), specific fish species that concentrate toxic pollutants in their flesh, or larger fish within a species that may have accumulated higher concentrations of a pollutant over a longer lifetime than a smaller (i.e., younger) fish.

EPA evaluates the national extent of toxic contamination in fish and shellfish by counting the total number of waterbodies with consumption advisories in effect. EPA used its database, the National Listing of Fish Consumption Advisories, to tabulate the number of State advisories. EPA built the database to centralize fish consumption advisory information separately maintained in various State agencies and the U.S. Fish and Wildlife Service. EPA contacted each State in the fall of 1994 to update the database.

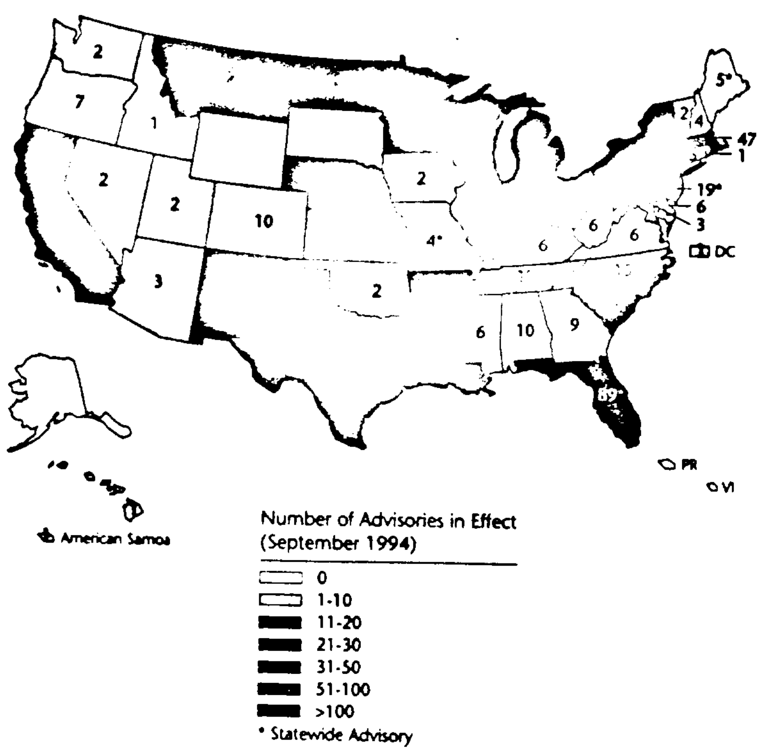
The 1994 EPA National Listing of Fish Consumption Advisories listed 1,531 advisories in effect in 47 States, the District of Columbia, and American Samoa (Figure 7-1). The database counts one advisory per waterbody, regardless of the number of species affected and the number of toxic pollutants detected at dangerous concentrations in fish sampled within a waterbody (see Appendix E, Table E-1, for individual State data).

EPA cannot identify States with a high proportion of toxic contamination based solely on the number of fish consumption advisories issued by each State. National statistics on advisories are difficult to interpret because the intensity and coverage of State monitoring programs vary widely from State to State and each State can set its own criteria for issuing advisories. Simply comparing the total number of fish advisories in each State unfairly penalizes States with superior toxicants monitoring programs and strict criteria for issuing consumption warnings.

The EPA has advocated consistent criteria and methods for issuing

Figure 7-1

Fish Consumption Advisories in the United States



Note: States that perform routine fish tissue analysis (such as the Great Lakes States) will detect more cases of fish contamination and issue more advisories than States with less rigorous fish sampling programs. In many cases, the States with the most fish advisories support the best monitoring programs for measuring toxic contamination in fish, and their water quality is no worse than the water quality in other States.

Based on data contained in the EPA National Listing of Fish Consumption Advisories acquired from the States in September 1994 (see Appendix E, Table E-1, for individual State data)

VOL 12

5563

R0038871

fish consumption advisories in several recent publications and workshops (see sidebar, page 131). However, it will be several years before the States implement consistent methods and criteria and establish a baseline inventory of advisories. EPA expects the States to issue more advisories as they sample more sites and detect contamination that previously went undetected.

Mercury, PCBs, chlordane, dioxins, and DDT (with its byproducts) caused almost all of the fish consumption advisories in effect in 1994 (Figure 7-2). EPA and the States have banned or restricted the use of PCBs, chlordane, and DDT for over a decade, yet these chlorinated hydrocarbon compounds persist in sediments and fish tissues and still threaten public health.

During the 1990s, the States began reporting widespread mercury contamination in fish. As States expanded their fish tissue monitoring programs, they found elevated concentrations of mercury in fish inhabiting remote lakes that were previously considered unpolluted. States from Wisconsin to Florida reported widespread mercury contamination in fish collected primarily from lakes. The source of the mercury contamination is difficult to identify because mercury naturally occurs in soils and rock formations. Natural processes, such as weathering of mercury deposits, release some mercury into surface waters. However, resource managers believe that human activities have accelerated the rate at which mercury accumulates in our waters and enters the food web.

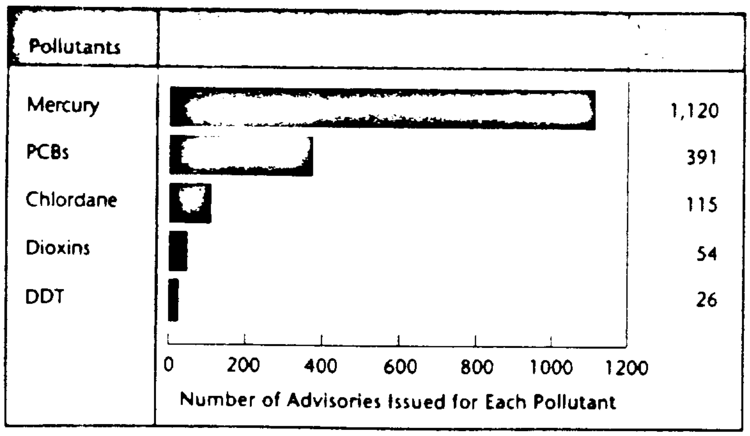
Air pollution may be the most significant source of mercury contamination in surface waters and fish. According to EPA's Toxics Release Inventory, almost all of the mercury released by permitted polluters enters the air; industries and waste treatment plants discharge very little mercury directly into surface waters. Emissions from waste incinerators, coal-fired plants, smelters, and mining operations may carry mercury many miles to remote watersheds (see sidebar, page 132). Other potential sources of mercury contamination include slag heaps from metal mines and land-disturbing activities that may mobilize natural mercury deposits, such as channelization, reservoir construction, and drainage projects.

Air emissions may further aggravate mercury contamination by generating acid precipitation that increases acidity in lakes. The accumulation of mercury in fish appears to correlate with acidity in a waterbody. Slightly acidic conditions promote the chemical conversion of mercury to a methylated form that

MERCURY
is the most common contaminant found in fish.

Figure 7-2

Pollutants Causing Fish Consumption Advisories



Based on data contained in Appendix E, Table E-2.

is more readily available for uptake and accumulation in fish. States, such as Louisiana, are using this correlation to target waterbodies with acidic pH and low buffering capacity for mercury sampling in fish.

EPA sponsored a symposium to gather and exchange the available information on mercury contamination in fish. The National Forum on Mercury in Fish met in September of 1994 to examine fate and transport of mercury in the environment and methods to assess the health effects of mercury.

The EPA Fish Consumption Advisory Database does not identify sources of contamination in fish. Sources of contamination are difficult to isolate because migratory fish may be exposed to toxic pollutants in the sediments and water column or may ingest toxic contaminants concentrated in prey miles from the sampling areas where they are collected. Furthermore, migratory or resident fish may be exposed to toxic pollutants that have been transported great distances from where they originated.

Bacterial and Viral Contamination

Waterborne viral and bacterial pollutants may also cause serious human illness and death. People can contract infectious hepatitis, gastroenteritis, dysentery, and cholera from waters receiving inadequately treated sewage. Bacteria and viruses may enter human systems through contact with contaminated swimming and bathing waters or through ingestion of contaminated drinking water or shellfish.

Shellfish Contamination

Contaminated shellfish pose a public health risk particularly to those who consume raw shellfish. Shellfish, such as oysters, clams, and mussels, extract their food (plankton) by filtering water over their gills. In contaminated waters, shellfish accumulate bacteria and viruses on their gills and mantle and within their digestive systems. If shellfish grown in contaminated waters are not cooked properly, consumers may ingest live bacteria and viruses.

To protect public health, the U.S. Food and Drug Administration administers the National Shellfish Sanitation Program (NSSP). The NSSP establishes minimum monitoring requirements and criteria for State shellfish programs that want to participate in interstate commerce of shellfish. States cannot sell shellfish outside of their State boundaries unless their shellfish sanitation program follows NSSP protocols. Coastal States routinely monitor shellfish harvesting areas for bacterial contamination and restrict shellfish harvests in contaminated waters. Most often, States measure concentrations of fecal coliform bacteria such as *Escherichia coli*, which are nonpathogenic bacteria that populate human digestive systems and occur in fecal wastes. Their presence in water samples is an indicator of sewage contamination that may pose a human health risk from pathogenic viruses and bacteria. Fecal bacteria, however, may exceed criteria even when no human sewage is present because birds and nonhuman mammals also excrete them.

The NSSP recognizes three types of shellfish harvesting restrictions:

In 1990, EPA began developing technical guidance to help the States adopt consistent criteria and methods for issuing fish consumption advisories. The guidance consists of four volumes:

- *Volume I: Fish Sampling and Analysis* recommends standard methods for sampling and analyzing contaminants in fish tissue.
- *Volume II: Risk Assessment and Fish Consumption Limits* suggests protocols for selecting criteria for unsafe concentrations of contaminants in fish.
- *Volume III: Risk Management* suggests protocols for determining if the health risk justifies issuing an advisory.
- *Volume IV: Risk Communication* recommends methods for informing the public about fish consumption advisories.

EPA published the first edition of Volume I in 1993 and released a second edition in the Fall of 1995. Volume II was issued in 1994. Volume III is due to be released in 1996, and Volume IV was released in the Spring of 1995. EPA presented the first two volumes to State, Tribal, and Regional managers at two workshops in 1994.

VOL 12

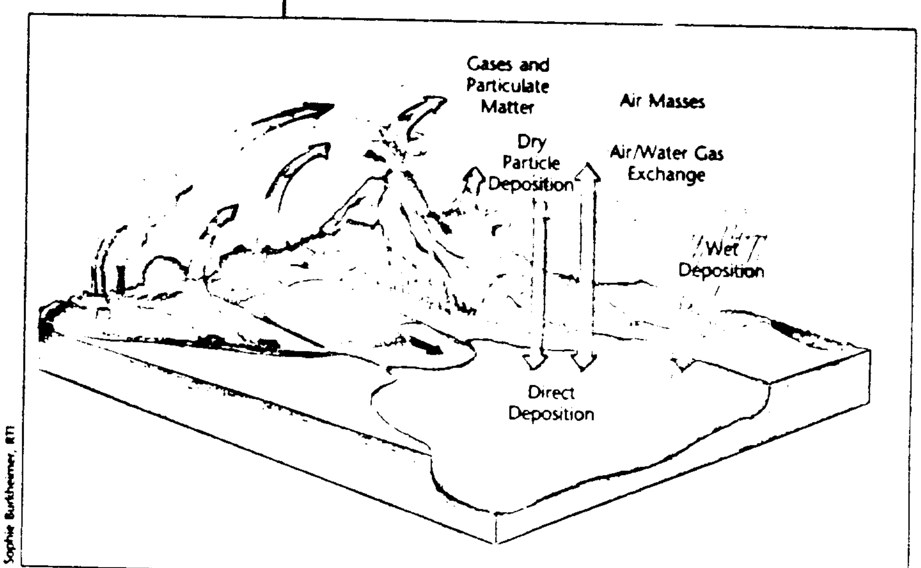
5556

Air Pollution Impacts on Water Quality

- Pollutants are released into the air from man-made or natural sources. Man-made sources include industrial stacks, municipal incinerators, pesticide applications, and vehicle exhaust. Natural sources can be volcanic eruptions, windblown gases and particles from forest fires, windblown dust and soil particles, and sea spray.

- Pollutants released to the air are carried by continental wind patterns away from their areas of origin. Depending on weather conditions and the chemical and physical properties of the pollutants, they can be carried varying distances from their sources and can undergo physical and chemical changes as they travel.

- Air pollutants are deposited to the earth or directly to waterbodies by either wet or dry deposition. Wet deposition occurs when pollutants are removed from the air by falling rain or snow. Dry deposition occurs when particles settle out of the air by gravity or when gases are transferred directly from the air into water. Air pollutants that deposit on land can be carried into a waterbody by stormwater runoff.



Source: Adapted from *The EPA Great Waters Program: An Introduction to the Issues and the Ecosystems*, 1994, EPA-453/B-94/030, Office of Air Quality Planning and Standards, Durham, North Carolina

- **Prohibited Waters** violate criteria consistently; therefore, shellfish cannot be harvested at any time.

- **Restricted Waters** may be harvested if the shellfish are transferred to clean waters to reduce concentrations of bacteria.

- **Conditionally Approved Waters** temporarily exceed bacteriological criteria following predictable events (such as a storm). Shellfish from these waters may be harvested when criteria are met.

The size of waters with shellfish harvesting restrictions does not equate with the size of polluted estuarine waters because States sometimes restrict harvesting in clean waters. The NSSP requires that a State prohibit shellfishing in clean waters if the State cannot monitor a waterbody on a routine schedule that ensures rapid detection of unsafe conditions. As a result, funding for monitoring activities can raise or lower the size of waters classified as "prohibited" even if water quality does not change. Georgia, for example, reported that funding for a new laboratory position during 1992 and 1993 restored shellfishing to clean waters previously classified as "prohibited" due to a lack of monitoring.

As a preventive measure, the States also automatically prohibit the harvest of shellfish near marinas and pipes that discharge wastewater. These closures protect the public from accidental releases of contaminated wastewater due to treatment plant malfunctions or overflows during severe weather. The preventive closures apply to marinas because fecal bacteria concentrations may increase during high use periods, such as weekends. The States prohibit shellfishing in these waters even though these waters may not contain harmful concentrations of fecal bacteria most of the time.

Despite these drawbacks, the size of waters with shellfishing restrictions is our most direct measure of impacts on the shellfishing resource. However, only 16 of the 27 coastal States and Territories reported the size of their estuarine waters affected by shellfish harvesting restrictions (Table 7-1). With so

Table 7-1. Shellfish Harvesting Restrictions Reported by the States

[a] The District of Columbia prohibits commercial harvest of shellfish in all of its waters.

Source: 1994 State Section 305(b) reports.

— Not reported in a numerical format.

VOL 12

5567

few States reporting numerical data, EPA cannot summarize the national scope of shellfish harvesting conditions at this time. The National Oceanic and Atmospheric Administration is developing a database to track State restrictions that should provide a more complete profile of shellfishing conditions in the future.

The reporting States prohibit, restrict, or conditionally approve shellfish harvesting in 6,052 square miles of estuarine waters. About one-third of these waters are conditionally approved, so the public can harvest shellfish from these waters when the State lifts temporary closures. For comparison, 12 States reported that almost 8,000 square miles of estuarine waters are fully approved for harvesting shellfish at all times (Appendix E, Table E-3, contains individual State data).

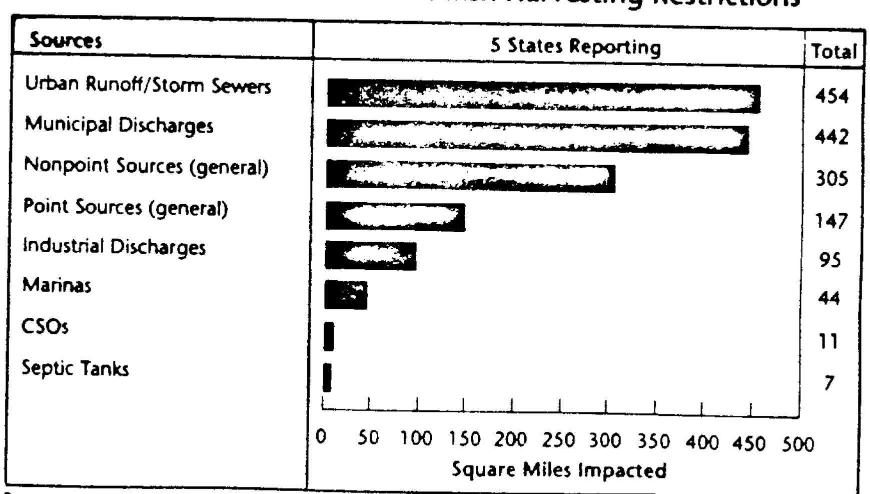
Only five States reported the size of shellfish restrictions caused by specific sources of pathogen indicators (Figure 7-3). Other States provided narrative information about sources degrading shellfish waters.

- Georgia reported that the State prohibits shellfish harvesting in 362 square miles of its waters. Harvesting is prohibited in 280 square miles of potential shellfish waters due to a lack of data. Most of Georgia's other restricted areas are closed because of their proximity to industrial discharge pipes and marinas.

- Louisiana reported that sewage treatment plant upgrades expanded areas open for shellfish harvesting, but the size of healthy oyster growth zones still decreased because of nonpoint source pollution, sewage from camps, saltwater intrusion, and marsh erosion.

Figure 7-3

Sources Associated with Shellfish Harvesting Restrictions



Based on data contained in Appendix E, Table E-4.

■ Maryland reported that nonpoint source runoff is the most pervasive source of bacterial contamination in the State's shellfish waters. Other sources include boating activity, agricultural runoff, seafood processing, and combined sewer overflows.

■ New Hampshire reported that the State has upgraded and constructed five treatment plants in recent years and eliminated several combined sewage outfalls discharging into coastal waters. The State plans to upgrade the four remaining sewage plants discharging into coastal waters and begin addressing nonpoint sources, such as septic tanks, by 1997.

Drinking Water Concerns

After decades of concerted effort, Americans can generally turn on their taps without worry about the quality of the drinking water that flows out. Yet many important questions about drinking water safety remain unsettled. The EPA reviewed available information concerning the safety of public water supplies and discovered that there are pockets of serious trouble, gaps in information, and emerging threats to drinking water safety.

Rising consumer awareness of pollution and other environmental problems has raised concerns about drinking water safety:

■ A 1993 survey commissioned by the National Geographic Society found that nearly one-third of Americans believe that their drinking water is either contaminated or may become contaminated in the future.

■ The rising sales of bottled water, now exceeding 2.2 billion gallons annually with a wholesale value estimated at over $2.4 billion, bear testimony to consumer concerns over tap water quality.

■ Consumer and environmental groups have lobbied for improved public information and education on drinking water safety issues, including monitoring, source water protection, and drinking water treatment.

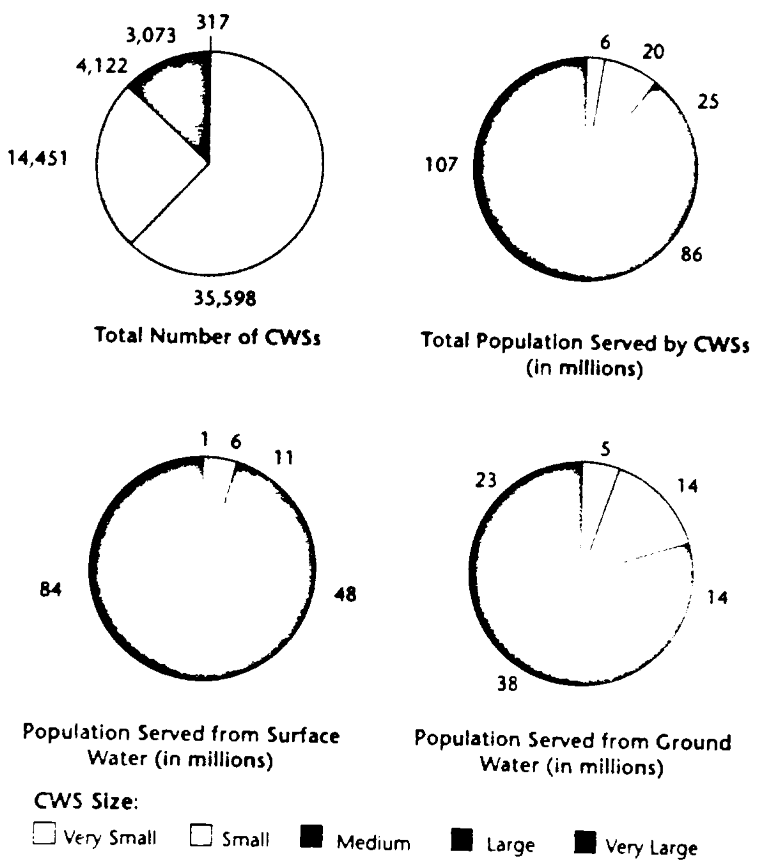
There are approximately 57,600 Community Water Systems that provide year-round drinking water to the homes of approximately 244 million Americans (roughly 90% of all U.S. households) (Figure 7-4). The EPA also regulates over 140,000 additional systems that provide year-round drinking water to people at schools, roadside rest stops, and other facilities. These community and noncommunity systems draw water from surface water or ground water and are subject to the drinking water regulations set forth under the Safe Drinking Water Act. Under this Act, water suppliers are required to conduct tests to determine whether drinking water quality meets safety standards (Figure 7-5). The suppliers must then report the results to the State agency responsible for drinking water protection.

Community Water Systems

The EPA estimates that almost 10% of Community Water Systems have experienced one or more violations of Federal safety standards in the past few years. Most of the violations relate to actual contamination by microorganisms or lead or the failure to adequately test drinking water quality. In fact, one system out of every three conducts only part of the monitoring required to verify drinking water safety.

Figure 7-4

Number of Community Water Systems (CWSs) and Population Served by Size of System



National Primary Drinking Water Regulations

The EPA has promulgated National Primary Drinking Water Regulations (NPDWRs) covering 84 contaminants. These contaminants include 21 volatile organic compounds, 35 synthetic organic compounds, 18 inorganic compounds, three radionuclides, five microorganisms, a water quality indicator, and a disinfection byproduct. Most of these regulations relate to contaminants that may be introduced into source water due to land use practices near the water supply. The NPDWRs provide enforceable standards that protect the quality of the Nation's drinking water.

Drinking Water Quality and Microbiological Contaminants

Thanks to basic drinking water disinfection, drinking water in the United States is virtually free of certain diseases. Cholera and typhoid fever, which afflict many people in other nations, have been effectively removed from our drinking water supplies. However, Americans are not free of drinking water problems posed by microbiological contaminants. Many of the following problems were due to microbiological contamination of source waters.

- In 1993, an estimated 403,000 residents of Milwaukee became ill from an outbreak of the common waterborne protozoan, *Cryptosporidium.*

- Residents of Sheboygan, Wisconsin, parts of New York City, and a large portion of the Washington,

VOL 12

5570

R0038878

DC, metropolitan area were advised to boil their tap water due to risks of microbiological contamination.

- States report that more than 850 Community Water Systems, collectively serving more than 1 million people, were ordered to issue "boil water" advisories.

- Drinking water contamination was not uncommon in 1993 following the summer floods in the midwestern and southern States.

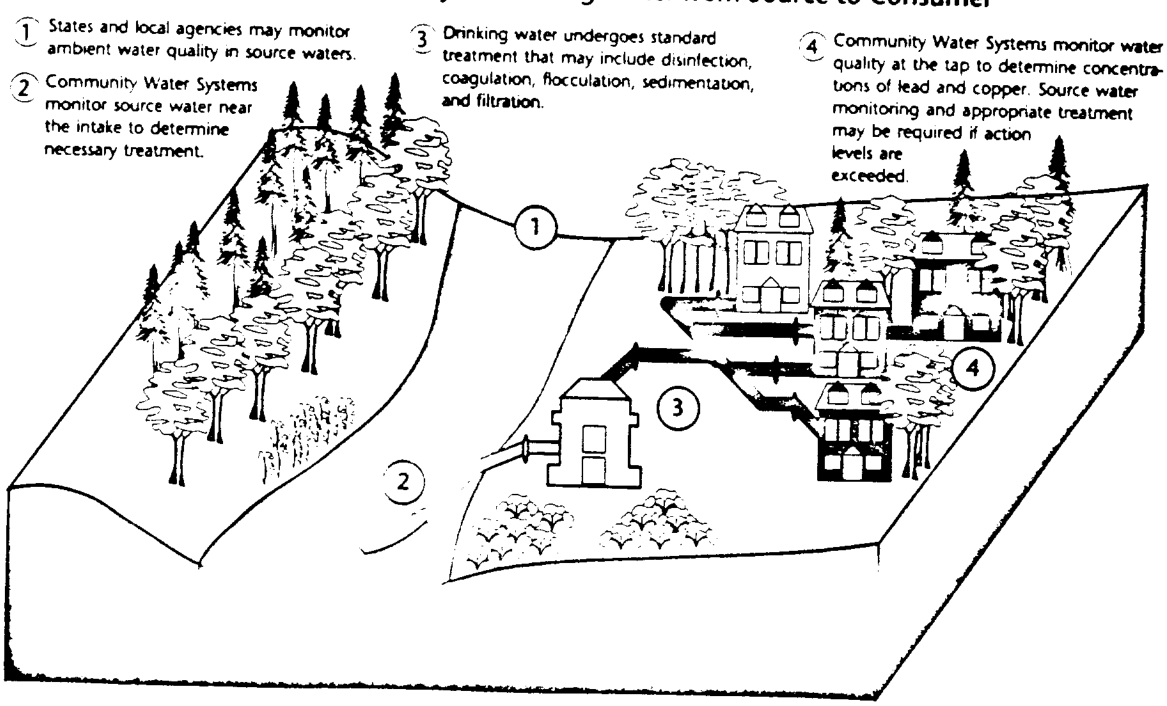
- In 1993, 67% of the Community Water Systems that violated NPDWRs did so by failing to meet microbiological requirements.

Drinking Water Quality and Chemical/Radiological Contaminants

A total of 16,294 Community Water Systems (nearly 29%) experienced violations of NPDWRs in 1992. Approximately 32% of Community Water Systems experienced violations of NPDWRs in 1993. Violations occurred in virtually every State and influenced the water quality of approximately 63 million people. Most of the violations affected very small systems serving between 25 and 500 people. The following violations of health-based standards occurred in 1993.

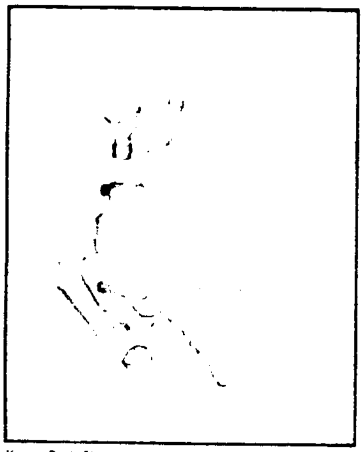
Figure 7-5

Monitoring the Quality of Drinking Water from Source to Consumer



VOL 12

5571



Kings Park Elementary, 3rd Grade, Springfield, VA

- The drinking water supplied to nearly 11% of the population served by Community Water Systems (26.5 million people) violated health-based standards.

- 1,516 Community Water Systems experienced violations for inorganic contaminants. These violations affected 7.2 million people.

- 852 Community Water Systems experienced violations for organic contaminants. These violations affected 8.7 million people.

- 576 Community Water Systems experienced violations for radiological contaminants. These violations affected 1.3 million people.

- 574 Community Water Systems experienced serious, frequent, or persistent noncompliance with chemical or radiological requirements (11% violated health-based standards for nitrate, 3% for fluoride, and 3% for radium).

- 12 Community Water Systems and 22 Noncommunity Water Systems experienced health-based violations related to trichloroethylene, a carcinogen used in textiles, adhesives, and metal degreasers.

- Other organic chemicals that caused health-based violations in drinking water supplies include atrazine, ethylene dibromide, and benzene.

Except for naturally occurring contaminants such as fluoride and radium, all of the violations mentioned above resulted from land-use practices near the affected water supplies.

The Benefits and Costs of Keeping Our Drinking Water Safe

As with many other environmental concerns, it is difficult to quantify the benefits of maintaining safe drinking water. As more water supply systems meet the standards set forth in the Act, EPA estimates that the following national health benefits may be realized.

- Reduced lead exposure for approximately 50 million Americans, and protection of approximately 200,000 children from dangerous levels of lead in their blood

- Prevention of more than 100,000 cases of gastrointestinal illnesses

- Reduced exposure to dozens of toxic contaminants that may affect the drinking water of millions of Americans

- Avoidance of more than 100 excess cancer cases each year from reduced exposure to carcinogenic contaminants in drinking water.

The costs of compliance with the Safe Drinking Water Act have also been estimated. These estimates are based on appraisals of the number of water supply systems that will need to invest in treatment to meet drinking water standards and anticipated treatment costs.

- The national costs attributable to compliance with existing drinking water safety regulations are estimated to be $1.4 billion annually.

- The projected effect on household water bills ranges from an increase of 25 cents per month for systems serving 1 million or more households to $12 per month for systems serving 100 or fewer households.

- Greater than two-thirds of the estimated costs relate to control of microbiological contaminants and lead in drinking water.

- The projected effect of monitoring requirements on household water bills ranges from an average of 1 cent to 35 cents per month for 90% of American households.

- For small Community Water Systems, however, the projected effect of monitoring requirements could exceed $10 per month.

Protecting Drinking Water Sources

Land use in both urban and rural settings may pose chemical and microbiological threats to current and future drinking water supplies. Urban uses of land have more than tripled since the 1950s, rising from 18.3 million acres to 56.6 million acres. Population growth and the expansion of urban land use are likely to pose new risks of contamination in areas that may not have been at risk before. In rural areas, the use of agricultural chemicals has doubled since the 1960s. Many States list agriculture as the leading source of water quality impairment in our Nation's rivers.

In a 1988 survey of surface water utilities and State drinking water agencies, the American Water Works Association investigated the relationship between land use and water treatment. Their results suggest that more advanced water treatment practices are necessary for source waters derived from watersheds where urban or agricultural land use practices predominate.

Virtually all groups interested in drinking water safety promote stronger efforts to prevent pollution from entering drinking water sources rather than relying solely on water treatment to reduce health threats. The EPA encourages source water protection activities geared at protecting surface water and ground water that is used for drinking water supply.

Recreational Restrictions

State reporting on recreational restrictions, such as beach closures, is often incomplete because most State agencies rely on local health departments to voluntarily monitor and report beach closures. Most State agencies that prepare the 305(b) reports do not have access to an inventory of beach closures. The information obtained varies in quality because health departments that monitor infrequently will detect fewer bacteria violations than health departments with rigorous beach monitoring schedules.

Twelve States reported that there were no contact recreation restrictions reported to them during the 1994 reporting cycle, but one State mentioned that unreported closures could exist. Twenty-two States identified 374 sites where recreation was restricted at least once during the reporting cycle (Appendix E, Table E-6, contains individual State data). Local health departments closed many of these

beach closures.

sites more than once. Pathogen indicator bacteria caused most of the restrictions, but Louisiana reported that advisories remain in effect at three sites where sediments are contaminated with toxic chemicals from an industry, an abandoned creosote factory, and an abandoned hazardous waste facility.

The States identified sewage treatment plant bypasses, malfunctions, and pipeline breaks as the most common sources of elevated bacteria concentrations in bathing areas. The States also reported that runoff, failing septic systems, a livestock operation, and combined sewer overflows restricted recreational activities.

Aquatic Ecosystem Concerns

Many native aquatic organisms are more sensitive than humans to toxic pollutants. In severe cases of contamination, toxic pollutants kill all aquatic life; in less severe cases, toxic pollutants eliminate some species from the aquatic community. The aquatic system deteriorates as toxic contaminants poison aquatic organisms (including fish, shellfish, benthic organisms, and plants), increase their susceptibility to disease, interfere with their reproduction, or reduce the viability of their young. Toxic pollutants also disrupt the chemical and physical balance in an aquatic ecosystem and indirectly cause mortality. Chapter 1 provides additional information about toxic pollutants.

Low oxygen concentrations, excessive temperatures, or high or low acidity can have more devastating impacts on aquatic communities than toxic pollutants. Organic pollutants (such as sewage, manure, food processing wastes, and lawn clippings) impose a biochemical oxygen demand (BOD) on receiving waters because bacteria consume oxygen as they decompose organic wastes. Nutrients also may indirectly deplete oxygen concentrations by feeding algal blooms (see Chapter 1 for a full discussion of dissolved oxygen depletion).

Acidity (the concentration of hydrogen ions measured as pH) drives many chemical reactions in living organisms. Many biological processes (such as reproduction) cannot function in either acidic (low pH) or alkaline (high pH) waters. Acidic conditions also aggravate toxic contamination problems because sediments release toxicants in acidic waters. Common sources of sulfuric acid, and, to a lesser extent, nitric acid, include mine drainage, runoff from mine tailings, and atmospheric deposition.

Alkaline conditions (high pH) may result indirectly from inputs of nutrients that induce excessive algal activity. In order to fuel photosynthesis, rapidly expanding algae populations may break down carbonate compounds after they consume all of the carbon dioxide available in the water column. As the algae convert carbonates to carbon dioxide, hydroxyl groups (OH^- ions) are released into the water column, raising the pH. Alkaline conditions (high pH) harm gill membranes on fish and other aquatic organisms. The pH may swing back down during the night as the algae halt photosynthesis and stop scavenging carbon dioxide from carbonates. At night, the algae also continue to respire, which returns carbon dioxide into the water column that can bind up the hydroxyl groups and lower pH. Such fluctuations in pH severely stress aquatic organisms.

Human activities on shore can aggravate physical and chemical conditions in waterbodies. The States report growing concern over instream impacts from removal of shoreline vegetation. Shoreline vegetation shades streams from excessive heat and binds shoreline soils together, which prevents sediment from entering the water column.

Fish Kills Caused by Pollution

The number of fish kills provides a limited indication of pollutant impacts on aquatic life because fish kills do not always result from pollution. Both natural conditions (such as drought, low flow, and warm water temperatures) and pollution can deplete dissolved oxygen in a waterbody and suffocate fish. Pollutants may also weaken fish and make them more susceptible to natural stressors, such as disease. In many cases, investigators cannot determine if pollution, natural causes, or both caused a fish kill because there is little evidence at the site of the fish kill. The exact location of the fish kill may be a mystery because currents can carry fish downstream from the source, further complicating the investigation.

Forty States, Tribes, Commissions, and Territories submitted numerical data about fish kills in their 1994 Section 305(b) reports (Appendix E, Table E-7a, contains individual State data). Two Tribes, the District of Columbia, the Delaware River Basin Commission, and New Hampshire stated that there were no fish kill incidents reported in their waters during 1992 and 1993. Thirty-five States and one Territory reported that pollution caused 737 fish kills in their waters (Figure 7-6). **This figure underestimates the real number of fish kills in the Nation because 15 States did not provide fish kill data and fish kills in remote areas may not be detected or reported to State fish and wildlife officials.**

EPA summarized the number of kills due to pollution, natural conditions, hydrologic modification,

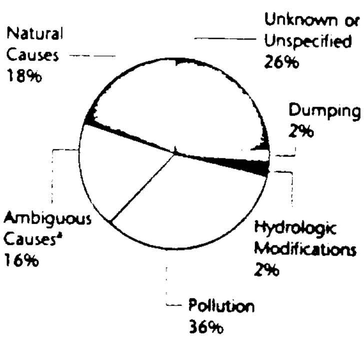
Figure 7-7

Causes of Fish Kills
(29 States reporting 1,454 fish kills)



Based on data contained in Appendix E, Table E-7b.

*Ambiguous causes include low dissolved oxygen without a specified source, algae blooms, red tide, disease, and thermal shock, which may be due to either pollution or natural conditions.

ambiguous causes, and unknown causes. EPA used the following criteria to classify the cause of fish kills:

- Pollution – the State clearly identified a specific pollutant responsible for the kill or clearly stated that oxygen was depleted by pollutants.

- Natural Conditions – the State used the term "natural" to describe the kill.

- Ambiguous Causes – the State attributed the kill to low oxygen concentrations, disease, red tides, algal blooms, or thermal shock and did not specify whether pollution contributed to these problems or not.

- Hydrologic Modifications – the State identified dam construction, dewatering, channelization, or drawdown as the cause of the kill.

- Dumping – throwing unwanted fish into waterbodies.

- Unknown – the State did not identify a cause of the kill.

EPA classified 1,454 total fish kills in 29 States that reported both the total number of fish kills and the number due to pollution (Figure 7-7). Pollution clearly caused about one-third of the fish kills. Natural conditions caused about one-fifth of the fish kills. Almost half of the fish kills were due to unknown or ambiguous causes.

The States reported that toxic pollutants caused more than half (55%) of the fish kills attributed to human activities (Figure 7-8). Toxic pollutants include pesticides,

The States reported that toxic pollutants caused more than half (55%) of the fish kills attributed to human activities.

Figure 7-8

Pollutants Causing Fish Kills

^a Toxic pollutants include pesticides, oil and gas, ammonia, chlorine, and unspecified toxic chemicals.

^b Oxygen-depleting substances include BOD, food processing wastes, and some industrial wastes. Does not include kills attributed to low dissolved oxygen from natural sources.

VOL 12 5576

herbicides (weed killers and defoliants), oil and gasoline products, chlorine, ammonia, metals, and unspecified hazardous substances. Pesticides were the most frequently identified toxic pollutant causing fish kills (Figure 7-9). Many pesticide kills occurred on small private lakes and ponds and impacted few fish, but several pesticide releases killed over 10,000 fish per incident. The States reported that agricultural application and runoff caused most fish kills from pesticides, but the States also reported that golf course maintenance and mosquito abatement projects released pesticides and killed fish. Historically, the most devastating pesticide kills have resulted from train derailments releasing highly concentrated pesticides and herbicides into waterbodies.

Following pesticides, oil and gasoline products (including jet fuel) and chlorine caused many fish kills. The States reported that oil and gasoline products entered waterbodies from traffic accidents, airport runoff, and leaking storage facilities. The States reported that chlorine from drinking water treatment plants, sewage plants, and swimming pools entered waterbodies in lethal concentrations. The States also reported that less common toxic pollutants caused fish kills, including road tar, deicing chemicals used at airports, and fire suppression foam used at the scene of traffic accidents.

The States reported that oxygen-depleting substances caused 20% of the fish kills attributed to human activities. In waterbodies, bacteria consume oxygen when they decompose substances containing organic plant, fish, or animal matter. Oxygen-depleting substances include food products and byproducts (such as molasses, bad milk, and seafood processing waste), agricultural feed, sewage, manure, rendering wastes, and other industrial wastes that contain plant or wood fibers. Sewage and manure can also contain high concentrations of ammonia, which is toxic to fish and other aquatic organisms. The States reported that sewage contributed to 5% of the fish kills due to pollution, and manure from animal and poultry operations contributed to 4% of the kills due to pollution.

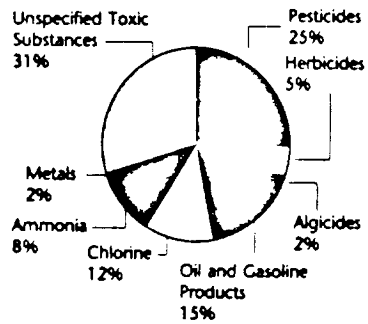
Thirty-five States listed sources of pollution causing fish kills (Figure 7-10). These States identified agriculture as the leading source of fish kills. Agricultural runoff may contain manure and fertilizer, in addition to pesticides and herbicides. Sewage treatment plants followed agriculture as the leading source of fish kills. Sewage treatment plants also release ammonia, nutrients, and oxygen-depleting substances into receiving waters. Sewage treatment plants also cause fish kills by discharging overchlorinated effluent. The other leading sources of fish kills included industry; spills and leaks from storage tanks, trucks, barges, trains, and pipelines; nonagricultural applications of pesticides; general runoff; and drinking water systems. Less common sources of fish kills included swimming pools, petroleum activities, land disposal of wastes, bridge demolition, fountain maintenance, and dam releases.

The summary data on fish kills obscure important variations in the number of fish killed and the value of the species affected during

Figure 7-9

Toxic Pollutants Causing Fish Kills

(33 States reporting 404 fish kills due to toxic pollutants)



Based on data contained in Appendix E, Table E-8b.

individual fish kill incidents. The summary data cannot distinguish a fish kill that affected 10 fish from a fish kill that affected several hundred thousand fish. Numbers of fish killed cannot measure the value of a fish kill because consumers and anglers value some fish species more highly than others, and we do not understand the value of different species in the ecosystem. The States reported that many desirable fish species were killed by pollution, including trout, salmon, perch, mullet, shad, bass, aholehole, crappie, bluegills, menhaden, herring, and catfish.

Sediment Contamination

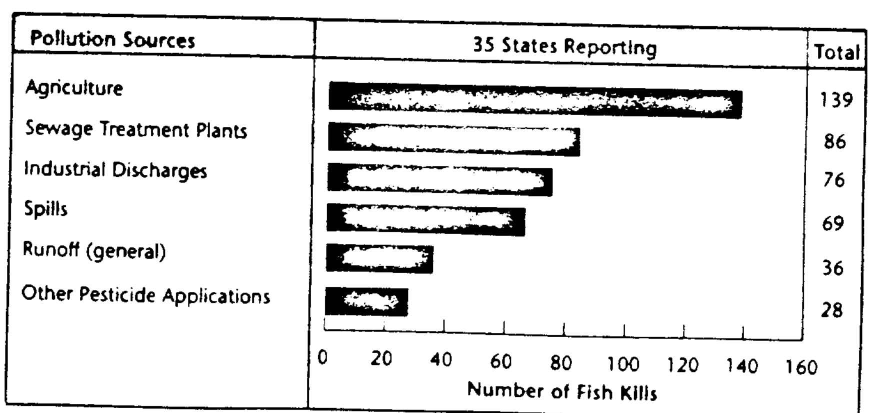
Many waterborne toxic pollutants settle to the bottom and partition between the sediment material and the solution in the interstitial water between the sediment particles. Bacteria degrade some toxicants in sediments, but many toxic contaminants (such as metals and PCBs) persist in sediments for many years after the original toxic source has been eliminated. Disruption of contaminated sediments or natural interactions may reintroduce toxicants into the water column for decades.

Dredging contaminated sediments may also reintroduce toxicants into the water column and food web. Due to these impacts, sediment contamination can obstruct maintenance dredging of harbors and navigation channels. Dredge spoil disposal methods (such as open water dumping, spreading on "reclaimed" lands, and diked containment areas) may also create new aquatic life threats.

Currently, no national criteria are in effect that define harmful concentrations of pollutants in sediment. However, EPA released draft sediment criteria for five pollutants (endrin, dieldrin, phenanthrene, fluoranthene, and acenaphthene) in January of 1994 for public comment and plans to publish final criteria for

Figure 7-10

Sources Associated with Fish Kills



Based on data contained in Appendix E, Table E-9.

the five toxicants in 1996 after responding to final comments. An approach for assessing metals contamination in sediments was presented to the EPA Science Advisory Board in January of 1995. The approach for determining metals toxicity in sediments received a very favorable review.

In 1994, 23 States reported incidents of sediment contamination in their 305(b) reports (see Appendix E, Table E-10, for individual State data). Several States preferred not to list contaminated sites until EPA publishes national criteria for screening sediment data. Other States lack the analytical tools and resources to conduct extensive sediment sampling and analysis. Therefore, the following discussion probably understates the extent of sediment contamination in the Nation's surface waters.

Twenty-two States listed 641 separate sites with contaminated sediments and identified pollutants detected in sediments. These States most frequently listed metals (e.g., mercury, cadmium, and zinc), PCBs, DDT (and its byproducts), chlordane, polyaromatic hydrocarbons (PAHs), and other priority organic toxic chemicals. These States also identified industrial and municipal discharges (past and present), landfills, resource extraction, abandoned hazardous waste disposal sites, and combined sewer overflows as the primary sources of sediment contamination.

EPA develops guidance and information sources to provide States with better tools for assessing and managing sediment contamination, including

- A compendium of sediment assessment methods (Fall 1992)
- Draft Sediment Quality Criteria for Non-ionic Organics (October 1993)
- National Sediment Inventory (Report to Congress, Spring 1996)
  - Evaluation of Contaminated Sediment Sites (Fall 1995)
  - Point Sources Inventory (Fall 1995)
  - Nonpoint Sources Inventory (Fall 1996)
- Sediment Remediation Methods (Spring 1993)
- EPA's Sediment Management Strategy will focus the Agency's resources on preventing, remediating, and managing disposal of dredged contaminated sediments (Summer 1994)
- A testing manual for evaluating sediment disposal in inland waters under Section 404 of the Clean Water Act (Spring 1994)
- Guidance documents describing methods for conducting acute toxicity tests, chronic toxicity tests, and bioaccumulation tests for sediments (Fall 1993)
- Methods for deriving sediment quality criteria for heavy metals (late 1997).

Waters Surveyed for Toxic Contamination

- River miles surveyed: 160,335
- Total river miles: 3.5 million

- Lake acres surveyed: 7.5 million
- Total lake acres: 40.8 million

- Great Lakes miles surveyed: 5,161
- Total Great Lakes shore miles: 5,559

- Estuarine waters surveyed: 7,865 square miles
- Total estuarine waters: 34,388 square miles (excluding Alaska)

- Ocean shore miles surveyed: 205
- Total ocean shore miles: 22,421 (excluding Alaska)

Total Waters Affected by Toxic Pollutants

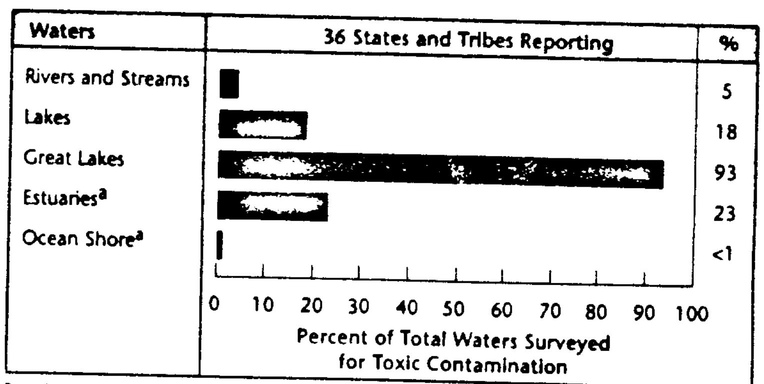
Responding to public concern about toxic pollutants, EPA requested that States track the overall extent of toxic contamination in their surface waters. Forty-two States and Tribes reported the size of waters surveyed for toxicants (either in the water column, sediments, or aquatic organisms) and the total waters found to contain elevated concentrations of toxic pollutants (see Figure 7-11 and Appendix E, Table E-11, for individual State data).

Thirty-six States and Tribes reported that they surveyed toxicants (primarily in the water column) in 160,335 miles of rivers and streams. These States and Tribes surveyed only 5% of the Nation's 3.5 million river miles for toxic contamination. The States and Tribes detected elevated concentrations of toxicants in 25% of the surveyed rivers and streams (Figure 7-12).

Thirty-four States and Tribes reported that they sampled

Figure 7-11

Waters Surveyed for Toxic Contamination



Based on data contained in Appendix E, Table E-11.
[a]Excluding the Alaska shoreline.

toxicants in more than 7.5 million acres of lakes, reservoirs, and ponds. The surveyed acres represent 18% of the Nation's 40.8 million lake acres. The States and Tribes found elevated concentrations of toxicants in 29% of the sampled lake acres.

Seventeen coastal States sampled toxicants in 23% of the Nation's estuarine waters. These States detected elevated toxic concentrations in 26% of the 7,865 square miles of estuarine waters that they sampled.

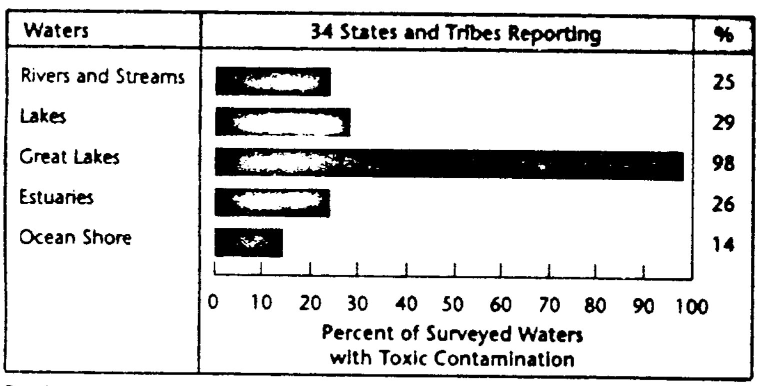
Only three States and the Virgin Islands reportedly surveyed toxicants in ocean shoreline waters. These States found elevated concentrations of toxicants in 14% of the sampled coastline, but this information cannot be applied nationally because the States surveyed less than 1% of the Nation's coastal waters (excluding the Alaska shoreline).

Five States reported that they surveyed most of their Great Lakes' shoreline for toxicants (primarily in fish tissue samples) and detected elevated toxicants in 98% of the shoreline.

The results do not describe the extent of toxic contamination in all waters across the Nation because most toxic pollutants are found in the sediment and the food chain, not in the water column.

Figure 7-12

Percentage of Surveyed Waters with Toxic Contamination



Based on data contained in Appendix E, Table E-11.

HIGHLIGHT HIGHLIGHT HIGHLIGHT

Protecting Our Drinking Water: EPA's Source Water Protection Initiative

Americans have long enjoyed the luxury of safe, affordable drinking water. A rising awareness of water pollution incidents, however, has caused people to be concerned about drinking water quality. Many communities have recognized that preventing the pollution of lakes, rivers, streams, and ground water is the key to ensuring the long-term safety of drinking water. This common sense approach is known as **source water protection**.

The Safe Drinking Water Act emphasizes monitoring and treatment to protect drinking water safety. However, protection based on monitoring and treatment alone is not sufficient. Nearly all groups interested in drinking water safety see a need for stronger efforts to prevent pollution from entering drinking water sources rather than relying solely on water treatment to reduce health threats.

The EPA encourages this prevention-oriented approach and is actively promoting the development of grass roots source water protection activities. As part of the Source Water Protection Initiative, EPA hopes to:

- Restore the public's rights and responsibilities to protect their drinking water
- Raise public confidence in the safety and quality of their drinking water supply
- Reduce the costs of providing safe drinking water.

Wellhead Protection Programs

Many States and communities are currently promoting source water protection in Wellhead Protection (WHP) programs. The 1986 Amendments to the Safe Drinking Water Act established the Wellhead Protection Program to aid communities in protecting their drinking water quality. Through wellhead protection, communities identify the land areas that contribute ground water to public water supply wells. They then develop plans to manage the potential sources of contamination in those vulnerable areas, thereby reducing the likelihood of polluting the drinking water source.

VOL 12

5582

R0038890

HIGHLIGHT HIGHLIGHT HIGHLIGHT

By the end of December 1994, a total of 37 States and Territories had EPA-approved WHP Programs in place. In addition, thousands of local WHP initiatives have been undertaken in communities across the Nation. As of 1993, approximately 3,800 communities that are dependent on ground water for drinking water had complete WHP programs.

Expanded Source Water Protection Goals

The idea of wellhead protection can apply to surface water supplies as well. The EPA is encouraging stronger watershed protection programs, through approaches available under the Federal Clean Water Act, to protect surface waters used for drinking water supplies. Source water protection, for both ground water and surface water, may offer significant advantages to both drinking water purveyors and consumers.

The EPA is planning a National Source Water Protection Workshop in 1996. This workshop will provide communities with the tools and information needed to establish source water protection programs. The workshop will be televised and will target communities that have delineated their source water protection areas and carried out source identification. The workshop will also assist communities in moving toward source management.

The EPA has also set the following interim and long-term source water protection goals:

- By 1997, establish a core network of 10,000 communities with active and comprehensive local WHP programs in place.
- By 1997, incorporate source water protection and source management as priority objectives in projects requiring financial assistance from other Federal programs.
- By 1997, begin to expand source water protection approaches to communities reliant on surface water for drinking water.
- By 2005, have 50% of all community water supplies covered by active and comprehensive local source water protection programs.

Healthy People 2000 Environmenta Health Water Objectives

Background

In the late 1980s the Public Health Service (PHS), working with over 300 government and non-government organizations, began developing *Healthy People 2000*, a set of public health goals and objectives for the year 2000. This initiative was a logical extension of their previous efforts, the *1990 Health Objectives for the Nation*. Both initiatives included sets of health objectives with targets to be achieved at the end of the respective decades. Both also included chapters that specifically focused on improvements in environmental health and objectives related to water quality and its relationship to human health.

Monitoring the 1990 environmental objectives had been severely limited by lack of data and the ongoing development of Federal regulations relating to specific media, including water. Therefore, one focus of *Healthy People 2000* was to identify objectives that were measurable. *Healthy People 2000* includes 16 environmental health objectives, three of which relate water to health; data to monitor these objectives have been available on either an annual or biennial basis since the year 1990 and will be available at least through the year 2000. At the end of 1994, 10 of the 16 objectives showed some progress toward their year 2000 targets.

Figure 1. Waterborne Disease Outbreaks, 1988-92.

5584

R0038892

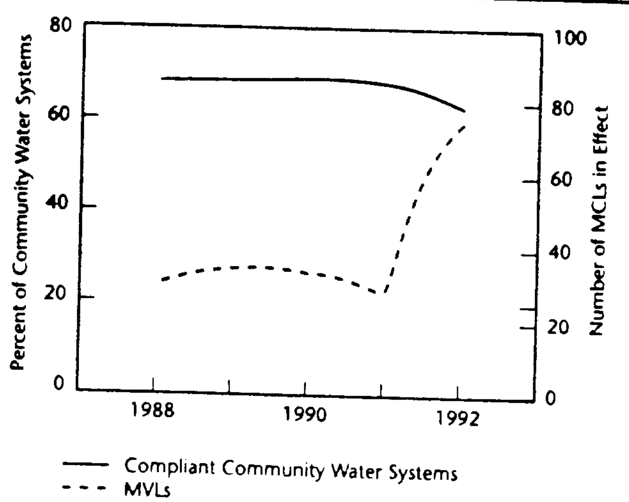
HIGHLIGHT HIGHLIGHT HIGHLIGHT

Water Objectives and Progress

The first of the three water-related objectives calls for a reduction in the number of outbreaks of waterborne diseases from infectious agents and chemical poisonings in drinking water to no more than 11 per year by the year 2000. The numbers of these rare events have fluctuated considerably since 1988 when 16 outbreaks were reported (see Figure 1). While public health officials work to maintain and improve the quality of drinking water, variations in physicians' reports to State Health Departments and the availability of resources to confirm the outbreak as waterborne hamper the monitoring of these outbreaks.

The second objective calls for an increase in the percentage of the population whose drinking water supply meets the Safe Drinking Water Act regulations. The data source for this objective is EPA's Federal Reporting Data System (FRDS). The proportions reported since the 1988 baseline appear to have changed little, but as Figure 2 indicates, the quantity and stringency of testing standards have continued to increase.

Third, *Healthy People 2000* monitors the quality of surface water using EPA's National Water Quality Inventory. As originally



Source: U.S. EPA, Federal Reporting Data System (FRDS).

HIGHLIGHT HIGHLIGHT HIGHLIGHT

written, this objective called for a decrease in the proportion of impaired surface water (specifically, rivers, lakes, and estuaries). The data available to date are shown in Figure 3; however, there were several limitations on accurately monitoring this objective. In consultation with EPA, this objective has been revised and will focus on increases in the proportion of waters that meet the specific designated uses of fish consumption and swimming.

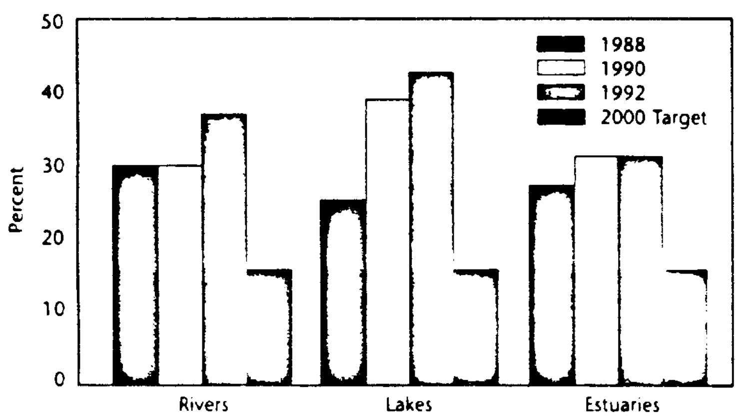

Figure 3. Proportion of Assessed Waters that Do Not Support Beneficial Uses, 1988-1992.

Data and Monitoring

Responsibility for aggregating the data for the 16 objectives is shared by the National Center for Environmental Health, the Agency for Toxic Disease Registry, and the National Center for Health Statistics, all of the Centers for Disease Control and Prevention. The National Institute of Health's National Institute of Environmental Health Sciences also shares the responsibility of monitoring these objectives. There has been extensive cooperation and data sharing with EPA on the beneficial use objective, which relies on data from the States, Tribes, and other jurisdictions. EPA and PHS are currently coordinating the development of EPA's National Environmental Goals and revising the *Healthy People 2000* Environmental Health objectives. The status of the *Healthy People 2000* objectives is reported annually in the *Healthy People 2000 Review*; environmental objectives are monitored using data from the Centers for Disease Control and Prevention, EPA, and other sources.

Mercury Contamination in Maine Lakes

EPA's Region 1 and the Maine Department of Environmental Protection have established a Regional Environmental Monitoring and Assessment Program (R-EMAP) project to study mercury contamination in Maine lakes. The Maine Department of Environmental Protection has found various populations of fish contaminated with heavy metals, PCBs, dioxin, and other chlorinated organic compounds, as stated in the EPA report *R-EMAP Regional Environmental Monitoring and Assessment Program*. Most of the contaminants have been associated with specific point source discharges. In addition, elevated levels of toxic contaminants (especially mercury) have been found in some lake biota at locations where there are no known discharges of toxic contaminants. Maine has issued a statewide advisory on the consumption of fish from any lake in the State. This and prior advisories have been very general and conservative.

Through the Regional Environmental Monitoring and Assessment Program, which uses the Environmental Monitoring and Assessment Program (EMAP) probability-based sampling grid and methodologies, the Maine Department of Environmental Protection has been able to conduct a statewide assessment of contaminated fish in Maine lakes. The project design and techniques adopted from EMAP are expected to enable scientists to conduct statistical analyses of the relationships of such intrinsic factors as age, size, and species of fish; limnological factors; and extrinsic factors (for example, land use or atmospheric deposition). The analyses are needed to issue more specific advisories identifying, in particular, high-risk lakes, species, and size classes. Also, this information is expected to be helpful in identifying future management needs to reduce mercury levels in the Maine lacustrine environment.

Chesapeake Bay Foundation, Richmond, VA

State and Tribal Recommendations

In their 1994 Section 305(b) reports, 40 States, Territories, and Tribes made recommendations for improving water quality management programs in order to achieve the goals of the CWA. The recommendations encompass a range of actions at the Congressional, Federal, State, Tribal, Territorial, and local levels and are often expressed in terms of State, Tribal, and Territorial objectives or continuing needs. It should be emphasized that the States, Tribes, and Territories reported the following recommendations and that this discussion does not attempt to assess the merits of their recommendations. Nor should this discussion be construed as an EPA or Administration endorsement of any State, Tribal, or Territorial recommendation. Many of the recommendations do, however, coincide with current EPA program concerns and priorities.

The most frequently reported recommendations address five major concerns:

- Nonpoint source abatement
- Financial and technical support from Federal agencies
- Interagency data sharing and management
- Watershed initiatives
- Ground water management.

Other concerns less frequently reported include toxic pollutants, lake management, public education, pollution prevention, waste management for animal and poultry operations, water quantity impacts on water quality, and multimedia cycling of pollutants among air, water, and soil. The following discussion summarizes the recommendations most frequently reported by the States, Tribes, and Territories. These recommendations are often linked and interdependent. For example, many States, Tribes, and Territories recommend that Federal agencies provide financial and technical support to implement watershed initiatives that provide a framework for monitoring and managing nonpoint source pollution. The following discussion touches on the connections between State, Tribal, and Territorial concerns and recommendations.

Nonpoint Source Abatement and Watershed Protection Initiatives

Recommendations most often cited by the States, Tribes, and Territories concern the identification, prevention, and control of nonpoint sources (NPSs) of pollution, such as agricultural runoff and runoff from construction sites. The States and other entities most frequently cite

R0038898

the need for additional funding for the development of better monitoring and assessment methods to detect NPS impacts, identify specific NPSs responsible for impacts, and measure the effectiveness of NPS controls. Many States reported that new monitoring methods are needed to distinguish point source impacts from NPS impacts and to identify specific nonpoint sources responsible for water quality degradation. For example, **Rhode Island**'s 305(b) report states:

> Decision makers at this time do not have adequate instream and site-specific water quality data. NPS management plans are currently based on generic nonpoint pollution source "types" (e.g., agriculture, urban stormwater, etc.) and cannot provide adequate prioritization of BMP controls on a specific watershed or subwatershed level.

Rhode Island suggests that a small percentage of CWA Section 319 NPS Federal funds be made available for wet weather NPS monitoring. Rhode Island reports that additional funding for NPS monitoring is needed to update their assessment of NPS impacts and determine the effectiveness of implemented BMPs.

Many States link nonpoint source monitoring and abatement to adoption of a watershed management approach. The States report that a watershed protection approach can be used to target waterbodies for intensive NPS monitoring and to integrate local, State, and Federal efforts to control NPS impacts. The watershed approach encourages local involvement and enables States to maximize efficient use of funds by coordinating point source controls and NPS management. For example, **New Jersey**'s 305(b) report states:

> A watershed approach can require intensive site-specific monitoring designed to assess pollution sources and loading and fill data gaps . . . Detailed assessments of pollution sources, both point and nonpoint, on a local basis, would allow management efforts to institute pollution controls on a finely detailed level. Working with local governmental agencies and environmental/citizen groups can provide the Department [of Environmental Protection] with enormous amounts of information regarding local activities, land uses, and point sources that either can potentially or are known to impair local water quality. These same agencies and groups can act to change land uses, zoning regulations, agricultural practices, etc.

Nebraska's 305(b) report suggests that States and other governing entities can use the watershed approach to prioritize watersheds for more efficient allocation of funds to implement NPS projects:

> The Nebraska Department of Environmental Quality should continue with its systematic assessment of watersheds identified as either suspected or unknown with regards to nonpoint source pollution impacts. These assessments

State and Tribal Recommendations

In their 1994 Section 305(b) reports, 40 States, Territories, and Tribes made recommendations for improving water quality management programs in order to achieve the goals of the CWA. The recommendations encompass a range of actions at the Congressional, Federal, State, Tribal, Territorial, and local levels and are often expressed in terms of State, Tribal, and Territorial objectives or continuing needs. It should be emphasized that the States, Tribes, and Territories reported the following recommendations and that this discussion does not attempt to assess the merits of their recommendations. Nor should this discussion be construed as an EPA or Administration endorsement of any State, Tribal, or Territorial recommendation. Many of the recommendations do, however, coincide with current EPA program concerns and priorities.

The most frequently reported recommendations address five major concerns:

- Nonpoint source abatement
- Financial and technical support from Federal agencies
- Interagency data sharing and management
- Watershed initiatives
- Ground water management.

Other concerns less frequently reported include toxic pollutants, lake management, public education, pollution prevention, waste management for animal and poultry operations, water quantity impacts on water quality, and multimedia cycling of pollutants among air, water, and soil. The following discussion summarizes the recommendations most frequently reported by the States, Tribes, and Territories. These recommendations are often linked and interdependent. For example, many States, Tribes, and Territories recommend that Federal agencies provide financial and technical support to implement watershed initiatives that provide a framework for monitoring and managing nonpoint source pollution. The following discussion touches on the connections between State, Tribal, and Territorial concerns and recommendations.

Nonpoint Source Abatement and Watershed Protection Initiatives

Recommendations most often cited by the States, Tribes, and Territories concern the identification, prevention, and control of nonpoint sources (NPSs) of pollution, such as agricultural runoff and runoff from construction sites. The States and other entities most frequently cite

should document the presence and quantify the magnitude of water quality impacts and beneficial use impairment due to nonpoint sources. Through the Nebraska Nonpoint Source Management Program, a listing of priority watersheds should be defined and action plans developed in order to expedite the funding and implementation process for nonpoint source projects.

The States, Tribes, and Territories also recommend implementing a watershed approach to address other water quality issues (in addition to NPS pollution) within a holistic strategy. **Illinois'** Section 305(b) report recommends that Federal agencies grant flexibility to the States so that they can incorporate numerous program elements into a watershed approach:

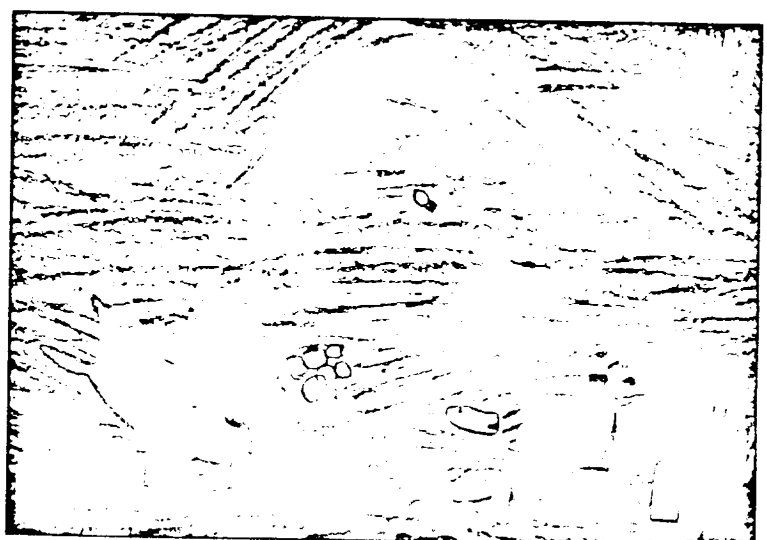
> As States' watershed planning and management efforts continue to evolve, Federal oversight of various program activities will need to provide States with flexibility needed to implement a watershed approach. Resources and incentives will need to be provided to assist States in making further progress, particularly in regard to: data availability/coordination; incorporating ground water resource issues; determination of those watersheds needing to develop watershed implementation plans based on available resources; and coordination with other agencies and the public.

Illinois' report also refers to the links between the availability of financial resources, implementation of a watershed approach, and management of NPS pollution:

> In approaching water quality from a watershed approach, there is an immediate need for assessment and planning related to correction and prevention of NPS pollution. This effort will require both resources and time to be accomplished correctly.

Although many States, Tribes, and Territories report that implementing a watershed approach may require additional financial support, several States recommend adopting the watershed approach to maximize efficient use of their declining budgets. **Massachusetts' 305(b)** report states:

Many States, Tribes, and Territories link NPS monitoring and abatement to adoption of a watershed management approach.



Steve Winward, age 8, Kings Park Elementary, Springfield, VA

> Better coordination and exchange of information with other agencies is needed because of the Department [of Environmental Protection]'s decreasing monitoring resources. To help alleviate this problem, the Commonwealth has adopted a watershed approach. This approach ensures interagency and intergovernmental coordination, allowing limited resources to be used to their fullest.

Many States and other governing entities report that shrinking budgets are a widespread problem that threatens existing water quality monitoring and assessment programs in addition to new initiatives.

Financial and Technical Support

Most States, Tribes, and Territories expressed a common concern that they will not be able to maintain current water quality monitoring and assessment activities if Federal funding shrinks. **Rhode Island's** 1994 305(b) report states:

> Federal funding for monitoring work is rapidly decreasing on an annual basis. At the same time, States are under severe fiscal constraints in their annual budget projections. Present funding does not provide for a long-term commitment to continue sampling such new water quality stations. There is no easy solution currently available to solve this fiscal dilemma. Citizens' monitoring groups will most likely become an important resource in the State's efforts to follow present water quality conditions over future years, but such efforts cannot replace State mandates to monitor trends and present water quality conditions.

Wisconsin's 305(b) report expresses the views reported by numerous States, Tribes, and Territories:

> With the shift in attention to problems more diverse and complex, it is essential that more and better uniform data collection and analysis procedures be established to accurately determine the condition of the Nation's waters and identify trends in water quality degradation and track progress . . . One problem with many water quality programs is there is no mechanism for funding the monitoring needed for good science.

New Mexico recommends full funding for all research programs related to water quality:

> The U.S. Congress should provide adequate funding to EPA, the USGS, and other appropriate Federal agencies to support basic ecological, hydrologic, medical, public health, and other research relevant to water quality protection and to support technical assistance and technology transfer to the States.

The States and other entities are also concerned about funding for water quality management

VOL 12

5594

R0038902

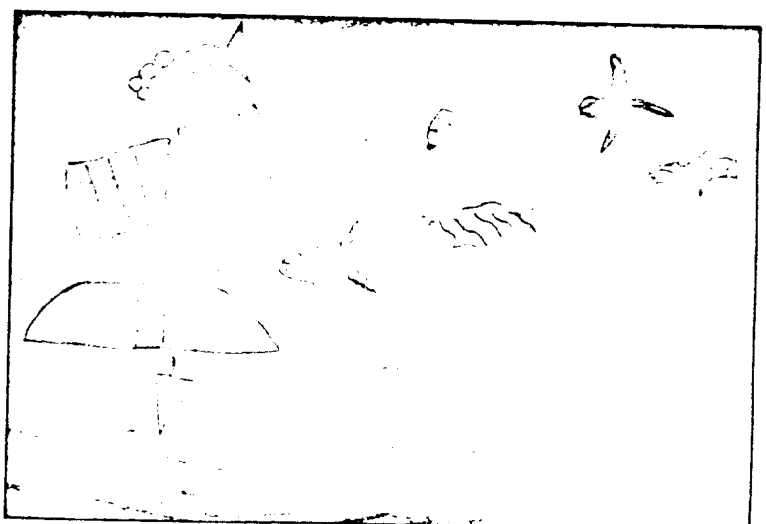
programs in general. Many States specifically request that Congress maintain funding for the CWA Section 314 Clean Lakes Program. In most States, lake monitoring lags behind monitoring of rivers and streams. Without Section 314 grants, many States could not support lake monitoring and assessment activities or restoration projects. Resources and incentives are also needed to address: data availability and coordination, ground water resource issues, wetlands issues, fish contamination, interagency coordination, public education, regulatory enforcement and compliance, biological criteria development, pollution prevention and source reduction, land management practices, and developing technologies.

Both Tribes and States recommend that Congress change funding allocation rules in the CWA that limit funds for Tribal water quality management programs. The **Campo Indian Reservation's** 305(b) report recommends that Congress revise CWA Section 518 to remove the cap on Federal funding for Tribal water programs:

> Although the CWA was amended in 1987 to treat Indian Tribes as States under certain CWA sections, funding available to Tribes has not followed the designation. A concern of paramount importance to the success of water quality management programs for the Campo Indian Reservation, and all other Indian Reservations pursuing authority under sections of the CWA, is the adequate amount of CWA (e.g., Sections 106 and 319) funding available for Indian Tribes. Under Section 518 of the CWA, a maximum budget for Indian Tribes has been set at less than 1% of the U.S. EPA's CWA Section budget. Considering that there are 345 Reservations in the U.S., the allocated funding falls far short of treating Indian Tribes as States for funding under CWA Sections. A more reasonable allocation for funding Indian Tribes under the CWA would be to replace the less than 1% maximum with minimum funding amounts.

New Mexico's 305(b) report also recommends expanding funding for Tribal water quality programs while maintaining State funding:

> The funding set aside for Indian Tribes in the CWA puts Tribes in direct competition with States



Kings Park Elementary, 3rd grade, Springfield, VA

Th...
T...
th...
v...
and g...
of national conc...

for the limited available Federal funding. The funding provided to Tribes is inadequate to develop or implement effective water quality programs. The U.S. Congress should provide sufficient dedicated funds to Indian Tribes so that they can develop and implement effective water quality programs. These funds should be in addition to, not in place of, monies allocated to the States.

Many States, Territories, and the District of Columbia stressed the need for continued appropriations to maintain or expand their Revolving Fund programs for wastewater treatment plant construction. The States and other governing entities are also concerned about the high cost of abating combined sewer overflows (CSOs). Michigan states that municipalities need funds to implement State CSO control strategies. Rhode Island suggests that EPA and Congress allocate special funding for implementing CSO mitigation measures that would be administered through the Revolving Loan programs.

The States, Tribes, and Territories also request that EPA continue to provide technical support and guidance on issues of national concern. Specifically, their recommendations include the following:

- Develop technical guidance for evaluating sources of runoff pollution
- Provide additional guidance for assessing waterbodies with biological and chemical data and establishing biological standards
- Provide guidance on stormwater and CSO permitting
- Finalize sediment contamination criteria
- Improve consistency in the implementation of whole effluent toxicity limits in the National Pollutant Discharge Elimination System (NPDES) program
- Continue to sponsor professional training courses for the States and other governing entities on the subjects of permit writing, compliance inspections and sampling, and enforcement
- Provide resources and technical support for geographic information systems.

In addition, the States and other governing entities look to EPA to improve coordination among water quality programs.

Interagency Data Sharing and Management

The need for better coordination among State, Tribal, Territorial, and Federal water quality programs is an underlying theme of many of the Section 305(b) reports. Coordination is needed among agencies as well as across programs in all areas of water quality concerns. Better coordination can eliminate duplicative monitoring activities (thereby stretching limited funds) and ensure that generated data are of adequate quality to be shared among programs. Improved coordination and data sharing are also essential elements of a watershed approach.

Twenty-one States, Tribes, and Territories expressed concern that data sharing is restricted by the lack of common protocols for data collection, analysis, and storage. Arizona's 305(b) report states:

> Water quality information is collected and disseminated by numerous Federal, State, and local governments throughout Arizona. The ability of different agencies to use this vast database is hampered by many issues, including data collection approaches, comparable methods, translation of databases, and policies on data and information sharing.

Several States reference the work of the Intergovernmental Task Force on Monitoring (ITFM) as a positive approach for addressing data comparability and sharing issues. In addition to ITFM participation, the States and other entities suggest that EPA work with them to develop national monitoring and assessment strategies. **Wisconsin** suggests that

- U.S. EPA should develop a national monitoring strategy for the assessment of the Nation's waters, including provisions for making funding of monitoring part of each program and accommodating State priorities for data collection and waterbody evaluation.

- U.S. EPA's monitoring programs should support ecosystem management by using certain flora and fauna from the ecosystem being evaluated as "ecosystem indicators" to set a standard for when a waterbody is in good health.

Data sharing is of special interest to Tribes because Tribal water quality is usually dependent upon water quality and watershed activities outside the jurisdiction of the Tribe. The Tribes need data from outside of their jurisdictions to identify sources of water quality degradation and to negotiate solutions with non-Tribal parties. The **Soboba Band of Mission Indians'** 305(b) report states:

> Negotiations are presently beginning with major off-Reservation water users, with the aim of fairly and finally apportioning the waters of the basin. Nondegradation of water quality will be the basic element of the Band's position in these negotiations. As part of these negotiations, sharing and cooperative analysis of data on the hydrology and water quality of the San Jacinto watershed will be necessary. It is the Band's hope and intent that this affirmative approach to water management should lead to a systematic, integrated water quality monitoring program for the basin that will be of lasting benefit to all water users.

Ground Water Concerns

Many of the States and other governing entities recommend that EPA develop a comprehensive framework for coordinating programs and eliminating inconsistencies among Federal programs that address ground water. However, the States also suggest that they should continue to play the primary role in

Many States

managing and implementing ground water protection programs. For example, New Mexico's 305(b) report states:

> Existing Federal statutes including the CWA, the Safe Drinking Water Act, the Resource Conservation and Recovery Act, the Insecticide, Fungicide and Rodenticide Act, and the Comprehensive Environmental Response, Compensation, and Liability Act of 1980 (Superfund) establish differing criteria and procedures to control ground water quality . . . These programs have not addressed ground water in a coordinated manner and have created administrative and statutory inconsistencies which may be obstacles to effective ground water quality management. Inconsistencies between Federal laws relating to ground water quality should be removed . . . The U.S. Congress should adopt legislation providing that once a State adopts ground water quality standards satisfying national minimum criteria, then those State standards become the basis for cleanup or control of any and all Federal programs relating to protection of ground water in the State.

Other States concur that EPA should coordinate ground water management and provide technical support to States and other jurisdictions implementing specific ground water protection and restoration measures at the local level. Wisconsin's 305(b) report states:

> U.S. EPA should develop a coordinated ground water management strategy in conjunction with other appropriate Federal agencies that includes a drought strategy and allocation scheme. U.S. EPA should serve as a resource agency that provides technical assistance for ground water quality issues as opposed to mandating a process and administrative oversight. U.S. EPA needs to provide guidance and regional consistency on the use of nitrogen fertilizers due to increasing concentrations of harmful nitrate-nitrogen in ground water nationwide.

Michigan's 305(b) report states:

> The State is restricted in some areas of ground water program development by a lack of action at the Federal level. To avoid preemption problems, the State relies on the Federal government to set certain standards that are later incorporated into State programs. The State is also relying on the Federal government for basic scientific data relating to the health impacts of the synergistic effects of the chemical combinations most often found in contaminated water supplies.

VOL 12

5598

A number of States, Tribes, and Territories expressed concerns about the continued ability to fund State and Federal ground water research and protection programs. Tribes express numerous concerns about ground water quality because many Tribal lands lack reliable surface water supplies due to upstream withdrawals, arid climates, or a lack of surface waters within Tribal boundaries. Even Tribes in non-arid climates rely on ground water to supply large portions of their domestic water supply. The Tribes recommend that ground water monitoring be enhanced on Tribal lands and development of wellhead protection programs move forward.

Conclusions

In general, the States, Tribes, and Territories recommend that EPA continue to provide general guidance for establishing minimum program elements while allowing the States flexibility for developing and implementing specific programs tailored to their individual conditions and needs. The States and other governing entities also recommend that Congress continue to fund the development and distribution of technical support by EPA and other Federal agencies, including the USGS. Many States, Tribes, and Territories reported that funding for water quality monitoring should be maintained, if not increased, because monitoring plays a critical role in defining water quality issues and measuring the effectiveness of water quality management programs.

The States and other entities also recommend that EPA continue to advocate the watershed approach for integrating monitoring activities, data sharing, ground and surface water management, wetlands management, interagency activities, and point and nonpoint source management. However, the States and other entities suggest that they should maintain control over the development and implementation of the watershed approach within their jurisdictions.

Individual State and Territorial Summaries

This section provides individual summaries of the water quality survey data reported by the States and Territories in their 1994 Section 305(b) reports. The summaries provide a general overview of water quality conditions and the most frequently identified water quality problems in each State and Territory. However, the use support data contained in these summaries are not comparable because the States and Territories do not use comparable criteria and monitoring strategies to measure their water quality. States and Territories with strict criteria for defining healthy waters are more likely to report that a high percentage of their waters are in poor condition. Similarly, States with progressive monitoring programs are more likely to identify water quality problems and to report that a high percentage of their waters do not fully support designated uses. As a result, one cannot assume that water quality is worse in those States and Territories that report a high percentage of impacted waters in the following summaries.

Environmental Management
Water Quality Branch
P.O. Box 301463
Montgomery, AL 36130-1463
(334) 271-7829

Surface Water Quality

Since enactment of the Clean Water Act of 1972, water quality has substantially improved near industrial and municipal facilities. However, pollution still prevents about 29% of the surveyed stream miles, 15% of the surveyed lake acres, and 20% of the surveyed estuaries from fully supporting aquatic life use. Oxygen-depleting wastes and nutrients are the most common pollutants impacting rivers and coastal waters. The leading sources of river pollution include agriculture, municipal wastewater treatment plants, and resource extraction. In coastal waters, the leading sources of pollution are urban runoff and storm sewers, municipal sewage treatment plants, and combined sewer overflows.

Toxic priority organic chemicals impact the most lake acres, usually in the form of a fish consumption advisory. These pollutants may accumulate in fish tissue at a concentration that greatly exceeds the concentration in the surrounding water. Unknown sources and industrial dischargers are responsible for the greatest acreage of impaired lake waters.

Special State concerns include impacts from the poultry broiler industry, forestry activities, animal waste runoff, and hydroelectric generating facilities.

Ground Water Quality

The Geological Survey of Alabama monitoring well network indicates relatively good ground water quality. However, the number of ground water contamination incidents has increased significantly in the past few years due to better reporting under the Underground Storage Tank Program and increased public awareness of ground water issues. Alabama has established pesticide monitoring and a Wellhead Protection Program to identify nonpoint sources of ground water contamination and further protect public water supplies.

Programs to Restore Water Quality

In 1992, the Alabama Department of Environmental Management (ADEM) initiated the Flint Creek watershed project to simultaneously manage the many sources degrading Flint Creek, including intensive livestock and poultry operations, crop production, municipal dischargers, household septic systems, widespread littering, and urban runoff. Numerous Federal, State, and local agencies play a role in the watershed project, which includes data collection activities, public education and outreach, and development of a total maximum daily load (TMDL) model for the watershed. The model output will show the mix of point and nonpoint loadings that can be permitted without violating instream water quality standards. ADEM expects to increase use of the watershed protection approach.

Programs to Assess Water Quality

Alabama's surface water monitoring program includes a fixed station ambient network, reservoir sampling, fish tissue sampling, intensive wasteload allocation surveys, water quality demonstration surveys, and compliance monitoring of point source discharges. As a first step in establishing biological criteria, ADEM is assessing the habitats and corresponding resident biota at several candidate reference streams.

Surface Water Quality

Good water quality fully supports swimming uses in 59% of Arizona's surveyed river miles and 94% of their surveyed lake acres. However, Arizona reported that 51% of their surveyed stream miles and 28% of their surveyed lake acres do not fully support aquatic life uses. Arizona reported that metals, turbidity, salinity, and suspended solids were the stressors most frequently identified in streams. The leading stressors in lakes were salinity, metals, inorganics, and low dissolved oxygen. Natural sources, agriculture, and hydrologic modification (stream bank destabilization, channelization, dam construction, flow regulation, and removal of shoreline vegetation) were the most common sources of stressors in both streams and lakes, followed by resource extraction (mining) in streams and urban runoff in lakes. Nonpoint sources played a role in degrading 96% of the impaired river miles and 93% of the impaired lake acres.

Ground Water Quality

Arizona is gradually establishing a network of water quality index wells in principal aquifers to measure ground water quality conditions and document future trends. Existing data indicate that ground water generally supports drinking water uses, but nitrates, petroleum products, volatile organic chemicals, heavy metals, pesticides, radioactive elements, and bacteria cause localized contamination in Arizona. Both natural sources and human sources (including agriculture, leaking underground storage tanks, and septic tanks) generate these contaminants.

The State has established 50 ground water basin boundaries, four of which are designated Active Management Areas because they encompass the largest population centers with the greatest ground water demands. A Comprehensive State Groundwater Protection Program has been initiated as a demonstration project in Tucson. Under this program, the State will work with all interested parties to set priorities for ground water management and mitigate existing water quality problems.

Programs to Restore Water Quality

Arizona's nonpoint source control program integrates regulatory controls with nonregulatory education and demonstration projects. Regulatory programs include the Aquifer Protection Permit Program, the Pesticide Contamination Program, and best management requirements for controlling nitrogen at concentrated animal feeding operations. The State is also developing best management practices for timber activities, grazing activities, urban runoff, and sand and gravel operations. Arizona's point source control program encompasses planning, facility construction loans, permits, pretreatment, inspections, permit compliance, and enforcement.

Programs to Assess Water Quality

Recently, Federal and State agencies increased efforts to coordinate monitoring, provide more consistent monitoring protocols, and provide mechanisms to share data, spurred by tightened budgets. Monitoring programs in Arizona include a fixed station network, complaint investigations and special studies, priority pollutant monitoring, and monitoring to support biocriteria development. ADEQ will develop narrative biological criteria with biological, physical, and chemical data collected at over 100 biological reference sites in 1992, 1993, and 1994.

Bill Keith
Arkansas Department of Pollution Control and Ecology
P.O. Box 8913
Little Rock, AR 72219-8913
(501) 562-7444

Surface Water Quality

The Arkansas Department of Pollution Control and Ecology (DPCE) reported that 56% of their surveyed rivers and streams and 100% of their surveyed lake acres have good water quality that fully supports aquatic life uses. Good water quality also fully supports swimming use in 81% of the surveyed river miles and 100% of the surveyed lake acres. Siltation and turbidity are the most frequently identified pollutants impairing Arkansas' rivers and streams, followed by bacteria and nutrients. Agriculture is the leading source of pollution in the State's rivers and streams and has been identified as a source of pollution in four lakes. Municipal wastewater treatment plants, mining, and forestry also impact rivers and streams. Arkansas has limited data on the extent of pollution in lakes.

Special State concerns include the protection of natural wetlands by mechanisms other than discharge permits and the development of more effective methods to identify nonpoint source impacts. Arkansas is also concerned about impacts from the expansion of confined animal production operations and major sources of turbidity and silt including road construction, road maintenance, riparian land clearing, streambed gravel removal, and urban construction.

Ground Water Quality

Nitrate contamination was detected in some domestic wells sampled in portions of the State undergoing rapid expansion of poultry and livestock operations, including northwest Arkansas, the Arkansas River Valley, and southwest Arkansas. In northwest Arkansas, nitrate contamination was documented in 5% to 7% of the domestic wells sampled. Wells sampled in pristine areas of northwest Arkansas were not contaminated.

VOL 12

5608

Programs to Restore Water Quality

Arkansas has focused nonpoint source management efforts on controlling waste from confined animal production operations. Arkansas utilizes education, technical assistance, financial assistance, and voluntary and regulatory activities to control nonpoint source pollution from poultry, swine, and dairy operations. Liquid waste systems are regulated by permit and dry waste systems are controlled by voluntary implementation of BMPs in targeted watersheds. Water quality is monitored during watershed projects to evaluate the effectiveness of the BMPs.

Programs to Assess Water Quality

Arkansas classifies its water resources by ecoregion with similar physical, chemical, and biological characteristics. There are seven ecoregions including the Delta, Gulf Coastal, Ouchita Mountain, Arkansas River Valley, Boston Mountain, and Ozark Mountain Regions. By classifying water resources in this manner, Arkansas can identify the most common land uses within each region and address the issues that threaten the water quality.

The State has increased surface water and ground water monitoring to determine the fate of animal waste applied to pastures. Arkansas also conducted 10 water quality surveys in watersheds throughout the State to determine point and nonpoint sources of pollution impacting water quality.

(916) 657-0642

Surface Water Quality

Siltation, pesticides, nutrients, and bacteria impair the most river miles in California. The leading sources of degradation in California's rivers and streams are agriculture, unspecified nonpoint sources, forestry activities, urban runoff and storm sewers, and resource extraction. In lakes, siltation, metals, and nutrients are the most common pollutants. Construction and land development pose the greatest threat to lake water quality, followed by urban runoff and storm sewers, forestry, and land disposal of wastes.

Metals, pesticides, trace elements, and unknown toxic contaminants are the most frequently identified pollutants in estuaries, harbors, and bays. Urban runoff and storm sewers are the leading source of pollution in California's coastal waters, followed by municipal sewage treatment plants, agriculture, hydrologic and habitat modifications, resource extraction, and industrial dischargers. Oceans and open bays are degraded by urban runoff and storm sewers, agriculture, and atmospheric deposition.

Ground Water Quality

California assigns beneficial uses to its ground water. Salinity, total dissolved solids, and chlorides are the most frequently identified pollutants impairing use of ground water in California. The State also reports that trace inorganic elements, flow alterations, and nitrates degrade over 1,000 square miles of ground water aquifers.

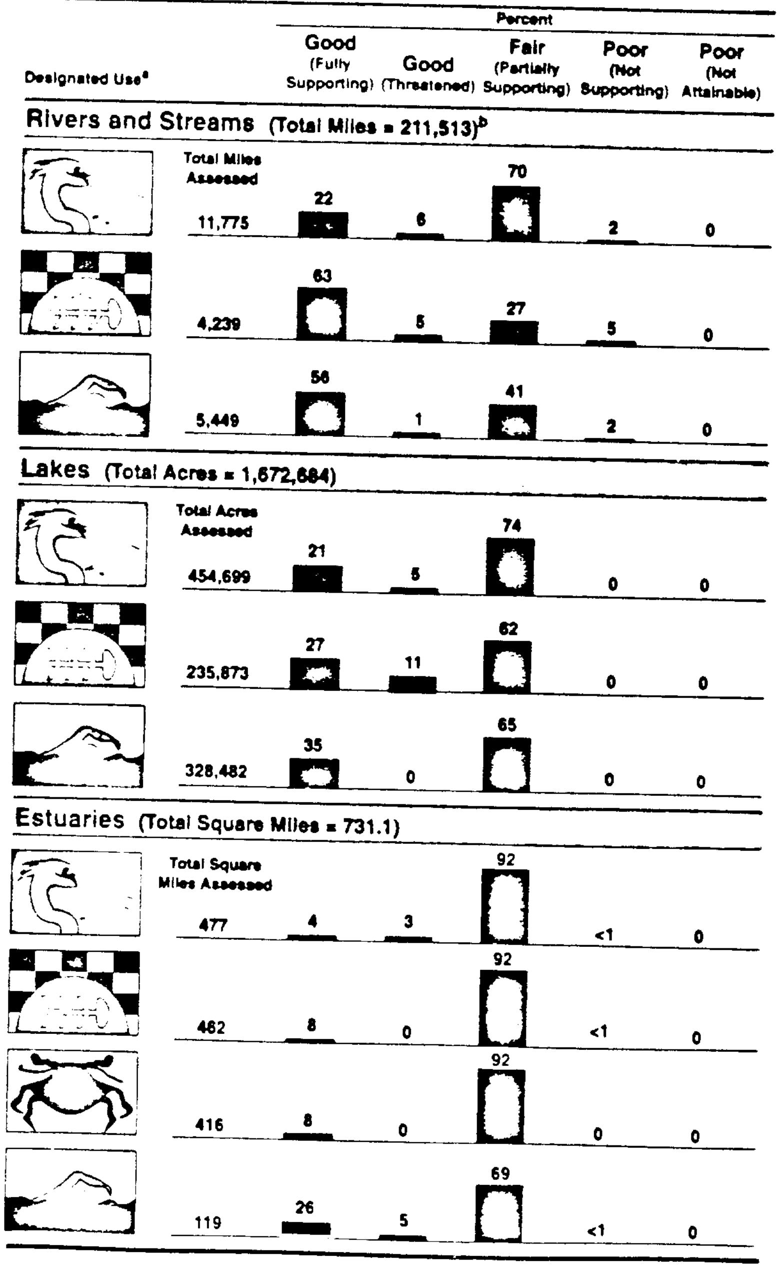
Programs to Restore Water Quality

No information was provided in the 1994 305(b) report.

Programs to Assess Water Quality

No information was provided in the 1994 305(b) report.

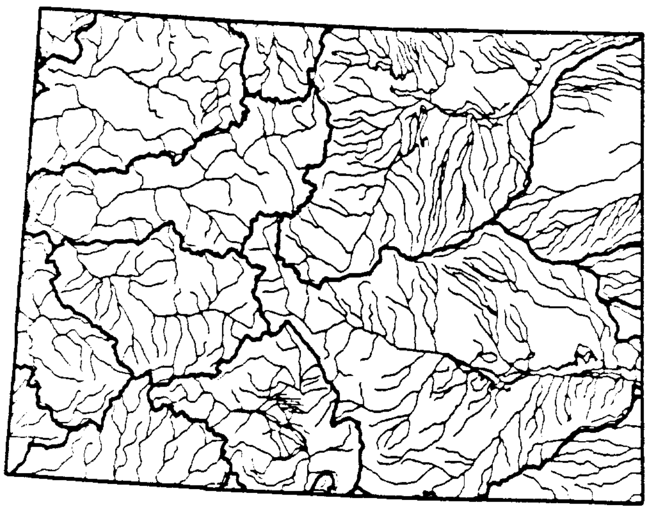
Individual Use Support in California



[a] A subset of California's designated uses appear in this figure. Refer to the State's 305(b) report for a full description of the State's uses.

[b] Includes nonperennial streams that dry up and do not flow all year.

Colorado



— Basin Boundaries
(USGS 6-Digit Hydrologic Unit)

For a copy of the Colorado 1994 305(b) report, contact:

John Farrow
Colorado Department of Public Health and Environment
Water Quality Control Division
4300 Cherry Creek Drive, South
Denver, CO 80222-1530
(303) 692-3575

Surface Water Quality

Colorado reports that 89% of its surveyed river miles and 91% of its surveyed lake acres have good water quality that fully supports designated uses. Metals are the most frequently identified pollutant in rivers and lakes. High nutrient concentrations also degrade many lake acres. Agriculture and mining are the leading sources of pollution in rivers. Agriculture, construction, urban runoff, and municipal sewage treatment plants are the leading sources of pollution in lakes.

Ground Water Quality

Ground water quality in Colorado ranges from excellent in mountain areas where snow fall is heavy, to poor in alluvial aquifers of major rivers. Naturally occurring soluble minerals along with human activities are responsible for significant degradation of some aquifers. Nitrates and salts from agricultural activities have contaminated many of Colorado's shallow aquifers. In mining areas, acidic water and metals contaminate aquifers. Colorado protects ground water quality with statewide numeric criteria for organic chemicals, a narrative standard to maintain ambient conditions or Maximum Contaminant Levels of inorganic chemicals and metals, and specific use classifications and standards for ground water areas. Colorado also regulates discharges to ground water from wastewater treatment impoundments and land application systems with a permit system.

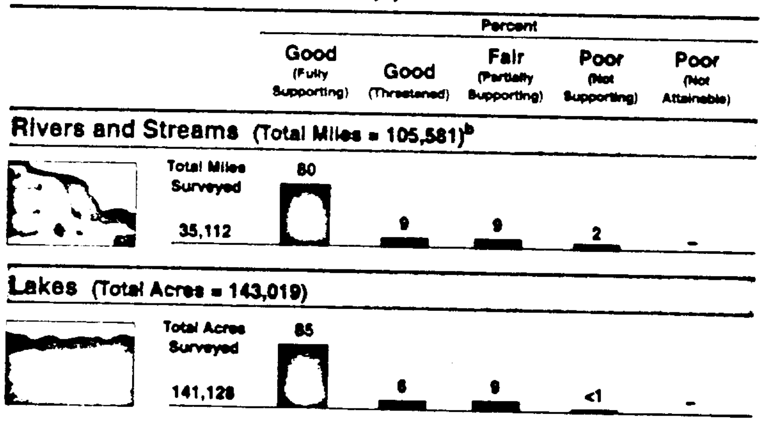
Programs to Restore Water Quality

Colorado's nonpoint source program supports a wide range of projects. Ten projects were funded to identify appropriate treatment options for waters polluted by abandoned mines. Several projects identified and funded implementation of good management practices for riparian (streamside) areas. Under another project, Colorado developed agreements with the U.S. Bureau of Land Management and the U.S. Forest Service to ensure that these agencies apply effective best management practices to control nonpoint runoff from grazing, timber harvesting, and road construction activities on Federal lands.

Programs to Assess Water Quality

During the 1994 305(b) reporting cycle, Colorado switched over from a statewide monitoring program to a basinwide monitoring strategy. The basinwide monitoring strategy allows that State to intensify monitoring in one basin per year, rather than perform infrequent sampling statewide. Colorado retained some of the old fixed-station sampling sites to monitor statewide trends in water quality conditions.

Overall[a] Use Support in Colorado



- Not reported.
[a] Overall use support is presented because Colorado did not report individual use support in their 1994 Section 305(b) report.

Connecticut

Hartford, CT 06106-5127
(860) 424-3827 or (860) 424-3020

Surface Water Quality

Connecticut has restored over 300 miles of large rivers since enactment of Connecticut's State Clean Water Act in 1967. Back in 1967, about 663 river miles (or 74% of the State's 893 miles of large rivers and streams) were unfit for fishing and swimming. In 1994, Connecticut reported that 222 river miles (25%) do not fully support aquatic life uses and 248 miles (28%) do not support swimming due to bacteria, PCBs, metals, oxygen-demanding wastes, ammonia, nutrients, and habitat alteration. Sources of these pollutants include urban runoff and storm sewers, industrial dischargers, municipal sewage treatment plants, and in-place contaminants. Threats to Connecticut's reservoir and lake quality include failing septic systems, erosion and sedimentation from construction and agriculture, agricultural wastes, fertilizers, and stormwater runoff.

Hypoxia (low dissolved oxygen) is the most widespread problem in Connecticut's estuarine waters in Long Island Sound. Bacteria also prevent shellfish harvesting and an advisory restricts consumption of bluefish and striped bass contaminated with PCBs. Connecticut's estuarine waters are impacted by municipal sewage treatment plants, combined sewer overflows, industrial discharges and runoff, failing septic systems, urban runoff, and atmospheric deposition. Historic waste disposal practices also contaminated sediments in Connecticut's harbors and bays.

Ground Water Quality

The State and USGS have identified about 1,600 contaminated public and private wells since the Connecticut Department of Environmental Protection (DEP) began keeping records in 1980. Connecticut's Wellhead Protection Program incorporates water supply planning, discharge permitting, water diversion, site remediation, prohibited activities, and numerous nonpoint source controls.

Programs to Restore Water Quality

Ensuring that all citizens can share in the benefits of clean water will require continued permit enforcement, additional advanced wastewater treatment, combined sewer separation, continued aquatic toxicity control, and resolution of nonpoint source issues. To date, 14 sewage treatment facilities have installed advanced treatment to remove nutrients. Nonpoint source management includes education projects and a permitting program for land application of sewage, agricultural sources, and solid waste management facilities.

Wetlands are protected by the State's Clean Water Act and Standards of Water Quality. Each municipality has an Inland Wetlands Agency that regulates filling and establishes regulated buffer areas with DEP training and oversight. Connecticut's courts have strongly upheld enforcement of the wetlands acts and supported regulation of buffer areas to protect wetlands.

Programs to Assess Water Quality

Connecticut samples physical and chemical parameters at 27 fixed stream sites and biological parameters at 47 stream sites. Other activities include intensive biological surveys, toxicity testing, and fish and shellfish tissue sampling for accumulation of toxic chemicals.

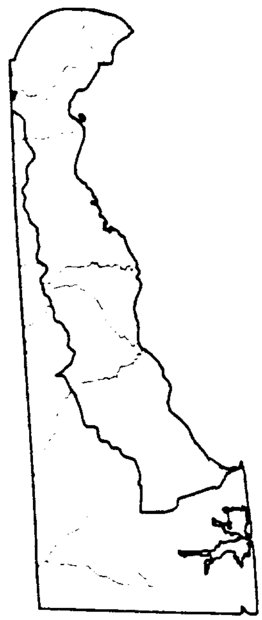
Delaware



— Basin Boundaries
(USGS 6-Digit Hydrologic Unit)

For a copy of the Delaware 1994 305(b) report, contact:

Brad Smith
Delaware Department of Natural Resources and Environmental Control
Division of Water Resources
P.O. Box 1401
Dover, DE 19903
(302) 739-4590

Surface Water Quality

Delaware's rivers and streams generally meet standards for aquatic life uses, but 93% of the surveyed stream miles and 76% of the surveyed lake acres do not meet bacteria criteria for swimming. Bacteria are the most widespread contaminant in Delaware's surface waters, but nutrients and toxics pose the most serious threats to aquatic life and human health. Excessive nutrients stimulate algal blooms and growth of aquatic weeds. Toxics result in six fish consumption restrictions in three basins, including Red Clay Creek, Red Lion Creek, the St. Jones River, and the Delaware Estuary. Agricultural runoff, septic systems, urban runoff, municipal sewage treatment plants, and industrial dischargers are the primary sources of nutrients and toxics in Delaware's surface waters.

Ground Water Quality

High-quality ground water provides two-thirds of Delaware's domestic water supply. However, nitrates, synthetic organic chemicals, saltwater, and iron contaminate isolated wells in some areas. In the agricultural areas of Kent and Sussex counties, nitrates in ground water are a potential health concern and a potential source of nutrient contamination in surface waters. Synthetic organic chemicals have entered some ground waters from leaking industrial underground storage tanks, landfills, abandoned hazardous waste sites, chemical spills and leaks, septic systems, and agricultural activities.

Programs to Restore Water Quality

The Department of Natural Resources and Environmental Control (DNREC) adopted a watershed approach to determine the most effective and efficient methods for protecting water quality or abating existing problems. Under the watershed approach, DNREC will evaluate all sources of pollution that may impact a waterway and target the most significant sources for management. The Appoquinimink River subbasin, the Nanticoke River subbasin, the Delaware's Inland Bays subbasin, and the Christina River subbasin are priority watersheds targeted for development of integrated pollution control strategies.

Delaware's Wellhead Protection Program establishes cooperative arrangements with local governments to manage sources of ground water contamination. The State may assist local governments in enacting zoning ordinances, site plan reviews, operating standards, source prohibitions, public education, and ground water monitoring.

Programs to Assess Water Quality

Delaware's Ambient Surface Water Quality Program includes fixed-station monitoring and biological surveys employing rapid bioassessment protocols. Delaware is developing and testing new protocols for sampling biological data in order to determine whether specific biological criteria can be developed to determine support of designated uses.

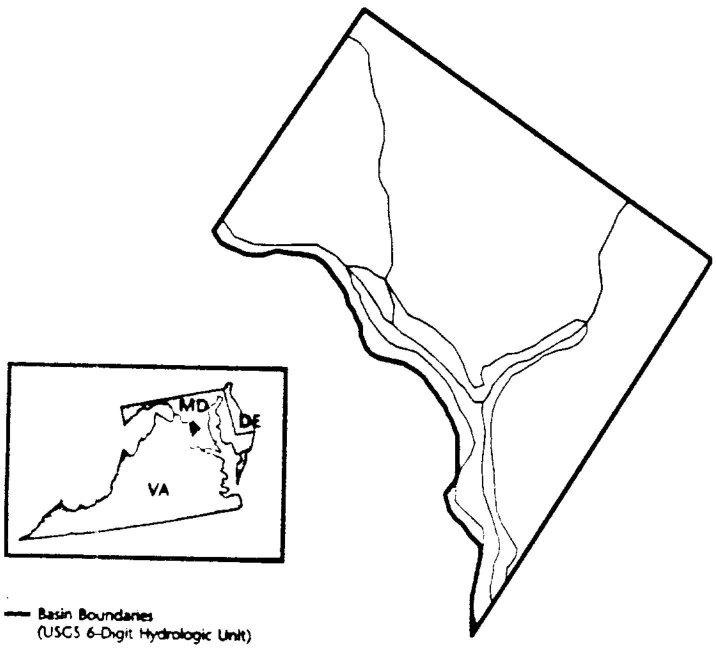
VOL 12
5617

District of Columbia



For a copy of the District of Columbia 1994 305(b) report, contact:

Dr. Hamid Karimi
Department of Consumer and Regulatory Affairs
Environmental Regulation Administration
Water Quality Monitoring Branch
2100 Martin Luther King Jr. Avenue, SE
Washington, DC 20020
(202) 645-6601

Surface Water Quality

Poor water quality still characterizes the District's surface waters, but water quality has stabilized and is improving in some areas. The recovery of submerged aquatic vegetation and fish communities in the Anacostia and Potomac Rivers provides qualitative evidence that water quality is improving. However, a fish consumption advisory and a swimming ban remain in effect for all District surface waters, and sediment contamination degrades aquatic life on the Anacostia River. Combined sewer overflows are the main source of bacterial pollution that causes unsafe swimming conditions. Urban runoff may be the source of high concentrations of cadmium, mercury, lead, PCBs, PAHs, and DDT found in sediment samples.

Ground Water Quality

During the 1994 305(b) assessment period, the District initiated ground water monitoring. The first round of sampling revealed that the ground water is potable. Some pollutants were detected at low concentrations in isolated cases. Ground water is not a public drinking water source in the District, but the District has a comprehensive State ground water protection program to assess and manage the resource. The program includes an ambient ground water sampling network, ground water quality regulations (including numerical and narrative criteria), and guidelines for preventing and remediating ground water quality degradation.

Programs to Restore Water Quality

The District is implementing innovative stormwater runoff controls for urban areas and promoting the watershed protection approach to clean up waterbodies that cross political boundaries, such as the Anacostia River. The District needs Maryland's cooperation to control pollution entering upstream tributaries located in Maryland. Additional funds will be needed to implement urban stormwater retrofits, CSO controls, and revegetation projects in both the District and Maryland to improve water quality in the Anacostia River.

Programs to Assess Water Quality

The District performs monthly physical and chemical sampling at 80 fixed stations on the Potomac River, the Anacostia River, and their tributaries. The District samples phytoplankton (microscopic plants) monthly at 15 stations and zooplankton at 3 stations. The District samples metals in the water column four times a year and analyzes toxic pollutants in fish tissue once a year. In 1992 and 1993, the District conducted rapid bioassessments on 29 waterbodies.

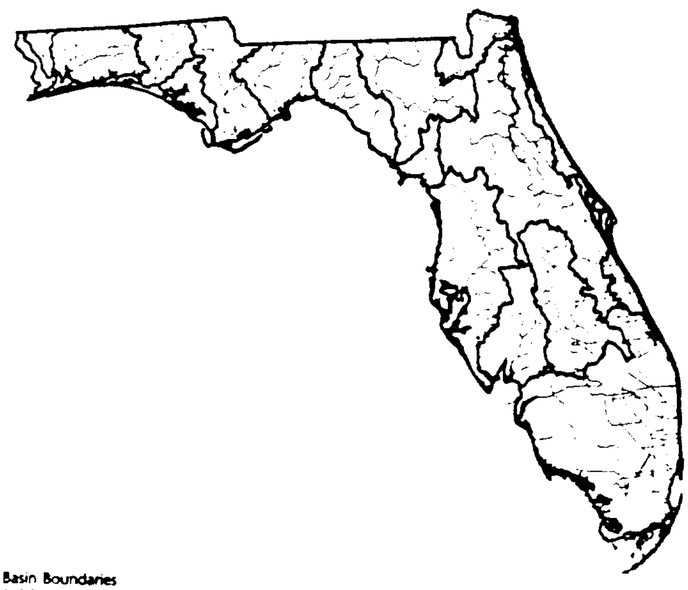
Florida



— Basin Boundaries
(USGS 6-Digit Hydrologic Unit)

For a copy of the Florida 1994 305(b) report, contact:

Joe Hand
Florida Dept. of Environmental Regulation
Twin Towers Building
2600 Blair Stone Road
Tallahassee, FL 32399-2400
(904) 921-9926

Surface Water Quality

Overall, the majority of Florida's surface waters are of good quality, but problems exist around densely populated urban areas, primarily in central and southern Florida. In rivers, nutrient enrichment, low dissolved oxygen, high bacteria counts, turbidity, and suspended solids degrade water quality. In lakes, the leading problems include algal blooms, turbidity, and nutrient enrichment. In estuaries, algal blooms, nutrient enrichment, low dissolved oxygen, and turbidity degrade quality. Urban stormwater, agricultural runoff, domestic wastewater, industrial wastewater, and hydrologic modifications are the major sources of water pollution in Florida.

Special State concerns include massive fish kills (as much as 20 tons of fish) in the Pensacola Bay system, widespread toxic contamination in sediments, widespread mercury contamination in fish, bacterial contamination in the Miami River, and algal blooms and extensive die-off of mangroves and seagrasses in Florida Bay.

Ground Water Quality

Data from 1,919 wells in Florida's ambient monitoring network indicate generally good water quality, but local ground water contamination problems exist. Agricultural chemicals, including aldicarb, alachlor, bromacil, simazine, and ethylene dibromide (EDB) have caused local and regional (in the case of EDB) problems. Other threats include petroleum products from leaking underground storage tanks, nitrates from dairy and other livestock operations, fertilizers and pesticides in stormwater runoff, and toxic chemicals in leachate from hazardous waste sites. The State requires periodic testing of all community water systems for 118 toxic organic chemicals.

Programs to Restore Water Quality

Florida controls point source pollution with its own discharge permitting process similar to the NPDES program. The State permits about 4,600 ground water and surface water discharge facilities. The State also encourages reuse of treated wastewater (primarily for irrigation) and discharge into constructed wetlands as an alternative to direct discharge into natural surface waters and ground water.

Florida's Stormwater Rule and implementing regulations are the core of the State's nonpoint source program. These regulations require all new developments to retain the first inch of runoff water in ponds to settle out sediment and other pollutants. Ongoing contracts focus on best management practices for other nonpoint sources, including agriculture, septic tanks, landfills, mining, and hydrologic modification.

Programs to Assess Water Quality

Florida's Surface Water Assessment Program (SWAMP) will identify ecoregion subregions and develop community bioassessment protocols; develop and implement a sampling network to monitor water quality trends and determine current conditions; and perform special water quality assessments if funds are available. The State defined 13 ecological subregions for the State and has established 66 reference stream sites for developing bioassessment protocols.

W.M. Winn, III
Georgia Environmental Protection Division
Water Quality Management Program
Floyd Towers, East
205 Butler Street, SE
Atlanta, GA 30334
(404) 656-4905

Surface Water Quality

Improvements in wastewater treatment by industries and municipalities have made it possible for Georgians to fish and swim in areas where water quality conditions were unacceptable for decades. Water quality in Georgia streams, lakes, and estuaries during 1992 and 1993 was good, but the number of stream miles and lake acres not fully supporting designated uses increased. The number of fish advisories also grew from four to nine during 1992-1994. However, this is a result of more stringent stream standards, increased sampling, and access to additional data. Persistent problems include mud, litter, bacteria, pesticides, fertilizers, metals, oils, suds, and other pollutants washed into rivers and lakes by stormwater.

Ground Water Quality

Georgia's ambient Ground Water Monitoring Network consists of 150 wells sampled periodically. To date, increasing nitrate concentrations in the Coastal Plain are the only adverse trend detected by the monitoring network, but nitrate concentrations are still well below harmful levels in most wells. Additional nitrate sampling in 500 wells revealed that nitrate concentrations exceeded EPA's Maximum Contaminant Level (MCL) in less than 1% of the tested wells. Pesticide monitoring indicates that pesticides do not threaten Georgia's drinking water aquifers at this time.

Programs to Restore Water Quality

Comprehensive river basin management planning will provide a basis for integrating point and nonpoint source water protection efforts within the State and with neighboring States. In 1992, the Georgia General Assembly passed Senate Bill 637, which requires the

VOL 12

5622

Department of Natural Resources to develop management plans for each river basin in the State. The State began developing comprehensive plans for the Chattahoochee and Flint River Basins in 1992 and the Oconee and Coosa River Basins in 1993. Georgia is also participating in a Tri-State Comprehensive Study with the Corps of Engineers, Alabama, and Florida to develop interstate agreements for maintaining flow and allocating assimilative capacity. Other interstate basin projects include the Savannah Watershed Project with South Carolina and the Suwannee River Basin Planning Project with the Georgia and Florida Soil Conservation Services.

Programs to Assess Water Quality

Georgia continued sampling at 145 fixed monitoring stations, conducted 14 intensive surveys, and performed over 600 compliance sampling inspections during 1992 and 1993. Georgia also sampled toxic substances in effluent from point source dischargers, streams, sediment, and fish tissues at selected sites throughout the State. The State assessed the overall toxicity in wastewater effluent with both acute and chronic aquatic toxicity tests.

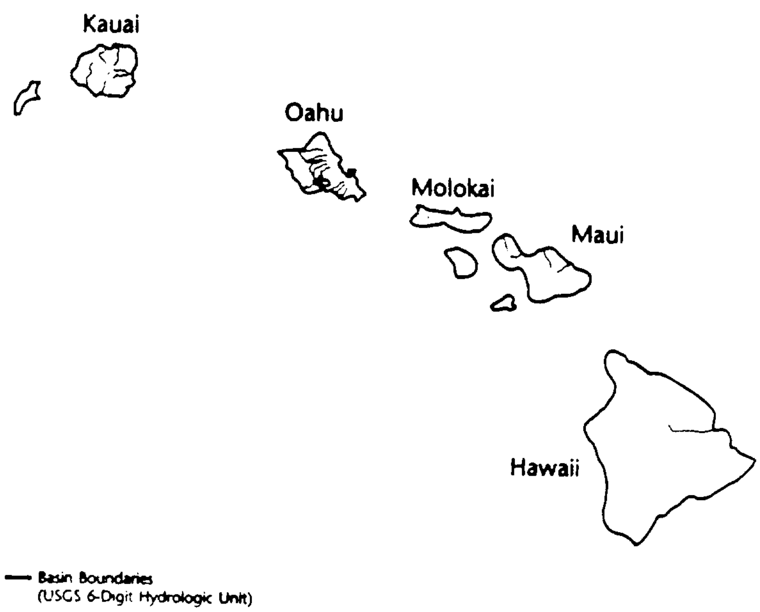
Hawaii



For a copy of the Hawaii 1994 305(b) report, contact:

Eugene Akazawa, Monitoring Supervisor
Hawaii Department of Health
Clean Water Branch
919 Ala Moana Blvd.
Honolulu, HI 96814
(808) 586-4309

Surface Water Quality

Most of Hawaii's waterbodies have variable water quality due to stormwater runoff. During dry weather, most streams and estuaries have good water quality that fully supports beneficial uses, but the quality declines when stormwater runoff carries pollutants into surface waters. The most significant pollution problems in Hawaii are siltation and turbidity, nutrients, fertilizers, toxics, pathogens, and pH from nonpoint sources, including agriculture and urban runoff. Very few point sources discharge into Hawaii's streams; most industrial facilities and wastewater treatment plants discharge into coastal waters. Other concerns include explosive algae growth in West Maui and Kahului Bay, a fish consumption advisory for lead in talipia caught in Manoa Stream, and sediment contamination from discontinued wastewater discharges at Wailoa Pond and Hilo Bay.

Ground Water Quality

Compared to mainland States, Hawaii has very few ground water problems due to a long history of land use controls for ground water protection. Prior to 1961, the State designated watershed reserves to protect the purity of rainfall recharging ground water. The Underground Injection Control Program also prohibits wastewater injection in areas surrounded by "no-pass" lines. However, aquifers outside of reserves and no-pass lines may be impacted by injection wells, household wastewater disposal systems, such as seepage pits and cesspools, landfills, leaking underground storage tanks, and agricultural return flows.

Programs to Restore Water Quality

County governments are required to set erosion control standards for various types of soil and land uses. These standards include criteria, techniques, and methods for controlling sediment erosion from land-disturbing activities. The State would like to enact ordinances that require the rating of pesticides on their potential to migrate through soil into ground water. The State would regulate the use of pesticides that pose a threat to ground water. Until more stringent ordinances can be enacted, the State recommends using alternatives to pesticides, such as natural predators and other biological controls. The State also encourages the use of low-toxicity, degradable chemicals for home gardens, landscaping, and golf courses.

Programs to Assess Water Quality

Hawaii has scaled back its water quality monitoring program because of budgetary constraints. The State has halted toxics monitoring, fish tissue contamination monitoring, and biological monitoring and eliminated sampling at numerous fixed monitoring stations. The State also reduced the frequency of bacterial monitoring at coastal beaches. The State does not expect conditions to change in the near future.

Overall[a] Use Support in Hawaii

	Total Surveyed	Percent: Good (Fully Supporting)	Good (Threatened)	Fair (Partially Supporting)	Poor (Not Supporting)	Poor (Not Attainable)

Surface Water Quality

Idaho omitted its water quality assessment for surface waters in their 1994 305(b) report because the State is in the middle of a major overhaul of its water quality management program. Idaho is restructuring its program around the watershed protection approach. As a first step, Idaho is redesignating its waterbodies and expanding its assessment database to include smaller streams that previously were not assessed. The State postponed its water quality assessment until all surface waters are designated and classified under a consistent system.

Idaho's Department of Environmental Quality (DEQ) identified several waterbodies with significant problems. Heavy metals and nutrients impact the Coeur d'Alene River drainage, while nutrients and sediment impact Henry's Fork. The middle Snake River exhibits severe eutrophication from nutrient enrichment. Mercury contaminates fish tissue in Brownlee Reservoir, and the Cascade Reservoir does not support agricultural uses due to overenrichment with nutrients.

Ground Water Quality

The Idaho Statewide Monitoring Program for Ground Water samples over 800 wells. This program and other specific projects have indicated that nitrates, petroleum products, solvents, and pesticides are the most prevalent pollutants in ground water. The Idaho Legislature adopted the Ground Water Quality Plan in 1992. This plan sets four priority issues: (1) evaluation of existing ground water programs, (2) development of State ground water standards, (3) development of a State wellhead protection program, and (4) classification of Idaho's aquifers. Ground water quality protection programs in Idaho include underground injection control, ground water vulnerability mapping, and management for animal waste, landfills, pesticides application, underground storage tanks, and sewage disposal.

VOL 12

5526

VOL 12

Programs to Restore Water Quality

EPA has primary responsibility for issuing NPDES permits in Idaho. Idaho's DEQ is concerned that EPA is not issuing permits for minor point source dischargers, and inspections of permitted and unpermitted dischargers are rare. Neither DEQ or EPA have sufficient staff to conduct compliance inspections. Without oversight, there are no assurances that these facilities are being properly operated and meet water quality standards.

Programs to Assess Water Quality

DEQ operates a water quality monitoring program that measures biological, physical, and chemical parameters. Data collection varies in intensity, from desktop reviews of existing data (Basic or Level I), through qualitative surveys and inventories that cannot be repeated with confidence (Reconnaissance or Level II), to quantitative measurements that can be repeated and yield data suitable for statistical analysis (Intensive or Level III).

Surface Water Quality

Overall water quality has steadily improved over the past 24 years since enactment of the Illinois Environmental Protection Act. Trend analysis generally indicates stable or improving trends in stream concentrations of dissolved oxygen, oxygen-depleting wastes, and ammonia consistent with the continued decline in point source impacts. However, dissolved oxygen depletion and ammonia still impair streams, as do nutrients, siltation, habitat/flow alterations, metals, and suspended solids. The State is also concerned about upward trends in nutrient concentrations detected in several basins that probably result from nonpoint sources. Other major sources of river pollution include persistent point sources, hydrologic/habitat modification, urban runoff, and resource extraction.

Trend analysis also indicates improving water quality in lakes. The most prevalent causes of remaining pollution in lakes include nutrients, suspended solids, and siltation. The most prevalent sources of pollution in lakes include contaminated sediments, agriculture, and hydrologic/habitat alterations.

Water quality also continues to improve in the Illinois portion of Lake Michigan. Trophic status improved from mesotrophic/eutrophic conditions in the 1970s to oligotrophic conditions today.

Ground Water Quality

Ground water quality is generally good, but past and present activities contaminate ground water in isolated areas. Ground water is contaminated around leaking underground gasoline storage tanks, large aboveground petroleum storage facilities, agricultural chemical operations, salt piles, landfills, and waste treatment, storage, and disposal facilities.

Programs to Restore Water Quality

The Illinois Environmental Protection Agency (IEPA), Bureau of Water, is committed to implementing a Targeted Watershed Approach in which high-risk watersheds are identified, prioritized, and selected for integrated and cooperative assessment and protection. This approach represents an expansion

VOL 12

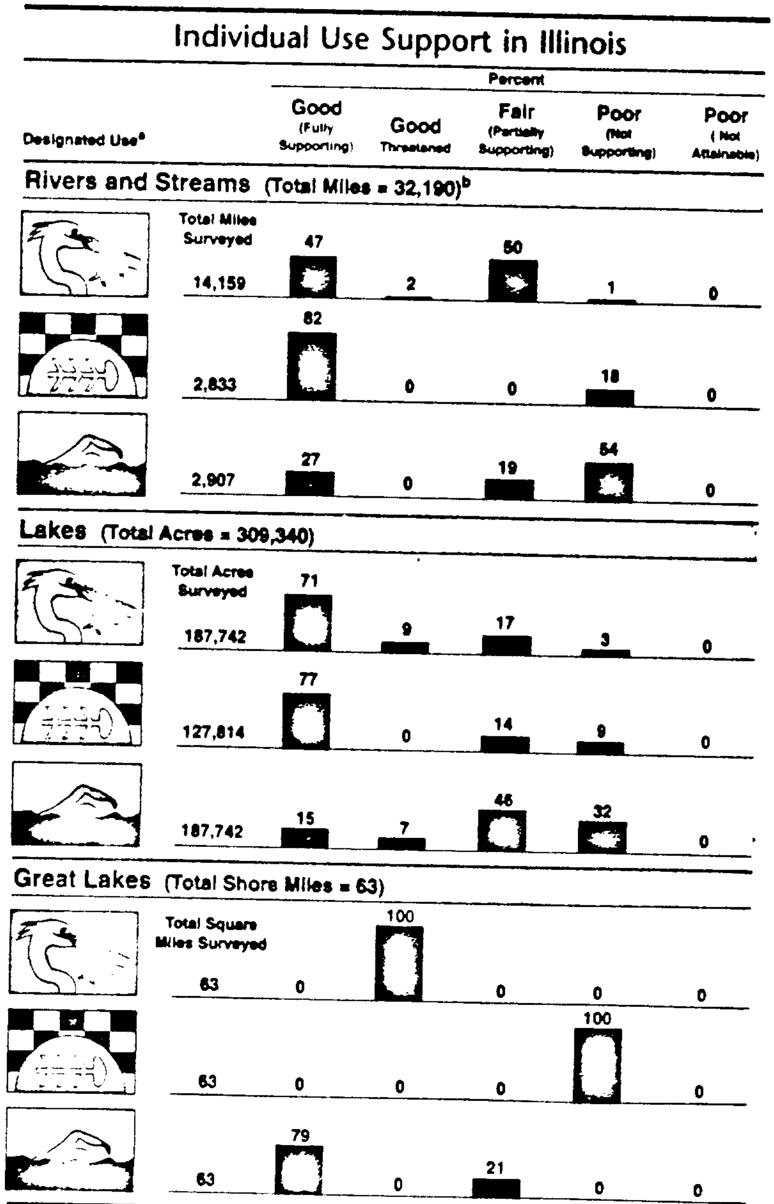
5528

and evolution of their previous efforts in geographic targeting. Current nonpoint source program activities focus on improving public awareness and adding land use data to the nonpoint source database available statewide.

Illinois established a Great Lakes Program Office in FY93 to oversee all Lake Michigan programs on a multimedia basis. Activities include promotion of pollution prevention for all sources of toxics in all media (such as air and water).

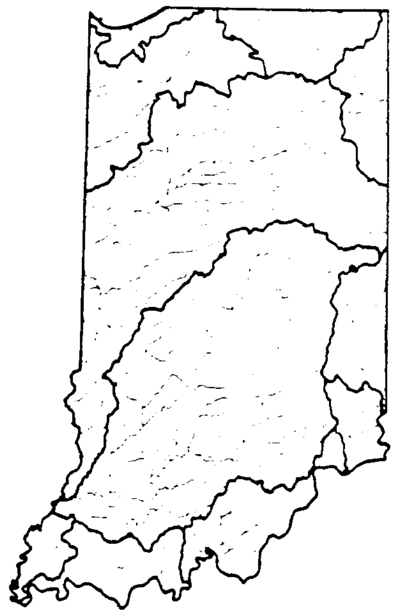
Programs to Assess Water Quality

The Division of Water Pollution Control spent $5.5 million on a diverse set of monitoring programs during 1992 and 1993. These programs include ambient and toxicity monitoring, pesticide monitoring, intensive river basin surveys, fish contaminant monitoring, and volunteer lake monitoring. These programs generate a rich inventory of monitoring data for assessing water quality conditions across the State. IEPA based their 1994 assessments on data from nearly 3,500 stations.



[a] A subset of Illinois designated uses appear in this figure. Refer to the State's 305(b) report for a full description of the State's uses.
[b] Includes nonperennial streams that dry up and do not flow all year.

Indiana



For a copy of the Indiana 1994 305(b) report, contact:

Dennis Clark
Indiana Department of Environmental Management
Office of Water Management
P.O. Box 6015
Indianapolis, IN 46206-6015
(317) 243-5037

Surface Water Quality

Over 99% of the surveyed lake acres and 79% of the surveyed river miles have good water quality that fully supports aquatic life. However, only 18% of the surveyed river miles support swimming due to high bacteria concentrations. A fish consumption advisory impairs all of Indiana's Lake Michigan shoreline. The pollutants most frequently identified in Indiana waters include bacteria, priority organic compounds, oxygen-depleting wastes, pesticides, metals, cyanide, and ammonia. The sources of these pollutants include industrial facilities, municipal/semipublic wastewater systems, combined sewer overflows, and agricultural nonpoint sources.

Indiana identified elevated concentrations of toxic substances in about 8% of the river miles monitored for toxics. High concentrations of PCBs, pesticides, and metals were most common in sediment samples and in fish tissue samples. Less than 1% of the surveyed lake acres contained elevated concentrations of toxic substances in their sediment.

Ground Water Quality

Indiana has a plentiful ground water resource serving 60% of its population for drinking water and filling many of the water needs of business, industry, and agriculture. Although most of Indiana's ground water has not been shown to be adversely impacted by human activities, the State has documented over 863 sites of ground water contamination. Nitrates are the most common pollutant detected in wells, followed by volatile organic chemicals and heavy metals. In agricultural regions, data indicate that 7% to 10% of the rural drinking water wells contain unacceptable nitrate concentrations and some detectable quantity of pesticides. Heavy metal contamination is associated with waste disposal sites.

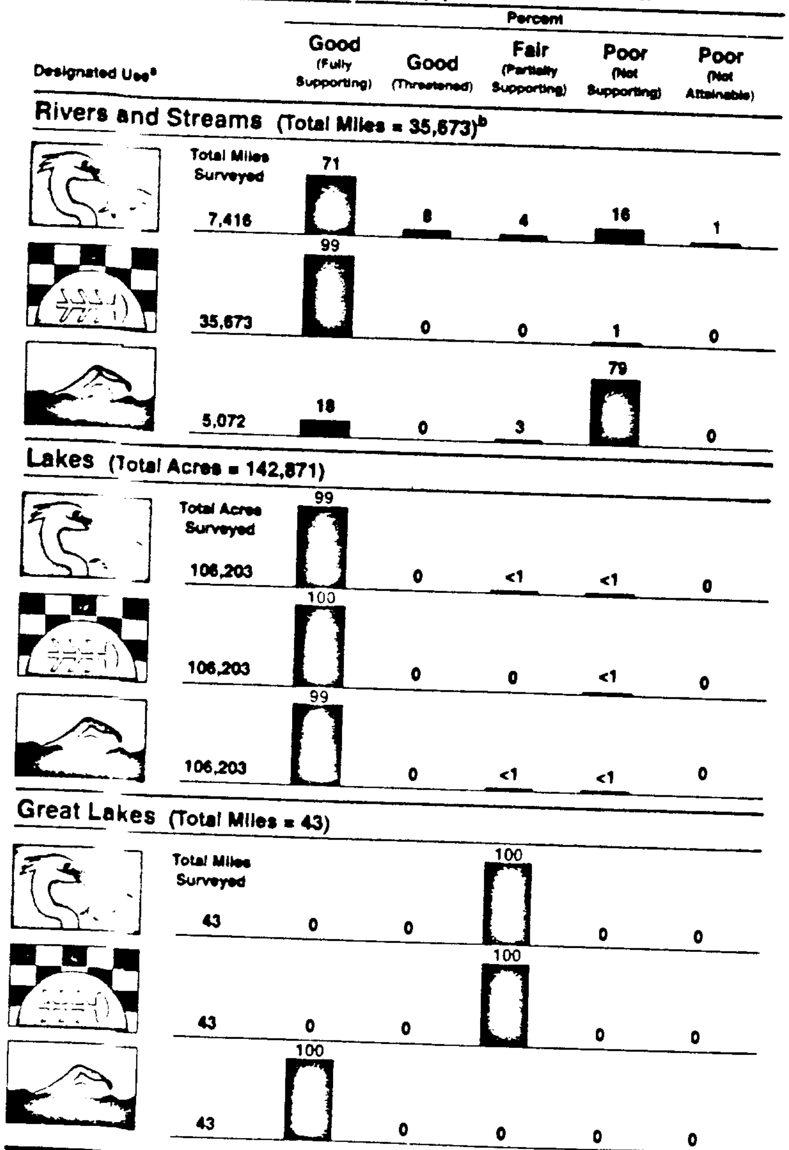
Programs to Restore Water Quality

Since 1972, Indiana has spent over $1.4 billion in Federal construction grants, $207 million in State funds, and $190 million in matching local funds to construct or upgrade sewage treatment facilities. As a result of these expenditures, 53% of Indiana's population is now served by advanced sewage treatment. The State issues NPDES permits to ensure that these new and improved facilities control pollution. Indiana is increasing enforcement activities to ensure compliance with permit requirements.

Programs to Assess Water Quality

Indiana initiated a 5-year baseline biological sampling program in 1989. As of 1994, the State had collected 2,000 aquatic insect samples at 439 sites representing 81% of the State's geographical area. In the future, the State will be able to detect deviations from the baseline dataset. Indiana and EPA Region 5 are also developing fish community measurements for evaluating biological integrity in Indiana's rivers and streams.

Individual Use Support in Indiana



[a] A subset of Indiana's designated uses appear in this figure. Refer to the State's 305(b) report for a full description of the State's uses.
[b] Includes nonperennial streams that dry up and do not flow all year.

John Olson
Iowa Department of Natural Resources
Water Resources Section
900 East Grand Avenue
Wallace State Office Building
Des Moines, IA 50319
(515) 281-8905

Surface Water Quality

Sediment and plant nutrients from agricultural sources, modifications to stream habitat and hydrology, and natural conditions (such as shallowness in lakes) impair aquatic life uses in 48% of the surveyed rivers, 35% of the surveyed lakes, and 33% of the surveyed flood control reservoirs. Swimming use is impaired in 92% of the 556 surveyed river miles and 27% of the surveyed lakes, ponds, and reservoirs. Saylorville, Coralville, and Rathburn Reservoirs have good water quality that fully supports all designated uses, but siltation severely impacts Red Rock Reservoir. Point sources still pollute about 5% of the surveyed stream miles and one lake.

Ground Water Quality

Ground water supplies about 80% of all Iowa's drinking water. Agricultural chemicals, underground storage tanks, agricultural drainage wells, livestock wastes, and improper management of hazardous substances all contribute to some degree to ground water contamination in Iowa. Nitrate concentrations exceed the EPA's Maximum Contaminant Level in 10 of the State's 1,140 public ground water supplies. Several studies have detected low levels of common agricultural pesticides and synthetic organic compounds, such as solvents and degreasers, in both untreated and treated ground water. In most cases, the contaminants appear in small concentrations thought to pose no immediate threat to public health, but little is known about the health effects of long-term exposure to low concentrations of these chemicals.

Programs to Restore Water Quality

In 1979, Iowa began implementing its agricultural nonpoint control strategy with education projects and cost-share programs to control sediment, the greatest pollutant, by volume, in the State. Later, Iowa adopted rules that require that land disposal of animal wastes not contaminate surface and ground waters. Landfill rules establish specific siting, design, operation, and monitoring criteria, and require annual inspections and permit renewals every 3 years. Iowa also regulates construction in floodplains to limit soil erosion and impacts on aquatic life.

Programs to Assess Water Quality

Iowa's DNR maintains a fixed sampling network and conducts special intensive studies at selected sites. The State routinely monitors metals, ammonia, and residual chlorine at the fixed sampling sites, but not pesticides. However, pesticides were monitored for special studies examining the fate of pesticides in Iowa rivers and levels of pesticides in water supply reservoirs. Limited monitoring for toxics in sediment was conducted as part of a special study in 1992 and 1993. Routine sampling has not included biological sampling in the past, but the role of biological sampling continues to grow. In 1994, Iowa initiated a pilot study to establish biologically based water quality criteria for wadeable streams in each ecoregion.

Mike Butler
Kansas Department of Health and Environment
Office of Science and Support
Forbes Field, Building 740
Topeka, KS 66620
(913) 296-5580

Surface Water Quality

Suspended solids and dissolved solids impair aquatic life uses in 93% of Kansas' surveyed streams. Bacteria also prevent 95% of the surveyed streams from fully supporting swimming uses. Runoff from feedlots, animal holding areas, and pastureland introduce pathogen bacteria into rivers and streams. Discharges of undertreated or untreated wastewater from sewage treatment plants also elevate pathogen bacteria levels in Kansas waters. Erosion of farmland soils and urban runoff are the principal sources of suspended solids. Irrigation return flows, oil and natural gas extraction activities, and natural sources introduce dissolved solids.

Cultural eutrophication is responsible for 34% of poor water quality conditions in Kansas' surveyed lakes, and pesticides impair an additional 23% of the surveyed lakes. Overall, agricultural activities are responsible for almost half of the pollution in the State's lakes. Agricultural activities and hydromodification are the major sources of impacts in wetlands.

Ground Water Quality

The Kansas Department of Health and Environment (DHE) has documented ground water contamination from human activities at nearly 350 sites in the State. Underground storage tanks, oil and natural gas operations, and agriculture are the most significant sources of ground water contamination in Kansas. Kansas maintains a ground water monitoring network of 242 wells. During 1990-1993, nitrate concentrations exceeded EPA's Maximum Contaminant Level in 11% of 618 ground water samples. A State Wellhead Protection Program is still under development, and several Kansas communities are developing local plans.

VOL 12

Programs to Restore Water Quality

Kansas requires permits for livestock operations that utilize wastewater control facilities (such as manure pits, ponds, or lagoons); confine 300 or more head of cattle, hogs, sheep, or a combination of all three; or house a commercial poultry flock of 1,000 or more birds. DHE may also require permits for other livestock operations that have the potential to create pollution problems, such as open lots located adjacent to creeks or operations with a history of improper wastewater disposal practices. The major elements of the Kansas Nonpoint Source Pollution Control Program include interagency coordination, information and education, technical assistance, enforcement, and water quality certification.

Programs to Assess Water Quality

Every year, DHE collects and analyzes about 1,500 surface water samples, 50 aquatic insect samples, and 40 composite fish tissue samples from stations located throughout the State. Wastewater samples are collected at about 50 municipal sewage treatment plants, 20 industrial facilities, and 3 Federal facilities to evaluate compliance with discharge permit requirements. DHE also conducts special studies and prepares about 100 site-specific water quality summaries at the request of private citizens or other interested parties.

Tom VanArsdall
Department for Environmental Protection
Division of Water
14 Reilly Road
Frankfort Office Park
Frankfort, KY 40601
(502) 564-3410

Surface Water Quality

About 83% of Kentucky's surveyed rivers (including the Ohio River) and 95% of surveyed lake acres have good water quality that fully supports aquatic life. Swimming use is fully supported in 100% of the surveyed lake acres, but 52% of the surveyed river miles do not fully support swimming due to elevated bacteria levels. Fecal coliform bacteria, siltation, and oxygen-depleting substances are the most common pollutants in Kentucky rivers. Sewage treatment facilities are still a leading source of fecal coliform bacteria and oxygen-depleting substances, followed by agricultural runoff, septic tanks, and straight pipe discharges. Surface mining and agriculture are the major sources of siltation. Nutrients from agricultural runoff and septic tanks have the most widespread impacts on lakes.

Declining trends in chloride concentrations and nutrients provide evidence of improving water quality in Kentucky's rivers and streams. The State also lifted a swimming advisory on 76 miles of the North Fork Kentucky River, although the advisory remains in effect on 86 miles. Fish consumption advisories remain posted on three creeks for PCBs and on the Ohio River for PCBs and chlordane. The State issued new advisories for the Green River Lake because of PCB spills from a gas pipeline compressor station and for five ponds on the West Kentucky Wildlife Management Area because of mercury contamination from unknown sources.

Ground Water Quality

Underground storage tanks, septic tanks, abandoned hazardous waste sites, agricultural activities, and landfills are estimated to be the top five sources of ground water contamination in Kentucky. Bacteria is the major pollutant in ground water. The State is concerned about the lack of ground water data, absence of ground water regulations, and the potential for ground water pollution in karst regions of the State.

VOL 12

5636

VOL 12

Programs to Restore Water Quality

Kentucky's revolving fund program supported 26 wastewater treatment projects completed in 1992-93 and another 25 ongoing projects. These projects either replaced outdated or inadequate treatment facilities or provided centralized treatment for the first time. Kentucky requires toxicity testing of point source discharges and permits for stormwater outfalls and combined sewer overflows. The nonpoint source program oversees projects addressing watershed remediation, education, training, technical assistance, and evaluation of best management practices.

Programs to Assess Water Quality

Kentucky sampled 44 ambient monitoring stations characterizing about 1,432 stream miles during the reporting period. The State performed biological sampling at 24 of these stations. Seven lakes were sampled to detect eutrophication trends and 2 lakes were sampled to analyze the impact of suspended solids on recreational activities. The State also performed five intensive studies to evaluate point source and nonpoint source impacts, establish baseline water quality measurements, and reevaluate water quality in several streams.

Individual Use Support in Kentucky

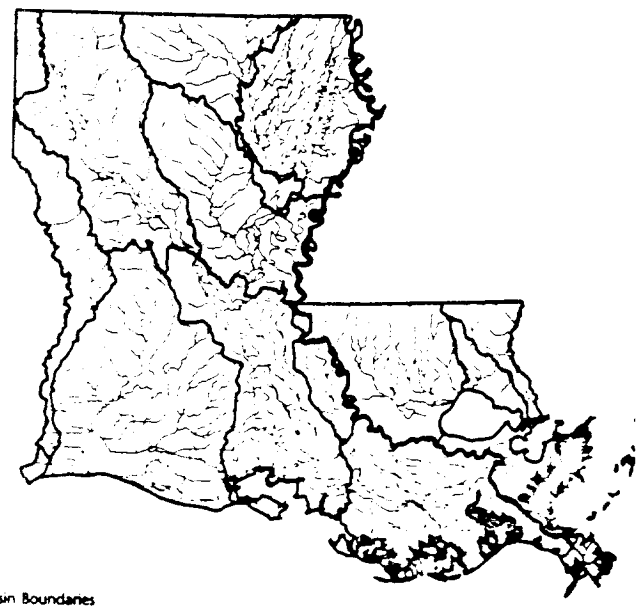
Louisiana



— Basin Boundaries
(USGS 6-Digit Hydrologic Unit)

For a copy of the Louisiana 1994 305(b) report, contact:

Albert E. Hindrichs
Louisiana Department of Environmental Quality
Office of Water Resources
Water Quality Management Division
P.O. Box 82215
Baton Rouge, LA 70884-2215
(504) 765-0511

Surface Water Quality

About 49% of the surveyed stream miles, 40% of the surveyed lake acres, and 70% of the surveyed estuarine waters have good water quality that fully supports aquatic life. Fecal coliform bacteria continue to be the most common pollutant in Louisiana's rivers and streams, followed by low dissolved oxygen concentrations and nutrients. As a result of violation of fecal coliform bacteria standards, 55% of the surveyed river miles do not fully support swimming and other contact recreational activities. Thirty-six percent of the surveyed lake acres and 28% of the surveyed estuarine waters also do not fully support swimming. Sources of bacteria include sewage discharges from municipal treatment plants, subdivisions, trailer parks, and apartment complexes. Septic tanks, sewage/stormwater overflows, pastures, and rangeland also generate bacterial pollution. Agricultural runoff generates oxygen-depleting substances and nutrients.

In lakes, noxious aquatic plants (which result from high nutrient loads) are the most common problem, followed by bacteria, low dissolved oxygen, nutrients, and oil and grease. Upstream sources of pollutants impact the most lake acres (primarily in Lake Pontchartrain), followed by municipal point sources, industrial point sources, and petroleum extraction activities. In estuaries, oil and grease, nutrients, and bacteria are the most common pollutants. Upstream sources of contamination, petroleum extraction activities, municipal discharges, sewer/stormwater overflow, and septic tanks are the leading sources of pollution in estuaries. Hydrologic modification impacts one surveyed wetland.

Ground Water Quality

The quality of water in the State's major aquifer systems remains excellent. Of special concern, however, are the shallow aquifers and the water-bearing zones that are not used as major sources of water. These strata contribute significantly to the water balance of the deeper aquifers, but the shallow aquifers are increasingly threatened.

Programs to Restore Water Quality

Currently, most reductions in nonpoint source pollution result from cooperative demonstration projects due to a lack of regulatory authority in Louisiana to control nonpoint source pollution. These projects have demonstrated alternative rice farming management practices to reduce sediment and nutrients in the Mermentau River Basin, advocated lawn care management to reduce erosion and runoff in the Bayou Vermilion watershed, and reduced fecal coliform concentrations in the Tangipahoa River by implementing septic tank and dairy waste lagoon education programs and upgrading municipal wastewater treatment systems.

Programs to Assess Water Quality

The surface water monitoring program consists of a fixed-station monitoring network, intensive surveys, special studies, and wastewater discharge compliance sampling. The fixed network includes at least one long-term trend analysis station on the major stream in each basin of the State. The State positioned other fixed sampling sites to monitor targeted sources of pollution or waterbodies. Louisiana does not maintain a regular fish tissue sampling program.

- Not reported

[a] A subset of Louisiana's designated uses appear in this figure. Refer to the State's 305(b) report for a full description of the State's uses.

[b] Includes nonperennial streams that dry up and do not flow all year.

Phil Garwood
Maine Department of Environmental Protection
Bureau of Water Quality Control
State House Station 17
Augusta, ME 04333
(207) 287-7695

Surface Water Quality

Maine's water quality has significantly improved since enactment of the Clean Water Act in 1972. Atlantic salmon and other fish now return to Maine's rivers, and waters that were once open sewers are now clean enough to swim in. Ninety-nine percent of the State's river miles, 81% of the lake acres, and 90% of the estuarine waters have good water quality that fully supports aquatic life uses. Dioxin in fish tissue is the most significant problem in major rivers. Oxygen-depleting substances from nonpoint sources and bacteria from inadequate sewage treatment are the most significant problem in smaller rivers and streams. Lakes are impacted by oxygen-depleting substances from nonpoint sources, including urban runoff, agriculture, and forestry activities. Bacteria from municipal treatment plants and small dischargers contaminate shellfish beds in estuarine waters.

Ground Water Quality

The most significant ground water impacts include petroleum compounds from leaking underground and aboveground storage tanks, other organic chemicals from leaking storage facilities or disposal practices, and bacteria from surface disposal systems or other sources. Maine requires that all underground tanks be registered and that inadequate tanks be removed. About 23,000 tanks have been removed since 1986. Maine also regulates installation of underground storage tanks and closure of landfills to protect ground water resources from future leaks.

Programs to Restore Water Quality

Maine restored designated uses in 20 miles of rivers by working with Kraft pulp and paper mills to reduce the levels of dioxin in their discharges. Construction of small wastewater treatment systems also eliminated some bacteria problems and dissolved oxygen problems on small streams. However, as the State makes progress in restoring waters impacted by point sources, new water quality problems emerge from nonpoint sources. Therefore, the most important water quality initiatives for the future include implementing pollution prevention, nonpoint source management, watershed-based planning, coordinated land use management, and water quality monitoring. The State is linking pollution prevention with the watershed protection approach in a pilot project within the Androscoggin River basin. The State is providing local officials and citizen groups with technical assistance to identify problem areas and develop local solutions for reducing pollution generation throughout the watershed.

Programs to Assess Water Quality

Maine's surface water monitoring program includes ambient water quality monitoring, assimilative capacity and wasteload allocation studies, diagnostic studies, treatment plant compliance monitoring, and special investigations. Due to budgetary constraints, some of these activities are much more limited in scope than is desirable for accurately characterizing water quality conditions in Maine.

Surface Water Quality

Overall, Maryland's surface waters have good quality, but excess nutrients, suspended sediments, bacteria, toxic materials, or stream acidity impact some waters. The most serious water quality problem in Maryland is the continuing accumulation of nutrients in estuaries and lakes from agricultural runoff, urban runoff, natural nonpoint source runoff, and point source discharges. Excess nutrients stimulate algal blooms and low dissolved oxygen levels that adversely impact water supplies and aquatic life.

Sources of sediment include agricultural runoff, urban runoff, construction activities, natural erosion, dredging, forestry, and mining operations. In western Maryland, abandoned coal mines release acidic waters that severely impact some streams. Agricultural runoff, urban runoff, natural runoff, and failing septic systems elevate bacteria concentrations and cause continuous shellfish harvesting restrictions in about 104 square miles of estuarine waters and cause temporary restrictions in another 72.3 square miles after major rainstorms.

Ground Water Quality

Maryland's ground water resource is of generally good quality. Localized problems include excess nutrients (nitrates) from fertilizers and septic systems; bacteria from septic systems and surface contamination; saline water intrusion aggravated by ground water withdrawals in the coastal plain; toxic compounds from septic tanks, landfills, and spills; petroleum products from leaking storage facilities; and acidic conditions and metals from abandoned coal mine drainage in western Maryland. Control efforts are limited to implementing agricultural best management practices and enforcing regulations for septic tanks, underground storage tanks, land disposal practices, and well construction.

Programs to Restore Water Quality

Maryland manages nonpoint sources with individual programs for each individual nonpoint source category. Urban runoff is addressed through stormwater and sediment control laws that require development projects to maintain predevelopment runoff patterns through implementation of best management practices (BMPs), such as detention ponds or vegetated swales. The Agricultural Water Quality Management Program supports many approaches, including Soil Conservation and Water Quality Plans, implementation of BMPs, and education. The Agricultural Cost Share Program has provided State, and some Federal, funds to help offset the costs of implementing almost 8,000 agricultural BMPs since 1983. An Animal Waste Permit Program requires discharge permits for facilities that will have a definable discharge to waters of the State.

Programs to Assess Water Quality

Maryland's monitoring program includes a fixed-station network, compliance sampling at point source discharges, bioassay tests of effluent toxicity, special intensive sampling programs on the Potomac and Patuxent Rivers, acid deposition monitoring, fish tissue and shellstock sampling, bacterial sampling in shellfish waters, phytoplankton sampling, biological monitoring, and habitat assessments.

Individual Use Support in Maryland

Designated Use[a]	Total Surveyed	Good (Fully Supporting) %	Good (Threatened) %	Fair (Partially Supporting) %	Poor (Not Supporting) %	Poor (Not Attainable) %

Surface Water Quality

The 1994 report does not reflect the progress made in cleaning up Massachusetts' rivers and lakes because reporting total miles free of all contaminants obscures progress in removing some contaminants from many waters. The method of reporting survey results obscures the statewide reduction in oxygen-depleting wastes because bacteria, nutrients, toxic pollutants, ammonia, and acidity still impact about half of the surveyed river miles, lake acres, and estuarine waters in the State. The leading sources of contamination in Massachusetts' surface waters are stormwater runoff, combined sewer overflows, and municipal sewage treatment plants.

Quabbin Reservoir's 25,000 acres support swimming and aquatic life, but high levels of mercury in sport fish restrict fish consumption. Unlike other waterbody types, coastal water bacterial quality has deteriorated over the past 10 years, especially in areas such as Cape Cod where nonpoint source pollution has resulted in a tenfold increase in shellfish bed closures.

Ground Water Quality

Contaminants have been detected in at least 206 ground water suppy wells in 87 municipalities. Organic chemicals (especially TCE) contaminate 60% of these wells. Other contaminants include metals, chlorides, bacteria, inorganic chemicals, radiation, nutrients, turbidity, and pesticides. Since 1983, Massachusetts has required permits for all industrial discharges into ground waters and sanitary wastewater discharges of 15,000 gallons or more per day. The permits require varying degrees of wastewater treatment based on the quality and use of the receiving ground water. Additional controls are needed to eliminate contamination from septic systems and sludge disposal.

VOL 12

Programs to Restore Water Quality

Wastewater treatment plant construction has resulted in significant improvements in water quality, but $7 billion of unfunded wastewater needs remain. The Nonpoint Source Control Program has implemented 35 projects to provide technical assistance, implement best management practices, and educate the public. The State has also adopted a combined sewer overflow policy that provides engineering targets for cleanup and is presently addressing several CSO abatement projects.

Programs to Assess Water Quality

The Department of Environmental Protection (DEP) adopted a watershed planning approach to coordinate stream monitoring with wastewater discharge permitting, water withdrawa permitting, and nonpoint source control on a 5-year rotating schedule. The DEP is also adapting its monitoring strategies to provide information on nonpoint source pollution. For example, DEP will focus more on wet-weather sampling and biological monitoring and less on chemical monitoring during dry periods in order to gain a more complete understanding of the integrity of water resources.

Individual Use Support in Massachusetts

Michigan

For a copy of the Michigan 1994 305(b) report, contact:

Greg Goudy
Michigan Department of Natural Resources
Surface Water Quality Division
P.O. Box 30028
Lansing, MI 48909-7528
(517) 335-3310

Surface Water Quality

Ninety-eight percent of Michigan's surveyed river miles and 99% of Michigan's surveyed lake acres fully support aquatic life uses. Swimming use is also fully supported in 98% of the surveyed rivers and all of the surveyed lake acres. Priority organic chemicals (in fish) are the major cause of nonsupport in more river miles than any other pollutant, followed by siltation and sedimentation, metals, and bacteria. Leading sources of pollution in Michigan include unspecified nonpoint sources, agriculture, municipal and industrial discharges, combined sewers, and atmospheric deposition.

Very few lakes in Michigan completely fail to support fishing and swimming, but there is no doubt that both point and nonpoint sources have increased the rate of eutrophication (overenrichment), altered biological communities, and degraded the overall aesthetic and recreational quality of a great number of Michigan's fragile lake resources. Many more lakes are threatened by long-term, cumulative pollutant loads, especially in the rapidly growing communities on northern lower Michigan.

Four of the five Great Lakes border Michigan. The open waters of Lakes Superior, Michigan, and Huron have good quality. Poor water quality is restricted to a few degraded locations near shore. Lake Erie's water quality has improved dramatically in the last two decades. Once declared dead, Lake Erie now supports the largest walleye sport fishery on the Great Lakes. The dramatic improvements are due primarily to nutrient controls applied to sewage treatment plants, particularly in the Detroit area.

Ground Water Quality

Most of the ground water resource is of excellent quality, but certain aquifers have been contaminated with toxic materials leaking from waste disposal sites, businesses, or government facilities. The Michigan Ground Water Protection Strategy and Implementation Plan identifies specific program initiatives, schedules, and agency responsibilities for protecting the State's ground water resources.

Programs to Restore Water Quality

Major point source reductions in phosphorus and organic material loads have reduced or eliminated water quality problems in many Michigan waters. However, expanded efforts are needed to control nonpoint source pollution, eliminate combined sewer overflows, and reduce toxic contamination. Michigan has implemented an industrial pretreatment program, promulgated rules on the discharge of toxic substances, and regulated hazardous waste disposal facilities, but many toxicity problems are due to past activities that contaminated sediments.

Programs to Assess Water Quality

Between 1989 and 1993, the Department of Natural Resources devoted a significant amount of staff time to documenting water quality impacts from nonpoint sources of pollution and verifying information in the Michigan Nonpoint Source Assessment. Chemical, biological, and physical surveys were conducted to identify water quality standards violations and degraded biological communities in numerous watersheds.

Elizabeth Brinsmade
Minnesota Pollution Control Agency
Water Quality Division
520 Lafayette Road North
St. Paul, MN 55155
(612) 296-8861

Surface Water Quality

About 73% of the surveyed river miles have good quality that fully supports aquatic life uses and 39% of the surveyed rivers fully support swimming. Seventy-nine percent of the surveyed lake acres fully support swimming. The most common pollutants identified in rivers were bacteria, oxygen-depleting substances, pH (acidity), salinity/total dissolved solids/chlorides, and metals. Nonpoint sources generate most of the pollution in rivers. Minnesota's 272 miles of Lake Superior shoreline have fish consumption advisories. These advisories recommend some limits on fish meals consumed for certain species and size classes. Most of the pollution originated from point sources has been controlled, but runoff (especially in agricultural regions) still degrades water quality.

Ground Water Quality

The State maintains a Ground Water Monitoring and Assessment Program to evaluate the quality of ground waters that supply domestic water to 70% of Minnesota's population. The Program sampled 368 wells in the southeastern and southwestern regions of the State during 1992 and 1993. The samples were analyzed for 43 inorganic parameters and 68 volatile organic compounds. Monitoring detected nitrates in 62% of the wells and low levels of VOCs in 41 wells. Seven percent of the sampled wells contained nitrate concentrations exceeding EPA's Maximum Contaminant Level. Natural sources of manganese, iron, and arsenic also interfere with uses of ground water.

Programs to Restore Water Quality

During the 1994 reporting cycle, Minnesota revised its Nonpoint Source (NPS) Management Program with new strategies for addressing agricultural sources, forestry, urban runoff, contaminated sediments, feedlots, mining, and septic systems. The State also revised strategies for monitoring and assessing NPS impacts, educating the public, implementing BMPs, and applying the watershed protection approach to NPS management.

Minnesota adopted rules to implement the State's Wetlands Conservation Act and developed wetlands water quality standards during 1992 and 1993. The Wetland Conservation Act rules require that local governments regulate drain and fill activities in wetlands that are not designated public waters wetlands, which are listed on the Protected Waters Inventory. The rules allow the local governments to grant one or more of 25 exemptions for proposed activities on smaller wetlands with less inundation.

Programs to Assess Water Quality

Minnesota maintains an Ambient Stream Monitoring Program with 78 sampling stations. The State also performs fish tissue sampling, sediment monitoring, intensive surveys, biological surveys, and lake assessments and supports a citizen lake monitoring program. In 1994, the State completed the Minnesota River Assessment Project, a comprehensive study involving over 30 Federal, State, and local agencies. The project incorporated intensive biological monitoring and habitat assessments with traditional chemical monitoring to identify multiple sources and their impacts. A pilot use support methodology was used for rivers in the Minnesota River basin that reflected this comprehensive monitoring.

(601) 961-5158

Surface Water Quality

Mississippi reported that 81% of its surveyed rivers have fair water quality that periodically does not support aquatic life uses and another 5% have poor water quality that does not support aquatic life uses. About 35% of the surveyed rivers do not fully support swimming. The most common pollutants identified in Mississippi's rivers include nutrients, pesticides, siltation, oxygen-depleting substances, and bacteria. Agriculture is the most common source of pollution in rivers, followed by municipal sewage treatment plants.

About 65% of the surveyed lake acres have good water quality that fully supports aquatic life uses and 97% of the surveyed lake acres fully support swimming. Nutrients, siltation, pesticides, and oxygen-depleting substances are the most common pollutants in Mississippi lakes. Agriculture is also the dominant source of pollution in Mississippi's lakes.

In estuaries, 74% of the surveyed waters have good quality that fully supports aquatic life uses, but shellfishing activities are impaired in all of the surveyed estuarine waters. Bacteria and metals cause most of the impacts observed in estuaries. High bacteria levels are associated with shellfish harvesting restrictions. The State attributes impacts in estuarine waters to urban runoff/storm sewers, septic systems, and land disposal activities.

The State has posted six fish consumption advisories, including three commercial fishing bans due to elevated concentrations of PCBs, PCP, and dioxins detected in fish tissues.

Ground Water Quality

Extensive contamination of drinking water aquifers and public water supplies remains uncommon in Mississippi although localized ground water contamination has been detected at various facilities across the State. The most frequently identified sources of contamination are leaky underground storage tanks and faulty septic systems. Brine contamination is also a problem near oil fields. Little data exist for domestic wells that are seldom sampled. Ground water protection programs include the Pesticide Container Recycling Program, the Underground Storage Tank Program, the Underground Injection Control Program, the Agrichemical Ground Water

5650

R0038958

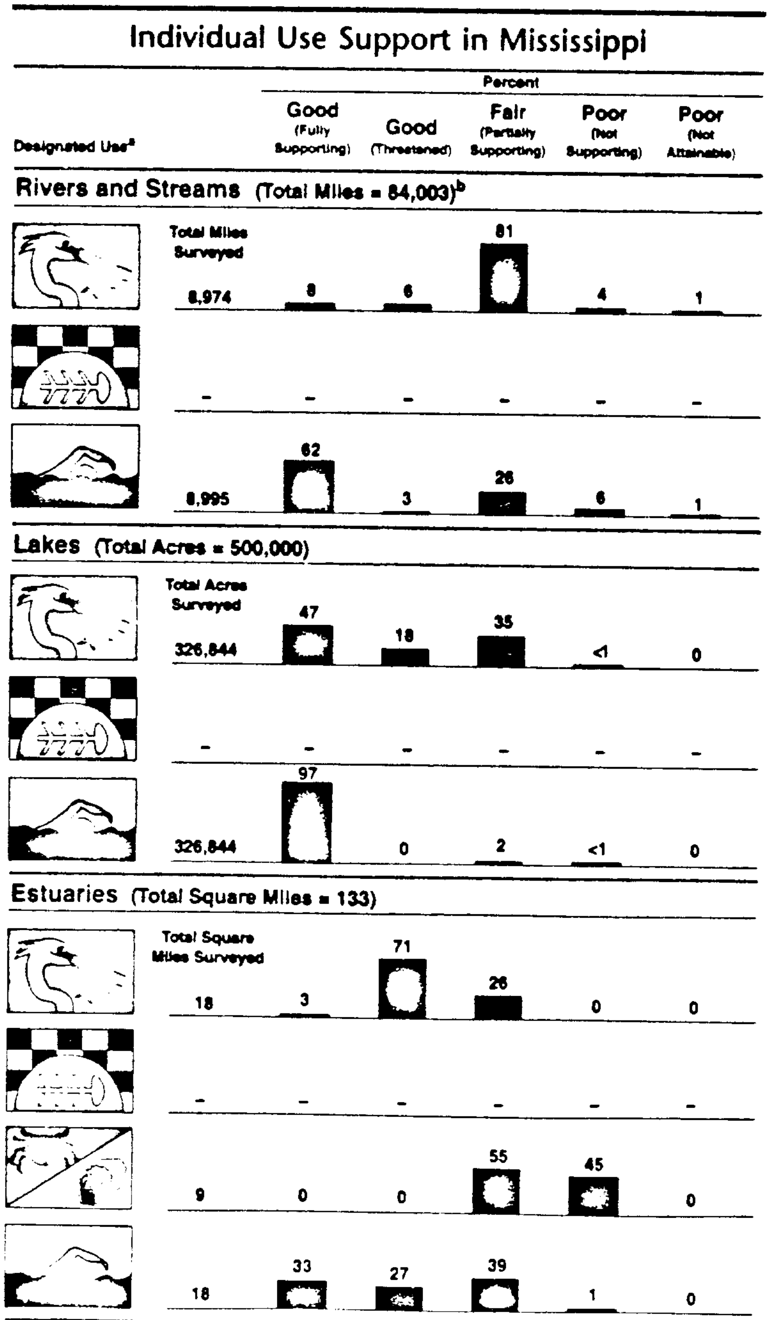
Monitoring Program, and the Wellhead Protection Program (approved by EPA in 1993).

Programs to Restore Water Quality

During 1993 and 1994, Mississippi developed regulations for conducting Section 401 Water Quality Certifications. The regulations enable the State to review Federal licenses and permits for compliance with State water quality standards. The comprehensive regulations went through public review and were adopted in February 1994. Mississippi also expanded its definition of waters of the State to include wetlands and ground waters.

Programs to Assess Water Quality

Each year, the State samples about 25 of their 57 historical fixed monitoring stations on a rotating schedule. The State monitors physical and chemical parameters bimonthly, metals in the water column twice a year, and biological parameters once a year. The development and implementation of a rapid bioassessment methodology has significantly increased coverage of State waters beyond the historic fixed stations. Several stations are also sampled annually for metals and pesticides in fish tissues. The State monitoring program is supplemented by a network of 27 stations operated by the USGS.



- Not reported

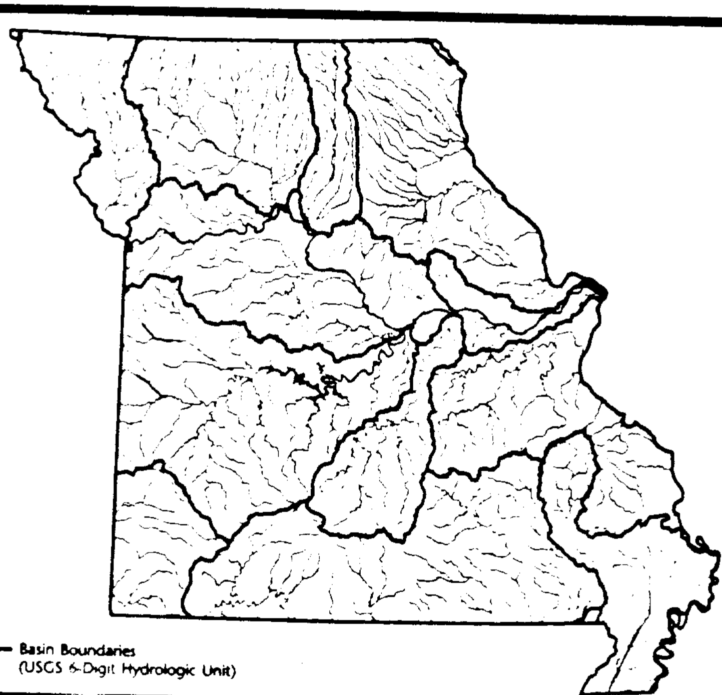
Missouri



— Basin Boundaries
(USGS 6-Digit Hydrologic Unit)

For a copy of the Missouri 1994 305(b) report, contact:

John Ford
Missouri Department of Natural Resources
Water Pollution Control Program
P.O. Box 176
Jefferson City, MO 65102-0176
(314) 751-7024

Surface Water Quality

Almost half of Missouri's rivers and streams have impaired aquatic habitat due to a combination of factors, including natural geology, climate, and agricultural land use. As a result of these factors, many streams suffer from low water volume, low dissolved oxygen concentrations, high water temperatures, and excessive siltation. In lakes, low dissolved oxygen from upstream dam releases, taste and odor problems, and pesticides are the most common ailments. Agriculture, urban runoff, and reservoir releases are the leading sources of lake degradation.

The Missouri Department of Health advises that the public restrict consumption of bottom-feeding fish (such as catfish, carp, and suckers) from non-Ozark streams or lakes to 1 pound per week due to high concentrations of chlordane, PCBs, and other contaminants in these fish.

Ground Water Quality

In general, ground water quantity and quality increases from north to south and west to east. Deep ground water aquifers in northern and western Missouri are not suitable for drinking water due to high concentrations of natural minerals. Nitrates and, to a much lesser extent, pesticides also contaminate wells in this region. About one-third of the private wells exceed drinking water standards for nitrates, and about 2% of private wells exceed drinking water standards for either atrazine or alachlor. Statewide, the highest priority concerns include ground water contamination from septic tanks, feedlots and pastureland, and underground storage tanks.

Programs to Restore Water Quality

Sewage treatment plant construction has restored many surface waters in Missouri, but overloaded older facilities still impact about 62 stream miles. Nonpoint source efforts have been less successful at restoring water quality. To date, the most successful activity has been the reclamation of abandoned coal mine lands, which is funded by a tax on coal that generates $1 million to $2 million annually. Stream miles impacted by abandoned coal mines fell from 100 miles to 42 miles as a result of reclamation projects.

Programs to Assess Water Quality

Missouri's water quality monitoring strategy features fixed-station chemical sampling, short-term intensive chemical surveys, rapid visual/bioassessments, and detailed biological monitoring to advance the development of biological criteria. The State also conducts toxicity testing and samples fish tissues for toxic chemicals. During 1992-94, four watershed projects featured concentrated monitoring activities designed to answer specific questions about animal waste management and farm chemical reduction options.

Individual Use Support in Missouri

Designated Use[a]	Total Surveyed	Percent: Good (Fully Supporting)	Good (Threatened)	Fair (Partially Supporting)	Poor (Not Supporting)	Poor (Not Attainable)

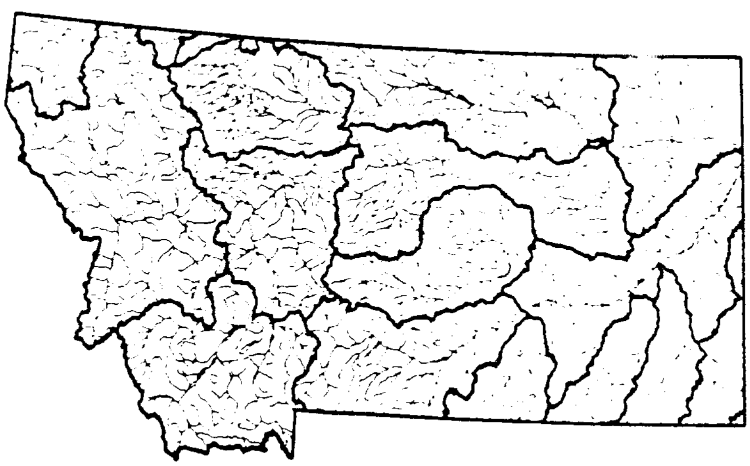
Montana



— Basin Boundaries
(USGS 6-Digit Hydrologic Unit)

For a copy of the Montana 1994 305(b) report, contact:

Christian J. Levine
Montana Department of Health
and Environmental Science
Water Quality Bureau
Cogswell Building
1400 Broadway
Helena, MT 59620
(406) 444-5342

Surface Water Quality

Most of Montana's rivers and streams (74%) have fair water quality that periodically fails to support aquatic life uses. Another 5% have poor water quality that consistently fails to support aquatic life uses. About 14% of the surveyed lake acres have good water quality that fully supports fish and aquatic life, 57% fully support swimming, and 62% fully support drinking water use. Agriculture (especially irrigated crop production and rangeland) impairs 60% of the surveyed stream miles and 45% of the surveyed lake acres. In general, nonpoint sources are a factor in 90% of the impaired rivers and 80% of the impaired lakes. Resource extraction, forestry, and municipal sewage treatment plants have less widespread impacts on water quality.

Ground Water Quality

More than 50% of Montanans get their domestic water supply from ground water sources. Ground water is plentiful and the quality is generally excellent, but Montana's aquifers are very vulnerable to pollution from human activities that will expand as the population expands throughout the river valleys. The Department of Health and Environmental Sciences and the Department of Natural Resources and Conservation are jointly preparing a Comprehensive Ground Water Protection Plan to protect ground water quality and quantity.

Programs to Restore Water Quality

Montana is actively pursuing interagency/interdisciplinary watershed planning and management. Currently, five large watershed projects are under way in Montana: the Flathead Lake Watershed Management Plan, the Blackfoot River Watershed Management Project, the Grassroots Planning Process for the Upper Clark Fork Basin, the Tri-State Clark Fork Pend Oreille Watershed Management Plan, and the Kootenai River Basin Program. Each program advocates collaboration by all interested parties to devise comprehensive management options that simultaneously address all major factors threatening or degrading water quality.

Programs to Assess Water Quality

Montana will need to expand its monitoring and assessment program to adequately measure the effectiveness of the State's nonpoint source control program and other watershed management programs. To date, only 10% of the State's stream miles and 2% of the lakes have been assessed. Fixed-station monitoring is limited to three of the State's 16 river basins: the Flathead and upper and lower Clark Fork basins. The Department will ask the State Legislature to fund additional staff and operating expenses to expand ambient monitoring in the State. The State is also concerned that the U.S. Geological Survey may discontinue trend monitoring in Montana.

Individual Use Support in Montana

Steven Walker
Nebraska Department of
Environmental Quality
Water Quality Division,
Surface Water Section
P.O. Box 98922, State House Station
Lincoln, NE 68509-8922
(402) 471-2875

Surface Water Quality

Agriculture is the most widespread source of water quality problems in Nebraska, but urban runoff also impacts the State's rivers and streams. Agricultural runoff introduces excess silt, bacteria, suspended solids, pesticides, and nutrients into surface waters. Municipal and industrial facilities may contribute ammonia, bacteria, and metals. Channelization and hydrologic modifications have impacted aquatic life in Nebraska streams by reducing the diversity and availability of habitat.

Elevated concentrations of metals, primarily arsenic, were the most common water quality problem identified in lakes, followed by siltation, low dissolved oxygen, and nutrients. Pesticides, primarily atrazine, also degraded 18 lakes. Nebraska applies more atrazine to crops than any other State in the United States. Sources of pollution in lakes include municipal sewage treatment plants, agriculture, construction, urban runoff, and hydrologic habitat modifications.

Ground Water Quality

Although natural ground water quality in Nebraska is good, hundreds of individual cases of ground water contamination have been documented in Nebraska and the number of contaminated wells increases every year. Major sources of ground water contamination include agricultural activities, industrial facilities, leaking underground storage tanks, oil or hazardous substance spills, solid waste landfills, wastewater lagoons, brine disposal pits, and septic systems.

Programs to Restore Water Quality

Until recently, Nebraska's Nonpoint Source (NPS) Management Program concentrated on protecting ground water resources. Surface water protection efforts consisted primarily of two federally funded demonstration projects on Long Pine Creek and Maple Creek. Now, Nebraska is evaluating the role of NPS pollution statewide. In 1994, Nebraska supported 35 NPS projects throughout the State.

Nebraska recently revised wetlands water quality standards to protect beneficial uses of aquatic life, aesthetics, wildlife, and agricultural water supply. The State also protects wetlands with the water quality certification program, permit requirements for underground injection activities and mineral exploration, and water quality monitoring.

Programs to Assess Water Quality

The State's Nonpoint Source Management Program cannot be effective without monitoring information to identify and prioritize waters impacted by NPS, develop NPS control plans, and evaluate the effectiveness of implemented best management practices. In response to this need, Nebraska developed an NPS surface water quality monitoring strategy to guide NPS monitoring projects. During 1992 and 1993, the State conducted 100 NPS screening assessments; 2 followup intensive NPS watershed assessments; BMP effectiveness studies in 10 watersheds; and a pesticide reconnaissance survey in the Big and Little Blue River Basin.

Individual Use Support in Nebraska

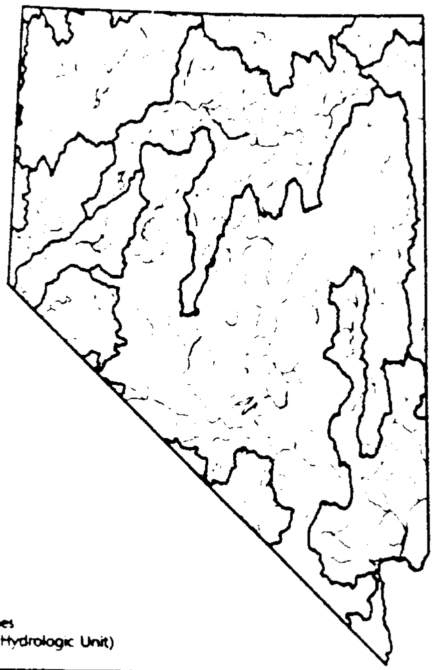
Nevada



— Basin Boundaries
(USGS 6-Digit Hydrologic Unit)

For a copy of the Nevada 1994 305(b) report, contact:

Glen Gentry
Bureau of Water Quality Planning
Division of Environmental Protection
123 West Nye Lane
Carson City, NV 89710
(702) 687-4670

Surface Water Quality

Only 10% (about 15,000 miles) of Nevada's rivers and streams flow year round, and most of these waters are inaccessible. For this reporting period, Nevada surveyed 1,440 miles of the 3,000 miles of accessible perennial streams with designated beneficial uses. Thirty percent of the surveyed stream miles have good water quality that fully supports aquatic life uses; 18% have fair water quality that sometimes does not support aquatic life uses; and 52% have poor water quality that does not support aquatic life uses. Thirty-eight percent of the surveyed streams fully support swimming and 62% do not fully support swimming. In lakes, 29% of the surveyed acres fully support aquatic life and swimming, and 71% partially support these uses.

Agricultural practices (irrigation, grazing, and flow regulation) have the greatest impact on Nevada's water resources. Agricultural sources generate large sediment and nutrient loads. Urban drainage systems contribute nutrients, heavy metals, and organic substances that deplete oxygen. Flow reductions also have a great impact on streams, limiting dilution of salts, minerals, and pollutants.

Ground Water Quality

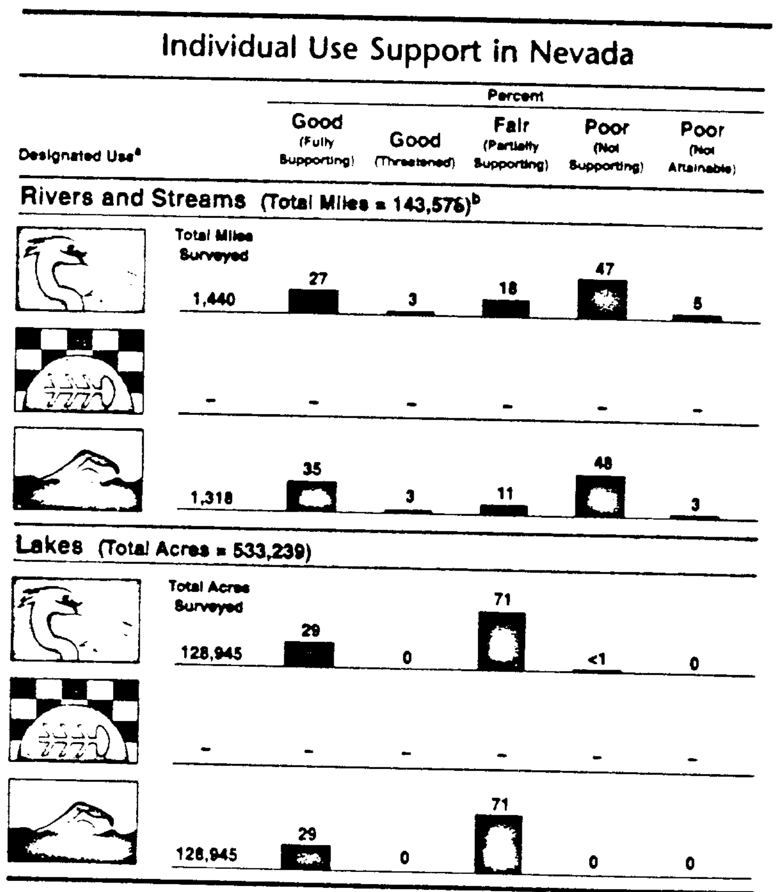
Nevada lacks comprehensive ground water protection legislation, but the State does have statutes that control individual sources of contamination, including mining, underground storage tanks, septic systems, handling of hazardous materials and waste, solid waste disposal, underground injection wells, agricultural practices, and wastewater disposal. Land use statutes also enable local authorities to implement Wellhead Protection Plans by adopting zoning ordinances, subdivision regulations, and site plan review procedures. Local authorities can implement certain source control programs at the local level.

Programs to Restore Water Quality

Nevada's Nonpoint Source Management Plan aims to reduce NPS pollution with interagency coordination, education programs, and incentives that encourage voluntary installation of best management practices. During 1992-1994, the State continued updating the *Handbook of Best Management Practices* and supported NPS assessment activities in each of the State's six major river basins. The State also completed a Wellhead Protection Plan for the State and began developing a State Ground Water Protection Policy.

Programs to Assess Water Quality

Several State, Federal, and local agencies regularly sample chemical and physical parameters at over 100 sites in the 14 hydrologic regions of the State. Nevada hopes to add biological monitoring at several routine sampling sites after the State adapts rapid bioassessment protocols to the arid conditions in Nevada. The State also coordinates intensive field studies on Nevada's major river systems, the Truckee River Basin, Carson River Basin, Walker River Basin, and the Humboldt River Basin. The State also monitors a number of lakes and reservoirs in conjunction with the Section 314 Clean Lakes Program.



- Not reported.

[a] A subset of Nevada's designated uses appear in this figure. Refer to the State's 305(b) report for a full description of the State's uses.

Concord, NH 03301
(603) 271-2457

Surface Water Quality

Overall, the quality of New Hampshire's surface waters is excellent. Over 99% of the State's river miles and 95% of the lake acres have excellent or good water quality that fully supports aquatic life uses and swimming. Poor water quality conditions are more widespread in estuaries; high bacterial levels interfere with shellfish harvesting in 66% of the estuarine waters. Bacteria is also the leading cause of impairment in rivers where high bacteria levels indicate unsafe swimming conditions. Nutrients are the major cause of impairment in lakes and ponds. The State suspects that nonpoint sources are responsible for most of the pollution entering the State's waters.

New Hampshire advises the public to restrict consumption of fish caught in the Androscoggin River below Berlin, the Connecticut River, Horseshoe Pond, and the Great Bay Estuary. One fish consumption advisory is posted on the Androscoggin River below Berlin due to elevated concentrations of dioxins in fish tissue. The James River Corporation paper mill in Berlin is the suspected source of the dioxins.

Ground Water Quality

New Hampshire's overall ground water quality is very good. In some localized areas, naturally occurring arsenic, fluoride, and radionuclides (principally radon) exceed drinking water standards. Releases from petroleum facilities, industrial operations, and landfills have contaminated isolated areas with petroleum or volatile organic compounds. Sodium is the only contaminant that has exhibited an increasing presence in ground water due to the widespread application of road salts in winter. New Hampshire is developing a Comprehensive State Ground Water Protection Program to coordinate their various ground water assessment, prevention, and restoration programs.

Programs to Restore Water Quality

Over the past 20 years, New Hampshire has eliminated or abated all significant untreated municipal and industrial wastewater discharges in State waters. Recently, the Department of Environmental Services (DES) initiated a watershed protection approach to identify and resolve remaining pollution problems. DES will compile watershed maps and land use data, identify major sources of pollution, model total maximum daily loads for pollutants, and revise discharge permits as needed in the State's five basins. DES estimates that each basin assessment will require 2 years to complete at current funding levels.

Programs to Assess Water Quality

DES implemented a rotating watershed monitoring program in 1989. In 1993, the rotation was temporarily halted so that the State could intensify monitoring at sites violating standards. During 1994 and 1995, DES will investigate sources of violations confirmed by the 1993 data.

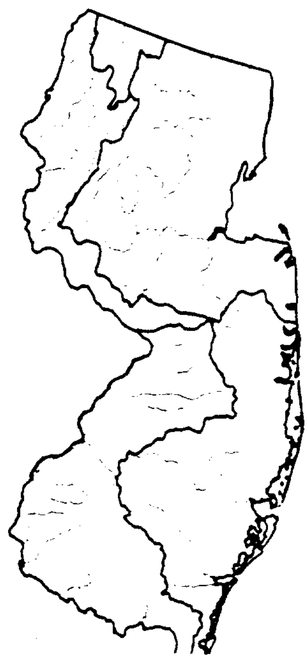
New Jersey



For a copy of the New Jersey 1994 305(b) report, contact:

Kevin Berry
NJ DEP
Office of Environmental Planning
401 East State St.
Trenton, NJ 08625
(609) 633-1179

Surface Water Quality

Sixty-eight percent of the 1,617 surveyed stream miles have good water quality that fully supports aquatic life, but New Jersey's high population density threatens these waters. Bacteria (which indicates unsafe swimming conditions) and nutrients are the most common pollutants in rivers and streams. All of the State's lakes are believed to be threatened or actively deteriorating. Bacterial contamination is the most widespread problem in estuaries, impairing both shellfish harvesting and swimming. Other problems include nutrients, low dissolved oxygen concentrations, pesticides, and priority organic chemicals. Major sources impacting New Jersey's waters include municipal treatment plants, industrial facilities, combined sewers, urban runoff, construction, agriculture, and land disposal of wastes (including septic tanks).

Ground Water Quality

There are currently over 6,000 ground water pollution investigations under way in New Jersey. The most common pollutants found in ground water are volatile organic compounds, metals, base neutral chemicals, acid-extractable chemicals, PCBs, and pesticides. Underground storage tanks are the most common source of ground water contamination, followed by landfills, surface spills, and industrial/commercial septic systems. New Jersey adopted new ground water quality standards in 1993 that revise the ground water classification system and establish numerical criteria for many pollutants. The standards also protect good ground water quality from degradation by future activities.

Programs to Restore Water Quality

New Jersey's Department of Environmental Protection (DEP) is adopting a watershed approach to water quality and quantity management. The watershed approach coordinates monitoring, modeling, planning, permitting, and enforcement activities within a geographic area that drains into a major river, lake, or estuary. The watershed approach allows all interested parties to participate in the development of consensus-based management options. DEP is currently conducting a watershed protection pilot project in the Whippany River watershed with local governments, permittees, regional interest groups, and private citizens.

Programs to Assess Water Quality

DEP's current monitoring program is centered around physical and chemical sampling at fixed stations designed to monitor long-term trends. Unfortunately, the fixed-station network cannot provide data to address other management needs, such as identifying specific sources of pollution and measuring the effectiveness of specific pollution control actions. Therefore, DEP recommends supplementing the fixed-station monitoring program with intensive watershed surveys to support watershed protection management projects. Intensive surveys would collect data to profile water quality over 24-hour periods, identify pollution sources, quantify pollution impacts, compare water quality data to flow conditions, model wasteload allocations, and determine assimilative capacity of waterbodies.

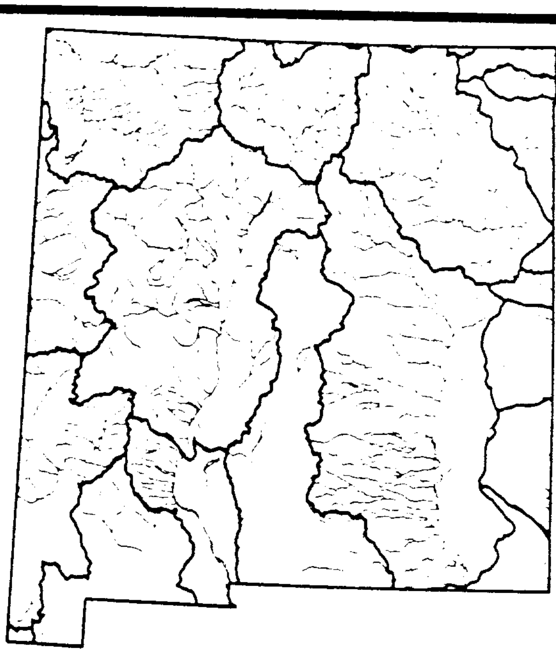
New Mexico



— Basin Boundaries
(USGS 6-Digit Hydrologic Unit)

For a copy of the New Mexico 1994 305(b) report, contact:

Erik Galloway
New Mexico Environment Department
Surface Water Quality Bureau
Evaluation and Planning Section
P.O. Box 26110
Santa Fe, NM 87502-6110
(505) 827-2923

Surface Water Quality

About 93% of New Mexico's surveyed stream miles have good water quality that fully supports aquatic life uses. Ninety-nine percent of the surveyed river miles fully support swimming. The leading problems in streams include habitat alterations (such as removal of streamside vegetation), siltation, metals, and nutrients. Nonpoint sources are responsible for over 93% of the degradation in New Mexico's 3,255 impaired stream miles. Municipal wastewater treatment plants impair about 4% of the degraded waters (124 stream miles).

Agriculture and recreational activities are the primary sources of nutrients, siltation, reduced shoreline vegetation, and bank destabilization that impairs aquatic life use in 91% of New Mexico's surveyed lake acres. Mercury contamination from unknown sources appears in fish caught at 22 reservoirs. However, water and sediment samples from surveyed lakes and reservoirs have not detected high concentrations of mercury. Fish may contain high concentrations of mercury in waters with minute quantities of mercury because the process of biomagnification concentrates mercury in fish tissue.

Ground Water Quality

About 88% of the population of New Mexico depends on ground water for drinking water. The Environment Department has identified at least 1,745 cases of ground water contamination since 1927. The most common source of ground water contamination is small household septic tanks and cesspools. Leaking underground storage tanks, injection wells, landfills, surface impoundments, oil and gas production, mining and milling, dairies, and miscellaneous industrial sources also contaminate ground water in New Mexico. New Mexico operates a ground water discharger permit program that includes ground water standards for intentional discharges and a spill cleanup provision for other discharges.

Programs to Restore Water Quality

New Mexico's Nonpoint Source Management Program contains a series of implementation milestones that were designed to establish goals while providing a method to measure progress and success of the program. Implementation consists of the coordination of efforts among NPS management agencies, promotion and implementation of best management practices, coordination of watershed projects, inspection and enforcement activities, consistency reviews, and education and outreach activities.

Programs to Assess Water Quality

New Mexico relies heavily on chemical and physical data to assess water quality. Fish tissue data became available in 1991, and data from biological surveys and bioassay tests were incorporated into the 1994 assessments where possible. The State also conducts extensive monitoring to determine the effectiveness of best management practices implemented under the Nonpoint Source Management Program. During the current 305(b) reporting cycle, New Mexico completed two special water quality surveys along the Rio Hondo and the Red River in Taos County.

Individual Use Support in New Mexico

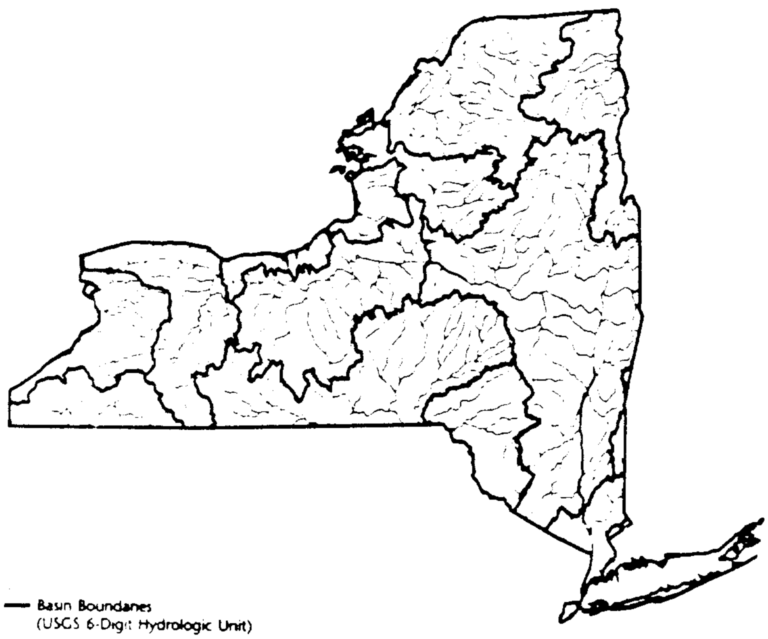
New York



For a copy of the New York 1994 305(b) report, contact:

George K. Hansen, P.E.
New York State Department of Environmental Conservation
Bureau of Monitoring and Assessment
50 Wolf Road
Albany, NY 12233
(518) 457-8819

Surface Water Quality

Ninety-one percent of New York's rivers and streams, 74% of the State's lake acres, 97% of the State's Great Lakes shoreline, and 99% of the bays and tidal waters have good water quality that fully supports aquatic life uses. Swimming is fully supported in 99% of the surveyed rivers, 78% of the surveyed lakes, 80% of the Great Lakes shoreline, and 93% of the surveyed estuarine waters. Eighty-five percent of New York's Great Lake's shoreline does not fully support fish consumption use because of a fish consumption advisory.

Agriculture is a major source of nutrients and silt that impair New York's rivers, lakes, and reservoirs. Hydrologic modification and habitat modification are also a major source of water quality impairment in rivers and lakes. Urban runoff is a major source of pollution in the State's estuaries. Bacteria from urban runoff and other sources close about 200,000 acres (16%) of potential shellfishing beds.

Contaminated sediments are the primary source of 7% of the impaired rivers and lakes, 76% of the impaired Great Lake's shoreline, and 27% of the impaired estuarine waters in New York State. Sediments are contaminated with PCBs, chlorinated organic pesticides, mercury, cadmium, mirex, and dioxins that bioconcentrate in the food chain and result in fish consumption advisories.

Sewage treatment plant construction and upgrades have had a significant impact on water quality. Since 1972, the size of rivers impacted by municipal sewage treatment facilities has declined from about 2,000 miles to 300 miles.

Ground Water Quality

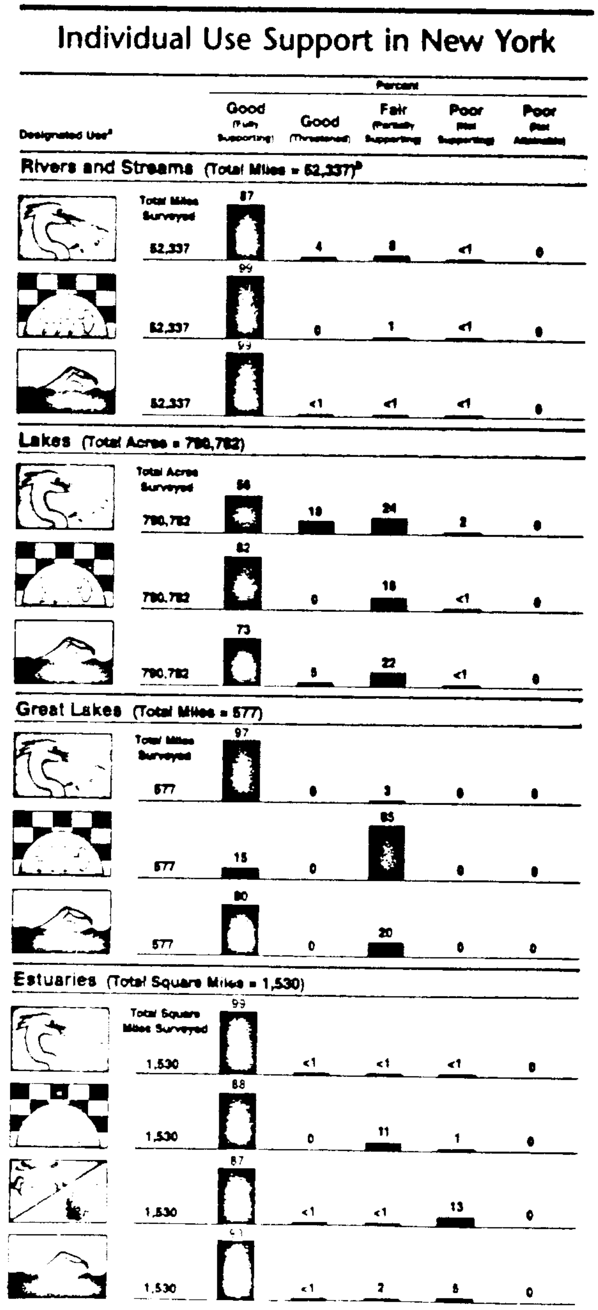
About 3% of the State's public water supply system wells (160 wells) are closed or abandoned due to contamination from organic chemicals. The most common contaminants are synthetic solvents and degreasers, gasoline and other petroleum products, and agricultural pesticides and herbicides (primarily aldicarb and carbofuran). The most common sources of organic solvents in ground water are spills, leaks, and improper handling at industrial and commercial facilities.

Programs to Restore Water Quality

Virtually every county of the State has a county water quality coordinating committee composed of local agencies (such as Cornell Cooperative Extension and soil and water conservation districts), local representatives from State and Federal agencies, and public interest groups. The county committees meet regularly to discuss local priorities and fashion local strategies to address nonpoint source pollution.

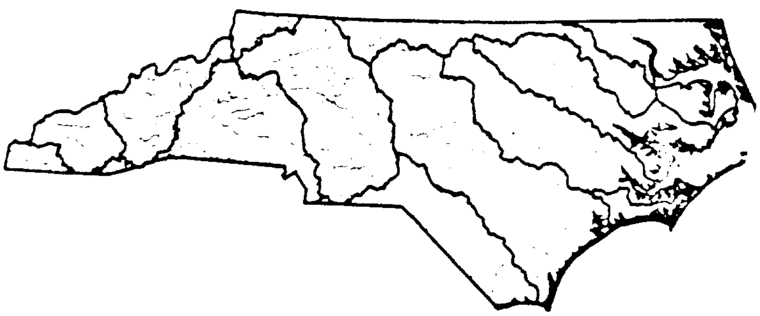
Programs to Assess Water Quality

In 1987, New York State implemented the Rotating Intensive Basin Studies (RIBS), an ambient monitoring program that concentrates monitoring activities on one-third of the State's hydrologic basins for 2-year periods. The DEC monitors the entire State every 6 years. Intensive monitoring clarifies cause-and-effect relationships between pollutants and water quality, measures the effectiveness of implemented pollution controls, and supports regulatory decisions.



[a] A subset of New York's designated uses appear in this figure. Refer to the State's 305(b) report for a full description of the State's uses.
[b] Includes nonperennial streams that dry up and do not flow all year.

North Carolina



— Basin Boundaries
(USGS 6-Digit Hydrologic Unit)

For a copy of the North Carolina 1994 305(b) report, contact:

Carol Metz
NC DEHNR
Division of Environmental Management
P.O. Box 29535
Raleigh, NC 27626-0535
(919) 733-5083

Surface Water Quality

About 70% of the State's surveyed freshwater rivers and streams have good water quality that fully supports aquatic life uses, 25% have fair water quality that partially supports aquatic life uses, and 5% have poor water quality that does not support aquatic life uses. Eighteen percent of the surveyed rivers do not fully support swimming. The major sources of impairment are agriculture (responsible for 56% of the impaired river miles), urban runoff (responsible for 13%), point sources (responsible for 12%), and construction (responsible for 11%). These sources generate siltation, bacteria, and organic wastes that deplete dissolved oxygen.

Only 3% of the surveyed lakes in North Carolina are impaired for swimming and aquatic life uses. A few lakes are impacted by dioxin, metals, and excessive nutrient enrichment. The Champion Paper mill on the Pigeon River is the source of dioxin contamination in Waterville Lake. The State and the mill implemented a dioxin minimization program in the mid-1980s and completed a modernization program in 1993 that will reduce water usage and discharges.

About 93% of the estuaries and sounds in North Carolina fully support designated uses. Agriculture, urban runoff, septic tanks, and point source discharges are the leading sources of nutrients, bacteria, and low dissolved oxygen that degrade estuaries.

Ground Water Quality

About half of the people in North Carolina use ground water as their primary supply of drinking water. Ground water quality is generally good, but new cases of ground water contamination affected 276 public water supplies during 1992-1993. The leading source of ground water contamination is leaking underground storage tanks, which contaminate ground water with gasoline, diesel fuel, and heating oil. During 1992 and 1993, North Carolina adopted new regulations for administering Leaking Underground Storage Tank funds and amended ground water standards.

Programs to Restore Water Quality

In 1992-1993, North Carolina continued its aggressive program to control nonpoint source pollution. North Carolina adopted a nondischarge rule for animal waste management implemented an innovative nutrient trading program between point and nonpoint sources in the Tar-Pamlico river basin, signed 2,500 new contracts under the Agricultural Cost Share Program to implement best management practices, and reclassified about 200 water supply watersheds for special protection.

Programs to Assess Water Quality

Surface water quality in North Carolina was primarily evaluated using physical and chemical data collected by the Division of Environmental Management (DEM) from a statewide fixed-station network and biological assessments. These include macroinvertebrate (aquatic insect) community surveys, fish community structure analyses, phytoplankton analyses, bioassays, and limnological review of lakes and watersheds. Other sources of information were point source monitoring data, shellfish closure reports, lake trophic state studies, and reports prepared by other local, State, and Federal agencies.

Michael Ell
North Dakota Department of Health
Division of Water Quality
P.O. Box 5520
Bismark, ND 58502
(701) 328-5210

Surface Water Quality

North Dakota reports that 78% of its surveyed rivers and streams have good water quality that fully supports aquatic life uses now, but good conditions are threatened in most of these streams. Eighty-nine percent of the surveyed streams fully support swimming. Elevated siltation, nutrients, ammonia, pathogens, oxygen-depleting wastes, and habitat alterations impair aquatic life use support in 22% of the surveyed rivers and impair swimming in 11% of the surveyed rivers. The leading sources of contamination are agriculture, removal of streamside vegetation, municipal sewage treatment plants, and other habitat alterations. Natural conditions, such as low flows, also contribute to violations of standards.

In lakes, 95% of the surveyed acres have good water quality that fully supports aquatic life uses, and 98% of the surveyed acres fully support swimming. Siltation, nutrients, oxygen-depleting substances, and suspended solids are the most widespread pollutants in North Dakota's lakes. The leading sources of pollution in lakes are agricultural activities (including nonirrigated crop production, pasture land, irrigated crop production, and feedlots), municipal sewage treatment plants, and urban runoff/storm sewers. Natural conditions also prevent some waters from fully supporting designated uses.

Ground Water Quality

North Dakota has not identified widespread ground water contamination, although some naturally occurring compounds may make the quality of ground water undesirable in a few aquifers. Where human-induced ground water contamination has occurred, the impacts have been attributed primarily to petroleum storage facilities, agricultural storage facilities, feedlots, poorly designed wells, abandoned wells, wastewater treatment lagoons, landfills, septic systems, and the underground injection of waste. Assessment and protection of ground water continue through ambient ground water quality monitoring activities, the implementation of wellhead protection projects, the Comprehensive Ground Water Protection Program, and the development of a State Management Plan for Pesticides.

Programs to Restore Water Quality

North Dakota's Nonpoint Source Pollution Management Program has provided financial support to 26 projects over the past 4 years. Although the size, type, and target audience of these projects vary, the projects share the same basic goals: (1) increase public awareness of nonpoint source pollution, (2) reduce or prevent the delivery of NPS pollutants to waters of the State, and (3) disseminate information on effective solutions to NPS pollution.

Programs to Assess Water Quality

The North Dakota Department of Health monitors physical and chemical parameters (such as dissolved oxygen, pH, total dissolved solids, and nutrients), toxic contaminants in fish, whole effluent toxicity, and fish community structure. North Dakota's ambient water quality monitoring network consists of 61 sampling sites on 31 rivers and streams.

Individual Use Support in North Dakota

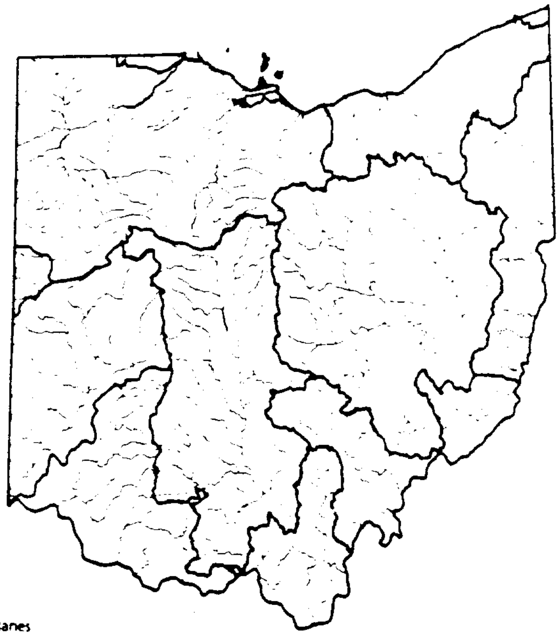
Ohio



— Basin Boundaries
(USGS 6-Digit Hydrologic Unit)

For a copy of the Ohio 1994 305(b) report, contact:

Ed Rankin
Ohio Environmental Protection Agency
Division of Surface Water
1685 Westbelt Drive
Columbus, OH 43228
(614) 728-3385

Surface Water Quality

Ohio based their 1994 assessments on data collected between 1988 and 1994. Ohio's assessment methods compare observed ecological characteristics (including data on aquatic insects, fish species, habitat, and streamside vegetation) with background conditions found at least-impacted reference sites for a given ecoregion and stream type.

Ohio identified ecological impacts from organic enrichment and low dissolved oxygen concentrations, siltation, habitat modification, metals, ammonia, and flow alterations. Fecal coliform bacteria indicate impaired swimming conditions in 9% of the surveyed river miles. These impacts stem from municipal discharges, runoff from agriculture, hydromodification, industrial discharges, mining, urban runoff, and combined sewer overflows.

Ohio estimates that wastewater treatment plant construction and upgrades have restored aquatic life to about 1,000 river miles since the 1970s. Since 1988, the percentage of surveyed river miles fully fit for swimming also grew from 49% to 60%. However, increasing threats from nonpoint sources could erode gains made with point source controls and slow the rate of restoration.

The most common impacts on Ohio lakes include nutrients, volume loss due to sedimentation, organic enrichment, and habitat alterations. Nonpoint sources, including agriculture, urban runoff, and septic systems, generate most of these impacts. However, municipal point sources still affect 63% of the surveyed lake acres.

Most of the Lake Erie shoreline is fit for recreational use, but a fish consumption advisory for channel catfish and carp remains in effect along the entire shoreline. Ohio also issued fish consumption advisories for all species of fish caught on 137 river miles and documented elevated levels of PCBs in fish caught at two small lakes.

Ground Water Quality

About 4.5 million Ohio residents depend upon wells for domestic water. Waste disposal activities, underground storage tank leaks, and spills are the dominant sources of ground water contamination in Ohio.

Programs to Restore Water Quality

To fully restore water quality, Ohio EPA advocates an ecosystem approach that confronts degradation on shore as well as in the water. Ohio's programs aim to correct nonchemical impacts, such as channel modification and the destruction of shoreline vegetation.

Programs to Assess Water Quality

Ohio pioneered the integration of biosurvey data, physical habitat data, and bioassays with water chemistry data to measure the overall integrity of water resources. Biological monitoring provides the foundation of Ohio's water programs because traditional chemical monitoring alone may not detect episodic pollution events or nonchemical impacts. Ohio EPA found that biosurvey data can increase the detection of aquatic life use impairment by about 35% to 50%.

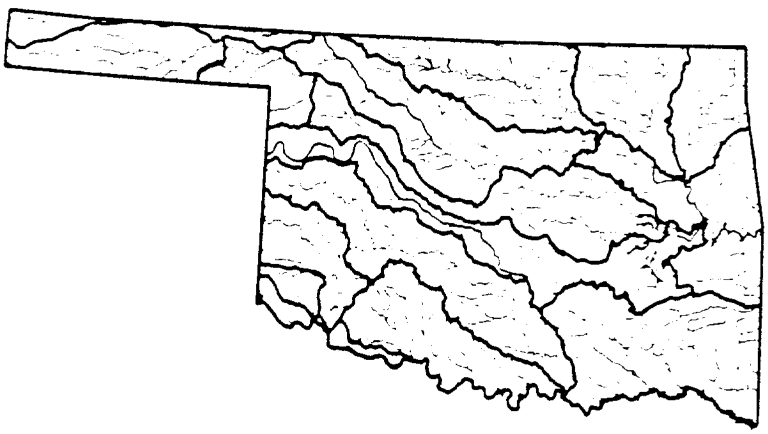
Oklahoma



— Basin Boundaries
(USGS 6-Digit Hydrologic Unit)

For a copy of the Oklahoma 1994 305(b) report, contact:

John Dyer
Oklahoma Department of Environmental Quality
Water Quality Division
1000 NE 10th Street
Oklahoma City, OK 73117-1212
(405) 271-5205

Surface Water Quality

Fifty-eight percent of the surveyed river miles have good water quality that fully supports aquatic life uses and 65% fully support swimming. The most common pollutants found in Oklahoma rivers are siltation, pesticides, nutrients, and suspended solids. Agriculture is the leading source of pollution in the State's rivers and streams, followed by petroleum extraction and hydrologic/habitat modifications.

Fifty-seven percent of the surveyed lake acres fully support aquatic life uses and 60% fully support swimming. The most widespread pollutants in Oklahoma's lakes are siltation, nutrients, suspended solids, and oxygen-depleting substances. Agriculture is also the most common source of pollution in lakes, followed by contaminated sediments and flow regulation. Several lakes are impacted by acid mine drainage, including the Gaines Creek arm of Lake Eufaula and the Lake O' the Cherokees.

Ground Water Quality

Ambient ground water monitoring has detected elevated nitrate concentrations in monitoring wells scattered across the State. Monitoring has also detected isolated cases of hydrocarbon contamination, elevated selenium and fluoride concentrations (probably due to natural sources), chloride contamination from discontinued oil field activities, metals from past mining operations, and gross alpha activity above maximum allowable limits. Industrial solvents contaminate a few sites near landfills, storage pits, and Tinker Air Force Base. The State rates agriculture, injection wells, septic tanks, surface impoundments, and industrial spills as the highest priority sources of ground water contamination.

Programs to Restore Water Quality

Oklahoma's nonpoint source control program is a cooperative effort of State, Federal, and local agencies that sponsors demonstration projects. The demonstration projects feature implementation of agricultural best management practices, water quality monitoring before and after BMP implementation, technical assistance, education, and development of comprehensive watershed management plans. Currently, Oklahoma is conducting five NPS projects in Comanche County, Greer and Beckham Counties, Custer County, Tillman County, and the Illinois River Basin.

Programs to Assess Water Quality

Oklahoma's Conservation Commission is conducting five large watershed studies in the Illinois River Basin, the Little River Basin, the Neosho (Grand) River Basin, the Southeast Oklahoma Multiple Basin, and the Poteau River/Wister Lake Project (a cooperative effort with the LeFlore Conservation District, the Water Board, and the USGS). All together, 385 sites will be sampled for chemical parameters and one-third of these sites will also be sampled for biological integrity.

Portland, OR 97204
(503) 229-6962

Surface Water Quality

Forty-three percent of Oregon's surveyed rivers have good water quality that fully supports designated uses, 30% have fair water quality that partially supports uses, and 27% have poor water quality that does not support uses. The most widespread problems in Oregon's streams are habitat alterations, high temperatures, and siltation from grazing, other agricultural activities, forestry, and recreation.

In lakes, 74% of the surveyed acres fully support uses, 12% partially support uses, and 14% do not support uses. The most common problems in Oregon's lakes are excess nutrients, pH (acidity), and low dissolved oxygen. DEQ suspects that agriculture and natural conditions (including shallow depth and high evaporation rates) are the most significant sources of lake problems.

Six percent of Oregon's estuarine waters have good quality and 94% have fair water quality due to periodic violations of bacteria standards. High concentrations of fecal bacteria usually result from bypasses at municipal wastewater treatment plants during rainfall events or improper management of animal wastes.

Ground Water Quality

Monitoring has detected nitrates, benzene, other volatile organic compounds, bacteria, herbicides, and pesticides in ground water. Suspected sources include septic systems, agriculture, highway maintenance, industry, and commerce. During 1992 and 1993, DEQ conducted statewide ground water monitoring, developed a ground water data management system, and issued 16 grants for research and education projects designed to protect ground water from nonpoint sources of pollution.

Programs to Restore Water Quality

Oregon recently initiated a Watershed Health Program to encourage public/private partnerships for managing water quality and ecosystem enhancement. Under the Watershed Health Program, field-based technical teams work closely with watershed councils composed of local residents and stakeholders to set priorities and fund projects. DEQ and other State agencies targeted the Grand Ronde Basin and the combined South Coast and Rogue Basins to begin implementing the Watershed Health Program with $10 million in State funds for 1994 and 1995. These basins were selected because of existing Total Maximum Daily Load programs.

Programs to Assess Water Quality

DEQ routinely monitors about 3,500 miles of streams in its ambient river monitoring program. These streams receive about 90% of the wastewater discharged by point sources throughout the State. During 1992 and 1993, DEQ increased the number of ambient river monitoring stations and expanded other monitoring programs, including ground water studies, continuous monitoring, mixing zone studies, and bioassessments. Recently, Oregon also initiated the Coos Bay toxics study, the Tillamook Bay National Estuary Program, and the Lower Columbia River Bi-State Program to provide more information on estuarine water quality.

Overall[a] Use Support in Oregon

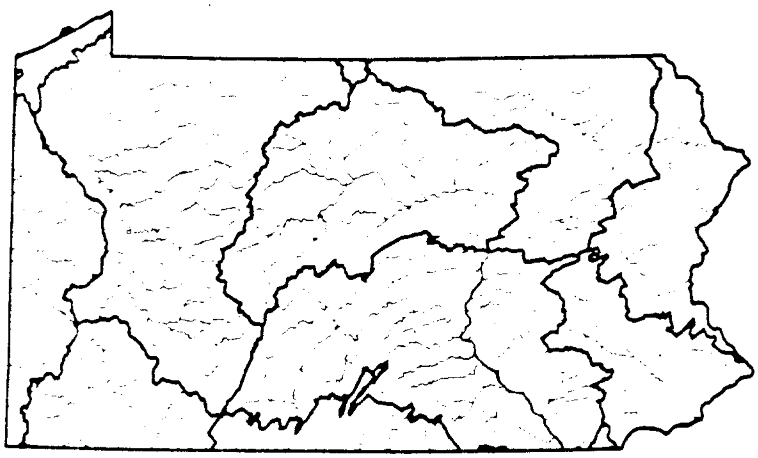
	Percent: Good (Fully Supporting)	Good (Threatened)	Fair (Partially Supporting)	Poor (Not Supporting)	Poor (Not Attainable)
Rivers and Streams (Total Miles = 114,823)[b] — Total Miles Surveyed 29,109	43	-	30	27	-
Lakes (Total Acres = 618,934) — Total Acres Surveyed 504,928	74	-	12	14	-
Estuaries (Total Square Miles = 206) — Total Square Miles Surveyed 60	6	-	94	0	-

- Not reported

[a] Overall use support is presented in this figure because Oregon did not report individual use support in their 1994 Section 305(b) report.

[b] Includes nonperennial streams that dry up and do not flow all year.

Pennsylvania



— Basin Boundaries
(USGS 6-Digit Hydrologic Unit)

For a copy of the Pennsylvania 1994 305(b) report, contact:

Robert Frey
Pennsylvania Department of Environmental Resources
Bureau of Water Quality Management
Division of Assessment and Standards
P.O Box 8465
Harrisburg, PA 17105-8465
(717) 783-3638

Surface Water Quality

Over 81% of the surveyed river miles have good water quality that fully supports aquatic life uses and swimming. About 8% have fair water quality that partially supports these uses, and 11% have poor water quality that does not support aquatic life uses and swimming. The most widespread pollutants are metals, which impact over 2,092 miles. Pollutants identified less frequently include suspended solids (impacting 603 miles), nutrients (impacting 586 miles), and pH (impacting 273 miles).

Abandoned mine drainage is the most significant source of surface water quality degradation in Pennsylvania. Drainage from mining sites pollutes at least 2,404 miles of streams representing 52% of all degraded streams in the Commonwealth. Other sources of degradation include agriculture (impacting 694 miles), municipal sewage treatment plants (impacting 241 miles), and industrial point sources (impacting 206 miles).

Pennsylvania has issued fish consumption advisories on 23 waterbodies. Most of the advisories are due to elevated concentrations of PCBs and chlordane in fish tissue, but a few advisories have been issued for mirex and mercury. In 1994, the State deactivated two advisories for dioxins on Codurus Creek and the South Branch of Codurus Creek as well as one advisory for chlordane on the Delaware River.

Ground Water Quality

Major sources of ground water contamination in Pennsylvania include leaking underground storage tanks, containers from hazardous materials facilities, and improper handling or overuse of fertilizer. Petroleum and petroleum byproducts are the most common pollutants in ground water. Coal mining and oil and gas production have also elevated concentrations of several elements (including chlorides, iron, barium, and strontium) in some regions of the Commonwealth. A Ground Water Quality Protection Strategy was adopted and released to the public in February 1992, and an Implementation Task Force was formed in August 1992. The Task Force reviewed all program regulations and scheduled revisions that will advance the Strategy goal of nondegradation of ground water quality.

Programs to Restore Water Quality

Eliminating acid mine drainage from abandoned mines will require up to $5 billion. The cost, difficulty, magnitude, and extent of the problem have hampered progress. To date, the Commonwealth has funded studies to determine the effectiveness of alternative techniques for treating mine drainage and preventing contamination. The U.S. Department of Agriculture (USDA) Natural Resources Conservation Service's Rural Abandoned Mines Program also reconstructs abandoned mine sites in Pennsylvania.

Programs to Assess Water Quality

The Water Quality Network monitors chemical and physical parameters almost monthly and biological parameters annually at 168 fixed stations on rivers, streams, and Lake Erie. In 1991, Pennsylvania began annual sampling at 15 to 20 lakes for 5 years. After 5 years, another set of lakes will be sampled annually for 5 years until 90 lakes have been monitored. The Commonwealth also conducts ambient ground water monitoring at 537 monitoring sites.

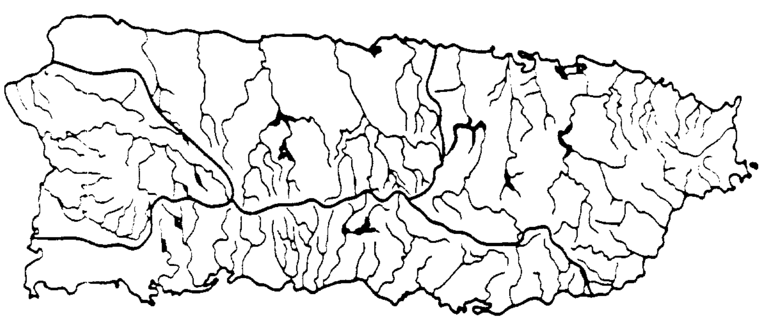
VOL 12

Puerto Rico



— Basin Boundaries
(USGS 6-Digit Hydrologic Unit)

For a copy of the Puerto Rico 1994 305(b) report, contact:

Eric H. Morales
Puerto Rico Environmental Quality Board
Water Quality Area
Box 11488
Santurce, PR 00910
(809) 751-5548

Surface Water Quality

In rivers and streams, 17% of the surveyed miles have good water quality that fully supports aquatic life uses, 32% partially support aquatic life uses, and 51% do not support aquatic life uses. Swimming is impaired in 79% of the surveyed rivers and streams. Low dissolved oxygen, pesticides, flow alteration, bacteria, and nutrients are the most widespread problems in rivers and streams. In lakes, 30% of the surveyed acres fully support aquatic life uses, 19% partially support these uses, and 51% do not support aquatic life uses. Swimming is impaired in 55% of the surveyed lake acres. Uses are impaired by inorganic chemicals, low dissolved oxygen concentrations, bacteria, priority organic chemicals, metals, and pesticides.

Only 16% of the assessed estuarine waters fully support aquatic life uses and only 17% fully support swimming due to oxygen-depleting organic substances, bacteria, and habitat alterations. Land disposal of wastes, urban runoff, agriculture, municipal sewage treatment plants, and natural conditions are the most common sources of water quality degradation in rivers, lakes, and estuaries. Industrial and municipal discharges also pollute beaches.

Ground Water Quality

Organic compounds, including dichloromethane, 1,1,2-trichloroethane, and toluene were detected below maximum contaminant levels in several wells. Four wells were closed due to bacterial contamination and high turbidity and two wells were shut down due to contamination from volatile organic compounds. The major sources of ground water contamination are septic tanks, livestock operations, agriculture, storage tanks, and landfills. Puerto Rico adopted ground water use classifications and water quality standards in 1990. In 1993, the Environmental Quality Board completed the ground water priority list that ranks critical areas for remediation and protection activities.

5680

Programs to Restore Water Quality

Puerto Rico requires permits or certificates for ground water and surface water discharges, underground storage tanks, and livestock operations. Certificates require livestock operations to implement animal waste management systems and other best management practices. During the 1992-1993 reporting period, Puerto Rico issued 194 certificates for livestock operations; inspected 427 livestock operations; implemented 77 BMPs in priority watersheds; offered 15 conferences to educate the public about nonpoint source pollution and controls, and monitored the effectiveness of BMPs implemented at poultry, dairy, and hog farms.

Programs to Assess Water Quality

Under a cooperative agreement with the government of Puerto Rico, the USGS collects bimonthly samples at 57 fixed surface water monitoring stations. The samples are analyzed for dissolved oxygen, nutrients, bacteria, and conventional parameters. Twice a year, the samples are analyzed for metals and several toxic substances. Puerto Rico also maintains a Permanent Coastal Water Quality Network of 88 stations and the San Juan Beachfront Special Monitoring Network of 22 stations sampled monthly for bacterial contamination.

Individual Use Support in Puerto Rico

Designated Use[a]	Total Surveyed	Good (Fully Supporting) %	Good (Threatened) %	Fair (Partially Supporting) %	Poor (Not Supporting) %	Poor (Not Attainable) %

Rhode Island

For a copy of the Rhode Island 1994 305(b) report, contact:

Connie Carey
Rhode Island Department of
Environmental Management
Division of Water Resources
291 Promenade St.
Providence, RI 02908-5767
(401) 277-6519

Surface Water Quality

Eighty-four percent of Rhode Island's rivers, 81% of lakes, and 96% of estuarine waters support aquatic life uses. However, many of these waters are considered threatened. About 80% of rivers, 94% of lakes, and 93% of estuaries fully support swimming. The most significant pollutants in Rhode Island's waters are heavy metals (especially copper and lead), priority organic chemicals (PCBs), bacteria, low dissolved oxygen, excess nutrients, and low pH/low buffering capacity. Recurring algae blooms, high nutrients, and high turbidity threaten the use of several surface waters for drinking water supplies.

Rivers and estuaries are impacted by industrial and municipal discharges, combined sewer overflows, urban runoff, highway runoff, failed septic systems, and contaminated sediments. Lakes are primarily impacted by nonpoint sources, including septic systems, atmospheric deposition, and land and road runoff.

Ground Water Quality

About 24% of the State's population is supplied with drinking water from public and private wells. Overall, Rhode Island's ground water has good to excellent quality, but over 100 contaminants have been detected in localized areas. Twenty-one community and eight noncommunity wells have been closed and 400 private wells have required treatment due to contamination. The most common pollutants are petroleum products, certain organic solvents, and nitrates. Significant pollution sources include leaking underground storage tanks, hazardous and industrial waste disposal sites, illegal or improper waste disposal, chemical and oil spills, landfills, septic systems, road salt storage and application, and fertilizer application.

Programs to Restore Water Quality

Rhode Island's Nonpoint Source Management Program sponsored the following activities during 1992-1993: (1) preparation of NPS management plans for 10 surface water supply watersheds; (2) development of a Community NPS Management Guide; (3) development of a Stormwater Design and Installation Manual; (4) preparation of a manual for selecting best management practices for marinas; (5) development of a *Community Wastewater Management Guidance Manual*; (6) mitigation projects at Greenwich Bay, including septic system inspections and replacements; (7) technical assistance to communities developing zoning or NPS control ordinances; and (8) revising and updating the Rhode Island NPS Management Plan.

Programs to Assess Water Quality

Rhode Island's monitoring program consists of: (1) discharge effluent monitoring, (2) the Beach Monitoring Program, (3) the Shellfish Growing Area Monitoring Program, (4) USGS Water Quality Trend Monitoring Fixed Stations, (5) supplemental monitoring stations sampled by the Rhode Island Department of Environmental Management, (6) biological monitoring, and (7) limited expansion of ambient water quality stream biological and chemical monitoring. During the 1992-1993 reporting cycle, Rhode Island added 25 toxics monitoring stations to previously unmonitored streams.

Individual Use Support in Rhode Island

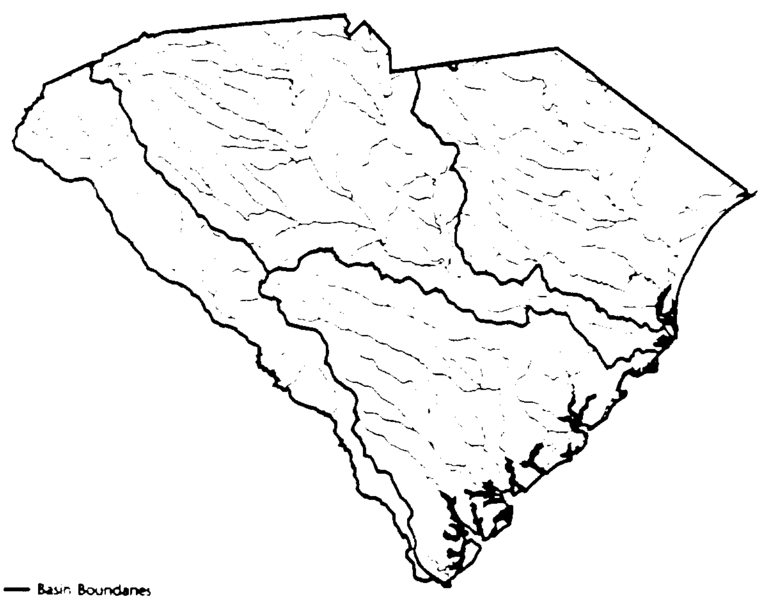
South Carolina



— Basin Boundaries
(USGS 6-Digit Hydrologic Unit)

For a copy of the South Carolina 1994 305(b) report, contact:

Gina Lowman
South Carolina Department of Health and Environmental Control
Bureau of Water Pollution Control
2600 Bull Street
Columbia SC 29201
(803) 734-5153

Surface Water Quality

Ninety-one percent of surveyed rivers, 99% of surveyed lakes, and 75% of estuaries have good water quality that fully supports aquatic life uses. Sixty-three percent of rivers, 99% of lakes, and 86% of estuaries fully support swimming. Unsuitable water quality is responsible for shellfish harvesting prohibitions in only 2% of the State's coastal shellfish waters. Another 11% of shellfish waters are closed as a precaution due to potential pollution from nearby marinas or point source discharges.

Bacteria are the most frequent cause of impairment (i.e., partial or nonsupport of designated uses) in rivers and streams; metals are the most frequent cause of impairment in lakes, but only 1% of lakes do not fully support uses; and low dissolved oxygen is the most frequent cause of impairment in estuaries. Toxic contaminants do not appear to be a widespread problem in South Carolina surface waters. Of all waters assessed, only 5% had elevated levels of metals and only 3% had concentrations of PCBs, pesticides, and organics above the assessment criteria.

Ground Water Quality

Overall ground water quality remains excellent, although the number of reported ground water contamination cases rose from 60 cases in 1980 to 2,207 cases in 1993. The increase in the number of contaminated sites is primarily due to expanded monitoring at underground storage tank sites. Leaking underground storage tanks are the most common source of contamination, impacting 1,741 sites, followed by leaking pits, ponds, and lagoons.

Programs to Restore Water Quality

The South Carolina Department of Health and Environmental Control (DHEC) initiated a Watershed

Water Quality Management Strategy (WWQMS) to integrate monitoring, assessment, problem identification and prioritization, water quality modeling, planning, permitting, and other management activities by river drainage basins. DHEC has delineated five major drainage basins encompassing 280 minor watersheds. Every year, DHEC will develop or revise a management plan and implementation strategy for one basin. It will take 5 years to assess all basins in the State. The basin strategies will refocus water quality protection and restoration priorities for allocation of limited resources.

Programs to Assess Water Quality

Year round, DHEC samples chemical and physical parameters monthly at fixed primary stations located in or near high-use waters. DHEC samples secondary stations (near discharges and areas with a history of water quality problems) monthly from May through October for fewer parameters. Each year, DHEC adds new watershed stations within the specific basin under investigation. Watershed stations are sampled monthly for 1 year corresponding with the WWQMS schedule.

Individual Use Support in South Carolina

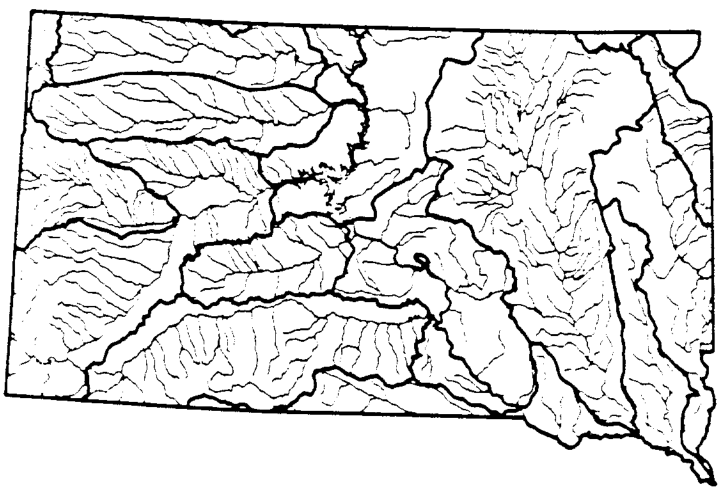
R0038993

South Dakota



— Basin Boundaries
(USGS 6-Digit Hydrologic Unit modified by South Dakota)

For a copy of the South Dakota 1994 305(b) report, contact:

Andrew Repsys
South Dakota Department of Environment and Natural Resources
Division of Water Resources Management
523 East Capitol, Joe Foss Building
Pierre, SD 57501-3181
(605) 773-3882

Surface Water Quality

Seventeen percent of South Dakota's surveyed rivers and streams fully support aquatic life uses and 83% do not fully support aquatic life uses. Thirty-five percent of the surveyed rivers also support swimming, and 65% of the surveyed rivers do not fully support swimming. The most common pollutants impacting South Dakota streams are suspended solids due to water erosion from croplands, gully erosion from rangelands, streambank erosion, and other natural forms of erosion. Ninety-eight percent of South Dakota's surveyed lake acres fully support aquatic life uses now, but the quality of these lakes is threatened. Similarly, 100% of the surveyed lake acres fully support swimming, but these waters are threatened. The most common pollutants in lakes are nutrients and sediments from agricultural runoff.

The high water conditions that prevailed in South Dakota for most of this reporting period greatly increased watershed erosion and sedimentation in lakes and streams. Suspended solids criteria were severely violated in many rivers and streams, and there was an increase in the incidence of fecal coliform bacteria in swimming areas at lakes. However, water quality improved in some lakes that experienced low water levels during the late 1980s, and high flows diluted bacteria in rivers and streams.

Ground Water Quality

Nitrates exceed EPA Maximum Contaminant Levels in more wells than any other pollutant. About 15% of the samples collected at three eastern State aquifers during 1988-1993 had nitrate concentrations that exceeded the State criteria of 10 mg/L. More than 7% of the samples collected from the Big Sioux aquifer consistently exceeded the nitrate standard. Potential sources of nitrate include commercial fertilizer use and manure applications. There were no violations of drinking water standards for petroleum products reported during 1992-1993, but petroleum products were involved in 81% of the spills reported during the period.

Programs to Restore Water Quality

Compliance with municipal wastewater discharge permit requirements has steadily risen from 37% in 1979 to 75% statewide in 1993 following construction of 162 wastewater treatment facilities. Compliance is even higher (97%) among the plants completed with EPA Construction Grants. South Dakota relies primarily on voluntary implementation of best management practices to control pollution from nonpoint sources, such as agricultural activities, forestry operations, and mining. The State has initiated over 50 BMP development and implementation projects.

Programs to Assess Water Quality

South Dakota conducts ambient water quality monitoring at established stations, special intensive surveys, intensive fish surveys, wasteload allocation surveys, and individual nonpoint source projects. The USGS, Corps of Engineers, and U.S. Forest Service also conduct routine monitoring throughout the State. Water samples are analyzed for chemical, physical, biological, and bacteriological parameters.

Individual Use Support in South Dakota

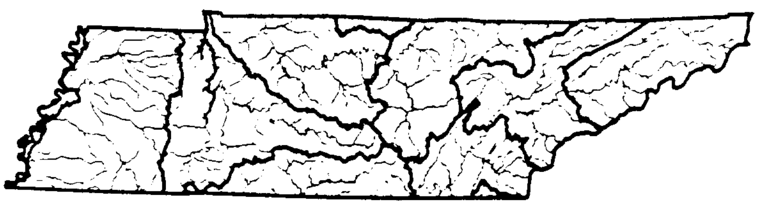
Tennessee



— Basin Boundaries
(USGS 6-Digit Hydrologic Unit)

For a copy of the Tennessee 1994 305(b) report, contact:

Greg Denton
Tennessee Department of
Environment and Conservation
Division of Water Pollution Control
401 Church Street, L&C Annex
Nashville, TN 37243-1534
(615) 532-0699

Surface Water Quality

Sixty-five percent of surveyed rivers and streams fully support aquatic life uses, 25% partially support these uses, and 10% are not supporting aquatic life uses due to severe pollution. Conventional pollutants (such as siltation, suspended solids, nutrients, and oxygen-depleting substances) affect the most river miles. Toxic materials, bacteria, and flow alterations impact rivers to a lesser extent. Major sources of pollutants include agriculture, hydromodification, and municipal point sources. Intense impacts from mining occur in the Cumberland Plateau region, and poor quality water discharged from dams impacts streams in east and middle Tennessee.

In lakes, 421,407 acres (78%) fully support aquatic life uses, 2,668 acres (less than 1%) are threatened, 27,987 acres (5%) partially support aquatic life uses, and 87,126 acres (16%) do not support these uses due to severe pollution. The most widespread problems in lakes include nutrients, low dissolved oxygen, siltation, and priority organics. Major sources of these pollutants are agriculture, municipal wastewater treatment plants, stream impoundments, hydrologic modification, mining, and nutrient addition.

Fish consumption advisories are posted on 142 miles of rivers and streams and over 84,000 acres of lakes due to elevated concentrations of chlordane, PCBs, dioxins, mercury, and other toxics in fish tissue samples. Swimming and wading are restricted in Chattanooga Creek and East Fork Poplar Creek due to toxic contamination from discontinued waste disposal practices.

Ground Water Quality

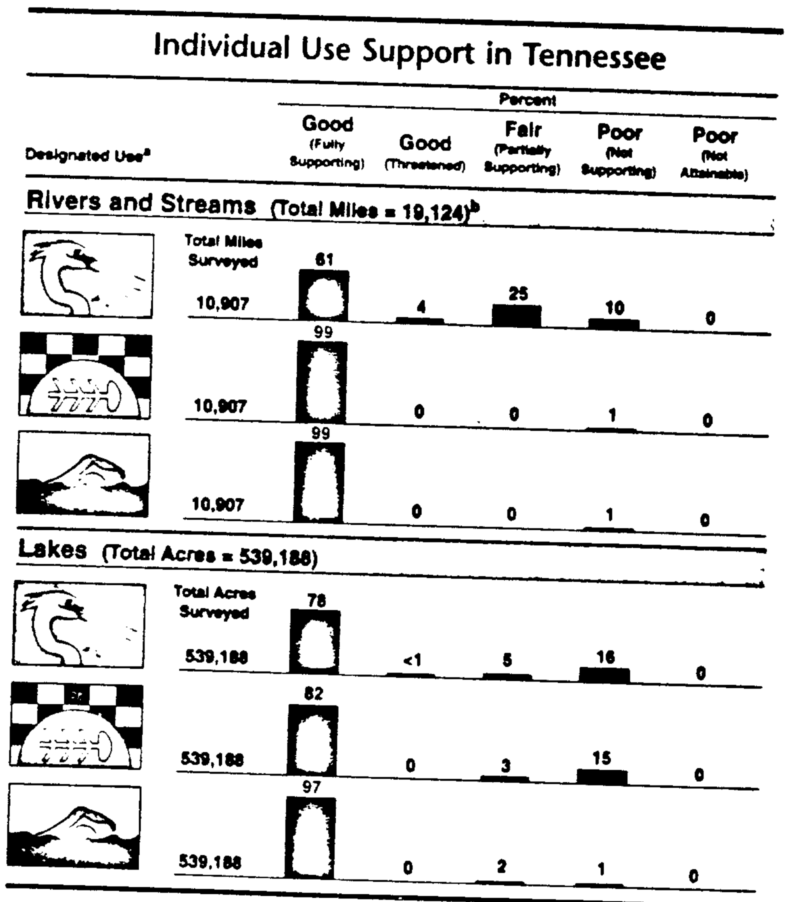
Ground water quality is generally good, but pollutants contaminate (or are thought to contaminate) the resource in localized areas. These pollutants include, but are not limited to, volatile and semivolatile organic chemicals, bacteria, metals, petroleum products, pesticides, and radioactive materials.

Programs to Restore Water Quality

Tennessee is considering issuing discharge permits on a rotating basis for each of the State's major river basins and is studying regionalized standards that take into account natural background conditions. The permits in each basin would be evaluated and reissued together on a 5-year cycle. Tennessee is also conducting several Total Maximum Daily Load studies that use a watershed approach to allocate maximum pollutant loading among all the point sources discharging into a stream or its tributaries.

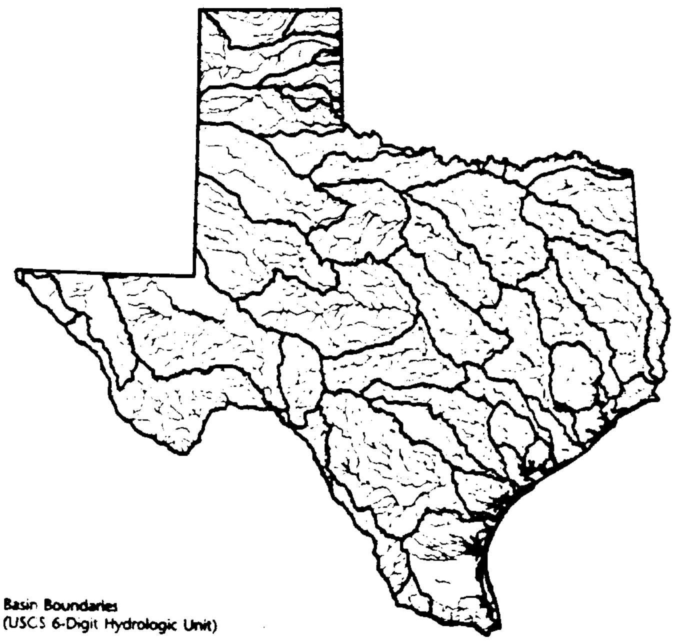
Programs to Assess Water Quality

Tennessee's ambient monitoring network consists of 156 active stations sampled quarterly for conventional pollutants (such as dissolved oxygen, bacteria, and suspended solids), nutrients, and selected metals. The State also performs intensive surveys at streams where State personnel suspect that human activities are degrading stream quality. Intensive surveys often include biological monitoring. The State samples toxic chemicals in fish and sediment at sites with suspected toxicity problems.



[a] A subset of Tennessee's designated uses appear in this figure. Refer to the State's 305(b) report for a full description of the State's uses.
[b] Includes nonperennial streams that dry up and do not flow all year.

Texas



— Basin Boundaries
(USGS 6-Digit Hydrologic Unit)

For a copy of the Texas 1994 305(b) report, contact:

Steve Twidwell
Texas Natural Resource Conservation Commission
P.O. Box 13087
Austin, TX 78711-3087
(512) 239-1000

Surface Water Quality

About 89% of the surveyed stream miles fully support aquatic life uses, 4% partially support these uses, and 6% do not support aquatic life uses. Swimming is impaired in 27% of the surveyed rivers and streams. The most common pollutants degrading rivers and streams are bacteria, metals, and oxygen-depleting substances. Major sources of pollution include municipal sewage treatment plants, unknown sources, pasture land runoff, and urban runoff.

In reservoirs, 98% of the surveyed surface acres fully support aquatic life uses and 2% partially support these uses. Less than 1% do not support aquatic life uses. Ninety-nine percent of the surveyed lake acres fully support swimming. The most common problems in reservoirs are low dissolved oxygen and elevated bacteria concentrations. Major sources that contributed to nonsupport of uses include unknown sources, natural sources (such as high temperature and shallow conditions), municipal sewage treatment plants, and industrial point sources.

The leading problem in estuaries is bacteria from unknown sources that contaminate shellfish beds. Fifty-nine percent of the surveyed estuarine waters fully support shellfishing use, 8% partially support this use, and 33% do not support shellfishing.

Ground Water Quality

About 44% of the municipal water is obtained from ground water in Texas. Natural contamination affects the quality of more ground water in the State than all other sources of contamination combined. Natural leaching from the aquifer matrix can elevate minerals, metals, and radioactive substances in ground water. The most common ground water contaminants from human activities are gasoline, diesel, and other petroleum products. Less common contaminants include volatile organic compounds and pesticides.

Programs to Restore Water Quality

The Texas Natural Resource Conservation Commission (TNRCC) launched a basin approach to water resource management with the Clean Rivers Program (CRP). The CRP is a first step in the development of a long-term, comprehensive and integrated geographic management approach aimed at improving coordination of natural resource functions in the agency. The basin approach will provide a framework for identifying problems, involving stakeholders, and integrating actions. The basin approach also allows for the use of risk-based targeting to prioritize issues and better allocate finite public resources.

Programs to Assess Water Quality

The TNRCC samples about 700 fixed stations as part of its Surface Water Quality Monitoring Program (SWQMP). The TNRCC samples different parameters and varies the frequency of sampling at each site to satisfy different needs. The TNRCC also conducts intensive surveys to evaluate potential impacts from point source dischargers during low flow conditions and special studies to investigate specific sources and pollutants. About 3,000 citizens also perform volunteer environmental monitoring in the Texas Watch Program.

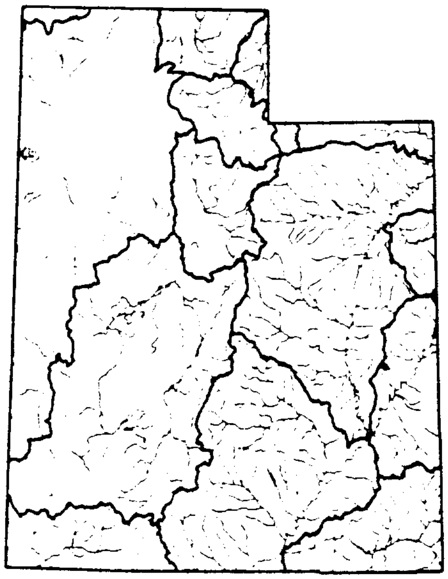
Utah



— Basin Boundaries
(USGS 6-Digit Hydrologic Unit)

For a copy of the Utah 1994 305(b) report, contact:

Thomas W. Toole
Utah Department of Environmental Quality
Division of Water Quality
P.O. Box 144870
Salt Lake City, UT 84114-4870
(801) 538-6859

Surface Water Quality

Of the 5,726 river miles surveyed, 75% fully support aquatic life uses, 20% partially support these uses, and 5% are not supporting aquatic life uses. The most common pollutants impacting rivers and streams are siltation and sediments, total dissolved solids, nutrients, and metals. Agricultural practices, such as grazing and irrigation, elevate nutrient and sediment loading into streams. Point sources also contribute to nutrient loads, while natural conditions introduce metals and sediments to streams in some areas. Resource extraction and associated activities, such as road construction, also impact Utah's rivers and streams.

About 61% of the surveyed lake acres fully support aquatic life uses, 32% partially support these uses, and 7% do not support aquatic life uses. The leading problems in lakes include nutrients, siltation, low dissolved oxygen, suspended solids, organic enrichment, noxious aquatic plants, and violations of pH criteria. The major sources of pollutants are grazing and irrigation, industrial and municipal point sources, drawdown of reservoirs, and natural conditions.

Fish and wildlife consumption advisories are posted on the lower portion of Ashley Creek drainage and Stewart Lake in Uintah County due to elevated levels of selenium found in fish, ducks, and American coots.

Ground Water Quality

In general, the quality of ground water in Utah has remained relatively good throughout the State, although some ground water degradation occurs in south central Utah in the metropolitan area of Salt Lake City and along the Wasatch Front area from Payson north to Brigham City. Sources of ground water degradation include irrigation, urbanization, landfills, mining and mine tailings, and drawdown. In 1994, new ground water regulations went into effect.

Programs to Restore Water Quality

The State's Nonpoint Source Task Force is responsible for coordinating nonpoint source programs in Utah. The Task Force is a broad-based group with representatives from Federal, State, and local agencies; local governments; agricultural groups; conservation organizations; and wildlife advocates. The Task Force helped State water quality and agricultural agencies prioritize watersheds in need of NPS pollution controls. As best management practices are implemented, the Task Force will update and revise the priority list.

Programs to Assess Water Quality

In 1993, Utah adopted a basinwide water quality monitoring approach. Utah initiated basinwide intensive studies in the Weber River Basin in 1993 and the Utah Lake-Jordan River Basin in 1994. A fixed-station network was also developed to evaluate general water quality across the State. Utah's surface water quality monitoring program consists of about 200 ambient stations, 7 salinity monitoring stations, and 30 biological monitoring sites. In addition, 135 industrial and municipal sites were monitored.

Individual Use Support in Utah

Designated Use[a]		Percent: Good (Fully Supporting)	Good (Threatened)	Fair (Partially Supporting)	Poor (Not Supporting)	Poor (Not Attainable)
Rivers and Streams (Total Miles = 85,916)[b]	Total Miles Surveyed

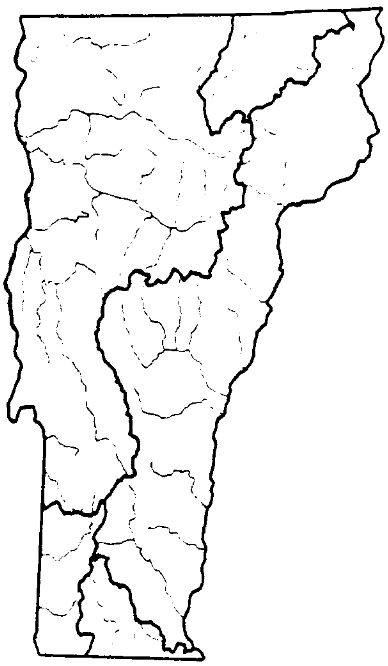
VOL 12

5593

Vermont



— Basin Boundaries (USGS 6-Digit Hydrologic Unit)

For a copy of the Vermont 1994 305(b) report, contact:

Jerome J. McArdle
Vermont Agency of Natural Resources
Dept. of Environmental Conservation
Water Quality Division
103 South Main Street,
Building 10 North
Waterbury, VT 05671-0408
(802) 244-6951

Surface Water Quality

Of the 5,264 miles of surveyed rivers and streams, 81% fully support aquatic life uses, 15% partially support these uses, and 4% do not support aquatic life uses. Ten percent of the surveyed rivers and streams do not fully support swimming. The most widespread impacts include siltation, thermal modifications, organic enrichment and low dissolved oxygen, nutrients, pathogens, and other habitat alterations. The principal sources of impacts are agricultural runoff, streambank destabilization and erosion, removal of streamside vegetation, upstream impoundments, flow regulation, and land development.

Sixty-four percent of the surveyed lake acres (excluding Lake Champlain) fully support aquatic life uses, 27% partially support these uses, and 9% do not support aquatic life uses. The most common problems in lakes include fluctuating water levels, nutrient enrichment, algal blooms, organic enrichment and low dissolved oxygen, siltation, and aquatic weeds. Eurasian watermilfoil, an aquatic weed, infests 13% of the State's lakes that are 20 acres or larger. Runoff from agricultural lands, roads, and streambank erosion are the most frequently identified sources of lake problems.

In Lake Champlain, nutrients are the major cause of impairment, followed by fish consumption advisories posted for trout contaminated with PCBs and walleye contaminated with mercury. Discovery of the zebra mussel in 1993 threatens all uses.

Ground Water Quality

The quality of Vermont's ground waters is not well understood due to a lack of resources required to gather and assess ground water data. Ground water contamination has been detected at hazardous waste sites. Other sources of concern include failing septic systems, old solid waste disposal sites, agriculture, road salt, leaking underground storage tanks, and landfills. The State needs to implement a Comprehensive Ground Water Protection Program, but lacks the financial and technical resources to do so.

Programs to Restore Water Quality

During the reporting period, Vermont implemented dechlorination at 18 publicly owned sewage treatment plants, which improved water quality in about 47 miles of rivers and streams. The State also completed construction of the last two planned sewage treatment plants and upgraded four other plants. To prevent habitat modifications, the State used the Section 401 water quality certification process to require minimum stream flows at four hydroelectric facilities. The stream flow requirements should improve water quality on 11 miles of streams.

Programs to Assess Water Quality

Vermont's monitoring activities balance short-term intensive and long-term trend monitoring. Notable monitoring activities include fixed-station monitoring on lakes and ponds, citizen monitoring, long-term acid rain lake monitoring, compliance monitoring for permitted dischargers, toxic discharge monitoring, fish contamination monitoring, and ambient biomonitoring of aquatic insects and fish.

Individual Use Support in Vermont

Designated Use[a]	Total Surveyed	Good (Fully Supporting) %	Good (Threatened) %	Fair (Partially Supporting) %	Poor (Not Supporting) %	Poor (Not Attainable) %
Rivers and Streams (Total Miles = 5,264)[b] — Total Miles Surveyed

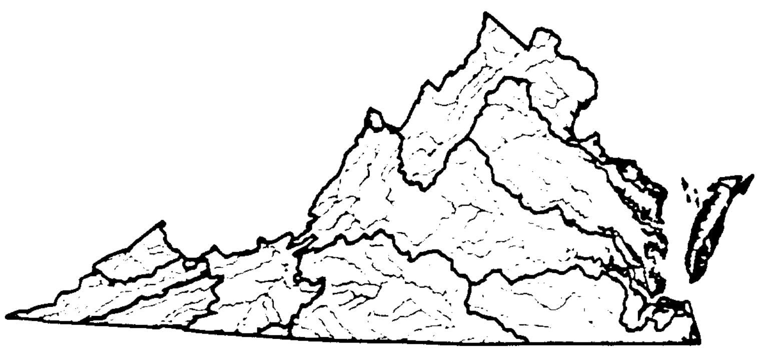
Virginia



— Basin Boundaries
(USGS 6-Digit Hydrologic Unit)

For a copy of the Virginia 1994 305(b) report, contact:

Carrie Gorsuch
Department of Environmental Quality
Water Division
Office of Water Resources Management
P.O. Box 10009
Richmond, VA 23240-0009
(804) 762-4290

Surface Water Quality

Of the 34,575 river miles surveyed, 90% fully support aquatic life use, another 5% fully support this use now but are threatened, and 5% do not fully support this use. As in past years, fecal coliform bacteria are the most widespread problem in rivers and streams. Agriculture and pasture land contribute much of the fecal coliform bacteria in Virginia's waters. Urban runoff also is a significant source of impacts in both rivers and estuaries.

Ninety-nine percent of Virginia's publicly owned lakes fully support their designated uses, and about 1% do not fully support uses. The most common problems in lakes include dissolved oxygen depletion, coliform bacteria, pH, and temperature, primarily from nonpoint sources.

In estuaries, 31% of the surveyed waters fully support aquatic life use, 64% support this use but are threatened, and 5% partially support this use. Nutrients are the most common problem in Virginia's estuarine waters, followed by organic enrichment and low dissolved oxygen concentrations. All of Virginia's Atlantic Ocean shoreline fully supports designated uses.

Six advisories limit fish consumption on 369 miles of Virginia's rivers and an undetermined number of miles of tidal tributaries to the James River. The Commonwealth lifted one advisory that had restricted fish consumption on the Jackson River and the Upper James River.

Ground Water Quality

Sampling by the Virginia Department of Health detected bacterial concentrations exceeding Maximum Contaminant Levels at 133 ground-water-based community public water systems in 1993. Nitrates and pesticides were also detected in a small percentage of the private wells sampled in a pilot study in Northampton County. Virginia revised ground water protection rules with the Ground Water Management Act of 1992.

Programs to Restore Water Quality

Virginia's Department of Environmental Quality recommends control measures for water quality problems identified in the 305(b) report in their Water Quality Management Plans (WQMPs). WQMPs establish a strategy for bringing impaired waters up to water quality standards and preventing the degradation of high-quality waters. Control measures are implemented through Virginia's point source permit program and application of best management practices for nonpoint sources.

Programs to Assess Water Quality

The Ambient Water Quality Monitoring Program grew to 896 monitoring stations, a 26% increase since the previous reporting period. These stations are sampled for chemical and physical parameters on a variable schedule. The Core Monitoring Program consists of a subset of 51 stations that are sampled for pesticides, metals, and organic chemicals in fish and sediment on a 3-year cycle. About 150 biological stations were also sampled during the 1992-1993 reporting cycle.

Individual Use Support in Virginia

Designated Use[a]	Total Surveyed	Percent: Good (Fully Supporting)	Good (Threatened)	Fair (Partially Supporting)	Poor (Not Supporting)	Poor (Not Attainable)

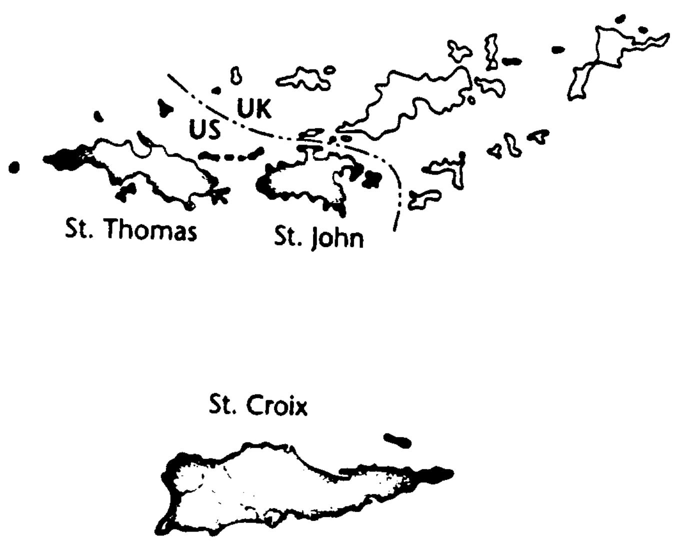
Virgin Islands



— Basin Boundaries
(USGS 6-Digit Hydrologic Unit)

For a copy of the Virgin Islands 1994 305(b) report, contact:

Anne Hanley
U.S. Virgin Islands Department of Planning and Natural Resources
Division of Environmental Protection
P.O. Box 4340
St. Thomas, VI 00801
(809) 773-0565

Surface Water Quality

The U.S. Virgin Islands consist of three main islands (St. Croix, St. Thomas, and St. John) and over 50 smaller islands and cays located in the Caribbean Sea. The islands lack perennial streams or large freshwater lakes or ponds. Water quality in the U.S. Virgin Islands is generally good but declining due to an increase in point source discharges and nonpoint source pollution entering the marine environment.

The Virgin Islands municipal sewage treatment plants, operated by the Virgin Islands Department of Public Works, are the major source of water quality violations in the Territory. Neglect, combined with a lack of qualified operators and maintenance staff, results in frequent breakdowns of lift stations, pump stations, and pipelines. Clogged and collapsed lines frequently cause unpermitted discharges into surface waters. Stormwater also overwhelms sewage treatment facilities and results in bypasses of raw or undertreated sewage into bays and lagoons.

Other water quality problems result from unpermitted discharges, permit violations by private industrial dischargers, oil spills, and unpermitted filling activities in mangrove swamps. Nonpoint sources of concern include failing septic systems, erosion from development, urban runoff, waste disposal from vessels, and spills.

Ground Water Quality

The Virgin Islands' ground water is contaminated with bacteria, saltwater, and volatile organic compounds. Septic tanks, leaking municipal sewer lines, and sewage bypasses contaminate ground water with bacteria. Overpumping of aquifers causes saltwater intrusion. VOC contamination is due to underground storage tanks and indiscriminate discharges of waste oil.

Programs to Restore Water Quality

The Territorial Pollution Discharge Elimination System (TPDES) requires permits for all point source discharges, but not all permitted facilities are in compliance with their permit requirements. During the 1992-1993 reporting period, the Division of Environmental Protection brought four major violators into compliance. The Virgin Islands is also developing new regulations for citing and constructing onsite sewage disposal systems and advocating best management practices in the *Revised Handbook for Homebuilders and Developers.*

Programs to Assess Water Quality

The Ambient Monitoring Program performs quarterly sampling at 64 fixed stations around St. Croix, 57 stations around St. Thomas, and 19 stations around St. John. Samples are analyzed for fecal coliforms, turbidity, dissolved oxygen, and temperature. Twenty stations on St. Croix were also sampled for phosphorus, nitrogen, and suspended solids. Intensive studies, which include biological sampling, are conducted at selected sites that may be affected by coastal development. The Virgin Islands does not monitor bacteria in shellfish waters or toxics in fish, water, or sediment.

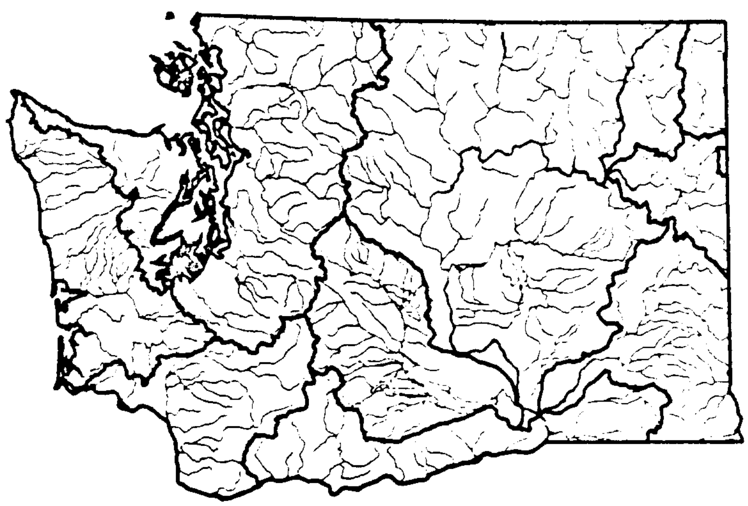
Overall[a] Use Support in Virgin Islands

		Percent				
		Good (Fully Supporting)	Good (Threatened)	Fair (Partially Supporting)	Poor (Not Supporting)	Poor (Not Attainable)
Estuaries (Total Square Miles = 5.9)						
	Total Square Miles Surveyed 5.6	62	17	10	11	0
Ocean Shoreline (Total Miles = 173)						
	Total Miles Surveyed 13	77	15	0	8	0

[a] Overall use support is presented in this figure because the Virgin Islands did not report individual use support in their 1994 Section 305(b) report.

Note: The Virgin Islands report that there are no perennial streams or significant lakes under their jurisdiction.

Washington



— Basin Boundaries
(USGS 6-Digit Hydrologic Unit)

For a copy of the Washington 1994 305(b) report, contact:

Steve Butkus
Washington Department of Ecology
P.O. Box 47600
Olympia, WA 98504-7600
(360) 407-6482

Surface Water Quality

Washington reports that 18% of their surveyed river miles fully support aquatic life uses, 22% partially support these uses, and 60% do not support aquatic life uses. In lakes, 35% of the surveyed acres fully support aquatic life uses, and 65% do not support aquatic life uses.

Thirty-two percent of the surveyed estuarine waters fully support aquatic life uses, 24% partially support these uses, and 44% do not support aquatic life uses.

Low levels of dissolved oxygen, often naturally occurring, are the major cause of impairment of designated uses in estuaries. Bacterial contamination, primarily from agricultural runoff, onsite wastewater disposal, and municipal wastewater treatment plants also causes impairment in estuaries. Major causes of impairment in lakes include nutrients, pesticides, siltation, flow alteration, and low dissolved oxygen. Agricultural production is the predominant source of impairment in lakes. Other sources include urban runoff, land disposal, septic tanks, and natural sources. In rivers and streams, agriculture is the major source of water quality degradation, followed by industrial point sources and hydro-habitat modification. Causes of water quality impairment from these sources include thermal modification, pathogen indicators, and ammonia.

Ground Water Quality

The highest priority ground water issues in Washington are nitrates, pesticides, and other agricultural chemicals from fertilizer applications, pesticide applications, and septic tanks.

Programs to Restore Water Quality

Washington provides financial incentives to encourage compliance with permit requirements, the principal vehicle for regulating point source discharges. The State also has extensive experience developing, funding, and implementing nonpoint source pollution prevention and control programs since the early 1970s. The State has developed nonpoint source control plans with best management practices for forest practices, dairy waste, irrigated agriculture, dryland agriculture, and urban stormwater. The State is now focusing attention on watershed planning. Efforts are currently geared toward prioritizing watersheds and developing comprehensive plans for the priority watersheds.

Programs to Assess Water Quality

Washington implements an aggressive program to monitor the quality of lakes, estuaries, and rivers and streams. The program makes use of fixed-station monitoring to track spatial and temporal water quality changes so as to ascertain the effectiveness of various water quality programs and be able to identify desirable adjustments to the programs.

Individual Use Support in Washington

Designated Use[a]	Surveyed	Good (Fully Supporting) %	Good (Threatened) %	Fair (Partially Supporting) %	Poor (Not Supporting) %	Poor (Not Attainable) %
Rivers and Streams (Total Miles = 73,886)[b]	Total Miles Surveyed					
	7,021	18	0	22	60	0
	651	0	0	38	62	0
	4,467	29	0	11	60	0
Lakes (Total Acres = 466,296)	Total Acres Surveyed

West Virginia

— Basin Boundaries
(USGS 6-Digit Hydrologic Unit)

For information about water quality in West Virginia, contact:

Mike Arcuri
West Virginia Division of
Environmental Protection
Office of Water Resources
1201 Greenbrier Street
Charleston, WV 25311
(304) 558-2108

Surface Water Quality

West Virginia reported that 42% of their surveyed river and stream miles have good water quality that fully supports aquatic life uses, and 75% fully support swimming. In lakes, 32% of the surveyed acres have good water quality that fully supports aquatic life uses and 100% fully support swimming.

Metals and siltation are the most common water quality problems in West Virginia's rivers and lakes. Fecal coliforms and acidity also impair a large number of river miles. In lakes, oxygen-depleting substances, acidity, nutrients, and algal blooms also impair a significant number of acres. Coal mining impaired the most stream miles, followed by municipal point sources and agriculture. Coal mining was also the leading source of degraded water quality in lakes, followed by forestry and agriculture.

West Virginia reported that fish consumption advisories are posted for the Kanawha River, Pocatalico River, Armour Creek, Ohio River, Shenandoah River, North Branch of the Potomac River, the Potomac River, and Flat Fork Creek. Five of the advisories were issued because of elevated dioxin concentrations in bottom feeders. The other advisories address PCBs and chlordane in suckers, carp, and channel catfish.

Ground Water Quality

West Virginia ranked mining and mine drainage as the highest priority source of ground water contamination in the State, followed by municipal landfills, surface water impoundments (including oil and gas brine pits), abandoned hazardous waste sites, and industrial landfills. West Virginia has documented or suspects that ground water has been contaminated by pesticides, petroleum compounds, other organic chemicals, bacteria, nitrates, brine/salinity, arsenic, and other metals.

Programs to Restore Water Quality

No information was available from the State.

Programs to Assess Water Quality

No information was available from the State.

Individual Use Support in West Virginia

Designated Use[a]	Total Surveyed	Percent: Good (Fully Supporting)	Good (Threatened)	Fair (Partially Supporting)	Poor (Not Supporting)	Poor (Not Attainable)
Rivers and Streams (Total Miles = 32,278)	Total Miles Surveyed

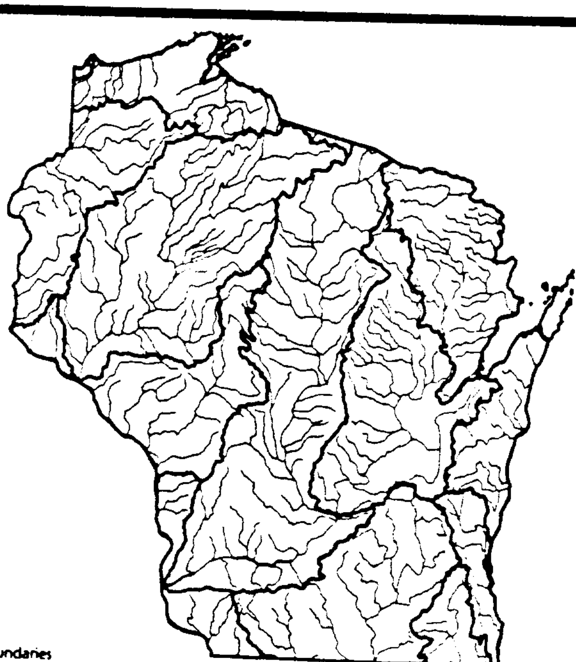
[b] Includes nonperennial streams that dry up and do not flow all year.

Wisconsin



— Basin Boundaries
(USGS 6-Digit Hydrologic Unit)

For a copy of the Wisconsin 1994 305(b) report, contact:

Meg Turville-Heitz
Wisconsin Department of Natural Resources
P.O. Box 7921
Madison, WI 53707
(608) 266-0152

Surface Water Quality

The Wisconsin Department of Natural Resources (WDNR) found that 78% of the surveyed river miles fully support aquatic life uses, 2% support these uses now but are threatened, 14% partially support aquatic life uses, and 6% do not support aquatic life uses. WDNR believes that the survey process underestimated the number of threatened river miles. The most prevalent problems in rivers are habitat and flow alterations, siltation, excessive nutrients, and oxygen-depleting substances. The sources of these problems are often polluted runoff, especially in agricultural areas, and river modifications, such as ditching, straightening, and the loss of wetlands alongside streams. Wastewater discharges also moderately impair more than 1,000 miles of streams.

About 57% of the surveyed lake acres fully support aquatic life uses, 3% support these uses but are threatened, 15% partially support these uses, and 25% do not support aquatic life uses. The primary source of lake degradation is deposition of airborne pollutants, especially mercury, and polluted runoff. All of Wisconsin's Great Lakes' shoreline partially supports fish consumption use due to fish consumption advisories posted throughout the Great Lakes. Bacteria from urban runoff also impair swimming along 60 miles of shoreline.

Ground Water Quality

The primary sources of ground water contamination in Wisconsin are agricultural activities, municipal landfills, leaking underground storage tanks, abandoned hazardous waste sites, and spills. Other sources include septic tanks and land application of wastewater. Nitrate-nitrogen is the most common ground water contaminant. Nitrates come from fertilizers, animal waste storage sites and feedlots, municipal and industrial wastewater and sludge disposal, refuse disposal areas, and leaking septic systems.

Programs to Restore Water Quality

WDNR is integrating multiple agencies, programs, interests, and jurisdictions in an "ecosystem approach" that looks at all parts of the ecosystem when addressing water quality—the land that drains to the waterbody, the air above it, the plants, animals, and people using it. Since the 1970s, WDNR has prepared water quality management plans for each of the State's river basins that summarize the condition of waters in each basin, identify improvements and needs, and make recommendations for cleanup or protection. WDNR updates the plans every 5 years and uses the plans to rank watersheds for priority projects under the Wisconsin Nonpoint Source Water Pollution Abatement Program and to address wastewater discharge concerns.

Programs to Assess Water Quality

In 1992, Wisconsin implemented a surface water monitoring strategy to support river basin planning. The strategy integrates monitoring and management activities in each of the State's river basins on the 5-year basin planning schedule. In recent years, Wisconsin has placed more emphasis on monitoring polluted runoff and toxic substances in bottom sediments and tissues of fish and wildlife.

Individual Use Support in Wisconsin

Designated Use[a]	Total Surveyed	Good (Fully Supporting) %	Good (Threatened) %	Fair (Partially Supporting) %	Poor (Not Supporting) %	Poor (Not Attainable) %

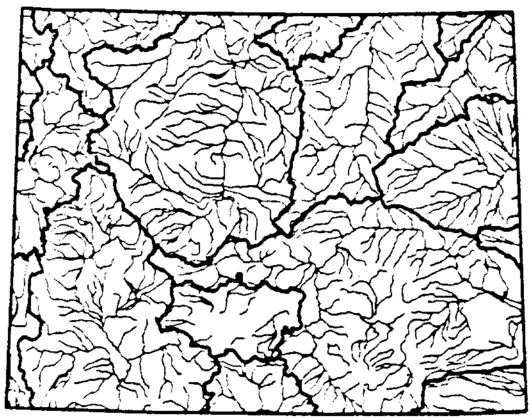
Wyoming



— Basin Boundaries
(USGS 6-Digit Hydrologic Unit)

For a copy of the Wyoming 1994 305(b) report, contact:

Beth Pratt
Wyoming Department of
Environmental Quality
Water Quality Division
Herschler Building
122 West 25th Street
Cheyenne, WY 82002
(307) 777-7079

Surface Water Quality

Of the 6,091 river miles surveyed, 13% fully support aquatic life uses, 22% fully support these uses now but are threatened, 63% partially support aquatic life uses, and 2% do not support aquatic life uses. The most widespread problems in rivers and streams are siltation and sediment, nutrients, total dissolved solids and salinity, flow alterations, and habitat alterations. The most prevalent sources of water quality problems in rivers and streams are rangeland, natural sources, irrigated cropland, pasture land, and construction of highways, roads, and bridges.

In lakes, 31% of the surveyed acres fully support aquatic life uses, 47% partially support these uses, and 22% do not support aquatic life uses. The leading problems in lakes are low dissolved oxygen concentrations and organic enrichment, nutrients, sediment and siltation, other inorganic substances, and metals. The most prevalent sources of water quality problems in lakes are natural sources, rangeland, irrigated cropland, flow regulation, and municipal sewage treatment plants.

The State's water quality survey is designed to identify water quality problems, so it is reasonable to assume that most of the unassessed waters are not impacted. However, the State lacks definitive information to that effect.

Ground Water Quality

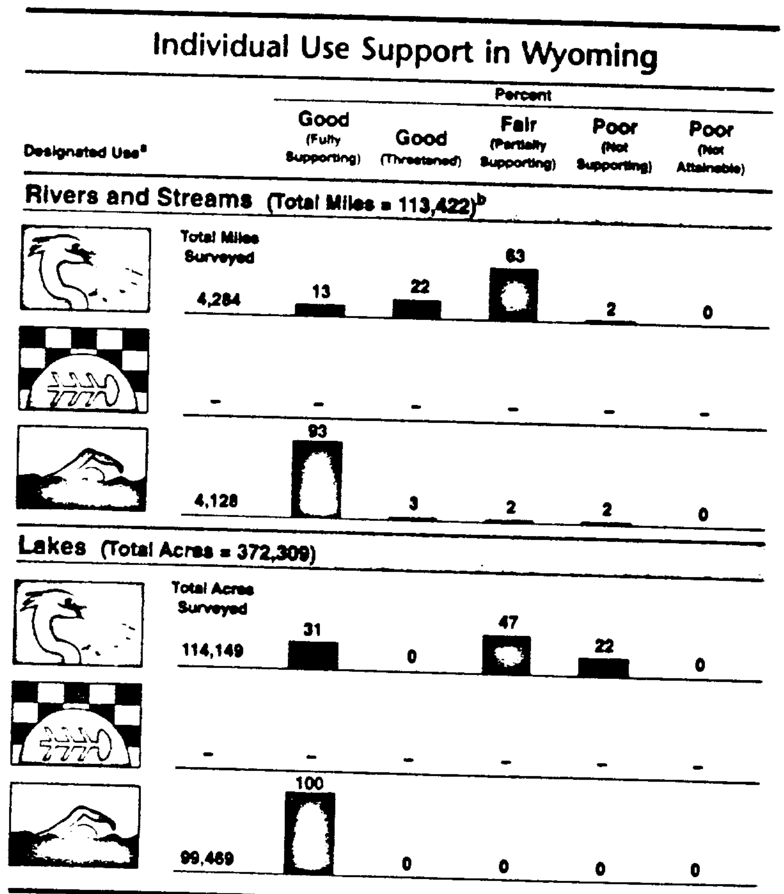
Some aquifers in Wyoming have naturally high levels of fluoride, selenium, and radionuclides. Petroleum products and nitrates are the most common pollutants in Wyoming's ground water, and leaking underground storage tanks are the most numerous source of contamination. Other sources include uranium and trona mineral mining, agricultural activities, mill tailings, spills, landfills, commercial and industrial sumps, septic tank leachfields, wastewater disposal ponds at coal-fired power plants and other industrial sites, and commercial oilfield disposal pits.

Programs to Restore Water Quality

Wyoming requires discharger permits and construction permits for all wastewater treatment facilities. The Department of Environmental Quality (DEQ) reviews proposed plans and specifications to ensure that plants meet minimum design criteria. Wyoming's nonpoint source program is a nonregulatory program that promotes better management practices for all land use activities, including grazing, timber harvesting, and hydrologic modifications.

Programs to Assess Water Quality

Wyoming is currently monitoring reference stream sites around the State in order to define characteristics of relatively undisturbed streams in each ecoregion. The State is sampling chemical and biological parameters, such as dissolved oxygen, nutrients, aquatic insect species composition, species abundance, and habitat conditions at the candidate reference stream sites. Once established, the reference site conditions will serve as the basis for assessing other streams in the same ecoregion or subecoregion. Wyoming will use the reference conditions to establish a volunteer biological monitoring program.



- Not reported

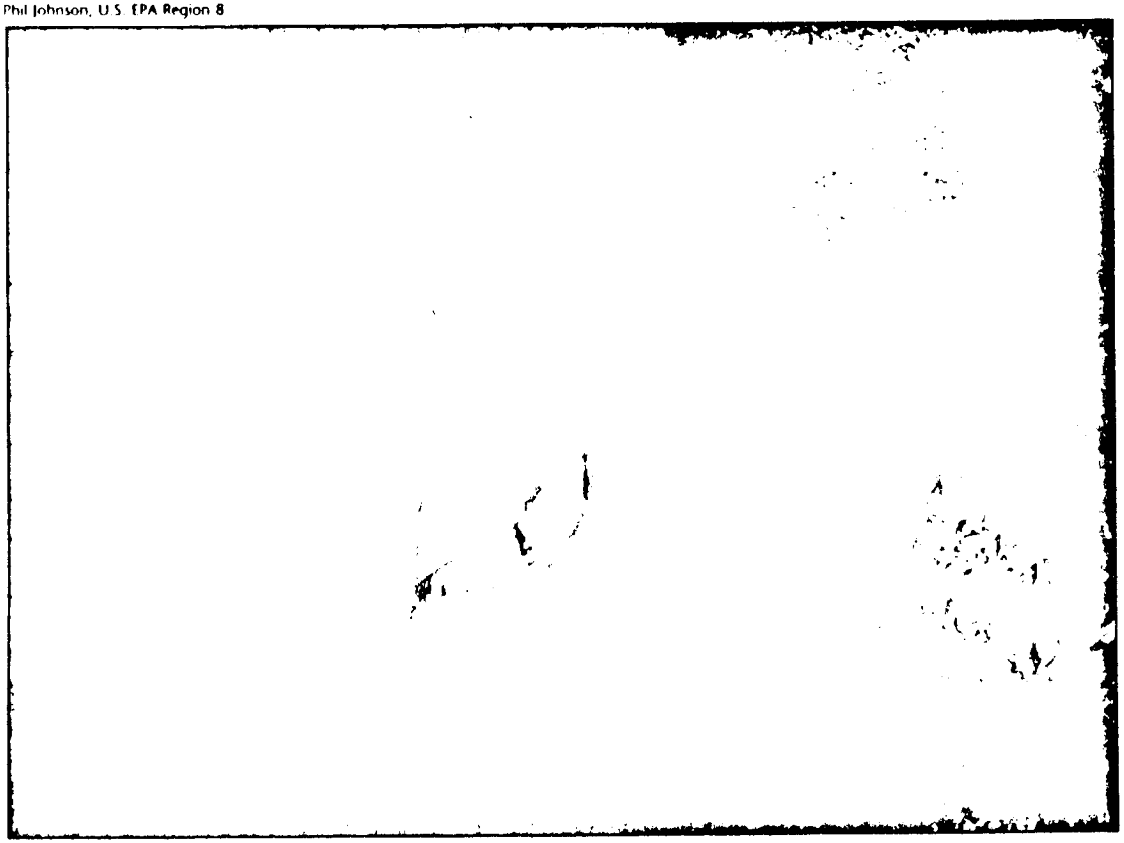
[a] A subset of Wyoming's designated uses appear in this figure. Refer to the State's 305(b) report for a full description of the State's uses.

[b] Includes nonperennial streams that dry up and do not flow all year.

VOL 12

5707

Phil Johnson, U.S. EPA Region 8



Tribal Summaries

This chapter provides individual summaries of the water quality survey data reported by six American Indian Tribes in their 1994 Section 305(b) reports. Tribal participation in the Section 305(b) process grew from two Tribes in 1992 to six Tribes during the 1994 reporting cycle, but Tribal water quality remains unrepresented in this report for the hundreds of other Tribes established throughout the country. Many of the other Tribes are in the process of developing water quality programs and standards but have not yet submitted a Section 305(b) report. As Tribal water quality programs become established, EPA expects Tribal participation in the Section 305(b) process to increase rapidly. To encourage Tribal participation, EPA has sponsored water quality monitoring and assessment training sessions at Tribal locations, prepared streamlined 305(b) reporting guidelines for Tribes that wish to participate in the process, and published a brochure, *Knowing Our Waters: Tribal Reporting Under Section 305(b)*. EPA hopes that subsequent reports to Congress will contain more information about water quality on Tribal lands.

Surface Water Quality

The Campo Indian Reservation covers 24.2 square miles in southeastern San Diego County, California. The Campo Indian Reservation has 31 miles of intermittent streams, 80 acres of freshwater wetlands, and 10 lakes with a combined surface area of 3.5 acres.

The natural water quality of Tribal streams, lakes, and wetlands ranges from good to excellent. There are no point source discharges within or upstream of the Reservation, but grazing livestock have degraded streams, lakes, and wetlands with manure containing fecal coliform bacteria, nutrients, and organic wastes. Livestock also trample streambeds and riparian habitats. Septic tanks and construction also threaten water quality.

Ground Water Quality

Ground water supplies 100% of the domestic water consumed on the Campo Indian Reservation. Nitrate and bacteria from nonpoint sources occasionally exceed drinking water standards in some domestic wells. The proximity of individual septic systems to drinking water wells poses a human health risk because Reservation soils do not have good purification properties. Elevated iron and manganese levels may be due to natural weathering of geologic materials.

Programs to Restore Water Quality

The Campo Environmental Protection Agency (CEPA) has authority to administer three Clean Water Act programs. The Section 106 Water Pollution Control Program supports infrastructure, the 305(b) assessment process, and development of a Water Quality Management Plan. The Tribe is inventorying its wetlands with funding from the Section 104(b)(3) State Wetlands Protection Program. The Tribe has used funding from the Section 319 Nonpoint

Source Program to stabilize stream banks, construct sediment retention structures, and fence streams and riparian zones to exclude livestock. CEPA will promulgate water quality standards in 1995 that will establish beneficial uses, water quality criteria, and antidegradation provisions for all Tribal waters.

In 1994, the General Council passed a resolution to suspend cattle grazing on the Reservation for at least 2 years and to concurrently restore degraded recreational water resources by creating fishing and swimming ponds for Tribal use.

Programs to Assess Water Quality

Streams, wetlands, and lakes on Tribal lands were not monitored until CEPA initiated its Water Pollution Control Program in 1992. Following EPA approval of CEPA's Quality Assurance Project Plan in May 1993, CEPA conducted short-term intensive surveys to meet the information needs of the 305(b) assessment process. Based on the results of the 1994 305(b) assessment, CEPA will develop a long-term surface water monitoring program for implementation in 1995. CEPA will consider including biological monitoring, physical and chemical monitoring, monthly bacterial monitoring in lakes, toxicity testing, and fish tissue monitoring in its monitoring program.

Individual Use Support in Campo Indian Reservation

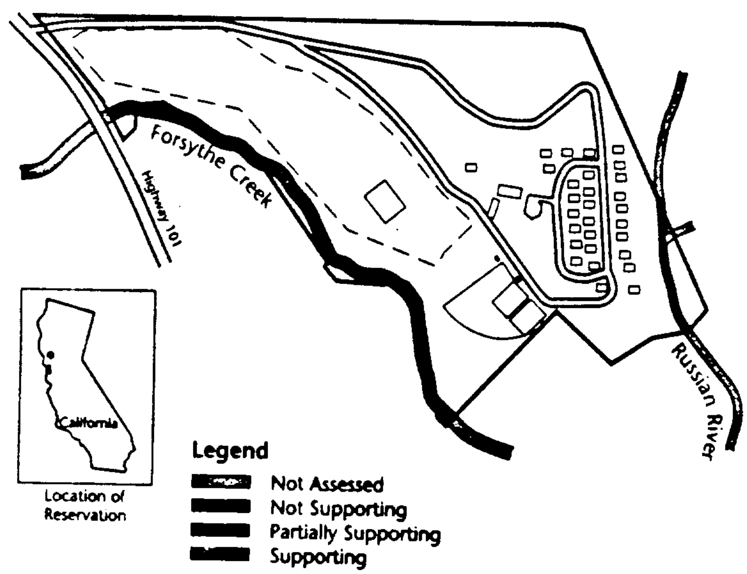
Coyote Valley Reservation



For a copy of the Coyote Valley Reservation 1994 305(b) report, contact:

Jean Hunt or Eddie Knight
The Coyote Valley Reservation
P.O. Box 39
Redwood Valley, CA 95470

Surface Water Quality

The Coyote Valley Band of the Pomo Indians is a federally recognized Indian Tribe, living on a 57-acre parcel of land in Mendocino County, California. Segments of the Russian River and Forsythe Creek flow past the Reservation, although flow diminishes in the summer and fall. Fishing, recreation, and religion are important uses for surface waters within the Reservation.

Currently, the Tribe is concerned about bacteria contamination in the Russian River, potential contamination of Forsythe Creek from a malfunctioning septic system leachfield, and habitat modifications in both streams that impact aquatic life. Past gravel mining operations removed gravel spawning beds, altered flow, and created very steep banks. In the past, upstream mining also elevated turbidity in Forsythe Creek. The Tribe is also concerned about a potential trend of increasing pH values and high water temperatures in Forsythe Creek during the summer.

Ground Water Quality

The Coyote Valley Reservation contains three known wells, but only two wells are operable, and only one well is in use. The old shallow irrigation well (Well A) was abandoned because it went dry after the gravel mining operation on Forsythe Creek lowered the water table. Well B, located adjacent to Forsythe Creek, is used to irrigate a walnut orchard. Well C, located on a ridge next to the Reservation's housing units, is not in use due to severe iron and taste problems. Sampling also detected high levels of barium, total dissolved solids, manganese, and conductivity in Wells B and C. However, samples from Well B did not contain organic chemicals, pesticides, or nitrate in detectable amounts. Human waste contamination from septic systems may pose the greatest threat to ground water quality.

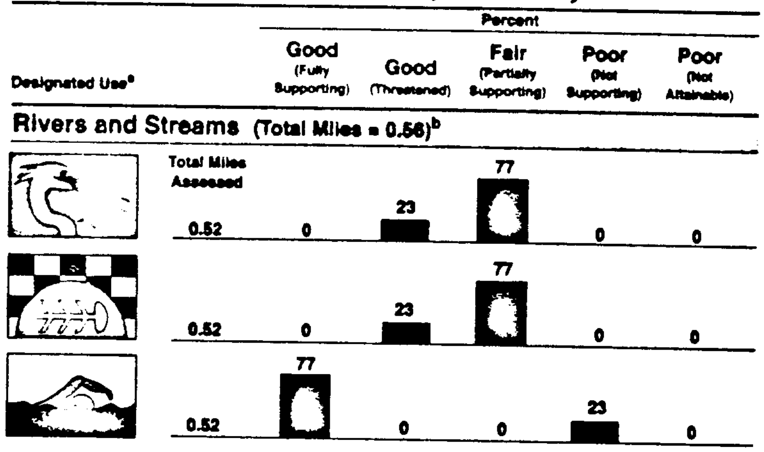
Programs to Restore Water Quality

Codes and ordinances for the Reservation will be established to create a Water Quality and Management Program for the Reservation. With codes in place, the Coyote Valley Tribal Council will gain the authority to restrain the discharge of pollutants that could endanger the Reservation water supply and affect the health and welfare of its people, as well as people in the adjacent communities.

Programs to Assess Water Quality

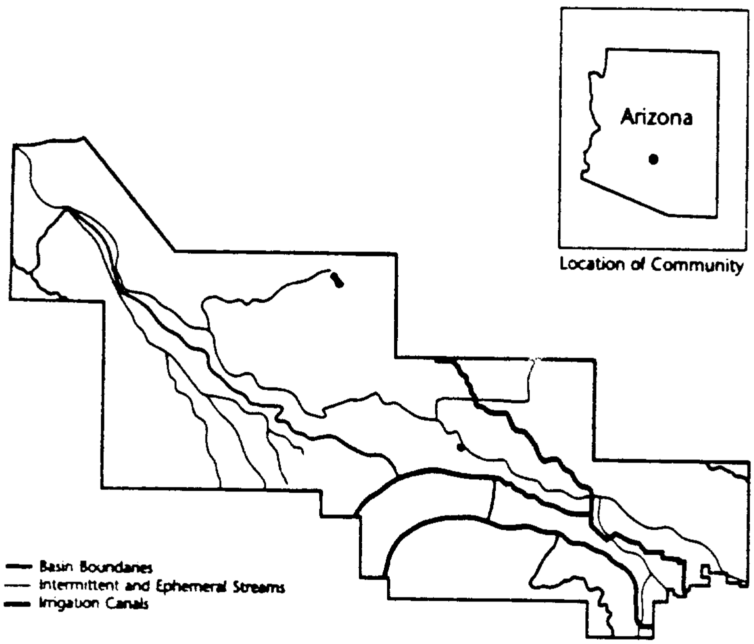
The Tribal Water Quality Manager will design a monitoring system with assistance from environmental consultants. The Water Quality Manager will sample a temporary monitoring station on Forsythe Creek and a proposed sampling station on the Russian River every month. A fisheries biologist will survey habitat on the rivers every other year, as funding permits.

Individual Use Support in Coyote Valley Reservation



[a] A subset of Coyote Valley Reservation's designated uses appear in this figure. Refer to the Tribe's 305(b) report for a full description of the Tribe's uses.
[b] Includes nonperennial streams that dry up and do not flow all year.

Gila River Indian Community



For a copy of the Gila River Indian Community 1994 305(b) report, contact:

Errol Blackwater
Gila River Indian Community
Water Quality Planning Office
Corner of Pima and Main Streets
Sacaton, AZ 85247
(602) 562-3203

Surface Water Quality

The Gila River Indian Community occupies 580 square miles in Central Arizona adjacent to the metropolitan Phoenix area. About 8,500 members of the Pima and Maricopa Tribes live in 22 small villages inside the Community. The Gila River is the major surface water feature in the Community, but its flow is interrupted by upstream diversions outside of the Community. Arid conditions and little vegetative cover cause sudden runoff with high suspended sediment loads.

Surface water was evaluated with qualitative information due to the lack of monitoring data. Most of the Community's surface waters have fair water quality that partially supports designated uses because of turbidity, siltation, salinity, and metals loading from rangeland, agriculture, irrigation return flows, and upstream mining. Information was not available for assessing effects of toxic contaminants and acid rain. There is no information about water quality conditions in wetlands.

Ground Water Quality

Community ground water quality generally complies with EPA's Maximum Contaminant Levels, but concentrations of total dissolved solids often exceed recommended concentrations. However, members of the Community have either adjusted to the aesthetic problem of high dissolved solids or begun purchasing bottled water, as have other ground water users in the metropolitan Phoenix area. Occasionally, concentrations of coliform bacteria, nitrates, and fluoride exceed recommended criteria in isolated wells. Pathogens from onsite sewage disposal systems have been detected in ground water and pose the primary public health concern. Other concerns include salinity and pesticides from large-scale agriculture and potential fuel or solvent leaks.

VOL 12

Programs to Restore Water Quality

The Gila River Indian Community needs a comprehensive water quality protection program, especially as nearby urban growth and agricultural expansion create additional pollution and place new demands on aquatic resources. As a first step, the Community's Water Quality Planning Office intends to address point sources of pollution through a Ground Water Protection Strategy. The Strategy will seek to eliminate all discharges that could reach ground water or require rapid mitigation if a discharge cannot be avoided. Principles of Arizona's Aquifer Protection Permit Program may serve as a basis for the Community's Strategy, but the Strategy will be streamlined and simple to implement. The Strategy may include technology-based or standards-based protocols for facilities and conditions for land use permits.

Programs to Assess Water Quality

The Community needs monitoring programs for ground water, surface water, and wetlands in order to assess use support and to support a water pollution control program.

Individual Use Support in Gila River Indian Community

Designated Use[a]	Total Assessed	Percent: Good (Fully Supporting)	Good (Threatened)	Fair (Partially Supporting)	Poor (Not Supporting)	Poor (Not Attainable)

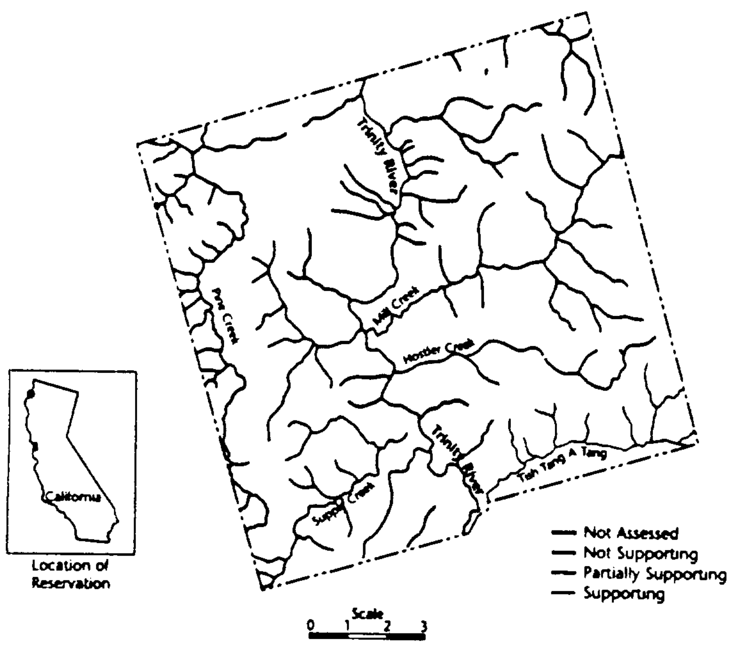
Hoopa Valley Indian Reservation



For a copy of the Hoopa Valley Indian Reservation 1994 305(b) report, contact:

Colleen Goff
P.O. Box 1314
Hoopa, CA 95546
(916) 625-4275

Surface Water Quality

The Hoopa Valley Indian Reservation covers almost 139 square miles in Humboldt County in northern California. The Reservation contains 133 miles of rivers and streams, including a section of the Trinity River, and 3,200 acres of wetlands. The Reservation does not contain any lakes.

Surface waters on the Reservation appear to be free of toxic organic chemicals, but poor forest management practices and mining operations, both on and off the Reservation, have caused significant siltation that has destroyed gravel spawning beds. Water diversions, including the damming of the Trinity River above the Reservation, have also stressed the fishery by lowering stream volume and flow velocity. Low flows raise water temperatures and reduce flushing of accumulated silt in the gravel beds. Upstream dams also stop gravel from moving downstream to replace excavated gravel. Elevated fecal coliform concentrations also impair drinking water use on the Reservation.

Ground Water Quality

Ground water sampling revealed elevated concentrations of lead, cadmium, manganese, iron, and fecal coliforms in some wells. The Tribe is concerned about potential contamination of ground water from leaking underground storage tanks, septic system leachfields, and abandoned hazardous waste sites with documented soil contamination. These sites contain dioxins, herbicides, nitrates, PCBs, metals, and other toxic organic chemicals. The Tribe's environmental consultants are designing a ground water sampling program to monitor potential threats to ground water.

Programs to Restore Water Quality

In 1990, EPA approved the Hoopa Valley Tribe's application for treatment as a State under the Section 106 Water Pollution Control Program of the Clean Water Act. Following approval, the Tribe received Section 106 funding to conduct a Water Quality Planning and Management Program on the Reservation. The Tribal Water Quality Manager is developing water quality criteria for the Reservation, with the help of environmental consultants. The proposed criteria will be reviewed by the Hoopa Valley Planning Department and the Tribal Council.

Programs to Assess Water Quality

In June of 1992, the Tribal Planning Office and its hired consultants sampled eight surface water sites and six ground water sites. The Tribe measured different pollutants at each site, depending on the surrounding land use activities, including conventional pollutants, toxic organic pollutants, metals, and fecal coliforms. The Tribe plans to establish fixed monitoring sites in the near future, which will complement ongoing biological monitoring conducted by the Hoopa Valley Fisheries Department on the Trinity River.

Individual Use Support in Hoopa Valley Indian Reservation

Phillip Tuwaletstiwa
The Hopi Tribe
Water Resources Program
Box 123
Kykotsmobi, AZ 86039
(520) 734-9307

Surface Water Quality

The 2,439-square-mile Hopi Reservation, located in northeastern Arizona, is bounded on all sides by the Navajo Reservation. Surface water on the Hopi Reservation consists primarily of intermittent or ephemeral streams. Only limited data regarding stream quality are available. The limited data indicate that some stream reaches may be deficient in oxygen, although this conclusion has not been verified by repeat monitoring.

In addition to the intermittent and ephemeral washes and streams, surface water on the Hopi Reservation occurs as springs where ground water discharges as seeps along washes or through fractures and joints within sandstone formations. The Hopi Tribe assessed 18 springs in 1992 and 1993. The assessment revealed that several springs had one or more exceedances of nitrate, selenium, total coliform, or fecal coliform. The primary potential sources of surface water contamination on the Hopi Reservation include mining activities outside of the Reservation, livestock grazing, domestic refuse, and wastewater lagoons.

Ground Water Quality

In general, ground water quality on the Hopi Reservation is good. Ground water from the N-aquifer provides drinking water of excellent quality to most of the Hopi villages. The D-aquifer, sandstones of the Mesaverde Group, and alluvium also provide ground water to shallow stock and domestic wells, but the quality of the water from these sources is generally of poorer quality than the water supplied by the N-aquifer.

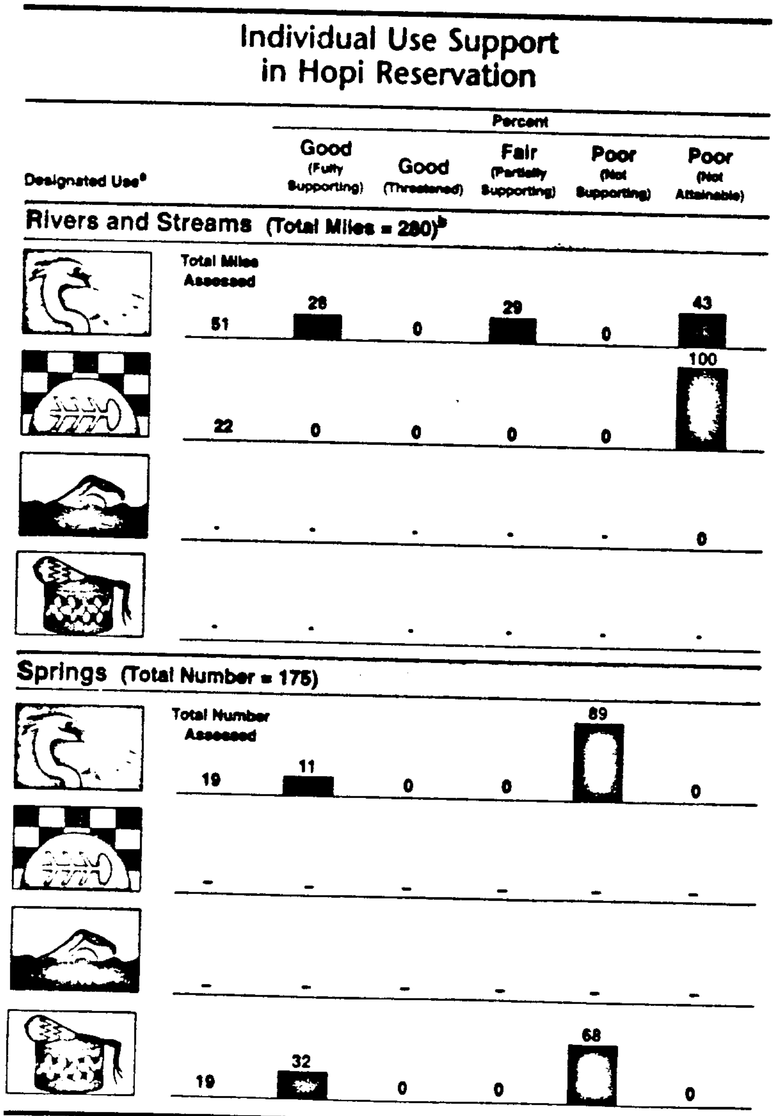
Mining activities outside of the Reservation are the most significant threat to the N-aquifer. Extensive pumping at the Peabody Coal Company Black Mesa mine may induce leakage of poorer quality D-aquifer water into the N-aquifer. This potential problem is being investigated under an ongoing monitoring program conducted by the U.S. Geological Survey. In addition, the U.S. Department of Energy is investigating ground water impacts from abandoned uranium tailings at Tuba City. Other potential sources of contamination in shallow wells include domestic refuse, underground storage tanks, livestock grazing, wastewater lagoons, and septic tanks.

Programs to Restore Water Quality

Draft water quality standards (including an antidegradation policy) were prepared for the Tribe in 1993. The Tribe is also reviewing a proposed general maintenance program to control sewage lagoons. The Tribe has repeatedly applied for EPA grants to investigate nonpoint source pollution on the Reservation, but the applications were denied.

Programs to Assess Water Quality

The Tribe focused on monitoring springs and ground water during the 1994 reporting cycle. Future surface water monitoring will assess aquatic life in springs, lakes, and streams; baseflow and storm flow in streams; and biological, sediment, and chemical content of streams and springs.

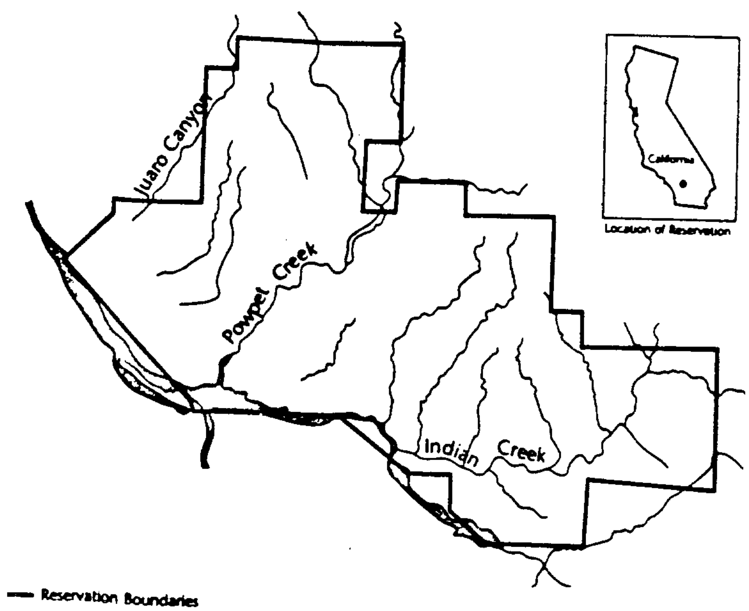


- Not reported

[a] A subset of the Hopi Tribe's designated uses appear in this figure. Refer to the Tribe's 305(b) report for a full description of the Tribe's uses.

[b] Includes nonperennial streams that dry up and do not flow all year.

Soboba Band of Mission Indians



For a copy of the Soboba Band of Mission Indians 1994 305(b) report, contact:

Jamie S. Megee
Soboba Band of Mission Indians
P.O. Box 487
San Jacinto, CA 92581
(909) 654-2765

Surface Water Quality

The Soboba Reservation encompasses about 9.2 square miles in southern California about 80 miles east of Los Angeles. The San Jacinto River is the major surface water feature on the Reservation. At one time, the San Jacinto River flowed year round, but upstream diversions and ground water withdrawals outside of the Reservation have reduced the flow to intermittent status for many years.

The chemical quality of surface water on the Soboba Reservation is excellent and remains unimpaired to date, based on very limited data. The quality of surface water, to the extent it is available, fully supports the existing uses of ground water recharge, wildlife habitat, and recreation. Overall, the greatest threat to water quality on the Soboba Reservation is the reduction of surface flows and ground water storage by off-Reservation diversions and pumping.

Ground Water Quality

Three major water supply wells extract water from two aquifers on the Soboba Reservation. Ground water overdraft outside the Reservation has seriously reduced the withdrawal capacity of the Reservation's wells and aquifers. The chemical quality of ground water on the Soboba Reservation is excellent and remains unimpaired to date. The single most critical threat to water quality is a proposal by the Eastern Municipal Water District to routinely recharge treated effluent at a site within 600 feet of an existing Soboba well.

Programs to Restore Water Quality

There are no formal water pollution control programs in place on the Reservation. However, the Band has achieved compliance with EPA monitoring and treatment requirements for its domestic ground water supply system and the Band is considering development of a wellhead protection program. In addition, the Band is seeking assistance from EPA under the Indian Environmental General Assistance Program to educate the Band about water quality issues, establish water resource protection ordinances, and undertake other water protection initiatives.

The Soboba Band is continuing its struggle to assert and defend its water rights. The Soboba Band has started negotiating with the major water users outside of the Reservation to fairly apportion the waters of the basin. Nondegradation of water quality will be a basic element of the Band's position in these negotiations.

Programs to Assess Water Quality

The Band advocates sharing and cooperative analysis of data on the hydrology and water quality of the San Jacinto watershed to facilitate water rights negotiations. This affirmative approach to water resource management should lead to a systematic, integrated water quality monitoring program for the basin that will benefit all users.

Individual Use Support in Soboba Band of Mission Indians

Interstate Commission Summaries

Interstate Commissions provide a forum for joint administration of large waterbodies that flow through or border multiple States and other jurisdictions, such as the Ohio River and the Delaware River and Estuarine System. Each Commission has its own set of objectives and protocols, but the Commissions share a cooperative framework that embodies many of the principles advocated by EPA's watershed management approach. For example, Interstate Commissions can examine and address factors throughout the basin that contribute to water quality problems without facing obstacles imposed by political boundaries. The information presented here summarizes the data submitted by four Interstate Commissions in their 1994 Section 305(b) reports.

VOL 12

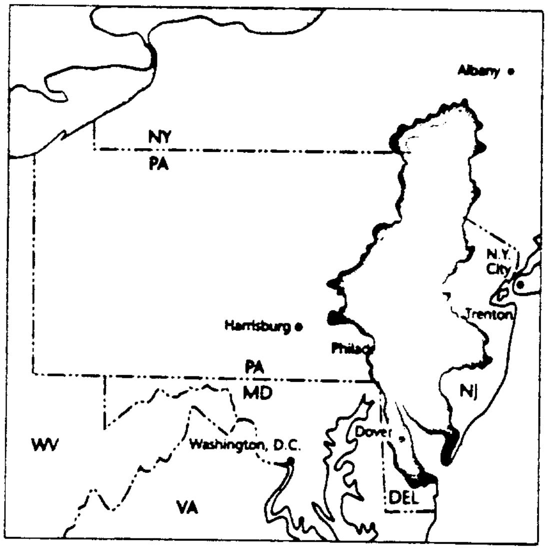
Delaware River Basin Commission



— Basin Boundaries
(USGS 6-Digit Hydrologic Unit)

For a copy of the Delaware River Basin Commission 1994 305(b) report, contact:

Robert Kausch
Delaware River Basin Commission
P.O. Box 7360
West Trenton, NJ 08628-0360
(609) 883-9500, ext. 252

Surface Water Quality

The Delaware River Basin covers portions of Delaware, New Jersey, New York, and Pennsylvania. The Delaware River system consists of a 207-mile freshwater segment, an 85-mile tidal reach, and the Delaware Bay. Nearly 8 million people reside in the Basin, which is also the home of numerous industrial facilities and the port facilities of Philadelphia, Camden, and Wilmington.

All of the riverine waters and 94% of the estuarine waters in the Basin have good water quality that fully supports aquatic life uses. Three percent of the riverine waters do not support fish consumption and 2% have fair quality that partially supports swimming. In estuarine waters, poor water quality impairs shellfishing in 29% of the surveyed waters. Low dissolved oxygen concentrations and toxic contaminants in sediment degrade portions of the lower tidal river and estuary. Fecal coliform bacteria and high pH values impair a few miles of the Delaware River. As of April 1994, fish consumption advisories were posted on about 6 miles of the Delaware River and 22 square miles of the tidal river, cautioning the public to restrict consumption of channel catfish, white perch, and american eels contaminated with PCBs and chlordane.

In general, water quality has improved since the 1992 305(b) assessment period. Tidal river oxygen levels were higher during the critical summer period, residues of toxic chemicals in fish and shellfish declined, and populations of important fish species (such as striped bass and American shad) increased during the 1994 assessment period.

Programs to Restore Water Quality

For many years, the Delaware River Basin Commission and the surrounding States have implemented an aggressive program to reduce point source discharges of oxygen-depleting wastes and other pollutants. These programs will continue, in addition to new efforts to determine the role of stormwater runoff. The Commission also adopted new Special Protection Waters regulations to protect existing high water quality in the upper reaches of the nontidal river from the effects of future population growth and development. The Commission also promotes a comprehensive watershed management approach to coordinate several layers of governmental regulatory programs impacting the Delaware River Basin.

Programs to Assess Water Quality

The Commission conducts an intensive monitoring program along the entire length of the Delaware River and Estuary. At least a dozen parameters are sampled at most stations, located about 7 miles apart. The new Special Protection Waters regulations require even more sophisticated monitoring and modeling, such as biological monitoring and continuous water quality monitoring. The Combined Sewer Overflow Study and the Toxics Study will both require additional specialized water quality analyses in order to understand how and why water quality is affected. New management programs will very likely require customized monitoring programs.

Individual Use Support in the Delaware River Basin

Designated Use[a]	Total Miles Assessed	Percent: Good (Fully Supporting)	Good (Threatened)	Fair (Partially Supporting)	Poor (Not Supporting)	Poor (Not Attainable)
Rivers and Streams (Total Miles = 206)

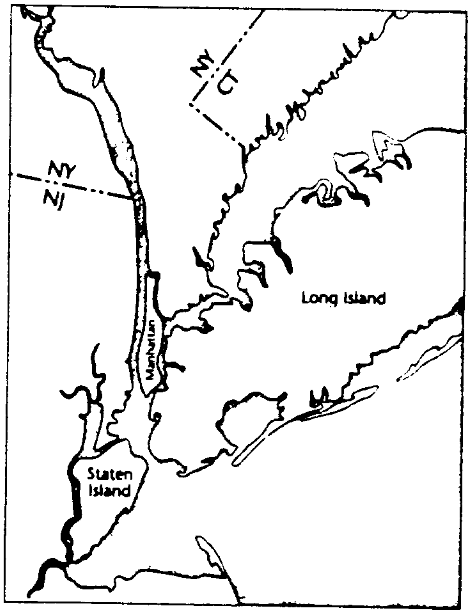
Interstate Sanitation Commission



— Basin Boundaries
(USGS 6-Digit Hydrologic Unit)

For a copy of the Interstate Sanitation Commission 1994 305(b) report, contact:

Howard Golub
Interstate Sanitation Commission
311 West 43rd Street
New York, NY 10036
(212) 582-0380

Surface Water Quality

Established in 1936 by Federal mandate, the Interstate Sanitation Commission (ISC) is a tristate environmental agency of the States of New Jersey, New York, and Connecticut. The Interstate Sanitation District encompasses approximately 797 square miles of estuarine waters in the Metropolitan Area shared by the States, including the Arthur Kill/ Kill Van Kuli, Lower Hudson River, Newark Bay, Raritan Bay, Sandy Hook Bay, and Upper New York Bay.

In general, water quality in the District waters improved during the 1992-1993 reporting cycle. Dissolved oxygen concentrations increased and bacteria densities decreased. The reduction in bacteria is due to the Commission's year-round disinfection regulations (which took effect in 1986), and the elimination of discharges receiving only primary treatment at Middlesex and Hudson Counties.

Topics of concern to the ISC include compliance with ISC regulations, toxic contamination in District waters, pollution from combined sewer overflows, closed shellfish waters, and wastewater treatment capacity to handle growing flows from major building projects.

Ground Water Quality

The ISC's primary focus is on surface waters shared by the States of New Jersey, New York, and Connecticut.

Programs to Restore Water Quality

The ISC actively participates in the Long Island Sound Study, the New York-New Jersey Harbor Estuary Program (HEP), the New York Bight Restoration Plan, and the Dredged Material Management Plan for the Port of New York and New Jersey. The ISC has representatives on the Management Committees and various workgroups for each program. For the HEP, the ISC organized a meeting entitled "Current Beach Closure Practices in New York, New Jersey, and Connecticut: Review and Recommendations" in

November 1993. Representatives of State, county, and municipal health departments and environmental agencies were invited to discuss bathing beach monitoring and closure policies. The public and environmental advocacy groups were also invited. The ISC reported the results to the HEP Pathogens Work Group.

During 1993, the ISC inspected 71 CSO outfalls in an effort to identify and eliminate all dry weather discharges. The ISC notified the States of dry weather discharges detected during field investigations and worked with the States to eliminate dry weather discharges.

Programs to Assess Water Quality

The ISC performs intensive ambient water quality surveys and samples effluent discharged by publicly owned and private wastewater treatment facilities and industrial facilities into District waterways. By agreement, the ISC's effluent requirements are incorporated into the individual discharge permits issued by the participating States.

Individual Use Support in Interstate Sanitation Commission Waters

Designated Use[a]		Percent: Good (Fully Supporting)	Good (Threatened)	Fair (Partially Supporting)	Poor (Not Supporting)	Poor (Not Attainable)

Note: All waters under the jurisdiction of the Interstate Sanitation Commission are estuarine.

Ohio River Valley Water Sanitation Commission (ORSANCO)

— Basin Boundaries
(USGS 6-Digit Hydrologic Unit)

For a copy of the ORSANCO 1994 305(b) report, contact:

Jason Heath
ORSANCO
5735 Kellogg Avenue
Cincinnati, OH 45228-1112
(513) 231-7719

Surface Water Quality

The Ohio River Valley Water Sanitation Commission (ORSANCO) was established in 1948 by the signing of the Ohio River Valley Water Sanitation Compact by Illinois, Indiana, Kentucky, New York, Ohio, Pennsylvania, Virginia, and West Virginia. ORSANCO is an interstate agency with multiple responsibilities that include detecting interstate spills, developing waste treatment standards, and monitoring and assessing the Ohio River mainstem. The mainstem runs 981 miles from Pittsburgh, Pennsylvania, to Cairo, Illinois.

The most common problems in the Ohio River are PCB and chlordane contamination in fish and bacteria, pesticides, and metals in the water column. The States have issued fish consumption advisories along the entire length of the Ohio River based on ORSANCO data. ORSANCO also suspects that community combined sewer overflows along the entire length of the river elevate bacteria levels and impair swimming. ORSANCO detected bacteria contamination at all seven monitoring stations downstream of major urban areas with a large number of CSOs.

Copper, lead, and zinc exceeded criteria for protecting warm water aquatic life in waters near the Gallipolis-Huntington area, Cincinnati, Louisville, and the Paducah area. Acid mine drainage is a suspected source of some metals in the Ohio River.

Public water supply use of the Ohio River is impaired by 1,2-dichloroethane near Paducah and by atrazine near Louisville and the mouth of the River at Grand Chain, Illinois. The extent of atrazine contamination is unknown because few sites are monitored for atrazine.

NOTE: A more detailed account of water quality throughout the entire Ohio River Basin is presented in Chapter 12.

Ground Water Quality

ORSANCO does not have jurisdiction over ground water in the Ohio River Basin.

Programs to Restore Water Quality

In 1992, an interagency workgroup developed a CSO program for the Ohio River Basin with general recommendations to improve coordination of State CSO strategies. In 1993, ORSANCO added requirements for CSOs to the Pollution Control Standards for the Ohio River and the Commissioners adopted a strategy for monitoring CSO impacts on Ohio River quality. The Commission also established a Nonpoint Source Pollution Abatement Task Force composed of ORSANCO Commissioners, representatives from State NPS control agencies, and representatives from industries that generate NPS pollution.

Programs to Assess Water Quality

ORSANCO operates several monitoring programs on the Ohio River mainstem and several major tributaries, including fixed-station chemical sampling, daily sampling of volatile organic chemicals at water supply intakes, bacterial monitoring, fish tissue sampling, and fish community monitoring. ORSANCO uses the Modified Index of Well Being (MIwb) to assess fish community characteristics, such as total biomass and species diversity.

Individual Use Support in the Ohio River Valley Basin

Designated Use[a]	Total Miles Assessed	Percent: Good (Fully Supporting)	Good (Threatened)	Fair (Partially Supporting)	Poor (Not Supporting)	Poor (Not Attainable)
Rivers and Streams (Total Miles = 37,600)[b]

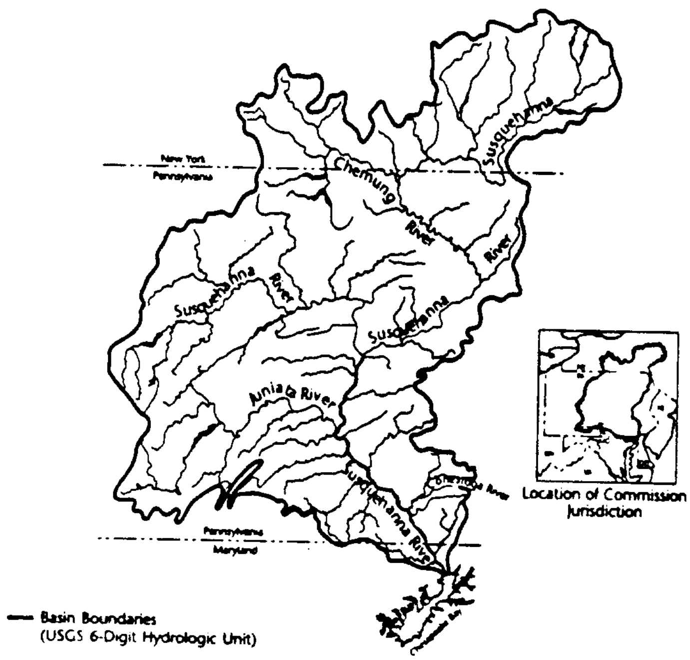
Susquehanna River Basin Commission



For a copy of the Susquehanna River Basin Commission 1994 305(b) report, contact:

Robert E. Edwards
Susquehanna River Basin Commission
Resource Quality Management and Protection
1721 North Front Street
Harrisburg, PA 17102-0423
(717) 238-0423

Surface Water Quality

The Susquehanna River drains 27,510 square miles from parts of New York, Pennsylvania, and Maryland, and delivers over half of the fresh water entering the Chesapeake Bay. The Susquehanna River Basin Commission (SRBC) surveyed 17,464 miles of the 31,193 miles of rivers and streams in the Susquehanna River Basin. Over 90% of the surveyed river miles fully support designated uses, 4% partially support uses, and 6% do not support one or more designated uses. Metals, low pH, and nutrients are the primary causes of stream impacts in the Basin. Coal mine drainage is the source of most of the metals and pH problems degrading streams. Sources of nutrients include municipal and domestic wastewater discharges, agricultural runoff, and ground water inflow from agricultural areas.

During past reporting cycles, SRBC did not conduct any lake or reservoir assessments. However, a 2-year project funded by EPA and Pennsylvania should provide a foundation of lake data upon which SRBC can launch its lake assessment program.

Ground Water Quality

Ground water in the Basin is generally of adequate quality for most uses. Many of the ground water quality problems in the Basin are related to naturally dissolved constituents (such as iron, sulfate, and dissolved solids) from the geologic unit from which the water originates. The SRBC is concerned about ground water contamination from septic systems and agricultural activities.

Programs to Restore Water Quality

The Susquehanna River Basin Compact assigns primary responsibility for water quality management and control to the signatory States.

The SRBC's role is to provide a regional perspective for coordinating local, State, and Federal water quality management efforts. For example, the SRBC reviews proposed discharge permits (issued by the States) and evaluates potential interstate and regional impacts. The SRBC also recommends modifications to State water quality standards to improve consistency among the States.

Programs to Assess Water Quality

The SRBC's role in interstate and regional issues shaped the Commission's monitoring program. The SRBC's fixed-station monitoring network collects base flow data and seasonal-storm nutrient data on the Susquehanna mainstem and major tributaries to assist the Chesapeake Bay Program in evaluating nutrient reduction projects. The SRBC also established an interstate stream water quality network to evaluate streams crossing State boundaries for compliance with State water quality standards. Biological monitoring is conducted annually at 29 sites. The SRBC also conducts intensive subregional surveys to analyze regional water quality and biological conditions.

Overall[a] Use Support in the Susquehanna River Basin

		Percent				
		Good (Fully Supporting)	Good (Threatened)	Fair (Partially Supporting)	Poor (Not Supporting)	Poor (Not Attainable)
Rivers and Streams (Total Miles = 31,193)[b]						
	Total Miles Assessed 17,464	90	-	4	6	-
Lakes (Total Acres = 79,687)						
	Total Acres Assessed -	-	-	-	-	-

- Not reported.

[a] Overall use support is presented in this figure because the Commission did not report individual use support in their 1994 Section 305(b) report.

[b] Includes nonperennial streams that dry up and do not flow all year.

The Watershed Protection Approach and Place-based Management Programs

Watershed Protection Approach

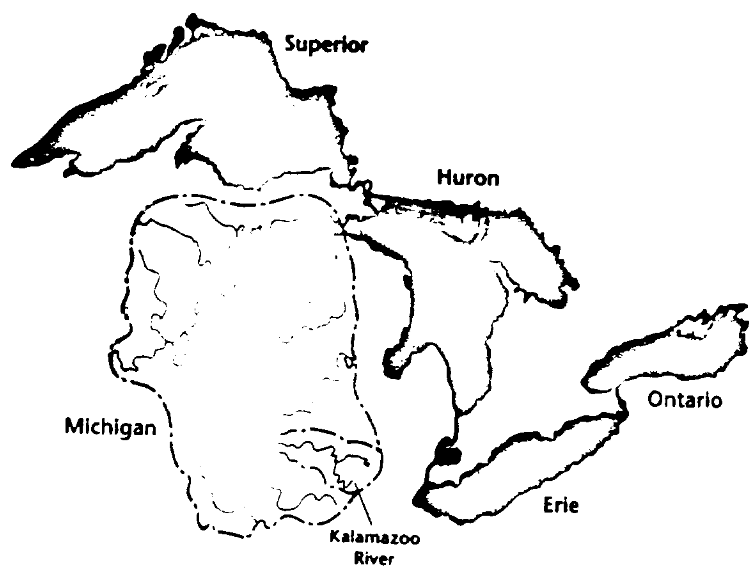
Introduction

The Nation's aquatic resources are among its most valuable assets. Although significant strides have been made in reducing the impacts of discrete pollutant sources, our aquatic resources remain at risk from a combination of point sources and complex nonpoint sources, including air pollution. Since 1991, the EPA has promoted the watershed protection approach as a holistic framework for addressing complex pollution problems.

The watershed protection approach is a place-based strategy that integrates water quality management activities within hydrologically defined drainage basins–watersheds–rather than areas defined by political boundaries. Thus, for a given watershed, the approach encompasses not only the water resource (such as a stream, lake, estuary, or ground water aquifer), but all the land from which water drains to the resource (Figure 12-1). To protect water resources, it is increasingly important to address the condition of land areas within the watershed because water carries the effects of human activities throughout the watershed as it drains off the land into surface waters or leaches into the ground water.

Figure 12-1

Watershed Management Units in the Great Lakes Basin



The watershed protection approach may be applied to watersheds of all sizes. Watershed size varies, depending on the objectives and scope of a watershed initiative. For example, partnerships are developing comprehensive management strategies for the entire Great Lakes Basin, the watershed draining into each Great Lake, and the watersheds draining into individual areas of concern on the Great Lakes, such as the Kalamazoo River watershed. Each level of detail provides additional insight about the factors contributing to complex water quality problems.

VOL 12

5734

Several key principles guide the watershed protection approach:

■ **Place-based focus** – Resource management activities are directed within specific geographical areas, usually defined by watershed boundaries, areas overlying or recharging ground water, or a combination of both.

■ **Stakeholder involvement and partnerships** – Watershed initiatives involve the people most likely to be affected by management decisions in the decision making process. Stakeholder participation ensures that the objectives of the watershed initiative will include economic stability and that the people who depend on the water resources in the watershed will participate in planning and implementation activities. Watershed initiatives also establish partnerships between Federal, State, and local agencies and nongovernmental organizations with interests in the watershed.

■ **Environmental objectives** – The stakeholders and partners identify environmental objectives (such as "populations of striped bass will stabilize or increase") rather than programmatic objectives (such as "the State will eliminate the backlog of discharge permit renewals") to measure success of the watershed initiative. The environmental objectives are based on the condition of the ecological resource and the needs of people in the watershed.

■ **Problem identification and prioritization** – The stakeholders and partners use sound scientific data and methods to identify and prioritize the primary threats to human and ecosystem health within the watershed. Consistent with the Agency's mission, EPA views ecosystems as the interactions of complex communities that include people; thus, healthy ecosystems provide for the health and welfare of humans as well as other living things.

■ **Integrated actions** – The stakeholders and partners take corrective actions in a comprehensive and integrated manner, evaluate success, and refine actions if necessary. The watershed protection approach coordinates activities conducted by numerous government agencies and nongovernmental organizations to maximize efficient use of limited resources.

EPA's Office of Water envisions the watershed protection approach as the primary mechanism for achieving clean water and healthy, sustainable ecosystems throughout the Nation. The watershed protection approach enables stakeholders to take a comprehensive look at ecosystem issues and tailor corrective actions to local concerns within the coordinated framework of a national water program. The emphasis on public participation also provides an opportunity to incorporate environmental justice issues into watershed restoration and protection solutions.

In May of 1994, the EPA Assistant Administrator for Water, Robert Perciasepe, created the Watershed Management Policy Committee to coordinate the EPA water program's support of the watershed protection approach. During 1995, EPA's water program managers, under the direction of the Watershed Policy Committee, evaluated their programs and identified additional activities needed to support the watershed protection approach in an action plan. The action plans address several broad directions:

- Enhance interagency coordination at the Federal, State, and local levels.

- Build State, Tribal, and Territorial watershed protection capabilities by encouraging States and Tribes to integrate existing programs (such as NPDES Permitting Programs, Section 319 Nonpoint Source Programs, Comprehensive State Ground Water Protection Programs, and State Wetlands Conservation Plans) using comprehensive State, Tribal, and Territorial watershed approaches.

- Develop tools (such as methods, models, criteria, indicators, data management, and monitoring techniques) for implementing the watershed protection approach.

- Provide training on watershed approach concepts and tools.

- Improve coordination within EPA, and streamline program requirements (such as allowing multipurpose planning, funding, and reporting for watershed efforts).

- Reach out to watershed stakeholders by publicizing accomplishments at meetings and conferences and in newsletters and publications.

EPA's Office of Water will continue to promote and support the watershed protection approach. This approach relies on active participation by local governments and citizens who have the most direct knowledge of local problems and opportunities in their watersheds. However, the Office of Water will look to the States, Tribes, and Territories to create the framework for supporting local efforts because most EPA programs are implemented by the States, Tribes, and Territories.

EPA's Office of Water has already taken steps to reorient and coordinate its programs to support the comprehensive watershed protection approach (see the highlight on the NPDES Watershed Strategy). In addition, EPA is supporting watershed management projects across the Nation that coordinate numerous agencies to simultaneously achieve multiple objectives. These projects are implemented by the States with EPA support channeled through various Office of Water programs, including the Section 319 Nonpoint Source Program, the Section 320 National Estuary Program, the Wetlands Grant Program, and the Comprehensive State Ground Water Protection Program (see highlight on the Bear River Project).

The Office of Water will continue to build upon its experience with established place-based programs, such as the Chesapeake Bay Program and the Great Lakes National Program, to eliminate barriers to the watershed protection approach. These integrated programs (described later in this chapter) laid the foundation for the Agency's shift toward comprehensive watershed management and continue to provide models for implementing the "place-based approach" to environmental problem solving.

HIGHLIGHT HIGHLIGHT HIGHLIGHT

The National Pollutant Discharge Elimination System (NPDES) Watershed Strategy

On March 21, 1994, EPA issued the NPDES Watershed Strategy to fully integrate the NPDES permit program into the watershed protection approach. Over the past 20 years, the NPDES program has employed permitting requirements to achieve significant reductions in pollutant discharges to surface waters from industrial and municipal facilities (see Chapter 10 for a full description of the Point Source Control Program). In most cases, the States have assumed responsibility for implementing the NPDES permit program. In recent years, the NPDES program expanded to address remaining sources of pollutant discharges, including combined sewer overflows and storm water discharges. The NPDES Watershed Strategy provides a cost-effective mechanism for addressing the remaining point sources of environmental impacts while maintaining successful control of traditional discharges.

The NPDES Strategy outlines national objectives and implementation activities to (1) integrate NPDES program functions into the broader watershed protection approach, and (2) support development of statewide watershed or basin approaches. The Strategy identifies six essential items that EPA Headquarters and the Regions must support:

- Statewide coordination – promote development of watershed or basin management frameworks that identify the roles and responsibilities of participating programs, long-term programmatic and environmental goals, geographically delineated basins, and a schedule for periodically evaluating the environmental conditions in each basin.

- NPDES permits – encourage States to develop basin management plans that synchronize permit issuance within basins.

- Monitoring and assessment – encourage the States to develop statewide monitoring strategies that coordinate collection and analysis of data with NPDES permit issuance and other management activities within basins.

- Programmatic measures and environmental indicators – revise national accountability measures to facilitate implementation of watershed protection activities and establish new measures of success that reflect progress toward

VOL 12

5737

HIGHLIGHT HIGHLIGHT HIGHLIGHT

achieving watershed protection goals.

■ Public participation – promote long-term public support for basin management activities by providing opportunities for the public to participate in goal development, priority setting, strategy development, and implementation.

■ Enforcement – coordinate compliance and enforcement programs and activities at the Federal, State, Territorial, and Tribal levels to focus resources on priority point sources within identified basins.

The NPDES Watershed Strategy is intended to support ongoing State and Tribal initiatives and supplement the efforts of other environmental programs by identifying areas where the NPDES program can contribute. The Strategy recognizes that the NPDES program may play a central role in a number of watersheds, but point sources will not represent the primary stressors in many watersheds. In such cases, the NPDES program can support and facilitate activities for meeting environmental objectives, such as monitoring and public participation.

Several State and EPA Regions have taken significant steps toward integrating NPDES program activities into the broader watershed protection approach, but the NPDES Watershed Strategy remains largely untapped. To promote implementation at the national level, each EPA Regional Office completed the following action items during FY95:

■ Regional State-by-State Assessments and Action Plans – assess current watershed protection activities in each State and develop Regional action plans that identify how the Region will support and facilitate each State's movement toward the watershed protection approach.

■ State/EPA Workplan Agreements – include specific activities within workplans that will promote the central components of the NPDES Watershed Strategy.

■ Internal Coordination – develop Regional strategies that describe the Regional decision making processes, oversight role, and internal coordination efforts necessary to ensure support for the watershed protection approach.

HIGHLIGHT HIGHLIGHT HIGHLIGHT

Implementing the Watershed Protection Approach on the Bear River, Utah

The Bear River has a 7,600-square mile watershed located in Wyoming, Utah, and Idaho. The Utah Division of Water Resources initiated the project in an effort to resolve major environmental problems:

- Soil erosion, increased sediment loadings, coliforms, and high nutrient loadings due to animal feeding operations, dairies, urban development, roads, oil and gas exploration, and silviculture
- Riparian vegetation removal
- Stream channelization
- Degraded stream channels and streambanks.

Interest in increasing the use of the river as a drinking water source for the growing urban population in the lower basin and along the Wasatch Front prompted the Utah Legislature to enact the Bear River Development Act and fund a Bear River water development and management plan. The effort is to address both water development and water quality issues, with a water quality plan that includes a broad-reaching analysis of pollutant loading to the river as well as chemical, biological, and physical habitat assessments. Because the Bear River encompasses Utah, Wyoming, and Idaho, a regional planning effort has been initiated. The purpose of the regional effort is to share information, coordinate planning efforts, and involve "grassroots" direction and participation. An array of water projects in the Bear River Basin initiated by different organizations and groups are being coordinated through the Bear River Watershed Water Quality Coordination Committee.

For example, the State of Utah, EPA, and the U.S. Department of Agriculture (USDA) initiated a watershed restoration project on the Little Bear River (one of the major tributaries in the basin) using funds from USDA and EPA. The project includes stream channel and riparian habitat restoration, land management, and animal waste treatment actions. Several additional nonpoint source projects are now under way in Wyoming that are aimed at restoring tributary streams that have been impacted by channelization, streambank modification, and riparian habitat loss.

Place-based Management Programs

Introduction

The programs described in this section (the Great Waterbodies Program, the Great Waters Program, and the National Estuary Program) embody a watershed protection approach at different scales. The Great Waterbodies Program and the Great Waters Program target entire drainage basins, such as the Gulf of Mexico, which drains two-thirds of the continental United States and a large portion of Mexico. The National Estuary Program (NEP) targets clusters of watersheds that drain into a specific estuary, such as Galveston Bay. NEP sites may be nested within a larger basin targeted by the Great Waterbodies or Great Waters Programs, such as the Gulf of Mexico.

Although scales differ, these programs share a common place-based ecosystem approach to solving water quality problems. The ecosystem approach recognizes that all components of the environment are interconnected and that pollution released in one area can cause problems in another. This concept requires all responsible parties to recognize and reduce impacts. Therefore, managing pollution on the ecosystem level requires building institutional frameworks that involve all affected parties, such as agricultural interests, environmental advocacy organizations, industry, government agencies, and private citizens. Consensus is a key to managing pollution on the ecosystem level.

The ecosystem approach also encourages pollution prevention and efforts to avoid actions that can even indirectly lead to contamination of the waterbody. Although such ecosystem perspectives are hardly new, they are more often applied to much smaller units such as watersheds.

The Great Waterbodies Program

Background

The Great Waterbodies Program manages water quality protection in the three largest watersheds targeted by EPA: the Gulf of Mexico, the Great Lakes, and the Chesapeake Bay.

The Gulf of Mexico

Background

The Gulf of Mexico is fed by rivers draining a vast area in five countries. The Gulf's watershed, which covers almost 2 million square miles, is far larger than any other in the Nation. It includes two-thirds of the continental United States, one-half of Mexico, and parts of Canada, Guatemala, and Cuba. Over 1.1 million square miles of the Gulf's watershed are in the Mississippi River drainage system, making the Mississippi the single largest freshwater riverine influence on the Gulf.

The Gulf of Mexico is enormously productive and diverse. Covering 600,000 square miles, the Gulf provides habitat for a majority

VOL 12

5741

R0039049

of U.S. migratory waterfowl. Its commercial fisheries produced 1.7 billion pounds of fish, oysters, shrimp, and crabs in 1993, and almost 90% of U.S. offshore oil and gas comes from Gulf waters. Seven of our Nation's busiest ports border its shores, and many nations of the world fish its waters. As a recreational resource, the Gulf and adjacent estuaries provide a playground for sport fishing, diving, water skiing, sailing, swimming, sunbathing, beachcombing, or just plain relaxing.

However, the health and vitality of the Gulf have been declining in recent years, caused in part by increasing populations along its coast and upstream tributaries in the watershed and the growing demand upon its resources and in part by the accumulation of years of careless depletion, abuse, and neglect of its environment. These problems in the Gulf have reduced its ability to regenerate naturally. The result has been alarming damage and destruction of the Gulf's ecosystem and habitats, particularly wetlands and seagrasses. An estimated 50 square miles of Gulf wetlands were lost each year between the mid-1950s and the 1970s. These losses stem from: marine debris, toxic substances and pesticides, coastal and shoreline erosion, nutrient enrichment, alterations in freshwater inflow, nonpoint source runoff, and contaminants from inefficient or nonexistent septic systems. The effects are seen in decreasing populations of waterfowl and marine wildlife, increasing degradation and loss of wetlands and other habitat, and growing threats to human health from environmental pollution.

In response to signs of serious long-term environmental damage throughout the Gulf's coastal and marine ecosystem, the Gulf of Mexico Program (GMP) was established in August 1988 with EPA as the lead Federal agency. The Program Office is located at Stennis Space Center in Mississippi. Its main purpose is to develop and help implement a strategy to protect, restore, and maintain the health and productivity of the Gulf. The GMP is a grass roots program that serves as a catalyst to promote sharing of information, pooling of resources, and coordination of efforts to restore and reclaim wetlands and wildlife habitat, clean up existing pollution, and prevent future contamination and destruction of Gulf resources.

Because of the immense geographical expanse of the Gulf, as well as the numerous, and diverse nature of, environmental threats to it, no one agency has the expertise and authority needed to deal effectively with the vast array of problems that threaten the Gulf. In response to this, the GMP office at Stennis Space Center has evolved into a multiagency organization with staff from the Natural Resources Conservation Service, National Oceanic and Atmospheric Administration/National Marine Fisheries Service, Fish and Wildlife Service, Food and Drug Administration, National Aeronautics and Space Administration, Mississippi Cooperative Extension Service, and Mississippi Soil and Water Conservation Districts. This multi-agency staff assists in directing the organizational and operational strategy of the program on a day-to-day basis to more effectively deal with Gulf issues. In

COMMERCIAL FISHERIES on the Gulf of Mexico produced 1.7 billion pounds of fish and seafood in 1993.

VOL 12

The goals of the Gulf of Mexico Program are to

- *Protect, restore, and enhance the coastal and marine waters of the Gulf and its natural coastal habitats*
- *Sustain living resources*
- *Protect human health and the food supply*
- *Ensure recreational use of Gulf shores, beaches, and waters in ways consistent with the economic well-being of the region.*

addition, advantages of this staff include a broad-based in-house expertise and a far-reaching networking capability.

The GMP mobilizes Federal, State, and local government; business and industry; academia; and the community at large through programs of public awareness, information dissemination, forum discussions, citizen committees, and technology application. A Policy Review Board and the Management Committee determine the scope and focus of GMP activities. The program also receives input from a Technical Advisory Committee and a Citizen's Advisory Committee. The GMP Office, eight technical issue committees, and the operations and support committees coordinate the collection, integration, and reporting of pertinent data and information.

The issue committees are responsible for documenting environmental problems and management goals, available government and private resources, and potential solutions relating to specific issue areas. The issue committees are composed of individuals from Federal, State, and local agencies and from industry, science, education, business, citizen groups, and private organizations. These committees cover a broad range of issues, including habitat degradation, public health, freshwater inflow, marine debris, coastal and shoreline erosion, nutrient enrichment, toxics and pesticides, and living aquatic resources. They develop and present their findings in GMP documents called Action Agendas, which describe strategies to build upon programs already under way and to develop new cooperative mechanisms with other public and private organizations. The Action Agendas also provide strategies to monitor and assess the effectiveness of ongoing efforts and to communicate information to individuals and agencies that can best use it. Two additional committees provide operational support for public education and outreach and data and information transfer activities for the entire GMP.

Partnership for Action

On December 10, 1992, EPA; the Governors of Alabama, Florida, Louisiana, Mississippi, and Texas; the Chair of the Citizens Advisory Committee; and representatives of 10 other Federal agencies signed a Gulf of Mexico Program Partnership for Action agreement for protecting, restoring, and enhancing the Gulf of Mexico and adjacent lands. The partnership document includes vision and goal statements and nine 5-year challenges for the GMP. The goals established for the Gulf of Mexico Program are to protect, restore, and enhance the coastal and marine waters of the Gulf of Mexico and its natural coastal habitats, to sustain living resources, to protect human health and the food supply, and to ensure the recreational use of Gulf shores, beaches, and waters in ways consistent with the economic well-being of the region.

The 10 environmental challenges commit the signatory agencies to pledge their efforts, over the next 5 years, to obtain the knowledge and resources to

5743

- Significantly reduce the rate of loss of coastal wetlands
- Achieve an increase in Gulf Coast seagrass beds
- Enhance the sustainability of Gulf commercial and recreational fisheries
- Protect human health and the food supply by reducing inputs of nutrients, toxic substances, and pathogens to the Gulf
- Increase Gulf shellfish beds available for safe harvesting by 10%
- Ensure that all Gulf beaches are safe for swimming and recreational uses
- Reduce by at least 10% the amount of trash on beaches
- Improve and expand coastal habitats that support migratory birds, fish, and other living resources
- Expand public education/outreach tailored for each Gulf Coast county or parish
- Reduce critical coastal and shoreline erosion.

The GMP structure has been streamlined to better meet the needs of the new 5-year environmental challenges. In addition, EPA has restructured its management scheme for the GMP to increase Regional involvement in the program as it moves to implement environmental protection and restoration activities.

The Gulf waters are impacted not only by the United States, but by Mexico and, to a lesser extent, by islands in the Caribbean Sea. The GMP has expanded its activities to provide support to this international community. By promoting Special Area Designation under MARPOL Annex V, the Program has advanced the emplacement of regulations to reduce the discharge of ship-generated waste in the Gulf and Caribbean; the discharge of any plastics is prohibited under Annex V. Additional assistance to Caribbean countries is provided through participation in the United Nations Environmental Programme via their Caribbean Environment Program (CEPPOL) and the Intergovernmental Oceanographic Commission, which focus on addressing land-based sources of pollution for the Caribbean.

The GMP is also advancing technology transfer with Mexico. The Program of Ecology, Fisheries and Oceanography of the Gulf of Mexico (EPOMEX) participates in the GMP's Living Aquatic Resources committee and in other Program activities. EPOMEX is an agency that coordinates the scientific research of institutions of higher education in the areas of the coastal zone and its biological resources and the conservation of the marine environment, coupling science with resource managers and policy makers in the Gulf of Mexico.

Take-Action Projects

During 1992, the GMP launched important environmental projects in each of the five Gulf States to demonstrate that GMP strategies and methods could achieve positive results quickly. Called "Take-Action Projects," they primarily address habitat protection and restoration and public health. They are designed for Gulf-wide application to help restore the environment.

VOL 12

5744

Water Quality

In Louisiana, Florida, and Alabama, several Take-Action Projects deal with pollution and contaminants from inadequate treatment of human waste—a main cause of damage to Gulf coastal ecosystems and a major concern to public health officials and to the tourism and seafood industries.

- An innovative wastewater treatment system is being monitored in a pilot project near the Port Fourchon/Bay Marchand area of Lafourche Parish, Louisiana. The upwelling injection system filters human wastewater through a sand/soil bed to remove fecal coliforms and enteric viruses—the primary pollutants and contaminants in human waste. The system uses inexpensive, easy to install equipment that has potential use throughout the Gulf's system of rivers and bayous. Monitoring and mathematical modeling will be used to evaluate the improvement of environmental conditions in nearby oyster beds.

- A Take-Action Project is under way in Florida's Suwannee Sound and Appalachicola National Estuarine Research Reserve to upgrade existing septic systems that pollute coastal waters. Contamination from fecal coliforms has required suspension of oyster harvesting and threatened to close beaches. Health officials are monitoring improvements to oyster habitat and recreational uses of coastal waters.

- The use of peat moss as a medium for filtration and biological treatment of household wastewater is being demonstrated in Weeks Bay, Alabama. Use of this raw material and renewable resource as a sewage treatment medium is intended to reduce fecal coliforms in nearby oyster-producing waters.

Pollution Prevention

The State of Mississippi has developed a common sense publication entitled *The Gulf of Mexico Citizens Pollution Prevention Handbook*. Written in nontechnical language, the handbook describes the Gulf of Mexico and explains why it is a valuable resource to our Nation's economy and quality of life. This take-action guide provides a detailed listing of contacts for more information, and it explains specific ways that everyone in the Gulf region can be actively involved in restoring and preserving the environmental quality of the Gulf.

Habitat Protection

Based on a Texas program called Coastal Preserves, a GMP Take-Action Project called Gulf Ecological Management Sites (GEMS), seeks innovative approaches to protect coastal tracts that have been identified as important to the Gulf ecosystem. In some cases, areas may be preserved as wilderness. In others, they would be conserved—that is, carefully monitored and managed to maintain their vitality as wildlife and marine life habitat while being used for hunting, fishing, resource extraction, recreation, or other development. Ideally, these tracts would be under the management and protection of a government agency or established environmental organization.

To promote the concept Gulf-wide, the GMP sponsored a GEMS Workshop in New Orleans to share

VOL 12

5745

information about the need to protect such areas; to discuss the resources available to help manage, preserve, or conserve them; and to develop a strategy for generating Gulf-wide support and funding for protecting the most valuable of these tracts.

■ Adopting this concept, Mississippi established a Coastal Preserves Program and set aside a donated portion of the Graveline Bayou Estuary. This area has been placed under the protection and management of the State's Department of Marine Resources.

■ Protection of oyster habitat is the goal of a Take-Action Project in Alabama. Oyster beds and reef systems in the shallow waters of Mobile Bay, often harmed unintentionally by boaters and fishermen, have been marked with buoys and signs to help boaters and fishermen avoid damaging them in the future.

Habitat Restoration

The degradation (and in many cases, complete disappearance) of wildlife and marine life habitats is one of the most serious environmental problems of the Gulf ecosystem. Restoration of these habitats is the focus of numerous GMP Take-Action Projects throughout the Gulf Region. Wetlands, reefs, seagrasses, and the quality of the water in these habitats are among the most significant concerns receiving immediate attention.

Seagrass Beds

One of several Take-Action Projects in Alabama's Mobile Bay is an innovative program to restore damaged or destroyed seagrass beds—a major habitat for fish, shrimp, and crabs. A new approach being developed is less costly and labor intensive than current methods of transplanting from existing seagrass beds. Seagrasses are germinated from the seeds of wild plants, grown in the natural environment within protected mesh-covered trays, then planted in designated areas where seagrass beds are in decline or are known to have once existed. Low in cost and requiring very little equipment or technical knowledge, this program lends itself extremely well to hands-on participation by concerned citizens and can be easily implemented Gulf-wide.

Salt Marsh Wetlands

Another Take-Action Project in Alabama's Mobile Bay is the restoration of a salt marsh wetland on an abandoned site near the Dauphin Island Sea Lab. A wildlife habitat before the Civil War, this marsh wetland was filled in and used for a number of land uses including grave sites and large septic tank reservoirs. The objective of this project is to accelerate the natural reclamation process of tidal action and provide a model for future manmade marsh and wetlands areas. A team of scientists is carefully monitoring the marsh reconstruction (from initial sloping of the land and planting of marsh and wetlands flora, to rebuilding of the adjacent dune system) and will conduct a long-term evaluation of the habitat's health and development. This "living marsh" will also serve as an outdoor exhibit for the nearby *Estuarium*—a marine sciences museum intended to educate the

Great Lakes Shoreline Miles Surveyed by States and Tribes

1994 ■ 5,224 miles = 94% surveyed

public about the marine flora and fauna found in the surrounding area.

Oyster Beds

In Louisiana, Florida, and Alabama, the number of oyster reefs that have been closed to harvesting operations has steadily increased in recent years due to bacterial contamination from inadequately treated human waste. The solution is a series of Take-Action Projects to install upgraded septic systems or innovative sewage treatment systems in areas affecting the oyster beds. In a few short years, these low-cost, easy-to-install systems are expected to revitalize oyster habitats and help rebuild associated commercial operations.

■ In Louisiana, the Nation's number one producer of oysters, a take-action project in cooperation with the National Estuary Program targets 240,000 acres of the Barataria-Terrebonne Estuary that contain 68% of the State's private oyster leases—an area increasingly closed to harvesting. Likewise, the oyster-producing areas near Suwannee Sound and Appalachicola Bay (Florida) and Weeks Bay (Alabama) will benefit from similar projects to improve sewage treatment systems.

■ Another Take-Action Project in Alabama's Mobile Bay aims to restore and create oyster habitat with a certain type of Mexican coral taken from dead reef deposits found inland and used to form new living reefs for young oysters to grow on. This first-of-its-kind application of such coral will shorten the time it takes for oyster reefs to form. If successful, it could have far-reaching impacts in reef restoration Gulf-wide.

The Great Lakes Basin

Background: Water Quality in the Great Lakes

Great Lakes water quality is classically divided into two issues: nutrients and toxicants. Together with the Great Lakes States and the Province of Ontario, the United States and Canada have worked to implement a broad strategy to reduce loadings in both categories. In addition, the two countries have acted in acknowledgment of the interrelationship among water quality and many other elements of the ecosystem, including habitat and community structure, and the dynamics of exchange with the atmosphere and sediments.

During the past two decades, the United States and Canada have corrected many of the nutrient enrichment problems in the Great Lakes region that attracted national attention in the 1960s. Since 1970, phosphorus detergent restrictions, municipal sewage treatment plant construction and upgrades, and agricultural practices that reduce runoff have cut the annual phosphorus load into the Great Lakes in half.

The decline in phosphorus loadings is most evident in Lake Erie, which receives more effluent from sewage treatment plants and sediment from agricultural lands than the other Great Lakes. Lake Erie also experienced a concurrent decline in phytoplankton biomass, an indicator of trophic condition and nutrient enrichment. This decline in phytoplankton biomass, accompanied by dramatic improvements in water clarity and greatly reduced occurrences of anoxia in the Lake's eastern basin, provides evidence that the phosphorus controls implemented in the 1970s and 1980s have reversed Lake Erie's severe nutrient enrichment problems of the 1960s.

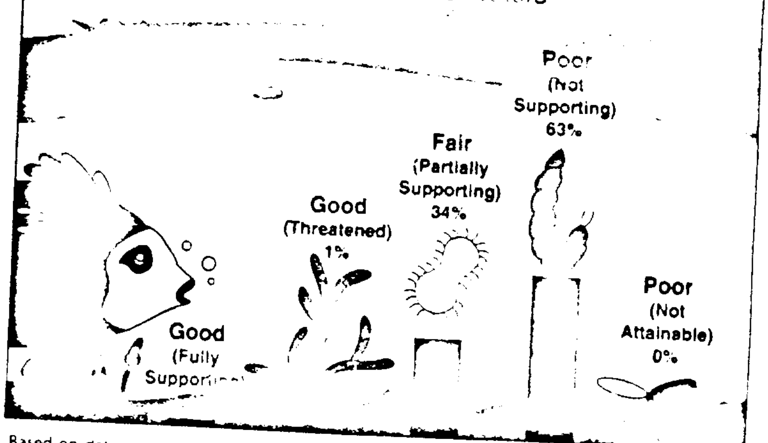
This picture is complicated by the recent invasion by, and profusion of, the zebra mussel, an exotic, or nonnative, species. Its impact is not yet well quantified but is believed to be substantial. The zebra mussel is a very effective filter feeder and is generally thought to have had a profound effect on plankton community structures in Lake Erie and elsewhere in the Great Lakes with concomitant changes in the food chain as energy is rerouted into the benthic (or bottom-dweller) community. Recent invasions of other exotic species, such as the spring water flea (*bythotrephes*) and two species of gobey, combined with introductions of Pacific salmon and the rusty crayfish, have dramatically altered the structure of the Great Lakes' communities.

Despite dramatic declines in the occurrence of algal blooms, fish kills, and localized "dead" zones depleted of oxygen, less visible problems continue to degrade water quality in the Great Lakes. The States report that toxic contamination is the most prevalent and persistent water pollution problem in the Great Lakes. The eight States bordering the Lakes have issued advisories to restrict consumption of fish caught along their entire shorelines. Depending upon location, mercury, PCBs, pesticides, or dioxins are variously found in fish tissues at levels that exceed standards set to protect human health. As a result, virtually all of the waters along the Great Lakes shoreline fail to fully support fish consumption and therefore fail to fully support overall designated uses (Figure 12-2). The levels of most organochlorine contaminants have declined dramatically since control measures began in the mid-1970s. As a result, although the trend seems to be leveling off, concentrations of these contaminants in fish tissue have declined. Toxaphene (or toxaphene-like compounds), however, appears to be running counter to this trend in Lakes Superior and Michigan, where fewer declines and even some increases have appeared. It is not clear, however, whether or not this increase can be attributed to historical use of the pesticide, toxaphene, or if the increase is due to the introduction of a similar compound from an unidentified source.

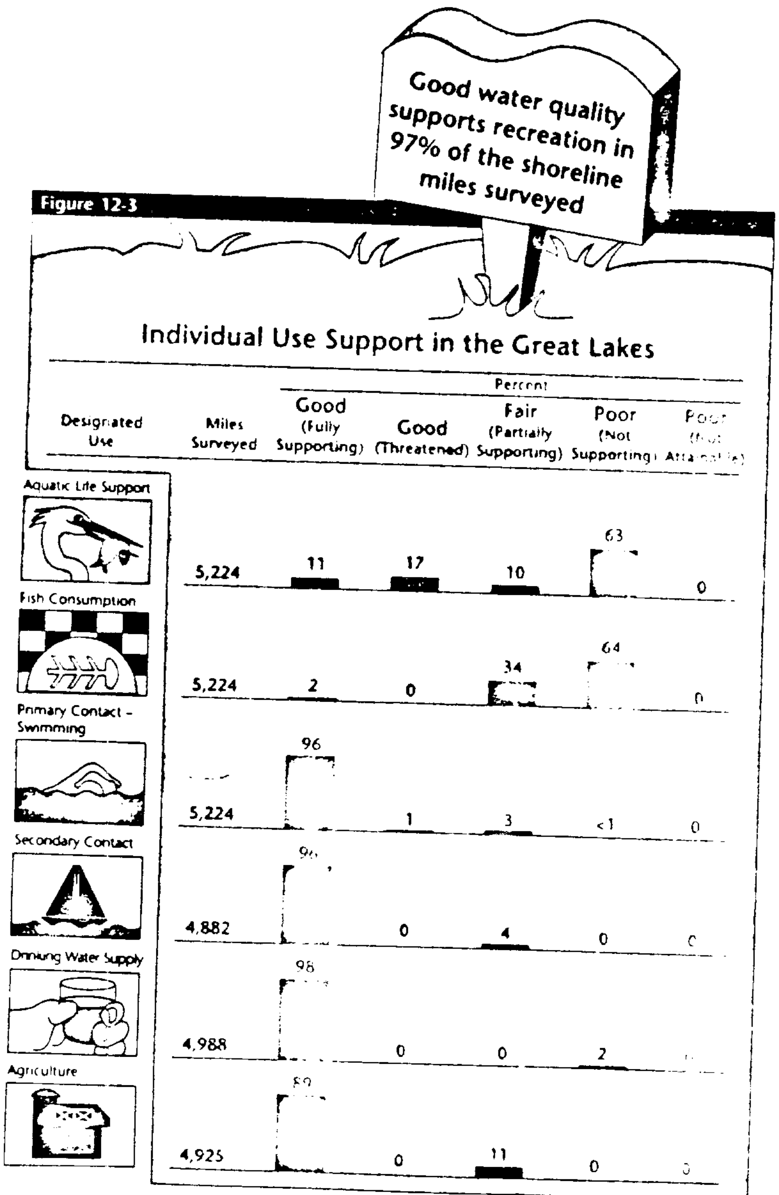
CONSIDERABLE SUCCESS has been had in controlling conventional pollutants and some toxic pollutants, but the Great Lakes are still subject to the effects of other toxic pollutants.

Figure 12-2

Overall Use Support
in Surveyed Great Lakes Shoreline Waters



Based on data contained in Appendix F, Table F-2.



Based on data contained in Appendix F, Table F-3

Efforts are under way by the U.S. EPA and Canada to determine the source of the toxaphene and toxaphene-like compounds. Fish consumption advisories have been issued for the Great Lakes due to apparent "toxaphene."

Although fish consumption use is impaired throughout the Lakes, more than 96% of the Great Lakes shoreline fully supports recreational uses and drinking water supply use (Figure 12-3). However, in the well-publicized outbreak of Cryptosporidiosis in 1993, storm flows carried pathogens from the Milwaukee River uplands well into Lake Michigan, where the pathogens entered the Milwaukee municipal drinking water intake, resulting in over 100 deaths and thousands of illnesses.

The individual use support data submitted by the States indicate that the remaining problems on the Lakes have the greatest impact on fishing activities and aquatic life. Aquatic life impacts include depleted fish populations and reproduction problems in pisciverous (fish-eating) birds (Table 12-1 and box). Aquatic life impacts result from persistent toxic pollutant burdens in birds, habitat degradation and destruction, and competition and predation by nonnative species, such as the zebra mussel and the sea lamprey.

The States reported that priority organic chemicals (primarily PCBs) are the most prevalent cause of impairment in their Great Lakes waters (Figure 12-4). These toxic chemicals persist in fish tissues, wildlife tissues, and sediment. The States reported much lower incidences of metal contamination, depressed

Trends in PCB Contamination in the Great Lakes

Research conducted by the United States and Canada in the Great Lakes indicates that PCB concentrations in wildlife have declined dramatically since the EPA banned most uses of PCBs in 1976. However, the PCB concentrations in fish persist well above concentrations set to protect public health, and the persistent PCB burdens in some fish, mammals, and birds still may impair reproductive success. For example, concentrations of PCBs in Lake Michigan lake trout declined by about 90% since 1970, but remain at about 180 times the target goal of 0.014 parts per million. Similarly, body burdens of PCBs in a colony of Forster's terns near Green Bay, Wisconsin, declined by 66% while hatching success tripled between 1983 and 1988. However, the terns' offspring continued to suffer "wasting" and other fatal health problems, which may have resulted from the contaminant burdens in the adult birds. For additional information, see D. De Vault, D.M. Whittle, and S. Rang, *Toxic Contaminants in the Great Lakes*, SOLEC Working Paper presented at State of the Lakes Ecosystem Conference, Chicago, IL (EPA 905-D-94-001a, October 1994).

Table 12. Effects of Toxic Contamination on Fish and Wildlife in the Great Lakes

Species	Population Decrease	Effects on Reproduction	Eggshell Thinning	Birth Defects	Behavioral Changes	Biochemical Changes	Mortality
Mink	X	X	NA	NE	NE	NE	X
Otter	X		NA	NE	NE	NE	?
Double-crested Cormorant	X	X	X	X		X	?
Black-crowned Night Heron	X	X	X	X		X	?
Bald Eagle	X	X	X	NE		NE	NE
Herring Gull		X	X	X	X	X	X
Ring-billed Gull				X		NE	X

oxygen conditions, and nutrient pollution.

Only four of the eight Great Lakes States measured the size of their Great Lakes shoreline polluted by specific sources. These States have jurisdiction over one-third of the Great Lakes shoreline, so their findings do not necessarily reflect conditions throughout the Great Lakes Basin (Figure 12-5).

- Wisconsin identified air pollution and discontinued discharges as sources of pollutants contaminating all 1,017 of their surveyed shoreline miles. Wisconsin also identified smaller areas impacted by contaminated sediments, nonpoint sources, industrial and municipal discharges, agriculture, urban runoff and storm sewers, combined sewer overflows, and land disposal of waste.

- Indiana attributed all of the pollution along its entire 43-mile shoreline to air pollution, agriculture, and industrial and municipal discharges.

- Ohio reported that nonpoint sources pollute 86 miles of its 236 miles of shoreline, in-place contaminants impact 33 miles, and land disposal of waste impacts 24 miles of shoreline.

- New York identified many sources of pollutants in their Great Lakes waters, but the State attributes the most miles of degradation to contaminated sediments (439 miles) and land disposal of waste (374 miles).

Building Institutional Frameworks for the Great Lakes

Rehabilitating the Great Lakes requires cooperation from numerous organizations because pollutants originate in both Canada and the United States as well as other countries, and pollutants enter the Lakes via multiple media (i.e., air, ground water, and surface water). The International Joint Commission (IJC), established by the 1909 Boundary Waters Treaty, lays the foundation of the institutional framework for managing the Great Lakes. Under the auspices of that Treaty, the United States and Canada signed the Great Lakes Water Quality Agreement in 1978 (see further discussion on page 322). Representatives from the Governments of the United States and Canada, the Province of Ontario, and the eight States bordering the Lakes sit on the IJC's Water Quality Board.

The IJC Water Quality Board makes recommendations to the United States and Canada regarding actions needed to maintain the integrity of the Great Lakes ecosystem. It provides various platforms for addressing Great Lakes issues. The Board also monitors and reports upon the progress of the two nations in meeting their commitments under the Agreement and evaluates and comments upon their environmental policies and actions.

The EPA Great Lakes National Program Office (GLNPO) coordinates activities within the United States at all government levels, working with nongovernment organizations to protect and restore the Lakes. One vehicle for this coordination is the *Joint Federal/State*

5-Year Strategy (1992-97) for Protecting the Great Lakes. GLNPO provides additional leadership through its annual *Great Lakes Program Priorities and Funding Guidance.* It also serves as a liaison and provides information to the Canadian members of the IJC and the Canadian counterparts to the EPA. GLNPO is responsible for direct negotiations and cooperation with Canadian Federal agencies through the Binational Executive Committee.

The Great Lakes States and the Federal agencies work together to provide a broad range of routine monitoring of the Lakes and their basin. The States and U.S. Geological Survey perform most tributary monitoring, and State agencies and the U.S. Fish and Wildlife Service, together with the National Biological Service, collect tributary and open Lakes fish for contaminant monitoring. GLNPO conducts essentially all the United States' open Lakes water quality and sediment monitoring and carries out contaminant analyses on fish sampled by other agencies. It also carries out, and is the primary funding source for, major special studies, such as those for mass balance of Lake Michigan and Green Bay.

The Great Lakes governors have worked together on a number of common issues over the years. For example, the Great Lakes Protection Fund was formed by the Great Lakes Governors in 1989. The mission of the Fund is to identify, demonstrate, and promote regional action to enhance the health of the Great Lakes ecosystem. It is the Nation's first multistate environmental endowment. The Great Lakes States have pledged $100 million to its permanent endowment.

Public-private partnerships support the institutional framework for managing the Great Lakes water quality. Special boards, commissions, and committees composed of representatives from universities, environmental organizations, agricultural interests, industry, shipping interests, and government play vital roles in coordinating policy and management decisions. Some of these groups focus on local areas and issues, while others represent national organizations. To better coordinate their activities on the Great Lakes Basin, groups have begun to support umbrella organizations, such as Great Lakes United. Great Lakes United, started in 1982, represents more than 180 affiliated groups in the United States and Canada. One of its goals is to facilitate citizen involvement in decision making processes. Other Great Lakes environmental organizations have a specific geographic focus, such as the Lake Michigan Federation, or concentrate on a narrower topical area, such as the Tip of the Mitt Watershed Council, which primarily addresses land use issues (especially wetlands issues).

The Great Lakes Commission is a binationally chartered independent organization that integrates environmental concerns with economic development concerns. The Commission's members are appointed by the States, Canadian Provinces, and both Federal governments. The members issue reports on subjects such as the environmental impacts of transportation options in the Great Lakes Region. The reports provide data for decision-making by the government bodies with authority to manage the Lakes. The Commission is working under a

The 1978 Great Lakes Water Quality Agreement (GLWQA), as amended in 1987, established a commitment by the United States and Canada to restore and protect the Great Lakes.

cooperative agreement with GLNPO to operate the Great Lakes Information Network (GLIN), an Internet Server. The GLIN provides a major outlet and source for Great Lakes environmental information.

Private conservation groups are also working with government agencies to protect natural areas in the Great Lakes Basin. GLNPO is funding 69 restoration and protection projects based, in part, on findings of the Great Legacy Project. The Great Legacy Project, sponsored to a considerable extent by GLNPO, includes efforts by the Nature Conservancy of Canada and the United States and other conservation groups to pool natural heritage data from several public agencies and land trusts and to apply geographic targeting approaches to identify particularly high-quality resource areas. Since 1992, GLNPO has instituted and formalized a competitive process to select high-priority on-the-ground habitat protection, restoration, and remediation projects.

In 1994, GLNPO completed a statutory 6-year mandate, the Assessment and Remediation of Contaminated Sediments (ARCS) Program, working with academic, commercial, State, and local experts to develop and test new sediment remediation technologies. In both the habitat and sediment remediation arenas, it has organized significant training events and conferences to benefit both the public and private sectors.

In the fall of 1994, GLNPO and its Canadian counterpart in Environment Canada, together with the eight Great Lakes States, the Council of Great Lakes Industries, environmental groups, and the Province of Ontario, convened a partnered endeavor to provide all sectors of the Great Lakes community with a synopsis of the state of knowledge on the Great Lakes ecosystem. This effort took two forms: the State of the Lakes Ecosystem Conference, a major conference for senior environmental managers, and a set of six peer-reviewed draft topical papers and an integration paper. The papers were presented at the conference and designed to provide a comprehensive snapshot of the condition of the Lakes' ecosystems.

They provided a starting point for a series of topical and Lake-by-Lake discussions that became a framework for interaction and communication among disparate and sometimes traditionally opposed sectors.

The draft papers are posted on the Internet GLIN server for public access and comment. Comments from attendees and the Great Lakes community provided a final level of review prior to publication in mid-1995. The conveners of the State of the Lakes Ecosystem Conference worked with the authors to incorporate discussion and commentary into the final papers.

The Great Lakes Water Quality Agreement

The 1978 Great Lakes Water Quality Agreement (GLWQA), as amended in 1987, established a commitment by the United States and Canada to restore and protect the Great Lakes. The Amendments to the Agreement stress two central concepts: (1) the ecosystem approach, and (2) the virtual elimination of persistent toxic substances. The Agreement set a limited number of ecosystem-based objectives for water quality, biota, habitat, and beneficial uses of the Lakes. The Agreement also institutionalized the Areas of Concern concept as well as commitments to develop Remedial Action Plans and Lakewide Management Plans to address Great Lakes problems.

Although there has been considerable progress in addressing impacts from point and nonpoint loadings of conventional pollutants under the GLWQA, the Great Lakes are still highly vulnerable to toxic pollutants. The IJC released a set of recommendations identifying 11 "critical pollutants" for which management scrutiny is warranted throughout the Basin. These chemicals and possible sources are presented in Table 12-2.

The Great Lakes Water Quality Initiative

The Great Lakes Water Quality Initiative (GLWQI) is a key element of the environmental protection efforts undertaken by the United States in the Great Lakes Basin. The purpose of the Initiative is to provide a consistent level of protection in the Basin from the effects of toxic pollutants. This will further the national goal to restore, maintain, and protect the waters of this particularly valuable and sensitive ecosystem.

On March 23, 1995, EPA published *Water Quality Guidance for the Great Lakes System* in the *Federal Register* (60 CFR 15366). EPA issued the Guidance under the terms of the Great Lakes Critical Programs Act of 1990. Now that the Guidance is available, the next step is for the States and Tribes to incorporate provisions consistent with the Guidance into their laws and regulations within 2 years.

Foundations

The GLWQI was organized by EPA at the request of the Great Lakes States in 1989. State governors had signed an agreement in 1986 to promote consistency in their environmental programs for the Great Lakes Basin. At the same time, the governors had requested that EPA facilitate these efforts to promote consistency, and, in 1989, the Council of Great Lakes Governors unanimously reaffirmed their participation in the GLWQI, with U.S. EPA Region 5 (Chicago, IL) taking the lead role.

The Initiative provided a forum for a regional dialogue to establish minimum requirements that would reduce disparities between State water quality controls in the Great Lakes Basin. The scope of the Initiative included development of proposed Great Lakes water quality guidance for Great Lakes-specific water quality criteria and methodologies to protect aquatic life, wildlife, and human health; procedures to implement water quality criteria; and an antidegradation policy.

Organization and Process

The open dialogue used in the Initiative was exemplary and is a model for the future. Three committees were formed to carry out the Initiative:

- A Steering Committee (composed of directors of water programs in the Great Lakes States' environmental agencies and EPA's National and Regional Offices)

VOL 12

5756

Chemical	Production and Release	Source
2,3,7,8-TCDD (dioxin) and 2,3,7,8-TCDF (furan)	Unintentional	Contaminant in herbicides used in agriculture, range, and forest management. Also produced as a byproduct of combustion of fossil fuels and waste incineration and through production of pentachlorophenol (PCP) and pulp and paper production processes. 2,3,7,8-TCDD is the most toxic of 75 congeners (forms) of dioxin, and 2,3,7,8-TCDF is the most toxic of 135 congeners of furan.
Benzo[*a*]pyrene (b[*a*]p)	Unintentional	Product of incomplete combustion of fossil fuels and wood, including forest fires, grills (charcoal broiling), auto exhaust, and waste incineration. One of a large family of polynuclear aromatic hydrocarbons (PAHs).
DDT[a] and its breakdown products (including DDE)	Intentional[d]	Insecticide; used heavily for mosquito control in tropical areas. Banned for use in the U.S. and Canada with some exceptions for gypsy moth control. Once used extensively in North America and worldwide.
Dieldrin[a]	Intentional[d]	Insecticide used extensively at one time, especially on fruit.
Hexachlorobenzene (HCB)	Unintentional	Byproduct of combustion of fuels and waste incineration and of manufacturing processes using chlorine. Found as a contaminant in chlorinated pesticides.
Alkylated lead	Intentional	Used as a fuel additive and in solder, pipes, and paint.
	Unintentional	Released through combustion of fuel, waste, and cigarettes, and from pipes, cans, and paint chips.
Mirex[b]	Intentional[d]	Fire retardant; pesticide used to control fire ants. Breaks down to more toxic form, photomirex, in presence of sunlight.
	Unintentional	Present sources are residuals from manufacturing sites, spills, and land disposal.
Mercury	Intentional	Used in metallurgy, batteries, thermometers, electrical switches, and disinfectants.
	Unintentional	Byproduct of chlor-alkali, gold mining, paint, and electrical equipment manufacturing processes. Also occurs naturally in soils and sediments. Releases into the aquatic environment may be accelerated by sulfate deposition (i.e., acid rain) and leaching from landfills.
Polychlorinated biphenyls (PCB)[c]	Intentional[d]	Insulating fluids used in electrical capacitors and transformers and in the production of hydraulic fluids, lubricants, and inks. Was previously used as a vehicle for pesticide dispersal. PCBs comprise a family of 209 congeners of varying toxicity.
	Unintentional	Primarily released to the environment through leakage, spills, and waste storage and disposal. Leaches from soil and sediment deposits.
Toxaphene[a]	Intentional[d]	Insecticide used on cotton. Substitute for DDT. Use in Great Lakes Basin not documented, but the presence of toxaphene in the Great Lakes raised the issue of long-range transport, or atmospheric deposition. Efforts are under way by EPA and Canada to identify the sources of the increased levels of toxaphene and toxaphene-like compounds.

[a] Use restricted in the United States and Canada.

[b] Banned for use in the United States and Canada.

[c] Manufacture and new uses prohibited in the United States and Canada.

[d] The intentional production and release of the chemical occurred, for the most part, prior to the issuance of bans and restrictions that currently limit the use of the chemical in the United States and Canada.

discussed policy and scientific and technical issues, directed the work of the Technical Work Group, and ratified final proposals.

- The Technical Work Group (consisting of technical staff from the Great Lakes States' environmental agencies, EPA, the U.S. Fish and Wildlife Service, and the National Park Service) prepared proposals on elements of the Guidance for consideration by the Steering Committee.

- The Public Participation Group (consisting of representatives from environmental groups, municipalities, industry, and academia) observed the deliberations of the other two committees, advised them of the public's concerns, and kept its various constituencies apprised of ongoing activities and issues.

From the start, one of the Committees' goals was to develop the Guidance elements in an open public forum, drawing upon the extensive expertise and interest of individuals and groups within the Great Lakes community.

Great Lakes Critical Programs Act

The Initiative efforts were well under way when Congress enacted the Great Lakes Critical Programs Act of 1990 to amend the Clean Water Act. The general purpose of these amendments was to improve the effectiveness of EPA's existing programs in the Great Lakes. The Act required EPA to publish proposed and final water quality guidance that specifies minimum requirements for waters in the Great Lakes System in three areas: (1) water quality standards (including numerical limits on pollutants in ambient Great Lakes waters to protect human health, aquatic life, and wildlife; (2) antidegradation policies; and (3) implementation procedures.

The Act also requires the Great Lakes States to adopt provisions in their programs that are consistent with the final Guidance within 2 years of EPA's publication. In the absence of such action, EPA is required to promulgate any necessary requirements within that 2-year period. In addition, Indian Tribes authorized to administer an NPDES program or water quality standards program in the Great Lakes Basin will also need to adopt provisions consistent with the final Guidance into their water programs.

To carry out the Act, EPA proposed regulations for implementing the Guidance on April 16, 1993, and invited comment from the public. States and EPA conducted public meetings in all the Great Lakes States during the comment period, including two EPA public meetings. As a result, EPA received over 26,500 pages of comments from over 6,000 commenters. EPA reviewed all of this information in developing the final Guidance that was published in March of 1995.

Conclusion

The final Guidance represents a milestone in efforts by Great Lakes stakeholders to define and apply innovative and comprehensive environmental programs for protecting and restoring the Great Lakes. In particular, the publication of the final Guidance culminates 6 years of intensive cooperative effort that included participation by the eight Great Lakes States, the environmental community, academia, industry, municipalities, and EPA regional and national Offices.

The final Guidance will help establish consistent, enforceable, long-term protection with respect to all types of pollutants, but will place short-term emphasis on the types of long-lasting pollutants that accumulate in the food web and pose a threat to the Great Lakes System. The Initiative Committees devoted considerable effort to identifying such chemicals—persistent bioaccumulative pollutants termed "bioaccumulative chemicals of concern" (BCCs)—and developing the most appropriate criteria, methodologies, policies, and procedures to address them. The special provisions for BCCs, initially developed by the Initiative Committees and incorporated into the final Guidance, include antidegradation procedures to minimize future problems; general phaseout and elimination of mixing zones for BCCs (except in limited circumstances) to reduce their overall loadings to the Lakes; more extensive data generation requirements to ensure that BCCs are not underregulated for lack of data; and development of water quality criteria that will protect wildlife that feed on aquatic prey.

The GLWQI also supports more comprehensive management plans for the Great Lakes envisaged by the Great Lakes Water Quality Agreement of 1987 between the United States and Canada. Lakewide Management Plans (LaMPs) for each Great Lake and Remedial Action Plans (RAPs) for each of 42 Great Lakes "Areas of Concern" are under development by EPA, the States, local governments, and Canada. The GLWQI contributes to the implementation of all of these efforts because it defines levels of protection needed for any pollutant that might threaten the Great Lakes.

The GLWQI represents a partnership between the States and Federal government to protect this unique national resource. EPA is currently providing technical assistance to the States. Over the past 20 years great progress has been made to improve the quality of water in the Great Lakes, and the GLWQI represents a further step in ensuring the health and quality of the Great Lakes in the future.

Remedial Action Plans for Areas of Concern

Implementing control measures for pollutants usually begins in smaller drainages and waterbodies. At the smallest geographic scale, the IJC initially identified 42 Areas of Concern (AOCs) located primarily along river mouths or harbors where beneficial uses were impaired. Altogether, the IJC identified 14 types of use impairment ranging from limitations on use of water for commerce to fish consumption restrictions, reproductive problems among wildlife, and restrictions on disposal of dredged sediments.

The United States later designated Presque Isle Bay (in Pennsylvania) as the 43rd AOC, but Canada delisted Collingwood Harbor (in Ontario), returning the total number of AOCs to 42. The United States and Canada designated all 42 as AOCs, all of which face major toxics concerns. Thirty-five of the 42 AOCs report toxics concerns in ambient water, 41 of 42 report toxics in sediments, and 38 of 42 AOCs restrict consumption of fish harvested from local waters because of elevated toxic concentrations in fish tissues.

In 1985, the Great Lakes States and the Canadian Provinces agreed to develop and implement a Remedial Action Plan for each AOC. In 1987, the United States and Canadian Federal Governments incorporated the commitment to develop RAPs into the Great Lakes Water Quality Agreement. A complete RAP encompasses the following stages and has a planning document associated with each milestone:

STAGE 1 – Identifies the nature of the problem(s) and summarizes available information.

STAGE 2 – Specifies remedial and regulatory measures needed to restore beneficial uses.

STAGE 3 – Measures and summarizes results as progress is achieved in implementing management plans.

Of the 32 U.S. RAPs, 5 had been completed through Stage 2 and 19 others had been completed or nearly completed through Stage 1 by the end of 1994.

One of the RAPs, Fox River/ Green Bay, faced particular difficulties in identifying the comparative significance of various sources of certain contaminants, especially PCBs. In an unprecedented partnership, GLNPO joined with the Office of Research and Development, several State agencies in Wisconsin and Michigan, other Federal agencies, and several academic institutions, to sponsor the Fox River/ Green Bay Mass Balance Study from 1987 through 1994. This study demonstrated the feasibility of the mass balance approach for identifying the relative contributions to toxicant-induced environmental problems, and it provided the RAP committee and the State of Wisconsin with a unique tool to forecast the effects of proposed environmental management decisions.

Lakewide Management Plans

Lakewide Management Plans are the next level of geographic integration envisioned in the Great Lakes Water Quality Agreement. These plans are whole lake planning efforts. Under the Agreement, LaMPs are to employ an ecosystem approach founded on the same use impairments forming the basis of the RAP process. While focusing primarily on the effects of toxics, the LaMPs will also address habitat and nutrient concerns. Public involvement is a critical element in LaMP development.

The first effort at lakewide management was the Lake Ontario Toxics Management Plan (LOTMP), undertaken via a 1987 Declaration of Intent (known as the "Four-Party Agreement") among the U.S. EPA, Environment Canada, New York State Department of Environmental Conservation, and the Province of Ontario. This Agreement anticipated, in many respects, the LaMP concept expressed in the 1987 revisions to the GLWQA. The LOTMP effort is chaired by EPA Region 2. The Plan first developed a list of critical pollutants for Lake Ontario in

VOL 12

5760

1989. The "Four Parties" agreed at that time to undertake revisions that would permit the LOTMP to become the LaMP for Lake Ontario. Since then, there have been two major revisions of the LOTMP and, in August 1994, GLNPO and Region 2 cooperatively undertook an intensive month-long special study monitoring organic contaminants in the water and sediments of Lake Ontario. Public hearings on the first draft of the Plan as a Stage 1 LaMP are under way.

The United States has prepared the LaMP for the Lake Michigan Basin, which is contained entirely in this country. The effort is headed up by EPA Region 5 and involves all of the Lake Michigan States: Wisconsin, Illinois, Indiana, and Michigan. Although impacts from nutrients and un-ionized ammonia toxicity persist, most of the problems in Lake Michigan stem from toxic contaminants already in the Lake system and ongoing toxic loadings from point and nonpoint sources. Future iterations of the LaMP will address all 14 beneficial use impairments.

Building on work in progress at the various AOCs, the Lake Michigan LaMP will look at the lake ecosystem as a whole and identify a set of critical pollutants. In some cases, this is a subset of the range of pollutants being addressed at smaller geographic units such as the AOCs. In other cases, pollutants that are not of the highest concern in localized areas but are deemed critical to the entire Lake Michigan ecosystem may warrant scrutiny. The LaMP will propose a tiered concept for developing management actions.

Currently, there is a major effort under way on the part of GLNPO with the assistance of the Office of Research and Development Environmental Research Laboratory-Duluth, Region 5, and the Lake Michigan States (Wisconsin, Illinois, Indiana, and Michigan) to carry out a full-scale mass balance study of Lake Michigan. This Study, begun in the spring of 1994, is an effort to provide the LaMP with a more definitive understanding of loadings and fates of four toxic substances (PCB congeners, trans-nonachlor, atrazine, and mercury). It will project the effects of various management scenarios selected by the LaMP Management Committee. The Stage 1 Lake Michigan LaMP first draft was published in January 1992 and revised in September 1993. A final version is anticipated by the end of 1995.

The LaMPs for each Great Lake will also encourage pollution prevention approaches. Lake Superior provides perhaps the best opportunity to implement pollution prevention because it is the least impacted of the Great Lakes. Lake Superior has been spared much of the extreme ecological disruptions associated with industrial and municipal discharges, introduction of exotic species, and overharvesting of the fisheries that have had devastating impacts on the lower Great Lakes, especially Lakes Ontario and Erie.

In the Fall of 1991, the United States, Canada, and the States of Minnesota, Wisconsin, and Michigan and the Province of Ontario formally agreed on a new regional agreement to protect Lake Superior from toxic pollution. The Binational Program seeks to encourage

VOL 12

5761

pollution prevention and expand authorities (where appropriate) to implement a goal of zero pollutant discharge and emission of nine persistent bioaccumulative toxic substances. As a first step, both the U.S. and the Canadian governments will work to freeze loadings of toxic discharges. The United States and Canada issued a draft Stage 1 LaMP for Lake Superior in February 1994 and expect to transmit a Stage 1 version incorporating public comments to the IJC in the near future. A draft Stage 2 LaMP is expected to be made available to the public by the time of the IJC's biennial meeting in September 1995.

The LaMP for Lake Erie is now in the early stages of development with a binational Management Committee and Workgroup in place. The Workgroup, under the direction of the Management Committee, has begun developing ecosystem objectives and assessing the status of beneficial uses for Lake Erie. The Workgroup has also initiated a variety of public involvement activities, including developing a Lake Erie Forum and requesting comments on a concept paper outlining the LaMP framework.

Pollution Prevention Initiatives

The EPA GLNPO is working with EPA Regions 2, 3, and 5, the States, and their Canadian counterparts to promote pollution prevention as the most effective approach to achieve the GLWQA goal of virtually eliminating discharges of persistent toxic substances in the Great Lakes. In 1991, EPA and the States developed the Great Lakes Pollution Prevention Action Plan to highlight how EPA and the States will minimize the use, production, and release of toxic substances at the source. The Action Plan targets persistent bioaccumulative toxic substances for reduction or elimination.

The GLNPO has allocated significant funding and developed a formal process for funding numerous pollution prevention grants throughout the Great Lakes Basin for the past 3 years. The three Great Lakes Regions of EPA are using the pollution prevention approach to prioritize solutions. The Regions view pollution prevention as a voluntary program that falls back on regulation as needed. The 1992 program goal was surpassed by over 100 million pounds in reduced contaminant releases into the environment.

The EPA Regions and Great Lakes States are implementing the National 38/50 Program in the Great Lakes Basin. Under this program, EPA has received voluntary commitments from industry to reduce the emission of 17 priority pollutants by 50% by the end of 1995. This goal is expected to be achieved ahead of schedule. As part of the Binational Program to Protect Lake Superior, EPA and the States are also cooperating with Canada to undertake a virtual elimination initiative for Lake Superior that seeks first to eliminate new contributions of Great Lakes critical pollutants, with special emphasis on mercury. The EPA is also working with utilities located within the Great Lakes Basin to accelerate the phaseout of transformers containing PCBs.

The Chesapeake Bay Program

Background

Now in its twelfth year, the EPA Chesapeake Bay Program is a regional partnership of Federal, State, and local participants that has directed and coordinated Chesapeake Bay restoration since 1983 when the historic Chesapeake Bay Agreement was signed. The partners in this agreement are the State of Maryland, the Commonwealths of Pennsylvania and Virginia, the District of Columbia, the Chesapeake Bay Commission, and the EPA, representing the Federal Government, as well as participating advisory groups.

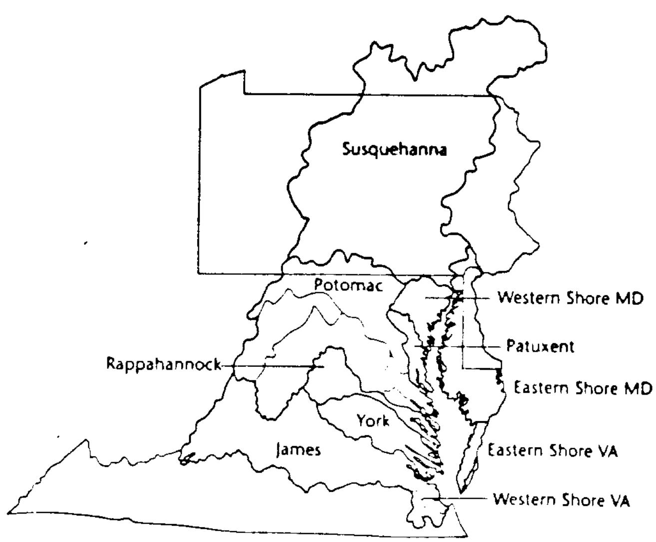
Considered a national and international model for estuarine restoration and protection, the Chesapeake Bay Program is still a "work in progress." Since 1983, milestones in the evolution of the program include the 1987 Chesapeake Bay Agreement, which set a goal of a 40% reduction of nutrients entering the Bay by the year 2000. In the 1992 amendments to the Agreement, the partners reaffirmed the 40% nutrient reduction goal, agreed to cap nutrient loadings beyond the year 2000, and agreed to attack nutrients at their source by applying the 40% goal to the 10 major tributaries of the Bay. The agreements have also stressed management of the Bay as a whole ecosystem, using the restoration of both habitat and living resources as measures of progress.

Federal agencies also play a significant role in the Chesapeake Bay Program. The Federal Government owns 1.6 million acres of land in the Bay watershed. In 1994, officials from 25 Federal agencies and departments signed the Agreement of Federal Agencies on Ecosystem Management in the Chesapeake Bay. This Agreement set out a number of specific goals and commitments for Federal agencies on their lands throughout the watershed, as well as new cooperative efforts by Federal agencies elsewhere.

The Chesapeake Bay is an enormously complex and dynamic system of fishes, waterfowl, and vegetation in an estuary where salt water from the Atlantic Ocean and fresh water from the many tributaries of the Bay come together (Figure 12-6). A host of complicated interactions having physical, chemical,

Figure 12-6

Chesapeake Bay Watershed with Its 10 Subwatersheds



and biological dimensions present formidable challenges to the understanding and management of this great estuary (Figure 12-7).

If we liken the Chesapeake Bay to a patient in the hospital undergoing treatment for a life-threatening illness, we can now report that the patient's vital signs, such as living resources, habitat, and water quality are stabilized and the patient is out of intensive care. Some vital signs, such as striped bass and Bay grasses have improved dramatically, others, such as oysters, are still in danger, with still other vital signs mixed but stable. Nutrient levels continue on their downward slope, with phosphorus reduction outstripping that of nitrogen. Dissolved oxygen remains unchanged but has stopped declining. In the following sections, these findings are examined in more detail.

Figure 12-7

Effects of Pollutants in the Chesapeake Bay

Stresses on the Ecosystem

Land Use

The Chesapeake Bay's watershed, radically changed by European settlement three centuries ago, continues to undergo changes that reflect how we use the land in this 64,000-square-mile expanse. Urban, suburban, and agricultural lands all leach more pollutants into the Bay than do natural forests and wetlands. About 40% of the land is no longer in its natural state and we are losing wetlands at a rate of 8 acres per day.

Data from 1990 show that forest is the dominant land use within the Bay watershed, constituting about 59% of the land, mostly in areas far removed from the Bay's shoreline. Agricultural land, including pasture and cropland, constitutes about 33% of the watershed. Urban and suburban lands are generally close to the Bay and its tidal tributaries and cover about 7% of the watershed. Wetlands, critical habitat environments, represent about 1%. Nutrient and sediment loads from forest land are low compared to urban and agricultural land uses.

Based on projections of a steadily increasing population, the largest change in land use will be from forest and agriculture to urban and suburban. In 1985, about 4.0 million acres of the watershed were urban or suburban. This number is projected to increase to about 5.4 million acres by the year 2000, an increase of 35% over the 1985 acreage. Between 1982 and 1989, 20,000 acres, about 2.5% of wetlands, were lost primarily through filling, draining, or conversion to open water. This represents a loss of about 8 acres per day.

Population

Population growth is the single most important factor underlying the various stresses on the Bay ecosystem. In 1950, the Bay's watershed contained 8.4 million residents. By 1990, this figure had grown to 14.2 million and, by 2020, there will be an estimated 17.4 million people living in the watershed. An expanding population relies on highways and automobiles, increasing both the number of cars on the road and the miles driven. The growing population also requires land for homes, transportation, shops, jobs, and recreation. Forests and other lands of environmental significance are often converted to meet these needs.

An ever-increasing population has resulted in higher wastewater flows to the Chesapeake Bay (Figure 12-8). As a result of improved wastewater treatment and bans on detergents containing phosphorus, point source loads of phosphorus have been reduced by 70% since a peak in the 1970s, despite a 40% increase in total flow. Nitrogen controls, just recently implemented, are already starting to reduce the levels of this pollutant entering the Bay from point sources such as industry and municipal sewage treatment plants.

Along with changes in land use, population growth also results in higher flows from wastewater treatment plants. This wastewater contains the nutrients phosphorus and nitrogen, excessive quantities of which are the primary pollution threats facing Bay waters. The Federal Construction Grants Program provided improved treatment at municipal plants to remove phosphorus, resulting in a sharp decline in phosphorus discharges between 1970 and 1980. These reductions have continued since 1980 with additional treatment plant upgrades and the implementation of phosphorus bans that prohibit the use of this nutrient in household detergents. Overall, phosphorus loads have declined by about 70% since the 1970s. Nitrogen discharges increased steadily between 1950 and 1985. Improved treatment at both industrial and municipal wastewater facilities is responsible for reductions in nitrogen discharges since 1985. Innovative technologies, such as biological nutrient removal (BNR) provide better management of the sewage treatment process, resulting in lower nitrogen and phosphorus levels.

The signatories of the Chesapeake Bay Agreement have committed to develop and implement nutrient reduction strategies—the Tributary Strategies—that will reduce the 1985 combined point and nonpoint source loads by 40% by the year 2000. Great strides have been made in reducing point source phosphorus loads. Continued reductions are needed, especially in nitrogen, however, to offset flow increases in areas of rapid population growth.

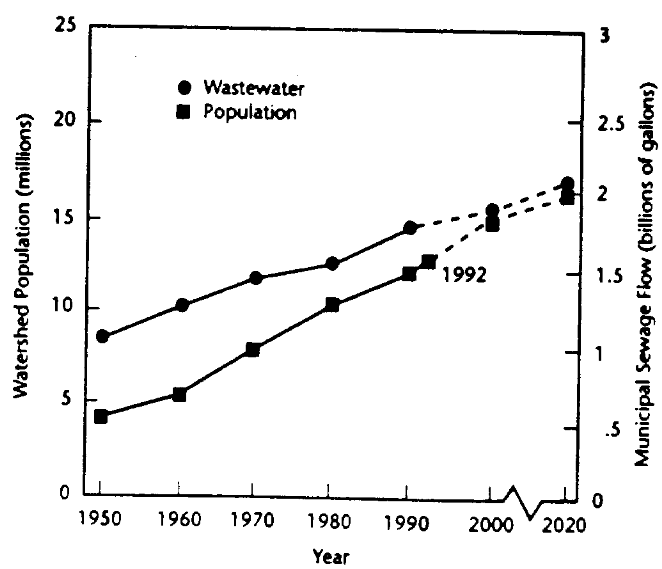
Impacts on the Ecosystem

Rivers – Nutrient and sediment pollution from the Susquehanna and Potomac Rivers, the two largest freshwater tributaries feeding the Bay, show encouraging signs. After many years of increasing nitrogen concentrations, most of the Bay's tributaries are showing a leveling off of this trend and some are actually showing a decline (Figure 12-9). Such results demonstrate that point and nonpoint source abatement programs instituted over the past 10 years are producing the desired results.

The quality of fresh water entering the Chesapeake Bay from the surrounding nontidal tributaries is an important factor in the water

Figure 12-8

Watershed Population and Wastewater Flow



VOL 12

5766

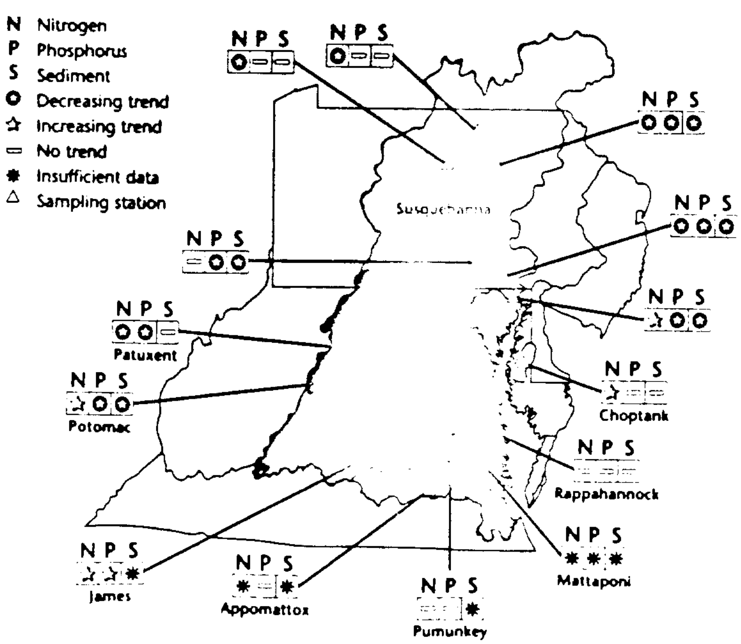
R0039074

and habitat quality of the estuary. When taken as a whole, results from cooperative monitoring of input from the Bay's rivers generally show very encouraging signs.

Historical data from the 1970s and more recent data for 1984-1993 show that the concentrations of several important pollutants are either declining or leveling off after previously increasing trends. Point and nonpoint source controls appear to be having an impact on the total phosphorus concentrations for a number of the rivers. The phosphate detergent bans enacted in Maryland, Virginia, Pennsylvania, and the District of Columbia during the mid-1980s have clearly contributed to the lowering of phosphorus inputs from the rivers. Even nitrogen, which has only recently been targeted for load reductions is showing declines in parts of the Susquehanna and Patuxent Rivers.

Figure 12-9

Pollutant Trends in the Bay's Rivers



Estuaries – Nutrient levels in the tidal saline waters of the Chesapeake Bay and its tributaries are responding to the trends seen in the inputs of nutrients from the nontidal rivers (Figure 12-10). Many regions are showing declines in phosphorus levels. Nitrogen flowing into the Bay has stopped increasing in most areas. Despite these promising trends, dissolved oxygen levels are still low enough to cause severe impacts and stressful conditions in the mainstem of the Bay and several of the larger tributaries (Figure 12-11).

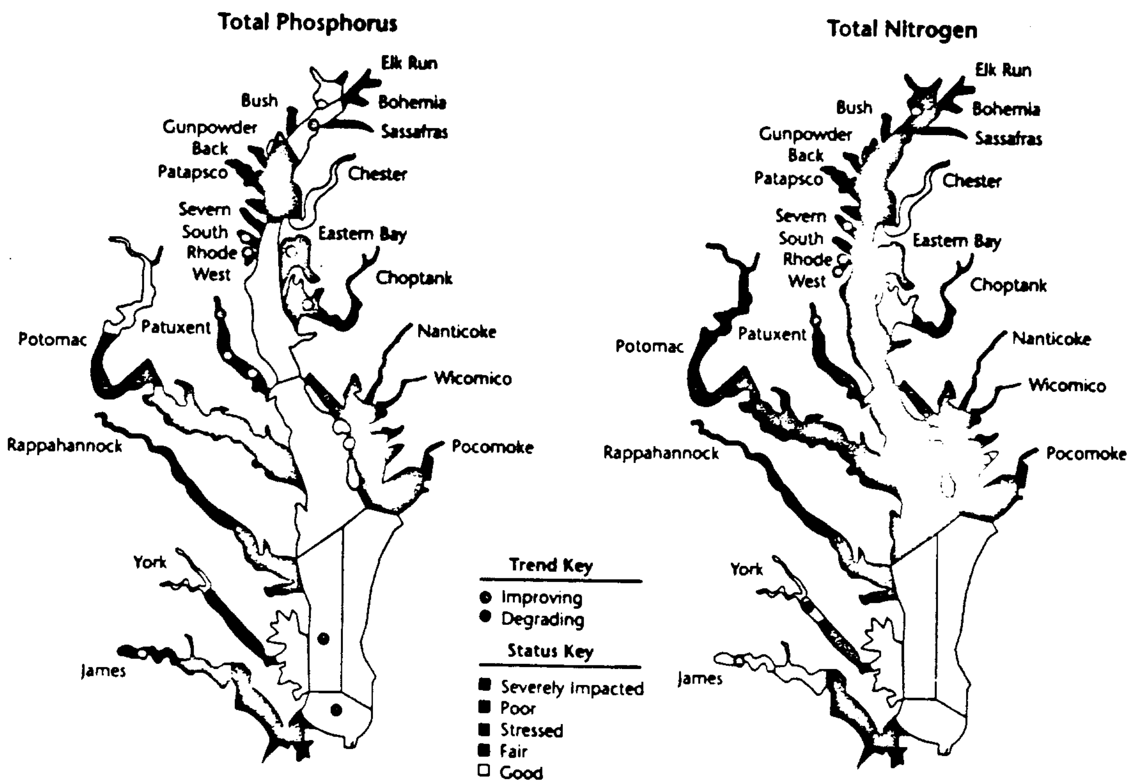
The main causes of the Bay's poor water quality and aquatic habitat loss are elevated levels of the nutrients nitrogen and phosphorus. Both are natural fertilizers found in animal waste, soil, and even the atmosphere. In excessive amounts, these nutrients cause an excessive growth of algae, which clouds the water and blocks the sunlight that is essential for submerged aquatic grasses. When the algae die, they sink and decompose, using up the dissolved oxygen in the water. Low oxygen conditions may cause the eggs and larvae of fish to die. The growth and reproduction of oysters, clams, and other bottom-dwelling animals are impaired. Adult fish find their habitat reduced and their feeding inhibited. Animals that cannot move may die.

Nitrogen concentrations in the water appear to be declining in some areas, especially Maryland's upper western shore, the Patuxent River, and the James River in Virginia. In all areas of the Bay and its tributaries, phosphorus concentrations are either declining or have remained stable since 1984. Changes in dissolved oxygen conditions are few and do not show any consistent pattern. The observed changes are primarily due to improved treatment at industrial and municipal point sources located in the major metropolitan areas that surround the upper tidal tributaries.

Sediment - Potentially toxic contaminants stored in the Bay's bottom sediments from years of

Figure 12-10

Nutrient Status and Trends



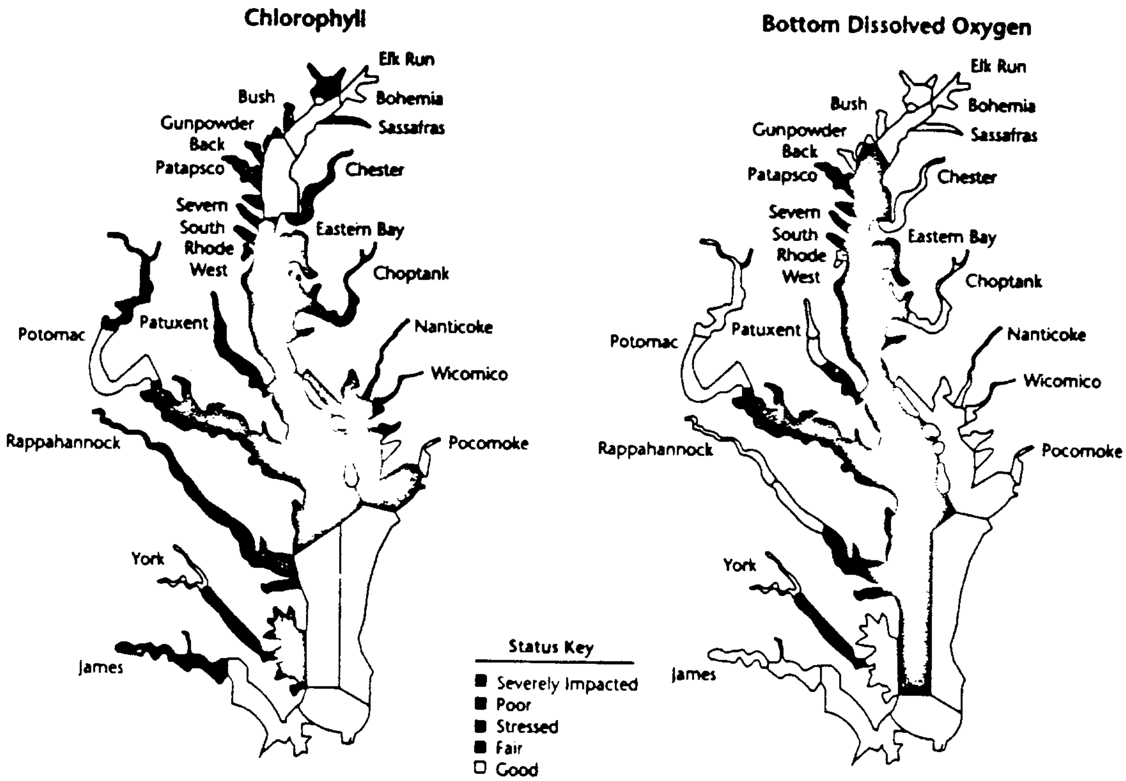
NOTE: Nutrient and chlorophyll status shadings are based on relative levels compared to similar salinity regions elsewhere in the Bay and its tributaries. If the nutrient levels were shown as absolute levels, the upper tributaries would have the highest nutrient levels.

pollution reach levels of concern only in a few localized areas that have intensive industrial activity and high population densities. The inputs of many of these pollutants have already been reduced but additional measures are being studied to mitigate any possible toxic impacts.

Many types of contaminants, including trace metals, organic compounds (such as PAHs and PCBs), and pesticides (such as DDT, chlordane, and atrazine), pose a threat to Bay waters. Most of these contaminants cling to particles suspended in the water and settle to the bottom; therefore, their concentrations in sediments are typically much higher than in the water. Monitoring toxic substances in the sediment is an efficient method of

Figure 12-11

Algae and Dissolved Oxygen Status



VOL 12

5769

R0039077

determining contamination levels in the Bay and identifying areas that may require further evaluation of potential contaminant problems.

Living Resource Response

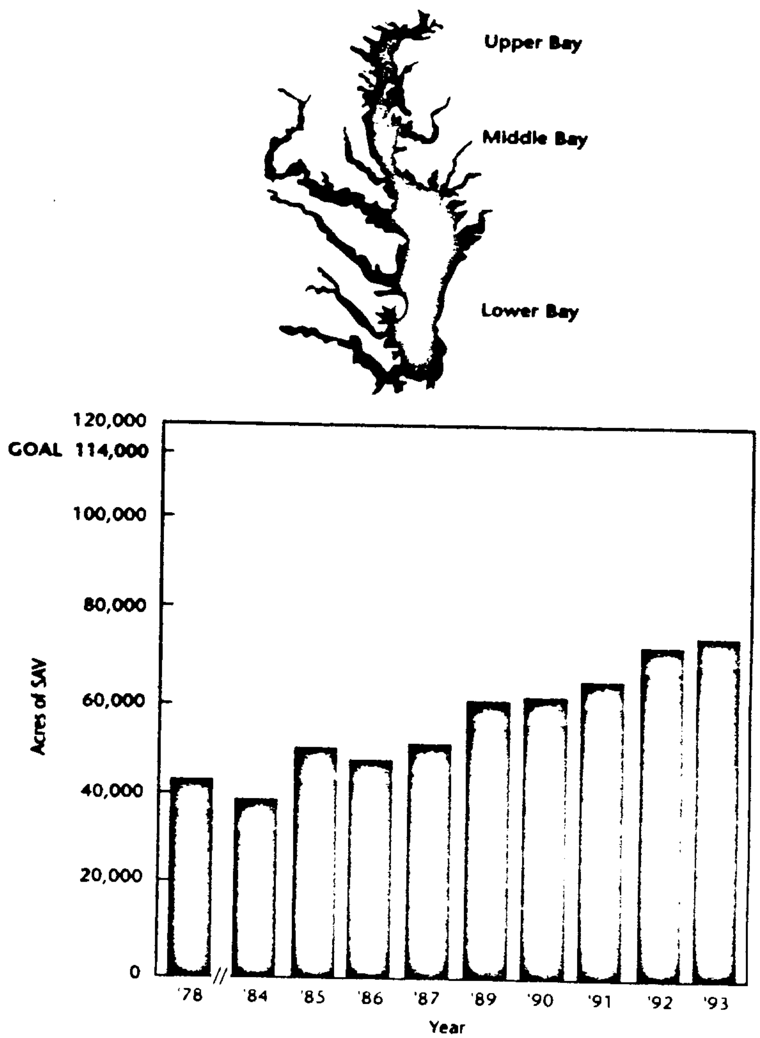
Submerged Aquatic Vegetation – Submerged aquatic vegetation (SAV), a critical habitat for fish, crabs, and waterfowl, has increased 75% since 1978 in response to improving water quality (Figure 12-12). These increases achieve about 64% of the initial restoration goal. Survey results for 1994 show a 10% decrease in the acreage of SAV due largely to record freshwater flows in spring that transported increased nutrient and sediment loads into the Bay. Additional improvements in water quality will be needed to sustain the resurgence in SAV.

The strong link between water quality and SAV distribution and abundance makes SAV plant communities good barometers of the Chesapeake Bay's health. SAV historically covered vast areas of the Bay's shallow waters and nurtured a rich variety of Bay life. During the late 1960s and early 1970s, however, Bay SAV populations experienced a dramatic decline due to increased nutrient and sediment pollution from development within the watershed.

Significant progress has been made in defining water quality requirements for SAV in the Bay. Those requirements emphasize good water clarity and low levels of suspended sediment, nutrients, and algae. The Chesapeake Executive Council used this new information about SAV in 1993 to establish an SAV restoration goal of 114,000 acres Bay-wide.

Figure 12-12

Trends in Submerged Aquatic Vegetation



NOTE: The Chesapeake Executive Council established an SAV restoration goal of 114,000 acres in 1993.

Recent changes in Chesapeake Bay SAV populations suggest that most of these populations can rebound rapidly if water quality conditions are improved and maintained. Some areas may not become revegetated even after the return of suitable water quality conditions, however, due to a lack of SAV propagules either within or close to these areas.

Biological Communities – Important biological communities in the Bay, such as plankton and benthos, reveal underlying concerns in the food web that sustain some of the more visible Bay species. Zooplankton describes the community of floating, often microscopic animals that inhabit aquatic environments. Zooplankton are the most plentiful animals in the Chesapeake Bay and its tributaries. The most common zooplankton are the crustacea, which include animals such as crab and barnacle larvae.

Zooplankton are proving to be good indicators of water quality conditions, habitat quality for living resources, and the effects of toxic contamination in the Bay. Several studies have indicated that sufficient numbers of zooplankton during the critical life stages of larval striped bass are vitally important to their growth and survival. Zooplankton act as a critical link between water quality and living resources, and zooplankton environmental indicators are currently under development for use in assessing the health of the Chesapeake Bay.

Phytoplankton refers to the community of floating, mostly microscopic plants or algae that inhabit aquatic environments. They are a critical component of the Chesapeake Bay ecosystem and represent the first biological response to the Bay's nutrient enrichment problem. Phytoplankton are particularly important to the Bay ecosystem because they are primary producers, converting energy from sunlight into food for animals such as zooplankton, oysters, and fish. Although phytoplankton form the foundation of the food chain in the Bay, problems can occur if this community grows out of control due to excess nutrients.

"Benthos" describes an invertebrate community of organisms that live on or in the bottom sediments. This community includes a wide variety of organisms such as clams, oysters, and small crustaceans, in addition to the blood and clam worms commonly used as bait.

Because most benthic invertebrates have limited mobility and cannot avoid changes in habitat quality, they are often used as reliable and sensitive environmental indicators. Some benthic organisms are commercially important and all have important functions in the Bay ecosystem. They act as nutrient recyclers and important links in the Bay's food chain, feeding on microscopic plankton and serving as food for the bottom-feeding blue crab and fish such as spot and croaker.

Most of the areas with severely or moderately degraded benthic communities are located in deeper tributary channels and the deep trench of the Bay and experience stress from low concentrations of dissolved oxygen. Sediment concentrations of toxic substances appear to have a secondary, but significant, influence on benthic community condition, primarily in industrialized

VOL 12

5771

areas such as the Elizabeth, Anacostia, and Patapsco Rivers.

Results indicate that implementation of the 1972 Clean Water Act resulted in large reductions in the quantity of contaminants discharged through industrial wastewater outfalls or sent to municipal wastewater plants and ultimately to Chesapeake Bay. Generally, contaminant concentrations in the sediment have been substantially reduced in the past two decades. Subsequent revisions of the Clean Water Act and the Clean Air Act required additional measures to reduce the discharge of trace metal and organic contaminants and prevent toxic impacts.

The Chesapeake Bay Program recently completed evaluating its toxic substances reduction strategy to better define the nature, extent, and magnitude of toxics problems in the Chesapeake Bay.

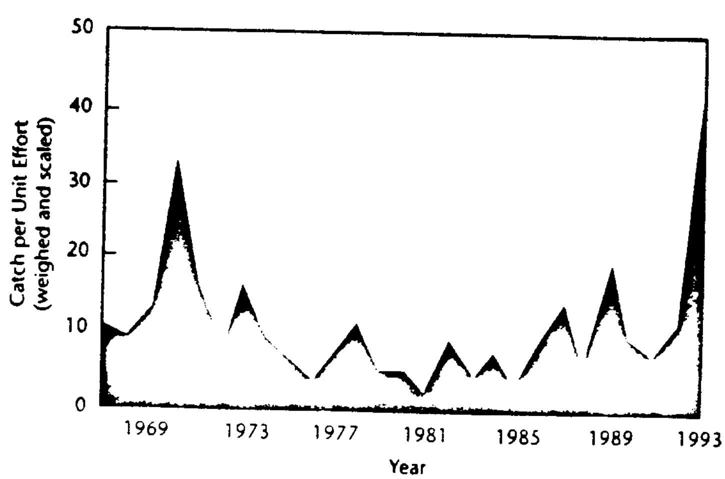
Striped Bass – Due to improved reproduction and better control of the harvest, striped bass, also known as rockfish, have made a remarkable recovery over the past decade. The increasing numbers of striped bass (*Morone saxatilis*) seen darting through Bay waters are a tribute to interagency cooperation in the management of an important Bay resource. Monitoring data show that significant progress has been made in rebuilding the population from the all-time lows of the 1980s (Figure 12-13). Striped bass spend most of their adult life in the ocean, returning each spring to spawn in tidal fresh or brackish waters found along the Atlantic coast, with the principal spawning and nursery areas found in the Chesapeake Bay. The increased abundance of striped bass is due largely to the implementation of coastwide fishing restrictions, including a fishing ban in Chesapeake Bay, allowing more fish to reach sexual maturity.

Shad - American shad, which spawn in the Bay's tributaries, have suffered population declines over the past century from overharvesting, dam construction that blocks migration routes, and habitat degradation. Once one of the most commercially valuable species in the Chesapeake Bay, American shad (*Alosa sapidissima*) populations have declined to a shadow of their former abundance. Historical overharvesting and habitat degradation, combined with stream impediments blocking miles of spawning and nursery grounds, have been cited as the main causes for this reduction.

Due to declining stocks, Maryland placed a moratorium on shad

Figure 12-13

Baywide Striped Bass Juvenile Index



in 1980, prohibiting the sale, capture, or possession of shad caught in Maryland waters of the Chesapeake Bay. The District of Columbia also placed a moratorium on American and hickory shad in 1989 and Virginia imposed a moratorium in 1994. None of these management decisions affect the coastal "intercept" fishery, which continues to harvest the species all along the Atlantic coast, although Maryland has proposed to end the coastal fishery in 1995.

In 1989, the Chesapeake Bay Program established an Alosid Fisheries Management Plan to protect, restore, and enhance Bay-wide stocks of American shad, hickory shad, blueback herring, and alewife. Efforts have focused on habitat restoration, restocking, reduction of fishing effort, and stock assessment survey improvement. Through these efforts, managers and researchers hope to restore a once valuable species to its former abundance in the Bay.

An integral component of the shad's long-term success is its ability to return to its upstream spawning habitat. The removal of blockages and construction of denil fishways and fish elevators to create fish passages has reopened 175 miles of river to anadromous fish throughout the Bay watershed. Many new projects are under way. The Bay Program has committed to reopening 582 miles of stream habitat by 1998 and 1,356 miles by 2003.

Blue Crab – The blue crab is currently the most important commercial and recreational fishery in the Bay. With increasing fishing pressures and relatively low harvests in recent years, there is growing concern for the health of the stocks. Both Maryland and Virginia have recently implemented new regulations on commercial and recreational crabbers to protect this important resource.

With the decline of other species in the Bay and the resultant increase in crab harvesting pressure, concern about the future of this great resource is mounting.

A priority for improving management of the blue crab fishery is to enhance our understanding of crab population dynamics. Knowledge of both environmental and anthropogenic factors contributing to annual fluctuations in reproductive success and population levels is essential for effective fishery management.

As with other Chesapeake Bay fisheries, a comprehensive approach to managing the blue crab is needed because biological, physical, economic, and social aspects of the fishery are shared among the Bay's jurisdictions. To provide such an approach, a Bay-wide blue crab fishery management plan was developed in 1989 to sustain the ecological and economic value of the blue crab stock. The plan has already resulted in the implementation of better fishery practices and more effective monitoring of the blue crab stock, as mentioned previously. A revised plan based on more accurate data and requiring further conservation measures will be completed in 1995.

Oysters – Prospects for the Bay's oyster population remain poor. Overharvesting, habitat loss, and disease have all conspired over the years to deplete the stocks severely.

New management efforts have been developed to improve this situation.

Oyster harvesting has been an integral part of the Bay region's economic development and cultural heritage. The filtering capabilities of the oyster enable it to remove large quantities of algae and sediment from the water column, while its shells provide habitat for a variety of benthic organisms and fish species. Some scientists feel that the restoration of this creature is an important key to improving water quality and the overall health of the Bay.

In 1989 the Chesapeake Bay Program established an oyster management plan with the goal of conserving oyster stocks while maintaining a viable fishery. In the latest effort to restore oyster stocks in Maryland, 40 representatives including watermen, academics, State officials, environmentalists, and aquaculturists joined in an Oyster Roundtable to address the oyster's dilemma. These discussions led to the signing of an "action plan" with several recommendations for aquaculture, research, and the designation of special "recovery areas." This management plan is the first of its kind to recognize the ecological importance of the oyster in addition to its commercial value.

Waterfowl – The Bay's waterfowl consist of several species, not all of which are indigenous. A long-term decline in the abundance of the native waterfowl is of great concern. The necessary corrective action to reverse this trend is habitat improvement and resurgence of SAV.

Historically, waterfowl were so abundant they seemed to blanket areas of the Bay. Today, their numbers are greatly reduced. Widespread deterioration of shallow water habitats and wetlands, coupled with increasing human disturbance, have reduced the ability of many Bay areas to support waterfowl. Overall, waterfowl are declining in the Bay, with the largest declines occurring in the Canada goose population. The black duck continues its gradual decline, as do scooters, oldsquaw, and goldeneye. Merganser, bufflehead, mallard, and the nonindigenous mute swan populations are increasing.

Conclusions

The connection between human activities on land and Chesapeake Bay degradation is clear. Overharvesting also contributes to declines in the Bay's living resources. While the findings in this report allow for much optimism, they also warn that we are far from declaring victory in our fight to save the Chesapeake Bay. The results show that the Chesapeake Bay is an interconnected system and that activities on the land and mismanagement of the resources can set off a chain of events that ultimately yields degraded conditions in the water and loss of living resources. The results also show that these conditions, which have resulted from almost 300 years of abuse, are reversible.

Overall, the Chesapeake Bay still shows symptoms related to stress from an expanding population and the changes such growth brings about in land use. However, the concentrated restoration and management effort begun 12 years ago has produced tangible results—a state of the Chesapeake Bay that is better today than it was when we

VOL 12

5774

R0039082

> THE NEP currently supports 28 estuary projects.

started—and promises the future will be even brighter.

We cannot return the Chesapeake Bay to its pristine, or original, state, nor will we ever have the uninhabited expanses that our parents and grandparents knew. We will probably never go back to the days when we could harvest oysters by the tens of millions of bushels nor to the days when we could catch as many 40-pound rockfish as our boat could hold. Those days are gone forever. But, we can have relatively clean water and large, protected areas of marsh and shoreline. We can have viable fish and bird populations, although never the "limitless" stocks of fish for all to harvest. The lessons we learn from these experiences, and our willingness to act on them, will determine the state of the Chesapeake Bay that we leave to future generations.

The National Estuary Program

The National Estuary Program embodies the ecosystem approach by building coalitions, addressing multiple sources of contamination, pursuing habitat protection as a pollution control mechanism, and investigating cross-media transfer of pollutants from air and soil into estuarine waters.

Congress recognizes that estuaries are unique and endangered ecosystems and that traditional water pollution control programs alone cannot address the more complex issues associated with estuaries. These issues include protecting living resources and their habitats, controlling diffuse sources of pollutants, and managing estuaries as watershed ecosystems. Responding to the unmet needs of estuarine ecosystems, Congress established the National Estuary Program in 1987 under Section 320 of the Clean Water Act.

The NEP adopts a geographic, basinwide approach to environmental management. A State governor nominates an estuary in his or her State for participation in the program. The State must demonstrate a likelihood for success in protecting candidate estuaries and provide evidence of institutional, financial, and political commitment to solving estuarine problems.

If an estuary meets the NEP guidelines, the EPA Administrator convenes a management conference of representatives from interested Federal, Regional, State, and local governments; affected industries; scientific and academic institutions; and citizen organizations. The management conference defines program goals and objectives, identifies problems, and designs strategies to prevent and control pollution and manage natural resources in the estuarine basin. Each management conference develops and initiates implementation of a Comprehensive Conservation and Management Plan (CCMP) to restore and protect its estuary.

With the addition of seven estuary programs in July 1995, the NEP currently supports 28 estuary projects (Figure 12-14):

- Puget Sound in Washington State
- Columbia River in Oregon and Washington
- Tillamook Bay in Oregon
- San Francisco Bay Estuary in California
- Morro Bay in California

- Santa Monica Bay in California
- Corpus Christi Bay in Texas
- Galveston Bay in Texas
- Barataria-Terrebonne Estuarine Complex in Louisiana
- Mobile Bay in Alabama
- Tampa Bay in Florida
- Sarasota Bay in Florida
- Charlotte Bay in Florida
- Indian River Lagoon in Florida
- San Juan Bay in Puerto Rico
- Albemarle-Pamlico Sounds in North Carolina
- Maryland Coastal Bays in Maryland
- Delaware Inland Bays in Delaware
- Delaware Estuary in New Jersey, Pennsylvania, and Delaware
- Barnegat Bay in New Jersey
- New York-New Jersey Harbor in New York and New Jersey
- Long Island Sound in Connecticut and New York
- Peconic Bay in New York
- Narragansett Bay in Rhode Island
- Buzzards Bay in Massachusetts
- Massachusetts Bay in Massachusetts
- New Hampshire Estuaries in New Hampshire
- Casco Bay in Maine.

These 28 estuaries are nationally significant in their economic value as well as in their ability to support living resources. The project sites also represent a broad range of environmental conditions in estuaries throughout the United States and its Territories.

The NEP integrates science and decisionmaking for the protection, restoration, and maintenance of estuaries. Through a characterization process, scientists from Federal, State, and local government agencies, academic institutions, and the private sector analyze an estuary's problems and their causes and work with estuary managers to suggest remedies. Because the NEP is not a research program, it relies heavily on past and current research of other agencies and institutions to support its work.

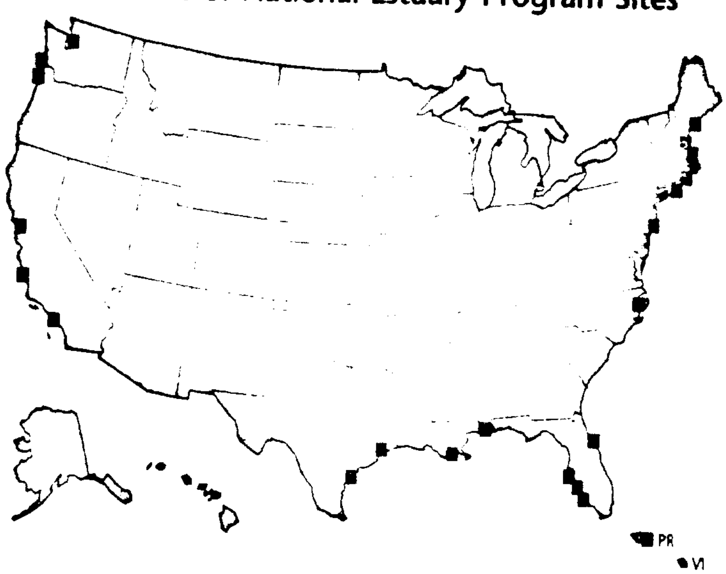
Appendix C, Table C-10, lists physical and economic characteristics of the NEP estuarine basins. The table also describes each estuary's susceptibility to pollution in terms of its ability to flush out and dilute pollutants. This information is being evaluated as part of a national survey of nutrient enrichment in estuaries, sponsored jointly by EPA and NOAA.

Estuarine Problems

Each of the 28 estuaries in the NEP is unique, yet the estuaries share common threats and stressors. Each estuary faces expanding human activity near its shores that

Figure 12-14

Locations of National Estuary Program Sites



VOL 12

5776

> NATIONAL ESTUARY programs are addressing eutrophication, toxic contamination, pathogen contamination, and habitat modification in their estuaries.

may degrade water quality and habitat. Eutrophication, toxic substances (including metals), pathogens, and changes to living resources and habitats top the list of problems being addressed by the NEP Management Conferences. Tables C-11, C-12, and C-13 in Appendix C list the problems stressing the NEP sites.

Eutrophication

Nutrients enter waterways through sewage treatment plant discharges, stormwater runoff from lawns and agricultural lands, faulty septic tanks, and even ground water discharges. (For example, nitrates are believed to leach into ground water and discharge into the Delaware Inland Bays.) Algae and bacteria respond to elevated inputs of nutrients by rapidly reproducing. Decomposition of the algae consumes oxygen and causes hypoxia–low concentrations of dissolved oxygen.

■ The Long Island Sound Study Management Conference (which includes representatives from NOAA, State and County agencies in Connecticut and New York, and New York City) is focusing on sources of hypoxia in the basin surrounding the Sound. During recent summers, poor water circulation exacerbated hypoxia problems in parts of the Sound. The Long Island Sound Study identified nitrogen as the primary nutrient linked to hypoxia in the Sound and concluded that discharges from sewage treatment plants and runoff are the leading controllable sources of nitrogen loadings to the estuary.

■ The Delaware Inland Bays Management Conference is focusing on the Inland Bays' capacity to assimilate nutrients. First, the study identified critical information gaps and planned research projects to fill the gaps. Ongoing research projects target four goals: (1) determine ground water contributions of nutrients, (2) develop a mass balance model of nutrient cycling between ground water and the Inland Bays, (3) define nutrient transport processes in the Inland Bays' basin, and (4) develop a strategy for using living resources as indicators of water quality. The project coordinates public input and research conducted by Federal, State, academic, and private scientists in an attempt to characterize the estuary and develop a Comprehensive Conservation and Management Plan.

Toxic Substances

■ Metals in Massachusetts Bay illustrate the impact from sewage treatment plants, atmospheric deposition, and polluted tributaries. The Bay receives high metal loading from the Merrimack River. The Comprehensive Conservation and Management Plan for the Bay will have to address sources of metals contaminating the Merrimack River as well as sources discharging metals directly into the Bay.

■ Sediment core samples collected at Narragansett Bay revealed that most metal concentrations peaked during the 1950s and have declined by an average of 60% since the 1950s. The study attributes declines in metal concentrations to improvements in sewage treatment.

■ The Casco Bay Estuary Project focuses on the extent of toxic contamination in Bay sediments. Heavy metal concentrations in Casco Bay sediments exceed concentrations in most NEP estuaries. The Casco Bay study detected heavy metals, PCBs, PAHs, pesticides, dioxins, and other organic compounds in the Casco Bay sediments. NOAA's flounder liver survey revealed heavy concentrations of lead, copper, zinc, silver, and PCBs in fish captured in Casco Bay.

Pathogens

Pathogens are bacteria and viruses that cause diseases. To protect public health, State agencies prohibit the harvest of shellfish in waters contaminated with pathogens or pathogen indicators, such as fecal coliforms. Waters contaminated with pathogens also pose a health risk to swimmers, surfers, and divers.

■ A growing network of shellfish farms on the Indian River Lagoon serves as a monitoring system to alert scientists and managers to water quality problems in the Lagoon, including the presence of pathogens.

■ Elevated counts of bacterial and viral indicators in two Santa Monica storm drains raised concern about the safety of swimming near storm drain outfalls. Additional sampling confirmed elevated bacterial indicator counts in the surf zone and in storm drain runoff. However, the data were inadequate to calculate health risks. The study recommended additional research to determine the source of fecal organisms and viruses in the storm drains and the dispersion of runoff along the shoreline.

Living Resources and Their Habitat

Overharvesting and loss of habitats have led to a decline of valuable species, an increase in populations of less desirable species, and a decrease in the diversity of living resources in estuaries. Land development in upland areas increases sedimentation in waterways; construction in wetlands destroys this valuable filter system and habitat for juvenile fish; bulkheading interferes with natural plant and animal shoreline interactions; and dredge and fill activities create turbid waters, destroy habitat, and interfere with circulation patterns. In Florida, ongoing estuary projects study the effects of habitat changes, rapid growth and development, and sewage treatment plant expansion on living resources.

■ The Florida Marine Research Institute is conducting cooperative studies of fish-habitat relationships in Tampa Bay with NOAA funding channeled through the Florida Department of Environmental Regulation. These studies examine fish community structure along the salinity gradient, fish density in seagrass beds and unvegetated habitats, and the use of microhabitats by economically valuable fish species. The State will enter the results of this research into a database for predicting the effects of future habitat modifications.

- In Sarasota Bay, water quality trends indicate that nutrient and salinity levels and the alkalinity/acidity ratio have decreased over time. The decrease reflects a shift from agrarian to urban land use. On the eastern shore, submerged aquatic vegetation has declined, particularly in an area within transport range of a seawater treatment plant outfall. Although the total concentration of suspended solids is elevated, researchers cannot link increased biomass to decreased light resulting from the sewage plant discharges. Further studies are investigating another possible cause of the vegetation losses: the formation of insoluble calcium carbonate from the soluble bicarbonate present in the sewage plant effluent.

- The Bay Study Group of the City of Tampa has conducted extensive monitoring in Tampa Bay. Monitoring at middle Tampa Bay and Hillsborough Bay indicate wastewater plant upgrades implemented in 1979 reduced nitrogen and chlorophyll concentrations and blue-green algae levels in Hillsborough Bay. Dissolved oxygen concentrations and water transparency also increased. At the same time, sea grasses colonized shallow areas around Hillsborough Bay, which had been barren of attached vegetation for several decades preceding the sewage plant upgrades. The Bay Study Group has documented a fourfold increase in the quantity of sea grasses since they began monitoring sea grass in 1986.

Although historical information and current investigations have expanded our understanding of estuarine problems, cooperative scientific studies must continue to evaluate management options for correcting estuarine impairments. Knowledge of estuarine systems lays the foundation for successful management plans.

Looking to the Future: Trends and Needs

Closer Integration with EPA Programs

There is growing concern about impacts on estuaries from air deposition, solid and hazardous waste sites, and contaminated ground water. Several NEP projects are investigating cross-media pollutant sources. The Long Island Sound Study is investigating the role that vehicle emissions play in polluting the Sound. Work at Superfund sites in Puget Sound and Buzzards Bay has been coordinated with NEP projects, but even closer ties between remediation activities at waste sites and estuary projects are needed. Although the New York-New Jersey Harbor estuarine program addresses the problems caused by solid waste, few projects deal directly with trash by encouraging household recycling and waste reduction. With cooperation from the Rhode Island business community, the Narragansett Bay Project is performing hazardous waste audits and encouraging source reduction, recycling, and safer chemical substitution.

Though much interaction among EPA's base programs is under way, more integration is needed at EPA Regional Offices and Headquarters.

A Scientific/Management/ Public Partnership

Using the scientific knowledge gathered and interpreted during the characterization phase ensures that the public, elected officials, and special interest groups–all part of the Management Conference–understand the problems of the estuary and are prepared to support the measures needed to correct the problems.

This process is simple in theory but complex in practice. Scientists do not always agree on the causes of a problem or the solutions. Furthermore, scientists and managers do not always communicate well with each other. In the NEP, managers operate on a 5-year plan; yet scientists rarely operate on a fixed 5-year plan. Under the auspices of the Management Conferences, however, scientists are focusing their research and applying their results to project managers' needs and time constraints. Managers are challenging scientists to direct their studies to meet Management Conference needs for short-term answers. The Management Conference enhances communication between scientists and managers and results in better solutions to management issues.

Members of the public often express concerns about highly visible problems, yet these issues may not be the most important problems for the Management Conference to consider. In fact, spending resources on a highly visible but relatively insignificant problem could divert attention from a crucial matter. It is imperative, therefore, that scientific findings be widely communicated and form the basis for public education efforts.

- Faced with diverse constituencies, each with a different idea of what constitutes a monitoring program appropriate for Santa Monica Bay, the Santa Monica Bay Restoration Program held a 2-day consensus-building conference for scientists, managers, dischargers, regulators, and public interest group representatives. The conference goal was to outline monitoring objectives that would guide the development of detailed hypotheses and sampling and analysis plans. Conference participants were led through a set of structured exercises that focused on the overall concerns driving the regulatory/monitoring system, agreement on a monitoring philosophy for the Bay, and determination of which Bay resources were the most highly valued. These exercises were followed by a decisionmaking process through which specific monitoring objectives were developed. The selected objectives reflected management goals, scientific knowledge, and public concerns.

Every estuary program in the NEP has a public participation and education component. Solutions to pollution problems are grounded in scientific information, but protection of habitats and commitment to action are dependent upon public education. Through education and participation, the public gains an understanding of the estuary and its problems, the will to act to solve immediate problems, and the desire to be stewards of the ecosystem for the future.

IT IS IMPERATIVE that scientific findings be widely communicated and form the basis for public education efforts.

ONE OF OUR MAJOR CHALLENGES is to control nonpoint sources resulting from population growth and their impacts on estuarine habitats.

Priority Concerns

The public, in partnership with scientists and government managers, faces enormous challenges compounded by the population growth projected to continue in the coastal zone well into the 21st century. We will need to manage this growth more effectively to protect our coastal resources. Critical management areas that must be addressed include general growth and development, nonpoint sources, and natural habitat destruction.

Growth and Development

Coastal population growth and development patterns disrupt natural processes in coastal ecosystems and threaten both the ecologic and economic values of estuaries. As we approach the year 2000, we must improve conventional pollution controls and accelerate enforcement actions. However, new strategies are required to solve the more complex problems brought about by increasing pressure to develop rural areas and sensitive pristine areas.

Shoreline development often strips vegetation and eliminates wetlands, which exposes the land to erosion. Increased sedimentation in shallow waters chokes underwater grasses and threatens fish and shellfish habitats. Development near shorelines also damages life-sustaining habitats for shore birds and animals.

As development replaces vegetation with less pervious surfaces (such as buildings, parking lots, and roads), rainwater cannot seep slowly into the soil and replenish ground water. Instead, storm water runs off the impervious surfaces, collecting pollutants deposited from the air, and delivers the pollutants directly into surface waters. Without wetlands and other vegetated areas, the land cannot filter pollutants from storm water runoff before it enters estuarine waters. Looking ahead, our major challenge is controlling nonpoint sources resulting from population growth and their impacts on estuarine habitats.

Nonpoint Source Control

Section 319 of the Clean Water Act provides funding for some nonpoint source control projects in estuarine waters (see Chapter 11 for a full discussion of the Section 319 Nonpoint Source Program). States employ both voluntary and regulatory controls to encourage implementation of best management practices to minimize nonpoint source pollution generated by agriculture, construction, silviculture, marinas, and urbanization.

The 1990 amendments to the Coastal Zone Management Act (CZMA) require States with federally approved coastal zone management programs to develop nonpoint source pollution control programs in coastal areas. Each State's program will consist of selected management measures for source categories, such as construction, marinas, and agriculture. The States will develop and implement the coastal nonpoint source programs through existing State coastal zone management programs administered by NOAA under Section 306 of the CZMA and State nonpoint source programs administered by EPA under Section 319 of the Clean Water Act.

In January 1993, EPA issued *Guidance Specifying Management Measures for Sources of Nonpoint Pollution in Coastal Waters* and NOAA and EPA jointly issued *Coastal Nonpoint Pollution Control Program: Program Development and Approval Guidance*. Please turn to Chapter 15 for additional information about the Coastal Nonpoint Source Pollution Control Program.

Habitat Protection

NEP projects are looking beyond traditional pollution control approaches toward strategies that address total estuarine ecosystem health. These strategies base habitat protection plans on a scientific understanding of how ecosystems function. These long-term strategies require further coordination of research and monitoring activities performed by EPA, NOAA, individual NEP projects, marine academic institutions, and other Federal and State agencies.

While long-term strategies are being developed, management conferences act locally to address immediate threats to estuarine habitats. For example, management conferences limit fish harvesting, replant seagrass beds, seek building restrictions such as setback requirements, create land conservation areas, and curb harmful uses of waterways. Such efforts are not implemented in all NEP sites but will likely be more widespread in the future.

Management conferences will need to work even more closely with agencies such as the U.S. Fish and Wildlife Service and the U.S. Army Corps of Engineers to improve our understanding of habitat problems and develop new technologies to mitigate adverse impacts. Examples of new technologies include stabilizing shorelines with vegetation instead of bulkheads and techniques for creating wetlands. EPA is working with Management Conferences to increase habitat mitigation activities, such as removing dams blocking fish migrations and eliminating freshwater diversions.

Steps in the Right Direction

The NEP recognizes that it may take decades to fulfill Congress' directive to restore and protect estuaries of national significance. In the short term, however, progress continues. Each estuary project in the NEP is focusing on the key environmental problems in its estuary and integrating protection efforts conducted by Federal, State, and local agencies. NEP projects are considering air and land pollution sources in addition to controls for traditional point source polluters. Finally, NEP projects are developing restoration and protection strategies based upon an understanding of estuarine ecosystem functions and encouraging the public to care for estuarine ecosystems.

The Great Waters Program

Introduction

Section 112(m) of the 1990 Amendments to the Clean Air Act directs EPA, in cooperation with NOAA, to assess the atmospheric deposition of hazardous air pollutants (HAPs) to the Great Lakes, Lake Champlain (bordering Vermont and New York), Chesapeake Bay, and coastal waters in the National Estuary Program and the National Estuarine Reserve System (Figure 12-15). The main objective of this assessment is to provide a biennial report to Congress on the issue of atmospheric deposition to the Great Waters. The essential goal of the Great Waters Program is to evaluate whether the problem of atmospheric deposition to these aquatic ecosystems is a significant one, and, if so, what should be done to prevent adverse effects on human health and the environment.

Specifically, Section 112(m) requires that EPA establish deposition monitoring networks in the Great Waters, as well as conduct additional study, such as assessing sources and deposition rates, evaluating adverse effects, research on monitoring methods, and biotic sampling. The reports to Congress address three main issues: (1) the contribution of atmospheric deposition to total pollutant loading to the Great Waters; (2) the adverse effects on human health and the environment; and (3) sources of the pollutants. In addition, EPA must determine whether the other regulatory programs under Section 112 are "adequate to prevent serious adverse effects to public health and serious or widespread environmental effects, including those effects resulting from indirect exposure pathways." EPA must then promulgate such changes under Section 112 that may be necessary to prevent adverse effects and make recommendations regarding any regulatory changes under any other applicable Federal legislation necessary to ensure protection of human health and the environment.

Progress Under Section 112(m)

EPA has made progress implementing the specific monitoring requirements of Section 112(m). In 1992, EPA established five master (regional background) stations to collect wet and dry toxics deposition samples at each of the Great Lakes as part of the Integrated Atmospheric Deposition Network, a joint effort between the United States and Canada. EPA and the

Chesapeake Bay States began collecting toxics samples at three stations on the Bay in 1990. EPA is also involved in mercury deposition monitoring on Lake Champlain and interacts with a State-run toxics deposition program for the Lake.

EPA has implemented many other activities to expand our understanding of atmospheric deposition of HAPs and related risks to human health and the environment:

- Conducted an extensive literature review and supported the development of three background documents leading up to preparation and release of the first Great Waters Program Report to Congress in May 1994

- Assessed the 1990 Amendments' list of 189 HAPs to determine which HAPs are most likely to be problematic when deposited in aquatic systems

- Preparing a national screening level emission inventory for specific pollutants in Section 112(c)(6), as well as assisting the Great Lakes States in developing a comprehensive toxics emission inventory and database system

- Developing prototype long-range mercury transport models and indirect mercury exposure models

- Conducting sampling to evaluate deposition to Galveston Bay and Tampa Bay with methods that will complement other Great Waters work

- Analyzing existing ambient air metals samples for the Gulf of Mexico States

- Conducting a scoping level mass-balance for nitrogen in the Gulf of Mexico

- Assessing the urban contribution to atmospheric loading, as well as evaluating other processes and parameters through field measurements for use in modeling

- Evaluating chemical exposure and health effects from consumption of Great Lakes fish with the Center for Disease Control's Agency for Toxic Substances and Disease Registry (ATSDR)

- Monitoring air toxics with EPA Region 5, the Southeast Chicago Initiative, and ATSDR

- Participating in development of a Lake Michigan Mass Balance for four high-priority chemicals.

Many of these activities are performed with cooperating Federal, State, and local agencies. EPA also leverages relevant activities performed by other agencies, including the Lake Michigan Urban Air Toxics Study, metals and NO_x monitoring in Chesapeake Bay, sample analysis for the Integrated Atmospheric Deposition Study, the Great Lakes regional toxics emission inventory, and the compilation of available emissions inventory data on a national scale.

The Great Waters Report to Congress

In May of 1994, EPA's Office of Air Quality Planning and Standards submitted the first Great Waters Program Report to Congress, *Deposition of Air Pollutants to the*

Great Waters. This first Report to Congress summarizes the current understanding of atmospheric deposition of toxic chemicals to the Great Waters and identifies key regulatory and research needs.

EPA and NOAA relied heavily on participation by independent scientists to help prepare *Deposition of Air Pollutants to the Great Waters*. As a first step, EPA sponsored a literature search on the topic of atmospheric deposition of chemicals to surface waters, identifying more than 1,100 scientific publications. EPA then convened three committees of leading independent scientists and charged them with evaluating and summarizing the literature in the three areas identified in Section 112(m):

- Adverse human health and environmental effects of atmospheric deposition to the Great Waters

- Relative atmospheric loadings to the Great Waters

- Sources contributing to atmospheric deposition in the Great Waters.

Each committee prepared a draft paper that was the topic of discussion at a workshop sponsored by EPA in the fall of 1992. Attendees of the workshop included committee members, other independent scientists, EPA scientists, EPA program representatives, and representatives from groups such as NOAA, State agencies, industry, and environmental groups. Following the workshop, the committees prepared final background documents that became the foundation for the Report to Congress. The contents of the Report to Congress are summarized below.

Exposure and Effects of Atmospheric Deposition

Over the past three decades, scientists have collected a large and convincing body of evidence showing that toxic chemicals released to air can travel long distances and be deposited on land or water at locations far from their original sources. Perhaps most notably, it appears that PCBs and some other pollutants that are persistent in the environment (including several pesticides that have not been used in significant amounts in the United States since the 1970s) have become widely distributed in the environment. These toxic chemicals remain in our environment and continue to cycle between air, water, soil, and biota (living organisms) even after their manufacture, use, or release has stopped. Their persistence increases the potential for exposure to these toxic chemicals.

Pollutants of concern (see sidebar) also accumulate in body tissues and magnify up the food web, with each level accumulating the toxics from its diet and passing the burden along to the animal in the next level of the food web. Top consumers in the food web, usually consumers of large fish, may accumulate chemical concentrations many millions of times greater than the concentrations present in the water. Fish consumption advisories have been issued in hundreds of waterbodies nationwide, including the Great Lakes, as a result of unsafe concentrations of chemicals in fish

VOL 12 5785

R0039093

due to biomagnification (see Chapter 7 for more information about fish consumption advisories).

Significant adverse effects on human health and wildlife have been observed due to exposure (especially through fish consumption) to persistent pollutants that bioaccumulate. Adverse effects range from immune system disease and reproductive problems in wildlife to subtle developmental and neurological impacts on children and fetuses. Although most of the chemicals of concern are probable human carcinogens, many are also developmental toxicants capable of altering the formation and function of critical body systems and organs. Therefore, developing embryos, fetuses, and breast-fed infants are particularly sensitive to these chemicals through exposure of the mother.

Ecological effects attributable to pollutants of concern are significant and can be subtle or delayed in onset, such as immune function

VOL 12

5786

R0039094

impairment, reproductive problems, or neurological changes—all of which can affect population survival. Other adverse ecological effects are caused by nitrogen compounds. Atmospheric sources of nitrogen exacerbate nutrient enrichment (or eutrophication) of coastal waterbodies, which results in impacts that range from nuisance algal blooms to the depletion of oxygen and resultant fish kills.

Relative Pollutant Loadings from Atmospheric Deposition

Studies show that significant portions of loadings to the Great Waters of the pollutants of concern are coming from the atmosphere. For example, 76% to 89% of the loadings of PCBs to Lake Superior and up to 40% of the loadings of nitrogen into the Chesapeake Bay are estimated to come from air pollution. However, insufficient data are available to quantify the overall relative atmospheric loadings for all of the HAPs entering all of the Great Waters. Therefore, relative loadings estimates are, and will continue to be, chemical-specific and waterbody-specific. The absolute quantity of atmospheric loadings also warrants attention because even small loadings of pollutants that bioaccumulate can result in significant pollutant burdens in fish and, ultimately, in humans.

Sources of Atmospheric Pollutant Loadings

Pollutants of concern in the Great Waters originate from both local and distant sources. Many sources of atmospheric pollutants that enter the Great Waters have been identified, including waste incinerators at industrial and municipal facilities, power plants, petroleum refineries, motor vehicles, various manufacturing processes, and residential combustion of fossil fuels. However, determining the particular sources responsible for deposited pollutants is quite difficult because a combination of sources generate the atmospheric loadings entering any particular waterbody, and transport distances vary depending on the characteristics of the chemicals, emissions, and weather conditions. Additional data are needed to identify and characterize the specific sources responsible for pollutants that are deposited to the Great Waters.

Recommendations and Actions

EPA considered the implications of action and inaction, while also recognizing that Section 112(m) mandates that EPA should act to "prevent" adverse effects and to "assure protection of human health and the environment." EPA recommends that reasonable actions are justified by the available scientific information and should be implemented now while research continues. Although there are significant uncertainties in the available information, there is enough convincing evidence to prompt action. Adverse effects of the chemicals of concern are evident and studies of selected waters show that significant proportions of toxic pollution come from the atmosphere. EPA believes that the characteristics of toxicity, persistence, and tendency to bioaccumulate warrant special treatment of the

Great Waters pollutants of concern. However, the actions recommended by EPA focus on chemicals of concern rather than specific sources because the linkage between specific sources and subsequent deposition and effects has yet to be demonstrated. NOAA concurs with the principles of this policy.

EPA's recommendations for action fall into three strategic themes. First, EPA will continue ongoing efforts to implement Section 112 and other sections of the Clean Air Act and use the results of the Report to Congress in the development of policy that will reduce emissions of Great Waters pollutants of concern. Under this theme, EPA will take actions that include: publishing emission standards affecting important chemicals of concern ahead of schedule, where possible; evaluating the adequacy of control technologies for important pollutants; publishing an advance notice of proposed rulemaking (ANPR) for establishment of lesser-quantity emission rates (LQERs) to define smaller sources to be regulated as major sources and evaluating which Great Waters pollutants warrant establishment of an LQER; evaluating which area sources should be regulated with maximum achievable control technology (MACT); and considering appropriate emission levels requiring regulation when sources are modified.

Second, EPA recognizes the need for an integrated multimedia approach to the problems of the Great Waters and, therefore, will utilize authorities beyond the Clean Air Act to reduce human and environmental exposure to pollutants of concern. Under this theme, EPA will take actions that include using the Great Waters Core Project Management Group as a coordinating body to communicate with other offices and agencies. The objectives will be to coordinate work and especially to identify lead offices to implement recommendations; support changes to the Clean Water Act that address nonwaterborne sources of water pollution; address the exportation of banned pesticides; emphasize pollution prevention efforts to reduce environmental loadings of pollutants of concern; and facilitate information sharing between EPA and other agencies.

Third, EPA will continue to support research activities and will develop and implement a program strategy to define further necessary research. Under this theme, EPA will take actions that include focusing research planning on a mass-balance approach to determine relative loadings; using an appropriate mix of monitoring, modeling, and emission inventory tasks in conducting mass-balance work; assessing the need for tools to be developed for risk assessment for total exposure to pollutants of concern and for regulatory benefits assessment; and continuing to support ongoing research efforts.

Copies of the first Great Waters Program Report to Congress, *Deposition of Air Pollutants to the Great Waters*, can be obtained, as supplies permit, from the Library Services Offices (MD-35), U.S. Environmental Protection Agency, Research Triangle Park, North Carolina 27711, or, for a nominal fee, from the National Technical Information Service (NTIS), 5285 Port Royal Road, Springfield, Virginia 22161, phone: 1-800-553-NTIS or 703-487-4650. The NTIS number for the Report to Congress is PB94-203 320. The following technical support documents may also be obtained from NTIS: the Effects Support Document (PB95-166 997), the Relative Loading Support Document (PB95-166 963), and the Sources Support Document (PB95-155 040).

HIGHLIGHT HIGHLIGHT HIGHLIGHT

Waters of the Ohio River and Tennessee River Basin – A Vital Natural Resource

About This Highlight...

You may notice that this highlight is a little different from the rest of this report. It covers an entire river basin rather than a single State, it summarizes information on use support by hydrologic unit, and the style and format are (hopefully) easier for general audiences to understand.

These features are the result of recommendations on how to improve communication of environmental information to the public that were developed by the Intergovernmental Task Force on Monitoring, a group working to improve water quality monitoring nationwide. The chapter also incorporates similar suggestions from an EPA working group. If these changes are well received, we will incorporate them more extensively in the next *National Water Quality Inventory* and in other related publications.

From trout streams in the mountains of western Pennsylvania to industrial ports along the Ohio and Tennessee Rivers, waters of the Ohio River and Tennessee River basin play a vital role in the economy and quality of life in a part of the United States roughly the size of France. Covering parts of 14 States, the Ohio and Tennessee River basin provides a place to live and work for over 26 million people.

Water Uses

Pittsburgh, Cincinnati, Louisville, Columbus, Indianapolis, Chattanooga, Nashville, and hundreds of other towns depend on the basin's rivers to provide water for their residents and industries. Shippers rely on the nearly 2,600 miles of navigable waterways for reliable, cost-effective transportation of raw materials and other commodities.

Power plants in the Ohio and Tennessee River basin produce about 10% of the Nation's electricity and are strategically located along waterways so they will have adequate supplies of cooling water for operation. Farmers irrigate their crops with water from these streams and lakes to help feed their families and the Nation.

Boaters, skiers, swimmers, anglers, kayakers, and other water sports enthusiasts use the basin's many lakes and streams to satisfy their recreational interests, pumping millions of dollars into local economies. And the thousands of species of fish, mussels, insects, birds, and other wildlife that spend at least part of their lives in the basin's lakes and streams are the food web that supports recreational and commercial fishing, waterfowl hunting, and many other commercial enterprises.

Water Use Designation and Criteria

To help ensure that the Ohio and Tennessee River basin's waters are clean enough to support these varied uses, each State specifies the uses each of the

HIGHLIGHT HIGHLIGHT HIGHLIGHT

waters in its borders should support. For each designated use, the States and EPA have developed a set of water quality criteria that the waterbodies must meet.

These criteria include limits on chemical contaminants, and many States now include standards for the integrity of aquatic biological communities, particularly for those waters classified for supporting aquatic life uses.

How Clean Are the Waters of the Ohio River and Tennessee River Basin?

Good News for Aquatic Life

About 75% of the streams and river miles surveyed in the Ohio and Tennessee River basin fully support aquatic life uses, and another 15% partially support those uses. For 5% of the fully supporting category, there is some threat to that status. Only 10% of surveyed stream miles are judged as not supporting aquatic life uses, based on evaluation guidelines recommended by EPA.

. . . And for Recreation

For water contact recreation such as swimming, wading, and skiing, 78% of surveyed miles fully support those uses, with about 5% of that category also threatened. For 14% of the surveyed miles, water quality is not good enough to support contact recreation.

How About Drinking Water?

Only about 2% of the basin's waters were evaluated for their suitability as sources of drinking water supplies. Most of the surveyed reaches (78%) fully support this use, with that support threatened for about 5%. For only 7% is water quality so poor that, based on EPA guidelines, they do not support this use.

What's the Big Picture for the Ohio River and Tennessee River Basin?

Although it's reassuring that most of the streams surveyed in the Ohio and Tennessee River basin fully support a variety of uses, most of us want to know how our area compares with others, and whether any of the problem streams are nearby.

Figure 1 summarizes information on aquatic life use support for the whole Ohio and Tennessee River basin. Each area in the map represents land that drains into one moderate-sized stream or stream segment. Each area is shaded with one of five patterns based on the relative amount of stream miles that fully support aquatic life uses versus the amount that does not support aquatic life uses, according to EPA guidance.

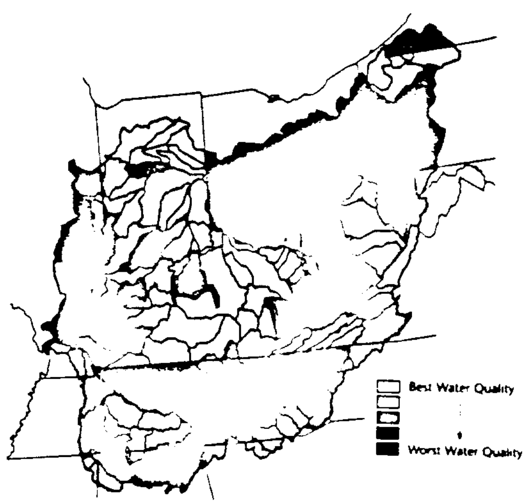

Figure 1. Aquatic life use support: Ohio River and Tennessee River subbasins.

VOL 12

5790

R0039098

HIGHLIGHT HIGHLIGHT HIGHLIGHT

The map points out some important facts about comparing information across broad areas. How well you can evaluate use support throughout a large basin depends on the availability of enough of the right information and on States using comparable assessment techniques and interpretations. For example, there is a distinct boundary along the Ohio-Indiana border between relatively good conditions for aquatic life use support in Indiana and relatively poor conditions in Ohio. In reality, there probably isn't much difference in stream quality, but Ohio has much more information available, and depends heavily on biological data to evaluate aquatic life use support. Similar use support boundaries are apparent along several other State lines in this map.

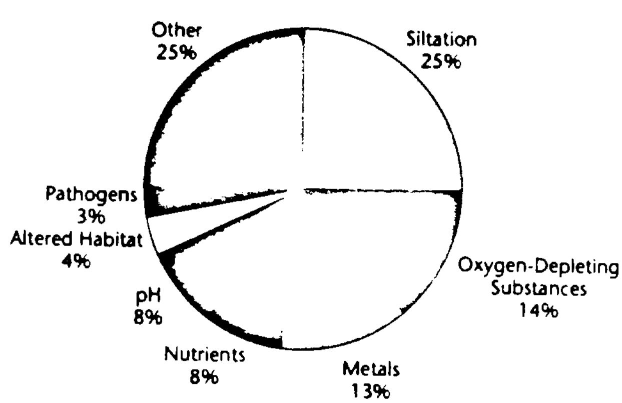

Figure 2. Pollutants and processes impairing aquatic life use in the Ohio River and Tennessee River Basin.

What Are the Main Pollutants? And Where Do They Come From?

Pollutants

As Figure 2 illustrates, Ohio and Tennessee River basin States report that siltation impairs aquatic life in more stream miles than any other pollutant. Organic enrichment, such as inadequately treated wastes, runoff from confined animal production operations, and some types of industrial wastes, is the second largest category of pollutant impairing aquatic life uses.

The States report that bacterial contamination is the main reason some streams are not suitable for swimming and other contact recreation uses. Only two States reported on causes of nonsupport for drinking water supply uses, citing pesticides and other toxic organic chemicals as the main problem.

The most common contaminants that cause Sates to issue advisories about limiting or avoiding consumption of certain fish are PCBs, chlordane, and mercury.

Sources

Mining and other types of resource extraction, including petroleum extraction and processing, are the most common source of pollutants in the Ohio and Tennessee River basin (see Figure 3). Without proper controls, these types of activities are sources of siltation, acidity, and metals contamination of streams.

Agricultural sources are the second largest source category, contributing silt, nutrients, bacteria, and organic enrichment to streams. Within this category, cropland and pastureland are the largest sources, followed by animal holding and management areas and feedlots.

But Isn't Sewage Responsible for Most Pollution?

The third largest category of pollutant sources is all types of urban activities. Together, urban runoff and wastewater treatment plant discharges account for almost as many impaired stream miles as do agricultural sources.

So, What's the Bottom Line?

The most important message from this summary of conditions throughout the Ohio and Tennessee River basin is that our Nation's water pollution control programs are working. Most of the region's streams are suitable for people to use for fishing, swimming, and obtaining water to be treated and distributed to their homes.

In addition, the basin's streams and rivers support a productive economy, providing habitat for fish, cooling and process waters for industries, navigation for raw materials, and a place for the public to recreate.

Perhaps the second most important message is that the work of protecting and improving water quality is never done, and it is everyone's business. As control of wastewater discharges improves, runoff from city streets, home lawns, pastures and croplands, and other land disturbances become a bigger part of the equation.

But these "nonpoint" sources are much more difficult to control. Effective reduction of pollution from these sources requires individuals to accept responsibility for how their actions affect water quality. All of us—farmers, homeowners, contractors, students, motorists—have to recognize our contributions to the problem and change the way we do things!

Where Did the Data Come From? How Complete Are They?

The information in this chapter is based on assessments reported by the 14 Ohio River and Tennessee River basin States. Of the basin's 255,000 miles of streams, they collectively reported on 83,000 miles (33%) for aquatic life use support, 44,000 miles (17%) for contact recreation, and 6,200 miles (2%) for drinking water. No information on lakes, wetlands, or ground water is included in this highlight, simply because it wasn't practical to try to evaluate that information for the whole Ohio and Tennessee River basin with the time and resources available.

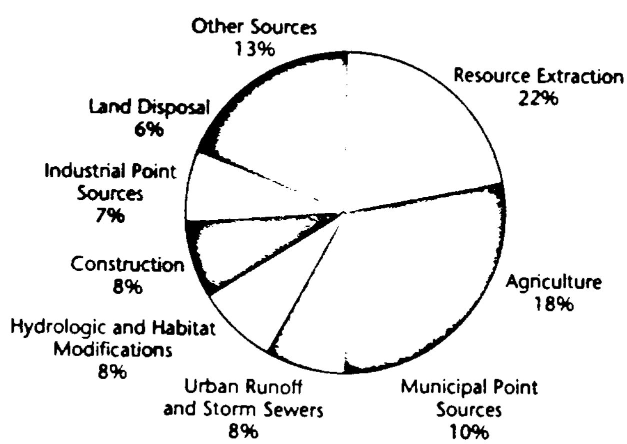

Figure 3. Sources of pollutants and processes impairing aquatic life use in the Ohio River and Tennessee River Basin.

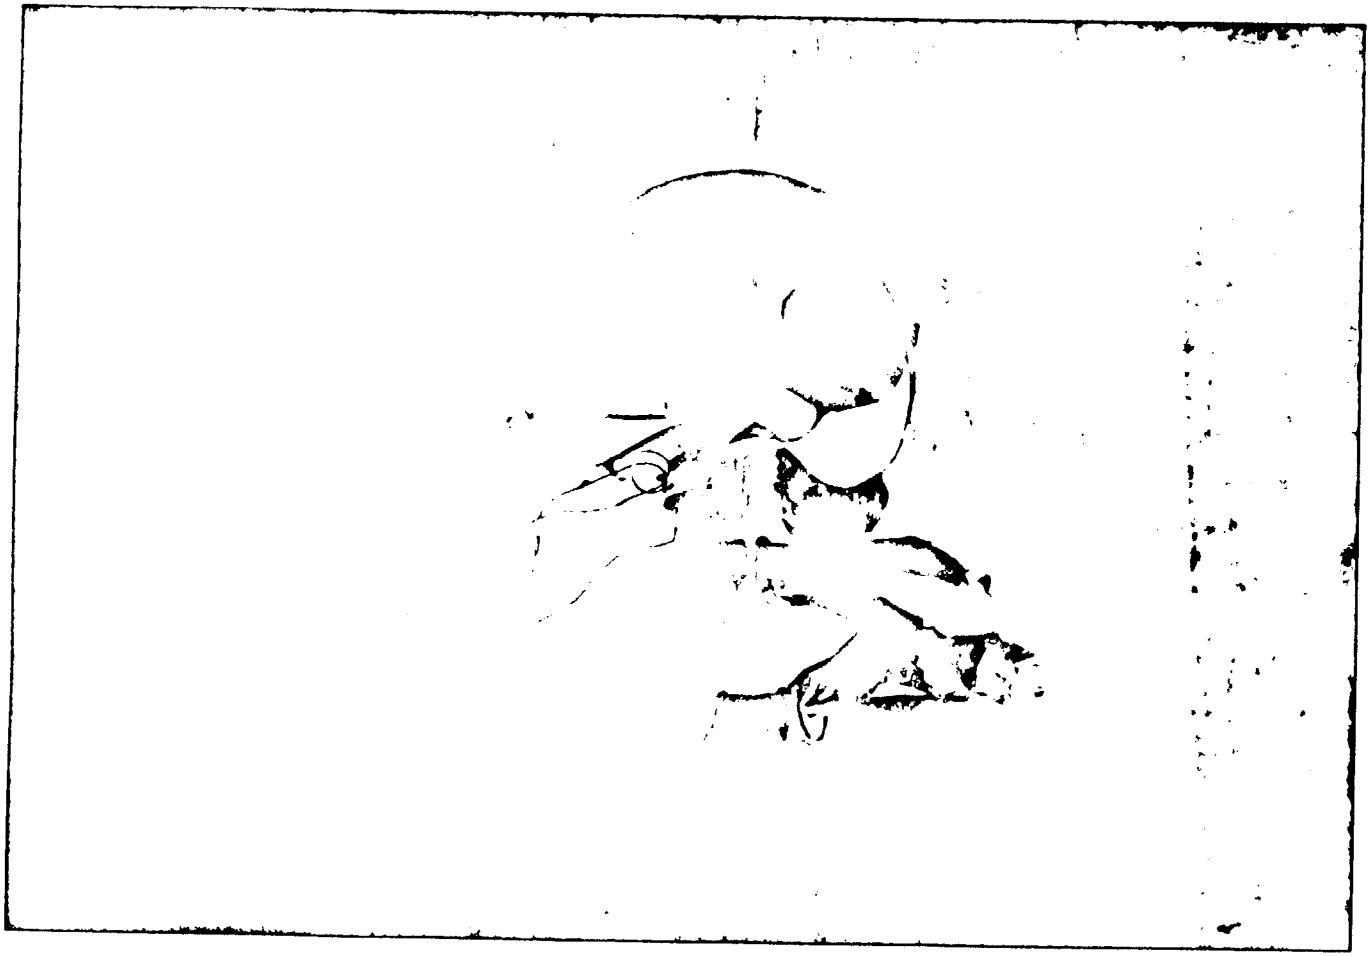
Phil Johnson, U.S. EPA, Region 8



Water Monitoring and Assessment Programs

Introduction

Water quality monitoring is essential for an understanding of the condition of water resources and to provide a basis for effective policies that promote wise use and management of those resources. A large number of Federal, Tribal, State, and local agencies and private sector organizations currently collect water quality information for a wide range of purposes that can generally be divided into five categories: (1) status and trends, (2) detection of existing and emerging problems and setting priorities among them, (3) designing and implementing programs, (4) evaluating program or project success, and (5) emergency response monitoring.

Numerous public and private groups conduct many and varied monitoring programs to fulfill one or more of these purposes. This chapter discusses current conditions of water resource quality monitoring in the United States and efforts to establish an integrated nationwide monitoring strategy.

Overview of National Monitoring Activity

Water resource quality monitoring is conducted by Federal, interstate, State, local, and Tribal agencies, as well as public, private, and volunteer organizations. A recent study undertaken by the Intergovernmental Task Force on Monitoring Water Quality indicates that 18 Federal agencies conduct approximately 141 separate monitoring programs across the country, as do all States and Territories, local governments, and an increasing number of American Indian Tribes.

At the Federal level, ambient water quality data are collected by the U.S. Geological Survey, the U.S. Fish and Wildlife Service, the U.S. Forest Service, the Bureau of Reclamation, the National Park Service, EPA, National Oceanic and Atmospheric Administration, the Tennessee Valley Authority, the Bonneville Power Administration, the U.S. Army Corps of Engineers, the Bureau of Land Management (BLM), and various other organizations within the Departments of Agriculture (USDA), Energy, Defense (DOE), and Interior. Of this group, the USGS, FWS, EPA, NOAA, and TVA have either long-term regional or both regional and national programs for water quality monitoring. The other agencies and organizations monitor ambient water quality primarily at site-specific or project scales, usually for limited periods of time.

Results from Federal monitoring programs have provided important information at the national and

In addition to monitoring performed by States, Tribes, and Territories,

18 FEDERAL AGENCIES

conduct 141 monitoring programs across the country.

MONITORING DATA are needed to characterize water quality and assess the effectiveness of water management and regulatory programs.

regional scales. For example, USGS data indicate that fecal bacteria counts and total phosphorus concentrations have decreased at a considerable number of stations across the United States from the late 1970s to the late 1980s. The FWS and NOAA data show that bioaccumulation of trace elements, pesticides, and trace industrial compounds has occurred at many locations in our rivers, estuaries, and near-coastal areas. And data from EPA monitoring indicate substantial improvement in the phosphorous concentrations of the Chesapeake Bay during the past 6 years.

Similarly, within each State, both State and local monitoring programs have provided the data to characterize State water resource quality and assess the effectiveness of water management and regulatory programs. A growing number of Tribes are also monitoring their water resources. Contributing to the picture are the monitoring programs run by industrial and municipal dischargers, by private groups, and by volunteer monitoring organizations.

This wealth of information from individual agencies, however, cannot be easily aggregated to provide an overview of national water quality conditions because of inconsistencies among the various agencies in monitoring purpose and design as well as data collection methods and assessment procedures. In addition, data are often stored without accompanying descriptors, thus other data users cannot determine if they can use the data for their own purposes.

Effects of Changes in Water Programs

In addition to this multiplicity of effort, water programs themselves are changing, necessitating similar changes in water monitoring activities. The country is moving beyond single-media command-and-control programs into more holistic management programs based on risk assessment and reduction. New emphases include watershed, ecoregion, and geographically based programs; a focus on biological, ecological, and habitat integrity and diversity; wet weather runoff control programs such as those for nonpoint sources, stormwater, and combined sewer overflows; and wetlands and sediment contamination programs. Traditional monitoring programs must be expanded to include assessment of biological and ecological resources and new methods must be developed to identify and control pollution from hard-to-trace, diffuse sources of pollution such as wet weather runoff and sediment contamination.

Intergovernmental Task Force on Monitoring Water Quality

In January of 1992, representatives from EPA, USGS, NOAA, FWS, COE, USDA, DOE, Office of Management and Budget (OMB), and seven State agencies and one interstate agency formed a 3-year

Intergovernmental Task Force on Monitoring Water Quality (ITFM) to prepare a strategy for improving water quality monitoring nationwide. The Tennessee Valley Authority, National Park Service, one State, and one American Indian Tribe, have since been added. The ITFM is part of the implementation of OMB memorandum 92-01 to strengthen coordination of water information across the country. The USGS has lead responsibility for this under its Water Information Coordination Program.

The ITFM is chaired by the U.S. EPA with the USGS as vice chair and Executive Secretariat. To date, over 100 additional Federal, State, and interstate agency representatives have been involved in the deliberations of the ITFM and its six task groups:

- Institutional Framework
- Environmental Indicators
- Methods
- Data Management Sharing
- Assessment and Reporting
- Ground Water.

The ITFM is considering the full range of nationwide water resources, including surface and ground waters, near-coastal waters, associated aquatic communities and habitat, wetlands, and sediment. Water resource protection factors include human and ecological health and the uses designated for the Nation's waters through State and Tribal water quality standards. Monitoring activities include gathering data on physical, chemical/toxicological, and biological/ecological/habitat parameters.

The mission of the ITFM is to develop and implement a national strategic plan to achieve effective collection, interpretation, and presentation of water quality data and to improve the availability of existing information for decisionmaking at all levels of government. To accomplish this, the ITFM has recommended and will facilitate implementation of an integrated nationwide voluntary strategy that will meet the nationwide objectives of various monitoring programs, make more efficient use of available resources, distribute information more effectively, and provide comparable data and consistent reporting of water quality status and trends.

A permanent National Monitoring Council will provide guidelines and support for comparable field and laboratory methods, quality assurance/quality control, environmental indicators, data management and sharing, ancillary data, interpretation techniques, and training. Regional data collection under the national guidelines would provide the needed information for nationwide assessment of water resource quality.

The ITFM and its successor, the National Monitoring Council, are also producing products that can be used by monitoring programs nationwide, such as an outline for a recommended monitoring program, environmental indicator selection criteria, and a matrix of indicators to support assessment of State and Tribal designated uses.

Major Nationwide Monitoring Programs

■ Environmental Monitoring and Assessment Program (EMAP)

EPA's Office of Research and Development initiated EMAP in 1990 to provide information on the current status and long-term trends in the condition of the ecological resources of the United States. EMAP develops indicators to measure ecological condition, monitors for those indicators, and presents analyses of data in periodic reports. Site selection is based on a random design within natural resource areas so individual results can be interpolated with confidence to the condition of the Nation as a whole. EMAP, in cooperation with NOAA and the FWS, monitors seven resource groups: Near Coastal Waters, Surface Waters, Wetlands, Forests, Arid Lands, Agroecosystems, and Great Lakes.

■ National Acid Precipitation Assessment Program (NAPAP)

During the 1970s, the effects of acid rain on the environment and human health became a major concern for many scientists, public policy officials, public interest groups, the media, and the general population. Reports were published linking emissions from industry, electric power plants, and automobiles with acid rain. Many believed that acid rain damages crops, forests, buildings, animals, fish, and human health. Congress established NAPAP under the Acid Precipitation Act of 1980 to provide the information needed for policy and regulatory decisions on acidic deposition. The areas of investigation addressed by NAPAP Task Groups are Emissions and Controls, Atmospheric Processes, Atmospheric Transport and Modeling, Atmospheric Deposition and Air Quality Monitoring, Terrestrial Effects, Aquatic Effects, and Effects on Materials and Cultural Resources. NAPAP has also developed Assessment Work Groups in the areas of Atmospheric Visibility, Human Health Effects, and Economic Valuation.

■ U.S. Geological Survey, National Water Quality Assessment Program (NAWQA)

The USGS developed NAWQA to provide a nationally consistent description of current water quality conditions for a large part of the Nation's water resources; to define long-term trends (or lack thereof) in water quality; and to identify, describe, and explain, to the extent possible, the major factors that affect observed water quality conditions and trends. This program is concerned with both ground and surface water quality; ultimately, 60 drainage basins will be monitored under this program.

■ U.S. Geological Survey, National Stream Quality Accounting Network (NASQAN)

This network is composed of 420 stations on large rivers, located at the outlets of major drainage basins to collectively measure a large fraction of total runoff in the United States. The stations reflect general water quality conditions in the country. Measurements at NASQAN sites include inorganic constituents, radionuclides, and bacteria, but exclude routine analyses for organic chemicals.

■ U.S. Geological Survey, the Hydrologic Benchmark Network (HBN)

Composed of 55 stations located in relatively pristine headwater basins, this network is designed to define baseline water quality conditions and the effects of atmospheric deposition on water quality. The Network measures inorganic constituents, radionuclides, and bacterial contamination, among other parameters.

Both NASQAN and HBN achieve their objectives but neither is designed to provide a statistically representative sample of basins throughout the Nation, nor are stations in NASQAN purposefully located downstream from industry, municipal, and urban runoff outfalls to isolate and measure maximum impacts. These network design considerations are a component of the NAWQA program.

■ U.S. Geological Survey, the National Atmospheric Deposition Program/National Trends Network

Composed of 200 sampling sites within the interagency NAPAP, this network is designed to determine spatial patterns and temporal trends in chemical wet-only deposition. It supports research into impacts on aquatic and terrestrial ecosystems. Measurements are limited to inorganic constituents only.

■ U.S. Army Corps of Engineers Water Resource Monitoring

The COE routinely monitors physical and chemical water quality parameters at most of its 541 reservoir projects. The Corps monitors to aid in day-to-day operational decision-making, determine status and trends, identify and solve problems, evaluate project performance, and respond to emergencies. In addition, the Corps collects and evaluates water quality data for its hazardous and toxic waste site cleanup program, for special studies such as the Chesapeake Bay Program, and for many other Corps mission responsibilities. Many of these project data sets are temporary and spatially quite extensive, often covering much of a project's watershed and tailwater. There has been a gradual trend toward increasing biological monitoring to evaluate project performance. All data are maintained at local Corps offices.

■ U.S. Fish and Wildlife Service, National Contaminant Biomonitoring Program (NCBP)

This program, now being revised, determines tissue residue levels in fish and birds nationwide. The fish tissue part of the program consists of 110 stations at nonrandomly selected points along the Nation's major rivers and in the Great Lakes. Fish tissues are analyzed for organic contaminants (pesticides and industrial chemicals) and seven elements. Sampling has been conducted on a 2- to 4-year basis since the mid-1960s.

VOL 12

5798

The National Biological Service

Secretary of the Interior, Bruce Babbitt, proposed the creation of an independent, non-advocacy biological science bureau within the Department of the Interior. The National Biological Service (NBS) provides information and technical assistance. The NBS was created by incorporating elements from eight bureaus within the Department. The NBS has three major functions:

- *biological and ecological research*
- *inventory and monitoring of the Nation's biological resources*
- *information transfer activities.*

The NBS became operational on November 11, 1993.

■ U.S. Fish and Wildlife Service, Biomonitoring of Environmental Status and Trends (BEST) Program

This program, now under development, has three major goals: (1) to determine the status and trends of contaminants and their effect on natural resources; (2) to identify and assess the major factors affecting resources and provide current and predictive information to alleviate impacts; and (3) to provide summary information in a timely manner to decisionmakers and the public. The BEST Program has two major components: FWS lands and FWS trust species and their habitats. Activities include collection and evaluation of existing data for site characterization and bioassessment data from four general categories–ecological surveys, tissue residue, organism health or biomarkers, and toxicity tests/bioassays.

■ U.S. Fish and Wildlife Service, National Wetlands Inventory (NWI) Program

This program determines status and trends of U.S. wetlands to produce comprehensive, statistically valid acreage estimates of the Nation's wetlands. This information is widely distributed and mandated by the Emergency Wetland Resource Act of 1986. To date, more than 32,000 detailed wetlands maps have been completed covering 72% of the coterminous United States, 22% of Alaska, and all of Hawaii and Puerto Rico.

■ National Oceanic and Atmospheric Administration, National Status and Trends Program (NS&T)

NOAA conducts the NS&T, which includes the Benthic Surveillance Program and the Mussel Watch Program. Indicators for determining the effects on marine biotas of contaminated sediments are currently under development. Parameters that are sampled for NS&T include accumulated compounds in the tissues and conditions of physical features of selected biota as well as sediment chemistry.

■ National Oceanic and Atmospheric Administration, National Estuarine Research Reserves

The National Estuarine Research Reserve System was created to protect representative areas of the estuarine environment and to provide a system of protected sites for long-term monitoring and research. It is a State-Federal partnership managed by NOAA under the Coastal Zone Management Act. The Act requires nomination of a reserve site by the Governor of a State and designation by the Secretary of Commerce. Since 1972, NOAA has kept this partnership, and the evolving statutory mission of the program, by providing resources and guidance to the States, by developing national programs, and by shaping the legislation into an operating program. Twenty-one reserves have been designated including sites in Hawaii, Puerto Rico, the Great Lakes, the Gulf of Mexico, the Atlantic Coast, and the West Coast.

■ Tennessee Valley Authority, Water Resource Monitoring

TVA conducts a regional water resource monitoring program to evaluate ecological health and suitability for body-contact recreation of reservoirs and major streams in the Tennessee Valley and to evaluate the suitability for human consumption of fish in those waters. The program includes systematic measurement of physical, chemical, and biological variables at strategic locations. Results are used to draw attention to pollution problems, to set cleanup goals, and to measure the effectiveness of water quality improvement efforts over time. TVA also monitors aquatic plant and mosquito populations around TVA lakes to help target management efforts. Monitoring of conditions in tailwaters below several dams focuses on prioritizing facilities for reaeration of reservoir releases and providing data to evaluate the effectiveness of those efforts.

■ U.S. Department of Agriculture, Resource Conservation Act of 1977

Mandated by the Resource Conservation Act (RCA) of 1977, the USDA is "to provide for furthering the conservation, protection, and enhancement of the Nation's soil, water, and related resources for sustained use." In recognition of the importance of, and need for, obtaining and maintaining information on the current status of soil, water, and related resources, USDA makes a continuing appraisal of the soil, water, and related resources of the Nation. The objective of the appraisal currently under way is to present information to assist policy decisionmakers and program managers to form better policies and programs to address soil, water, and other environmental concerns for the next 2 decades.

RCA appraisals include data on: the quality and quantity of soil, water, and related resources, including fish and wildlife habitats; the capability and limitations of those resources for meeting current and projected demands on the resource base; the changes that have occurred in the status and condition of those resources resulting from various past uses, including the impact of farming technologies, techniques, and practices; and the current Federal and State laws, policies, programs, rights, regulations, ownerships, and their trends and other considerations relating to the use, development, and conservation of soil, water, and related resources.

Developed by the Interagency Work Group on Water Quality, the *Guide to Federal Water Quality Programs and Information* is an attempt to inventory all significant Federal water quality programs and information of national scope or interest. The guide contains information on (1) factors affecting water quality including underlying demographic pressures; use of the land, water, and resources; and pollutant loading; (2) ambient water quality information, including biological, chemical, and physical/ecological conditions; (3) other effects of water pollution including waterborne disease outbreaks; and (4) a listing of programs established to preserve,

For a description of other Federal water quality programs, see the Guide to Federal Water Quality Programs and Information, *available from EPA's Public Information Clearinghouse at (202) 260-7751.*

protect, and restore water quality. For a copy of the Guide, contact EPA's Public Information Clearinghouse (PIC) at (202) 260-7751.

Office of Water Programs to Support Monitoring

Environmental Indicators

The EPA Office of Water (OW) is developing a strategic plan that outlines its future directions and articulates its goals. To measure success toward these goals, OW is establishing indicators to accurately characterize the health of national water resources and measure how well the waters meet their designated uses. This effort has identified data sources to track the indicators. Future indicator development activities include developing comparable monitoring and reporting mechanisms by working with other agencies and national trends programs, such as EPA's EMAP and USGS' NAWQA, through the ITFM.

> EPA's OFFICE OF WATER is developing indicators to characterize the health of national water resources.

Monitoring Program Grant Guidance

EPA gives grants to States to assist them in administering pollution prevention and control programs, including monitoring activities. EPA, working with States and the ITFM, has developed an outline for a recommended monitoring program. A comprehensive monitoring program would include both ambient monitoring and monitoring to determine the effectiveness of individual projects and individual programs designed to protect waterbodies or control sources of pollution. Recommended elements of a monitoring program include monitoring program objectives; a monitoring design description; written protocols that are comparable with others; analytical laboratory support; quality assurance and quality control procedures; data storage, management, and sharing; water resource assessment and reporting; training; and integration of work with partners, including volunteer monitoring groups.

305(b) Consistency Workgroup

The 305(b) Consistency Workgroup, convened in 1990, was expanded in 1992 and 1994 to address issues of consistency in water quality reporting and to improve accuracy and coverage of State assessments. The 1994 305(b) Consistency Workgroup consists of representatives of 23 States, 3 Tribes, 1 Territory, 1 Interstate Commission, 6 Federal agencies, the 10 EPA Regions, and EPA Headquarters. This standing workgroup, which will develop future 305(b) guidance, makes recommendations to improve each iteration of guidance to the States. Recent recommendations have included refining total State waters estimates and providing more detailed guidance for aquatic life use support assessments, including appropriate methods for using biological data along with physical and chemical data.

Water Monitor Newsletter

Since the early 1980s, EPA has issued a regular status report on monitoring activities at EPA and among the States. Now known as the *Water Monitor*, this report provides monthly updates on State, EPA Regional, and EPA Headquarter activities in areas such as biological monitoring, total maximum daily load development, biological criteria and protocol development, volunteer monitoring, and the watershed approach. New documents and upcoming meetings are highlighted. To obtain a copy or be placed on the mailing list for the *Water Monitor*, write to Editor, *Water Monitor*, AWPD (4503F), 401 M St. SW, Washington, DC 20460.

Biological Monitoring

The Biological Criteria Program

Priorities established since 1987 (initiated jointly by the States and EPA) encourage the States to first develop, and then adopt as appropriate, narrative and quantitative biological criteria (biocriteria) into their water quality standards and assessment programs. This successful approach has resulted in about 30 States developing quantitative biocriteria, including three States that formally adopted quantitative biocriteria into their water quality standards. For the status of specific State programs, please refer to Appendix G.

To support this priority, the Agency has provided guidance for development and implementation of biocriteria (see sidebar). Several future guidance documents will provide additional technical information to facilitate activities directed toward that implementation. When fully implemented, biocriteria will expand and improve water quality standards programs, help to quantify impairment of beneficial uses, and aid States and Tribes in setting program priorities. These criteria will be useful because they provide for

BIOLOGICAL CRITERIA directly measure the condition of the living resource at risk.

direct measurement of the condition of the living resource at risk, detect problems that other methods may miss or underestimate, and provide a systematic process for measuring progress resulting from the implementation of water resource quality programs. Biocriteria are intended to supplement, rather than replace, chemical and toxicological methods.

Bioassessment Protocols

In 1989, EPA's Office of Water issued rapid bioassessment protocols (RBPs) for streams as a tool intended to provide States with biological monitoring methods to supplement traditional instream chemical analyses. The key concept underlying these protocols is the comparison of the structure and function of the aquatic community in the context of habitat quality at a given stream study site to that of an ecological reference site or condition. On the basis of this comparison, a water resource quality assessment can be made. EPA has provided technical support and training to States to encourage the implementation of the RBPs and biological criteria. Currently, over 30 States have active RBP-based water resource monitoring programs for streams, another three are under development, and three States go beyond the guidelines. Updated RBP guidance is being developed to aid States in adapting the original protocol framework to go beyond a single reference site approach to including ecoregional reference conditions that fit a variety of ecological regions. Over 30 States either have, or are developing, ecoregional reference conditions. Modified RBPs are also being prepared for other water resource types including lakes/reservoirs and estuaries. Work is also under way to evaluate the effectiveness of RBPs for assessing combined sewer overflows. In addition, a generic quality assurance/quality control (QA/QC) guidance will be available in the Fall of 1995. For a copy, please contact the EPA Monitoring Branch at 202-260-7046.

Quality Assurance/Quality Control for Biological Monitoring and Biological Assessment

The U.S. EPA Office of Water and Office of Research and Development are assembling generic guidance documents for production of quality assurance project plans for biological monitoring and assessment. This work is currently under way and involves review and input from State and EPA regional monitoring personnel.

Fish Advisory Guidance and Databases

In response to interest on the part of States to have nationally consistent methods for issuing fish consumption advisories, EPA's Office of Science and Technology (OST), Standards and Applied Science Division, is developing national guidance documents. This guidance, developed in cooperation with States, Tribes, and others, is presented in a four-volume set of documents titled *Guidance for Assessing Chemical Contaminant Data for Use in Fish Advisories, Volume I: Fish Sampling and Analysis* (September

VOL 12

5803

R0039111

1993); *Volume II: Risk Assessment and Fish Consumption Limits* (June 1994); *Volume III: Risk Management* (FY95); and *Volume IV: Risk Communication* (FY95).

In addition to this guidance, OST has developed two databases, one for States to report fish advisory information and another that contains fish tissue contaminant data. The Fish Advisory Database contains fish advisory information reported nationwide by States including the waterbody affected, the type of fish species, the type of advisory, and a contact person. It is updated annually and can be obtained by contacting the EPA Fish Contaminants Section at the following address or by calling (202) 260-1305:

Fish Advisory Database Coordinator
U.S. EPA (4305)
Office of Science and Technology
401 M Street, SW
Washington, DC 20460

OST established the National Fish Tissue Data Repository (NFTDR) to (1) simplify data exchange by improving the comparability and integrity of fish tissue data;
(2) encourage greater regional and interstate cooperation; and (3) assist States and Tribes in their data collection efforts by providing ongoing technical assistance. Currently, the NFTDR is part of EPA's Ocean Discharge Evaluation System (ODES) Database and there is relatively little fish tissue data in the NFTDR. To make the NFTDR more accessible, EPA intends to modify the NFTDR and incorporate it as a major prototype during the modernization (Phase III) of EPA's STORET (STOrage and RETrieval) Database (see page 374 for more information about STORET and ODES). The use of real fish tissue data during prototype development should help EPA identify needed data fields and test the data structure.

During 1996, EPA intends to completely convert the NFTDR to a STORET-based fish tissue database. The primary benefit of including the NFTDR as a subset of STORET is that one "platform" will be able to store both water quality data and biological data, such as fish tissue information. Existing data sets would be able to easily migrate to the new STORET system when it is completed in 1997. Additional information may be obtained by writing to the following address:

NFTDR
U.S. EPA (4305)
401 M Street, SW
Washington, DC 20460

National Study of Chemical Residues in Fish

In late 1992, EPA issued a report on results of the EPA National Study of Chemical Residues in Fish (NSCRF), formerly called the National Bioaccumulation Study. This study is a followup to the EPA National Dioxin Study and substantially broadens that work with regard to both the number of chemicals analyzed and the number of sites examined. The NSCRF was a screening study designed to determine the extent to which water pollutants are bioaccumulating in fish and to identify correlations with sources of the contamination within a watershed/drainage basin.

For further information about databases and information systems, see the Office of Water Environmental and Program Information Systems Compendium available from the EPA Office of Water at (202) 260-5684.

Specific Water Program Monitoring

National Estuary Program Monitoring Guidance

EPA is developing guidance on the design, implementation, and evaluation of estuary monitoring programs required under Section 320 of the Clean Water Act. The guidance document identifies the major steps involved in developing and implementing estuary monitoring programs, documents existing monitoring methods, and describes their use in monitoring the effectiveness of estuarine management actions. Case studies of existing programs are included.

Nonpoint Source National Monitoring Program

EPA developed the Section 319 National Monitoring Program to improve our understanding of nonpoint source (NPS) pollution and to scientifically evaluate the effectiveness of NPS pollution control activities. Under this program, EPA's Regional Offices nominate projects by forwarding State proposals to EPA Headquarters for review and concurrence. Projects are selected on a competitive basis from within each of the EPA Regions. EPA works with project sponsors to develop approvable 6- to 10-year projects. The project sponsors then work through the State/EPA Section 319 process to obtain approval and funding. As of June 1995, 11 projects have been approved. More information about the Section 319 National Monitoring Program is provided in Chapter 15.

Wetlands Monitoring

EPA's Wetlands Division is now working closely with FWS and EPA's EMAP-Wetlands Program to characterize the ecological status and trends of existing wetlands. Standardized protocols are being developed for measuring wetlands conditions. See Chapter 15 for further information about EPA and State wetlands monitoring and protection programs.

Ground Water Monitoring

EPA's support for State Ground Water Protection Programs has expanded in line with the Ground Water Task Force's recommendations in the report *Protecting the Nation's Ground Water: EPA's Strategy for the 1990's*. This document addresses the development of consistent data collection protocols to improve accessibility, quality, and the usefulness of ground water quality data. To that end, the Ground Water Minimum Set of Data Elements for Ground Water Quality was finalized requiring their use for EPA ground water monitoring.

Volunteer Monitoring Programs

EPA's Office of Water encourages all citizens to learn about their water resources and supports volunteer monitoring because of its many benefits. Volunteer monitors

VOL 12

5805

- build awareness of pollution problems
- become trained in pollution prevention
- help clean up problem sites
- provide data for waters that may otherwise be unassessed, with accompanying data on the methods used to collect the data
- increase the amount of water quality information available to decisionmakers at all levels of government.

Among the uses of volunteer data are delineating and characterizing watersheds, screening for water quality problems, and measuring baseline conditions and trends.

EPA supports volunteer monitoring by providing technical guidance and forums for exchanging volunteer information. For example, EPA sponsors biennial national conferences that bring together volunteer organizers, State and local agencies, environmental groups, school groups, and the business sector. EPA also maintains an electronic bulletin board forum for volunteer monitors, distributes a national newsletter for volunteers, and maintains a directory of volunteer monitoring programs across the Nation. EPA has released guidance for planning and implementing volunteer monitoring programs as well as guidance covering volunteer monitoring methods.

Many of EPA's 10 Regional Offices are actively involved in volunteer monitoring. Their support activities include providing technical assistance related to quality assurance and quality control, serving as contacts for volunteer programs in the Region, managing grants to State agencies that include provisions for volunteer water monitoring and public participation, and providing information exchange

EPA Volunteer Monitoring Materials

EPA's Volunteer Monitoring Program. EPA-841F-95-001. February 1995. Contains a general description of EPA activities to promote volunteer monitoring.

Volunteer Monitoring. EPA-800-F-93-008. September 1993. A brief fact sheet about volunteer monitoring, including examples of how volunteers have improved the environment.

Starting Out in Volunteer Water Monitoring. EPA-841-B-92-002. August 1992. A brief fact sheet about how to become involved in volunteer monitoring.

National Directory of Citizen Volunteer Environmental Monitoring Programs, Fourth Edition. EPA-841-B-94-001. January 1994. Contains information about 519 volunteer monitoring programs across the Nation.

Proceedings of the Fourth National Citizen's Volunteer Water Monitoring Conference. EPA-841-R-94-003. February 1995. Presents proceedings from the fourth national conference held in Portland, Oregon, in 1994.

Proceedings of the Third National Citizen's Volunteer Water Monitoring Conference. EPA-841/R-92-004. September 1992. Presents proceedings from the third national conference held in Annapolis, Maryland, in 1992.

Volunteer Stream Monitoring: A Methods Manual. EPA-841-D-95-001. 1995. Presents information and methods for volunteer monitoring of streams.

services for volunteers. Some offices hold Regional workshops to bring volunteers together and build partnerships.

In the coming years, EPA plans to continue developing technical tools for volunteers, including guidance on assuring quality data collection. EPA will also continue encouraging cooperation and information exchange among volunteer programs and between volunteers and State, local, Tribal, and Federal agencies. A common theme of all of these activities will be a commitment to increase the diversity of the volunteer monitoring community nationwide.

EPA Data and Information Systems

Storet Modernization

The STORET (STOrage and RETrieval) Database of ambient water quality data, first developed in 1964, is one of the oldest and largest water information systems currently in use. It is maintained by the Office of Wetlands, Oceans, and Watersheds. STORET stores information on ambient, intensive survey, effluent, and biological water quality monitoring and provides users with an array of analytical tools and linkages to other data systems. STORET primarily contains chemical and physical water quality monitoring data, with biological sampling and site information stored in the associated BIOS (Biological System) Database, another major component. ODES (Ocean Data Evaluation System) is a separately maintained and linked information system specifically for water quality and biological data for marine, estuarine, and freshwater environments. ODES users can access STORET information for further manipulation using ODES graphical and modeling tools.

EPA information systems are being called upon to respond to new program needs, including geographically oriented management approaches, storage of ground water quality and associated geologic data and biological and habitat assessment information, and to enhance sharing of data (across EPA, other Federal, State, and local programs). STORET, BIOS, and ODES are undergoing a major modernization scheduled to be complete in 1997 with interim products throughout, including a full prototype in late 1995. This effort will result in a more flexible, efficient, and usable state-of-the-art information system, which, in turn, will provide improved tools for ground and surface water quality decisionmaking.

For more information on STORET modernization and the prototype now available for testing, contact:

Phil Lindenstruth

Washington, DC 20460
(202) 260-6549

The Waterbody System

The Waterbody System (WBS) is a data management tool used by States to record assessments of ambient water quality for surface waters. Although originally designed to facilitate the reporting under

Section 305(b), the WBS is used by many States to track results of all their ambient water quality assessments. During the 1994 reporting cycle, 27 States, Territories, and Interstate Water Commissions submitted WBS data files.

The Waterbody System contains information that program managers can access quickly on the water quality status of a particular waterbody. Data elements include waterbody identification, water quality status, assessment information, designated use evaluations, causes of impairment (nutrients, pesticides, siltation, etc.), and sources of impairment (municipal treatment plants, agricultural runoff, etc.).

Enhanced twice since it was originally developed in 1988, system users communicate regularly with each other and can receive user information and support from the Monitoring Branch at EPA Headquarters.

The Permit Compliance System

The Permit Compliance System (PCS) is an information management system maintained by the Office of Wastewater Enforcement and Compliance (OWEC) to track the permit, compliance, and enforcement status of facilities regulated by the National Pollutant Discharge Elimination System program under the Clean Water Act. PCS tracks information about wastewater treatment and industrial and Federal facilities discharging into navigable rivers. Tracked items include facility and discharge characteristics, permit conditions, inspections, enforcement actions, and compliance schedules. PCS distinguishes between major and minor facilities based on the potential threat to human health or the environment. Only major facilities must provide complete records to PCS, currently numbered at around 7,100; however, States and Regions do submit information for approximately 56,300 minor facilities. PCS users are able to use graphical and statistical tools to analyze PCS data and can use a PCS/STORET interface to link the systems and support additional analyses.

The Toxics Release Inventory

The Emergency Planning and Community Right-to-Know Act (EPCRA) of 1986 established the Toxics Release Inventory (TRI), a public database that contains information about toxic chemical releases to water, air, and land from manufacturing facilities. The TRI contains data submitted annually by individual manufacturing facilities subject to the EPCRA reporting requirements. The EPCRA reporting requirements apply to manufacturing facilities that

- Employ 10 or more full-time employees

- Manufacture or process over 25,000 pounds of any chemical or chemical category listed in the EPCRA, or use more than 10,000 pounds of any chemical or chemical category listed in the EPCRA

- Conduct selected manufacturing operations in the industry groups specified in the U.S. Government Standard Industrial Classification (SIC) Codes 20 through 39, including chemicals, petroleum refining, primary metals, fabricated metals, paper, plastics, and transportation equipment (see sidebar).

The EPCRA regulations require that eligible manufacturing facilities identify the toxic chemicals they released (from a list of more than 300 individual chemicals and 20 chemical categories); the quantity of each chemical released to the air, water, and land; and the quantity of each chemical transferred off site for treatment, disposal, or recycling. In response to the Pollution Prevention Act of 1991, facilities are also required to report additional information about waste management and source reduction activities. The reported data are stored in the TRI and in State files available to the public.

The TRI database provides the public with direct access to toxic chemical release and transfer data at the local, State, regional, or national level. The public can use the TRI data to identify potential concerns in local waterbodies or throughout the Nation. With TRI data, the public can work with industry and government to reduce toxic chemical releases and the risks associated with them.

Industry can use the TRI data to obtain an overview of use and release of toxic chemicals, to identify and reduce costs associated with toxic waste, to identify promising areas of pollution prevention, to establish reduction targets, and to measure and document progress toward chemical release reduction goals. The public access of the TRI data has prompted many facilities to work with their communities to develop effective strategies for reducing environmental and human health risks posed by toxic chemical releases.

Federal, State, and local governments can use the TRI data to identify hot spots, compare facilities or geographic areas, evaluate pollution control and prevention programs, and track progress in reducing waste. The Office of Water has used TRI data with other pertinent exposure and toxicity data to identify and prioritize contaminants in drinking water, to identify and quantify inputs of toxic chemicals into the Gulf of Mexico, and to compile data on toxic releases into municipal treatment plants.

The TRI database has some limitations. TRI captures only a portion of all toxic chemical releases nationwide because nonindustrial sources, such as dry cleaners and auto service stations, are not required to submit TRI data. In addition, the TRI data alone are not sufficient to calculate potential adverse effects on human health from toxic chemicals because TRI does not track exposure of the public to released chemicals.

The TRI data are available to the public online through the National Library of Medicine's TOXNET system and through the Right-to-Know Network (RTK NET), which is sponsored by the Unison Institute, a nonprofit organization. TRI data are also available on CD-ROM and on individual State diskettes. For information about obtaining TRI data, the public can call the TRI User Support Service (202-260-1531) or the EPCRA Information Hotline (1-800-535-0202).

TRI users can obtain additional information about health effects and ecotoxicity of chemicals in the TRI database from PC-TRIFACTS, an auxiliary software package developed by EPA.

Contaminated Sediment Strategy

In early 1993, EPA issued its Contaminated Sediment Management Strategy: A Proposal for Discussion. Then, in August 1994, the Strategy Document, *EPA's Contaminated Sediment Management Strategy*, was announced in the *Federal Register*. One of its main objectives is to describe EPA's current understanding of the extent and severity of sediment contamination. EPA's Contaminated Sediment Management Strategy describes actions that the Agency will take to accomplish the following four strategic goals: (1) prevent further sediment contamination that may cause unacceptable ecological or human health risks; (2) when practical, clean up existing sediment contamination that adversely affects the Nation's waterbodies or their uses, or that causes other significant effects on human health or the environment; (3) ensure that sediment dredging and dredged material disposal continue to be managed in an environmentally sound manner; and (4) develop and consistently apply methodologies for analyzing contaminated sediments. To accomplish these goals, EPA will continue to develop and improve methods for identifying contaminated sediments, to provide a basis for assessment of sediment contamination, to outline steps to reduce risk supported by sound science, and to outline a strategy for assessing the extent and severity of sediment contamination.

One of the initial steps to implement not only this strategy but to meet mandated statutory requirements to address and resolve contaminated sediment problems is to develop national inventories of contaminated sediment sites and pollutant sources (point and nonpoint). During the past 3 years, EPA's Office of Science and Technology has compiled the National Sediment Inventory (NSI), an extensive geographically referenced database of sediment quality monitoring and pollutant source information for the Nation's freshwater and estuarine ecosystems. The Site Inventory component of the NSI contains detailed monitoring data on sediment chemistry and biological effects collected by Federal and State agencies beginning in 1980. The Point Source Inventory component of the NSI contains over 22,000 individual records of point source discharges of 118 different chemicals from municipal, Federal, and industrial facilities in 1992. The NSI database will be continually updated and improved. Based on an evaluation of current data, OST will produce an assessment of the national extent and severity of sediment contamination across the country and present the results in a Report to Congress in early 1996.

For more information about the NSI, contact the OST Standards and Applied Science Division:

THE NATIONAL SEDIMENT INVENTORY documents the extent, severity, and causes of sediment contamination across country.

Nonpoint Source Information Exchange

The Nonpoint Source Information Exchange, housed at the Assessment and Watershed Protection Division of EPA's Office of Water, is designed to serve as a national center for the exchange of information concerning (1) the nature of nonpoint source pollution, (2) NPS management techniques and methods, and (3) institutional arrangements for the planning and implementation of NPS management including financial arrangements.

The Exchange contains two major activities: a technical bulletin, the *NPS News-Notes*, published approximately eight times per year, and the NPS Electronic Bulletin Board System (NPS BBS). The target audience for the *News-Notes* is State and local water quality managers although, with a circulation of over 10,000, other interested parties including public officials, environmental groups, private industry, citizens, and academics receive *News-Notes* regularly.

The NPS BBS, first opened in 1991, provides timely and relevant NPS and other information to a similar audience. There are more than 1,200 users of the NPS BBS who, through the system, can access several special interest areas: Agricultural Issues, Fish Consumption Advisories and Bans, Waterbody System Users Group, NPS Research, Watershed Restoration Network, Total Maximum Daily Loads, Coastal Nonpoint Source Pollution, and Volunteer Monitoring. Also available are on-line searchable databases such as the Clean Lakes Clearinghouse, *NPS News-Notes* database, the Fish Consumption Bans and Advisories database, and the National Registry of Watershed Projects.

Great Lakes Envirofacts

The Great Lakes National Program Office (GLNPO) is initiating a computer system development pilot effort called Great Lakes Envirofacts (GLEF) to assist managers and technical staff in developing strategies to reduce toxic chemical loadings. The keystone goal of GLNPO's data integration program is the development of a system to enable technical staff to access, display, analyze, and present Great Lakes multimedia and geographic information from their desk top, providing environmental decisionmaking support for Great Lakes Program managers. The GLEF pilot project will explore both the system requirements of Great Lakes Program staff and the technical means (hardware, software, and telecommunications) to begin realizing its keystone goal.

The GLEF will build upon the Envirofacts/Gateway system developed by EPA's Office of Information Resources Management (OIRM) Program Systems Division (PSD). The Envirofacts database stores environmental monitoring and program (e.g., PCS, TRIS, FINDS) information in a relational structure. Gateway is a graphical user interface that provides spatially referenced access to the Envirofacts database. The Great Lakes Envirofacts project will be the first implementation of the Gateway/Envirofacts concept, testing its capability and utility for the Great Lakes Program.

Other Information Clearinghouses & Electronic Bulletin Boards

Several other clearinghouses, electronic bulletin boards, newsletters, and information updates on water quality activities have been developed by EPA for use by State and local governments, Federal agencies, and the public. These include COASTNET bulletin board for coastal waters and estuary protection activities, the Clean Lakes Clearinghouse, the *Contaminated Sediment News* bulletin, and the Office of Science and Technology's Resource Center.

EPA's Water Channel

The Office of Water's Office of Wetlands, Oceans, and Watersheds has established the Water Channel on EPA's Internet site. The Water Channel broadcasts water information and tools for communities and American citizens to understand and use in managing their own environmental resources. It is a means to promote and strengthen partnerships to manage, protect, and restore America's water resources. Information is meant to flow from those who have it to those who need it.

You can get to know EPA's water programs and people. You can browse newsletters, fact sheets, brochures, publications, regulations, press releases, and congressional testimony. You can learn about the quality of our Nation's water resources and our environmental goals. You will get ideas about how you can get involved, like volunteer monitoring. You can choose from an array of opportunities to learn more by using the Wetlands and Drinking Water hotlines or ordering publications on-line. Those looking for technical assistance and data will find water quality monitoring methods, tools, and access to STORET water quality data. You can connect to countless other sources of environmental information at other Internet sites. You can send EPA comments, suggestions, or requests for information not yet available on the Water Channel.

The Water Channel offerings will continue to grow. Watch for new information, links to partners, homepages, and services. Visit frequently and stay in touch with EPA water programs at work across the Nation to help you manage and protect the environment.

The Water Channel utilizes EPA's public access servers with Internet connectivity. It can be accessed over the World Wide Web or Gopher. Enter the Universal Resource Locator (URL) for the EPA homepage (**http://www.epa.gov**) and go to EPA Offices and Regions and then to Office of Water or enter **http://www.epa.gov/OWOW** for direct access. Users need an Internet provider with an Internet Protocol (IP) address, at least a 386 or comparable personal computer, 4 megabytes of RAM, and tools for viewing the graphics on the World Wide Web.

For more information on the Water Channel, call Karen Klima at 202/260-7087 or send an e-mail to OW-OWOW-Internet-Comments@EPAMAIL.EPA.GOV. If you encounter problems with EPA's public access server, contact EPA via e-mail at internet_support@unixmail.rtpnc.epa.gov.

Nutrients in Ground Water and Surface Water of the United States—An Analysis of Data through 1992 by the U.S. Geological Survey

Historical data on nutrient (nitrogen and phosphorus) concentrations in ground and surface water samples were compiled from 20 study units of the U.S. Geological Survey's National Water-Quality Assessment (NAWQA) Program and five supplemental study areas. The resultant data sets contain analyses of about 12,000 ground water and more than 22,000 surface water samples. These data were interpreted on regional and national scales by relating the distributions of nutrient concentrations to ancillary data, such as land use, soil characteristics, and hydrogeology.

Nitrate was the nutrient of greatest concern in ground water. It is the only nutrient that is regulated by a national drinking water standard. Nitrate concentrations in ground water were elevated primarily in agricultural areas (see Figure 1). Concentrations in about 16% of the samples collected in agricultural areas exceeded the drinking water standard. Concentrations were highest in shallow ground water, less than 100 feet below land surface. The standard was exceeded in only about 1% of samples collected from public supply wells.

A variety of factors influenced nitrate concentrations in ground water beneath agricultural areas. Concentrations were higher in areas where soil and geologic characteristics promoted rapid movement of water to the aquifer. Elevated

Figure 1. Nitrate Concentrations in Ground Water Beneath Agricultural Areas in NAWQA Study Units.

VOL 12

58/5

R0039123

HIGHLIGHT HI GHT HIGHLIGHT

concentrations commonly occurred in areas underlain by permeable materials, such as carbonate bedrock or unconsolidated sand and gravel, and where soils are generally well drained.

In areas where water movement was impeded, denitrification might lead to low concentrations of nitrate in the ground water. Low concentrations were also related to interspersion of pasture and woodland with cropland in agricultural areas. Elevated nitrate concentrations in areas of more homogeneous cropland probably were a result of intensive nitrogen fertilizer application on large tracts of land. Because of the time involved for ground water to move vertically in some areas, the full effect of current nitrogen fertilizer applications might not be noted in some aquifers for many years. Likewise, the effects of implementing management practices to improve water quality might not be evident for many years.

Certain regions of the United States seemed more vulnerable to nitrate contamination of ground water in agricultural areas. Regions of greater vulnerability included parts of the Northeast, Midwest, and West Coast. The well-drained soils typical in these regions have little capacity to hold water and nutrients; therefore, these soils receive some of the largest applications of fertilizer and irrigation in the Nation. The agricultural land is intensively cultivated for row crops, with little interspersion of pasture and woodland. Regional patterns and the distribution of local characteristics could be useful in identifying areas of potential nitrate problems.

Nutrient concentrations in surface water also were generally related to land use. Nitrate concentrations were highest in samples from sites downstream from agricultural or urban areas (see Figure 2). However, concentrations were not as high as in ground water and rarely exceeded the drinking water standard. Elevated concentrations of nitrate in surface water of the northeastern United States might be related to large amounts of atmospheric deposition (acid rain). High concentrations in parts of the Midwest might be related to tile drainage of agricultural fields.

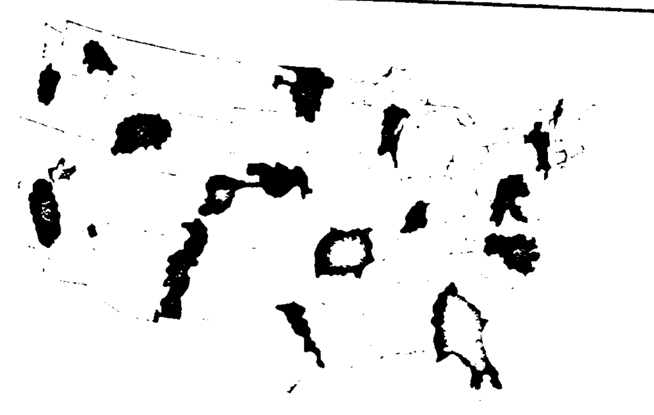

Figure 2. Nitrate Concentrations in Surface Water Downstream from Agricultural Areas in NAWQA Study Units.

VOL 12

58/6

R0039124

HIGHLIGHT HIGHLIGHT HIGHLIGHT

Ammonia and phosphorus concentrations were highest downstream from urban areas. These concentrations generally were high enough to warrant concerns about toxicity to fish and accelerated eutrophication. Recent improvements in wastewater treatment have decreased ammonia concentrations downstream from some urban areas, but the result has been an increase in nitrate concentrations. This condition limits the direct threat of toxicity but does not change the potential for eutrophication.

Information on environmental factors that affect water quality is useful to identify drainage basins throughout the Nation with the greatest vulnerability for nutrient contamination and to delineate areas where ground water or surface water contamination is most likely to occur. The results presented in this report suggest that the best management strategies will differ among regional areas of the Nation. Understanding the regional patterns and environmental factors that affect nutrient concentrations in ground water and surface water is critical for designing programs to manage and protect water resources.

Results from this study are summarized in the following report: David K. Mueller et al., 1995, *Nutrients in Ground Water and Surface Water of the United States—An Analysis of Data through 1992*, U.S. Geological Survey Water-Resources Investigation Report 95-4031, 74 pp. The report can be ordered from USGS Map Distribution, Box 25286, Bldg. 810, Denver Federal Center, Denver, CO 80025, phone 303-236-7477; FAX 303-236-1972.

TVA "Vital Signs" Monitoring

About 10 years ago, the Tennessee Valley Authority (TVA) began a thorough review of its traditional water quality monitoring efforts. Familiar issues—budget pressures and the "data-rich, information-poor" syndrome—were the motivating factors. From that initial review and subsequent critical scrutiny, TVA has developed a "vital signs" monitoring program that reports to the public each spring on the fishability, swimmability, and ecological health of 30 TVA reservoirs and major tributaries.

The annual report is a user-friendly magazine, *RiverPulse*, that is mailed to about 13,000 individuals who have called to request it and is distributed through marinas, parks, TVA visitor centers, and other public outlets. Feedback from readers indicates that this annual report is well received and very effectively communicates technical information to nontechnical audiences. Many of its features are being adopted by other organizations that report to the public on environmental conditions.

RiverPulse summarizes monitoring information collected during the previous spring, summer, and fall. Informal technical reports document monitoring methods, analyses, and results. The monitoring program integrates physical and chemical monitoring of streams and reservoir waters with quantitative evaluations of benthic invertebrate and fish communities to develop an ecological health rating for each lake. A sediment chemistry and toxicity component of the rating was eliminated in 1995 as a result of budget constraints. Fish tissue contamination monitoring and associated State-promulgated fish consumption advisories provide information on fishability, and results of bacteriological sampling at beaches and informal recreation areas are the basis for the swimmability ratings.

Copies of *RiverPulse* can be obtained by calling (615) 751-2333. More information on TVA's monitoring program can be obtained by leaving a message at this number, by calling Dr. Neil Carriker at (615) 751-7330, or by sending an e-mail message to ncarrik@mhs-tva.attmail.com.

Point Source Control Program

Treating Municipal Wastewater

Municipal treatment facilities receive wastewater from residential sources as well as from industry and storm water runoff. The array of pollutants that may be associated with these sources includes suspended solids, organics, pesticides, heavy metals, nutrients, acids, viruses, and bacteria.

Adequate treatment of municipal wastewater is important for the protection of the Nation's water resources and public health. Without adequate treatment, this pollution poses a serious threat to aquatic life, commercial and recreational opportunities, surface water drinking supplies, ground water drinking supplies, and the general health and stability of the Nation's stream, river, lake, estuarine, and coastal ecosystems.

The Clean Water Act requires municipalities to achieve treatment levels based on technology performance. The 1981 CWA amendments extended the deadline for eligible treatment plants to achieve "secondary treatment" to July 1, 1988. Secondary treatment removes at least 85% of several key conventional pollutants. If secondary treatment is not enough to meet water quality standards, the Clean Water Act mandates additional treatment as necessary.

Historically, under the Clean Water Act, EPA has been authorized to help municipalities solve their wastewater treatment problems by providing grants for construction. Since 1972, EPA, through the Construction Grants Program, has provided approximately $54 billion to municipalities to construct or improve their wastewater treatment systems.

In the 1987 Amendments to the Clean Water Act, Congress and the President agreed to phase out the Construction Grants Program. In its place, the State Revolving Fund (SRF) was created and has resulted in the creation of revolving loan funds in each State and Puerto Rico. The goal of the SRF program is to establish independent and permanent sources of funding in each State. Capitalization of these funds is provided by the Federal (80%) and State (20%) governments. Congress appropriated more than $10.3 billion through fiscal year 1995 for State Revolving Funds. In addition to providing loans for construction of wastewater treatment facilities, SRFs allow funding for many activities not previously eligible under the Construction Grants Program, including control of nonpoint source runoff and estuary protection projects.

THE STATE REVOLVING FUND PROGRAM provides grants to States to establish loan programs that finance a variety of water pollution control activities.

The Amendments of 1987 also included new water quality requirements. The primary programs with new enforceable requirements are those dealing with storm water, toxic discharges, and sludge use and disposal. The SRF loan program provides States with more discretion than ever before in selecting projects for funding. States are now able to finance projects they may consider to be of higher priority, such as nonpoint source, estuarine, combined sewer overflow, or storm water control projects. All States and Puerto Rico had approved SRF programs in place as of September 1990.

EPA has awarded over $11.1 billion to States to capitalize SRF programs since 1988. States have contributed about $2.2 billion to meet the 20% match requirement. In addition, 21 States have issued about $5.4 billion in leverage bonds to further capitalize their SRF programs. From these and other sources, capitalization of SRF programs totals about $19 billion through fiscal year 1995.

The Administration remains committed to the State Revolving Fund Program to continue capitalization of the program to a level such that 51 State programs are able to issue in excess of $2 billion in loans annually for the foreseeable future.

Funding Needs for Wastewater Treatment

The Needs Survey, a biennial report to Congress, is the primary mechanism for assessing municipal wastewater treatment needs nationwide. The 1992 Needs Survey focuses on the expanded CWA funding eligibilities under the SRF in the 1987 Amendments to the Clean Water Act. Models were used to supplement documented needs estimates for combined sewer overflows. Models were also used to develop preliminary urban storm water and agricultural and silvicultural nonpoint source pollution control implementation costs since very little documentation of specific projects or costs was available from the States.

EPA's needs estimates include those facilities and activities for which a water quality or public health problem could be documented using specific criteria established by EPA. The capital investment necessary to satisfy all categories of need is presented in Table 14-1. Costs for operation and maintenance are not eligible for SRF funding and therefore are not included. Additional nonconstruction estimates are included for program development costs associated with storm water and NPS control. The 1992 total documented and modeled needs are $137.1 billion to satisfy all categories of needs eligible for SRF funding for the design year (2012) population.

This amount included $50.1 billion in modeled needs for CSO, storm water, and NPS pollution control. For storm water and NPS, the estimates exclude operation and maintenance costs (O&M) since O&M costs are ineligible for SRF funding. However, O&M costs are the major costs associated with storm water and NPS program implementation. Only agriculture and silviculture NPS pollution control costs were estimated. Many types of NPS pollution were not addressed: abandoned mines, urban areas, septic systems, contaminated sediments, hydromodification, and atmospheric deposition.

The needs estimate for the Nation rose in constant dollars by $53.4 billion (39%) from 1990 to 1992. The increase was due to a variety of factors, primarily improved documentation of SRF eligibilities and the use of models to capture full CSO, as well as partial urban storm water and NPS costs.

Treating Industrial Wastewater

The Clean Water Act required EPA to establish uniform, nationally consistent effluent limitation guidelines for industrial discharges. At this time, EPA has established Best Available Technology Economically Achievable (BATEA) and Best Conventional Pollutant Control Technology (BCT) guidelines for about 28 industrial categories. EPA has also promulgated technology-based guidelines for approximately

15 additional secondary industries that represent Best Practicable Control Technology Currently Available (BPT) levels. EPA is studying an additional dozen industries for future guidelines development.

In addition to these technology-based requirements, EPA, in 1984, issued a policy on the water-quality-based control of toxic pollutants discharged by point sources. In 1985, EPA issued the *Technical Support Document for Water Quality-Based Toxics Control* to support the national policy. EPA updated and enhanced this document in 1991. Both the policy and guidance recommend using overall toxicity as a measure of adverse water quality impact and as a regulatory parameter. In 1989, EPA amended its NPDES regulations to clarify the use of effluent discharge limitations for whole-effluent toxicity in addition to specific toxic chemicals. The use of whole-effluent toxicity as a regulatory tool coupled with controls for specific chemicals provides a powerful means of detecting and controlling toxic problems.

Permitting, Compliance, and Enforcement

EPA and the States use rigorous permit conditions to control point source discharges from industrial and municipal wastewater treatment facilities. During the early 1980s, the rate of permit issuance fell behind the rate of permit expiration, and large backlogs of unissued permits developed. Efforts to remedy these backlogs have been largely successful, especially for major permits. Table 14-2 illustrates the status of permit issuance as of February 1993.

Once the permit is established, compliance with these conditions is essential for achieving water quality improvements. Despite examples of water quality improvements associated with upgrading municipal facilities, 10% of major municipal treatment plants are in significant noncompliance with applicable permit conditions. Industrial permittees have historically achieved a higher rate of compliance; 7% of industrial facilities are in significant noncompliance with their permit conditions.

EPA and States with approved NPDES programs are responsible for ensuring that municipal and industrial facilities comply with the terms of their discharge permits. Currently, 40 States have approval from EPA to administer their own NPDES programs. This responsibility includes issuing permits, conducting compliance inspections and other compliance monitoring activities, and enforcing compliance. EPA has the lead implementation responsibility in the remaining States. EPA and the States evaluate compliance by screening self-monitoring reports submitted by the permitted facility. Facilities that are determined to be in noncompliance are subject to Federal as well as State enforcement action.

Figure 14-1 illustrates rates of significant noncompliance based on statistics maintained by EPA from March 1988 through December 1994. Significant noncompliance is based upon violations of a permit, administrative order, and judicial order requirements. Examples of violations for permits include exceedances of monthly average effluent limits at least twice during a

VOL 12

5823

6-month period or any exceedance of limits set by an administrative order. Discharge monitoring reports or pretreatment schedules more than 30 days late are also considered in significant noncompliance. Significant noncompliance rates for municipal and industrial facilities jumped in FY90 primarily because, for the first time, EPA calculated noncompliance directly from its automated database. Therefore, if data are not entered into the Permit Compliance System in a timely manner, the system will automatically determine that the facility is not in compliance. EPA is continuing to refine its tracking of compliance with permit conditions to better reflect instances of noncompliance by the regulated community.

National Municipal Policy

Due to the generally poor municipal compliance record, and because of congressional concern over the performance of treatment works built primarily with Federal funds, EPA developed the National

INDUSTRIAL FACILITIES have a higher rate of compliance with discharge permits than do municipal facilities.

VOL 12

5824

R0039132

Municipal Policy (NMP) to address the failure of publicly owned treatment works (POTWs) to meet treatment levels required for compliance with the CWA. On January 23, 1984, the EPA Administrator signed the NMP into effect. The NMP clarified and emphasized EPA's resolve to ensure that municipalities comply with the Clean Water Act as quickly as possible, regardless of whether Federal grant assistance was available for treatment plant construction.

The deadline established for full compliance with the Clean Water Act was July 1, 1988. By this date, all municipal treatment facilities were to be in compliance with the secondary treatment requirement of Section 301(b)(1)(B) of the CWA or with more stringent limitations established to meet State water quality standards. Of the total universe of 3,731 major municipal facilities, 1,478 facilities were identified as requiring construction to meet the 1988 deadline. By July 1, 1988, all but 423 municipal facilities had achieved compliance with the requirements. Since the 1988 deadline, 188 facilities have come into compliance, and, of the remaining 235 facilities, all but 50 have been placed on enforceable compliance schedules. EPA is continuing to track the progress of these facilities in meeting the requirements of the CWA.

In the 1987 Water Quality Act amendments to the CWA, EPA was given authority to seek administrative penalties from permittees in noncompliance with the Act's requirements. EPA issued guidance and delegated the authority for issuing these orders to the regional level in August 1987. The first Administrative Penalty Order (APO) was issued in September 1987. Through October 1990, 396 APOs have been issued assessing a total of $7.5 million in penalties. These orders have been an effective tool in expeditiously addressing violations of the CWA and represent an integral component of EPA's overall enforcement strategy.

Controlling Toxicants

The 1987 amendments to the Clean Water Act reinforced both the water-quality-based and technology-based approaches to point source control, requiring EPA to develop and update technology-based standards and adding specific direction as to how water-quality-based limits should be used to achieve additional improvements. One of the Act's primary emphases lay in strengthening the Nation's toxics control program.

Identifying Waters Impaired by Toxicants

Section 304(l) of the CWA required States to develop lists of impaired waters, identify point sources and the amounts of pollutants they discharge that cause toxic impacts, and develop an individual control strategy (ICS) for each such point source. These ICSs are NPDES permits with new or more stringent limits on the toxic pollutants of concern. The individual control strategies must be accompanied by supporting documentation to show that the permit limits are sufficient to meet water quality standards as

VOL 12

5825

soon as possible but no later than 3 years after establishment of the ICS. The general effect of Section 304(l) was to immediately focus national surface water quality protection programs on addressing known water quality problems due entirely or substantially to point source discharges of Section 307(a) toxic pollutants. Under Section 304(l), EPA and States identified 678 facilities in the United States that were required to have individual control strategies. ICSs have been established for 593 of these facilities.

In developing lists of impaired waters under Section 304(l), States used a variety of available data sources (including State Section 305(b) reports). At a minimum, dilution analyses were conducted based on existing or readily available data. EPA asked States to assemble data quickly to report preliminary lists of waters, point sources, and amounts of discharged pollutants by April 1, 1988, in their Section 305(b) reports. These lists were then to be refined and expanded by the statutory deadline of February 4, 1989

Through the 304(l) effort, 529 waterbodies were identified as being impaired entirely or substantially by point source discharges of Section 307(a) toxic pollutants. In addition, 678 point sources were listed as being responsible for impairing the quality of those waters. There are also 18,770 waters on the "long" list that includes all waters impaired by any pollutant from either point sources or nonpoint sources. Currently, approximately 87% of the ICSs required are in place as EPA-approved or drafted NPDES permits. The long list will be used for long-term planning and setting of priorities for activities such as monitoring, total maximum daily load development, nonpoint source controls, and permit revisions.

EPA implements control measures for all toxic pollutants as part of its ongoing surface water program. Section 304(l) emphasized implementing point source controls to protect particularly impaired surface waters for priority toxic pollutants. EPA will continue identifying impaired waters and controlling the discharge of toxic and other pollutants through existing reporting, standards setting, and permitting programs.

Toxicity Testing

On March 9, 1984, EPA issued a policy designed to reduce or eliminate toxics discharge and help achieve the objectives of the Clean Water Act. The "Policy for the Development of Water Quality-Based Permit Limitations for Toxic Pollutants" (49 FR 9016) described EPA's integrated toxics control program. The integrated program consisted of the application of both chemical-specific and biological methods to address the discharge of toxic pollutants. To support this policy, EPA issued the *Technical Support Document for Water Quality-Based Toxics Control (TSD)* guidance. EPA continued the development of the toxics control program by revising the TSD in 1991 and by including some aspects of the policy in NPDES regulations at 40 CFR 122.44(d)(1) in June 1989.

Toxicity reduction evaluations (TREs) identify and implement whatever actions are needed to reduce

VOL 12

5826

R0039134

VOL 12

51 jurisdictions include ... effluent ... criteria in ... discharge permits.

effluent toxicity to the levels specified in the permit. TREs combine toxicity testing, chemical analyses, source investigations, and treatability studies to determine either the actual causative agents of effluent toxicity or the control methods that will reduce effluent toxicity. EPA is currently documenting successful TREs conducted by permittees, States, and EPA researchers. Methods and procedures for conducting TREs are described in several EPA guidance documents and referenced in the TSD.

In December 1994, EPA conducted a survey of 50 States, 7 Territories, and 3 Tribes to determine the extent of implementation of whole effluent toxicity (WET) controls for industrial and municipal point sources. Fifty-one jurisdictions incorporate WET limits in discharge permits based on numeric criteria or narrative criteria for toxics. Fifteen jurisdictions have numeric WET criteria (acute and/or chronic criteria) in their standards.

The National Pretreatment Program

29 STATES have EPA ... to ad... pret... program.

The primary goal of the National Pretreatment Program is to protect POTWs and the environment from the adverse impact that may occur when toxic, hazardous, and concentrated conventional wastes are discharged into sewer systems from industrial sources. To achieve this goal, the EPA has promulgated national pretreatment standards for pollutants that: (1) interfere with the operation of a POTW, including interference with its use or disposal of municipal sludge; or (2) pass through the POTW and contaminate the receiving stream or are otherwise incompatible with the operation of the treatment works. In addition, the program is intended to improve opportunities to recycle and reclaim municipal and industrial wastewaters and sludges. The prevention of interference, the prevention of pass-through, and the improvement of opportunities to recycle wastewater and sludge are the three regulatory objectives of the National Pretreatment Program. These objectives are accomplished through a pollution control strategy with two elements:

- **National Categorical Standards:** National technology-based standards developed by EPA Headquarters reflecting best available technology (BAT) in establishing effluent limits for the 126 "priority pollutants" as well as for conventional and nonconventional pollutants for specific industrial categories.

- **Prohibited Discharge Standards:**

General Prohibitions: National regulatory prohibitions established by EPA against pollutant discharges from any nondomestic user that cause pass-through or interference at the POTW.

Specific Prohibitions: National regulatory prohibitions established by EPA against pollutant discharges from any nondomestic user that cause: (1) fire or explosive hazard, (2) corrosive structural damage, (3) interference due to obstruction, (4) interference due to flow rate or

5827

concentration, (5) interference due to heat, (6) interference from petroleum-based oil, and (7) acute worker health and safety problems from toxic gases.

Local Limits: Enforceable local effluent limitations developed by POTWs on a case-by-case basis to reflect site-specific concerns and implement the Federal general and specific prohibited discharge standards as well as State and local regulations.

To ensure the success of the pretreatment program, EPA also issues guidance documents and has conducted scores of training seminars to assist POTWs in developing, implementing, and enforcing effective pretreatment programs.

The primary focus for pretreatment implementation is at the local level since the POTW is in the best position to regulate its industrial users. States may become involved in pretreatment implementation through a formal approval process in which the Federal Government transfers its oversight responsibilities to the State. The Federal Government, through the EPA, is involved in pretreatment through standard setting, policy development, and oversight of program implementation by approved States and POTWs in States without approved pretreatment programs. At present, 28 States have received approval from EPA to administer the pretreatment program, including five States that have chosen to directly regulate the industrial community in their States in lieu of local program approval and implementation. In addition, 1,481 local programs have been approved by either EPA or approved States, and another 50 programs are under development. The pretreatment program currently regulates approximately 30,500 significant industrial users (SIUs).

On July 24, 1990, the EPA promulgated the Domestic Sewage Study (DSS) final rule, which implements the recommendations made in the DSS. Specifically, the rule is designed to improve the control of hazardous wastes discharged to POTWs as well as strengthen the enforcement of pretreatment program requirements. In addition, the rule requires that POTWs conduct toxicity testing of their effluents. A continuing task will be to integrate the implementation of these requirements into the normal operations of the POTWs' pretreatment programs.

The environmental accomplishments of the National Pretreatment Program have been significant. Nationwide, EPA estimates that toxic pollutant loadings to POTWs have decreased by up to 75% through pretreatment. In many cases, the effects on surface water and sludge have been dramatic. Between 1975 and 1985, for example, 15 POTWs discharging to San Francisco Bay decreased their overall metals loadings by 80%, despite a 15% increase in POTW flows. In Wisconsin, 14 of 24 POTWs reported marked decreases in average total metals concentrations in their sludge after approval of their local pretreatment programs.

The compliance status of industrial users and POTWs is an indicator of the programmatic success of pretreatment implementation. Based

> THE PRETREATMENT PROGRAM regulates approximately 30,500 significant industrial users discharging into POTWs.

> EPA ESTIMATES that toxic pollutant loadings to POTWs have decreased by up to 75% through pretreatment.

VOL 12

5828

R0039136

on data reported by POTWs or States, approximately 54% of significant industrial users of sewage treatment plants are in significant noncompliance with discharge standards and/or reporting and self-monitoring requirements. This compares with a rate of 6% significant noncompliance for the major industries in the NPDES program, which discharge directly to waterbodies. According to data in EPA's national database, 39% of POTWs are failing to implement at least one significant component of their approved pretreatment programs.

EPA has focused its oversight and enforcement resources on ensuring that local municipalities properly implement their approved programs. Toward that end, on October 4, 1989, EPA announced the National Pretreatment Enforcement Initiative against cities for failure to adequately implement their approved pretreatment programs. In this action, EPA joined with several States in bringing civil judicial suits or administrative penalties against 61 cities. This effort was designed to alert cities as to their requirements under the pretreatment program and to ensure adequate implementation of the program. A followup announcement was made on May 1, 1991, containing 755 additional actions against both POTWs and significant industrial users.

In July 1991, EPA issued a report to Congress on the effectiveness of the pretreatment program as required under Section 519 of the CWA. This report analyzed the major strengths and weaknesses of the program and has provided direction for improving the program.

Managing Sewage Sludge

The need for effective sewage sludge management is continuous and growing. In the United States, the quantity of municipal sewage sludge produced annually has almost doubled since 1972. Municipalities currently generate approximately 5.3 million dry metric tons of wastewater sludge per year, or approximately 47 pounds per person per year (dry weight basis). Improper sewage sludge management could lead to significant environmental degradation of water, land, and air as well as adverse human health conditions.

Prior to the 1987 amendments to the Clean Water Act, the authorities and regulations related to the use and disposal of sewage sludge were fragmented and did not provide States and municipalities with adequate guidelines on which to base sludge management decisions. There was no single legislative approach or framework for integrating the various Federal laws to ensure that sludge would be used or disposed of in a consistent or environmentally acceptable manner.

Section 406 of the Water Quality Act of 1987, which amends Section 405 of the Clean Water Act, for the first time sets forth a comprehensive program for reducing the environmental risks and maximizing the beneficial uses of sludge. The program is based on the development of technical requirements for sludge use and disposal and the implementation of such requirements directly through the rule and through permits.

VOL 12

5829

R0039137

In May 1989, EPA promulgated regulations for including sewage sludge conditions in NPDES permits and for issuing sludge-only permits. These rules also outline the requirements for States to seek EPA approval to implement the new statutory requirements.

EPA is the permitting authority for sewage sludge since there are currently no approved State programs. Initially, EPA is relying strongly on the self-implementing nature of the technical regulations. In February 1993, EPA amended the permitting regulations to establish a tiered permit application schedule. EPA is focusing its initial permitting efforts on

- Sewage sludge incinerators (which require site-specific pollutant limits)
- Facilities posing a threat to human health and the environment
- Facilities needing a permit to promote beneficial use
- Facilities with NPDES permits up for renewal.

In implementing the new sewage sludge requirements, EPA is also focusing on approving State programs and educating the general public and the regulated community.

On February 19, 1993, EPA published the Standards for the Use or Disposal of Sewage Sludge. This regulation pertains to land application, incineration, landfilling, and surface disposal of sewage sludge. The standards for each use or disposal practice consist of general requirements, pollutant limits, management practices, and operational standards. The final rule also includes monitoring, recordkeeping, and reporting requirements.

Standards apply to publicly and privately owned treatment works that generate or treat domestic sewage sludge, as well as to any person who uses or disposes of sewage sludge from such treatment works. The rule requires compliance with these standards as expeditiously as possible but not later than 12 months after the date the rule is published, or within 24 months of publication if construction of new pollution control facilities is required to comply with the regulations.

New Initiatives in Point Source Control

Combined Sewer Overflow Control

Currently about 1,100 communities nationwide use combined sewer systems, which are designed to carry sanitary and industrial wastewater and storm water. These facilities are mainly located in older cities in the Northeast, the midwest, and along the west coast. Combined sewer overflows occur when the capacity of the combined sewer system is exceeded during a storm event. During these storm events, part of the combined flow in the collection system is discharged untreated into receiving waters. The overflows may contain high levels of suspended solids, floatables, heavy metals, nutrients, bacteria, and other pollutants. Pollution from CSOs can pose health risks, degrade

VOL 12

5830

R0039138

the ecology of receiving waters, and impair the designated use of water resources.

EPA published the first National Combined Sewer Overflow Control Strategy in the *Federal Register* on September 8, 1989, at 54 FR 37370. Although implementation of the 1989 strategy resulted in some progress toward controlling CSOs, EPA determined, in August 1991, that implementation of the 1989 strategy was not proceeding rapidly enough.

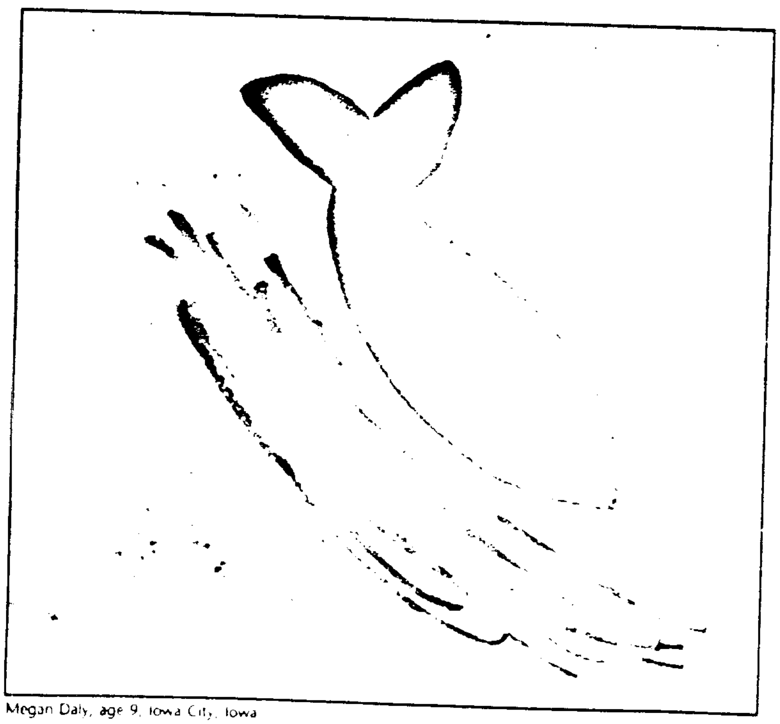
During the summer of 1992, EPA conducted a negotiated policy dialogue with key stakeholders. Based on the negotiated policy dialogue and subsequent negotiations between municipal and environmental groups and States, a CSO Framework Document was submitted to EPA's Office of Water for consideration as part of the development of a draft CSO policy. Although the framework was not the result of consensus among the negotiating parties, significant agreement was reached, allowing OW to use the framework as the basis to develop a draft CSO policy.

On December 22, 1992, the Assistant Administrator for Water and the Assistant Administrator for Enforcement issued a draft CSO Control Policy (dated December 18, 1992) for comment. The final CSO Control Policy was published in the *Federal Register* on April 19, 1994 (59 FR 18688).

The main purposes of the Policy are to elaborate on the 1989 National CSO Control Strategy and to expedite compliance with the requirements of the Clean Water Act.

The Policy is being developed to provide guidance to permittees with CSOs, NPDES authorities, and State water quality standards authorities on coordinating the planning, selection, sizing, and construction of CSO controls that meet the requirements of the CWA and to allow for public involvement during the decisionmaking process.

The CSO Policy represents a comprehensive national strategy to ensure that municipalities, NPDES permitting authorities, water quality standards authorities, and the public engage in a comprehensive and coordinated planning effort to achieve cost-effective CSO controls that ultimately meet appropriate health and environmental objectives, including compliance with water quality standards. The Policy recognizes the site-specific nature of



Megan Daly, age 9, Iowa City, Iowa

VOL 12

5831

R0039139

CSOs and their impacts and provides the flexibility necessary to tailor controls to local situations.

Contained in the Policy are provisions for developing appropriate site-specific NPDES permit requirements for all combined sewer systems that overflow as a result of wet weather events and enforcement initiatives to require the immediate elimination of overflows that occur during dry weather and to ensure that the remaining CWA requirements are complied with as soon as practicable. The 1992 Needs Survey modeled the cost of compliance with the draft 1992 CSO Policy. The Needs Survey estimated that the national capital cost of CSO corrections will be $41.2 billion. The modeled estimate compares to the State-documented costs of $22.4 billion for 375 of the approximately 1,300 CSOs needing correction.

EPA is preparing a number of guidance documents to assist in the implementation of the final policy. Specific programmatic areas that this guidance will address are implementing minimum CSO control measures by all communities with CSOs; monitoring and modeling of combined sewer systems, CSO discharges, and receiving water impacts; preparing long-term CSO control plans by CSO communities; and drafting NPDES permit requirements for CSO discharges by EPA and State NPDES permit writers.

NPDES Stormwater Controls

Since 1972, State and EPA efforts under the NPDES program have traditionally focused on controlling pollutant discharges from POTWs and industrial process wastewaters. As these sources of pollution came increasingly under control, the need for controlling pollutants in stormwater point source discharges became more critical to efforts to achieve the goals of the CWA. As reflected in this report, stormwater discharges from a variety of sources, including storm sewers discharging urban runoff, construction site runoff, runoff from resource extraction activities, and runoff from land disposal sites, are major sources of use impairment.

Section 402(p) of the CWA amendments of 1987 established a timetable and framework for EPA to address stormwater discharges under the NPDES program. Section 402(p) required EPA to develop a two-phase program to control point source discharges of storm water. On November 16, 1990, EPA promulgated permit application requirements for the first phase for discharges from municipal separate storm sewer systems serving populations of 100,000 or more and for stormwater discharges associated with industrial activity including:

- Manufacturing facilities
- Construction operations or activities disturbing 5 or more acres
- Hazardous waste treatment, storage, and disposal facilities
- Landfills
- POTWs with approved pretreatment programs and/or discharging over 1 million gallons per day

VOL 12

5832

R0039140

- Recycling facilities
- Power plants
- Mining operations
- Some oil and gas operations
- Airport facilities
- Certain transportation facilities (such as vehicle maintenance areas).

Permits were required to be issued for these sources, for the most part, by October 1, 1993.

For the second phase, EPA prepared a study that identified potential stormwater discharges, not regulated under Phase I, to be controlled to protect water quality. The study, entitled "Storm Water Discharges Potentially Addressed by Phase II of the National Pollutant Discharge Elimination System Storm Water Program," was submitted to Congress in March 1995. The study identifies the nature and extent of pollutants in these discharges and proposes one possible option for controlling these discharges.

To explore additional options for a Phase II stormwater program, EPA convened a Federal Advisory Committee subcommittee comprised of a broad spectrum of stakeholders. The subcommittee will provide EPA with recommendations for a Phase II stormwater program by December 1996. EPA is required under a consent decree to propose regulations by September 1, 1997, and finalize regulations by March 1, 1999.

Pollution Prevention

EPA has established an Office of Pollution Prevention that works with other program offices to improve pollution prevention activities within the Agency. For example, an Agency pollution prevention policy has been developed, and a strategy to address pollution prevention in manufacturing and chemical use has been drafted. Future strategies will focus on the municipal water and wastewater, agricultural, energy, and transportation sectors. A subcommittee comprising representatives from EPA Headquarters and Regions has been formed to develop an Agency-wide training strategy to ensure that pollution prevention concepts are integrated into all Agency activities.

In terms of the point source control program, the Agency's draft pollution prevention strategy recognizes the importance of permitting and enforcement activities and will continue support for a strong program in these areas. Training is being provided to familiarize NPDES permit writers with pollution prevention opportunities, how their permit decisions can affect other media, and how to effectively communicate the concept of pollution prevention to industrial managers.

Nonpoint Source Control Program

Background

Nonpoint source pollution generally results from land runoff, atmospheric deposition, drainage, or seepage of contaminants. Major sources of nonpoint pollution include agricultural runoff, runoff from urban areas, and runoff from silvicultural operations. Siltation and nutrients are the pollutants responsible for most of the nonpoint source impacts to the Nation's surface waters. These diffuse sources are often harder to identify, isolate, and control than traditional point sources. As a result, from 1972 to 1987, EPA and the States placed primary focus on addressing the obvious problems due to municipal and industrial discharges: issuing permits for point source discharges, then inspecting, monitoring, and enforcing those permits to ensure that point sources met the Clean Water Act requirements.

Sections 208 and 303(e) of the Clean Water Act of 1972 established the initial framework for addressing nonpoint sources of pollution. States and local planning agencies analyzed the extent of NPS pollution and developed water quality management programs to control it with funds provided by EPA under Section 208. Best management practices were evaluated, assessment models and methods were developed, and other types of technical assistance were made available to State and local water quality managers.

The National Section 319 Program

In 1987, Congress enacted Section 319 of the Clean Water Act, which established a national program to control nonpoint sources of water pollution. Section 319 created a three-stage national program to be implemented by the States with Federal approval and assistance. States were to address nonpoint source pollution by (1) developing nonpoint source assessment reports, (2) adopting nonpoint source management programs, and (3) implementing the management programs over a multiyear timeframe.

All States and Territories now have EPA-approved nonpoint source assessments. EPA has also fully approved 55 State nonpoint source management programs and has approved the high-priority portions of all remaining State management programs.

Section 319 also authorizes EPA to issue annual grants to States to assist them in implementing their EPA-approved programs. From FY90 through FY95, Congress appropriated approximately $372 million for Section 319 assistance. EPA first issued guidance on the award and management of Section 319 funds in February 1991 following extensive public comment. In June 1993 the guidance was updated to incorporate suggestions from EPA Regions and a workgroup of State program managers and lessons learned during 3 years of awarding and managing Section 319 grants. The guidance encourages States to focus Section 319 funds on high-priority activities including:

- Controlling particularly difficult or serious nonpoint source problems, including, but not limited to, problems resulting from mining activities
- Implementing innovative methods or practices for controlling nonpoint sources of pollution, including regulatory (e.g., enforcement) programs
- Controlling interstate nonpoint source pollution problems
- Carrying out ground water quality protection activities that are part of a comprehensive nonpoint source pollution control program
- Addressing nationally significant, high-risk nonpoint source problems and focusing implementation activities in priority watershed or ground water areas
- Comprehensively integrating existing programs to control nonpoint source pollution
- Providing for monitoring and evaluation of program effectiveness, including using water quality monitoring protocols
- Demonstrating a long-term commitment to building the institutions necessary for effective nonpoint source management
- Emphasizing pollution prevention mechanisms
- Protecting particularly sensitive and ecologically significant waters (e.g., wetlands, estuaries, wild and scenic rivers, exceptional fisheries)
- Promoting comprehensive watershed management
- Providing for the use of antidegradation provisions and other measures necessary to ensure that population growth, new development, and new or expanded economic activity do not result in impairment of high-quality waters and waters currently meeting water quality standards
- Addressing urban storm water that is not subject to NPDES permit requirements
- Promoting implementation of coastal nonpoint source management measures developed pursuant to Section 6217(g) of the Coastal Zone Act Reauthorization Amendments of 1990.

Roughly half of each State's annual award supports statewide program activity (staffing, public education and outreach, technical assistance) and half supports specific projects to prevent or reduce nonpoint source pollution at the watershed level.

EPA and the States have recently begun a process to examine and improve national and State nonpoint source programs to enhance program processes as well as substantially improve water quality. As a first step, EPA, in close cooperation with the States, developed additional guidance in April 1995 that provides greater flexibility to the States for strengthening and implementing their nonpoint source management programs.

Funding under Section 319 is also available to American Indian Tribes with approved nonpoint source assessment and management programs. In September 1994, EPA issued *A Tribal Guide to the Section 319(h) Nonpoint Source Grant Program* to provide Tribes with an overview of the Section 319(h) grant process and to assist Tribes in working with EPA Regions to meet the basic requirements for grant eligibility.

Section 319 National Monitoring Program

EPA developed the Section 319 National Monitoring Program to improve technical understanding of nonpoint pollution and the effectiveness of various nonpoint source control technologies. This program selects watershed projects that consistently monitor water quality and land management with standardized protocols for 6 to 10 years. As of June 1995, EPA had approved and funded 11 projects in the States of Vermont, Wisconsin, Pennsylvania, North Carolina, Michigan, Iowa, Nebraska, Arizona, Illinois, Washington, and California. EPA has also funded a pilot ground water demonstration project in Idaho. Several of these projects are summarized here.

The Lake Champlain, Vermont, project is a paired watershed study that will be carried out cooperatively by the University of Vermont and the Vermont Department of Environmental Conservation. The study is designed to examine the effectiveness of best management practices installed in two treatment watersheds to control sediment, nutrients, and bacteria contributions from livestock. The study calls for 2 years of pretreatment data collection, 1 year of monitoring during implementation of nonpoint controls, and 3 years of postimplementation monitoring. Data will be collected on a number of parameters, including total suspended solids, total phosphorus, total Kjeldahl nitrogen, fecal coliform, water temperature, dissolved oxygen, conductivity, fish, and macroinvertebrates. Land use and agricultural activity will also be monitored intensively in each watershed.

Otter Creek, Wisconsin, is a low-gradient warm water stream in the Sheboygan River watershed, which drains to Lake Michigan. Land use in the watershed is primarily agricultural. Data collected in 1992 indicated that the stream is highly degraded, impacted by nonpoint sources from barnyards, upland erosion, manure spreading, streambank erosion, and pastures along the creek. Habitat degradation—e.g., lack of cover, disturbed banks, and an absence of pools—also contributes to the stream's problems. The project, which includes a paired watershed and upstream-downstream studies, will encompass the monitoring of chemical, physical, and biological parameters and the implementation of nonpoint source controls. A number of State and Federal agencies are cooperating on this project. The Wisconsin Department of Natural Resources is providing technical assistance and has administrative and monitoring responsibilities; the USGS is carrying out chemical and physical monitoring; Sheboygan County is providing cost-share assistance and designing nonpoint source controls; and U.S. Department of Agriculture Soil Conservation Service (USDA-SCS), University of Wisconsin Extension, and USDA's Agricultural Stabilization and Conservation Service (ASCS) will also assist in implementation of the project.

The Sny Magill watershed project in Iowa incorporates paired watershed and upstream-downstream studies to monitor and assess improvements in water quality resulting from the implementation of nonpoint source controls. Land use in the Sny Magill watershed, the study site in the paired watershed study, is entirely agricultural with no industrial or urban areas. Land use consists predominantly of cropland (corn, oats, and alfalfa), pasture, and forest. Sediment is the major pollutant but nutrients, pesticides, and animal waste are also of concern. The USDA will provide technical assistance, cost sharing, and educational programs to assist agricultural producers in implementing nonpoint source control measures such as sediment control, stream corridor management improvements, and animal waste management systems. Land treatment application will be coordinated with water quality monitoring.

The Bloody Run watershed (a neighboring watershed of approximately the same size) serves as the paired comparison watershed, or control site. Primary monitoring sites were established on both watersheds to measure discharge and suspended sediment. Other sites on both creeks will be sampled for chemical and physical water quality variables on a weekly to monthly basis. A habitat assessment will be conducted along stretches of both stream corridors annually, fishing surveys will be conducted annually, and biomonitoring of macroinvertebrates will be performed bimonthly.

The Long Creek project is located in south-central North Carolina. The watershed contains mixed agricultural and urban/industrial land use. Long Creek serves as the primary water supply for Bessemer City (population 5,000). Sediment from eroding cropland is the major problem in the upper third of the watershed (above the water supply intake). Long Creek is impaired mainly by bacteria and nutrients from urban areas and animal holding facilities below the intake. Proposed nonpoint controls include implementing the land use restrictions of the State watershed protection law for areas above the water supply intake, erosion and sediment controls, animal waste management, and livestock exclusion. Water quality monitoring will include a single station before and after improved erosion control near the water intake, an upstream/downstream design on the Creek above and below the dairy farm, and a paired watershed design at a cropland runoff site on the dairy. Continuous and grab samples will be collected at various sites to provide the data needed to assess the effectiveness of the nonpoint controls.

The Morro Bay watershed, located on the central coast of California, is an important biological and economic resource. Morro Bay estuary is considered to be one of the least altered estuaries on the California coast. However, heavy development activities have resulted in an increase of nonpoint source pollutants entering the watershed. The nonpoint source pollutants of primary concern include sediment, bacteria, metals, nutrients, and organic chemicals. At present rates of sedimentation, Morro Bay could be lost as an open water estuary within 300 years. Not only has the accelerated sedimentation rate negatively impacted fish and macroinvertebrate species, it has also resulted in significant economic losses to the oyster industry. This project was developed to characterize the sedimentation rate and other water quality conditions in one of the Bay's tributaries, evaluate the effectiveness of several best management practices in improving water and habitat quality, and evaluate the overall water quality at selected sites within the watershed.

Reports on Section 319 Activities

As required by Congress, EPA published a report about Section 319, *Managing Nonpoint Source Pollution*, in 1992. This report described the Section 319 Program, summarized the State nonpoint source assessment reports submitted to EPA, and described Regional and State activities implemented to control nonpoint source pollution. In 1994, EPA published *Section 319(h) Success Stories*, which provided examples of successful solutions to nonpoint source pollution problems from States, Territories, and Tribes. The described projects include information and education programs, streambank stabilization projects, animal waste management projects, and urban runoff projects.

Nonpoint Source Management Programs and Implementation

The States, local governments, community groups, and EPA Regions have initiated many innovative projects across the Nation to manage nonpoint source pollution problems. The projects described in this section exemplify the diversity of approaches that have been applied to NPS pollution prevention and control. In some cases, prevention or control is only beginning. In other situations, prevention and/or control measures have been in place long enough to show significant results. For additional information about the following projects, please contact Steve Dressing at (202) 260-7110.

North and South Rivers Watershed, Massachusetts

The closing of shellfish beds contaminated from bacterial pollution concerned many citizens in the North and South Rivers watershed, located south of Boston above Plymouth. This concern propelled the North and South Rivers Watershed Association into action, assembling volunteers to sample water quality before, during, and after rainstorms to determine the extent and sources of bacterial contamination. The volunteer monitors found that bacterial pollution, which was particularly widespread after rainfalls, was caused primarily by failing septic systems, stormwater discharges, illegal septic tie-ins, and roosting birds.

Funding for the monitoring was provided by a Section 319 grant of approximately $35,000 and other private funding sources. As part of their project, the group worked with individual polluters to correct situations and with the local boards of health to enforce local ordinances. As a result, the volunteers made great progress in cleaning up both the North and South Rivers. In addition, the data gathered throughout the project will supplement that of the Massachusetts Division of Marine Fisheries, the agency that determines the schedule for additional shellfish harvesting days.

Statewide Stormwater Runoff Control, New York

Although many waterbodies in New York suffer from stormwater runoff in developed areas, New York chose to focus on preventing new development from causing further problems. With approximately $285,000 in Section 319 funds over several years, the State has established an extensive information and education program to address stormwater runoff from new development.

The 319 grants have provided funding for a number of projects. These projects include reprinting an urban erosion and sediment control manual, which contains standards and specifications for erosion and sediment control measures common to construction sites; production of a State Department of Environmental Conservation document on reducing the impacts of stormwater runoff from new development; enabling Department of Conservation staff to work directly with local governments and assisting them in developing local ordinances; conducting a variety of training courses on erosion and sediment control; development of a cooperative agreement that created the Sea Grant Extension storm drain stenciling program; and development of a video entitled *Luck Isn't Enough: The Fight for Clean Water.*

Mammoth Cave National Park, Kentucky

The Mammoth Cave National Park is a major tourist site, attracting over 2 million visitors annually. However, the unusual geology that attracts visitors to the park also makes it particularly vulnerable to poor water quality. Instead of flowing into surface streams, rain falling within the karst (limestone formation) sinkhole plain in and around the park flows into some 15,000 active sinkholes. The water travels through underground streams and caves, including Mammoth Cave, before emerging as spring water in the Green River. In the past several years, the State has become concerned that water quality degradation from intensive agriculture (due to excessive nutrients and bacterial contamination) could seriously affect the area.

The Mammoth Cave/Karst Area Water Quality Project was designed to reduce pollution in the park area and the surrounding karst sinkhole plain. The Kentucky Division of Water used part of its Section 319 grant to support the project's water quality monitoring, technical assistance, and installation of nonpoint source controls on demonstration farms in fiscal years 1991 through 1993. Activities were coordinated by a technical advisory committee formed with representatives from a number of State government agencies, citizens, and land users. Other agencies involved with the project include ASCS, SCS, National Park Service, and Tennessee Valley Authority.

Nolichucky River Watershed, Tennessee

Concern over nonpoint source water pollution from livestock production prompted Tennessee to target five subwatersheds in the Nolichucky River watershed. Animal waste systems were installed to store animal wastes and manure, which farmers later use to fertilize crops. A Section 319 grant of $58,000 provided assistance for installing best management practices in the watershed and also allowed project staff to monitor the water quality to measure the effectiveness of management practices. A year after installation, the Tennessee Department of Health found statistically valid improvements in benthic habitat in two watersheds.

Nanticoke Watershed, Delaware

Trap Pond in the Nanticoke watershed is the recreational focus for Trap Pond State Park. Increasing bacterial contamination and symptoms of accelerated eutrophication and algal blooms were evident as water quality in the lake became degraded. Two probable causes were identified: a direct discharge from an underground septic system and livestock with direct access to the stream. The problem with the leaking septic system was corrected and a Section 319 grant of $84,000 was awarded to implement animal waste management systems and nutrient management plans on farms throughout the watershed. All of the producers fenced livestock out of streams and some 98% of the producers installed manure storage facilities, buffer strips, and other best management practices.

West Lake Reservoir, Iowa

West Lake is the surface reservoir for Osceola and Woodburn, cities located in south-central Iowa. The lake was impaired by sediment, pesticides, and nutrients primarily from row crop agriculture. A Section 319 grant of nearly $170,000 was awarded for program staffing and implementing best management practices. Best management practices such as no-till and integrated crop management reduced sediment delivery and herbicide levels to the lake. In addition, a voluntary atrazine ban assisted in the lake's recovery.

Big Sioux Aquifer, South Dakota

The Big Sioux Aquifer and other smaller surface aquifers lie under approximately 1,000 square miles of eastern South Dakota. The aquifers supply drinking water to about one-third of the State's population. Although no widespread pollution problem existed, studies had uncovered isolated cases of nitrate contamination in the aquifer. With a grant from Section 319 funds and contributions from citizens and other organizations, the East Dakota Water Development District (EDWDD) began the Big Sioux Aquifer Protection Project. The goal of the project was to protect the Big Sioux Aquifer and other sensitive aquifers from contamination through information and education efforts and the development of local zoning ordinances.

As part of the project, the EDWDD also identified shallow aquifers vulnerable to contamination; located 30 public water supply wells within the project area; gathered information about the public water supply wells to help delineate a wellhead protection area for each one; installed 48 monitoring wells within nine wellhead protection areas to provide an early detection system; and used the Farm*A*Syst Program to inform landowners in rural areas about threats to their domestic wells. The group also developed a model ground water protection ordinance; as of August 1993, two cities and nine counties had adopted similar ordinances.

Pearl Harbor Bay Watershed, Hawaii

Soil erosion and heavy siltation in the East Loch of Pearl Harbor prompted the U.S. Navy to request that the South Oahu Soil and Water Conservation District hold an interagency meeting to explore ways to prevent soil erosion from all land uses in Hawaii. As a result of the meeting, the Pearl Harbor Estuary Program Interagency Committee (PHEPIC) was formed; its membership consisted of 17 agencies and groups.

Through the use of Section 319 funds in concert with other monies, PHEPIC began a public education and information campaign. As part of these efforts, a storm drain stenciling project was undertaken to raise public awareness about how storm drains are connected directly to streams and the ocean. Section 319 funds were also used in cooperation with Hawaii's Department of Transportation and Department of Highways in a demonstration project to restore a severely eroded site adjacent to the Pearl Country Club. This project involved revegetation of eroding roadside cuts with drought-tolerant, low-maintenance vegetation.

Funding for Nonpoint Source Control

In addition to Section 319 funds, several States have taken advantage of State Revolving Funds to provide loans to finance nonpoint source and other water pollution control programs. SRFs were originally established to assist States in upgrading their sewage treatment systems, but the 1987 amendments to the Clean Water Act provide States with the opportunity to use these funds for nonpoint source control. SRF loans are particularly suitable for funding structural BMP construction, such as stormwater detention ponds and manure storage structures.

Numerous States, including Washington, California, Delaware, and Ohio, are using SRF loans to fund a wide variety of nonpoint programs. Approved projects will retrofit failed septic tanks, construct stormwater management structures, remediate leaking underground storage tanks, and build poultry composting facilities. As States meet sewage treatment system upgrade requirements, SRF funds will become increasingly available to address nonpoint source problems.

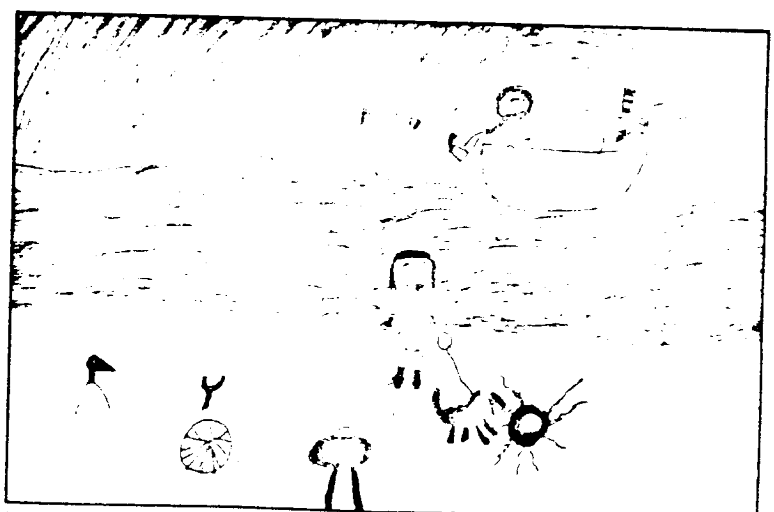
Coastal Nonpoint Pollution Control Program

As this report shows, serious water quality problems associated with nonpoint pollution still remain. The shift in population toward the coasts and associated development pressures moved Congress to provide States with new information and tools to achieve more effective protection of coastal waters from nonpoint pollutants. Congress enacted the Coastal Zone Act Reauthorization Amendments (CZARA) of 1990, which established under Section 6217 a new coastal nonpoint source pollution control program to be incorporated into both State Section 319 (CWA) programs and State Coastal Zone Management Act (CZMA) programs. NOAA administers the CZMA and EPA administers Section 319, and the two agencies have worked cooperatively toward implementing Section 6217.

Section 6217 requires that States with federally approved coastal zone management programs develop and implement Coastal Nonpoint Pollution Control Programs to ensure protection and restoration of coastal waters. Twenty-nine States and Territories, including several Great Lakes States, currently have approved coastal zone management programs.

Under CZARA, State Coastal Nonpoint Pollution Control Programs must provide for implementation of (1) management measures specified by EPA in the national technical guidance, and (2) additional, more stringent measures developed by each State as necessary to attain and maintain water quality standards where the baseline measures do not accomplish this

CZARA integrates State Nonpoint Pollution Control Programs with State Coastal Zone Management Programs.



Kings Park Elementary, 3rd Grade, Springfield, VA

objective. The CZARA further provides that States' Coastal Zone Management Programs must contain enforceable policies and mechanisms to ensure implementation of the baseline and additional management measures.

EPA issued final technical guidance in January 1993 titled *Guidance Specifying Management Measures for Sources of Nonpoint Pollution in Coastal Waters*. This guidance specifies management measures for five major categories of nonpoint pollution: agricultural runoff, urban runoff, silvicultural runoff, hydromodification, and marinas and recreational boating. The guidance also describes specific practices that may be used to achieve the level of prevention or control specified in the management measures.

EPA and NOAA have also issued joint program guidance to assist the States in developing coastal nonpoint pollution control programs. Final program guidance was issued in January 1993. The program guidance addresses issues related to development by the States of coastal nonpoint programs for joint approval by NOAA and EPA. In addition, NOAA and EPA have recently taken steps to provide States and Territories significant additional time and flexibility in developing and implementing their coastal nonpoint programs. The States must submit coastal nonpoint control programs to NOAA and EPA within 30 months of issuance of the management measures guidelines (July 1995). NOAA and EPA then have 6 months to complete their review of the coastal nonpoint programs.

Between November 1993 and June 1995, NOAA and EPA met with over 20 coastal States and Territories to review their progress in developing coastal nonpoint programs. These "threshold reviews" have assisted States in identifying where additional work may be necessary for meeting the requirements of Section 6217 and have enhanced NOAA's and EPA's understanding of the variety of State programs and approaches for controlling nonpoint pollution.

Protecting Lakes

Background

Since the early 1980s, and especially with the 1987 CWA reauthorization, nonpoint source impacts and multimedia issues such as acid rain have received increased attention in Federal regulations. Addressing these more holistic concerns has led to lake programs and projects that are closely coordinated with other Federal, State, Tribal, or local initiatives.

EPA encouraged States to develop and implement lake projects on a watershed basis. This ensures that restoration activities are long term and comprehensive. Under this approach, nonpoint source control, ground water protection, water quality permitting, estuarine protection and cleanup, and wetlands protection issues can be addressed in a holistic manner.

Biennial Lake Assessment

Under the 1987 CWA reauthorization, several new provisions were added to the original provisions encouraging States to identify their publicly owned lakes and classify them according to their eutrophic condition. Lake assessment information was to be updated in a fashion analogous to other State water quality assessments and reported biennially following the same timelines as the Section 305(b) reports. Most States now include their Section 314 lake assessments in their 305(b) reports. Recent procedural changes to the regulations governing the Water Quality Planning and Management Program (FRL-3979-8, *Federal Register*, Vol. 57, No. 143, Friday, July 24, 1992) now clearly specify that lake assessment materials should be part of the 305(b) report submittals.

Publicly Owned Lakes

Section 314 requires that States report on their "significant publicly owned lakes"–leaving the definition of "significant" up to the individual State. States have defined significant publicly owned lakes with varied physical and legal criteria, but most States have included minimum size criteria and recreational use caveats in their definitions. For example, New Hampshire's definition of significant publicly owned lakes is "any freshwater lake or pond that has a surface area of 10 or more acres, is not private, and does not prohibit recreational activity." As a general rule of thumb, most States settle on a set of significant lakes ranging in number from less than a hundred (for smaller States) to a few hundred lakes in larger western or midwestern States. However, some States classify all of their lakes as significant publicly owned lakes.

The States typically focus on highly utilized lakes because local

VOL 12

5848

Many citizen and lake associations monitor lakes.

Choiakarn Punovirivarat, age 8, Bruner Elementary, North Las Vegas, NV

citizens and governments are more likely to assist in control and restoration projects and assume ongoing stewardship for these lakes and their watersheds. High-value lakes attract a diverse group of local stakeholders to anchor the activities associated with lake projects.

Lake Beneficial Use Impairments and Trends

The 1987 CWA Amendments contain many provisions encouraging a water-quality-based approach to pollution assessment, planning, and management activities. Biennial lake assessments are now expected to make use of available information to document publicly owned lakes where uses are known to be impaired as well as lakes where there is evidence of water quality deterioration. Many States use EPA's Waterbody System to produce summary tables that categorize lake acreages by use attainment (e.g., fully supporting, threatened, partially supporting, or not supporting). Summary tables are also generally provided that categorize the major causes and sources of pollution. However, many States still lack water quality standards specific to lakes, thereby complicating the process of lake water quality assessment.

Under the 305(b) reporting process of the Clean Water Act, States are encouraged to provide waterbody-specific summaries of various public health and aquatic life concerns. This can include information on fishing advisories, fish kills, sites with sediment contamination, restrictions on surface water drinking supplies, bathing area restrictions, and incidents of waterborne diseases. This information is reported for all waterbody types, including lakes. Perhaps the most common concern reported is the contamination of fish tissue by toxicants, leading to fish consumption warnings or advisories. Although this information is certainly valuable, many States have difficulty relating fish consumption advisory data clearly to provisions in their own water quality standards. For instance, a public health agency may declare a fish consumption advisory for a lake based on trigger values for some toxicant (for instance, mercury) that are not tied to numeric standards criteria for any particular beneficial use. States are making progress in achieving consistency in their reporting of concerns such as fish consumption advisories in relation to their reporting State beneficial use attainment status. However, results for these two types of assessment information may require careful scrutiny to avoid misinterpretation.

Continued Importance of Trophic Status Classifications

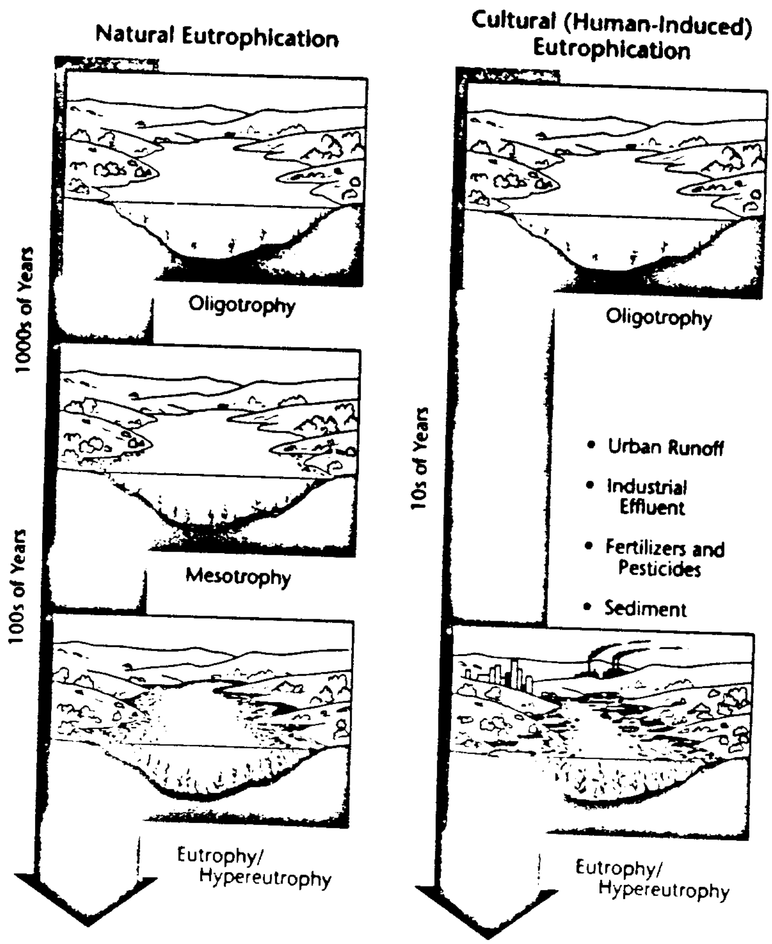
Reporting on trophic conditions is still a central feature under the 1987 CWA reauthorization, and most States still use ranking systems based primarily on trophic status information as the foundation for protecting lakes.

Trophic condition is a characterization of a lake's biological productivity based on the availability of plant nutrients. Commonly accepted systems for describing trophic status recognize a range of conditions, with oligotrophic indicating the least biologically productive lakes and eutrophic indicating significantly higher levels of productivity. For national reporting purposes, the following categories are recommended: oligotrophic, mesotrophic, eutrophic, and hypereutrophic. For those lakes showing exceptionally high levels of organic materials and associated reduced pH levels, humic substances, and natural color, the term dystrophic is used.

Both natural lakes and manmade reservoirs usually show shifts in their trophic condition over time (Figure 16-1). It is important, however, to distinguish between natural eutrophication, the process by which lakes gradually evolve and age, and cultural eutrophication, which can be defined as the culturally induced rapid acceleration of the natural eutrophication process. The natural eutrophication process ordinarily may take centuries, as lakes naturally shift from an oligotrophic to a more eutrophic status. Sedimentation processes will eventually lead to trophic shifts in manmade impoundments, generally in a much shorter time period than for natural lakes. Reservoirs, therefore, have effective lives ranging from a few decades to perhaps a few hundred years. Newly impounded reservoirs may initially be characterized as eutrophic because of the decay of woody debris but may shift to a less eutrophic status for most of the impoundment's useful life. The cultural eutrophication process, for either natural lakes or reservoirs, involves the rapid (over a matter of

Figure 16-1

The Progression of Eutrophication



(left column) The progression of natural lake aging or eutrophication through nutrient-poor (oligotrophy) to nutrient-rich (eutrophy) sites. Hypereutrophy represents extreme productivity characterized by algal blooms or dense macrophyte populations (or both) plus a high level of sedimentation. The diagram depicts the natural process of gradual nutrient enrichment and basin filling over a long period of time (e.g., thousands of years).
(right column) Cultural eutrophication in which lake aging is greatly accelerated (e.g., tens of years) by increased inputs of nutrients and sediments into a lake, as a result of watershed disturbance by humans.

> Trop... Acc... are th... lake cl... used in ... rank... publicly ow...

years or a few decades) eutrophying of the waterbody because of human-induced external nutrient and sediment inputs.

Because there is an inherent dynamic aspect to the trophic balances in lakes, caution must be exercised in characterizing anything other than an oligotrophic condition as undesirable. On the other hand, many types of anthropogenic stresses may result in rapid trophic status shifts. If a lake shows rapid progression toward a state exhibiting excessive algae growth, rapid organic and inorganic sedimentation, and seasonal or diurnal dissolved oxygen deficiencies leading to obnoxious odors, fish kills, or a shift in the composition of aquatic life forms to less desirable forms, then an advanced stage of cultural eutrophication is very likely. Most commonly, large external inputs of nutrients from point and/or nonpoint sources leads to an undesirable stage of cultural eutrophication. Restoring a lake to a more desirable trophic condition will then require reductions in the external nutrient loading and possibly in-lake restoration activities to mitigate the impacts of previous pollution inputs.

When evidence suggests that pollution factors are driving the lake to a more eutrophic state, a State will likely rate that waterbody as a relatively high priority candidate for management attention. Other types of information are helpful in prioritizing a public lake's management needs (e.g., documentation of trends and consideration of factors such as acidity or toxics), but trophic status assessments are still the backbone of the classification systems used in most States.

At least half the States make use of a trophic classification methodology developed by R.E. Carlson in the 1970s. Carlson worked primarily with natural lakes in the Midwest. He developed a series of indices involving simple logarithmic transformations of monitoring records based on total phosphorus, chlorophyll *a*, and Secchi depth. For many lakes, these parameters provide a measure of the principal cause of cultural eutrophication (the nutrient phosphorus), a reasonable indicator of the standing crop of algae associated with nutrients (chlorophyll *a* is the major photosynthetic pigment in algal phytoplankton), and a measure of unwanted reduction in water transparency due to elevated levels of algal biomass.

The formulas for these trophic status indexes (TSIs) were calibrated to conditions in the Midwest so that an increase of 10 index units would match a change in lake eutrophic condition to the next highest status (e.g., from oligotrophic to mesotrophic). For many lakes studied by Carlson, there was a strong correlation among the predictions provided by the TSIs. Because it is generally much less expensive to gather total phosphorus data than chlorophyll *a* data and much easier to measure a light transparency from a Secchi disk than to develop actual water chemistry data, there has been a tendency to rely heavily on Secchi disk measurements when using a Carlson TSI to characterize trophic state.

Well over half the States use one or more of the Carlson TSIs or indices very similar to Carlson's. For the 1994 305(b) reporting cycle, there is a noticeable tendency on the part of the States to use greater discretion when the only measurement for a TSI comes from Secchi disk readings. Without other information about a lake, and especially reservoirs where reductions in transparency may be due more to suspended inorganic particles than to blooms of algae or due to location of the sampling site or other factors, a Secchi measurement may give false signals as to the degree of biological productivity.

States are increasingly using TSIs based on phosphorus or, where possible, chlorophyll *a* measurements. However, light transparency data may still be useful, especially when correlated with visual observations of color. Even if loss of transparency is due more to turbidity and suspended solids than to algae, it may indicate unwanted sedimentation problems affecting trophic balances and a lake's recreation value. When available, long time series of Secchi depth readings are often a good tool for trend analysis. Secchi readings, often collected by volunteer monitoring groups, can therefore still play an important role in a State's lake monitoring programs; but, for the highest quality characterization of lake trophic status, measurements more closely related to biological process and food chain dynamics are preferred.

Many States are evaluating different ways to supplement methods such as Carlson TSIs to make cost-effective characterizations of trophic status. For instance, using a broader range of parameters, there are other standard indexes that may prove helpful; many of these indexes were originally developed in the 1970s as part of EPA's pioneering National Eutrophication Survey. Whatever the general form in a TSI formula, it is highly desirable to regionalize the system to conditions found in a specific State or ecoregion. States such as North Carolina have developed regional indices, and Oregon, Minnesota, and Arkansas have applied ecoregion concepts in interpreting their lake monitoring data. Oklahoma and Texas are also evaluating different methods to assess trophic status in reservoirs.

Many States are now exploring ways to develop biologically based (bioassessment) techniques. For instance, the presence or absence of certain types of zooplankton is often strongly correlated with a well-balanced biological community. Diverse and healthy populations of algae-consuming zooplanktons such as *Daphnia pulex* can help prevent the buildup of objectionable algal biomass even in lakes showing appreciable nutrient inputs. Shifts in the populations of game fish or plankton-eating forage fish can sometimes lead to a decimation of the zooplankton, allowing algae to flourish. Biomanipulation techniques aimed at increasing the populations of top predator fishes or reducing the populations of forage fishes can often correct the trophic imbalances. Bioassessments of the plankton communities or the fish populations can therefore indicate overall trophic status. Other techniques being explored look at benthos or macrophytes in lake littoral areas. These techniques can be valuable supplements to the more traditional Carlson TSIs that focus on algal standing crop, nutrients, or transparency parameters.

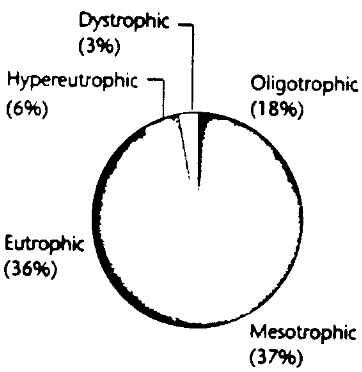
In 1994, 41 States reported that 18% of the 9,735 lakes they assessed for trophic status were oligotrophic, 37% were

VOL 12

5852

Figure 16-2

Trophic Status of Assessed Lakes



Based on data contained in Appendix H, Table H-1.

mesotrophic, 36% were eutrophic, 6% were hypereutrophic, and 3% were dystrophic (Figure 16-2). This information may be somewhat biased, as States often assess lakes in response to a problem or public complaint or because of their easy accessibility. It is likely that more remote lakes–which are probably less impaired–are underrepresented in these assessments.

Lake Acidity Impacts

During the 1980s, considerable national attention focused on how pollution can lower the pH of receiving waters, especially lakes. Acidity can pose a direct threat to aquatic life and lake recreational amenities. Major potential sources include atmospheric deposition and acid mine drainage. EPA coordinated a major multi-agency study called the National Acid Precipitation Assessment Program (NAPAP) to study acid deposition. A wealth of data were collected on many lakes and stream systems under NAPAP. NAPAP also provided insights into promising monitoring designs to document receiving waters with actual acidity problems or sensitivities to potential acid impacts.

NAPAP concluded that the incidence of serious acidification problems was far more limited than originally feared, and this Federal hypothesis seems to be reflected in evidence reported by the States in their lake water quality assessments. At least for significant publicly owned lakes, the Adirondacks area of New York emerges as the only region showing appreciable numbers of public lakes with significant acidification damage.

In addition to impacts from acidity per se, low pH conditions can accentuate impacts from a variety of toxicants. For instance, many metals show increased availability as the pH drops and, where acid mine drainage is involved, the pollutant source for the acidity may also be a source of toxicants. Acidity may also accentuate the impacts on aquatic organisms of a variety of toxics and may often increase bioaccumulation or biomagnification processes that move toxicants into the tissues of fish and thus into the food chain. Toxic accumulations in sediment also complicate the use of lake restoration techniques such as dredging.

Acidic lakes are generally found in areas where watershed soils have limited buffering capabilities. Acid rain or acid mine drainage can then depress a lake's pH levels to a point at which many forms of aquatic life are stressed or eliminated. Table 16-1 summarizes some of the common biological effects at progressively lower pH ranges.

In the eastern United States, such areas as southern New Jersey have been shown to have limited natural buffering capacity, making many lakes potentially vulnerable to acid deposition impacts. In addition to lakes, some States are concerned about acidity impacts on high-gradient trout streams. Where the acidity concerns affect whole watersheds, this encourages a search for mitigation techniques that could benefit both lakes and streams. New York has undertaken some innovative demonstration projects aimed at liming whole watershed areas instead of the more traditional strategy of liming just the lakes.

States have documented areas where local geological and soil factors may render lakes deficient in natural buffering capacity and therefore vulnerable to acidity stress. Such sensitive areas seem quite prevalent in high-altitude glacial lakes in mountainous areas in the Rockies and several western States. A major concern here is low pH water introduced from snowpack meltwater. Many of these high-altitude lakes may show a seasonal pulse of low pH inflows, usually during the Spring. The ecological consequences are not entirely clear, and States such as Colorado and Washington will continue to study this episodic phenomenon.

Serious impacts from acid mine drainage also seem relatively rare. No State has found clear documentation of acidity impacts related to active mining activities. However, there is some concern about abandoned mine workings. At least one State, Oklahoma, is undertaking a study on a portion of the Eufaula Reservoir that lies in a region with a long history of surface and hard rock coal mining activities.

In light of these concerns, Congress added provisions for State lake assessment reporting to document known instances of acidity or toxics impact to public lakes in the 1987 CWA reauthorization. If such issues are related to actual impairments or pose real degradation threats, States are encouraged to document methods and procedures that could mitigate the harmful effects of high acidity or toxic metals and other toxic substances.

In 1994, 26 States reported that, of the 5,933 lakes assessed for acidity, 9% exhibited acidity and 16% were threatened by acidity. Over half of these lakes exhibiting acidity and roughly one-quarter of the lakes threatened by acidity were in New York. Very little information was provided by States regarding the sources of acidity to impacted or threatened lakes.

Table 16-1. Effects of pH on Aquatic Life

pH Range	General Biological Effects
6.5 to 6.0	Some adverse effects for highly acid-sensitive species
6.0 to 5.5	Loss of sensitive minnows and forage fish; decreased reproductive success for trout and walleye
5.5 to 5.0	Loss of many common sports fish and additional nongame species
5.0 to 4.5	Loss of most sports fish; very few fishes able to survive and reproduce where pH levels commonly below 4.5

Toxic Effects on Lakes

In the 1987 CWA reauthorization, there was an expectation that if toxics concerns were encountered in lakes, they might be tied to an anticipated widespread incidence of acidity problems. As discussed above, evidence submitted by the States and from the Federal NAPAP investigations suggests that lake acidity problems are much rarer than anticipated. Toxics concerns States have submitted, therefore, are generally not related to depressed pH levels.

[illegible] concerns in lakes.

Many States do report serious toxics concerns, with the most common centering on fish consumption advisories. Most States maintain programs to sample fish tissues from their major public lakes. These collections also generally involve sampling of ambient water and sediments. Rarely do ambient water levels exceed detection limits for heavy metals or common pesticides. For sediments and fish flesh, however, virtually all States have at least one public lake at which elevated levels of some toxicant have been documented. Any exceedances of

FDA alert levels or other Federal or State threshold levels will be noted in the 305(b) reporting process. Especially for contaminants in fish flesh, State health authorities will issue consumption advisories so that the public can make appropriate fish consumption decisions.

If a State has established provisions in its water quality standards regarding these public health issues, lakes may be reported as showing beneficial use impairments. Where such standards are not well-defined, the information may show up only in the 305(b) sections dealing with public health/aquatic life concerns. If it is carried over into the use attainment portion of the 305(b) documents, States may choose to characterize the concern as a 305(b) "assessment" issue. This is a rapidly evolving field, with many States attempting to add public health features to their water quality standards or expanded standards' provisions for wildlife protection.

Because many of the toxicants in question are persistent substances (e.g., chlordane or PCBs), it is often likely that there are no active pollutant sources; rather the problems are related to in-place contaminants. This situation is compounded by the fact that many of the organic or heavy metal toxicants are multimedia problems, with any ongoing pollutant loading coming from atmospheric deposition. The sources for such "air pollution" inputs are generally not well known; in some cases the ultimate sources may even lie outside the United States, reflecting pollution processes on a hemispheric or global scale. Faced with these uncertainties, most States are continuing to gather monitoring data and are adopting risk management strategies.

In 1994, 39 States and Territories reported that they found elevated concentrations of toxic contaminants in fish, sediment, or water column samples representing over 2 million lake acres. These States surveyed more than 7.5 million lake acres for toxic contaminants, many of which had known or suspected toxicity problems. This information is difficult to interpret because States do concentrate their monitoring efforts on lakes with problems, and each State uses its own criteria for defining "elevated" concentrations of contaminants.

Trends in Significant Public Lakes

A final provision in the 1987 CWA reauthorization encourages States to make use of available information to identify trends in water quality for public lakes. With the possible exception of bog-like dystrophic lakes, lakes do naturally display shifts in trophic status over time, as well as pollution-induced trends. Trend analysis can therefore be extremely valuable in documenting the eutrophication rate. Where possible, trend assessments should look not only at shifts in trophic status but at all water quality issues, including trends involving toxic contaminants.

The majority of States do attempt some sort of trend determination. Frequently, determinations are made based on best professional judgment (BPJ) rather than more quantitative tests. Virtually every State that presents such BPJ trends

VOL 12

5855

assessments notes that confidence limits or other measures of reliability or precision are not available.

While the desirability of trend assessments is widely recognized, States still face challenges in gathering adequate information to statistically document trend signals. Although States continue to explore ways to detect empirically significant trends, virtually every State expressed the need to acquire additional data, a common estimate being that at least 10 years of observations would be needed to apply more rigorous statistical methods. Another common theme is that the patterns displayed in many lakes do not seem to be linear. Most available statistical tests are geared to spotting simple, linear trends. Where the underlying physical patterns are nonlinear or cyclical, more complex analyses are needed.

Some States do apply quantitative analysis techniques for lake assessments. Illinois used linear regressions combined with examination of scatter plots of the raw data and residuals. From 213 lakes, over half (56%) of the lakes had complicated fluctuating patterns suggesting cyclical or nonlinear patterns, perhaps related to weather variability. Illinois, therefore, felt that additional data and further analysis would be worthwhile. Wisconsin and Minnesota used the Seasonal Kendall tau test to look at trends in water clarity. This is a nonparametric test considered by many to be generally preferable to parametric tests for use with water quality data. Wisconsin looked at 40 lakes, with the test suggesting increasing trends (clearer water) for 16 lakes and decreasing trends for 6 lakes. Minnesota reported trends in Secchi transparency for the 16 lakes with 8 or more years of data. At a 10% detection level, 13 lakes were considered to have a significant decline in transparency and 44 lakes were considered to have a significant increase in transparency.

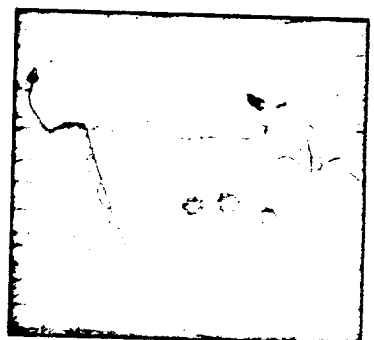
In 1994, 24 States reported that of the 1,828 lakes assessed for trends, 14% were improving, 68% were stable, and 18% were degrading. This information may be somewhat biased, as States often assess trends in lakes that are part of a management study or because of their easy accessibility. It is likely that more remote lakes are underrepresented in these assessments.

Pollution Control and Restoration Techniques

Managing lake quality often requires a combination of in-lake restoration measures and pollution controls, including watershed management measures:

Restoration measures are implemented to reduce existing pollution problems. Examples of in-lake restoration measures include harvesting aquatic weeds, dredging sediment, and adding chemicals to precipitate nutrients out of the water column. Restoration measures may not address the source of the pollution.

Pollution controls deal with the sources of pollutants degrading lake water quality or threatening to impair lake water quality. Control measures include planning activities, regulatory actions, and implementation of best management practices



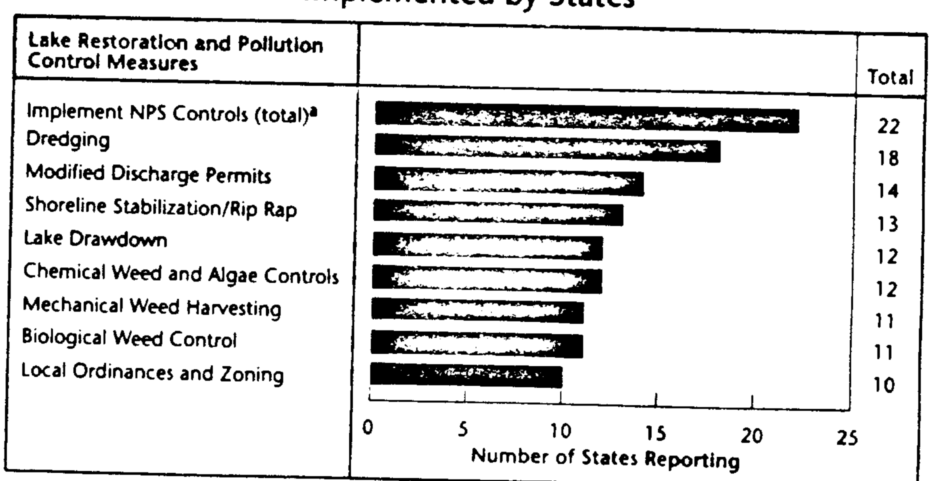
Case Kepner, age 8, Bruner Elementary, North Las Vegas, NV to reduce nonpoint sources of pollutants. Watershed management plans and lake management plans are examples of planning measures. Watershed management plans simultaneously address multiple sources of pollutants, such as runoff from urbanized areas, agricultural activities, and failing septic systems along the lake shore. Regulatory measures include point source discharge prohibitions and phosphate detergent bans.

States are asked to provide materials on their lake restoration techniques. For example, States may provide specific restoration techniques from which they will draw to develop lake-specific management plans. Where possible, States are encouraged to document specific techniques recommended for individual publicly owned lakes.

During the 1980s, most States implemented chemical and mechanical in-lake restoration measures to control aquatic weeds and algae. In 1994, the States reported that they still implement in-lake treatments, but they most frequently implement best management practices (BMPs) to control nonpoint sources of nutrients and siltation (Figure 16-3). Twenty-two States reported that they implemented BMPs to control NPS pollution entering more than 171 lakes. The States reported that they implemented agricultural practices to reduce soil erosion, managed animal waste, constructed retention and detention basins to cleanse

Figure 16-3

Lake Restoration and Pollution Control Measures Implemented by States



[a]Includes best management practices, such as conservation tillage, sediment detention basins, vegetated buffers, and animal waste management.

urban stormwater, revegetated shorelines, and constructed or restored wetlands to remove pollutants before they entered lake waters.

Clean Lakes Demonstrations

The 1987 amendments to Clean Water Act Section 314 established the Demonstration Program for lakes. The Act requires that the EPA Administrator give priority consideration to the following 10 lakes for inclusion in the Demonstration Program: Lake Worth, Texas; Lake Houston, Texas; Beaver Lake, Arkansas; Greenwood Lake, New Jersey; Deal Lake, New Jersey; Alcyon Lake, New Jersey; Gorton's Pond, Rhode Island; Lake Washington, Rhode Island; Lake Bomoseen, Vermont; and Sauk Lake, Minnesota.

These 10 lakes have water quality problems common to many lakes throughout the United States. Most of the water quality problems fall into two categories: (1) excessive siltation and sediment influx and (2) high levels of nutrient loading.

These water quality problems have many sources, but most can be linked to the development of the lakes' watersheds. Urbanization can increase runoff from lawns, highways, stormwater outfalls, and other surfaces. Shoreline development can result in increased nutrient loading from inadequate septic systems and the use of fertilizers on lawns. Rural development can lead to water quality problems as well. Farms and animal production facilities on or near lakes use and generate large quantities of nitrogen and phosphorus from animal feed, fertilizers, pesticides, and animal waste. Runoff from these facilities or fields can significantly increase the nutrient load to a lake. Soil erosion that occurs during construction or from poorly maintained commercial, residential, or agricultural lands can cause a significant influx of silt and sediment to a lake.

Demonstration Lakes

Lake Worth. Lake Worth is the primary source of drinking water for the City of Fort Worth, Texas. It is also a major recreational resource and is surrounded by almost 4,000 acres of public parks. In recent years, however, uses of the lake have been impaired by siltation and the unchecked growth of aquatic plants in the shallow areas of the lake. Studies conducted over the past 30 years have given project principals a clear understanding of the history and present condition of the lake and its watershed as well as a coherent restoration plan. This project enjoys very active public participation, cooperation with the U.S. Army Corps of Engineers, and coordination through an interagency planning committee composed of Federal, State, and local entities. With the workplan approved and engineering designs prepared, the restoration project is well under way and active. The project involves installation of an innovative pressurized wastewater collection system, enhancement of existing wetlands for nutrient uptake, dam operation adjustments to raise the water level, and removal of stumps and abandoned dock pilings.

Lake Houston. This 12,350-acre impoundment serves as a water supply and recreational lake for the City of Houston, Texas. Originally, the lake had a storage capacity of more than 160,000 acre-feet, but over the years the capacity of the lake has decreased by more than 18%. Studies indicate that the diminished capacity results from constant sedimentation and that uses of the lake are impaired by the excessive growth of aquatic plants. The current water quality problems are caused by runoff, primarily from urbanized areas around the lake, and point source discharges. Feasibility studies are under way to examine several restoration and pollution prevention methods for the lake, and the City of Houston is independently conducting a comprehensive lake and watershed study.

Beaver Lake. Located near Fayetteville, Arkansas, Beaver Lake is a 28,190-acre reservoir that serves as a drinking water supply and recreational facility for the surrounding population of more than 200,000 people. Although the lake has escaped any significant impairment to date, the State of Arkansas is concerned that rapid commercial, agricultural, and residential development threatens the water quality of the lake. Over the years, the Beaver Lake watershed has been studied extensively through the cooperative efforts of several Federal agencies. All recognize that runoff from the growing number of chicken and swine farms in the watershed could eventually affect the quality of the drinking water supply. Studies indicate that water clarity in the upper reservoir has been decreasing as a result of siltation and algal blooms. The source of the silt and nutrients is believed to be the increased number of confined animal production facilities and the spreading of the waste from the facilities on nearby pastures. EPA and the State of Arkansas are encouraging farmers to use best management practices voluntarily to reduce the potential for nutrient loading to the lake. The Army Corps of Engineers undertook an extensive effort to characterize the water quality of the lake and to determine the impacts of the surrounding watershed. Monitoring data indicate that the trophic status of the lake has not changed significantly since 1970. Although point sources of pollution to the lake have decreased, nonpoint sources have increased, resulting in no net change in nutrient input. No specific restoration measures have been recommended.

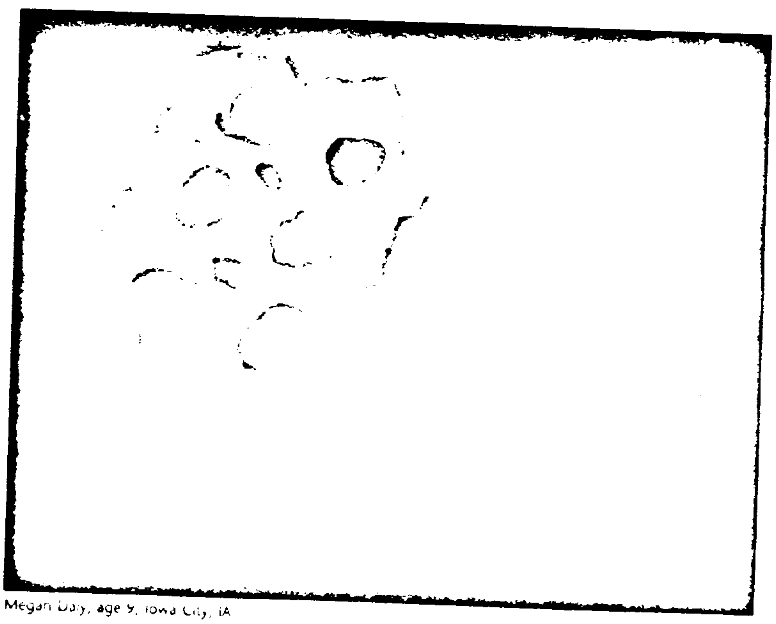
Greenwood Lake. Historic Greenwood Lake is unique among the Demonstration Program lakes because it is located in two States, New Jersey and New York. The lake, divided almost in half by the New York/New Jersey State line, is part of the headwaters for the Wanaque Reservoir, which is a major water source for northern New Jersey and a popular recreational area. Although Greenwood Lake is still a

VOL 12

5859

thriving water resource, it shows signs of water quality degradation: adverse changes in fishery populations, excessive growth of aquatic plants, and unpleasant odors and taste. This degradation is caused by increased nutrient and sediment loadings, which are the result of development in the watershed, stormwater runoff, septic discharges, and point source discharges into tributaries of the lake. Sources of lake pollution have been identified and a 10-part restoration plan was developed in the 1980s. Some portions of the plan—specifically lake drawdown and aquatic plant harvesting—were implemented as early as 1985. In addition, sewage treatment facilities have been upgraded, stormwater control measures have been implemented for new developments, and runoff conveyances have been maintained. Ongoing efforts include lake level drawdown, weed harvesting, development of a stormwater management plan prioritizing sites, construction of stormwater detention basins, and a public education program. Preliminary results indicate that the recurrence of excessive aquatic plants has decreased. In addition to the efforts of the States and EPA, the COE has developed a dredging plan for the lake.

Deal Lake. Deal Lake is the largest freshwater body in Monmouth County, New Jersey. By 1950, sedimentation, algal blooms, and bacteria concentrations had become so excessive that recreational uses were impeded or prohibited. State and local interest in restoring the lake culminated in 1983 in a State-sponsored comprehensive diagnostic/feasibility study. This study determined the primary source of sediment to be an old landfill located upstream of the lake. The source of nutrients and bacteria appears to be excrement from the abundant waterfowl that inhabit the lake. This study also defined a remediation plan that included in-lake work such as dredging and drawdown, as well as watershed management elements such as stabilization of the upstream landfill, stormwater management, erosion control, and the protection of sensitive habitats. The remediation plan was initiated in 1988 with $1 million of State funds. After the landfill was stabilized, a heavily sedimented portion of the lake was restored by dredging, construction of a sediment trap, wetland enhancement, and reclamation of



Megan Daly, age 9, Iowa City, IA

surface water habitat. Further activities completed or ongoing include (1) construction of stormwater detention basins, (2) dredging to create a new retention site, (3) development of watershed and "sensitive lands" management plans, and (4) public education and consultation with area schools.

Alcyon Lake. Alcyon Lake is a small manmade lake located in Pitman, New Jersey. The lake has been a center of community activity since the 1890s when Alcyon Park was built on the lakeshore. In 1951, Alcyon Park was sold and essentially abandoned. By 1980, three sources of pollution had been identified: (1) the LiPari Landfill, an abandoned chemical waste dump; (2) urban stormwater runoff; and (3) agricultural runoff. This pollution had been ongoing for over 20 years. In 1980, it was determined that the major problem at the lake was the discharge of approximately 150,000 gallons of chemical waste from the LiPari Landfill. The LiPari Landfill was designated as a Superfund project and the landfill is now contained. The Superfund Program is now dredging contaminated sediments from the lake and area streams and wetlands. Under the Clean Water Act, the Lake Demonstration Programs focused on the urban and agricultural sources of pollution to the lake. This effort is in progress and includes (1) examination of the stormwater drainage system to identify problem areas, (2) a volunteer monitoring program, (3) public participation meetings and an education program, (4) streambank stabilization, and (5) a joint effort with the Soil Conservation Service (recently renamed the Natural Resources Conservation Service) to implement watershed erosion control measures.

Gorton's Pond. Located near Warwick, Gorton's Pond is in a heavily urbanized area of Rhode Island. Consequently, it has many of the pollution problems associated with residential and commercial development. These include surface runoff that contains oil, grease, bacteria, fertilizers (nutrients), and sediment. Resulting problems are algal blooms, overgrowth of aquatic vegetation, and a decline in the fishery. Recommendations from an initial study stressed that the restoration plan must deal with the causes of the water pollution—land use practices in the watershed—as well as in-lake work. Land use management recommendations included erosion and sediment control, particularly during construction and at stormwater outfalls; stormwater treatment and/or diversion; and elimination of point and nonpoint source discharges such as onsite sewage disposal systems. In-lake methods proposed included limited dredging, nutrient inactivation, and aquatic plant harvesting. The design phase of a stormwater infiltration basin has been completed but the basin has not been constructed.

Lake Washington. Located in upper northwestern Rhode Island, Lake Washington is a shallow basin constructed more than 80 years ago. In recent years, excessive growth of aquatic vegetation, algal blooms, and increased sedimentation have occurred. The decomposition of the aquatic plants and algae has decreased the dissolved oxygen content in the water, threatening the survival of the fish population. Part of the water quality problems stem from the fact that the lake has a naturally low inflow of water, primarily ground water, and consequently has poor flushing. In addition, many lakeshore residents are on septic systems that have exceeded their useful life. A further source of pollution is runoff from a highway that abuts the lakeshore. Failing septic systems have been identified as the primary source of nutrients to the lake, and a centralized wastewater treatment system has been recommended. In-lake work such as drawdown, harvesting, and algicides may also be needed, as well as watershed management activities such as revision of local land ordinances, rip rap and vegetative swells, land acquisition, and better maintenance of stormwater drainage systems.

Lake Bomoseen. Lake Bomoseen is the largest lake located entirely within Vermont. It covers 2,364 acres and has an average depth of 27 feet. As a result, the lake is a major recreational resource and contributes to the economy of the region. Since 1982, the aquatic plant Eurasian water milfoil has spread rapidly in some areas of the lake. It is estimated that the plant occupies more than 600 acres of the lake out to a depth of 20 feet. The Eurasian milfoil coverage is very dense and has severely restricted use of the lake. In the 1980s mechanical harvesters were used to remove the plants from the lake's surface, but this method proved to be ineffective and uneconomical in controlling the plant growth. In 1989, staff of the Vermont Department of Environmental Conservation (DEC) discovered a dramatic decline in milfoil growth in Brownington Pond in northeastern Vermont. The decline appeared to be associated with the presence of a particular native herbivorous (plant-eating) aquatic weevil that feeds on Eurasian milfoil. In 1990, DEC began a 5-year research project on the use of the native insect as a biological control for milfoil in Lake Bomoseen as well as the other 25 lakes in Vermont that have a milfoil problem. The goal of the project is to determine the extent to which the aquatic weevil might contribute to milfoil reduction and the suitability of Lake Bomoseen and other lakes for weevil introduction. The project has involved determining the distribution and abundance of the native weevil in Vermont lakes, field collection of adult weevils for rearing stock, weevil rearing in a laboratory greenhouse, introduction of weevils into specific lake sites, and monitoring to determine survival of the weevils and feeding damage to milfoil plants. Results from the quantitative sampling effort done at the three weevil introduction sites on Lake Bomoseen are not yet available. However, visual observations indicate that the weevils have damaged the milfoil at all three sites and that some milfoil populations in shallow water are starting to collapse. Norton Brook Reservoir also received weevil introductions; however, introductions at this site were discontinued due to a lack of positive results. Unlike the observations at Bomoseen, little evidence of

VOL 12

5862

R0039170

surviving weevils and weevil feeding damage was seen at this site. Therefore, at this point it is difficult to predict how successful the weevils will be at reducing Eurasian milfoil.

Sauk Lake. Sauk Lake covers 2,111 acres in central Minnesota and has a predominantly agricultural watershed encompassing 5 counties, 49 townships, and 28 cities. The overgrowth of aquatic plants and algae has severely curtailed or entirely discontinued the recreational uses of the lake. The sources of nutrient and sediment pollution are agricultural and urban runoff within the watershed and upstream of Sauk Lake. The State has begun to control these sources and prevent pollution in the upstream Lake Osakis watershed area. Measures include agricultural best management practices such as no-till farming and feedlot runoff diversion, streambank and shoreline erosion control, urban stormwater diversion, and a community education program. Meanwhile, the Army Corps of Engineers has been implementing a harvesting effort to reduce the aquatic plants in Sauk Lake.

Wetlands Protection Programs

A variety of public and private programs protect wetlands. The Conservation Foundation organized the bipartisan National Wetlands Policy Forum in 1987 to coordinate these disparate efforts and develop a national, coordinated vision for wetlands protection. The Forum issued a report in November 1988 containing over 100 recommended actions for all levels of government and the private sector. It established an interim goal to achieve no overall net loss of the Nation's wetlands base and a long-term goal to increase the quantity and quality of the Nation's wetlands resource base. Shortly after coming into office, the Clinton Administration convened an interagency working group to address concerns with Federal wetlands policy. After hearing from States, developers, farmers, environmental interests, members of Congress, and scientists, the working group developed a comprehensive 40-point plan for wetlands protection to make wetlands programs more fair, flexible, and effective. This plan was issued on August 24, 1993.

Section 404

Section 404 of the Clean Water Act continues to provide the primary Federal vehicle for regulating certain activities in wetlands. Section 404 establishes a permit program for discharges of dredged or fill material into waters of the United States, including wetlands.

The U.S. Army Corps of Engineers and EPA jointly implement the Section 404 program. The COE is responsible for reviewing permit applications and making permit decisions. EPA establishes the environmental criteria for making permit decisions and has the authority to review and veto Section 404 permits proposed for issuance by the COE. EPA is also responsible for determining geographic jurisdiction of the Section 404 permit program, interpreting statutory exemptions, and overseeing Section 404 permit programs assumed by individual States. To date, only two States (Michigan and New Jersey) have assumed the Section 404 permit program from the COE. The COE and EPA share responsibility for enforcing Section 404 requirements.

The COE issues individual Section 404 permits for specific projects or general permits (Table 17-1). Applications for individual permits go through a review process that includes opportunities for EPA, other Federal agencies (such as the U.S. Fish and Wildlife Service and the National Marine Fisheries Service), State agencies, and the public to comment. However, the vast majority of activities proposed in wetlands are covered by Section 404 general permits. For example, in FY94, over 48,000 people applied to the COE for a Section 404 permit. Eighty-two percent of these applications were covered by general permits and were processed in an average of 16 days. It is estimated that another 50,000 activities are covered by

The Administration's Wetlands Plan emphasizes improving Federal wetlands policy by

- *Streamlining wetlands permitting programs*
- *Increasing cooperation with private landowners to protect and restore wetlands*
- *Basing wetlands protection on good science and sound judgment*
- *Increasing participation by States, Tribes, local governments, and the public in wetlands protection*

VOL 12

general permits that do not require notification of the COE at all.

General permits allow the COE to permit certain activities without performing a separate individual permit review. Some general permits require notification of the COE before an activity begins. There are three types of general permits:

- Nationwide permits (NWPs) authorize specific activities across the entire Nation. NWPs cover categories of activities that the COE determines will have only minimal individual and cumulative impacts on the environment. Currently, 36 NWPs authorize activities including construction of minor road crossings and farm buildings, bank stabilization activities, some cranberry operations, and the filling of up to 10 acres of isolated or headwater wetlands.

- Regional permits authorize types of activities within a geographic area defined by a COE District Office. Regional permits may authorize activities in a specific waterbody, a county, a State, a COE district, or multiple States within a COE district.

- Programmatic general permits are issued to an entity that the COE determines may regulate activities within its jurisdictional wetlands. Under a programmatic general permit, the COE defers its permit decision to the regulating entity but reserves its authority to require an individual permit. Under State programmatic general permits (SPGPs), the COE defers permit decisions to a State program for specific activities throughout the State or in a significant portion of the State.

Currently, the COE and EPA are promoting the development of SPGPs to increase State involvement in wetlands protection and minimize duplicative State and Federal review of activities proposed in wetlands. Each SPGP is a unique arrangement developed by a State and the COE to take advantage of the strengths of the individual State wetlands program. SPGPs may cover all

5867

General Permits (streamlined permit review procedures)				Individual Permits
Nationwide Permits	Regional Permits	Programmatic Permits		
		State Programmatic Permits	Others	
• Cover 36 types of activities that the COE determines to have minimal adverse impacts on the environment	• Developed by COE District Offices to cover activities in a specified region	• COE defers permit decisions to State agency while reserving authority to require an individual permit	• Special Management Agencies • Watershed Planning Commissions	• Required for major projects that have the potential to cause significant adverse impacts • Project must undergo interagency review • Opportunity for public comment • Opportunity for 401 certification review

regulated activities in a State or a select set of activities in a portion of the State. Several States have adopted comprehensive SPGPs that replace many or all COE-issued nationwide general permits (see highlight on page 442).

SPGPs simplify the regulatory process and increase State control over their wetlands resources. Carefully developed SPGPs can improve wetlands protection while reducing regulatory demands on landowners.

Wetlands Water Quality Standards

Water quality standards for wetlands ensure that the provisions of CWA Section 303 that apply to other surface waters are also applied to wetlands. In July 1990, EPA issued guidance to States for the development of wetlands water quality standards. Figure 17-1 indicates the State's progress in developing these standards (see Appendix D, Table D-5, for individual State data).

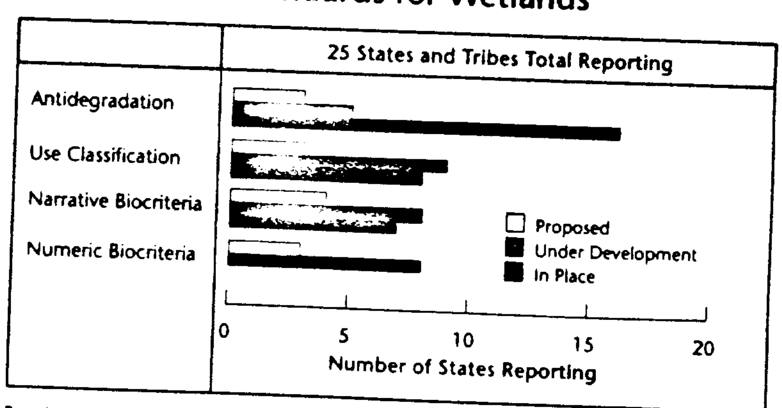
Water quality standards have three major components: designated uses, criteria to protect those uses, and an antidegradation policy. States designate uses that must, at a minimum, meet the goals of the CWA by providing for the protection and propagation of fish, shellfish, and wildlife and for recreation in and on the water. States may choose to designate additional uses for their wetlands, such as flood water attenuation or ground water recharge where appropriate. Once uses are designated, States are required to adopt criteria sufficient to protect their designated uses.

Criteria are general narrative statements or specific numerical values such as concentrations of contaminants and water quality characteristics. Narrative criteria can be particularly appropriate for wetlands when quantitative data do not exist. An example of a narrative criterion is "natural hydrological conditions necessary to support the biological and physical characteristics naturally present in wetlands shall be protected."

Standards provide the foundation for a broad range of water quality management activities under the CWA including, but not limited to, monitoring for the Section 305(b) report, permitting under Sections 402 and 404, water quality certification under Section 401, and the control of nonpoint source pollution under Section 319.

Figure 17-1

Development of State Water Quality Standards for Wetlands



Based on data contained in Appendix D, Table D-5.

Water Quality Certification of Federal Permits and Licenses

Section 401 of the CWA gives States and eligible American Indian Tribes the authority to grant, condition, or deny certification of federally permitted or licensed activities that may result in a discharge to U.S. waters, including wetlands. Such activities include discharge of dredged or fill material permits under Section 404 of the Clean Water Act, point source discharge permits under Section 402 of the Clean Water Act, and Federal Energy Regulatory Commission's hydropower licenses. States review these permits to ensure that they meet State water quality standards.

In 1989, EPA issued guidance to States and American Indian Tribes on how to use 401 certification authority to protect wetlands. Section 401 certification can be a powerful tool for protecting wetlands from unacceptable degradation or destruction, especially when implemented in conjunction with wetlands-specific water quality standards. Section 401 grants States and Tribes the authority to deny certification or require conditions for certification if the State or Tribe determines that an applicant has failed to demonstrate that a project will comply with State or Tribal water quality standards. If a State or eligible Tribe denies Section 401 certification, the Federal permitting or licensing agency cannot issue the permit or license.

Most States now use their Section 401 certification programs to review activities requiring both Section 404 individual permits and selected general permits. Until recently, many States waived their right to review and certify individual and general Section 404 permits because these States had not defined water quality standards for wetlands or codified regulations for implementing their 401 certification program into State law. Now, most States report that they use the Section 401 certification process to review Section 404 projects and to require mitigation if there is no alternative to degradation of wetlands.

Ideally, 401 certification should be used to augment State programs because it applies only to projects requiring Federal permits or licenses. Activities that do not require permits, such as some ground water withdrawals, are not covered.

State Wetlands Conservation Plans

State Wetlands Conservation Plans (SWCPs) are strategies that integrate regulatory and cooperative approaches to achieve State wetlands management goals, such as no overall net loss of wetlands. SWCPs are not meant to create a new level of bureaucracy. Instead, SWCPs improve government and private-sector effectiveness and efficiency by identifying gaps in wetlands protection programs and identifying opportunities to improve wetlands programs.

A large number of land- and water-based activities impact wetlands. These activities are not addressed by a single Federal, State,

VOL 12

5869

or local agency program. Although many public and private programs and activities protect wetlands, these programs are often limited in scope and are not well coordinated. Also, these programs often do not address all of the problems affecting wetlands.

States, Territories, and Tribes are well positioned between Federal and local government to take the lead in integrating and expanding wetlands protection and management programs. They are experienced in managing federally mandated environmental programs under the Clean Water Act and the Coastal Zone Management Act. They are uniquely equipped to help resolve local and regional conflicts and identify the local economic and geographic factors that may influence wetlands protection.

- Texas' SWCP will focus on nonregulatory and voluntary approaches to wetlands protection to complement its regulatory program. The plan will encourage development of economic incentives for private landowners to protect wetlands and educational outreach for State and local officials.

- Tennessee's plan focuses on a strategy to collect wetlands information for outreach and education to private owners of wetlands as well as to regional and local decision-makers. Current implementation efforts include identification of critical functions of major wetlands types, priority sites for acquisition and/or restoration, as well as maintenance and restoration of natural floodplain hydrology through digitization and use of remote sensing.

- Maine's SWCP will focus on ways to establish better coordination between State and Federal regulatory programs as well as new nonregulatory mechanisms to foster voluntary stewardship. In addition, the State expects to use an ecosystem framework to guide the prioritization of wetlands for comprehensive protection and to review and improve compensatory mitigation policies.

Wetlands Monitoring/ Biocriteria Programs

Historically, wetlands protection efforts have concentrated on regulating the widespread destruction of wetlands due to the discharge of dredged and fill material and on conservation of wetlands to maximize tangible benefits such as hunting and fishing. States have only recently begun to take steps toward control of other disturbances that can result in the degradation of wetlands. Such disturbances include hydrologic alteration, vegetation clearing, introduction of alien species, habitat fragmentation, chemical pollutants, sedimentation, and changes in pH, dissolved oxygen, and temperature. The use of water quality standards is an important tool for States to use to address these causes of wetlands degradation.

Assessment of the biological integrity of a wetland is crucial to characterizing water quality because aquatic life tends to reflect the ecological health of a waterbody (including physical and chemical conditions) and will reflect a range of diverse degrading impacts on a

For more information:

- *See the Statewide Wetlands Strategies guidebook, which is available from Island Press (1-800-828-1302).*
- *Ask for copies of the SWCP brochure "Why Develop a State Wetland Conservation Plan?" from the EPA Wetlands Information Hotline (1-800-832-7828) (contractor operated).*

system. Measuring and tracking biological integrity is the best way to ensure that numerous degrading impacts, however subtle or long term, are detected and monitored.

A biocriteria program seeks to characterize the biological integrity of relatively undegraded wetlands or "reference" wetlands and uses this information to set reasonable goals for wetlands within a given eco-region or area. These goals, or beneficial uses, when written as aquatic life use designations (ALUDs) and codified in a State's water quality standards, guide the restoration of degraded wetlands and maintenance of biological integrity in all wetlands.

Supporting biocriteria are developed for each aquatic life use to define biological and ecological characteristics that wetlands must possess to attain an ALUD. Biocriteria generally begin as narrative statements and are assigned numeric values as more data are gathered. It is through this system of biological goal-setting, monitoring, assessment, and updating of biocriteria and ALUDs that the water quality improvement and protection goals of the CWA are achieved.

The extent and importance of impacts to wetlands will become clear only with systematic biomonitoring of reference sites, comparison with degraded wetlands, and research on the links between the type of disturbance and the ecological integrity of wetlands. Without these data, and programs to protect the quality as well as quantity of wetlands resources, wetlands losses will continue.

Although State progress toward development of biocriteria programs is limited and varied, several States have begun systematic long-term regional monitoring and monitoring of reference sites necessary to support a wetlands biocriteria program. Currently, Kentucky, Minnesota, Montana, and New Mexico are developing such programs. Other States have initated projects, often limited to a specific region, wetlands type, or monitoring method, that will help them gain experience and acquire data needed for launching a statewide wetlands biomonitoring program.

Swampbuster

The Swampbuster provisions of the 1985 Food Security Act and the 1990 Food, Agriculture, Conservation and Trade Act ("Farm Bills") deny crop subsidy payments and all other agricultural benefits to farm operators who convert wetlands to cropland after December 23, 1985, or who modify wetlands to make cropping possible after November 28, 1990. The U.S. Department of Agriculture's Natural Resources Conservation Service (formerly the Soil Conservation Service) is responsible for determining compliance with Swampbuster provisions and for determining whether agricultural lands fall under the jurisdiction of Federal wetlands laws, including both the Swampbuster provisions and Clean Water Act Section 404.

State Programs to Protect Wetlands

States protect their wetlands with a variety of approaches, including use of CWA authorities (such as Sections 401 and 303), permitting programs, coastal management programs, wetlands acquisition programs, natural heritage programs, and integration with other programs. For this report, States described particularly innovative or effective approaches they use to protect wetlands.

State-Reported Information

The following trends emerged from individual State reporting:

- Most States have defined wetlands as waters of the State, which offers general protection through antidegradation clauses and designated uses that apply to all waters of a State. However, most States have not developed specific wetlands water quality standards and designated uses that protect wetlands' unique functions, such as flood attenuation and filtration.

- Without specific wetlands uses and standards, the Section 401 certification process relies heavily on antidegradation clauses to prevent significant degradation of wetlands.

- In many cases, the States use the Section 401 certification process to add conditions to Section 404 permits that minimize the size of wetlands destroyed or degraded by proposed activities to the extent practicable.

States often add conditions that require compensatory mitigation for destroyed wetlands, but the States do not have the resources to perform enforcement inspections or followup monitoring to ensure that the constructed wetlands are functioning properly.

- More States are monitoring selected, largely unimpacted wetlands to establish baseline conditions in healthy wetlands. The States will use this information to monitor the relative performance of constructed wetlands and to help establish biocriteria and water quality standards for wetlands.

Some highlights from individual State reports are as follows:

- The District of Columbia adopted narrative criteria for wetlands in their 1994 water quality standards. Wetlands are now classified for designated use categories of Class C (the protection and propagation of fish, shellfish, and wildlife) and Class D (the protection of human health related to consumption of fish and shellfish). Wetlands are now protected from significant adverse hydrologic modifications, excessive sedimentation, deposition of toxic substances in toxic amounts, nutrient imbalances, and other adverse impacts from human activities.

- Massachusetts made significant progress in establishing wetlands-specific criteria. The State defined wetlands as waters of the State, designated uses for wetlands, adopted aesthetic narrative criteria and very general numeric criteria for wetlands, and drafted an antidegradation policy. The State intends to complete and implement the antidegradation policy; draft narrative biological criteria; develop specific numeric criteria for appropriate parameters; develop criteria

VOL 12

5872

R0039180

for designating wetlands and Outstanding Resource Waters; and incorporate these standards and criteria into the State 401 Water Quality Certification Program. The State also drafted regulations for implementing the 401 program during the 1994 reporting cycle.

■ During 1992 and 1993, Minnesota completed rules to implement the 1991 Minnesota Wetlands Conservation Act. These rules require local governments to regulate the draining and filling of wetlands not classified as "public waters wetlands." Twenty-five exemptions are included in the Wetlands Conservation Act and Rules. Minnesota also began comprehensive wetlands conservation planning in 1993. An interagency task force staffed through the Minnesota Department of Natural Resources will develop statewide wetlands goals and guidance for coordinating local, State, and Federal wetlands programs.

Minnesota added specific definitions of wetlands to their water quality standards, assigned water use classifications to wetlands, adopted narrative nondegradation standards to protect wetlands, and implemented a wetlands mitigation process. The Minnesota Pollution Control Agency began surveying reference wetlands sites to develop biological and chemical criteria for the wetlands use classifications and to assess the biological and chemical health of wetlands throughout the State.

■ Nebraska adopted specific wetlands water quality standards in November 1993. The standards classify wetlands into two categories: isolated wetlands and surface water overflow wetlands that are adjacent to lakes or streams. The beneficial uses of aquatic life, wildlife habitat, agricultural use, and aesthetics are assigned to all wetlands. In addition, surface water overflow wetlands are protected for the assigned beneficial uses of the adjacent lake or stream. The State assigned narrative water quality criteria to protect the beneficial uses and numeric criteria to protect uses from toxic pollutants.

■ Ohio is in the process of drafting standards to protect the functional values of wetlands, including designated uses, narrative criteria, and an antidegradation policy specifically for wetlands. The State is also developing performance goals for wetlands mitigation projects and designing a monitoring program to support both wetlands water quality standards and the mitigation performance goals.

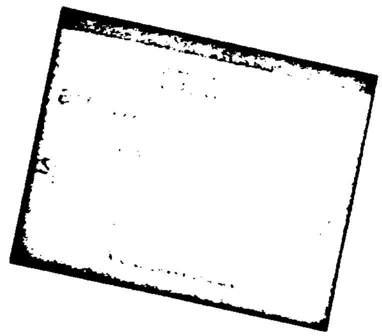
■ Wisconsin Administrative Code NR 103 established wetlands water quality standards in 1991 that include narrative criteria to protect specific wetlands values and functions, such as storm and flood water storage, water cycle functions, filtration of pollutants, shoreline protection, wildlife habitat, and recreational and scientific values.

The standards have greatly enhanced the effectiveness of Wisconsin's Section 401 Water Quality Certification Program by providing legal criteria for denying or adding conditions to proposed activities that will have a significant adverse impact on wetlands values and functions. The standards have controlled impacts to wetlands without halting all activities in wetlands—the State granted 401 Certification to more than half of the wetlands permit applications reviewed between 1991 and 1994.

Summary

There are a variety of public and private programs to protect wetlands. A forum was held in 1987 to coordinate these and provide national direction in the area of wetlands. Section 404 of the Clean Water Act is the major Federal program for regulating activities in wetlands. Other important tools to protect wetlands include voluntary stewardship, wetlands water quality standards, State water quality certification, State wetlands conservation plans, emergency wetlands reserve and conservation reserve programs, and Swampbuster provisions of the Farm bills, as well as incorporating wetlands considerations into other programs such as the Section 319 Nonpoint Source Program.

States reported that they are making progress in developing their programs to protect wetlands, especially in the areas of application of 401 certification, development of water quality standards for wetlands, State programmatic general permits, and formation of more efficient joint application procedures for permits. Despite these efforts, States reported that they continue to lose wetlands and the pressure to develop in wetlands remains high. In addition, there is little known about the quality of the remaining wetlands. States put forward a variety of recommendations on how to improve protection of wetlands, including consideration of wetlands on a landscape or ecosystem basis, development of scientific tools for States to assess and monitor ecological and water quality functions of wetlands, greater sensitivity for arid climates, and regulation of additional activities that impact wetlands.



More information on wetlands can be obtained from EPA's W[illegible] Hotline at 1-[illegible]32-7828 (9 a.m. to 5 p.m., eastern standard time).

HIGHLIGHT HIGHLIGHT HIGHLIGHT

The New Hampshire State Programmatic General Permit

On June 1, 1992, the U.S. Army Corps of Engineers (COE) issued a New Hampshire State Programmatic General Permit (NHSPGP) and simultaneously revoked most nationwide permits for use in the State of New Hampshire. These actions streamlined the wetlands permitting process by consolidating the Federal Section 404 permit review process with New Hampshire's own comprehensive permitting process for activities proposed in wetlands. The actions also eliminated much of the confusion surrounding nationwide general permits.

Under the NHSPGP, the New Hampshire Department of Environmental Services (DES) Wetlands Bureau and the New Hampshire Wetlands Board perform the initial review of all projects proposed in the State's wetlands. The Wetlands Board makes the initial permit decisions, based on information and recommendations provided by DES. The New Hampshire Wetlands Laws of 1967 and 1969 require permits from the Wetlands Board for all projects proposed in the State's wetlands, regardless of project size. There are no exemptions for agricultural or silvicultural activities or activities proposed by Federal, State, or local agencies. The Wetlands Board consists of representatives from eight State agencies and four members of the public.

The Wetlands Board issues three types of permits for activities proposed in wetlands:

- Minimum impact permits for projects that impact less than 3,000 square feet
- Minor impact permits for projects that impact less than 20,000 square feet (about half an acre)
- Major impact permits for projects that impact more than 20,000 square feet.

The NHSPGP establishes the following procedures for processing each of the New Hampshire permits.

HIGHLIGHT HIGHLIGHT HIGHLIGHT

- All projects that receive a minimum impact permit from the Wetlands Board automatically fall under the NHSPGP, with no COE action required. The Wetlands Board notifies permit applicants that the permitted project may commence without COE action.

- The COE and other Federal agencies screen projects that receive a minor impact permit from the Wetlands Board to determine if the project meets conditions of the NHSPGP or requires an individual Section 404 permit. The COE notifies the applicant within 30 days if an individual Section 404 permit is required. Projects with minor impact permits are approved automatically if the COE does not intervene in 30 days and the project meets the conditions of the NHSPGP.

- The COE and other Federal agencies screen projects that receive a major impact permit from the Wetlands Board to determine if the project meets conditions of the NHSPGP or requires an individual Section 404 permit. The COE should notify the applicant within 30 days if an individual Section 404 permit is required, but lack of notification does not provide automatic approval for major projects. The applicant must receive affirmative notification before they initiate projects with major impact permits.

The following categories of projects and activities are excluded from the NHSPGP and automatically require an individual Federal Section 404 permit:

- Projects that will fill more than 3 acres of wetlands or other U.S. waters

- New boating facilities, including marinas, yacht clubs, boat clubs, and public docks

- Projects within the limits of a COE navigation project

- Discharge of spoils in the ocean

VOL 12

5876

HIGHLIGHT

- Improvement dredging in the lower Merrimack River, the Connecticut River, Lake Umbagog, and tidal waters

- Breakwaters extending more than 50 feet from the shoreline

- Projects adversely affecting a National Park, National Forest, National Wildlife Refuge, endangered species, or a National Wild and Scenic River

- Any project likely to jeopardize the continued existence of threatened or endangered species

- Projects of national concern (such as significant fill of wetlands or projects that could affect archeological sites).

During the first year of NHSPGP implementation, New Hampshire reported a 76% reduction in the number of Section 404 individual permits issued and a sevenfold increase in the number of projects receiving documented Federal compliance with Section 404. The NHSPGP process appears to benefit everyone. The NHSPGP relieves permit applicants of time-consuming parallel State and Federal permitting procedures, reduces the COE's average review period for general permits, and frees up limited Federal and State staff to review major projects.

The NHSPGP also eliminates confusion over nationwide general permits. Prior to implementation of the NHSPGP, permit applicants who received nationwide permits often did not realize that they also needed a State permit. Conversely, applicants who received State permits often assumed that they qualified for a nationwide general permit and failed to apply for a required Section 404 individual permit.

The Administration's Wetlands Plan

Shortly after coming into office, the Clinton Administration convened an interagency working group to address legitimate concerns with Federal wetlands policy. After hearing from States, developers, farmers, environmental interests, members of Congress, and scientists, the working group developed a comprehensive 40-point plan to enhance wetlands protection while making wetlands regulations more fair, flexible, and effective. The plan was issued on August 24, 1993.

The Administration Wetlands Plan emphasizes improving Federal wetlands policy by streamlining wetlands permitting programs; increasing cooperation with private landowners to protect and restore wetlands; basing wetlands protection on good science and sound judgment; and increasing participation by States, Tribes, local governments, and the public in wetlands protection. The Administration has already taken a number of actions to implement the Wetlands Plan, including the following steps:

- Proposed a nationwide general permit and created an administrative process to minimize the regulatory burden on small landowners for small projects on their land
- Clarified, by regulation, that prior converted croplands are not wetlands under both the Swampbuster and CWA programs
- Gave the U.S. Department of Agriculture the responsibility for identifying wetlands on agricultural lands for both Swampbuster and CWA programs
- Issued policies that have increased flexibility in wetlands permitting and reduced burdens on permit applicants
- Allowed for greater flexibility in permitting requirements in Alaska, due to the unique circumstances in that State
- Made it easier for permit applicants to use mitigation "banks"
- Requested increased funding for the Wetlands Reserve Program to assist farmers who want to restore wetlands

5879

HIGHLIGHT HIGHLIGHT HIGHLIGHT

- Increased funding to States, Tribes, and local governments for wetlands programs.

These efforts are only the first steps that the Administration is taking to reduce the burden of Federal wetlands regulations. Activities currently under development include

- Clarifying exemptions of man-made wetlands from Federal jurisdiction
- Establishing clear and firm deadlines for COE permit decisions
- Allowing administrative appeals of permit denials and wetlands jurisdictional determinations as an alternative to expensive and time-consuming litigation
- Establishing a wetlands delineator certification program to expedite regulatory decisions and improve the quality and consistency of wetlands delineations performed by private consultants
- Improving wetlands assessment techniques so that permit decisions better reflect the fact that all wetlands do not function in the same manner
- Developing guidance to promote the use of Section 404 programmatic general permits that reduce overlap between State and Federal wetlands permitting procedures and provide additional flexibility to State and local governments
- Expanding the Wetlands Reserve Program to all 50 States and allowing more types of land to qualify for the program.

Most of these actions ease the Federal wetlands permitting burden on small landowners and farmers. The Administration is committed to meeting our Nation's wetlands protection objectives without imposing unnecessary burdens on America's farmers and individuals who own property that happens to include wetlands.

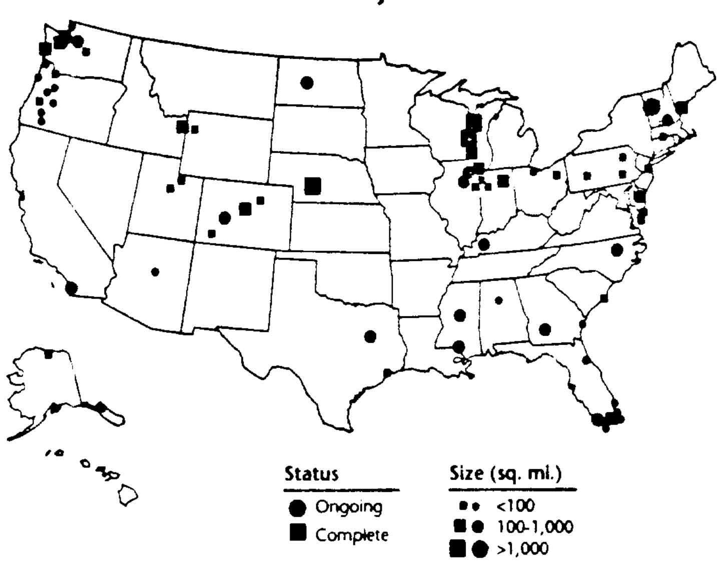
EPA Wetlands Advance Identification (ADID)

This highlight describes the advance identification of disposal areas (ADID), a planning process used to identify wetlands and other waters that are generally suitable or unsuitable for the discharge of dredged and fill material. It highlights how the ADID process works and the status of ongoing projects.

Status of EPA Wetlands ADID Projects – 1993



How the ADID Process Works

The ADID process involves collecting and distributing information on the values and functions of wetlands areas. EPA conducts the process in cooperation with the U.S. Army Corps of Engineers and in consultation with States or Tribes and local interests. Local communities can use this information to help them better understand the values and functions of wetlands in their areas. It also serves as a preliminary indication of factors likely to be considered during review of a Section 404 permit application.

The ADID process is intended to add predictability to the wetlands permitting process as well as better account for the impacts of losses from multiple projects within a geographic area.

Although an ADID study generally classifies wetland areas as suitable or unsuitable for the discharge of dredged or fill material, the classification does not constitute either a permit approval or denial and should be used only as a guide by community planners, landowners, and project proponents in planning future activities. The classification is strictly advisory.

Status of ADID Projects

As of February 1993, 38 ADID projects had been completed and 33 were ongoing. The projects range in size from less than 100 acres to more than 4,000 square miles and are located from Alaska to Florida, as shown in the map. ADID projects can be resource-intensive activities, although some have been completed in as little as 6 months.

Regional EPA experience indicates that the smaller or more local the ADID project boundaries, the more complete and effective the analysis and results. For example, ADID projects have been initiated by local entities to facilitate planning efforts such as the one undertaken in West Eugene, Oregon. In this particular study, local ADID efforts led to an abbreviated Section 404 permit process. Because the ADID was incorporated into the City of Eugene's general comprehensive plan and because Oregon land-use policies have the effect of local land-use law, the ADID effort streamlined the regulatory process. These local efforts have proven to be one of the more successful ways of generating support for wetlands protection. Local cooperation and support are vital to the success of ADID projects.

The number of ADID projects has increased over time, and EPA expects more States, Tribes, localities, and private organizations to become involved in providing funds and otherwise supporting ADID or other comprehensive planning efforts. Because ADID efforts are usually based on watershed planning, they are extremely compatible with geographic and ecosystem initiatives such as EPA's Watershed Protection Approach.

Wetlands Mitigation Banking

Mitigation banking has the potential to play a significant role in the Section 404 regulatory program by reducing uncertainty and delays as well as improving the success of wetlands mitigation efforts. Landowners needing to mitigate or compensate for authorized impacts to wetlands associated with development activities may have the option of purchasing credits from an approved mitigation bank rather than restoring or creating wetlands on or near the development site.

A wetlands mitigation bank is a wetlands area that has been restored, created, enhanced, or (in exceptional circumstances) preserved, which is then set aside to compensate for future conversions of wetlands for development activities. A wetlands bank may be created when a government agency, a corporation, or a nonprofit organization undertakes such activities under a formal agreement with a regulatory agency. The value of a bank is determined by quantifying the wetlands values restored or created in terms of "credits."

Benefits of Mitigation Banking

- Banking can provide more cost-effective mitigation and reduce uncertainty and delays for qualified projects, especially when the project is associated with a comprehensive planning effort.
- Opportunities for successful mitigation are increased since the wetlands can be functional in advance of project impacts.
- Banking can eliminate or reduce the temporal losses of wetlands values that typically occur when mitigation is initiated during or after the development impacts occur.
- Consolidation of numerous small, isolated, or fragmented mitigation projects into a single large parcel may result in increased ecological benefits.
- A mitigation bank can bring scientific and planning expertise and financial resources together, thereby increasing the likelihood of success in a way not practical for individual mitigation efforts.

VOL 12

R0039191

HIGHLIGH HI GHT HIGHLIGHT

Status

The Administration supports mitigation banking and is developing interagency guidance for the establishment and use of mitigation banks. Approximately 100 mitigation banks are in operation or are proposed for construction in 34 States across the country, including the first private entrepreneurial banks.

Jeff Reynolds, Raleigh, NC

Ground Water Protection Programs

Fifty-one percent of the Nation's population depended upon ground water as a source of drinking water in 1990 (U.S. Geological Survey Circular 1081, 1993). In addition to providing much of our Nation with drinking water, ground water is used for agricultural, industrial, commercial, and mining purposes.

The importance of our Nation's ground water resources is evident. Unfortunately, ground water is vulnerable to human contamination, and, in the 1994 305(b) reports, States identified 66 contaminant sources that threaten the integrity of ground water resources. Because it is expensive and technologically complex to remediate ground water resources that have been adversely impacted by human activities, ground water protection has become the focus of numerous State and Federal programs.

This chapter presents an overview of ground water protection programs and activities that have been described by the States in their 1994 305(b) reports and the laws and programs instituted by the Federal Government to provide a framework for ground water protection for the States.

State Programs

In their 1994 State 305(b) reports, States provided narratives detailing legislation, statutes, rules, and/or regulations dedicated to ground water protection that are in place, pending, or under development. The narratives also highlighted major studies undertaken by the States in the interest of ground water protection, issues related to ground water quality that are currently of concern or may be in the future, and progress in developing and implementing ground water protection programs. The purpose of these narratives was to provide an indication of the comprehensive nature of ground water protection activities among the States.

Clearly, States are committed to a number of activities to address existing ground water contamination problems and to prevent future impairments of the resource. These activities include enacting legislation aimed at the development of comprehensive ground water protection programs and promulgating protection regulations; adopting and implementing ground water protection strategies; adopting ground water classification and mapping programs; and establishing

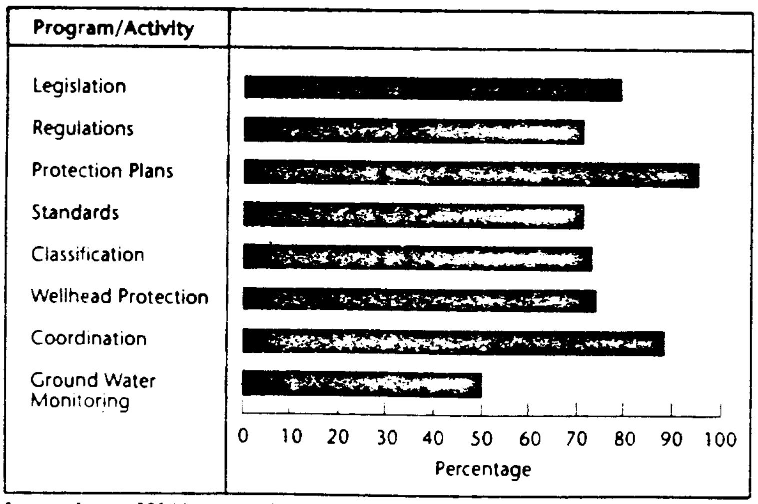
Wellhead Protection (WHP) Programs. Figure 18-1 presents the percentage of States, Territories, and Tribes reporting on each of these activities. As shown, States are making excellent progress in developing and implementing programs related to ground water protection.

Ground Water Protection Legislation

Forty-six of the 58 responding States, Territories, and Tribes report some form of current or pending legislation geared specifically to ground water protection. Generally, legislation focuses on the need for program development, increased data collection, and public education activities. In many States and Tribes, legislation also mandates strict technical controls such as discharge permits, underground storage tank registrations, and protection standards. Additionally, some States and Tribes have enacted legislation establishing a policy to restore and maintain ground water quality and remediate pollution that has occurred.

Figure 18-1

Percentage of Reporting States Having Implemented Programs or Activities



Source: Section 305(b) reports submitted by States, Tribes, and Territories.

Minnesota passed the Ground Water Protection Act (GWPA) of 1989 and continues to fund projects such as ground water monitoring and data management, increased control of pesticides and fertilizers, agricultural chemical cleanups, and local water plans. The law also states that ground water quality should be maintained so that it is continually free of human-induced pollutants.

The Michigan Legislature enacted the Environmental Response Act to identify, prioritize, and fund the cleanup of environmentally contaminated sites in cases where responsible parties do not provide relief. The Michigan Department of Natural Resources coordinates the State program with the Federal Superfund program. The two programs are complementary in their goals and objectives.

The primary legislation for Illinois ground water protection, the Illinois Groundwater Protection Act (IGPA), was enacted in 1987. The Act establishes the policy of the State to "restore, protect and enhance the ground waters of the State, as a natural and public resource."

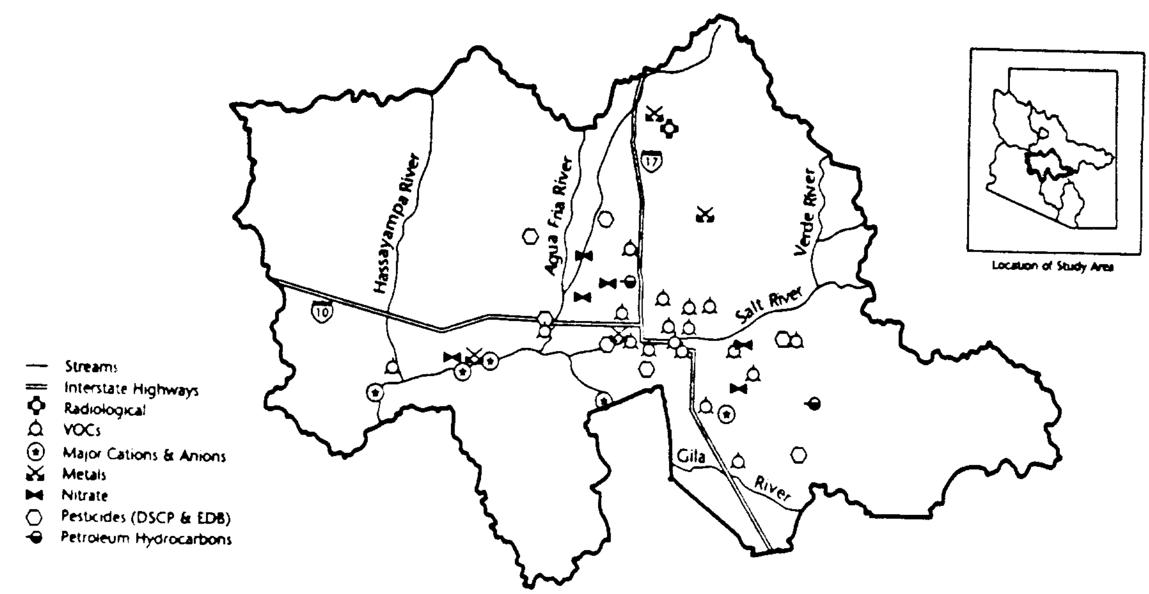
Discovery of extensive contamination in the State's ground water prompted Arizona to develop strong and comprehensive ground water legislation. The 1980 Ground Water Management Act promotes a strategy of preserving, enhancing, and protecting current water quality; remediating, minimizing, and preventing past, present, and future discharges to aquifers; and prohibiting discharges of toxic pollutants to aquifers. This Act defines several geographic areas in which ground water supplies are threatened. The State has designated these areas as Active Management Areas (AMAs). Figure 18-2 illustrates one AMA. Areas in which there is a possible or known threat to ground water resources are marked with the appropriate symbol. Management plans in these areas address the threats of both overdrafts and contaminants.

In Hawaii, problems with the quality and reliability of surface water supplies have led to concern over the protection of the State's ground water. The 1987 State Water Code protects ground water by authorizing the prohibition, control, and regulation of activities in areas vulnerable to ground water contamination. The State has adopted a policy of antidegradation and uses the authority established by this legislation to require proof that proposed activities will not degrade ground water before issuing a permit.

The Rhode Island legislature passed the Ground-Water Protection Act in 1985, establishing a

Figure 18-2

Ground Water Contamination in the Phoenix Active Management Area



Source: *Arizona Water Quality Assessment 1994*, Arizona Department of Environmental Quality.

VOL 12

5888

R0039196

comprehensive ground water protection policy. Reenacted in 1991, it emphasized restoring, enhancing, and maintaining the chemical, physical, and biological integrity of Rhode Island's ground water. The legislature passed this law based on the belief that ground water is a critical renewable resource that must be protected to ensure the availability of drinking water.

Ground Water Regulations

Of the 58 responding States, Territories, and Tribes, 41 report that they have established regulations specifically geared toward protection of ground water quality. In general, State and Tribal ground water protection regulations stipulate controls for the management of specific sources of contamination and standards for ground water quality protection. These standards may be used to apply limits on the allowable discharges from contaminant sources and/or to set contaminant concentration targets or threshold levels for ground water cleanup.

Nevada has adopted statutory authority and promulgated associated regulations to implement a mining strategy that is widely considered to be a model for western States in terms of both controls placed upon the mining industry and the explicit considerations of impacts on ground water quality. Regulations include several requirements for the purpose of protecting ground water by minimizing or preventing discharges from mining facilities.

The Florida Department of Environmental Regulation (DER) has established both general and specific permitting provisions for permitting discharges to ground water. The regulations require that all discharges to ground water meet certain water quality conditions, such as Florida's water quality standards.

South Carolina's ground water regulations establish a ground water classification system to protect public health and maintain and enhance ground water quality. They include general rules and specific water quality criteria to protect classified and existing water uses. The regulations also set forth narrative standards for classification and specific numeric water quality standards for ground water that is classified as a source of drinking water.

Ground Water Protection Plans

Fifty-five of the 58 responding States, Territories, and Tribes have adopted, or are in the process of developing, ground water protection plans. The general content of these plans includes: selection of goals and objectives for ground water problems identified in the jurisdiction; development of a ground water classification system; program coordination mechanisms for local, State, and Federal ground water protection activities; public education and/or involvement; development of an interagency ground water data collection system; legislative recommendations pertaining to the regulation of contaminating sources; development of a ground water monitoring system; establishment of a WHP Program; improvement of existing ground water protection programs; and development of statewide

VOL 12

5889

R0039197

standards for ground water quality. These plans provide the basis for their Comprehensive State Ground Water Protection Programs (CSGWPPs).

Texas outlines goals, needs, and recommendations in six important areas in its Ground Water Protection Plan: interagency coordination, hazardous and nonhazardous materials management, public water supply, rural water supply, research, and legislation. Within these areas, each of the following plan elements are discussed: status of existing programs, gaps or inadequacies in these programs, areas of currently unaddressed ground water issues, recommendations for changes or improvements in existing programs, and institution of new programs where needed.

The Indiana Plan is an agenda for State action to prevent, detect, and correct contamination and depletion of ground water resources. The implementation plan identifies key steps, schedules, responsibilities, resources, outputs, and contingencies to accomplish the objectives of the plan. This plan is to be adaptable to new Federal requirements, responsive to emerging issues and proprieties, and subject to revision based on experience.

As of January 1994, 8 of the 23 Nebraska Natural Resource Districts had developed local Ground Water Protection plans, including

- Stated goal to maintain ground water levels and quality at predevelopment levels forever

- Development of Ground Water Control areas with mandated permitting, spacing, and reporting requirements

- Development of Special Protection areas with required education, monitoring, and regulatory programs to reduce nonpoint source contamination

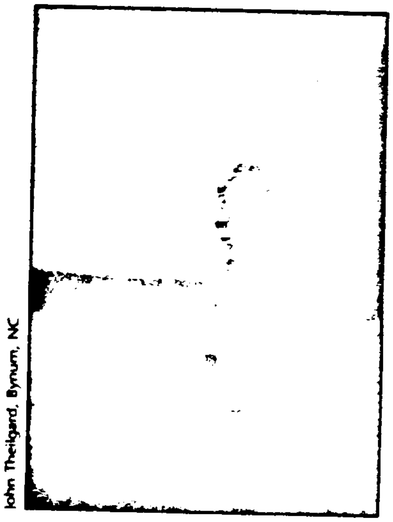
- Development of Ground Water Management Plans

- Development of Ground Water Quality Management Areas to manage nitrogen fertilizer application and irrigation practices.

Ground Water Protection Standards

Although many States and Tribes use Federal drinking water standards to direct their ground water protection activities, a number have tailored the standards to meet their specific conditions. State and Tribal ground water protection standards may be either narrative or numeric. Numeric standards set health-based maximum contaminant levels (MCLs) for specific compounds in ground water. Narrative standards are adopted for contaminants for which numeric standards have not been adopted. Forty-one States, Territories, and Tribes reported the development or implementation of ground water protection standards.

All ground water in South Carolina is classified as Class GB, which is ground water that meets the definition of an underground source of drinking water (USDW). All USDW supplies must have contaminant levels that are below MCLs set forth in the South Carolina *Primary Drinking Water Regulations*. Compounds for which standards or proposed MCLs do not exist are evaluated individually.



John Theilgard, Bynum, NC

Arizona's *Aquifer Water Quality Standards* are the cornerstone of the State's ground water protection program. All aquifers were initially classified and protected for drinking water use, and none has been reclassified. Numeric Aquifer Water Quality Standards were developed and adopted by Arizona as enforceable standards for the maximum permissible level of a parameter in a public water system. The Arizona Department of Environmental Quality has also adopted narrative aquifer water quality standards that allow regulation of pollutant discharges for which no numeric standards have been adopted.

Standards for ground water quality in Nebraska are intended to be the foundation for ground water point source programs in the State. Narrative standards deal primarily with beneficial uses of ground water. Beneficial uses of ground water, hydrologically connected ground waters, and surface waters are all protected. Numeric standards in the form of MCLs for various parameters are also provided. Some parameters listed are assigned "reserved status." This means that ground water standards have not been adopted for these parameters but will be in the future.

Ground Water Classification/Mapping Programs

Forty-two States, Territories, and Tribes have developed or are developing ground water classification systems to aid in the protection and management of their aquifers. Classification systems can be used as a basis for the maintenance and restoration of ground water quality, the development of ground water quality standards, and land use and pollution source management and regulation. Most ground water classification systems are based on the understanding that some human activities have the potential to degrade ground water. The systems are designed to restrict such activities to areas overlying aquifers containing lower quality waters while protecting the most vulnerable and ecologically important ground water systems. Most States and Tribes that have classification systems apply them to the permitting of discharges or potential discharges to ground water and the remediation of contaminated ground water. Some States may also use their systems to guide the development of new water supplies or to site certain types of industries.

The first tiers of a State's classification system are typically designed to identify and protect water that is currently used or has the potential to be used as a source of drinking water. The potential for drinking water use is generally based on water quality indicators, such as salinity and total dissolved solids, and potential yield. Some States and Tribes also place ecologically sensitive aquifers in the highest tiers of their classification systems.

Aquifers that do not meet these requirements or that are unsuitable for use because of poor ambient water quality or because of past contamination are generally classified for other types of uses, such as industrial processes or, in some cases, waste disposal.

The New Jersey Department of Environmental Protection and Energy has classified the State's ground water on a regional basis according to its hydrogeologic characteristics and designated uses. The State has applied a nondegradation policy to the most sensitive ecological area but allows minimal degradation in some other areas, recognizing that some human activities will adversely affect ground water.

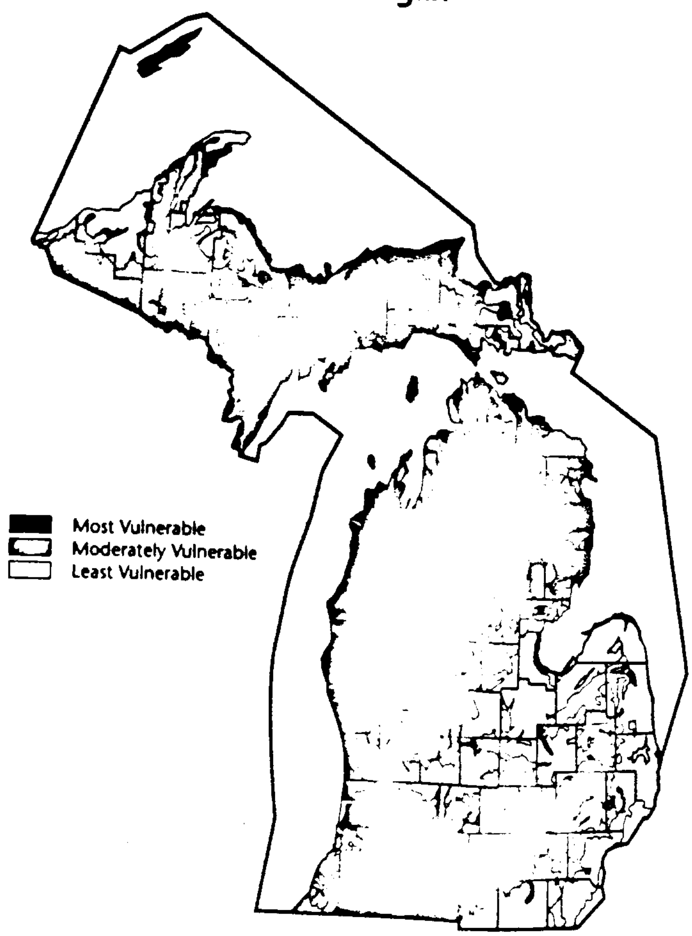
In 1992, Michigan State University Center for Remote Sensing mapped aquifer vulnerability to surface contamination for use in siting facilities or activities with a potential for ground water contamination. The most vulnerable areas constitute 31% of the State's land area and are composed of highly permeable soils over highly sensitive glacial drift, principally composed of sand and gravel (Figure 18-3). The moderately and least vulnerable areas make up 44% and 25% of the State, respectively.

As part of the development of a ground water classification system, the recharge areas for major aquifers in Rhode Island as well as approximately 450 sources of known and potential sources of ground water contamination have been mapped. The Rhode Island Department of Environmental Management (DEM) has made extensive use of the Rhode Island Geographic Information System (GIS) in this mapping. Maps can be produced with the GIS at different scales, in various formats, and with different layers of information. DEM encourages the use of these maps in local ground water protection efforts.

The lack of a classification system does not indicate a lower priority for ground water protection.

Figure 18-3

Aquifer Vulnerability to Surface Contamination in Michigan



Source: *Water Quality and Pollution Control*, Michigan 305(b) Report: Volume 13, Michigan Department of Natural Resources.

The majority of States, Territories, and Tribes that do not have explicit classification systems apply the same level of protection to all aquifers, with either a statewide antidegradation policy or the preservation of all ground water for drinking water use. For example, Minnesota does not employ a classification system. However, the State supports a nondegradation policy, promoting preventive measures to protect all ground water from degradation by human activities.

Wellhead Protection Programs

The 1986 Amendments to the Safe Drinking Water Act (SDWA) established the WHP Program. Under SDWA Section 1428, each State must prepare a WHP Plan and submit it to EPA for approval. By the end of April 1995, a total of 39 States had EPA-approved WHP Programs in place.

Six cases of benzene contamination were detected in public water supplies in Louisiana in 1992. Louisiana's WHP Program aided the communities in locating the sources of contamination and in the siting of new wells. Case studies of these communities prompted a coordinated effort between the WHP Program and the Louisiana Department of Environmental Quality Underground Storage Tank (UST) Division to see that all unregistered USTs are registered and all abandoned USTs within a 1,000-foot radius of public water supply wells are closed. This restrictive radius will increase with time.

Coordination of Protection Programs Among State Agencies

Historically, ground water protection programs have been overseen by many different agencies within the States, Territories, and Tribes, making coordination difficult for those programs. Coordinating the activities of these agencies to ensure an efficient ground water protection program has become a top priority in many jurisdictions. Fifty-one States, Territories, and Tribes report having developed a plan to coordinate ground water protection programs among their agencies.

The Illinois Ground Water Protection Act (IGPA) created the Interagency Coordinating Committee on Groundwater (ICCG) to direct efforts of State agencies and expedite implementation of ground water protection efforts. Ten State agencies actively participate in the ICCG. In order to direct overall comprehensive ground water protection efforts, the ICCG established the Governor-Appointed Groundwater Advisory Council (GAC), which is comprised of various interest groups, including business, industry, agriculture, regional planning, environmental, municipalities, water well drillers, and public water supplies.

Ground water protection in Colorado is a shared responsibility of many agencies at all levels of government. Colorado authorized four "implementing" agencies as partners in ground water protection: Mined Land Reclamation Board, The Oil and Gas Commission, the State Engineer (Division of Water Resources), and the Hazardous

VOL 12

5893

Materials and Waste Management Division of the Health Department. Each of the implementing agencies has developed regulations to protect ground water within the area of authority with which each agency is charged, and they annually report their progress to the Water Quality Control Division, the agency with final authority for protecting the resource.

Ground Water Monitoring Programs

Two types of ground water monitoring programs are used by States to collect data on ground water quality: ambient monitoring and compliance monitoring. Ambient monitoring programs measure background or existing water quality and are used to track long-term trends in contaminant concentrations. Compliance monitoring programs are required by Federal or State regulations (e.g., ground water monitoring at site cleanups under CERCLA, detection monitoring under RCRA, or community water supply monitoring under SDWA). Compliance monitoring activities measure for specific constituents to ensure that their concentrations in ground water are below regulated levels. In addition to ambient and compliance monitoring, States may also rely on monitoring data collected by Federal agencies, such as the USGS National Water Quality Assessment program, to assess basin ground water quality.

Chemical or constituent-based indicators are generally used as part of a monitoring program to define trends in ground water quality. The constituent-based indicators used in each State are typically selected based on local or regional water quality, contaminant use characteristics, or previously observed contamination patterns. By identifying changes in the concentrations of these constituents in ground water, land uses affecting vulnerable aquifers can be identified and corrected.

Administrative indicators are another form of indicator parameter that may be used by States. Administrative indicators assess the status of potential sources of contamination, such as the number of hazardous waste sites, the amount of leachable pesticides applied to land, the amount of toxic chemicals released annually, the number of abandoned water wells, or other changes in regional land use practices. These administrative indicators allow States to target their ground water protection and monitoring activities.

Table 18-1 summarizes the types of indicators and monitoring programs that States and Territories currently use to measure ground water quality. Appendix I, Table I-2, presents this information in greater detail. Data were obtained from review of 305(b) reports, monitoring program documentation, and contact with State officials. For conflicting sources, the most recent information is presented and the source is cited.

Virtually all of these States engage in some type of ground water quality monitoring program. Specifically, 23 States report active ambient monitoring programs. In addition, Colorado and Nevada have proposed ambient monitoring programs. Sixteen of these States

[a] Indicators suggested by EPA in the guidance document for the 305(b) report.
[b] State relies on programs below State level for ground water data.

NOTE: Although all States have federally mandated compliance monitoring programs, this table reports those States that use their compliance monitoring data to evaluate ground water quality.

report using specific constituent-based indicators to track trends in ground water quality statewide. Florida has focused the set of parameters monitored under their ambient program based on their understanding of local water quality patterns and contaminant sources. In regions of high agricultural land use, Florida focuses on nitrate and chloride levels in ground water. Similarly, Florida analyzes for certain trace metals (e.g., arsenic, barium, cadmium, chromium, copper, mercury, nickel, silver, and zinc) in regions of industrial land use. South Carolina has established a network of 114 public and private water supply wells that draw water from a single aquifer and are known not to be impacted by contaminants in order to assess ambient ground water quality statewide. South Carolina tests for 39 individual parameters once every 5 years on a rotating basis. Several States are also pursuing the use of indicators to screen for certain sets of water quality parameters in their monitoring programs. For example, Idaho is developing the use of immunoassays to assess the presence of pesticides in ground water. Idaho uses the immunoassay methods to analyze specifically for 2,4-D, alachlor, carbamate, carbofuran, cyanazine, metalachlor, and triazines.

In addition to ambient monitoring, 31 States report that they also use data from compliance monitoring activities to assess trends in ground water quality, and 18 use Federal monitoring data.

A total of 18 States use administrative indicators to track potential sources of contamination. Of these 18 States, 13 use indicators that were suggested by EPA in its guidance document for the 305(b) Water Quality Report to Congress. These indicators include MCL violations, point sources of pollution (e.g., underground storage tanks, military bases, RCRA, CERCLA, and other hazardous waste sites), nitrate contamination, and pesticide use.

Federal Programs

The Federal Government has instituted laws and programs to provide a framework to States, Territories, and Tribes for protection of our Nation's ground water resources. These include Federal statutes that mandate certain ground water protection activities and EPA programs that deal specifically with the control of contaminant source activities conducted under the authority of Federal statutes. Federal statutes include the Safe Drinking Water Act, the Clean Water Act, the Resource Conservation and Recovery Act, the Comprehensive Environmental Response, Compensation, and Liability Act, the Toxic Substances Control Act, the Federal Insecticide, Fungicide, and Rotenticide Act, and the Pollution Prevention Act.

Under these Acts, the EPA is responsible for 20 programs related to ground water protection. Most of these are regulatory programs that restrict or prevent specific activities from introducing contaminants onto the land, into the subsurface, or into ground water resources. The rest are nonregulatory and provide national guidance and technical assistance to jurisdictions to identify and protect their vulnerable ground water resources and integrate existing ground water protection

VOL 12

5897

R0039205

programs. Both types of programs are key components of EPA's successful ground water protection strategy when building partnerships with other EPA programs, Federal agencies, State and local governments, industry, environmental groups, and the regulated community. Several concepts fundamental to this approach to ground water protection are based on EPA's guiding principles: ecosystem protection, environmental justice, pollution prevention, strong science and data, partnerships, and compliance. They are:

- Review regulations for opportunities to get better environmental results at less cost; improve new rules through increased coordination.
- Actively promote pollution prevention as a standard business practice and a central ethic of environmental protection.
- Make it easier to provide, use, and publicly disseminate relevant pollution and environmental information.
- Assist companies that seek to obey but exceed legal requirements and consistently enforce the law against those that do not.
- Change permitting so that it works more efficiently, encourages innovation, and creates more opportunities for public participation.
- Give industry the incentives and flexibility to develop innovative technologies that meet and exceed environmental standards while cutting costs.

Highlights of a number of Federal ground water protection programs are presented according to the following protection categories: resource protection, pollutant source control, and pollution prevention.

Resource Protection

The protection of the Nation's ground water resources is addressed under the Clean Water Act and the Safe Drinking Water Act. The CWA encourages ground water protection, recognizing that ground water provides a significant proportion of the base flow to streams and lakes. Ground water protection afforded by the SDWA is focused on waters that supply public water systems (PWSs), and through implementation of the Wellhead Protection and Underground Injection Control Programs.

Clean Water Act

In the CWA (Public Law 92-500) of 1972 and in the CWA Amendments of 1977 (Public Law 95-217), Congress provided for the regulation of discharges into all navigable waters of the United States. Ground water protection is addressed in Section 102, providing for the development of Federal, State, and local comprehensive programs for reduction, elimination, and prevention of ground water contamination.

As part of the CWA, a process is established that allows for the generation of information concerning the quality of our Nation's ground water resources and the reporting of this information to EPA and the U.S. Congress. The requirements for this process are found in Sections 106(e)

VOL 12

5898

R0039206

and 305(b) of the CWA. Section 305(b) mandates that States develop a program to monitor the quality of their waters and report the status in this biennial National Water Quality Inventory Report to Congress. This process, referred to as the 305(b) process, is the principal means by which the EPA, Congress, and the public evaluate water quality, the progress made in maintaining and restoring water quality, and the extent to which problems remain.

Unfortunately, information reported on the quality of our Nation's ground water resources has not always provided a complete and accurate picture of overall ground water quality. This is due, in part, to the expense involved in collecting ground water monitoring data, the complex spatial variations of aquifer systems across the Nation, and the differing levels of sophistication among State programs. Recognizing this problem, EPA worked with States to develop guidelines for the comprehensive evaluation and reporting of ground water quality.

Appreciating that data collection and organization vary among the States and that a single data source for evaluating ground water quality does not exist, EPA suggested several different sources of data that may be used by States to evaluate their ground water quality. EPA then encouraged States to use available data that they believe reflects the quality of the resource. EPA also focused on allowing States to report information for aquifers or hydrogeologic settings that are a State priority due to high ground water demand or vulnerability. Using these guidelines, States will be able to provide a more meaningful interpretation of ground water quality.

Comprehensive State Ground Water Protection Program

Under the authority of the CWA Section 102, many States are developing Comprehensive State Ground Water Protection Programs tailored to their goals and priorities for the ground water resource. CSGWPPs will guide the future implementation of all State and Federal ground water programs and provide a framework for States to coordinate and set priorities for all ground-water-related activities. Each CSGWPP consists of six strategic components: a goal, a priority-setting mechanism, roles and responsibilities, management measures, information collection and management, and public participation.

The EPA is committed to working with States in developing and carrying out the CSGWPP approach. A State with an EPA-endorsed CSGWPP works in partnership with the EPA to further improve State ground water protection activities, develop a vision of integrated, resource-focused ground water protection, and identify ways that the Federal Government can support State ground water protection efforts.

Figure 18-4 shows the progress in implementing the CSGWPP approach. As of 1994, the EPA had approved four State CSGWPPs, and EPA endorsement is anticipated for an additional six States in 1995. Another 29 States are expected to submit CSGWPPs for EPA approval by the end of fiscal year 1996.

5899

Safe Drinking Water Act

The SDWA was passed by Congress in 1974 and amended in 1986. Under this Act, EPA sets national limits on contaminant levels in drinking water to ensure that the water is safe for human consumption. The principal ground water protection afforded by the SDWA comes through the enforcement of these limits through State and Federal supervision of public water systems. The SDWA also contains programs to implement the Wellhead Protection Program, the Sole Source Aquifer (SSA) Program, and the Underground Injection Control (UIC) Program, described below.

Approximately 93% of all PWSs (177,589 systems serving nearly 114 million people) obtain their water from a ground water source. These include systems that supply year-round water to households (46,880 Community Water Systems); systems that provide water to places such as schools, factories, and hospitals (23,221 Nontransient Noncommunity Water Systems); and systems that supply water to transitory customers such as campgrounds, motels, and gas stations (107,488 Transient Noncommunity Water Systems). Private, domestic wells are not regulated under the SDWA.

Drinking Water Standards

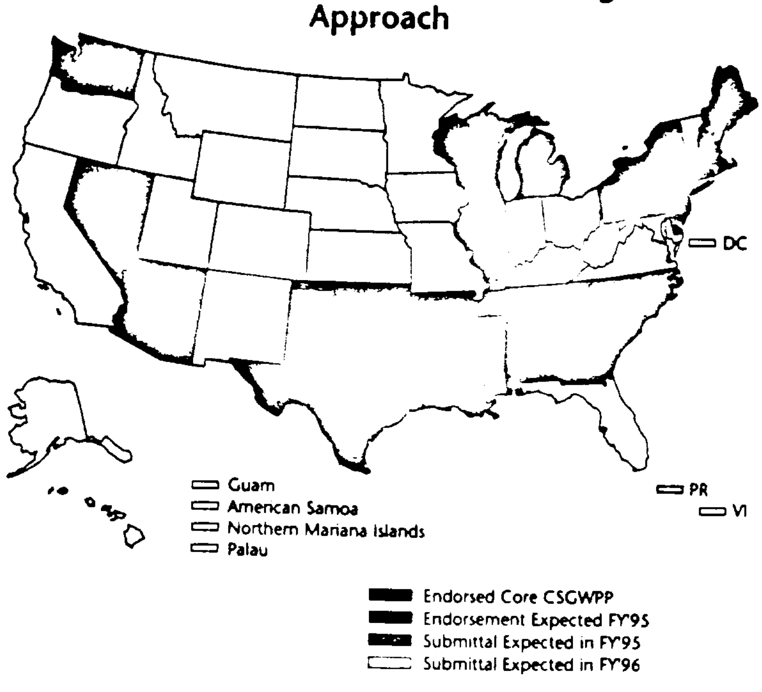
EPA, under the SDWA, seeks to ensure that public water supplies are free of contaminants that may cause health risks and to protect ground water resources by preventing the endangerment of underground sources of drinking water. EPA has pursued a twofold approach: (1) protecting drinking water at the tap, and (2) preventing contamination of ground water sources of drinking water supplies.

The 1986 Amendments to the SDWA provided for an expanded Federal role in protecting drinking water, mandating changes in nationwide safeguards, and new responsibilities to enforce them in the event of State inaction.

EPA has also focused on the prevention of contamination of

Figure 18.4

Progress in Implementing the Comprehensive State Ground Water Protection Program Approach



VOL 12

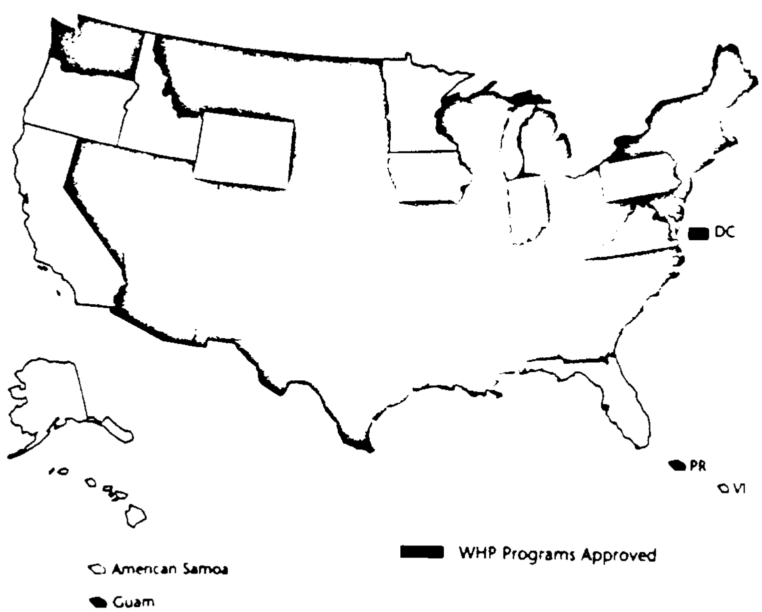
5900

R0039208

vulnerable ground water resources by assisting States in the development and implementation of comprehensive ground water protection plans. These plans address both the full range of actual and potential sources of ground water contamination and provide for local wellhead protection programs in the areas around public water wells. In addition, EPA has targeted specific activities to protect drinking water sources from the harmful effects of injection of wastes and other fluids. Utilizing authorities provided by the UIC, EPA is increasing emphasis on the vast number of diverse shallow (Class V) injection wells by developing technical industry guidance. EPA is also reviewing the permitting requirements for Class I hazardous waste wells and the imposition of more restrictive standards for all Class II oil and gas injection wells.

Figure 18-5

Status of Wellhead Protection Programs Across the U.S. and Territories



Wellhead Protection Program

The 1986 Amendments to the SDWA established the WHP Program. Under SDWA Section 1428, each State must prepare a WHP Plan and submit it to EPA for approval. The objective of this program is to protect public health through local action to prevent ground water contamination from reaching public wells by (1) identifying the areas around public water supply wells that contribute ground water to the well, and (2) managing potential sources of contamination in these areas to reduce threats to the resource.

By the end of April 1995, a total of 39 States and Territories had EPA-approved WHP Programs in place. Figure 18-5 illustrates the States and Territories having regulatory authority to implement WHP programs. EPA is working with the remaining States, Tribes, and Territories to help them develop WHP Programs. EPA's Office of Ground Water and Drinking Water is supporting the development and implementation of WHP at the local level through many efforts. For example, EPA-funded support is provided through the National Rural Water Association (NRWA) Ground Water/Wellhead Protection programs. These programs are currently being implemented voluntarily in 31 States. These States work to integrate their local programs with the WHP Program to meet State requirements. Figure 18-6 presents the States with active and pending NRWA Wellhead Protection programs.

EPA is also funding Wellhead Protection workshops for local decisionmakers. Eighty-eight of these workshops were held in 26 States. These workshops were attended by approximately 4,400 people.

In 1991, EPA funded a 2-year cooperative agreement with NRWA to promote ground water protection. This agreement was extended for an additional 2 years. At the conclusion of the first 4 years, over 2,000 communities in 26 States were actively involved in protecting their water supplies by implementing wellhead protection programs. These 2,000 communities represent 3,985,000 people in the rural areas of the United States who will have better-protected water supplies.

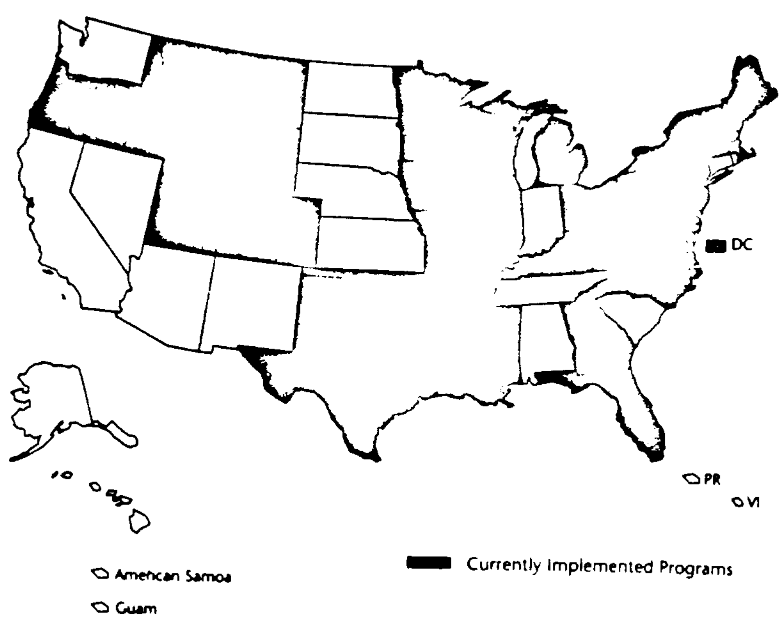
EPA also funded a 3-year cooperative agreement with the League of Woman Voters (LWV) to develop and test models of community outreach in 18 communities. Based on the experience in those communities, a guidebook entitled *Protect Your Groundwater: Educating for Action* was developed. The popularity of this guidebook led to a national videoconference of the same name. Broadcast in April 1994 to over 150 sites, the videoconference directly reached approximately 3,000 persons. Videotapes were made of the conference and distributed to LWV chapters across the country. The success of this videoconference has led to further cooperation with LWV to bring WHP to even more communities.

According to State 305(b) reports, WHP Programs have taken varying forms in the different States. Among the stages of WHP Program development reported by States are

- Grants to communities to explore and tailor WHP approaches to their needs
- Mapping of sensitive ground water protection areas
- Establishment of mandatory WHP programs to protect public water supply wells
- Establishment of public education and outreach programs
- Establishment of specific protection criteria for wells tapping confined aquifers and more stringent protection criteria for wells tapping unconfined aquifers.

Figure 18.6

States with National Rural Water Association Wellhead Protection Programs



Sole Source Aquifer Program

The Sole Source Aquifer protection program was established under Section 1424(e) of the SDWA of 1974. The program allows communities, individuals, and organizations to petition EPA to designate aquifers as the "sole or principal" source of drinking water for an area. Since the first SSA designation in 1975—the Edwards Aquifer in the area around San Antonio, Texas—64 designations have been made nationwide. Seven petitions were evaluated for possible designation at the end of 1994.

If the sole-source designation is approved for an aquifer, EPA is then authorized to review all Federal financially assisted projects to determine if, as a result of the project, the potential exists for adverse impacts to public health due to aquifer contamination. If the Federal financially assisted project is approved by EPA, the project may be implemented as planned with commitment of Federal financial assistance; however, if the potential exists for aquifer contamination, modifications to the project may be necessary prior to commitment of Federal financial assistance. Federal funds may be used to make these modifications to ensure that projects will not contaminate the aquifer.

Federal financially assisted projects undertaken in SSA areas may include a variety of activities involving several agencies. For instance, approximately 50% of the reported activities were initiated by Housing and Urban Development (HUD) through Community Development Block Grants. These include the construction of nursing homes, repair and construction of firehouses to avoid hydrocarbon runoff from equipment from entering the ground water, and installation of septic systems using proper non-polluting drainage construction. The Department of Agriculture Farmers Home Administration has invested in construction and preplanned siting programs for residential areas and ancillary facilities on a large scale.

The Department of Transportation assists in funding construction of roads, highways, mass transit, and certain railroad and airport facilities. This type of construction requires that the proper disposal of surface water runoff be dispersed rather than concentrated on the ground surface and avoid the flooding of local aquifers by runoff from salting stations, hydrocarbons from highway spills and general traffic use, including airports and hangar areas.

Designation helps project sponsors by providing a set of guidelines for aquifer quality review and ground water protection techniques. It also allows individuals, agencies, and States and Tribes the opportunity to develop strategies beyond the SSA program to protect drinking water aquifers, such as adopting Wellhead Protection Programs.

Figure 18-7 illustrates the number of projects reviewed, approved, and modifed for fiscal years 1990 through 1994. Only five projects were not approved during this same period: four projects in 1991 and one in 1992. There were no other unapproved projects after 1992. This curtailment is an indication that SSA project sponsors have adjusted to the ongoing SSA ground water protection program objectives.

Review of Figure 18-7 indicates the following:

- A total of 1,039 projects were reviewed over the 5-year period. Of these, 838 were approved and 74 were modified.

- Review of project modifications indicates that ground water protection was achieved through changes in drainage and spill containment, clear identification of SSA boundaries, more focused pre- and postconstruction activity monitoring, and review of initial project designs.

- For fiscal years 1992, 1993, and 1994, project modifications decreased by approximately 64% over previous years. This decrease reflects the maturing of the SSA program as a community ground water protection tool. Project sponsors and designers acknowledge that proper aquifer protection is required up front in the design phase and that incorporation of proper aquifer protection will expedite designations.

Pollutant Source Control

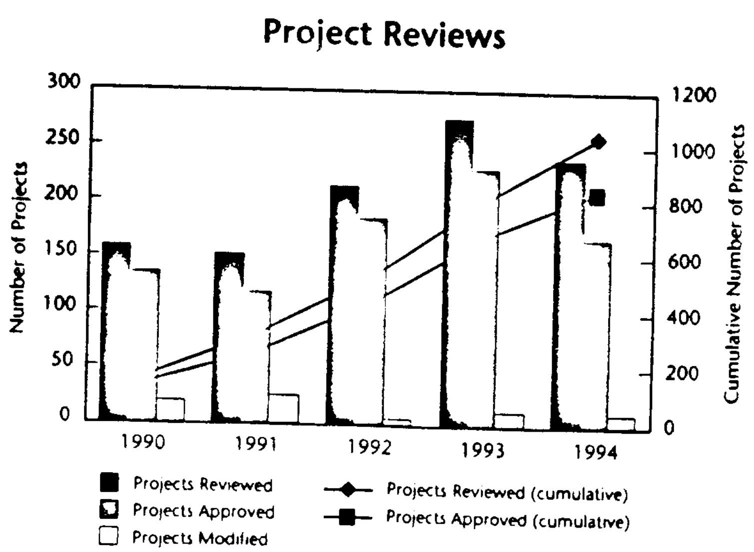
Four principal programs control pollutant sources under four different laws: underground storage tanks and solid and hazardous waste treatment, storage, and disposal are regulated under RCRA; underground injection of waste fluids is regulated under SDWA; abandoned waste is regulated under CERCLA; and nonpoint sources are controlled under CWA.

Resource Conservation and Recovery Act

The Resource Conservation and Recovery Act (Public Law 94-580) was passed by Congress in October 1976, amending the 1965 Solid Waste Disposal Act to address the problem of safe disposal of the huge volumes of solid and hazardous waste generated nationwide each year. This Act authorizes a regulatory program to identify and manage wastes that pose a substantial hazard to human health or the environment. RCRA is a part of EPA's comprehensive program to protect ground water resources. Protection is achieved through the development of regulations and methods for handling, storing, and disposing of hazardous material and through the regulation of underground storage tanks.

Poorly managed or poorly located municipal landfills rank high

Figure 18-7



VOL 12

5904

R0039212

Kings Park Elementary, 3rd Grade, Springfield, VA

among State ground water contamination concerns. Of the quarter million solid waste disposal facilities in the United States, about 6,000 are municipal solid waste facilities. Approximately 25% of these municipal facilities have ground water monitoring capabilities.

As of September 1994, there were 418 land disposal facilities subject to ground water monitoring requirements under RCRA. Approximately 221 of these facilities are conducting detection monitoring, 42 are conducting compliance monitoring, and 155 are undertaking corrective action.

Solid and Hazardous Waste

RCRA has evolved from a relatively limited program dealing with nonhazardous solid waste to a far-reaching program that also encompasses the handling, storage, and disposal of hazardous waste. Hazardous waste generators, transporters, and owner/operators of treatment, storage and disposal facilities (TSDFs) constitute the RCRA-regulated community. On November 8, 1984, Congress passed the Hazardous and Solid Waste Amendments (HSWA) to RCRA, thereby greatly expanding the nature and complexity of activities covered under RCRA.

The goals of RCRA, as set forth by Congress, are

- To protect human health and the environment
- To reduce waste and conserve energy and natural resources
- To reduce or eliminate the generation of hazardous waste as expeditiously as possible.

RCRA also requires the promulgation of standards related to underground storage tank systems for both chemicals and petroleum products.

In 1990 and 1991, RCRA programs continued to emphasize the preparation of risk assessment documents and development and evaluation of tests and procedures for conducting risk assessments. Health and Environmental Effects Documents, Reference Doses, and technical evaluations are provided to support the RCRA waste listing, permitting, and land disposal restriction programs. The 1990 program emphasized the development of health and environmental effects documents for the listing/delisting programs and reference doses for the land disposal restriction program. In addition, techniques for determining soil gas concentrations and constituents and for determining ground water contamination potential were evaluated under field and laboratory conditions. Guidelines for monitoring ground water around RCRA Subtitle D landfill facilities are being developed.

Underground Storage Tank Program

One of the primary goals of this program is to protect the Nation's ground water resources from releases by underground storage tanks containing petroleum or certain hazardous substances. The EPA works with State and local governments to implement Federal requirements for proper management of USTs. The EPA estimates that about 1.2 million federally regulated USTs are buried at over 500,000 sites nationwide. Nearly all USTs contain petroleum; about 30,000 USTs hold hazardous substances covered by the Federal regulations.

In 1988, EPA issued regulations setting minimum standards for new tanks (those installed after December 22, 1988) and existing tanks (those installed before December 22, 1988). By December 1998, existing USTs must be upgraded to meet minimum standards or be replaced with new tanks or be closed properly. Since 1988, more than 900,000 old USTs have been closed, thus eliminating a significant number of potential sources of ground water contamination. Of the remaining 1.2 million USTs, about 400,000 have already been upgraded or replaced.

New and existing USTs complying with EPA's standards can prevent leaks caused by spills, overfills, corrosion, and faulty installation. USTs complying with the leak detection requirements can identify releases quickly, before contamination spreads. Corrective action requirements secure responsible and timely cleanup of contaminated sites.

As of January 1995, more than 278,000 UST releases had been confirmed. The EPA estimates that about half of these releases have reached ground water. Over 110,000 contaminated sites have been cleaned up, and cleanups are under way at 100,000 more sites. EPA estimates that the total number of confirmed releases could reach 400,000 in the next several years, primarily due to releases discovered during the closure or replacement of old USTs. After this peak, EPA expects fewer releases as USTs comply with leak prevention requirements.

Congress created the Leaking Underground Storage Tank (LUST) Trust Fund in 1986 to provide money for overseeing corrective action taken by a responsible party and to provide money for cleanups at UST sites where the owner or operator is unknown, unwilling, or unable to respond or that require emergency action. Since 1986, $469 million has been dispersed to State UST programs for State officials to use for administration, oversight, and cleanup work.

UST owners and operators must also meet financial responsibility requirements that ensure they will have the resources to pay for costs associated with cleaning up releases and compensating third parties. The amount of coverage required ranges from $500,000 to $1 million, according to the type and size of the UST business. Many States have provided financial assurance funds to help their UST owners meet the financial responsibility requirements. These State funds raise over $1 billion annually for use on UST cleanups.

The Agency recognizes that, because of the large size and great diversity of the regulated community, State and local governments are in the best position to oversee USTs. EPA encourages States to seek State program approval so they may operate in lieu of the Federal program. To date, 20 States have received State Program Approval. All States have UST regulations and programs in place. The Agency also has developed a data management system that many States use to track the status of UST facilities, including their impact on ground water resources. EPA also has negotiated UST grants with all States and provided technical assistance and guidance for implementation and enforcement of UST regulations.

Safe Drinking Water Act

Pollutant source control is addressed under the SDWA through the UIC program.

Underground Injection Control Program

EPA's UIC program was developed to regulate underground injection wells and thereby ensure that underground sources of drinking water are protected. Injection wells are classified as follows:

- Class I: Wells used to inject hazardous substances or industrial and municipal waste beneath the lowermost formation containing a source of drinking water. There are 159 hazardous waste wells at 61 facilities and 350 nonhazardous waste wells at 197 facilities controlled by stringent design, construction, and operating requirements. The hazardous waste management facilities inject 9 billion gallons of fluids each year. This volume represents 89% of all hazardous waste that is land disposed.

- Class II: Wells used to inject fluids in the process of oil or natural gas production. More than 160,000 disposal and enhanced recovery wells inject brines into geologic formations. These wells inject approximately 3 billion gallons of produced brine and enhanced recovery fluids every day.

Together Class I and II injection wells dispose of a larger volume of hazardous waste into deep bedrock formation than all the other RCRA hazardous waste disposal facilities by a factor of eight.

- Class III: Wells used to inject fluids for the purpose of in situ mineral extraction.

- Class IV: Wells used to dispose of hazardous or radioactive waste into or above an underground drinking water source. These wells are banned.

- Class V: Class V injection wells are generally shallow wastewater disposal wells, stormwater, and agriculture drainage systems or other devices that can release nutrient and toxic fluids into the ground and eventually into water table aquifers. EPA estimates that more than 1 million Class V wells currently exist in the United States. A majority of Class V wells may pose little or no risk to human health. Others, however, may inject fluids containing bacteria, viruses, nitrate-nitrogen, and toxic chemicals that can contaminate the habitat and food supply of fish and wildlife species, the base flow for surface waterbodies, and the public drinking water supply. These wells include more than

Wells as Conduits of Contamination

Although anecdotal cases abound of wells serving as conduits that allow contaminants to enter an aquifer, few occurrences are documented. However, the publication *Drinking Water: Safeguards Are Not Preventing Contamination From Injected Oil and Gas Wastes* (GAO, 1989) provides a table of 23 documented cases of contamination of an underground source of drinking water via Class II oil and gas injection wells. Fourteen of these cases resulted from wells that were improperly plugged or constructed and/or had leaky casings. Nine other cases were the result of deliberate injection into an aquifer before its designation as an underground source of drinking water. What is particularly noteworthy in these cases is the enormous cost of cleanup. In one of the cases, the State (Kansas) authorized $300 million to begin cleanup because the contamination threatened a major municipal well field. In 18 of the other cases, no cleanup is intended because it is either impractical or too costly.

VOL 12

5907

100,000 shallow injection wells such as those used to dispose of waste from automotive service bays.

Currently, all shallow injection wells that do not endanger underground sources of drinking water are allowed; however, because of the diversity in the risks posed by Class V wells and the size and nature of the regulated community, EPA encourages a nontraditional regulatory approach to addressing these wells. A large proportion of the Class V wells are owned by small businesses. To effectively address the unique challenges posed by the Class V universe, EPA is implementing a comprehensive strategy for the management of Class V injection wells. The strategy involves a carefully tailored combination of guidance, education, and outreach and enhancing the use of existing regulatory authorities through some minor changes to the UIC regulations. The goal of the strategy will be to speed up the closure of potentially endangering Class V wells using current authorities and to promote the use of best management practices to ensure that other Class V wells do not endanger USDWs.

Grants allotted under Sections 1443(b) and 1451 of the SDWA may be used to support UIC activities to protect ground water resources. State and Federal UIC programs include permitting and review of permits to ensure that wells meet requirements for well construction, operation, monitoring, plugging, and abandonment, and financial responsibility to ensure that underground sources of drinking water are not endangered. Section 1422 provides EPA with authority to grant primary enforcement authority (primacy) to States to administer a UIC program in their States. Section 1425 allows an alternative test for EPA to use to approve a State's UIC program for Class II brine disposal wells.

EPA and States currently administer 57 UIC programs to maintain regulatory coverage of the almost one-half million underground injection wells. The majority of these programs are State-administered, as depicted in Figure 18-8. State agencies with primary enforcement authority respond to UIC violations. If a response cannot be made in a timely manner, EPA takes enforcement action.

In 1992 and 1993, EPA continued to review "no migration" petitions for hazardous waste injection wells to ensure conformance with RCRA and UIC provisions. EPA has targeted specific enforcement, outreach, and regulatory activities to protect drinking water sources from the harmful effects of injections of wastes and other fluids through the vast number of diverse Class V injection wells. The Class V rule has significant implications for the disposal of industrial wastes. EPA also plans to propose "area of review" requirements for all Class II wells.

EPA Regional offices administering UIC programs in nonprimacy States continue to review permit applications for injection wells and continue oversight of State primacy programs to ensure that UIC permits issued meet program requirements. Regional offices also continue to review petitions from operators of hazardous waste injection wells seeking exemptions from the injection well ban.

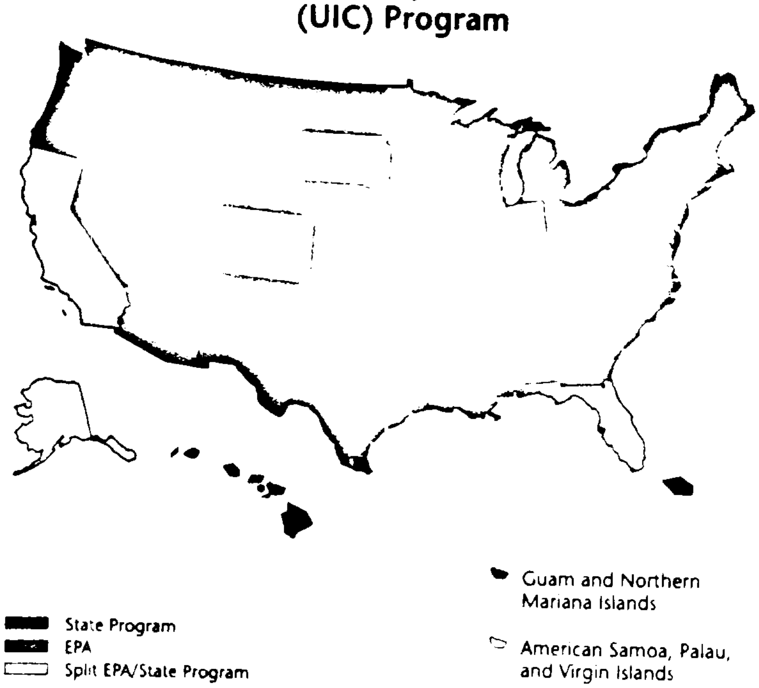
Comprehensive Environmental Response, Compensation, and Liability Act

The Comprehensive Environmental Response, Compensation, and Liability Act and the Superfund Amendments and Reauthorization Act of 1986 created several programs operated by EPA, States, Territories, and Tribes that act to protect and restore contaminated ground water. Restoration of contaminated ground water is one of the primary goals of the Superfund program. As stated in the National Contingency Plan, EPA expects to return usable ground waters to their beneficial uses, wherever possible, within a time frame that is reasonable given the particular circumstances of the site. Following are statistics related to Superfund restorations:

- In the absence of Superfund, 11.9 million people could be exposed to carcinogenic risk greater than 1 in a million, and 9.9 million people could be exposed to noncarcinogenic effects above health-based standards at National Priority List (NPL) sites.
- At 94% of NPL sites where ground waters were classified (426 of 453), the ground water is currently used or potentially usable as a source of drinking water. This suggests that only 6% of NPL sites involving ground water contamination are classified as nonusable aquifers (e.g., saline or nonpotable).
- Of the 622 NPL sites reporting ground water contamination near the site, the ground water is currently used for private water supplies at 42% of the sites and for public supplies at 27% of the sites.
- At the 67% of NPL sites where ground water is currently used for drinking water purposes, the ground water is potentially threatened by a migrating contaminant plume.
- Organic compounds are the predominant ground water contaminants for 89% of the sites for which remedies for ground water contamination have been selected. Table 18-2 lists the most frequently detected organic and inorganic constituents reported at NPL sites.
- Ground water contamination is associated with 63% of the sites for

Figure 18-8

Underground Injection Control (UIC) Program



VOL 12

5909

R0039217

which remedies have been selected (702 of 1,121).

- Generally, ground waters that are currently used or are potentially usable for drinking water supply are being cleaned to MCLs authorized under the SWDA. However, in some cases, more stringent State standards are used. At least 12 States have promulgated cleanup standards for ground water, including Massachusetts, West Virginia, Illinois, Minnesota, Wisconsin, New Mexico, Texas, Iowa, Nevada, South Dakota, Wyoming, and Washington.

Pollution Prevention

The Pollution Prevention Act of 1990 was enacted by Congress to promote pollution prevention and environmental protection goals. Under this Act, the EPA Office of Pollution Prevention and Toxics and the U.S. Department of Agriculture Cooperative State Research Service have worked cooperatively to lead the Nation in the development of environmentally sound agricultural policies. The Agriculture in Concert with the Environment Program promotes the use of sustainable agriculture and the integrated management of nutrients, pesticides, resources, and wastes to reduce the risks of environmental pollution. Grants allotted under this Act may be used to fund outreach projects involving education, demonstration, and training in sustainable agricultural practices that emphasize ground water protection and reducing the excessive use of nutrients and pesticides.

Grants are also available under this Act to support State and local pollution prevention programs that address the reduction of pollutants across all environmental media: air, land, surface water, ground water, and wetlands. These grants may be used to promote and coordinate existing State pollution prevention activities that focus on specific media, to develop new multimedia pollution prevention programs, to develop mechanisms to measure progress in multimedia pollution prevention, and to conduct education and outreach programs.

Grass Roots Ground Water Protection

As the impacts of ground water contamination become more widely known, volunteers and grass roots ground water protection initiatives are becoming common in communities across America. The programs range from volunteer-driven efforts to protect vital drinking water supplies through Wellhead Protection Programs, to volunteer-sponsored well water quality testing and public education on the sources of our drinking water.

The El Paso Experience

In late 1989, the Texas Water Commission targeted the city of El Paso, Texas, for a pilot project to protect the city's ground water. This pilot project marked the beginning of an innovative, volunteer-driven Wellhead Protection Program. A team of dedicated volunteers was coordinated through the El Paso Retired Senior Volunteer Program.

Over a 3½-day period, the 23 senior citizen volunteers surveyed possible sources of ground water contamination around all 138 public water wells that provide drinking water to the city of El Paso. They reviewed historical records, interviewed area residents, and conducted door-to-door surveys to catalog potential threats to their drinking water. The State estimated that the volunteer effort saved approximately $35,000, and resulted in the identification of approximately 20,000 potential sources of pollutants near the water wells.

The El Paso pollution source inventory formed the backbone of the El Paso Wellhead Protection Program and resulted in a city ordinance concerning the storage of hazardous materials within the vicinity of the public water wells. The effort has recently been expanded into Mexico, since the residents of the adjacent Mexican city of Ciudad Juarez also rely on drinking water from the same aquifers.

Oregon's Volunteer Well Water Nitrate Testing Project

The Oregon Department of Environmental Quality sponsored a project to encourage residents to test their well water for nitrate levels. The project was conducted from 1991 to 1993 and resulted in volunteers testing a total of 1,600 wells. The Oregon Ground Water Community Involvement Program was initiated to continue the nitrate testing program. The Program

HIGHLIGHT HIGHLIGHT HIGHLIGHT

provides volunteer training, resource materials and nitrate test kits and promotes public education through nitrate testing events and ground water forums.

League of Women Voters Ground Water Education Programs

The League of Women Voters (LWV) has sponsored a number of volunteer-led ground water education programs. The LWV in Rockford, Illinois, surveyed residents concerning their knowledge of water supply and ground water contamination concerns. Similar surveys were conducted by the LWV in Red Wing, Minnesota, and Salt Lake City, Utah. The LWV of Enid, Oklahoma, organized volunteers to conduct pollution source inventories around the city's five water well fields. Other LWV chapters have developed videos, brochures, and other educational materials concerning ground water protection and potential threats to ground water quality.

VOL 12

HIGHLIGHT HIGHLIGHT HIGHLIGHT

Protecting Our Drinking Water: The EPA's Source Water Protection Initiative

Americans have long enjoyed the luxury of safe, affordable drinking water. A rising awareness of water pollution incidents, however, has caused people to be concerned about drinking water quality. Many communities have recognized that preventing the pollution of lakes, rivers, streams, and ground water is the key to ensuring the long-term safety of drinking water. This common sense approach is known as **source water protection.**

The Safe Drinking Water Act emphasizes monitoring and treatment to protect drinking water safety. However, protection based on monitoring and treatment alone is not sufficient. Nearly all groups interested in drinking water safety see a need for stronger efforts to prevent pollution from entering drinking water sources rather than relying solely on water treatment to reduce health threats.

The EPA encourages this prevention-oriented approach and is actively promoting the development of grass roots source water protection activities. As part of the Source Water Protection Initiative, the EPA hopes to

- Restore the public's rights and responsibilities to protect their drinking water
- Raise public confidence in the safety and quality of their drinking water supply
- Reduce the costs of providing safe drinking water.

Wellhead Protection Programs

Many States and communities are currently promoting source water protection, in Wellhead Protection (WHP) programs. The 1986 Amendments to the Safe Drinking Water Act established the Wellhead Protection Program to aid communities in protecting their drinking water quality. Through wellhead protection, communities identify the land areas that contribute ground water to public water supply wells. They then develop plans to manage the potential sources of contamination in those vulnerable areas, thereby reducing the likelihood of polluting the drinking water source.

5913

HIGHLIGHT HI GHT HIGHLIGHT

VOL 12

By the end of December 1994, a total of 37 States and Territories had EPA-approved WHP Programs in place. In addition, thousands of local WHP initiatives have been undertaken in communities across the Nation. As of 1993, approximately 3,800 communities that are dependent on ground water for drinking water had complete WHP programs.

Expanded Source Water Protection Goals

The idea of wellhead protection can apply to surface water supplies as well. The EPA is encouraging stronger watershed protection programs, through approaches available under the Federal Clean Water Act, to protect surface waters used for drinking water supplies. Source water protection, for both ground water and surface water, may offer significant advantages to both drinking water purveyors and consumers.

The EPA is planning a National Source Water Protection Workshop in 1996. This workshop will provide communities with the tools and information needed to establish source water protection programs. The workshop will be televised and will target communities that have delineated their source water protection areas and carried out source identification. The workshop will also assist communities in moving toward source management.

The EPA has also set the following source water protection goals:

- By 1997, establish a core network of 10,000 communities with active and comprehensive local WHP programs in place.
- By 1997, incorporate source water protection and source management as priority objectives in projects requiring financial assistance from other Federal programs.
- By 1997, begin to expand source water protection approaches to communities reliant on surface water for drinking water.
- By 2005, have 50% of all community water supplies covered by active and comprehensive local source water protection programs.

5914

R0039222

HIGHLIGHT HIGHLIGHT HIGHLIGHT

Costs of Not Preventing Contamination of the Ground Water Resource

The sage adage that "An ounce of prevention is worth a pound of cure" is being borne out in the field of ground water protection. Three separate efforts to look at the cost of prevention versus remediation have found that there can be real cost advantages to promoting prevention of ground water contamination in the public and private sectors.

The analysis of prevention in Maine found that, for six large municipal water systems with contamination from salt storage, gasoline, landfill leachate, and industrial solvents, costs for well replacement, emergency supplies, water treatment, and/or remediation ranged from $500,000 to $1,500,000. Of the 2,000 small water systems in the State, perhaps as many as 70 are contaminated. For six small systems, remedial costs ranged from $6,000 to $155,000. Costs for preventing contamination in these cases were estimated to be 1/10th to 1/100th of the costs of remediation for the large systems and 1/5th to 1/10th for the small systems. Although remediation is thus more costly than prevention, whether prevention is more cost-effective in any particular instance depends on the risk that a water system without a particular type of preventive measure would need remediation and when any costs of remediation would be incurred.

The State of Washington's Wellhead Protection Program found that, in a sample of small communities ranging in size from 300 to 5,000 people affected by such contaminants as ethylene dibromide (an agricultural fumigant), gasoline, and trichloroethylene (TCE, a solvent), costs for cleanup and/or a new water supply ranged from $40,000 to $1,800,000, with costs continuing to be incurred. For a larger city—Tacoma—where TCE and other contaminants were found in a wellfield in concentrations more than 10 times the health standard, costs over the expected 18-year cleanup period are estimated to be $25 million.

Washington's Wellhead Protection Program catalogued the types of costs associated with contaminated public water supplies and found that they included

HIGHLIGHT HIGHLIGHT HIGHLIGHT

- Provision of emergency water supplies
- Construction and operation of water treatment facilities at the wellhead
- Well replacement
- Transmission line construction
- Hydrogeologic studies
- Remedial measures at or near the contamination source including soil removal, soil capping, and the installation and operation of "pump and treat" systems
- Additional administrative costs
- Public information and education
- Legal proceedings.

Intangible costs included

- Increased health risks
- Decreased ability to provide adequate volumes of water, especially in emergencies, such as fires
- Reduced consumer confidence
- Economic impairment
- Lost opportunity costs in spending funds for cleanup rather than other community needs
- Consumer hysteria and overreaction
- Disposal of wastewater from pump and treat facilities.

The Freshwater Foundation report, *Economic Implications of Groundwater Contamination to Companies and Cities* (1991), indicates that costs to 17 Minnesota cities for remediating ground water contamination was over $30 million, with seven cities reporting costs over $1 million and two reporting impacts in the $10 to $20 million range. Fourteen cases of ground water contamination involving corporations found that most businesses spent over $1 million, with five spending from $5 million to nearly $10 million. In addition to the technical and engineering remedial costs, a major corporate cost was legal fees.

Costs and Benefits of Water Pollution Control

Introduction

Section 305(b) of the Clean Water Act calls for States to prepare estimates of the economic and social costs necessary to achieve the objectives of the Act. States are also requested to report on the economic and social benefits of these achievements. None of the States, Territories, and Tribes reporting on their water quality programs attempted to describe the full extent of the economic costs and benefits associated with water quality improvement. Thus, the costs shown in this chapter are from the U.S. Department of Commerce, Bureau of Census, *Pollution Abatement Costs and Expenditures, 1992.* Pennsylvania and the District of Columbia submitted expenditure information on municipal wastewater treatment, which is included in this report as well.

The benefits described in this chapter are from many sources. Information from the Sport Fishing Institute, State reports, and EPA and other Federal sources was used to help measure environmental benefits achieved. It is important to understand the impossibility of measuring the total environmental benefits of water quality improvement. First, benefits are local and to measure the benefits of cleaner water in each locality would be impossible. Second, the methodology does not exist to measure the value of biodiversity or the value of the oxygen produced by a healthy ecosystem. Although these intrinsic values are very important, they are not measurable quantitatively or monetarily. This chapter provides some insight into the benefits of water quality improvement found throughout our Nation. When economic benefits data are not available, biological indicators are used to show stream improvement. The assumption is that, if the insect life in the stream is improving, eventually the fish will return and so will recreation, which has an economic value.

Costs of Water Quality Improvement

Estimates of the costs and benefits of water pollution control are shown in Table 19-1 derived from President Clinton's *Clean Water Act Initiative: Analysis of Costs and Benefits* published in 1994. This table shows the current and planned expenditures associated with the current implementation of the Clean Water Act requirements. Private sources are estimated to spend roughly $30 billion per year on water pollution control, municipalities spend about $23 billion per

VOL 12

5 9 / 9

year, agriculture spends approximately $500 million per year, State water programs spend $500 million per year, and Federal agencies spend approximately $10 billion per year. These total to a range of $63 billion to $65 billion per year spent on water pollution control.

Since 1972, EPA has invested over $64 billion in municipal wastewater treatment. State and local governments have contributed many more dollars. In 1972, only 42% of the population was served by secondary or better municipal wastewater treatment facilities. By 1992, this number had increased to more than 62% of the population. This achievement is impressive considering that, during this time, both the Nation's population and the volume of pollution flowing through our sewer systems increased by nearly 30%.

EPA has invested appproximately $1.4 billion since 1972 in maintaining State water quality programs through grants funded under Section 106 of the Clean Water Act. The goals of the Section 106 program are to assist States, Territories, and Tribes in establishing and maintaining adequate measures for preventing and controlling surface and ground water pollution. Other Federal agencies such as the Corps of Engineers, the U.S. Geological Survey, the Natural Resources Conservation Service, and the Fish and Wildlife Service have contributed substantially to the water pollution control efforts in this country.

Pennsylvania provided the most complete set of data. Pennsylvania reported that, during the past 5 years, new grants totaling more than $118.5 million in Federal funds were offered to Pennsylvania municipalities for construction of sewage treatment facilities. Actual dollar expenditures under this Federal grant program during this period amounted to $261.3 million,

Table 19.[illegible] Summary of Current and Planned Spending under the Existing CWA (millions $/year)

	Private Sources	Municipalities	Agriculture	State Water Programs*	Federal Agencies	Total (Quantified)
Pre-1987 Act	$25,286	$17,190	$191	$373	$9,564	$52,604
Nonpoint Source Controls/ Watershed		$389 - $591	$240 - $389	$125	$234	$988 - $1,339
Storm Water: Phase I	$3,990	$1,650 - $2,555				$5,640 - $6,545
CSOs		$3,450				$3,450
Other Costs	$943 - $1,073	$88				$1,031 - $1,161
Total	$30,219 - $30,349	$22,767 - $23,874	$431 - $580	$498	$9,798	$63,713 - $65,099

*Pre 1987 expenditures, estimated to be about $2.7 billion per year for administration and compliance, are not shown here because the cost of complying with the current and future water quality standards could not be estimated. The values shown here are only for administering the program.

Source: U.S. EPA 1994. *President Clinton's Clean Water Act Initiative: Analysis of Costs and Benefits.* EPA 800-S-94-001. Office of Water, Washington, DC.

which includes expenditures from grants made during prior years. Funding from other Federal agencies, including the Farmer's Home Administration and the Department of Commerce, has provided municipalities an additional $63.1 million for facilities planning and administration. State funds and grants issued by the Department of Environmental Resources (DER) and the Pennsylvania Department of Commerce have provided municipalities another $140.1 million for wastewater treatment facilities in the same 5-year period (Table 19-2). These facilities, as they begin operation, represent a significant effort in the cleanup of Pennsylvania's waters.

The District of Columbia estimates the capital cost for the Blue Plains wastewater treatment plant at about $600 million and operation and maintenance costs at about $110 million per year.

Benefits of Water Quality Improvement

Improvements in water quality are valuable to all Americans. Millions of people enjoy recreational activities like fishing, swimming, and boating on waters where these pursuits might not be possible without the control measures undertaken under the Clean Water Act. Cleaner water has reduced health risks to people who swim and fish. Cleaner water has contributed to more productive commercial and recreational fisheries in many parts of the country. It has lowered costs to agriculture and to industries that would otherwise have to treat contaminated water before using it. It has also lowered costs to drinking water systems that might otherwise have to install additional treatment technologies. Finally, cleaner water has

VOL 12

5921

provided important aesthetic benefits to Americans who derive value from knowing that waters are cleaner, even when they are unable to visit them.

Notwithstanding these important and substantial benefits of clean water, EPA has not quantified systematically all of the extraordinarily diverse improvements in water quality that have occurred since the Clean Water Act was passed, or that may be attributable to the Act. Moreover, such quantification must typically precede the valuation of improvements in dollar terms. Thus, the total magnitude of environmental, economic, and health-related benefits that result from improvements to water quality are not measurable given existing data and analytic methods. The following discussion describes, nonetheless, some of the benefits associated with water quality improvements.

Recreation

Outdoor recreation is a lucrative business in the United States. Much of our outdoor recreation activities depend on clean water. Sport fishing alone accounts for 1.3 million jobs and $19 billion in wages.* The Sport Fishing Institute (1994) estimates more than 50 million anglers spent more than $24 billion on fishing trips and equipment in 1991. The Institute claims that freshwater fishing "generates nearly 60% of the economic impacts within the sport fishing industry." Expenditures of this magnitude generated approximately $1 billion in State sales taxes and more than $2 billion in Federal income taxes.

The sport fishing industry is increasingly vocal about the need for clean water programs. Fifty million anglers, representing a significant portion of the U.S. population, receive direct benefits of improved water quality.

Eighty million Americans participate in outdoor (non-pool) swimming. Local and State economies are dependent on beach-related recreating, whether at ocean or lake beaches. In 1988, $1.3 to $5.4 billion was lost in the New York-New Jersey area due to beach closings resulting from water quality health standard violations.

Commercial Fishing

The value of U.S. commercial fish landings is about $3.5 billion annually and the industry's total contribution to the GNP is about $16.5 billion. Shellfish landings represent 45% of this total. Nearly 87% of the value of U.S. finfish landings are species-dependent on near-coastal waters for breeding and spawning.†

Good Water Quality Benefits the Economy

Good water quality is important for economic development. Companies that want to attract the best workers often locate in areas that are replete with parks and open spaces, where air and water quality

VOL 12

5922

R0039230

are good, and where recreational opportunities are abundant. These amenities are essential for the quality of life required by today's workforce.

The Institute for Southern Studies published a study in October 1994 illustrating the relationship between State economic growth and environmental quality. What this study shows is summed in a quote from Dr. Stephen Meyer of the Massachusetts Institute of Technology. Dr. Meyer concluded: "States with stronger environmental standards tended to have the higher growth in their gross state products, total employment, construction employment, and labor productivity than states that ranked lower environmentally." The study ranked Louisiana last for jobs and environmental quality. Eight other southern States (along with Indiana, Ohio, and Oklahoma) ranked among the 14 worst States in both categories. Hawaii, Vermont, and New Hampshire ranked among the top six States for both jobs and environmental quality. Six States ranked among the top 12 in both categories: Wisconsin, Minnesota, Colorado, Oregon, Massachusetts, and Maryland.*

There are industries that are dependent on a healthy, clean water supply. These industries range from the soft drink to the computer chip industry. For these industries, clean water is a valued economic input. The cleaner the source water, the less treatment the intake water requires. These savings are then passed on to their consumers.

The following discussion illustrates how various States and the District of Columbia benefit from improved water quality and describes some of the actions they are taking to rebuild the benefits lost two and three decades ago.

Water Quality Benefits Identified by States

Pennsylvania

Improved water quality conditions have enabled programs to be undertaken to reintroduce breeding populations of bald eagle, osprey, and river otter in Pennsylvania. The Pennsylvania Game Commission's Bald Eagle Recovery Project was carried out from 1983 to 1989. A total of 88 young eagles were released from hatching sites in the upper Delaware and lower Susquehanna River basins. In addition, eaglets were introduced to active nests in northwestern Pennsylvania to supplement populations in that area. As a result of this program, 13 bald eagle nests were found in 1992. All together, the nests produced 21 hatchlings. In 1993, a record 16 pairs of bald eagles attempted to nest in the Commonwealth. Even though some nests were abandoned due to the March blizzard, 15 eaglets were produced.

Through cooperative projects, over 100 osprey (fish hawks) were hatched in northeastern Pennsylvania in the early 1980s to form the nucleus of what has become a viable breeding population in the Poconos. In 1989, a hatching tower was constructed on the Hammond Dam in Tioga County, which can accommodate up to 16 ospreys. This project was initiated in 1990

* Hall, Bob. *Green and Gold.* Institute for Southern Studies. October 1994.

VOL 12

59233

R0039231

with nine ospreys, the first of approximately 70 to be released over 5 years. Cooperating parties have included the Game Commission, the Fish and Boat Commission, the National Audubon Society, the U.S. Army Corps of Engineers, and researchers from East Stroudsburg University and the Dubois Campus of Penn State University. In 1992, as many as 14 active osprey nests were located in the State. Nine were in the Poconos, three were in Lancaster County, and one each was in York and Somerset Counties.

River otter reintroductions began in 1982. From 1982 through 1989, 39 otters were released in the Kettle, Pine, and Loyalsock Creek basins in north central Pennsylvania. These otters have expanded their range and reproduced. Otter reintroductions in northwestern Pennsylvania began with the release of four otters in the Tionesta Creek basin in 1990. More otters were scheduled to be released in this basin during 1991. An April 1992 otter release in the Youghiogheny River brought them back to the drainage for the first time in more than 100 years. Five otters were released near Confluence as part of a cooperative program. Additional releases are planned. In addition, Maryland stocked 18 otters on the Youghiogheny near Oakland in 1989 and 1990. The success of these programs is due, in part, to improved water quality and resulting improved fisheries.

The following are estimates of the economic value of fishing and boating to the Pennsylvania economy. In 1992, a total of 1,081,163 fishing licenses were sold in the State. In addition, 735,237 Trout Stamps were sold. These sales provided $17 million in revenue to the Pennsylvania Fish and Boat Commission. Over 2 million people participated in fishing (anglers under age 16 do not need a license) and spent between $750 and $800 million in direct trip and equipment expenditures. This translates to an average of $750 to $800 per angler per year. This is a significant contribution to the economy.

In addition, there are 311,893 registered boats in Pennsylvania that generated $4.2 million in fees for the Fish and Boat Commission in 1992. An estimated 3 million Pennsylvanians participated in boating activities and contributed $3.056 billion to the economy for equipment, supplies, food, lodging, fuel, etc.

Connecticut

Entire industries are based wholly, or in part, on having clean water resources. These include fishing, boating, swimming, and a variety of recreation or tourism-related industries. An extensive survey was conducted by the University of Connecticut College of Agriculture and Natural Resources for EPA Region 1. The final report titled, *The Economic Importance of Long Island Sound's Water Quality Dependent Activities*, released in January 1992, was based on survey data collected between June 29 and November 29, 1990.

The study estimates that the value of Long Island Sound to the economies of New York and Connecticut for water-quality-dependent activities was $5.5 billion in 1990. Three billion dollars of this was attributed to Connecticut's economy. The following discussion briefly summarizes use valuations for

VOL 12

5924

R0039232

Connecticut's portion of Long Island Sound.

Commercial finfish and shellfish landings were estimated to be $53 million. Specific associated industries directly related to harvesting increases this value to $148.4 million. Additional industries relating to the processing, wholesaling, and retailing of fish and shellfish were not considered. Thus, the value this industry adds to the Connecticut economy is understated.

An estimated 7.5 million persons visited Connecticut's beaches in 1990. Studies conducted in Rhode Island and Florida indicate that this translates directly into $159.1 million for Connecticut's economy (on average, $21 per person per year). Related contributions to the State's tourism industry increase this estimate to $361.45 million.

Sportfishing constitutes another important industry in Long Island Sound. Roughly 330,000 people participated in the sport in 1991. Direct expenditures associated with sport fishing is estimated at $258.5 million (on average, $780 per angler per year). Related activities increase this estimate to $624.6 million contributed to Connecticut's economy (on average, $1,890 per angler per year).

Recreational boating represents the largest industry that depends on maintaining water quality. Direct expenditures for equipment and services were estimated at $836 million. This increased to $1.84 billion with the inclusion of related activities.

Finally, an attempt was made to estimate the value of salt marshes as a resource unto themselves and not as developable land. Many values, such as flood control and erosion buffers, were not assigned dollar values. A conservative estimate of the value of the marshes as spawning grounds and feeding areas for commercial and recreational fishes was calculated at $93.75 million. This value was equally divided between New York and Connecticut.

Connecticut's shellfish industry has grown from a harvest of 30,000 bushels in 1972 to 900,000 bushels in 1992 with a value exceeding $46 million. The shellfish industry contributes approximately $500,000 in goods and in-kind services to the Connecticut Department of Agriculture, which oversees the State's shellfish industry.

An estimated 392,419 acres are available for growing shellfish; of these, over 46,500 are currently cultivated. Eighty percent of all acreage available for shellfishing is currently approved or conditionally approved. The remaining 20% (78,009 acres) is closed. Four million bushels of oyster shells have been planted in an attempt to restore State public oyster beds. Management efforts of local shellfish commissions are increasing, and several towns, including Stamford, Norwalk, Guilford, and Madison, have begun "relay" programs to enhance recreational shellfishing.

Other fisheries, including lobsters, finfish, squid, hard clams, scallops, and conch, contribute significantly to Connecticut's fishery harvest. This harvest amounted to 19,200,000 pounds in 1992, combining live weight of fish, lobsters, and squid plus the meat of oysters, clams, scallops, and conch. At an off-vessel value of nearly $60 million, this makes Connecticut the

VOL 12

5925

largest aquaculture-producing State in the region.

District of Columbia

The stench of the Potomac River in the 1960s made recreation on or near the river undesirable. The change in the water quality today is readily discernible. Today residents and visitors recreate along its banks as well as partake in various boating activities on the river. Water sports such as rowing, wind surfing, and annual water vehicle competitions have become part of the Potomac River culture in the District. Increased development along the Georgetown and Alexandria water fronts are another symbol of the river's resurgence.

There has been a return of recreational fishing to District waters. Surveys conducted by fisheries management programs have clearly shown that fishing and the number of anglers have increased greatly. The sale of fishing licenses in the District provided the support for these surveys. The number of fishing licenses sold in 1993 (12,916) is more than two and one-half times the number sold in 1988 (4,900 licenses)—the first year fishing licenses were sold.

These benefits are real and it is important to note that they would not have been feasible without the leadership of the Federal Government, State government, local government, citizen groups, and industry all working together.

New York

New York State Department of Environmental Conservation published *20 Year Trends in Water Quality of Rivers and Streams in New York State* in 1993. The study reports trends in macroinvertebrates from 1972 to 1992. The increase in macroinvertebrates such as mayflies, caddisflies and stoneflies is a significant indicator of the improving health of a waterbody. The following describes 10 of New York's greatest success stories:

Canandaigua Outlet below Canandaigua – The stream in 1972 had 3 to 4 inches of black organic sludge downstream of the sewage discharge. Following the 1980 upgrading of the Canandaigua Sewage Treatment Plant, mayflies and caddisflies are now found at the downstream site.

Cattaraugus Creek, Gowanda – Water quality is now considered excellent in Cattaraugus Creek; the benthic fauna is dominated by intolerant species. Moderate to severe pollution from tannery and glue processing discharges was well documented in 1976. These discharges have since been eliminated.

Cayadutta Creek below Johnstown – Severe pollution was well documented at all sites downstream of the Gloversville-Johnstown wastewater treatment facility. Following the 1991 upgrade of the plant, species richness indicators increased from 8 to 23, and mayflies, stoneflies, and caddisflies were found, similar to the upstream site.

Lower Hudson River below Albany – All biological indices have improved below Albany since 1972 and may be attributed to many improvements in municipal and

VOL 12

5926

industrial sewage treatment. Several blue crabs were collected in this reach in 1992.

Mohawk River below Rome – From 1972 to 1989, species richness rose from 8 to 24 species, and mayflies, stoneflies, and caddisflies appeared. The change is attributed to improved treatment of both industrial and municipal wastes.

Mohawk River below Utica – Following the construction and upgrade of sewage treatment facilities, the macroinvertebrate fauna changed from a tolerant worm and midge fauna to a diverse fauna containing mayflies and caddisflies.

Oneida Creek below Oneida – The 1982 upgrade of the Oneida Sewage Treatment Plant changed the fauna from a severely impacted community of worms and midges to a diverse community of mayflies, stoneflies, and caddisflies.

Skaneateles Creek, entire length – Most sites were found to be severely impacted in 1972. In 1992, following improved treatment of most discharges, diverse communities were found, with numerous mayflies and caddisflies.

Tonawanda Creek below Batavia – The former fauna below the sewage discharge was a classic worm and midge sewage fauna. Following the 1990 completion of the new Batavia wastewater treatment facility, this formerly severely impacted site now harbors many mayflies and caddisflies.

Upper Hudson River below Glens Falls – Mayfly/caddisfly species increased from 1 to 7 from 1972 to 1986, following numerous improvements in treatment of municipal and industrial wastes. Biological changes were accompanied by improvements in water clarity.

Water Quality Benefits in the Nation's Waterbodies

Iowa's Swan Lake

In the early 1980s, Iowa's Swan Lake suffered from turbidity, sedimentation, nuisance algal blooms, and frequent fishkills. By 1990 conditions had changed:*

- In 1990, visits to Swan Lake State Park were up 170% from 1986 levels, and camping in the park more than doubled during the same period.
- Between 1982 and 1989, the number of anglers at the lake increased more than sevenfold.
- From 1987 through 1990, the value of fishing at Swan Lake exceeded $1.75 million.
- Between 1986 and 1990, concession income at the park quadrupled.
- Camping receipts in 1990 were 2.5 times higher than those of 1986.

Chesapeake Bay

A 1987 study estimated the value of the Chesapeake Bay to the commercial fishing industry, port

*U.S. EPA, *Clean Lakes Program Review*, 1992.

VOL 12

5927

and shipbuilding activities, and Bay-related tourism at $31.6 billion. Recreational activities, such as boating, fishing, hunting, sightseeing, and dining on the regional cuisine accounted for $8.4 billion per year.*

Gulf of Mexico†

There are almost 2 million registered motor boats in the five Gulf States and an estimated 4 million recreational anglers. In 1991 the National Marine Fisheries Service estimated there were 15.5 million marine recreational fishing trips in the Gulf of Mexico region. Private and rental boat anglers accounted for the highest percentage of the fishing effort.

The Gulf of Mexico is especially rich in fish and shellfish species. Three of the top 10 U.S. ports in terms of the value of fish landings are located in the Gulf States. Also, the Gulf had three of the top five States in terms of value in 1990: Louisiana, Texas, and Florida. Seventy percent of the 346 million pounds of shrimp landed in the U.S. in 1990 came from the Gulf States (250 million pounds) valued at $420 million. Other important shellfish include blue crabs and oysters. In 1989, Texas and Louisiana landed 11.7 million pounds of tuna valued at $22.5 million. The Gulf also accounted for 11.5 million pounds of shark valued at $7.9 million.

Great Lakes‡

The Great Lakes provide tremendous economic and ecological benefits to the area. One quarter of all U.S. industry and more than 70% of U.S. and 60% of Canadian steel mills are in the Great Lakes Basin. Over 23 million people depend on the Great Lakes for drinking water. The area affords habitat for a vast array of plant and animal species, many of which are native to the Great Lakes Basin.

Recreational benefits are also significant. Data from the mid-1980s indicate that recreational boating marinas employed almost 20,000 people. Boat sales and other boater spending (marina fees, licenses, repairs, etc.) amounted to almost $4 billion per year. Recreational fishing adds another $3 billion to $7 billion per year.

Water quality in the Great Lakes has improved significantly since the passage of the Clean Water Act in 1972. Although discharges from wastewater treatment plants have increased due to population growth and development pressures, levels of dissolved oxygen have steadily improved. Reductions in organic material, solids, and phosphorus are noteworthy as well. Phosphorus loadings to Green Bay from the Fox River decreased by 3.6 million pounds by 1982. Fish have returned to some harbors from which they had disappeared.

‡ U.S. EPA, Office of Water. *Clean Water: A Memorial Day Perspective.* Washington, DC: May 1994.

The number of double-crested cormorants, a water bird that all but vanished in the Great Lakes in the 1970s, has climbed to 12,000 nesting pairs. The number of bald eagles is nearing the highest level ever measured in Michigan.

Improvements in Great Lakes water quality have had a positive economic impact on the recreational fishing industry. Fishing licenses purchased in the county of Green Bay, Wisconsin, increased from 19,000 in 1970 to 51,000 in 1989. Boat registration more than doubled during the same period, leading to an increased demand for launch ramps and other boating facilities in the Green Bay area. The revitalization of the fishery resources in Lake Ontario has spurred the development of the charter boat fishing industry, boater and angler access sites, fishing derbies, and additional employment opportunities.

Water quality improvements and increased lakeside development have caused people to return to the shore of Lake Erie to enjoy boating, fishing, swimming, and other water-based activities. Algal blooms and bacteria counts in Ohio beach areas along Lake Erie have dropped more than 90% from 1968 to 1991. As a result, Ohio's waterfront has seen an increased number of boating, camping, and vacation resort facilities being constructed. From 1986 to 1993, there was a 30% increase in the number of marinas in the Lake Erie Basin. Ohio's Lake Erie tourism industry is now an $8.5 billion per year industry.

Lakeshore cities, such as Cleveland, Ohio, have begun to restore their shorelines, which were considered "dead" 25 years ago. A new harbor and festival park have already been completed. Several museums are completed or are under construction and an aquarium is planned.

Public reporting burden is estimated to average 15 minutes per response, including the time for reviewing instruction, gathering information, and completing and reviewing the collection of information. Send comments regarding this burden estimate or any other aspect of this collection of information, including suggestions for reducing the burden, to: Director, OPPE Regulatory Information Division, U.S. Environmental Protection Agency (2136), 401 M St., S.W., Washington, DC 20460. Include the OMB control number in any correspondence. Do not send the completed questionnaire to this address.

VOL 12

Order Form

Additional copies of this report and related water quality assessment documents can be ordered from the National Center for Environmental Publication and Information (NCEPI) or accessed electronically on the Internet through EPA's Water Information Network (see page 380 for instructions). To order hard copies, please check the boxes beside the documents that you would like to order and return this form to the address on the reverse, or fax this form to NCEPI at (513) 891-6685. Due to limited supply, we can send you only one copy of each publication. Allow 2 to 3 weeks for delivery.

VOL 12

Dear Land Manager:

The Soil Conservation Society of America was organized in 1945 with the objective to "Advance the Art and Science of Wise Land Use." Although the organization changed its name to the Soil and Water Conservation Society (SWCS) in 1987, its mission remains to promote excellence in land and water management in local communities and throughout the world. The Empire State Chapter of SWCS is the local, New York State unit of the international organization.

In 1988, the Chapter accepted the challenge of publishing and distributing erosion and sediment control guidelines for urban areas as an appropriate project within the stated objective of the Society. The Chapter has also accepted publishing and distribution responsibility for stormwater management guidelines. A variety of training is available using one or both of these manuals as references.

These guidelines will benefit all citizens, both those who install practices and those who benefit from their installation. I would like you, the users of these guidelines, a person concerned with proper land use, to know more about the Soil and Water Conservation Society.

SWCS is a non-profit, international organization with more than 13,000 members. Members of the Society help promote land and water management excellence through personal involvement and collective action.

5937

The members of the Society receive bi-monthly, the Journal of Soil and Water Conservation one of the most respected magazines in land and water management in the world. It has been published for more than 40 years and is a major benefit of being a member. Society members have an outstanding annual meeting each year at different locations throughout the U.S.A. and Canada. There are also many special conferences and working groups throughout the year. The activities are too numerous to discuss here, but if you would like additional information, write me at the address on this letter or call me during business hours at (607) 776-9631 ext. 2542. (The address of the International Headquarters is: Soil and Water Conservation Society, 7515 N.E. Ankeny Road, Ankeny, Iowa 50021).

I commend you for using a sound approach to preventing sediment problems in your community. The Empire State Chapter is pleased to provide you with these guidelines.

NEW YORK GUIDELINES FOR URBAN EROSION AND SEDIMENT CONTROL

REDUCING THE IMPACTS OF STORMWATER RUNOFF FROM NEW DEVELOPMENT

NEW YORK GUIDELINES FOR URBAN EROSION AND SEDIMENT CONTROL contains standards and specifications for erosion and sediment control measures commonly used on construction sites. Both vegetative and structural measures (permanent and temporary) are included in the manual. It also information on calculating storm water runoff and erosion rates as well as a sample soil erosion and sediment control ordinance. The manual is a valuable tool for planners, engineers, local officials, contractors and others involved in development activities.

Cost : $25.00

REDUCING THE IMPACTS OF STORMWATER RUNOFF FROM NEW DEVELOPMENTS contains guidance on reducing flooding and water quality impacts from new development through stormwater management and erosion and sediment control. This manual also contains information on stormwater management planning, performance standards and management practices. The manual is a valuable tool for planners, engineers, local officials, contractors and others involved in development activities.

This manual has been prepared by the New York State Department of Environmental Conservation and made available to the Empire State Chapter of the Soil and Water Conservation Society for distribution and reprinting.

Cost: $15.00

Copies of these documents may be purchased from some county Soil and Water Conservation Districts or directly from the Soil and Water Conservation Society, Empire State Chapter. Check with your local county Soil and Water Conservation District for availability before ordering direct.

If ordering direct from SWCS, please make check payable to "Empire State Chapter - SWCS". Mail this form with payment to:

PREFACE

The parent document "Guidelines for Erosion and Sediment Control in Urban Areas of New York State" was originally published by the USDA-Soil Conservation Service in 1972 to provide information on minimizing erosion and sediment problems on land undergoing urban development. These guidelines were used by soil and water conservation districts, planning boards, property owners, land developers, contractors and consultants.

Based upon the experience gained in the use of this document, a committee was formed in 1978 to update this guide. This committee contained specialists and representatives from:

New York State Soil & Water Conservation Committee

Agronomy Department, Cornell University

Agricultural Engineering Department, Cornell University

New York State Department of Environmental Conservation

New York State Department of Transportation

New York Chapter of Land Improvement Contractors of America

O'Brien and Gere Engineers, Inc.

USDA-Soil Conservation Service

This committee completed their draft document "Sediment and Erosion Control for Developing Areas" in May 1980. Before this document could be finalized, technological advances and increased demand for natural resource planning due to increased urban pressure on rural areas, caused an additional need for revision and expansion of the technical chapters.

In March 1985, work resumed on the guide to expand the standards and specifications to include temporary and permanent structural measures for erosion and water control, update the discipline vocabulary, incorporate the most recent methods and procedures available, and provide local planners and legislators examples of public administration. The guide was again revised in mid-1991 to incorporate general updates, a chapter on calculating runoff, a chapter on bio-engineering, the addition of temporary and permanent practices and a site specific example demonstrating the planning and design process.

Although the initial publication was written for internal Service and Soil and Water Conservation District use, the need and demand for this information has expanded throughout the State to other public service agencies and the general public. This document aims to help improve water quality, reduce sediment damage and associated maintenance costs of road ditches, storms sewers, streams, lakes, flood control structures, and improve the value of on-site detention basins for recreational use. It is distributed by the Empire State Chapter of the Soil and Water Conservation Society.

This guide can be used to assist local units of government in preparing and implementing their soil erosion and sediment control programs and in reviewing proposed site development plans; establish or encourage uniformity through standards in applying erosion control techniques; and help developers and planners to make maximum use of potential development sites by proper management of their natural resources. It is to this end the document was created.

Donald W. Lake, Jr., P.E.

INTRODUCTION

Purpose

These guidelines provide information on minimizing erosion and sediment problems on land undergoing urban development. They show how to use soil, water and plants to improve the quality of our environment. These guidelines were developed by the Soil Conservation Service (SCS) in cooperation with state and local agencies for use by soil and water conservation districts (hereafter referred to as districts). These guidelines also may be helpful to planning boards and other government bodies, property owners, land developers, contractors, consultants, and others.

Scope and Authority

The guidelines apply to urban lands where housing, industrial, institutional, recreational and highway developments are occurring or are imminent. They are statewide in scope and are somewhat generalized due to variations in climate, topography, geology, soils and plant requirements. Feasible ways to minimize erosion and sedimentation are varied and complex. Alternative methods can be used to solve a problem. Final decisions on measures to be used are made by local people.

The SCS, working through districts, has broad authority to help people solve problems of soil, water, and related resources. There may be times, however, when these problems or related conditions are referred to outside groups for advice or assistance. Any technical assistance given by SCS personnel must conform with local policies and procedures as well as standards established by the agency.

If authorized by districts, SCS can:

1. assist local groups or communities in reviewing and developing resource plans and evaluating benefits and costs of treatment measures;
2. provide technical assistance to install soil, water and plant conservation measures before or during construction;
3. give advice on maintenance programs for installed measures.

Erosion and Sediment Hazards Associated with Urban Developments

In the urbanizing process, many people may be adversely affected by development on relatively small areas of land. Uncontrolled erosion and sediment from these areas may cause considerable economic damage to individuals and society in general. Stream pollution and damages to public facilities and private homes are examples.

Hazards associated with urban developments include:

1. a large increase of soil exposed to erosion from wind and water;
2. increased water runoff, soil movement, sediment accumulation and peak flows caused by:
   - A. removal of plant cover;
   - B. a decrease in the area of soil which can absorb water because of construction of streets, buildings, sidewalks and parking lots;
   - C. changes in drainage areas caused by grading operations, diversions and streets;
   - D. changes in volume and duration of water concentrations caused by altering steepness, distance and surface roughness;
   - E. soil compaction by heavy equipment which can reduce the water intake of soils as much as 90 percent of the original rate;
   - F. prolonged exposure of unprotected sites and service areas to poor weather conditions.
3. altering the groundwater regime that may adversely affect drainage systems, slope stability, survival of existing vegetation and establishment of new plants;
4. exposing subsurface materials that are too rocky, too acid, or otherwise unfavorable for establishing plants;
5. obstructing streamflow with new buildings, dikes and landfills;
6. improper timing and sequence of construction and development activities;
7. abandonment of sites before completion of construction.

VOL 12

5951

BASIC PRINCIPLES OF EROSION AND SEDIMENT CONTROL

The Erosion and Sedimentation Processes

The standards, specifications and planning guidelines presented in this document are intended to be utilized when development activities change the natural topography and vegetative cover of an area. It is necessary to formulate and implement erosion and sediment control plans with urban land development because such development can increase erosion and sediment problems. To understand how erosion and sediment rates are increased requires an understanding of the processes themselves.

Soil erosion is the removal of soil by water, wind, ice, or gravity. This document deals primarily with the types of soil erosion caused by rainfall and surface runoff. Raindrops strike the soil surface at a velocity of approximately 25-30 feet per second and can cause splash erosion. Raindrop erosion causes particles of soil to be detached from the soil mass and splash into the air. After the soil particles are dislodged, they can be transported by surface runoff, which results when the soil becomes too saturated to absorb falling rain or when the rain falls at an intensity greater than the rate at which the water can enter the soil. Scouring of the exposed soil surface by runoff can cause further erosion. Runoff can become concentrated into rivulets or well defined channels up to several inches deep. This advanced stage is called rill erosion. If rills and grooves remain unrepaired, they may develop into gullies when more concentrated runoff flows downslope.

Sediment deposition occurs when the rate of surface flow is insufficient for the transport of soil particles. The heavier particles, such as sand and gravel, transport less readily than the lighter silt and clay particles. Previously deposited sediment may be suspended by runoff from another storm and transported farther downslope. In this way, sediment is carried intermittently downstream from its upland point of origin.

Factors That Influence Erosion

The erosion potential of a site is determined by five factors; soil erodibility, vegetative cover, topography, climate and season. Although the factors are interrelated as determinants of erosion potential, they are discussed separately for easy understanding.

1. **Soil Erodibility** - The vulnerability of a soil to erosion is known as erodibility. The soil structure, texture, and percentage of organic matter influence its erodibility. The most erodible soils generally contain high proportions of silt and very fine sand. The presence of clay or organic matter tends to decrease soil erodibility. Clays are sticky and tend to bind soil particles together. Organic matter helps to maintain stable soil structure (aggregates).

2. **Vegetative Cover** - Vegetation protects soil from the erosive forces of raindrop impact and runoff scour in several ways. Vegetation (top growth) shields the soil surface from raindrop impact while the root mass holds soil particles in place. Grass buffer strips can be used to filter sediment from the surface runoff. Grasses also slow the velocity of runoff, and help maintain the infiltration capacity of a soil. The establishment and maintenance of vegetation are the most important factors in minimizing erosion during development.

3. **Topography** - Slope length and steepness greatly influence both the volume and velocity of surface runoff. Long slopes deliver more runoff to the base of slopes and steep slopes increase runoff velocity. Both conditions enhance the potential for erosion to occur.

4. **Climate** - Climate also affects erosion potential in an area. Rainfall characteristics such as frequency, intensity, and duration directly influence the amount of runoff that is generated. As the frequency of rainfall increases, water has less chance to drain through the soil between storms. The soil will remain saturated for longer periods of time and stormwater runoff volume may be potentially greater. Therefore, erosion risks are high where rainfall is frequent, intense, or lengthy.

5. **Season** - Seasonal variation in temperature and rainfall defines periods of high erosion potential during the year. A high erosion potential may exist in the spring when the surface soil first thaws and the ground underneath remains frozen. A low intensity rainfall may cause substantial erosion because the frozen subsoil prevents water infiltration. In addition the erosion potential increases during the summer months due to more frequent, high intensity rainfall.

RESOURCE PLANNING IN URBAN AREAS

Resource Planning

Effective solutions to urban erosion and sediment problems begin with planning. Resource plans can guide and control urban growth preventing wasteful and haphazard developments.

Districts and the SCS have technical resource data and information that can serve as a basis for decision making by local authorities to fulfill the objectives established by plans. These objectives may include reserving best agricultural areas for cropland; maintaining an economic agricultural use; protecting historical, scenic and natural beauty areas; providing for open spaces and parks; developing attractive residential, institutional and industrial areas; and using floodplains and other problem areas for recreation buffer zones and conservation education uses.

Land Development Plans

As more specific plans, such as plans for subdivisions, are developed for smaller areas, SCS can furnish more detailed information and interpretations. This information will help determine the suitability of the site for the kind of development to be made. It will also help in planning and treating these lands to greatly reduce erosion and sediment problems during construction.

Certain basic data need to be assembled before adequate technical information and interpretations can be provided for a subdivision or other type of specific plan. These data consist primarily of:

1. <u>Geography of the Area to be Developed</u>

   Conditions of proposed areas to be developed need to be examined early in the planning stages. These conditions include location, accessibility, present land use, size of proposed tract, topography, drainage pattern, geology, hydrology, soils, vegetation and climate. Such information is obtained from on-site examinations and existing technical reports, maps, records and other documented material usually available from local sources.

2. <u>Study of Soils in the Area to be Developed</u>

   Soils information, interpretations and data are basic to urban land uses. These studies provide an understanding of the capabilities and general limitations of the site. They point out the feasibility of planned land uses, economic considerations and conservation requirements of the site.

   Soils information such as detailed soil maps and interpretation sheets may be available in local SCS and Soil and Water Conservation District offices and will specifically provide the following soils information:

   A. descriptions, erodibility, limitations and capabilities;

   B. engineering properties of soils;

   C. suitability of the soil as a resource material for topsoil, gravel, sand highways, dams and levees;

   D. site suitability for buildings, roads, winter grading, foundations, septic tank disposal fields, sanitary land fills, vegetation, reservoirs, dams, artificial drainage, recreational areas and wildlife development. Generalized soils information, also useful for some purposes, is usually available in SCS offices.

Erosion and Sediment Control Plan

An erosion and sediment control plan should be prepared for all land development and construction activities when it is determined that soil erosion and sedimentation, if not controlled, may have a significant affect on the environment. Appendix A, New York State Department of Environmental Conservation TOGS 5.1.10 provides guidance for initiating erosion and sediment control plans.

A great deal of information must be assimilated to develop an efficient plan to minimize erosion and control sedimentation at a construction site. An erosion and sediment control plan shows the site's existing topography, and how and when it will be altered. It also shows the erosion and sediment control measures that will be used to minimize the risk of sediment pollution, and how and when they will be implemented and maintained. The coordination of erosion and sediment control practices with construction activities is explained on the plan by a phasing schedule.

The Planning Process

The following procedure is recommended to develop a plan that will efficiently control erosion and sedimentation throughout the site development process.

1. <u>Plan the Development to Fit the Site</u>

   Assess the physical characteristics of the site to determine how it can be developed with the smallest risk of environmental damage. Minimize grading by utilizing the existing topography wherever possible. Avoid disturbing wetlands or other environmentally sensitive areas Minimize offsite impacts by maintaining vegetative buffer strips between disturbed and adjacent areas.

2. Determine Limits of Clearing and Grading

Decide exactly which areas must be disturbed in order to accommodate the proposed construction. Pay special attention to critical areas (e.g. steep slopes, highly erodible soils, surface water borders) which must be disturbed. Staged clearing and grading should be considered as an alternative to massive clearing and grading.

3. Divide the Site into Natural Drainage Areas

Determine how runoff will drain from the site. Consider how erosion and sedimentation can be controlled in each small drainage area before looking at the entire site. Remember, it is more advantageous to control erosion at the source and prevent any problems than to design perimeter controls to trap sediment.

4. Select Erosion and Sediment Control Practices

Erosion and sediment control practices can be divided into vegetative and structural controls. This handbook should be used for the selection and design of vegetative and structural practices. Vegetative and structural controls are outlined below.

A. Vegetative Controls - The best way to protect the soil surface and limit erosion is to preserve the existing vegetative groundcover. Where land disturbance is necessary, temporary seeding or mulching should be used on areas which will be exposed for long periods of time prior to construction. Permanent stabilization should be performed as soon as possible after completion of grading. Erosion and sediment control plans must contain provisions for permanent stabilization of disturbed areas. Seed type, soil amendments, seedbed preparation, and mulching should be described on the plans. Selection of permanent vegetation should include the following considerations for each plant species:

1) establishment requirements;
2) adaptability to site conditions;
3) aesthetic and natural resource values;
4) maintenance requirements.

B. Structural Controls - Structural sediment control practices may be necessary when disturbed areas cannot be promptly stabilized with vegetation. Structural practices shall be constructed and maintained in accordance with these guideline standards and specifications.

An acceptable erosion and sediment control plan includes:

1) a map of the existing topography and proposed grading;
2) provisions for erosion and sediment control;
3) a time schedule of proposed construction activity and erosion and sediment control implementation; and
4) maintenance phasing.

Standard symbols are used to facilitate the understanding and review of plans. The symbols, Figure 4.1 on page 4.3, are designed to be easy to apply to plans by drafting or by using stick on materials. They should be bold and easily discernible on the plans. The following scales are recommended for use on erosion and sediment control plans because they facilitate the plan review process: 1 in. = 20 ft., 1 in. = 30 ft., 1 in. = 40 ft., or 1 in. = 50 ft.

The contour interval for these plans shall be two feet or less. Other scales or contour intervals may be favored for special types of land disturbance projects. For example, strip mine plans are often drawn to scales of 1 in. = 200 ft. or 1 in. = 500 ft. with contour intervals of 5 to 20 feet. Consult the appropriate plan review agency prior to finalizing the selection of plan scale. A sample checklist is contained in the appendix.

Implementation of Erosion and Sediment Controls

Effective implementation of erosion and sediment controls requires good construction management. Proper management can reduce the need for maintenance of structural controls, regrading of severely eroded areas, and reconstruction of controls that were improperly implemented. Good site management results in efficient use of manpower and financial savings.

Site management for effective implementation of erosion and sediment controls involves the following:

1. Clear only what is required for immediate construction activity. Large projects should be cleared and graded as construction progresses. Mass clearing and grading of the entire site should be avoided.

   Restabilize disturbed areas as soon as possible after construction is completed. Certain sections of large construction projects may be completed before others and be ready for stabilization before the total project is completed. Waiting until the end of the project to commence all site stabilization may leave areas exposed for an unnecessarily long duration.

2. Divert offsite runoff from highly erodible soils and steep slopes and convey to stable areas.
3. Physically mark off limits of land disturbance on the site with tape, signs, or other methods, so the workers can see areas to be protected.
4. Make sure that all workers understand the major provisions of the erosion and sediment control plan.

VOL 12

5959

5. Designate responsibility for implementing the erosion and sediment control plan to one individual.
6. Implement a daily inspection program to determine when erosion and sediment control measures need maintenance or repair. Pay particular attention to the inspection following rainfall events.

Predicting Soil Losses

Estimates of soil losses can be made for construction sites by using the Universal Soil Loss Equation. This equation uses rainfall intensity or erosion index, soil erodibility, and slope factors in calculating the estimated soil loss. The equation is used to determine sheet and rill erosion losses on the site.

Predictions of soil losses in areas to be developed is directly related to resource planning. The predictions will influence the degree of planning and treatment required for proper control of erosion and sediment. Predicted soil losses may also create an awareness among developers, local government agencies and others of the urgent need to install conservation measures before or concurrent with construction.

Soil losses on a construction site may be predicted for a whole year, a part of a year or on the basis of "probability" storms and magnitudes of single storms. (Refer to Appendix B for instructions and examples on how the Universal Soil Loss Equation is used for this purpose.)

Estimating Sediment Yield

Sediment yield involves both soil erosion on the site and the transport mechanism acting to carry the eroded material off the site.

Where sediment yields from a developing area are needed for calculation of sediment basin design, etc., the methods in Section 8 can be used for determining the amount of the eroded material that will leave the site as sediment.

Planning Assistance

Planning assistance may be available from the county Soil and Water Conservation District.

Based upon data and information described above, planning assistance during the development of a plan may include the following considerations:

1. Planning of streets and lots should relate to site conditions. Streets laid out at right angles to contours often have excessive grades that increase erosion hazards and sedimentation.
2. Construction plans for public utilities should include steps needed to reduce sediment producing hazards when pipelines, electric transmission and telephone lines are installed.
3. Environmental quality is enhanced when open spaces, parks, recreational areas, ponds, wildlife habitat and other areas of public use become integral parts of the plan. These areas should be well delineated and protected from damages that may occur from nearby construction. Selections of such areas should be based upon soils, vegetation, water, topography, accessibility, wildlife, and aesthetic values.
4. Integrated surface and storm drainage systems are essential parts of any planned development. The plan should clearly specify: location and capacities of diversions and debris basins; paved or other types of lined chutes, outlets and waterways; drop inlets; open or closed drains; stream channel protection and bank erosion structures.
5. Stabilizing land with plant materials or mulches should be part of a planned development. Retention of existing natural vegetation in strategic areas is beneficial and desirable.
6. Installation of the control measures before or as soon as possible during construction will greatly reduce erosion and sediment damages.
7. Temporary and/or permanent erosion control measures may be needed. They should also be installed as soon as possible. Provisions for maintenance of these measures should be part of the plan and enforced.

Erosion and Sediment Control Ordinances and Subdivision Regulations

Local ordinances or regulations dealing with erosion and sediment controls enhance and implement resource planning and development in areas that are to be urbanized. The SCS does not, in any way, participate in the enactment or enforcement of ordinances. This is strictly the responsibility of authorized government agencies and officials. At the request of local Districts, the SCS can furnish any available technical information or data that may be useful to authorized local government agencies when preparing to formulate ordinances or regulations.

VOL 12 5960

STEPS IN THE SELECTION OF CONTROL MEASURES

Step 1: Identify Control Method - On any construction site the objective in erosion and sediment control is to prevent off-site sedimentation damage. Three basic methods are used to control erosion on construction sites: runoff control, soil stabilization, and sediment control. Controlling erosion should be the first line of defense. Where soil properties and topography of the site make the design of sediment trapping facilities impractical, runoff control and soil stabilization should be used. Controlling erosion is very effective for small disturbed areas such as single lots or small areas of a development that do not drain to a sediment trapping facility.

Sediment trapping facilities should be used on large developments where mass grading is planned, where it is impossible or impractical to control erosion, and where sediment particles are relatively large. A minimum of cost for erosion and sediment control is usually accomplished by using a combination of vegetative and structural erosion control and sedimentation control measures.

Step 2: Identify Problem Areas - Once a method of control is selected, potential erosion and sediment control problem areas are identified. Areas where erosion is to be controlled will usually fall into categories of slopes, graded areas or drainage ways. Slopes include graded rights-of-way, stockpile areas, and all cut or fill slopes. Graded areas include all stripped areas other than slopes. Drainage ways are areas where concentrations of water flow naturally or artificially, and the potential for gully erosion is high. Problem areas where sediment is to be controlled fall into categories of large or small drainage areas. Small areas are usually 1 acre or less while large areas are larger than 1 acre.

Step 3: Identify Required Strategy - The third step in erosion and sediment control planning is to follow the planning matrix from the problem area to the strategy that can be taken to solve the problem. Strategies can be used individually or in combination. For example, if there is a cut slope to be protected from erosion, the strategies may be to protect the ground surface, divert water from the slope or shorten it. Any combination of the above can be used. If no rainfall except that which falls on the slope has the potential to cause erosion and if the slope is relatively short, protecting the soil surface is often all that is required to solve the problem.

Step 4: Identify Control Measure Group - Once required strategies are identified, the planning matrix leads to the group or groups of control measures that will accomplish one strategy. Control measures within each group have similar purpose, scope, application, design, criteria, standard plans, and construction specifications. Therefore, any measure within a group will solve the problem in question.

Step 5: Select Specific Control Measure - The final step in erosion and sediment control planning can be accomplished by completing final design. This involves adaptation of any control measure within a group to solve the specific erosion and sediment control problem. From descriptions given to the right of each control measure, the one measure which is most economical, practical, efficient, and adaptable to the site can be chosen.

Once the specific control measure has been selected, the plan key symbol given in the matrix can be placed on the erosion and sediment control site plan to show where control measures will be used. Standardized design, plan, and construction specification sheets can then be completed for each control measure. This completes the planning for sedimentation control and soil erosion as part of the total natural resource plan.

Table 2.1
Erosion and Sediment Control Matrix

Practice	Primary Purpose	Site Characteristics	Estimated Design Life	Associated Practices
Brush Matting	Stabilize soil; prevent erosion	Streambank slopes	5-10 years	Rock slope protection, structural streambank protection, subsurface drain
Check Dam	Control sediment/ runoff	Drainage area ≤ 2 Ac.	1 year	Lined waterway, rock outlet protection
Construction Road Stabilization	Control sediment	All construction routes	2 years	Dust control, temporary swales, temporary or permanent seeding.
Debris Basin	Capture sediment	Maximum drainage area = 200 acres	Up to 25 years	Sediment basin
Diversion	Intercept and divert runoff	Minimum 10 yr. Design Q	10-25 years	Permanent seeding, rock outlet protection, level spreader, sediment basin
Dune Stabilization	Stabilize sand dunes	Sand dune reinforcement	5-10 years	--
Dust Control	Stabilize soil	Access points, construction roads	Site specific	Stabilized construction entrance, contruction road stabilization
Earth Dike	Control runoff	DA ≤10 Acres	1 year	Sediment trap, rock outlet protection, storm drain inlet
Grade Stabilization Structure	Prevent erosion	Minimum Design Q = 10 yr.; 24 hr.	10+ years	Permanent seeding, rock slope protection, structural streambank protection
Grassed Waterway	Convey runoff	Minimum 10 yr. Design Q	Min. 10 years	Rock outlet protection, vegetated waterways, sediment basin, level spreader
Land Grading	Stabilize soil	Site specific shaping	Permanent	Topsoiling, subsurface drain, seeding
Level Spreader	Discharge runoff	10 year Q; ≤30 cfs; outlet <10%	1 year	Diversion, grassed waterway, temporary swales
Lined Waterway, (rock materials)	Convey runoff	Minimum design Q = 10 yr. 24 hr.	Min. 10 years	Rock outlet protection, subsurface drain

Table 2.1 (cont'd)
Erosion and Sediment Control Matrix

Practice	Primary Purpose	Site Characteristics	Estimated Design Life	Associated Practices
Mulching	Stabilize soil	Site specific	1-2 years	Permanent seeding, Recreation area improvement
Paved Channel, (concrete)	Convey runoff	Minimum design Q = 10 yr. 24 hr.	Min. 10 years	Rock outlet protection, subsurface drain
Paved Flume	Convey runoff	Minimum design Q = 10 yr. 24 hr.	10 years	Rock outlet protection
Perimeter Dike/Swale	Divert runoff	Drainage area ≤5 Ac.	1 year	Sediment trap, level spreader, temporary seeding
Pipe Slope Drain	Convey runoff downslope	Drainage area ≤5 Ac.	1 year	Rock outlet protection
Portable Sediment Tank	Retain sediment	16 times pump discharge	2 years	Sediment trap, sediment basin
Protecting Vegetation	Preserve existing vegetation	Site specific	1-10 years	Recreation area improvement
Recreation Area Improvement	Protect areas/soils	Site specific	Permanent	Permanent seeding, mulching, topsoiling
Retaining Wall	Stabilize soil	Site specific constraints	10+ years	Rock slope protection, permanent seeding, subsurface drain
Riprap Slope Protection	Stabilize soil, Prevent erosion	Max. 1:5 to 1 slope	10 years	Lined waterway, rock outlet stabilization, structural streambank protection
Rock Dam	Capture sediment	Drainage Area ≤50 Ac.	3 years	Debris basin, sediment basin
Rock Outlet Protection	Prevent erosion	Rock varies with pipe discharge	10+ years	Diversion, grassed waterway, sediment basin, sediment traps
Sediment Basin	Capture sediment	Drainage Area ≤100 Ac.	3 years	Rock outlet protection, temporary seeding
Sediment Traps				
I. Pipe Outlet	Trap Sediment	Drainage Area ≤5 Ac.	2 years	Sediment basin, debris basin
II. Grass Outlet	Trap Sediment	Drainage area ≤5 Ac.	1 year	Rock outlet protection

Table 2.1 (cont'd)
Erosion and Sediment Control Matrix

Practice	Primary Purpose	Site Characteristics	Estimated Design Life	Associated Practices
III. Storm Inlet	Trap Sediment	Drainage area ≤3 Ac.	1 year	Rock outlet protection
IV. Swale	Trap Sediment	Drainage area ≤2 Ac.	1 year	Rock outlet protection
V. Stone Outlet	Trap Sediment	Drainage area ≤5 Ac.	2 years	Rock outlet protection
VI. Riprap Outlet	Trap Sediment	Drainage area ≤15 Ac.	2 years	Rock outlet protection
Seeding, Temporary	Stabilize soil	Site specific	1-2 years	Surface roughening, topsoiling, sodding
Seeding, Permanent	Stabilize soil	Site specific	Permanent	Surface roughening, topsoiling, sodding
Silt Fence	Control sediment	2:1 slopes maximum 50 ft. spacing	1 year	Strawbale dike
Sodding	Stabilize soil	Need quick cover, aesthetics	Permanent	Inlet protection, topsoiling, permanent seeding
Stabilized Construction Entrance	Control sediment	Access points	2 years	Filter fence, construction road stabilization
Storm Drain Inlet Protection				
I. Excavated	Trap Sediment	Drainage area ≤1 Ac.	1 year	Sediment traps, storm drain diversion
II. Filter Fabric	Trap Sediment	Drainage area ≤1 Ac.	6 months	Sediment traps, storm drain diversion
III. Stone and Block	Trap Sediment	Drainage area ≤1 Ac.	6 months	Sediment traps, storm drain diversion
IV. Sod	Trap Sediment	Drainage area ≤2 Ac.	5-10 years	Sediment traps, storm drain diversion
V. Curb	Trap Sediment	Drainage area ≤1 Ac.	6 months	Sediment traps, storm drain diversion
Straw Bale Dike	Control sediment	2:1 slopes maximum 25 ft. spacing	3 months	Silt fence

Table 2.1 (cont'd) Erosion and Sediment Control Matrix

Practice	Primary Purpose	Site Characteristics	Estimated Design Life	Associated Practices
Streambank Protection				
I. Structural	Prevent erosion	Minimum 10 yr. design Q; velocity >6 fps	10 years	Rock slope protection
II. Vegetative	Prevent erosion	Minimum 10 yr. design Q; velocity <6 fps	10 years	Structural streambank protection
Subsurface Drain	Intercept and convey drainage water	Drainage Coefficient - 1"	10 years	Rock outlet protection, land grading retaining wall
Sump Pit	Control sediment	Site specific	6 months	Sediment trap, sediment basin
Surface Roughening	Stabilize soil	Construction slopes	Permanent	Temporary seeding, perm. seeding, mulching
Temporary Access Waterway Crossings				
Temporary Access Bridge	Prevent sediment	8 ft. centerline piers	2 years	Rock slope protection
Temporary Access Culvert	Prevent sediment	Minimum 12 in.; 40 ft. length	2 years	Structural streambank protection
Temporary Access Road	Prevent sediment	Streambanks <4 ft.	1 year	Structural streambank protection
Temporary Storm Drain Diversion	Divert runoff	On site drainage area >50% total	1 year	Sediment trap/basin
Temporary Swale	Divert runoff	Drainage area ≤10 acres	1 year	Sediment traps, storm drain inlets, sediment basin, level spreader
Topsoiling	Provide growing conditions	Poor site soil characteristics	Permanent	Surface roughening, temporary seeding, permanent seeding
Vegetating Waterways	Stabilize soil	Site specific	Permanent	Grassed waterways, permanent seeding
Water Bars	Divert runoff	Slope areas <100 ft. width	2 years	Rock outlet protection, level spreader

VEGETATIVE MEASURES FOR EROSION AND SEDIMENT CONTROL, RECREATION, AND AESTHETICS IN URBAN AREAS

There are several basic principles that apply to establishing vegetation for any use.

1. Slopes should be stable. If they are too steep, continual sloughing will not allow a good stand to become established.
2. Excess surface and underground water must be controlled.
3. Whenever possible, stockpile and reapply topsoil to the areas that are to be vegetated.
4. Retain and protect trees, shrubs, and other natural plants wherever possible.
5. Select species of plants that are adapted to the site and for the intended use of the area. When clovers or trefoil are selected, inoculate seed at the time of planting with appropriate inoculum. The inoculum is a bacteria which lives on roots and converts nitrogen for plant use.
6. Prepare an adequate seed bed.
7. Apply needed lime and fertilizer.
8. Following seeding, firm soil where possible to get good soil seed contact.
9. Mulch to protect germinating plants from drying out and to prevent erosion.
10. Protect seeding for one year to allow development of a dense sod.
11. Use sod, rocks, netting, etc., in concentrated water flow areas.
12. Seed bare soil within 15 days of exposure, unless construction will begin within 30 days. If construction is suspended, or sections completed, areas should be seeded down or mulched immediately.

In the following section the Standard and Specifications for Critical Area Planting on page 3.3 should be followed to stabilize all bare soils except for: (1) waterways, (2) sand and gravel pits, (3) sand dunes and tidal banks, and (4) areas that will be closely mowed such as lawns, athletic fields, playgrounds, parks, and other recreation areas. For situations 1, 2, and 3, use the subject specification. For situation 4, refer to the Standard and Specifications for Recreation Area Improvement on page 3.5.

Tree and shrub planting generally does little for erosion control unless densely planted at which time the leaves and branches break the impact of rain drops. Overland flow of water under trees and shrubs can still cause erosion, therefore, grasses and/or legumes should be planted in conjunction with trees and shrubs.

Trees and shrubs are generally planted in urban areas for aesthetics, shade, noise reduction, screening, windbreaks and/or wildlife food and cover. "Trees Suitable for Landscape and Conservation Plantings in New York State", Table 3.3 in Standard and Specifications for Recreation Area Improvement on page 3.14 will be helpful in selecting species to do the intended job.

Directions for planting trees and shrubs are also contained in the Standard and Specifications for Recreation Area Improvement on page 3.5.

VOL 12

5977

VOL 12

5978

STANDARD AND SPECIFICATIONS FOR CRITICAL AREA SEEDINGS

Definition

Establishing grasses and/or legumes on critical areas. A critical area is any disturbed, denuded area.

Purpose

To reduce erosion and sedimentation. All bare areas of soil contribute to degradation of the local environment by contributing silt or dust. Vegetating bare areas, accompanied with an appropriate water management plan, will resolve pollution problems.

Conditions Where Practice Applies

This practice applies to all disturbed areas void of vegetation except where specific seeding/planting recommendations exist in other standards and specifications for specific uses such as recreation. This practice does not apply to sand dunes (see Standard and Specifiction for Vegetating Sand Dunes and Tidal Banks on page 3.41), or to sand and gravel pits which will not have topsoil replaced (see Standard and Specification for Vegetative Stabilization of Sand and Gravel Pits on page 3.37).

Criteria

1. Surface and subsurface water control practices may be required.

2. Planned use of the area must be considered when selecting an appropriate seed mix.

3. Site preparation will include:

   A. Seedbed preparation - scarify if compacted. Remove debris and obstacles such as rocks and stumps.

   B. Soil Amendments

      1) Lime to pH of 6.0.

      2) Fertilize with 600 lbs. of 5-10-10 or equivalent per acre (14 lbs./1000 sq. ft.).

   C. Seed Mixtures

      1) Temporary Seedings

         a. Ryegrass (annual or perennial) @ 30 lbs. per acre (0.7 lbs./1000 sq. ft.).

         b. Certified 'Aroostook' winter rye (cereal rye) @ 100 lbs. per acre (2.5 lbs./1000 sq. ft.).

      Use winter rye if seeding in October/November.

      2) Permanent Seedings

         a. Rough or occasionally mowed areas:

	lbs/acre	lbs/1000sq.ft
Empire birdsfoot trefoil[1] **OR**	8	0.20
Common white clover[1]	8	0.20
PLUS		
Tall fescue	20	0.45
PLUS		
Redtop **OR**	2	0.05
Ryegrass (perennial)	5	0.10

[1] add inoculant immediately prior to seeding.

         b. Frequently mowed areas: Refer to Standard and Specification for Recreation Area Improvement on page 3.5.

   D. Time of Seeding

   The optimum time for permanent seedings with legumes (birdsfoot trefoil or clover) is early spring.

   Permanent seedings may be made any time of year if properly mulched and adequate moisture is provided. Mid summer is not a good time to seed, but these seedings, if construction is complete, will facilitate covering the land. Portions may fail and may need reseeding the following year.

   Temporary seedings should be made within 24 hours of construction or disturbance. If not, the soil must be scarified prior to seeding.

   E. Method of Seeding

   Broadcasting, drilling with cultipack type seeder or hydroseeding are acceptable. Good soil to seed contact is the key to successful seedings.

   F. Mulching and Mulch Anchoring

   Mulching is essential to obtain a uniform stand of plants. See Standard and Specifications for Mulching on page 3.31.

G. Irrigation

Watering may be essential to establish a new seeding. Weather conditions and the intended use of the area will dictate when to water. Irrigation is a specialized practice and care needs to be taken not to exceed the application rate/infiltration rate of any given soil. Each application must be uniformly applied and 1 to 2 inches of water should be applied per application set up.

VOL 12

59800

STANDARD AND SPECIFICATIONS FOR RECREATION AREA IMPROVEMENT

VOL 12

5981

Definition

Establishing grasses, legumes, vines, shrubs, trees, or other plants or selectively reducing stand density and trimming woody plants to improve an area for recreation.

Purpose

To increase the attractiveness and usefulness of recreation areas and to protect the soil and plant resources.

Conditions Where Practice Applies

On any area planned for recreation use, lawns and areas that will be maintained in a closely mowed condition.

Specifications

ESTABLISHING GRASSES (Turfgrass)

The following applies for playgrounds, parks, athletic fields, camping areas, picnic areas, passive recreation areas such as lawns and similar areas.

1. Time of Planting

   Fall planting is preferred. Seed after August 15. In the spring plant until May 15.

   If seeding is done between May 15 and August 15, irrigation may be necessary to insure a successful seeding.

2. Site Preparation

   A. Install needed water and erosion control measures and bring area to be seeded to desired grades. A minimum of 4 in. topsoil is required.

   B. See Standard and Specification of Topsoiling on page 3.29

   C. Prepare seedbed loosening soil to a depth of 4 - 6 inches.

   D. Remove all stones over 1 inch in diameter, sticks and foreign matter from the surface.

   E. Lime to pH of 6.5.

   F. Fertilize as per soil test or apply 850 pounds of 5-10-10 or equivalent per acre (20 lbs/1,000 sq. ft.).

   G. Incorporate lime and fertilizer in top 2 - 4 inches of topsoil.

   H. Smooth and firm the seedbed.

3. Planting

   Use a cultipacker type seeder if possible. Seed to a depth of 1/8 to 1/4 inch. If seed is to be broadcast, cultipack or roll after seeding. If hydroseeded, lime and fertilizer may be applied through the seeder and rolling is not practical.

4. Mulching

   Mulch all seedings in accordance with Standard and Specifications for Mulching on page 3.31.

5. Seed Mixtures

   Select seed mixture for site conditions and intended use from Table 3.1 on page 3.9.

6. Select Adapted Varieties

   Select varieties from Table 3.2 on page 3.10, "Characteristics of Turfgrasses," based on intended use and site conditions.

   When Kentucky bluegrass is used it is desirable to use two or more varieties in the seeding for disease resistance.

   Tall fescue is a coarse grass but is the most resistant grass to foot traffic. Do not mix it with fine textured grasses such as bluegrass and red fescue.

   Common ryegrass and redtop which are relatively short lived species provide quick green cover. Improved lawn cultivars of perennial ryegrass provide excellent quality turf.

   Common white clover (Kent or New York) can be added to mixtures at the rate of 1 - 2 lbs/acre to help maintain green color during the dry summer period, however, they will not withstand heavy traffic. Avoid using around swimming areas as flowers attract bees which may be stepped on.

7. Fertilizing - First Year

   Three to four weeks after germination (spring seedings) apply 1 pound nitrogen/1,000 square feet using a complete fertilizer with a 2-1-1 or 4-1-3 ratio or as recommended by soil test results. Summer and early fall seedings, apply as above unless air temperatures are above 85° F for extended period. Wait until heat wave is over to fertilize. Late fall/winter seedings, fertilize in spring.

8. Restrict Use

New seedings should be protected from use for one full year to allow development of a dense sod with good root structure.

MAINTAINING GRASSES

1. Maintain a pH of 6.0 - 7.0.

2. Fertilize in late May to early June as follows with 10-10-10 analysis fertilizer at the rate of 10 lbs./1,000 sq. ft. and repeat in late August if sod density is not adequate. Top dress weak sod annually in the spring but at least once every 2 to 3 years.

3. Aerate compacted or heavily used areas, like athletic fields, annually as soon as soil moisture conditions permit. Aerate area six to eight times using a spoon or hollow tine type aeration. Do not use solid spike equipment.

4. Reseed bare and thin areas annually with original species.

ESTABLISHING TREES, SHRUBS, AND VINES

1. Planting nursery stock

A. Select species to serve the intended purpose. See Table 3.3 "Trees Suitable for Landscape and Conservation Plantings in New York" on page 3.14 Where planting of trees is to be done in recreation areas, use those species listed in Table 3.4, "Susceptibility of Tree Species to Compaction" on page 3.21 whenever possible. If the soil on the site is naturally well drained, those species in the "intermediate" group may be used. In no case should species having "susceptible" rating be planted or exposed to compaction unless the soil is clearly "compaction resistant." An example is the Palmyra gravelly soil.

B. Plant materials

1) Plants shall conform to the species, variety, size, number, and conditions as stated in a conservation plan or on a plant list shown on landscape drawings. "American Standard for Nursery Stock" by American Association of Nurserymen will be used to develop the plant list for landscape drawings and to check quality of plant materials.

2) Durable, legible labels with the scientific and common name and cultivar shall be securely attached to plants, bundles of seedlings, containers or flats.

C. Plant Protection

Prior to delivery, the trunk, branches, and foliage of the plants shall be sprayed with non-toxic antidesicant applied according to the manufacturers recommendations. Does not apply to state nursery seedlings.

D. Planting Time

Deciduous trees and shrubs: April 1 to June 1 and October 15 to December 15.

Evergreen trees and shrubs: April 1 to June 1 and September 1 to November 15

E. Spacing

Plant all trees and shrubs well back from buildings to allow for planting pits and mature crown size. The following are guides for planning:

Large trees:	50 - 60 feet apart
Small trees:	20 - 30 feet apart
Columnar species:	6 - 8 feet apart
Hedges:	1 - 4 feet apart
Shrubs:	for clumps, plan spacing so mature shrubs will be touching or overlapping by only 1 or 2 feet.

F. Site Preparation

1) Individual sites for planting seedlings can be prepared by scalping the sod away from a one foot square area where the seedling is to be planted.

2) All planting beds shall be cultivated to a depth of 8 inches and raked to remove sod clumps, weeds, stones, and other foreign material exceeding two inches in diameter.

G. Planting

1) Plants shall be located as shown on plans and/or drawings and where necessary located on the site by stakes, flags or other means.

2) The plants shall be set upright in holes as illustrated in Fig. 3.1 on page 3.7.

3) All plants shall be thoroughly watered on the same day of planting. Plants that have settled shall be reset to grade.

H. Wrapping

Immediately after planting wrap deciduous tree trunks from the bottom to the first limb with a 4 inch wide bituminous impregnated, insect resistant tape or paper manufactured for that purpose. Tie with jute (bag strings) at top and bottom.

I. Mulching

Mulch the disturbed area around individual trees and shrubs with a 4 inch layer of wood chips. Extend a 2 inch thick layer of mulch over tne saucer. Mulch planting beds with 2 inches of wood chips.

J. Pruning

After planting, prune to remove injured twigs and branches. Natural habit or shape of the plant should not be changed.

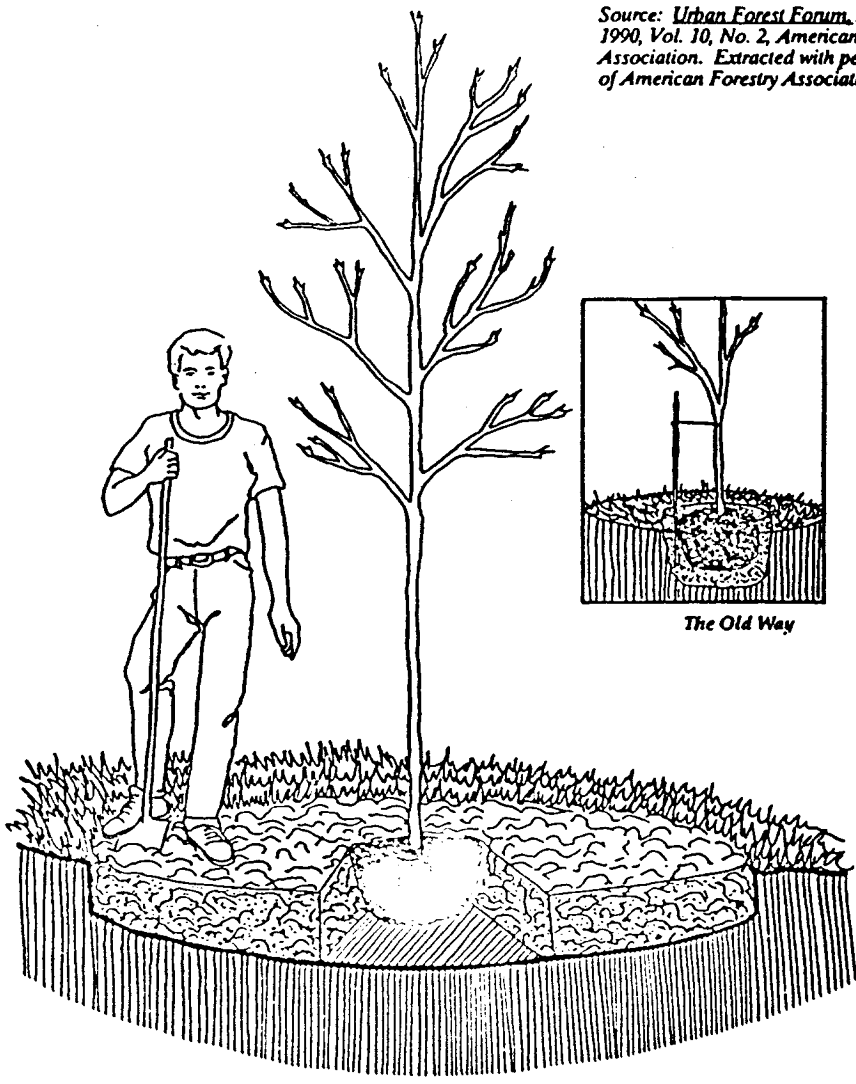
VOL 12

5982

FIGURE 3.1
New Tree Planting Procedure

Figure 2: New Tree Planting Procedure

Source: Urban Forest Forum, April/May 1990, Vol. 10, No. 2, American Forestry Association. Extracted with permission of American Forestry Association.



The Old Way

The new method of tree planting will result in better survival and growth than the old method. Grass competition and soil compaction are two of the most common factors in poor performance. The New Method: Prepare a planting area five times the diameter of the root ball or container. Use a rototiller and/or spades to loosen and mix the soil to a depth of about 12 inches. Organic matter (well decomposed) can be added. Dig a hole in the center to set the tree, so that the root ball will rest on solid ground. Backfill around the root area, pressing the soil but not packing it. Mulch the entire prepared area with 2 to 4 inches of bark, wood chips, decomposed sawdust, or leaves. Reference the article for a full explanation.

VOL 12

59883

K. Cleanup and Maintenance

1) After all work is complete all excess soils, peat moss, debris, etc., shall be removed from the site.

2) Water plants two weeks after planting. For two years water plants every two weeks during dry periods which exceed three weeks without a good soaking rain. Shrubs may require 5 to 10 gallons and trees 20 to 30 gallons for each watering.

3) Remove trunk wrap one year after planting.

2. Transplanting "Wild" Stock

Successful transplanting of wild stock will require heavy equipment and considerable labor as a large weight of soil must be moved with the roots.

A. Select trees and shrubs with good form and full crowns.

B. Transplant only when plants are dormant and soil is moist. Wrap soil ball with burlap to prevent soil from separating from roots.

C. Table 3.5 on page 3.21 shows minimum diameter and approximate weight of soil ball that must be moved with each size plant.

D. Plant and maintain as described above for nursery stock.

PRUNING AND THINNING

1. Pruning

A. Remove trees, limbs and limb stubs to the following widths and heights for the intended use.

Use	Cleared Width Each Side of Trail Tread (feet)	Cleared Height (feet)
TRAILS		
Hiking	1	8
Bicycle	2	10
Motorbike	2	10
Horse	2	12
X-Country Ski	Total: 3 - 12	12[1]
Snowmobile	Total: 6 - 12	12[1]
PICNIC & CAMPING AREAS		
Campfire/Grill	10 ft. dia.	15 + Locations

[1] Includes allowance for snow depth and snow load on branches.

B. Remove dead, diseased or dying limbs that may fall.

C. Do not remove more than one-third of the live crown of a tree in a year.

D. Cut limbs flush to the branch bark ridge.

E. Use the three cut pruning method on all branches over 2 inches in diameter: (1) under cut limb 6 - 12 in. from trunk; (2) cut through limb 1 - 2 in. further out limb: and (3) final cut down and slightly out from in front of branch bark ridge.

2. Thinning

A. Remove dead, diseased, dying, poorly anchored trees that pose a hazard to recreationists as well as those trees that interfere with intended use.

B. Clear trees from an area 10 feet in diameter around all fireplaces and grills.

C. To maintain grass cover in a wooded area thin according to formula Dx3 (average diameter of the trunk of overstory trees times three. Answer is in feet which is the spacing between trees to be left). For example, for trees with average diameter of 6 inches, spacing after thinning should leave trees 18 feet apart on average. Crown cover after thinning should be about 50 percent.

D. Selectively thin as needed to favor those trees that are most "resistant" to compaction around their roots. See Table 3.4, "Susceptibility of Tree Species to Compaction" on page 3.21. If the soil on the site is naturally well drained, those species in the "intermediate" group may also be favored. In no case should species in the "susceptible" group be favored unless they are on a compaction resistant soil (an example is the Palmyra gravelly soil).

PROTECTING TREES IN HEAVY COMPACTION AREAS

The compaction of soil over the roots of trees and shrubs by the trampling of recreationists, vehicular traffic, etc., reduces oxygen, water, and nutrient uptake by feeder roots. This weakens and may eventually kill the plants. Table 3.4, rates the "Susceptibility of Tree Species to Compaction" on page 3.21.

Where heavy compaction is anticipated, apply and maintain a 3 to 4 inch layer of undecayed wood chips or 2 inches of No. 2 washed, crushed gravel.

Table 3.1 Recreation Turfgrass Seed Mixtures

Site - Use	species (% by weight)	lbs/1,000 sq. ft.	lbs./acre
1. Sunny Sites (well, moderately well and somewhat poorly drained soils)			
a. Athletic fields and similar areas			
	80% Kentucky bluegrass blend	2.4-3.2	105-138
	20% perennial ryegrass	0.6-0.8	25-37
		3.0-4.0	130-175
	(for southern NY)		
	50% Kentucky bluegrass	1.5-2.0	65-88
	50% perennial ryegrass	1.5-2.0	65-87
		3.0-4.0	130-175
	100 % Tall fescue	3.4-4.6	150-200
b. General recreation areas and lawns (Medium to high maintenance)			
	65% Kentucky bluegrass blend	2.0-2.6	85-114
	20% perennial ryegrass	0.6-0.8	26-35
	15% fine fescue	0.4-0.6	19-26
		3.0-4.0	130-175
2. Sunny droughty sites - general recreation areas and lawns, low maintenance (somewhat excessively to excessively drained soils). Excluding Long Island.			
	65% fine fescue	2.6-3.3	114-143
	15% perennial ryegrass	0.6-0.7	26-33
	20% Kentucky bluegrass blend	0.8-1.0	35-44
		4.0-5.0	175-220
3. Shady dry sites (well to somewhat poorly drained soils).			
	65% fine fescue	2.6-3.3	114-143
	15% perennial ryegrass	0.6-0.7	26-33
	20% Kentucky bluegrass blend	0.8-1.0	35-44
		4.0-5.0	174-220
	80% blend of shade-tolerant Kentucky bluegrass	2.4-3.2	105-138
	20% perennial ryegrass	0.6-0.8	25-37
		3.0-4.0	130-175
4. Shady wet sites (somewhat poor to poorly drained soils).			
	70% rough bluegrass	1.4-2.1	60-91
	30% blend of shade-tolerant Kentucky bluegrass	0.6-0.9	25-39
		2.0-3.0	85-130

* recommended for shady sites

Table 3.3
Trees Suitable for Landscape and Conservation Plantings In New York

TREE SIZE:

Large Sized Trees (75' +) - Trees that exceed this height at maturity.

Medium Sized Trees (35'- 75') - Trees in this height range at maturity.

Small Sized Trees (15'- 35') - Trees relatively low at maturity.

VAR; (x) = varieties of the species are available for various uses.

FOLIAGE:

E = evergreen

c = colorful in fall

l = lustrous; shiny

D = deciduous

d = dense

u = unusual leaves

f = fine textured

SITE TOLERANCE:

cold = hardy in zones 2 and 3 (northeastern mountains)

wet = tolerant of moderately well to somewhat poorly drained soils.

dry = tolerant of sandy, gravelly, excessively drained soils.

shade = will tolerate some shady sites.

sea = trees which may tolerate seaside conditions.

city = trees that withstand usual city conditions.

PEST:

F = usually free   S = susceptible

FEATURES:

Habit = general shape of open grown plants.

Bo - broad open (wide)

Co - columnar

FEATURES: (cont'd)

Ho - horizontal branching

Na - narrow

Op - open

Ov - ovoid/oblong

Pe - pendulous

Py - pyramidal

Ro - round

S - spreading

Up - upright

Wo - wide/open

BRK; (x) = bark has interesting characteristics of color, texture or form.

FLR; (x) = flowers are colorful and interesting.

f = fragrant;

s = showy;

u = unusual shape.

FRU; (x) = fruits are interesting and/or edible.

LVS; (x) = leaves have attractive color and/or unusual shape.

USES:

WIND; (x) = suitable for windbreaks and screening.

SHD; (x) = suitable as lawn shade trees.

STRT; (x) = trees often selected for street planting.

WILD; F/c = trees offering food and cover to wildlife.

F = trees providing food from fruits.

W/c = trees offering winter cover.

BARR; (x) = trees which can be used as a barrier to some traffic.

ORN; (x) = trees whose main value is ornamental.

Table 3.4 Susceptibility of Tree Species to Compaction[1]

Resistant:

Box elder	Acer negundo
Green Ash	Fraxinus pennsylvanica
Honey locust	Gleditsia triacanthos
Eastern cottonwood	Populus deltoides
Swamp white oak	Quercus bicolor
Hophornbeam	Ostrya virginia
Willows	Salix spp.
American elm	Ulmus americana
Red elm	Ulmus rubra
Hawthornes	Crataegus spp.
Bur oak	Quercus macrocarpa
Northern white cedar	Thuja occidentalis

Intermediate:

Red maple	Acer rubrum
Silver maple	Acer saccarinum
Hackberry	Celtis occidentalis
Black gum	Nyssa sylvatica
Red oak	Quercus rubra
Basswood	Tilia americana
Sweetgum	Liquidambar styraciflua
Norway maple	Acer platanoides
Shagbark hickory	Carya ovata
London plane	Platanus x acerifolia
Pin oak	Quercus palustris

Susceptible:

Sugar maple	Acer saccarum
White pine	Pinus strobus
Blue spruce	Picea pungens
White oak	Quercus alba
Red pine	Pinus resinosa
Austrian pine	Pinus nigra
White ash	Fraxinus americana
Paper birch	Betula paprifera
Mountain ash	Sorbus aucuparia
Japanese maple	Acer palmatum

[1]If a tree species does not appear on the list, insufficient information is available to rate it for this purpose.

Table 3.5 - Size and Weight of Earth Ball Required to Transplant Wild Stock

STANDARD AND SPECIFICATIONS FOR VEGETATING WATERWAYS

Definition

Waterways are a natural or constructed outlet, shaped or graded. They are vegetated as needed for safe disposal of runoff water.

Purpose

To provide for the safe disposal of excess surface water from construction sites and urban areas without damage from erosion.

Conditions Where Practice Applies

This standard applies to vegetating waterways and similar water carrying structures.

Supplemental measures may be required with this practice. These may include subsurface drainage to permit the growth of suitable vegetation and to eliminate wet spots, a section stabilized with asphalt, stone or other suitable means, or additional storm drains to handle snowmelt or storm runoff.

Retardance factors for determining waterway dimensions are shown in Table 3.6 on page 3.25 and "Maximum Permissible Velocities for Selected Grass and Legume Seed Mixtures" are shown in Table 3.7 on page 3.26.

Design Criteria

Waterways or outlets shall be protected against erosion by vegetative means as soon after construction as practical. Vegetation must be well established before diversions or other channels are outletted into them. Consideration should be given to the use of jute matting, excelsior matting, or sodding of channels to provide erosion protection as soon after construction as possible.

1. Liming, fertilizing and seedbed preparation.
   - A. Lime to pH 6.5.
   - B. Apply at least 50 lbs. of N, P, and K per acre (1.0- 1.25 lbs/1,000 sq. ft.).
   - C. Lime and fertilizer shall be mixed thoroughly into the seedbed during preparation.
   - D. Channels, except for paved sections, shall have at least 4 inches of topsoil.
   - E. Remove stones and other obstructions that will hinder maintenance.
2. Timing of Seeding.
   - A. Early spring and late August are best.
   - B. Temporary cover to protect from erosion is recommended during periods when seedings may fail.
3. Seed Mixtures:

Mixtures	Rate per Acre (lbs)	Rate per 1,000 sqft. (lbs)
A. Birdsfoot trefoil or ladino clover[1]	8	0.20
Tall fescue or smooth bromegrass	20	0.45
Redtop[2]	2	0.05
	30	0.70
or		
B. Kentucky bluegrass[3]	25	0.60
Creeping Red fescue	20	0.50
Perennial ryegrass	10	0.20
	55	1.30

[1] Inoculate with appropriate inoculum immediately prior to seeding. Ladino or common white clover may be substituted for birdsfoot trefoil and seeded at the same rate.

[2] Perennial ryegrass may be substituted for the redtop but increase seeding rate to 5 lbs/acre (0.1 lb/1,000 sq.ft.).

[3] Use this mixture in areas which are mowed frequently. Common white clover may be added if desired and seeded at 8 lbs/acre (0.2 lb/1,000 sq. ft.)

4. Seeding.

Select the appropriate seed mixture and apply uniformly over the area. Rolling or cultipacking across the waterway is desirable.

Waterway centers or crucial areas may be sodded. efer to the Standard and Specification for Stabilization with Sod on page 3.35. Be sure sod is securely anchored using staples or stakes.

5. Mulching.

All seeded areas will be mulched. Channels more than 300 feet long and or where the slope is 5 percent or more, must have the mulch securely anchored. Refer to the Standard and Specification for Mulching on page 3.31 for details.

VOL 12

5999

6. Maintenance.

Fertilize, lime and mow as needed to maintain dense protective vegetative cover.

Waterways shall not be used for roadways.

If rills develop in the bottom of a waterway, prompt attention is required to avoid the formation of gullies. Either hay or straw bales, riprap, excelsior or filter fabric may be used during the establishment phase. See Figure 3.3, Rill Maintenance Measures on page 3.27. Spacing between rill maintenance barriers shall not exceed 100 feet.

Table 3.6
Retardance Factors for Various Grasses and Legumes

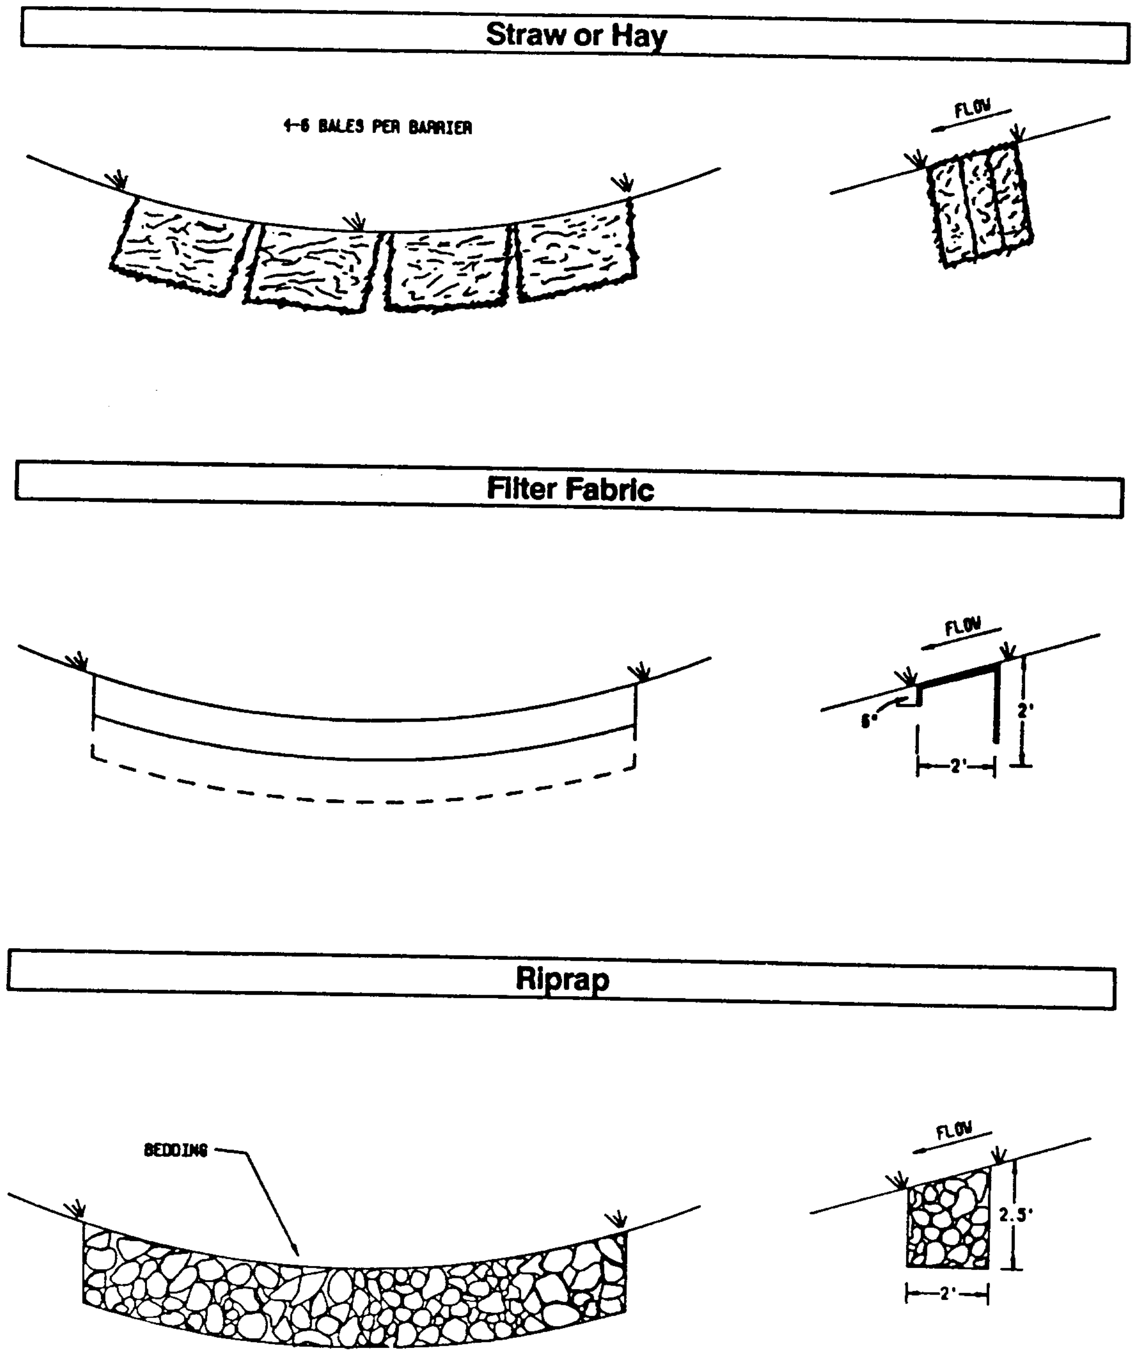
Retardance	Cover	Condition
A	Reed canarygrass..................................	Excellent stand, tall (average 36 inches)
B	Smooth bromegrass................................ Tall fescue....................................... Grass-legume mixture--Timothy, smooth bromegrass, or orchard grass with birdsfoot trefoil.......... Reed canarygrass................................. Tall fescue, with birdsfoot trefoil or ladino clover	Good stand, mowed (average 12 to 15 inches) Good stand, unmowed (average 18 inches) Good stand, uncut (average 20 inches) Good stand, mowed (average 12 to 15 inches) Good stand, uncut (average 18 inches)
C	Redtop... Grass-legume mixture--summer (Orchard grass, redtop, Annual ryegrass, and ladino or white clover)..... Kentucky bluegrass..............................	Good stand, headed (15 to 20 inches) Good stand, uncut (6 to 8 inches) Good stand, headed (6 to 12 inches)
D	Red fescue....................................... Grass-legume mixture--fall, spring (Orchard grass, redtop, Annual ryegrass, and white or ladino clover..	Good stand, headed (12 to 18 inches) Good stand, uncut (4 to 5 inches)

Table 3.7
Maximum Permissable Velocities for Selected Seed Mixtures

Cover	Slope range 2/ (percent)	Permissible Velocity 1/	
		Erosion resistant soils (ft. per sec.) K=0.10 - 0.35 3/	Easily eroded soils (ft. per sec.) K=0.36 - 0.80
Bermudgrass	0-5 5-10 over 10	8 7 6	6 5 4
Kentucky bluegrass Smooth brome Tall fescue	0-5 5-10 over 10	7 6 5	5 4 3
Grass mixtures Reed canarygrass	2/ 0-5 5-10	5 4	4 3
Redtop Alfalfa Red fescue	4/ 0-5	3.5	2.5
Sudangrass 5/	6/ 0-5	3.5	2.5

1/ Use velocities exceeding 5 feet per second only where good covers and proper maintenance can be obtained.
2/ Do not use on slopes steeper than 10 percent except for vegetated side slopes in combination with a stone, concrete, or highly resistant vegetative center section.
3/ K is the soil erodibility factor used in the Universal Soil Loss Equation. Consult USDA, SCS Technical Guide for list of K values for New York soils.
4/ Do not use on slopes steeper than 5 percent except for vegetated side slopes in combination with a stone, concrete, or highly resistant vegetative center section.
5/ Annuals—use on mild slopes or as temporary protection until permanent covers are established.
6/ Use on slopes steeper than 5 percent is not recommended.

Figure 3.2
Rill Maintenance Measures



VOL 12

60004

STANDARD AND SPECIFICATIONS FOR TOPSOILING

Definition

Spreading a specified quality and quantity of topsoil materials on graded or constructed subsoil areas.

Purpose

To provide acceptable plant cover growing conditions, thereby reducing erosion; to reduce irrigation water needs; to reduce the need for nitrogen fertilizer application.

Conditions Where Practice Applies

Topsoil is applied to subsoils that are droughty (low available moisture for plants), stony, slowly permeable, salty or extremely acid. It is also used to backfill around shrub and tree transplants.

Design Criteria

1. Preserve existing topsoil in place, thereby reducing the need for added topsoil.

2. Conserve and stockpile topsoil and friable fine textured subsoils that must be stripped from the excavated site and applied after final grading where vegetation will be established.

3. Refer to USDA Soil Conservation Service soil surveys or soil interpretation record sheets for further soil texture information.

Site Preparation (Where topsoil is to be added)

1. As needed, install erosion control practices such as diversions, channels, sediment traps and stabilizing measures or maintain if already installed.

2. Complete rough grading and final grade, allowing for depth of topsoil to be added.

3. Scarify all compact, slowly permeable, medium and fine textured subsoil areas. Scarify at approximately right angles to the slope direction in soil areas that are steeper than 5 percent.

4. Remove refuse, woody plant parts, stones over 3 inches in diameter, and other litter.

Topsoil Materials

1. Topsoil shall have at least 2 percent by weight of fine textured stable organic material, and no greater than 6 percent. Muck soil shall not be considered topsoil.

2. Topsoil shall have not less than 20 percent fine textured material (passing the No. 200 sieve) and not more than 15 percent clay.

3. Topsoil treated with soil sterilants or herbicides shall be so identified to the purchaser.

4. Topsoil shall be relatively free of stones over 1 & 1/2 inches diameter, trash, noxious weeds such as nutsedge and quackgrass, and will have less than 10 percent gravel by volume.

5. Topsoil containing soluble salts greater than 500 ppm shall not be used.

Application and Grading

1. Topsoil shall be distributed to a uniform depth over the area. It shall not be placed when it is partly frozen, muddy, or on frozen slopes or over ice, snow, or standing water puddles.

2. Topsoil placed and graded on slopes steeper than 5 percent shall be promptly fertilized, seeded, mulched and stabilized by "tracking" with suitable equipment.

3. Apply topsoil in the following amounts:

Site Conditions	Intended Use	Minimum Topsoil Depth
1. Deep sand or loamy sand	Mowed lawn	6 in.
	Tall legumes, unmowed	2 in.
	Tall grass, unmowed	1 in.
2. Deep sandy loam	Mowed lawn	5 in.
	Tall legumes, unmowed	2 in.
	Tall grass, unmowed	none
3. Six inches or more: silt loam, loam, or silt	Mowed lawn	4 in.
	Tall legumes, unmowed	1 in.
	Tall grass, unmowed	1 in.

VOL 12

6005

VOL 12

6006

STANDARD AND SPECIFICATIONS FOR MULCHING

Definition

Applying plant residues or other suitable materials to the soil surface.

Purpose

To conserve moisture and modify surface soil temperature fluctuations; prevent surface compaction or crusting; reduce runoff and erosion; control weeds; and help establish plant cover.

Conditions Where Practice Applies

On soils subject to erosion on which low residue producing crops, such as grapes, berries and small fruits are grown; on critical areas; and on soils that have a low infiltration rate.

Design Criteria

1. SITE PREPARATION

A. Prior to mulching, install the necessary temporary or permanent erosion control (structural) practices and drainage systems within or adjacent to area to be mulched.

B. Slope, grade and smooth the site if conventional equipment is to be used in applying and anchoring the mulch.

C. Remove all undesirable stones and other debris depending on anticipated land use.

D. Compacted or crusted soil surface should be loosened to at least two inches by disking or other suitable methods.

2. MULCHING MATERIALS

A. Select from attached Table 3.8 on page 3.32 the type of mulch and application rate that will best meet the need and availability of material.

B. If needed, select the anchoring method from Table 3.9 on page 3.34 that will best meet the need.

C. The best combination for grass/legume establishment is straw (small grain) mulch applied at 2 ton/acre (90 lbs/1,000 sq. ft.) and anchored with wood fiber mulch (hydromulch) at 500 - 750 lbs./acre (11 - 17 lbs./1,000 sq. ft.). The wood fiber mulch must be applied through a hydroseeder immediately after mulching.

VOL 12

6007

Table 3.8
Guide to Mulch Materials, Rates and Uses

Mulch Material	Quality Standards	Application Rates per 1000 Sq. Ft.	Application Rates per Acre	Depth of Application	Remarks
Sawdust green, or composted	Free from objectionable-coarse material.	83-500 cu. ft.	--	1-7"	Most effective as a mulch around ornamentals, small fruits and other nursery stock. Requires 30-35 lbs. N/ton to prevent N deficiency while decaying mulch. One cubic foot weighs 25 lbs
Wood Chips or Shavings	Green or air-dried Free of objectionable coarse material.	500-900 lbs.	10-20 tons	2-7"	Has about the same use and application as sawdust, but requires less N/ton (10 - 12 lbs.). Resistant to wind blowing. Decomposes slowly.
Wood Excelsior	Green or airdried burred wood fibers.	90 lbs. (1 bale)	2 tons	--	Decomposes slowly. Subject to some wind blowing. Packaged in 80-90 lbs. bales.
Wood Fiber Cellulose (Partly digested woodfibers)	Made from natural wood usually with green dye and dispersing agent.	50 lbs.	2,000 lbs.	--	Apply with hydromulcher. No tie down require. Less erosion control provided than 2 tons of hay or straw.
Compost or Manure	Well shredded,free of of excessive coarse materials.	400-600 lbs.	8-10 tons		Use straw manure where erosion control is needed. May create problem with weeds. Excellent moisture conserver. Resistant to wind blowing.
Cornstalks, shredded or chopped	Air-dried, shredded into 8" to 12" lengths.	150-300 lbs.	4-6 tons	--	Effective for erosion control, relatively slow to decompose. Excellent for mulch on crop fields. Resistant to wind blowing.
Gravel, Crushed Stone or Slag	Washed; Size 2B or 3A - 1 1/2".	9 cu. yds.	--	3"	Excellent mulch for short slopes and around plants and ornamentals. Use 2B where subject to traffic. (Approximately 2,000 lbs./cu.yd.). Frequently used over black plastic for better weed control.

Table 3.8 (cont'd)
Guide to Mulch Materials, Rates and Uses

Mulch Material	Quality Standards	Application Rates per 1000 Sq. Ft.	Application Rates per Acre	Depth of Application	Remarks
Hay or Straw	Air-dried; free of undesirable seeds & coarse materials	90-100 lbs. 2-3 bales	2 tons 100-120 bales	cover about 90 % surface	Use straw where mulch is maintained for more than three months. Subject to wind blowing unless anchored. Most commonly used mulching material. Best micro-environment for germinating seeds.
Peat Moss	Dried, compressed free of coarse materials	200-400 cu. ft.	1/2 -1 tons	2"-4"	Most effective as a mulch around ornamentals. Subject to wind blowing unless kept wet. 100 lbs. bales (6 cu.ft.). Excellent moisture holding capacity.
Jute Twisted Yarn	Undyed, unbleached plain weave. Warp 78 ends/yd., Weft 41 ends/yd. 60-90 lbs/roll	48" x 50 yds. or 48" x 75 yds.	--	-	Use without additional mulch. Tie down as per manufacturers specifications.
Excelsior Wood Fiber Mats	Interlocking web of excelsior fibers with photodegradable plastic netting	48"x100" 2 sided plastic, 48" x 180" 1 sided plastic	--	--	Use without additional mulch. Excellent for seeding establishment. Tie down as per manufacturers specifications. Approximately 72 lbs/roll for excelsior with plastic on both sides. Use two sided plastic for centerline of waterways.
Glass Fiber	1/4" thick, 7/16" dia., holes on 1" centers, 56 lb. rolls.	72"x30 yds.	--	--	Use without additional mulch. Tie down with T bars as per manufacturers specifications.
Plastic	2-4 mils	Variable	--	--	Use black for weed control. Effective for moisture conservation and weed control for small fruits and ornamentals.
Filter Fabrics	Woven or Spun	Variable	--	--	--
Straw or coconut fiber or combination	Photodegradable plastic net on one or two sides.	most are 6.5 ft. x 83.5 ft.	81 rolls	--	Designed to tolerate higher velocity water flow, centerlines of waterways.. 60 sq. yds. per roll.

Table 3.9
Mulch Anchoring Guide

Anchoring Method or Material	Kind of Mulch to be Anchored	How To Apply
A. Manual		
1. Peg and Twine	Hay or straw	After mulching, divide areas into blocks approx. 1 sq. yd. in size. Drive 4-6 pegs per block to within 2" to 3" of soil surface. Secure mulch to surface by stretching twine between pegs in criss-cross pattern on each block. Secure twine around each peg with 2 or more turns. Drive pegs flush with soil where mowing and maintenance is planned.
2. Mulch netting	Hay or straw	Staple the light-weight paper, jute, wood fiber, or plastic nettings to soil surface according to manufacturer's recommendations. Should be biodegradable. Most products are not suitable for foot traffic.
3. Soil & stones	Plastic	Plow a single furrow along edge of area to be covered with plastic, fold about 6" of plastic into the furrow and plow furrow slice back over plastic. Use stones to hold plastic down in other places as needed.
4. Cut-in	Hay or straw	Cut mulch into soil surface with square edged spade. Make cuts in contour rows spaced 18" apart. Most successful on contour in sandy soils.
B. Mechanical		
1. Asphalt spray (emulsion)	Compost, wood chips, wood shavings, hay or straw	Apply with suitable spray equipment using the following rates: asphalt emulsion 0.04 gallons per sq. yd.: on slopes use 200 gal/acre, on level use 150 gal/acre; liquid asphalt: (rapid, medium, or slow setting) 0.10 gallons per sq/yd., 400 gal/acre.
2. Wood cellulose	Hay or straw	Apply with hydroseeder immediately after mulching. Use 750 lbs wood fiber per acre. Some products contain an adhesive material.
3. Pick chain	Hay or straw	Use on slopes steeper than 3:1. Pull across slopes with suitable power equipment.
4. Mulch anchoring tool or disk	Hay or straw, manure/mostly straw	Apply mulch and use pull a mulch anchoring tool over mulch. When a disk (smooth) is used, set in straight position and pull across slope with suitable power equipment. Mulch material should be "tucked" into soil surface about 3".
5. Chemical	Hay or straw	Apply Terra Tack AR 120 lbs/ac in 480 gal. of water (#156/ac.) or Aerospray 70 (60 gal/ac.) according to manufacturer's instructions. Avoid application during rain. A 24 hour curing period and a soil temperature higher than 45° F are required.

STANDARD AND SPECIFICATIONS FOR STABILIZATION WITH SOD

Definition

Stabilizing silt producing areas by establishing long term stands of grass with sod.

Purpose

To stabilize the soil; reduce damage from sediment and runoff to downstream areas; enhance natural beauty.

Conditions Where Practice Applies

On exposed soils that have a potential for causing off site environmental damage where a quick vegetative cover is desired. Moisture, either applied or natural, is essential to success.

Design Criteria

1. Sod shall be bluegrass or a bluegrass/red fescue mixture or a perennial ryegrass for average sites. Use tall fescue for shady, droughty or otherwise more critical areas. For variety selection, see Table 3.2 on page 3.11.

2. Sod shall be machine cut at a uniform soil thickness of 3/4 inch, plus or minus 1/4 inch. Measurement for thickness shall exclude top growth and thatch.

3. Standard size sections of sod shall be strong enough to support their own weight and retain their size and shape when suspended vertically from a firm grasp on the upper 10 percent of the section.

4. Sod shall be free of weeds and undesirable coarse weedy grasses. Wild native or pasture grass sod shall not be used unless specified.

5. Sod shall not be harvested or transplanted when moisture content (excessively dry or wet) may adversely affect its survival.

6. Sod shall be harvested, delivered and installed within a period of 36 hours. Sod not transplanted within this period shall be inspected and approved by the contracting officer or his designated representative prior to its installation.

Site Preparation

Fertilizer and lime application rates shall be determined by soil tests. Under unusual circumstances where there is insufficient time for a complete soil test and the contracting officer agrees, fertilizer and lime materials may be applied in amounts shown in subsection 2 below.

1. Prior to sodding, the surface shall be smoothed and cleared of all trash, debris, and of all roots, brush, wire, grade stakes and other objects that would interfere with planting, fertilizing or maintenance operations.

2. Where the soil is acid or composed of heavy clays, ground limestone shall be spread at the rate of 100 lbs. per 1,000 square feet. In all soils 20 lbs. of 5-10-10 or equivalent, per 1,000 square feet shall be uniformly applied and mixed into the top 3 inches of soil with the required lime.

Sod Installation

1. The operation of laying, tamping and irrigating for any area sod shall be completed within eight hours. During periods of excessively high temperature the soil shall be lightly moistened immediately prior to laying the sod.

2. The first row of sod shall be laid in a straight line with subsequent rows placed parallel to and tightly wedged against each other. Lateral joints shall be staggered to promote more uniform growth and strength. Insure that sod is not stretched or overlapped and that all joints are butted tight in order to prevent voids which would cause air drying of the roots. On sloping areas where erosion may be a problem, sod shall be laid with the long edges parallel to the contour and with staggered joints.

3. Secure the sod by tamping and pegging or other approved methods. As sodding is completed in any one section, the entire area shall be rolled or tamped to insure solid contact of roots with the soil surface.

4. Sod shall be watered immediately after rolling or tamping until the underside of the new sod pad and soil surface below the sod are thoroughly wet.

Sod Maintenance

1. In the absence of adequate rainfall, watering shall be performed daily or as often as deemed necessary by the inspector during the first week and in sufficient quantities to maintain moist soil to a depth of 4 inches. Watering should be done during the heat of the day to help prevent wilting. Avoid excessive water during applications.

2. After the first week, sod shall be watered as necessary to maintain adequate moisture and insure establishment.

3. First mowing should not be attempted until sod is firmly rooted. No more than 1/3 of the grass leaf shall be removed by the initial cutting or subsequent cuttings. Grass height shall be maintained between 2 and 3 inches unless other-

VOL 12

601

wise specified. Avoid heavy mowing equipment for several weeks to prevent rutting.

4. Fertilize three to four weeks after sodding, applying 1 pound nitrogen/1,000 sq. ft. Use a complete fertilizer with a 2-1-1 ratio, or as recommended by soil test results.

5. Weed Control: Target herbicides for weeds present. Consult current Cornell Pest Control Recommendations for commercial turfgrass management or consult the local office of Cooperative Extension.

6. Disease Control: Consult the local office of the Cooperative Extension.

VOL 12

6012

STANDARD AND SPECIFICATIONS FOR VEGETATIVE STABILIZATION OF SAND AND GRAVEL PITS

Definition

Stabilizing inactive borrow areas with herbaceous, perennial plants.

Purpose

1. To stabilize the soil, preventing wind or water erosion from causing on-site or offsite damages.
2. To improve the aesthetic appeal and the ability of the site to support wildlife.

Condition Where Practice Applies

Sand and gravel borrow areas which have had:

1. The soil profile replaced to approximate original conditions.
2. Where the soil profile has been removed.

Design Criteria

1. The surface shall be graded with a maximum slope of 15 percent (8.5 degrees).
2. Rocks and other debris shall be removed from the site or buried during grading.
3. Surface materials shall be sampled and analyzed to determine:

   A) Percent fines (particles less than .074 mm - 200 mesh sieve).

   B) pH.

   C) Phosphorus and potassium availability.

4. Lime and fertilizer requirements:

   The surface material shall be limed to a pH of 6.0 using agricultural ground limestone. The lime shall be incorporated into the top 3 inches of surface material.

   Fertilizer shall be applied per soil test to achieve moderate levels of available phosphorus (P_2O_5) and potassium (K_2O). In addition, 30 pounds per acre of nitrogen in a slow release formulation shall be applied. The fertilizer will be incorporated (about 1/4 -1/2 inch) along with the seed. See subsection F, Planting instructions, of this standard.

5. Seeding mixture selection:

   A) Temporary cover may be obtained by seeding oats at 2 bu/acre.

   B) When the fines fraction is less than 15 percent, the following warm season grass mixture shall be used:

Species	Variety	Certified Seed PLS*/Acre (lbs)
Switchgrass	Blackwell, Shelter or Pathfinder	2.0
Coastal panicgrass	Atlantic	2.0
Big Bluestem	Niagara	4.0
Little Bluestem	Aldous or Camper	4.0
Sand Lovegrass	Nebraska 27 or Bend	2.0
Total mix (PLS/acre)		14.0 lbs.

*Pure Live Seed (PLS) = (% germination x % purity)/100.

Pounds to be seeded = (100 x lbs. of 100% PLS required)/% PLS of commercial seed being used.

   C) When the fines fraction is 15 percent or greater, one of the following grass/legume mixture shall be used:

Species	Variety	Live Seed per Acre(lbs.)
Tall fescue	Ky-31	10.0
Redtop	Common	2.0
Perennial ryegrass	Pennfine	5.0
Birdsfoot trefoil*	Empire	8.0
Total mix (lbs. PLS/acre)		25.0

* legume in seed mixture needs to be inoculated.

or

Species	Variety	Live Seed per Acre(lbs.)
Flatpea*	Lathco	10.0
Perennial pea*	Lancer	2.0
Crownvetch	Penngift/Chemung	10.0
Tall fescue	KY-31/Rebel	10.0
Total mix (lbs./acre)		32.0

* legume in seed mixture needs to be inoculated.

6. Planting instructions:

   A) Planting dates are early spring until May 20. The birdsfoot trefoil/grass mix may be fall seeded after August 15. A temporary cover of 2 bushels of oats/acre may be planted from August 15 to September 15 (oats will winter kill).

   B) The legumes shall be inoculated at 4 times the standard rate immediately prior to seeding.

C) The seed shall be uniformly broadcast mechanically, by hydroseeder, or by hand.

D) The seed and fertilizer shall be incorporated by either:

1) "Tracking" the area with a bulldozer having cleats at least 1 inch in depth. Operation of the dozer shall be perpendicular to the contour and such that the entire area is covered by the tracks.

2) Pulling a cultipacker over the entire site with the tines set to till no deeper than 1 inch.

E) The entire site shall be mulched with 3,000 pounds of small grain straw per acre when warm season grasses are planted. When the grass/legume mix is used, 4,000 pounds of grain straw will be used.

F) The mulch shall be anchored by the bulldozer tracking technique (may be simultaneous with seed incorporation) or by a method selected from Standard and Specification for Mulching on page 3.31.

7. Site protection:

For the seeding to be successful, vehicles and foot traffic must be kept off the site for at least 2 years.

VOL 12

6014

R0039322

STANDARD AND SPECIFICATIONS FOR PROTECTING VEGETATION DURING CONSTRUCTION

Definition

The protection of trees, shrubs, ground cover and other vegetation from damage by construction equipment.

Purpose

To preserve existing vegetation determined to be important for soil erosion control, water quality protection, shade, screening and other values.

Conditions Where Practice Applies

On planned construction sites in wooded areas where valued vegetation exists and needs to be preserved.

Design Criteria

1. Planning Considerations

A. Inventory:

1) Property boundaries, topography, vegetation and soils information should be gathered. Identify potentially high erosion areas, areas with tree windthrow potential, etc. A vegetative cover type map should be made on a copy of a topographic map which shows other natural and manmade features. Vegetation that is desirable to preserve because of its value for screening, shade, critical erosion control, endangered species, aesthetics, etc., should be identified and marked on the map.

2) Based upon these data, general statements should be prepared about the present condition, potential problem areas and unique features of the property.

B. Planning:

1) After engineering plans (plot maps) are prepared, another field review should take place and recommendations made as to vegetation to be saved. Minor adjustments in location of roads, dwellings and utilities may be needed. Construction on steep slopes, erodible soils, wetlands and streams should be avoided. Clearing limits should be delineated.

2) Areas to be seeded and planted should be identified. Remaining vegetation should blend with the surroundings and/or provide special function such as a filter strip, buffer zone or screen.

3) Trees and shrubs of special seasonal interest, such as flowering dogwood, red maple, striped maple, and shadbush and valuable potential shade trees should be identified and marked for special protective treatment as appropriate.

4) Trees to be cut should be marked on the plans. If timber can be removed for salable products, a forester should be consulted for marketing advice.

5) Trees that may become a hazard to people, personal property, or utilities should be designated to be removed. These include trees subject to windthrow, weak-wooded, disease-prone species, and trees with severely damaged root systems.

6) The vigor of remaining trees may be improved by a selective thinning. A forester should be consulted for implementing this practice.

2. Measures to Protect Vegetation

A. Limit soil placement over existing tree and shrub roots to a maximum of 3 inches. Soils with loamy texture and good structure should be used.

B. Use retaining walls and terraces to protect roots of trees and shrubs when grades are lowered. Lowered grades should start no closer than the dripline of the tree. For narrow-canopied trees and shrubs, the stem diameter in inches is converted to feet and doubled, such that a 10 inch tree should be protected to 20 feet.

C. Trenching across tree root systems should be the same minimum distance from the trunk, as in "B." Tunnels under root systems for underground utilities should start 18 inches or deeper below the normal ground surface. Tree roots which must be severed should be cut clean. Backfill material to be in contact with the roots should be topsoil or a prepared planting soil mixture.

D. Construct sturdy fences, wood or steel barriers, or other protective devices surrounding valuable vegetation from construction equipment.

Place barriers far enough from trees so that tall equipment such as backhoes and dumptrucks do not contact tree branches.

E. Construction limits should be identified and clearly marked to exclude equipment.

F. Avoid spills of oil/gas and other contaminants.

G. Obstructive and broken branches should be pruned properly. The branch collar on all branches whether living or dead should not be damaged. The 3 or 4 cut

VOL 12

6015

method should be used on all branches larger than two inches at the cut. First cut about one-third the way through the underside of the limb (about 6-12 inches from the tree thrunk). Then (approximatlely an inch further out) make a second cut through the limb from the upper side. When the branch is removed, there is no splintering of the main tree thrunk. Remove the stub. If the branch is larger than 5-6 inches in diameter, use the four cut system. Cuts 1 and 2 remain the same and cut 3 should be from the underside of the limb, on the outside of the branch collar, and cut 4 should be from the top and in alignment with the 3rd cut. Cut 3 should be 1/4 to 1/3 the way down the limb. This will prevent the bark from peeling down the trunk. Do not paint the cut surface.

H. Penalities for damage to valuable trees, shrubs and herbaceous plants should be clearly spelled out in the contract.

VOL 12

0601 6

STANDARD AND SPECIFICATIONS FOR VEGETATING SAND DUNES AND TIDAL BANKS

Definition

Establishing and maintaining vegetative cover for coastal shoreline protection.

Purpose

1. To stabilize frontal sand dunes and provide for sand entrapment for dune building where possible and necessary.

2. To provide for protection of dune vegetation from foot traffic and vehicles.

3. To stabilize tidal banks and provide for long term protection.

Conditions Where Practice Applies

On any coastal shoreline including the Great Lakes, where vegetation can be expected to effectively stabilize the site. To determine potential effectiveness, refer to the procedure outlined in Table 3.10, "Vegetative Treatment Potential for Eroding Tidal Shorelines in the Mid-Atlantic States" on page 3.453

Specifications

1. Sand Dunes

A. Where stabilization of existing sand dunes and/or reestablishment of beachgrass is needed.

1) Certified 'Cape' American beachgrass shall be planted on all frontal dunes. Planting shall be accomplished by April 30, following the planting recommendations found in Figure 3.3, Page 3.44 "Conservation Plant Sheet No. 28".

2) Certified 'Atlantic' coastal panicgrass shall be planted on back dunes at 10 pounds, pure live seed, per acre. Plant from March 1 to June 15. See pg. 3.37 to calculate actual pounds of pure live seed.

3) Immediately after planting a sand fence (snow fence) will be built to protect the beachgrass from vehicle and foot traffic. The fence shall surround the planted area at a distance of 15 feet from the planted area. Passageways should be provided to allow pedestrians to cross the planted area at 300 foot intervals. Boardwalks are desirable. Move the opening and boardwalk when beachgrass becomes weak.

B. Where sand dunes must be reconstructed through sand entrapment and shore conditions allow for sand deposition, a specialist from Sea Grant or SCS shall make the determinations of feasibility. Appropriate permits for altering shorelines must be obtained prior to work beginning.

2. Building, Planting and Maintaining Coastal Sand Dunes

Dune stabilization work must start at least one hundred (100) feet (horizontal distance) from the mean high tide (MHT) line as a minimum. Whenever feasible, leave room for two or more dune lines, a double layer of protection. Dunes grow toward the sand supply, which is the ocean or the lake.

A. Building the dune:

1) Vegetatively.

Where blowing sand is available, a simple, relatively inexpensive and successful method exists for building dunes. It consists of planting American beachgrass strips parallel to the coastline. As the windblown sand moves off the beach landward it drops its load of sand, beginning the natural cycle of dune growth. The row closest to the ocean should be at least 100 feet (horizontal distance) from the MHT line. The plantings will trap most of the windblown sand, particularly during the growing season when the grass will continue to grow up through the newly trapped sand.

Plant certified 'Cape' American beachgrass according to instructions found in Conservation Plant Sheet No. 28, Figure 3.3.

2) Sand Fences (Snow Fence Material).

Use of sand fence is effective. It is readily available. It may be more expensive than building dunes vegetatively, but is less expensive than doing it with machinery. Normally it is also much faster than with vegetation alone.

To form a barrier dune, erect the sand fences, a minimum of 100 feet (horizontal distance) from the MHT line in two (Three or four rows may be used where sufficient land area and sand is available.) parallel lines 30 or 40 feet apart. The fences should be roughly parallel to the water line and yet be as nearly as possible at a right angle to the prevailing winds. See Figure 3.5 on page 3.45.

Where this is not possible, erect a single line of fence parallel with the sea at least 140 feet from the MHT line and space 30 foot long perpendicular spurs 40 feet apart along the seaward side to trap lateral drift.

As the fences fill with sand, additional sets of fence can be placed over those filled until the barrier dune has reached a protective height.

To widen an old dune, the fencing should be set seaward at a distance of 15 feet from its base.

3) Materials -

Use standard 4 foot sand (snow) fence. The fence should be sound, free of decay, broken wire and missing or broken slats.

Wood posts, for fence support should be black locust, red cedar, white cedar or other wood of equal life or strength. They do not need to be treated. They should be a minimum of 6 ft. 6 in. long and a minimum diameter of 3 inches. Standard fence post length is usually 7 ft. - 8 ft. and should be used where possible.

Four (4) wire ties should be used to fasten fence to wood posts. Weave fence between posts so that every other post will have fence on ocean side of posts. Tie wires should be no smaller than 12 gauge galvanized wire.

Posts are to be set no further than 10 feet apart. Posts will be set at least 3 feet deep.

The bottom of the fence should be set about 3 inches into the sand, or a mechanical grader could be used to push some sand against the bottom of fence.

4) Sand fence plus vegetation -

The combination of these two approaches is more effective than either of two alone. The sand fence should be placed as discussed above. Bands of vegetation should then be planted parallel to the fence on the landward and seaward side as shown in Figure 3.5 on page 3.45. Each band of vegetation should be about 20 feet wide and placed 10 to 15 feet from the sand fence. As the sand fills between the two fences additional fence can be erected or the area between the fences can be planted as shown in Figure 3.6 on page 3.46. Such a combination can trap most or all the wind blown sand crossing the dune area and produce a much broader based dune than either approach alone.

3. Tidal Streams and Estuaries

The procedures to determine the effectiveness potential of stabilization of tidal streams and estuaries are found in Table 3.10.

Plants to be used are as follows:

A. Certified 'Cape' American Beachgrass.

B. Smooth cordgrass.

C. Saltmeadow cordgrass.

Planting instructions are found in Figure 3.7, USDA-SCS Conservation Plant Sheet No. 70 on page 3.46.

4. Additional Reference

Table 3.10
Vegetative Treatment Potential for Eroding Tidal Shorelines in the Mid-Atlantic States

DIRECTIONS FOR USE

1. Evaluate each of the first four shoreline variables and match the site characteristics of the variable to the appropriate descriptive category.
2. Place the Vegetative Treatment Potential (VTP) assigned for each of the four variables in the right hand column.
3. Obtain the Cumulative Vegetative Treatment Potential for variables 1, 2, 3 & 4 by adding the VTP for each.
4. If it is 23 or more, the potential for the site to be stabilized with vegetative is very good and the rest of the table need not be used. If it is below 23, go to step 5.
5. Determine the VTP for shoreline variable 5 through 9 and obtain the cumulative VTP for variables 1-9.
6. Compare the cumulative VTP score with the Vegetative Treatment Potential Scale at the bottom of this page.

SHORELINE VARIABLES — DIRECTION FOR USE — VTP

The Vegetative Treatment Potential (VTP) is located in bold type.

SHORELINE VARIABLES						VTP
1. Fetch: Average distance in miles of open water-measured perpendicular tothe shore and 45 degrees ither side of perpendicular to shore.	Less than 0.5 miles **8**	0.5 thru 1.4 miles **7**	1.5 thru 3.4 miles **4**	3.5 thru 4.9 miles **2**	over 5 miles[1] **0**	
2. General shape of shoreline for distance of 200 yards on each side of planting site.	Coves **8**	Irregular shoreline **3**		Headland or straight shoreline **0**		
3. Shoreline orientation: General geographic direction the shoreline faces.	Any less than 1/2 mile fetch **5**	West to North **3**	South to West **2**	South to East **1**	North to East **0**	
4. Boat traffic: Proximity of site torecreational & commercial boat traffic.	None **5**	1-10 per week within 1/2 mi. of shore. **3**	More than 10 per week within 1/2 mi. of shore. **2**	1-10 per week within 100 yds. of shore. **1**	More than 10 per week within 100 yds. of shore. **0**	

Cumulation Vegetative Treatment Potential for Variables 1, 2, 3 & 4 ______________

If this score is 23 or above, the potential for the site is very good and the rest of the table need not be used. If it is below 23, go to step 5 below.

5. Width of beach above mean high tide in feet	Greater than 10 ft. **3**	10 ft. thru 7 ft. **2**	6 ft. thru. 3 ft. **1**	Less than 3 ft. **0**	
6. Potential width[2] of Planting area in feet	More than 20 ft. **3**	20 ft. thru 15 ft. **2**	14 ft. thru 10 ft. **1**	Less than 10 ft. Do not plant	
7. On shore gradient slope from MLW to toe of bank.	below 8% **6**	8% thru 14% **3**	15% thru 20% **1**	Over 20% **0**	
8. Beach Vegetation	Vegetation below toe of slope **3**		No vegetation below toe of slope **0**		
9. Depth of sand[3] at mean high tide in inches.	more than 10 in. **3**	10 in. thru 3 in. **2**	less than 3 in. **0**		

Cumulative Vegetative Treatment Potential for Variables 1-9 ______________

1. Do not plant.
2. If tidal fluctuation is 2.5 feet or less, measure from MLW to toe of bank. If tidal fluctuation is over 2.5 feet, measure from MW to toe of bank.
3. Refers to depth of sand deposited by littoral drift over the substrata.

Vegetative Treatment Potential Scale

If the VTP is, Between	And	Potential of site to be Stabilized with Vegetation
40	33	Good
32	24	Fair
23	16	Poor
below 16		Do not plant

Figure 3.3
American Beachgrass Information Sheet
(Ammophila breviligulata Fern.)

Adapted from USDA-SCS Conservation Plant Sheet No. 28[2]

Use: Major use is to stabilize moving sand along the Atlantic Sea coast and Great Lakes region. It is the best species for the initial stabilization of frontal dunes.

Useful as an erosion control plant on non-dune areas where soils are very sandy and the site conditions make establishment of seeded species very difficult. Also used on soils high in salinity such as industrial waste needing vegetative cover.

Description: American beachgrass is a leafy, spreading, bunch-type grass with many stems per clump. It may reach a height of two to three feet. The seed head is a spike-like panicle, about ten inches long, and appears in late July or August. Leaves are long and narrow, and may become rolled or folded as it matures.

One outstanding growth characteristic is the strong underground stems (rhizomes) that spread beneath the sand and give rise to many new plants. Its vigorous growth enables the plant to withstand heavy deposits of sand and grow up through it.

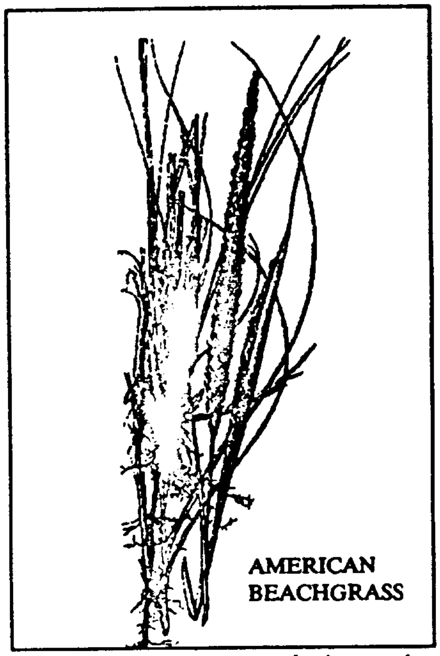
Adaptation: It is native to the mid-Atlantic coastal region from Maine to North Carolina, and the Great Lakes region. It will grow on island sites, high in sand and/or saline content, provided applications of fertilizers containing nitrogen are made.

Varieties: 'Cape' is the most recent variety and was developed by the Soil Conservation Service at the Cape May Plant Materials Center, Cape May Court House, N.J. 'Hatteras' developed by the Agricultural Experiment Station in North Carolina is a variety possibly better adapted to southern climates.

Source: Both are commercially available vegetatively. Seed not available.

Establishment: The best time to plant beachgrass is from October 1 to April 30. If properly planted, good survival can be expected at any time during this period except when soil is frozen. Summer plantings are not satisfactory. American beachgrass can be planted either by hand or by mechanical equipment designed for this work. The stems of plants called 'culms' are used for planting stock. Two or three culms are planted per hole. Space plants 18" by 18" unless wind erosion is severe, then spacing is reduced to 12" by 12". Stagger the plantings in alternate rows to provide maximum erosion control. On very stable areas where wind is not a factor, a spacing of 24" x 24" is suitable. An 18" x 18" spacing requires 58,500 culms per acre, or 1,350 culms per 1,000 square feet.

Beachgrass culms must be planted at least 8" deep. This prevents plants from drying out, as well as being blown out by the wind. A tiling or ditching spade is an excellent tool for opening the planting hole. A two man crew works best in planting on frontal dunes and loose sandy areas. The culms and roots must be kept moist before and during planting. Success of planting will increase if the stock is dormant or has made very little growth.



Fertilizer properly applied is the key to good vigorous growth, as coastal sands are rather infertile.

Fertilize annually in March or April with 30 to 40 pounds of inorganic Nitrogen per acre.

Management: Once the stand is well established, the rate of fertilizer applied can be reduced by half, or applied only when the stand appears to be weakening.

Pedestrian and vehicular traffic that bends or breaks the culms will seriously damage the plants and may kill them if traffic is intensive. On frontal dunes, any area devoid of protective cover is subject to blowing and eventual ruin. Replanting of beachgrass stands that become open should be an annual operating procedure.

Exclude vehicular traffic if possible and provide boardwalks for pedestrians. Move boardwalks when beachgrass underneath it begins to weaken.

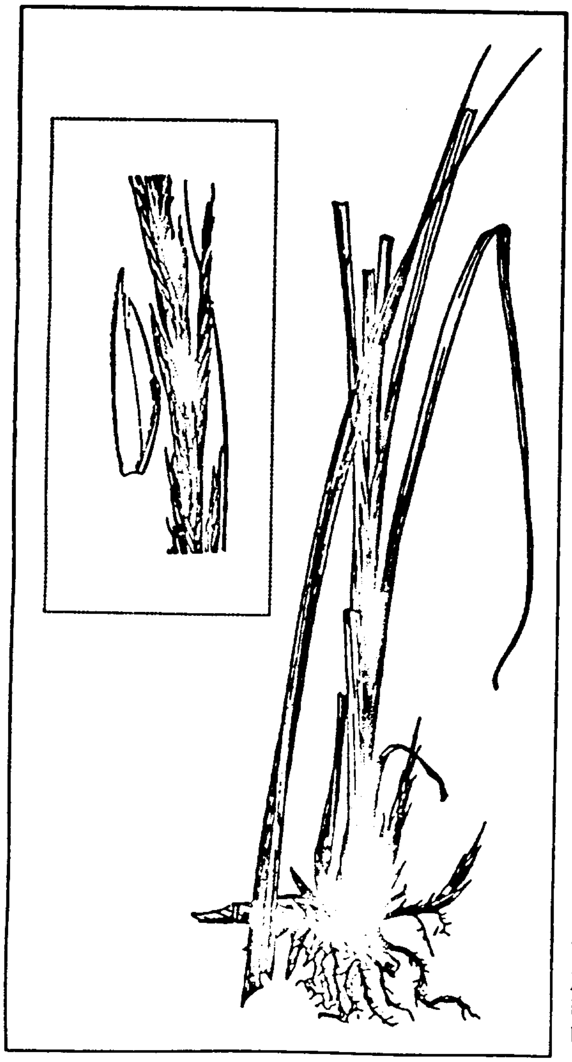
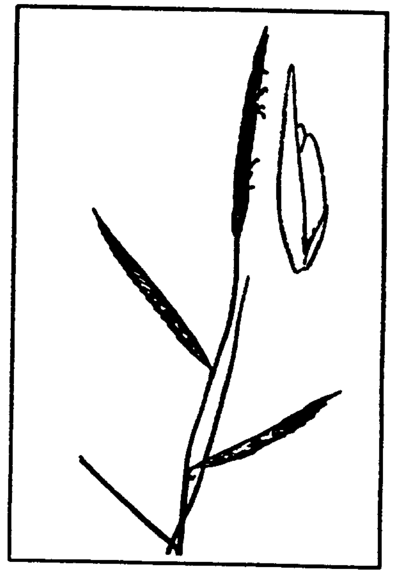
Figure 3.6
Cordgrass Information Sheet
Smooth Cordgrass (Spartina alterniflora)
and
Saltmeadow Cordgrass (Spartina patens)

Adapted from USDA-SCS Conservation Plant Sheet No. 70[3]

Description: Smooth cordgrass, a long life perennial, is the dominant, most productive marsh plant in the regularly flooded intertidal zone along the Atlantic and Gulf coast from Newfoundland to Florida and Texas. Smooth cordgrass grows three to seven feet tall with stems up to 1/2 inch in diameter. The leaves are twelve to twenty inches long, taporing to a point. The seedheads, produced in September and October, are ten to twelve inches long and hold twelve to fifteen spikelets, each two-three inches long. Its primary method of spread is by vigorous, hollow rhizomes.



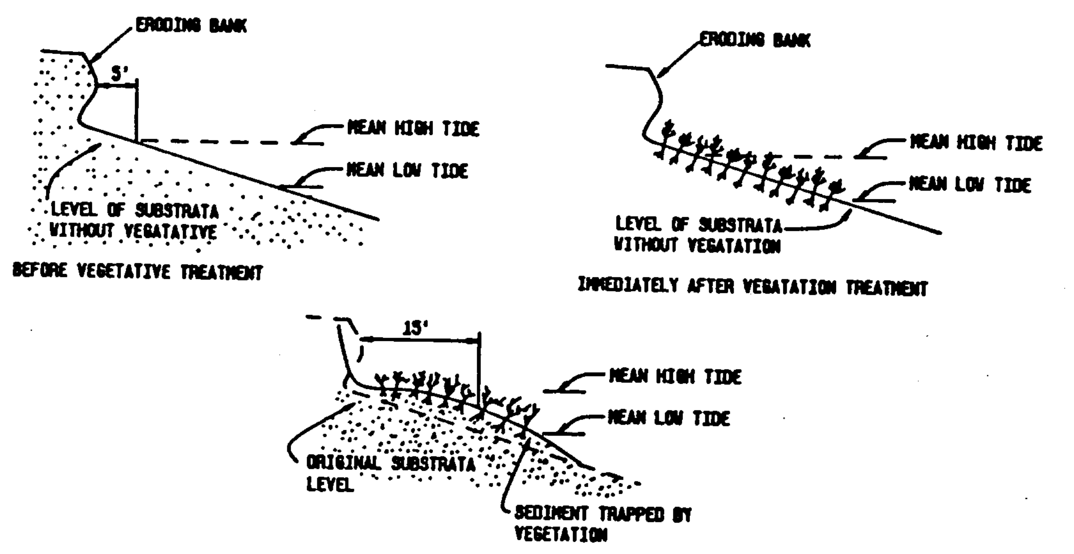


Saltmeadow cordgrass grows in salt marshes and sandy meadows along the Atlantic and Gulf coasts from Quebec to Florida and Texas. It occupies the area immediately above the intertidal zone. Mature plants are grayish green, usually one to three feet tall. The leaf sheath is rounded; the leaf blade is long and narrow, usually rolled inward giving a wiry appearance; the upper side of the leaf is rough. The seed heads produced in October have spikelets that grow almost at right angles to spikelets. Saltmeadow cordgrass reproduces rapidly by long, scally, slender rhizomes. Both smooth and saltmeadow cordgrasses are used by waterfowl as a source of food. Saltmeadow cordgrass is also used by muskrats for housing materials.

Uses: Because of their adaptation to brackish water, smooth and saltmeadow cordgrasses occur naturally or can be planted to stabilize eroding shorelines. Planted long the shoreline, the cordgrasses absorb the wave energy and collect the sediment brought in by water. As the sediment is dropped, the band of vegetation expands, pushing the mean high tide away from the tow of the bank, thus reducing the potential for continuous erosion as shown on page 3.49.

Establishment of Shoreline Plantings: Smooth cordgrass is planted between the mean low water level and the mean high water level. Saltmeadow cordgrass is planted above

Anticipated Results From Vegetative Treatment



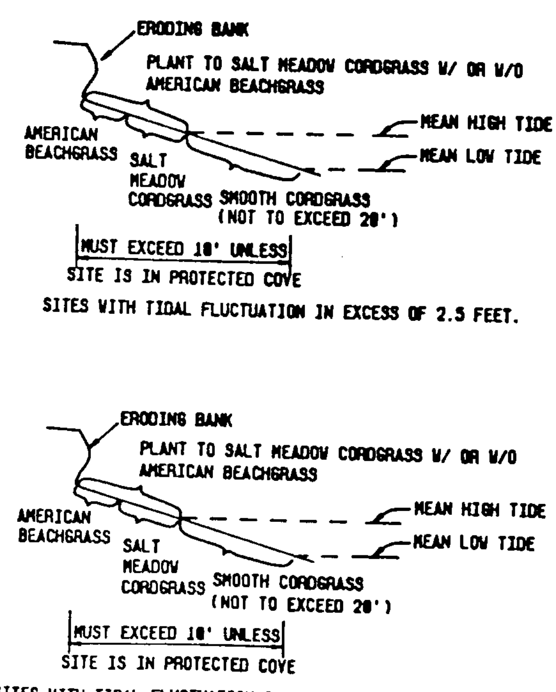
ANTICIPATED RESULTS FROM VEGETATIVE TREATMENT

the smooth cordgrass from mean high water to the toe of the slope. If the distance from the mean high water to the toe of the slope exceeds 10 feet, American beachgrass should also be planted in the upper part of the slope. See recommended planting arrangements.

Establishment of Plants: There are three types of plant materials that can be used for planting along the shoreline. One type is seedlings grown in peat pots. Such plants should be about 12 inches tall with 3-5 stems per container before they are large enough for transplanting. The container is planted with the root mass.

A second method is to grow the plants in containers which allow the plants with the root mass to slip out at the time of planting. Their size, etc., are the same as above. The advantage of this method is that it eliminates the barrier occasionally created by the peat pots that may produce a slight turbulence around the plant and wash it out.

Recommended Planting Arrangements



VOL 12

6023

A third type is to harvest culms from natural or cultivated stands which are then planted directly to the shoreline. If the plants are to be taken from natural stands, they should be growing in sandy substrata. The stands should be open and developing rather than dense and mature. The culms will be ready for digging and transplanting when the top growth is six to ten inches tall. Each culm should have a well developed root.

Methods one, two and three are equally recommended for smooth cordgrass. Methods one and two are recommended for saltmeadow cordgrass, although method three can be used but performance expectations will be less than with the other two methods.

When making plantings, place the hills 18 to 36 inches apart within and between rows. The spacing to be used is influenced by the severity of the site. On sites that have a potential of being washed away, the spacing should be closer. In protected areas where there is little danger from the planting being initially destroyed, the spacing can be wider. The hole made in the substrata should fully accommodate the plant roots. Be sure to seal the hole by pressing the soil around the roots with your heal.

One or two ounces of fertilizer should be placed in the bottom of the planting hole or in a separate hole to one side of the plant. If this approach is used, a slow released fertilizer such as Osmocote, at one ounce per hill is recommended. An alternate treatment is to broadcast about 500 lbs. of 10-10-10 fertilizer over the planted area at low tide about three weeks after planting. This amount is about twelve pounds per 1,000 sq. ft. Putting fertilizer in the hole at planting time and some about six weeks after planting will give the most rapid growth to the new plantings.

Plantings should be made between mid spring and July 1. The early spring plantings are more hazardous because of storms and less favorable soil temperatures. Actual dates are influenced by location. Late spring plantings are preferred.

Site Suitability: A high percentage of plantings made on tidal shorelines fail due to shoreline conditions, storms, etc. Most shoreline conditions can be identified and their likelihood of contributing to success or failure estimated. They are shown in Table 3.10. Its use is self-explanatory.

While the procedure outlined in Table 3.10 has been tested against actual plantings, there is no guarantee the outcome of the planting will be as the guideline suggests. For instance unexpected storms could completely eliminate the value of these guidelines and destroy the planting.

Management of Established Plantings: Plantings should be monitored frequently each year. Plants destroyed or washed out should be replanted as quickly as possible. If plant development and growth is inferior to surrounding natural marshes, fertilize in late May or June at low tide with 300-500 lbs. per acre of 10-10-10 fertilizer. All debris washed onto the plantings should be immediately removed to prevent smothering the plants.

Sources: Smooth and saltmeadow cordgrasses are available commercially or can be dug locally from an existing marsh. Because commercial sources are subject to change, contact your local USDA Soil Conservation Service office for sources closest to you.

BIOTECHNICAL SLOPE PROTECTION MEASURES FOR EROSION AND SEDIMENT CONTROL

Introduction

Biotechnical slope protection is the specialized use of woody plant materials to stabilize soil. As noted in Section 1, one of the factors that influences erosion is vegetative cover. The more cover soil has the more protected it is from the attacking forces of rainfall and runoff. Also working to hold the soil in place is the root mass that vegetation produces. Biotechnical measures generally combine basic engineering principles with plant science to create a system of stability for critical areas such as streambanks or roadside slopes. These systems may combine structural measures, such as those detailed in Section 5, with woody plants and shrubs to effect a strengthening of the soil structure and improved vegetative cover to resist surface erosion.

There are many advantages to biotechnical slope protection measures:

- they are often less expensive to install
- they don't require specialized skills to install
- generally heavy equipment is not required
- they are environmentally compatible
- they provide a natural aesthestic appearance
- they provide wildlife habitat and cover
- they can be self repairing during and after stress
- they use natural/native materials

On the other hand there are some disadvantages to these measures:

- higher risk due to less control with vegetation compared to structural practices
- require higher maintenance attention
- need an establishment period
- more sensitive to seasonal changes

Biotechnical slope protection is actually an old technology. These techniques have been practiced for centuries in Europe. The Soil Conservation Service used and promoted this technology in the 1940's in Vermont on the Winooski River and also in New York on Buffalo Creek where plant materials (willows) were used in combination with rock riprap, concrete slabs, pinned rock, and cellular modules to halt streambank erosion.

These biotechnical approaches are being "rediscovered" primarily due to their cost effectiveness over more traditional structural measures and for their environmental compatibility, aesthetics and wildlife benefits. There are many areas in towns and counties in New York that experience erosion on streambanks or sloughs on roadside slopes that could be controlled with biotechnical protection measures. The low cost and ease of installation is very attractive to units of government and highway departments looking to maximize their budget dollars.

Principles of Biotechnical Slope Protection

Generally a biotechnical slope protection system consists of both a structural or mechanical element and vegetative elements working together to stabilize a site specific condition. Structural components are employed to allow establishment of vegetative elements while at the same time providing a level of protection for stability. The vegetative components are not just landscaping plantings for a structural project, but perform a functional role in preventing erosion by protecting the surface while also stabilizing soil by preventing shallow mass movements.

Woody plant materials (usually dormant shrub willow branches) are placed into the soil in ways which provide an immediate degree of stability to the slope. As the branches take root and grow, the slope becomes more and more resistant to failure by shallow mass movements due to:

1. Mechanical reinforcement from the root system
2. Soil water depletion through transpiration and interception.
3. Buttressing and soil arching action from embedded stems.

The vegetation also tends to prevent surficial (rainfall) erosion by:

1. Binding and restraining soil particles in place
2. Filtering soil particles from runoff
3. Intercepting raindrops
4. Retarding velocity of runoff
5. Maintaining infiltration

As the stability improves, native vegetation will volunteer, helping to blend the site into the surroundings.

There are many techniques used in biotechnical work. Some of the most common are:

- wattling
- brush layering
- brush matting
- live cribwall
- live staking
- reed trench terracing
- gully - lead plugs

- breast - wall staking
- check dams for gully control
- wattle flow deflectors

Properly designed structural measures may be necessary to help protect the toe or face of a slope against scour or erosion from moving water and against mass-moving of soil. These structures are generally capable of resisting much higher lateral earth pressures and higher shear values than vegetation. They can be natural, such as field stone, rock and timbers; or they can be artificial like concrete, and steel. Some can be a combination like gabions which are wire baskets containing stone. These can be used as retaining walls, grade stabilization structures and slope protection. Many of these types of structures can be planted or vegetated with materials to strengthen the system.

Planning Considerations

There are many facets that need to be considered when designing a biotechnical system for a site:

Method - What is the appropriate method for the particular problem encountered?

Materials - What type should be selected? How much is needed to do the job? Where can they be obtained?

Schedule - When is the best time to maximize the successful rooting or germination of materials?

Equipment - Since this process is somewhat labor intensive it is necessary to make sure the proper type and amount of tools such as shovels, pick axe, tile spade, hammers etc. are available for proper installation of material.

Site characteristics - The need for engineering structures will depend on potential hazard, management of site water, soil conditions and providing site access. Aesthetics and follow-up maintenance are also important considerations. Protection from livestock is mandatory.

Plant Materials

Plant materials for biotechnical slope protection may be obtained in two basic ways. One method is to locate stands of appropriate species and obtain easements to harvest materials from these strands for incorporation in the project. Criteria for selecting native species are easy rooting; long, straight, flexible whips; and plentiful supply near the site.

A second method is to grow and harvest materials from managed production beds that are maintained for commercial distribution. This allows selection of cultivars that have proven performance records and high survival rates.

The most popular materials in use are the shrub willows. Willows have a tremendous ability to sprout roots and stems when in contact with moist soil. Willows are found growing in all parts of the world so biotechnical slope protection techniques employ them more than any other group of plants. Two of the tested, proven willow cultivars in the Northeast are:

'Streamco' purpleosier willow (Salix purpurea)

'Bankers' dwarf willow (Salix cottetii - hybrid)

'Streamco' and 'Bankers' willow are both shrubs. 'Streamco' has an ultimate height of 10-15 feet, while 'Bankers' is limited to 6-8 feet. Supplies of both are being developed by commercial and state nurseries in the Northeast.

In addition to willows, redosier dogwood and poplars are other groups of plants effective for use in biotechnical systems.

All plant materials should be installed on site within 8 hours of cutting unless provisions for proper storage are made. Materials should be fresh, dormant and non-dessicated when installed.

STANDARD AND SPECIFICATIONS FOR WATTLING

Definition

The placement of groups or bundles of twigs, whips, or withes in shallow trenches, on the contour, on either cut or fill slopes.

Purpose

To stabilize slopes by slowing water movement off the slope, increasing infiltration, trapping slope sediments, and increasing soil stability with root system.

Conditions Where Practice Applies

On sloping areas such as road cuts, slumped areas, road fills, gullies, and streambanks, subject to erosion, seepage, or weathering, which have a low to medium hazard potential should slope failure occur. Slopes must be 1:1 or flatter.

Design Criteria

Materials - Shall be a native or nursery grown cultivar that is capable of performing the intended function.

Wattles - Shall be made by forming the bundles 6-8 feet long, 4 inches minimum in diameter, from stems no more than 1 inch in diameter. The wattles should be tapered in each end in a manner that the wattle length is 18 inches longer than the individual stem length.

Lap - Wattles should be overlapped at the tapered ends a minimum of 1.5 feet.

Vertical Spacing - The spacing of the contours for the wattles is dependent on the degree of erosion or potential erosion at the site. Factors include slope steepness, soil type, drainage, and existing ground cover. The following is a general guide to selecting contour interval:

Slope	Contour Interval
1:1	3'
1.5:1	3'
2:1	4'
2.5:1	4'
3:1	5'
3.5:1	5'
4:1	6'
6:1	8'

See figure 4.1 on page 4.4 for details.

Construction Specifications

1. Wattles shall be 4 inches minimum in diameter and bundled with tapered ends to an overall length 18 inches longer than the stems.
2. Prior to wattling slope shall be smoothed and graded with obstructions removed. Any structural measures for revetment, drainage or surface water management will be installed first.
3. Anchor stakes will be placed on the slope at the designed contour interval.
4. Working from the bottom of the slope to the top, excavate wattle trench just above stakes. Place wattles in trench and anchor with additional stakes spaced at 18 inches. Cover wattles with soil leaving about 10% exposed to view. Wattles shall be overlapped 18 inches minimum in the trench.
5. Soil shall be worked into the wattle and compacted by walking on the wattling being covered.
6. All disturbed areas should be seeded upon completion of wattling operations.

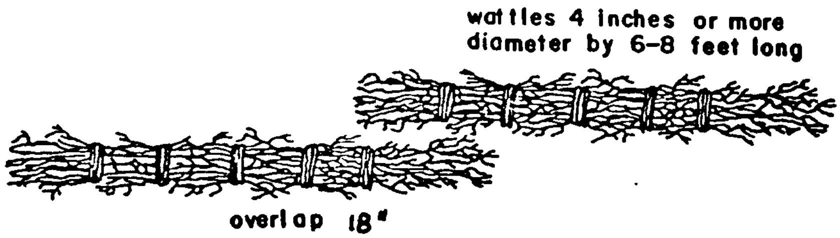
Maintenance

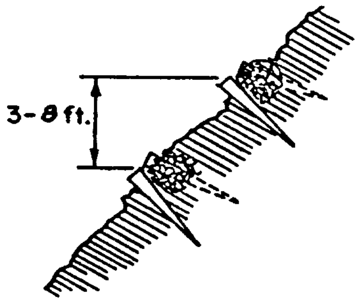
Regular inspection and maintenance of wattling installations should be conducted especially during the first year of establishment. Loose stakes should be reset and settled fill areas should be brought back to grade. Prompt corrections to gullies, sloughs or other evident problems should be made.

VOL 12

6033

Figure 4.1
Wattling Details





DESIGN TABLE					
SLOPE	1:1	2:1	3:1	4:1	6:1
CONTOUR INTERVAL	3	4	5	6	8

CONSTRUCTION SPECIFICATIONS

1. WATTLES SHALL BE 4" MINIMUM DIAMETER AND BUNDLED WITH TAPERED ENDS TO AN OVERALL LENGTH 18 INCHES LONGER THAN THE STEMS.
2. STRUCTURAL MEASURES SUCH AS REVETMENT, DRAINAGE, SURFACE DITCHES WILL BE INSTALLED PRIOR TO WATTLING. SLOPE SHALL BE GRADED AND SMOOTHED WITH OBSTRUCTIONS REMOVED.
3. ANCHOR STAKES WILL BE PLACED ON THE SLOPE AT THE DESIRED CONTOUR INTERVAL.
4. WORKING FROM THE BOTTOM OF THE SLOPE TO THE TOP, EXCAVATE WATTLE TRENCH JUST ABOVE THE STAKES. TRENCH SHALL BE HALF THE DIAMETER OF THE WATTLES. PLACE WATTLES IN TRENCH ANCHORING WITH ADDITIONAL STAKES AT 18 INCH INTERVALS. LOWER WATTLES WITH SOIL LEAVING ABOUT 10% EXPOSURE.
5. SOIL SHALL BE WORKED INTO THE WATTLES AND COMPACTED BY FOOT TRAFFIC.
6. ALL DISTURBED AREAS SHALL BE SEEDED UPON COMPLETION OF WATTLING OPERATIONS.

STANDARD AND SPECIFICATIONS FOR BRUSH MATTING

Definition

A mulch or mattress of hardwood brush layed on a slope and fastened down with stakes and wire.

Purpose

To protect the soil surface on slopes from erosive forces and act as a mulch for seeding and plant use until they are established.

Conditions Where Practice Applies

Brush matting is used primarily on streambanks where the velocity is less than 6 feet per second and excessive runoff from streamflow has created erosive conditions. This practice can resist temporary inundation but not scour or undercutting.

Design Criteria

Layer Thickness - The brush shall be a minimum of 12 inches thick.

Height - The matting shall be placed up the bank to the point of average high water. The toe of the matting should be located in a rock trench that extends from the normal water line to the channel bottom or 2 feet which ever is greater.

Slope - The maximum slope shall be 1.5:1.

Anchoring - The matting shall be anchored on the slope by a grid of 3 foot stakes driven on 3 foot centers each way. No. 9 galvanized wire is then tied between the stakes and tightened to secure the mat. The upstream edge of the mat should be keyed into the bank 2 feet.

Materials - The plant materials should be willow or dogwood brush placed downstream to upstream with stems inclined at approximately 30 degrees with the butt end placed upstream.

See figure 4.2 on page 4.6 for details.

Construction Specifications

1. Prepare slope surface by grading to a uniform, smooth surface clear of obstruction. Slopes should be planted before the brush matting is installed.
2. Lay hardwood brush beginning at the downstream end of the work. The toe should be installed first.
3. The butt end of the brush will be placed upstream and plant materials inclined approximately 30 degrees.
4. The upstream edge of the mat will be keyed into the slope 2 feet. Stakes will be driven throughout the mat on 3 foot centers each way beginning along the toe of the mat.
5. No. 9 galvanized wire will be attached to the stakes and tightened to secure the mat.
6. Slope areas above the matting will be shaped and seeded.

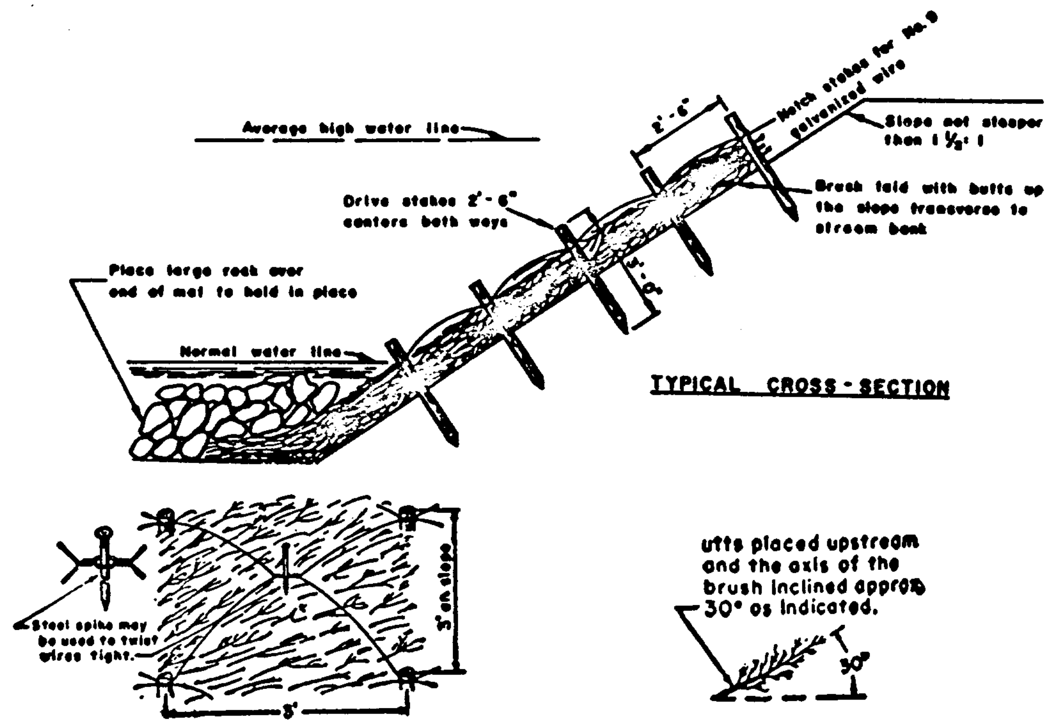
Maintenance

Scheduled inspections the first year are necessary to make sure the anchoring system is sound. Broken wire or missing stakes should be replaced immediately. Any toe material missing should be replaced.

6035

VOL 12

Figure 4.2
Brush Matting Details



CONSTRUCTION SPECIFICATIONS

1. PREPARE SLOPE SURFACE BY GRADING TO A UNIFORM, SMOOTH SURFACE.
2. LAY HARDWOOD BRUSH IN AN UPSTREAM DIRECTION BEGINNING AT THE DOWN-STREAM END. THE TOE SHOULD BE ESTABLISHED FIRST.
3. THE BUTT END OF THE BRUSH WILL BE PLACED UPSTREAM AND THE PLANT MATERIALS INCLINED APPROXIMATELY 30 DEGREES.
4. THE UPSTREAM EDGE OF THE MAT WILL BE KEYED INTO THE SLOPE 2 FEET. STAKES WILL BE DRIVEN THROUGHOUT THE MATTING ON 3 FOOT CENTERS EACH WAY BEGINNING ALONG THE TOE OF THE MAT.
5. NO. 9 GALVANIZED WIRE WILL BE ATTACHED TO THE STAKES OVER THE MAT AND TIGHTENED TO SECURE THE MAT.
6. SLOPE AREAS ABOVE THE MAT WILL BE SLOPED AND SEEDED.

6036

STANDARD AND SPECIFICATIONS FOR VEGETATIVE STREAMBANK PROTECTION

Definition

Stabilization of eroding streambanks by the use of designed vegetative measures.

Purpose

To protect exposed or eroded streambanks from the erosive forces of flowing water.

Conditions Where Practice Applies

Generally applicable where flows are less than 6 feet per second and the stream bottom is not subject to degradation and scour. Structural elements may be used at points of concentration such as toes to help establish the practice on the streambank.

Design Criteria

Each channel is unique and measures designed for vegetative streambank protection will depend on soil type, size of the stream, drainage area, bedload, ice flow potential and availability of plant materials.

Protection measures should carry up the bank slope to the average high water elevation. If this is not available use the 10 year storm to evaluate limits of the protection.

Streambank protection should begin at a stable location and end at a stable location along the bank. The channel bottom should be stable or stabilized prior to installing protective measures.

Ensure that all requirements of state law and all permit requirements of local, state and federal agencies are met.

Wattling - This technique uses bundles of branches which are staked into shallow trenches, then covered with soil. They are oriented along the contour and are placed in multiple rows to help stabilize a slope. See Standard and Specifications for Wattling on page 4.3

Brush Layering - This technique is generally used to stabilize slope areas above the flowline of streambanks as well as cut and fill slopes. It involves the use of long branches that are placed with cut ends into the slope on bulldozed terraces. The tops protrude outside the finished slope. A layer usually includes three layers of brush separated with a thin (3") layer of soil. On this layer a "lift" of 3-5 feet of soil is placed to form the next terrace and so forth. See figure 4.3 on page 4.8

Live Cribwall - This is a combination of vegetation and structural elements generally used along streams where flowing water is a hazard. Layers of logs are alternated with long branches protruding out between them. The logs are spiked together and anchored into the bank with earthfill behind them to create a wall. The live stems help tie the logs together and screen the wall. See figure 4.4 on page 4.8

Live staking - These are large stakes or poles sharpened at the bottom end and forced vertically into the soft earth along the waterline usually about 1 foot apart. Depending on the size of the poles and the composition of the streambank, machinery may be required to force them into the ground or to prepare holes for planting. The poles will grow forming a very thick barrier to flow. See figure 4.5 on page 4.9

Wattle Flow Deflectors - This describes the use of wattles along the stream or river banks to deflect flow or current away from the streambank. The wattles are placed in a trench, staked and backfilled at the appropriate downstream orientation. As the willows grow, the vertical stems extend the deflector upward improving the flow control during high water. Caution should be exercised when employing this method since deflecting flow can result in the creation of erosion problems in another location. See figure 4.6 on page 4.9

Brush Matting - This method uses hardwood brush layered along a streambank as a mattress and anchored in place with a grid of stakes and wire. The toe below the waterline is anchored by rock. This living blanket acts as a mulch for seedlings and plantings established in the bank. It also prevents erosion of sloped surfaces. See Standards and Specifications for Brush Matting on page 4.5

Maintenance

Due to the susceptibility of plant materials to the physical constraints of the site, climate conditions and animal populations, it is necessary to inspect installations frequently. This is especially important during the first year or two of establishment. Plant materials missing or damaged should be replaced as soon as possible. Sloughs or breaks in drainage pattern should be reestablished for the site as quickly as possible to maintain stability.

STRUCTURAL MEASURES FOR EROSION AND SEDIMENT CONTROL IN URBAN AREAS

VOL 12

6045

General

Uncontrolled runoff and excess erosion often occurs in urban developments, particularly during the construction stage. This erosion forms rills and gullies; washes out roads; scours cut and fill areas; fills road ditches, storm drains, and streams; and does other damage that is costly to the developers and damaging to land and water users below. Careful inclusion of proven conservation practices in the development plan can prevent or alleviate much of this damage and should be a part of every development plan.

These practices will usually be a combination of vegetative and structural measures. They may be temporary and serve only during the construction stage or they may be permanent in nature and become a part of the completed development. Permanent structural practices should be installed as early as possible in the construction stage. This section deals with the more common structural measures that may be used. Adequate designs, plans and specifications should be prepared for the measures to be used. A number of measures and specifications are included throughout this chapter. The user of this guide should determine those elements to be installed to control erosion selected from Section 2 and follow the criteria included in the specifications.

Introduction

Structural erosion and sediment control practices have been classified as either temporary or permanent, according to how they are used. Temporary structural practices are used during construction to prevent offsite sedimentation. The length of time that temporary practices are functional varies from project to project, since the sediment control strategy may change as construction activity progresses. Permanent structural practices are used to convey surface water runoff to a safe outlet. Permanent structural practices will remain in place and continue to function after the completion of construction.

Regardless of whether the practices are temporary or permanent, runoff control measures should be the first items constructed when grading begins, and be completely functional before downslope land disturbance takes place. Earthen structures such as diversions, dikes, and swales should be stabilized before being considered functional. Only after the runoff control structures are operational and sediment control measures are in place, should clearing and grading the rest of the construction site begin.

While clearing and grading the site, it is important to minimize the amount of sediment that is produced. In general, it is advantageous to clear only as much area as necessary to accommodate construction needs. Grade and stabilize large sites in stages whenever possible. Limiting the amount of disturbed area limits the amount of sediment that is generated, thus decreasing the amount of maintenance required on sediment control measures.

Sediment generated during the construction of cut and fill slopes can also be minimized through design and grading techniques. When designing either a cut or fill slope, factors to consider include slope length and steepness, soil type, and upslope drainage area. In general, it is important to leave soil surfaces on disturbed slopes in a roughened condition and to construct a water diversion practice at the top of slopes. Rough soils surfaces do not erode as readily as smooth soil surfaces.

Although design and grading techniques can reduce soil erosion, they cannot eliminate it entirely. Therefore, practices must be installed to prevent offsite sedimentation.

Even though the specific conditions of each site determine precisely what measures are necessary to control sedimentation, some general principles apply to the selection and placement of sediment control measures.

1. Prevent clean water from getting dirty by diverting runoff from upslope areas away from disturbed areas. Earth dikes, temporary swales, perimeter dike/swales, or diversions that outlet in stable areas can be used in this capacity.
2. Remove sediment from dirty water before the water leaves the site. The method of sediment removal depends upon how the water drains from the site. Concentrated flow must be diverted to a trapping device so that suspended sediment can be deposited. Dikes or swales that outlet into traps or basins can accomplish this. A storm drain system may be used to convey concentrated sediment laden water only if the system empties into a trap or basin. Otherwise, all storm drain inlets must be protected so that sediment laden water cannot enter the drainage system before being treated to remove the sediment.
3. Surface runoff draining in sheet flow must be filtered before the water leaves the site. Straw bale dikes, silt fences, or vegetative buffer strips can be used to filter sheet flow.

All practices selected and implemented, must be properly maintained in order to remain functional. Sediment accumulated in basins and traps must be removed and disposed of in a manner that minimizes erosion and sedimentation.

Other factors should be observed during construction in order to make erosion and sediment control measures more effective in pollution control.

These are:

1. Sprinkle or apply dust suppressors. Keep dust down to a tolerable limit on construction sites and haul roads.
2. Use temporary bridges or culverts where fording of streams is objectionable. Avoid borrow areas where pollution from this operation is inevitable.
3. Protect streams from chemicals, fuel, lubricants, sewage or other pollutants.
4. Avoid disposal of fill in floodplains or drainage ways. This reduces the capacity of these areas to pass flood flows.
5. Do not locate sanitary facilities over or adjacent to live streams, wells, or springs.
6. Locate storage yards and stockpiles where erosion and sediment hazards are slight. Where this is not possible, apply necessary paving and erosion control practices.

STANDARD AND SPECIFICATIONS FOR EARTH DIKE

Definition

A temporary berm or ridge or compacted soil, located in such a manner as to channel water to a desired location.

Purpose

The purpose of an earth dike is to direct runoff to a sediment trapping device, thereby reducing the potential for erosion and off site sedimentation. Earth dikes can also be used for diverting clean water away from disturbed areas.

Conditions Where Practice Applies

Earth dikes are often constructed across disturbed areas and around construction sites such as graded parking lots and subdivisions. The dikes shall remain in place until the disturbed areas are permanently stabilized.

Design Criteria

See Figure 5A.1 on page 5A.2 for details

General

	Dike A	Dike B
Drainage Area	<5 Ac	5-10 Ac
Dike Height	18 in.	36 in.
Dike Width	24 in.	36 in.
Flow Width	4 ft.	6 ft.
Flow Depth in Channel	8 in.	15 in.
Side Slopes	2:1 or Flatter	2:1 or Flatter
Grade	0.5% Min. 20% Max.	0.5% Min. 20% Max.

For drainage areas larger than 10 acres refer to the Standard and Specification for Diversion on page 5B.1.

Stabilization

Stabilization of the dike shall be completed within 10 days of installation in accordance with the standard and specifications for seed and straw mulch or straw mulch only if not in seeding season and flow channel shall be stabilized as per the following criteria:

Type of Treatment	Channel Grade[1]	Flow Channel A(≤5 Ac.)	Flow Channel B(5-10 Ac.)
1	0.5-3.0%	Seed & Straw Mulch	Seed & Straw Mulch
2	3.1-5.0%	Seed & Straw Mulch	Seed and cover with Jute or Excelsior, Sod, or lined with 2 in. stone
3	5.1-8.0%	Seed and cover with Jute, Exelsior, Sod or line with 2 in. stone	Line with 4-8 in. or stone or Recycled Concrete Equivalent[2]
4	8.1-20%	Line with 4-8 in. stone or Recycled Concrete Equivalent[2]	Engineering Design

[1] In highly erodible soils, as defined by the local approving agency, refer to the next higher slope grade for type of stabilization.

[2] Recycled Concrete Equivalent shall be concrete broken into the required size, and shall contain no steel reinforcement.

Outlet

Earth dikes shall have an outlet that functions with a minimum of erosion.

Runoff shall be conveyed to a sediment trapping device until the drainage area above the dike is adequately stabilized.

The on-site location may need to be adjusted to meet field conditions in order to utilize the most suitable outlet.

D - FLOW DEPTH	8"	15"

CONSTRUCTION SPECIFICATIONS

1. ALL DIKES SHALL BE COMPACTED BY EARTH-MOVING EQUIPMENT.
2. ALL DIKES SHALL HAVE POSITIVE DRAINAGE TO AN OUTLET.
3. TOP WIDTH MAY BE WIDER AND SIDE SLOPES BE FLATTER IF DESIRED TO FACILITATE CROSSING BY CONSTRUCTION TRAFFIC.
4. FIELD LOCATION SHOULD BE ADJUSTED AS NEEDED TO UTILIZE A STABILIZED SAFE OUTLET.
5. EARTH DIKES SHALL HAVE AN OUTLET THAT FUNCTIONS WITH A MINIMUM OF EROSION. RUNOFF SHALL BE CONVEYED TO A SEDIMENT TRAPPING DEVICE SUCH AS A SEDIMENT TRAP OR SEDIMENT BASIN WHERE EITHER THE DIKE CHANNEL OR THE DRAINAGE AREA ABOVE THE DIKE ARE NOT ADEQUATELY STABILIZED.
6. STABILIZATION SHALL BE: (A) IN ACCORDANCE WITH STANDARD SPECIFICATIONS FOR SEED AND STRAW MULCH IF NOT IN SEEDING SEASON. (B) FLOW CHANNEL AS PER THE CHART BELOW.

FLOW CHANNEL STABILIZATION

TYPE OF TREATMENT	TYPE OF GRADE	DIKE A	DIKE B
1	.5-3.0%	SEED AND STRAW MULCH	SEED AND STRAW MULCH
2	3.1-5.0%	SEED AND STRAW MULCH	SEED USING JUTE, OR EXCELSIOR; SOD; 2" STONE
3	5.1-8.0%	SEED WITH JUTE, OR SOD; 2" STONE	LINED RIPRAP 4-8"

STANDARD AND SPECIFICATION FOR TEMPORARY SWALE

Definition

A temporary excavated drainage way.

Purpose

The purpose of a temporary swale is to prevent runoff from entering disturbed areas by intercepting and diverting it to a stabilized outlet or to intercept sediment laden water and divert it to a sediment trapping device.

Conditions Where Practice Applies

Temporary Swales are constructed:

1. To divert flows from a disturbed area.
2. Intermittently across disturbed areas to shorten overland flow distances.
3. To direct sediment laden water along the base of slopes to a trapping device.
4. To transport offsite flows across disturbed areas such as rights-of-way.

Swales collecting runoff from disturbed areas shall remain in place until the disturbed areas are permanently stabilized.

Design Criteria

See Figure 5A.2 on page 5A.4 for details.

	Swale A	Swale B
Drainage Area	<5 Ac	5-10 Ac
Bottom Width of Flow Channel	4 ft	6 ft
Depth of Flow Channel	1 ft	1 ft
Side Slopes	2:1 or Flatter	2:1 or Flatter
Grade	0.5% Min. 20% Max.	0.5% Min. 20% Max.

For drainage areas larger than 10 acres, refer to the Standard and Specifications for Waterways on page 5B.11.

Stabilization

Stabilization of the swale shall be completed within 10 days of installation in accordance with the appropriate standard and specifications for vegetative stabilization or stabilization with mulch as determined by the time of year. The flow channel shall be stabilized as per the following criteria:

Type of Treatment	Channel Grade[1]	Flow Channel A(≤5 Ac)	Flow Channel B(5-10 Ac)
1	0.5-3.0%	Seed & Straw Mulch	Seed & Straw Mulch
2	3.1-5.0%	Seed & Straw Mulch	Seed and cover with Jute or Excelsior; Sod, or lined with 2 in. stone
3	5.1-8.0%	Seed and cover with Jute or Excelsior, Sod line with 2 in. stone	Line with 4-8 in. stone or Recycled Concrete Equivalent[2]
4	8.1-20%	Line with 4-8 in. stone or Recycled Concrete Equivalent[2]	Engineering Design

[1] In highly erodible soils, as defined by the local approving agency, refer to the next higher slope grade for type of stabilization.

[2] Recycled Concrete Equivalent shall be concrete broken into the required size, and shall contain no steel reinforcement.

Outlet

Swale shall have an outlet that functions with a minimum of erosion, and dissipates runoff velocity prior to discharge off the site.

Runoff shall be conveyed to a sediment trapping device such as a sediment trap or sediment basin until the drainage area above the swale is adequately stabilized.

The on-site location may need to be adjusted to meet field conditions in order to utilize the most suitable outlet condition.

If swale is used to divert flows from entering a disturbed area, a sediment trapping device may not be needed.

VOL 12

6056

STANDARD AND SPECIFICATIONS FOR PERIMETER DIKE/SWALE

VOL 12

Definition

A temporary ridge of soil excavated from an adjoining swale located along the perimeter of the site or disturbed area.

Purpose

The purpose of a perimeter dike/swale is to prevent off site storm runoff from entering a disturbed area and to prevent sediment laden storm runoff from leaving the construction site or disturbed area.

Conditions Where Practice Applies

Perimeter dike/swale is constructed to divert flows from entering a disturbed area, or along tops of slopes to prevent flows from eroding the slope, or along base of slopes to direct sediment laden flows to a trapping device.

The perimeter dike/swale shall remain in place until the disturbed areas are permanently stabilized.

Design Criteria

See Figure 5A.3 on page 5A.6 for details.

The perimeter dike/swale shall not be constructed outside the property lines without obtaining legal easements from effected adjacent property owners. A design is not required for perimeter dike/swale. The following criteria shall be used:

Drainage area - Less than 2 acres (for drainage areas larger than 2 acres but less than 10 acres see earth dike; for drainage areas larger than 10 acres, see standard and specifications for diversion).

Height - 18 inches minimum from bottom of swale to top of dike evenly divided between dike height and swale depth.

Bottom width of dike - 2 feet minimum.

Width of swale - 2 feet minimum.

Grade - Dependent upon topograpby, but shall have positive drainage (sufficient grade to drain) to an adequate outlet. Maximum allowable grade not to exceed 20 percent.

Stabilization - The disturbed area of the dike and swale shall be stabilized within 10 days of installation, in accordance with the standard and specifications for seed and straw mulch or straw mulch only if not in the seeding season.

Outlet

1. Perimeter dike/swale shall have an outlet that functions with a minimum of erosion.
2. Diverted runoff from a protected or stabilized upland area shall outlet directly onto an undisturbed stabilized area.
3. Diverted runoff from a disturbed or exposed upland area shall be conveyed to a sediment trapping device such as a sediment trap, sediment basin, or to an area protected by any of these practices.
4. The on-site location may need to be adjusted to meet field conditions in order to utilize the most suitable outlet.

CONSTRUCTION SPECIFICATIONS

1. ALL PERIMETER DIKE/SWALE SHALL HAVE UNINTERRUPTED POSITIVE GRADE TO AN OUTLET.
2. DIVERTED RUNOFF FROM A DISTRUBED AREA SHALL BE CONVEYED TO A SEDIMENT TRAPPING DEVICE.
3. DIVERTED RUNOFF FROM AN UNDISTURBED AREA SHALL OUTLET INTO AN UNDISTURBED STABILIZED AREA AT NON-EROSION VELOCITY.
4. THE SWALE SHALL BE EXCAVATED OR SHAPED TO LINE, GRADE, AND CROSS SECTION AS REQUIRED TO MEET THE CRITERIA SPECIFIED IN THE STANDARD.
5. STABILIZATION OF THE AREA DISTURBED BY THE DIKE AND SWALE SHALL BE DONE IN ACCORDANCE WITH THE STANDARD AND SPECIFICATION FOR SEED AND STRAW MULCH, AND SHALL BE DONE WITHIN 10 DAYS.
6. PERIODIC INSPECTION AND REQUIRED MAINTENANCE MUST BE PROVIDED AFTER EACH RAIN EVENT.

Max. Drainage Area Limit: 2 Acres

U.S. DEPARTMENT OF AGRICULTURE SOIL CONSERVATION SERVICE SYRACUSE, NEW YORK	PERIMETER DIKE/SWALE	STANDARD SYMBOL —PD—

STANDARD AND SPECIFICATIONS FOR TEMPORARY STORM DRAIN DIVERSION

Definition

The redirection of a storm drain line or outfall channel so that it may temporarily discharge into a sediment trapping device.

Purpose

To prevent sediment laden water from entering a watercourse, public or private property through a storm drain system, or to temporarily provide underground conveyance of sediment laden water to a sediment trapping device.

Conditions Where Practice Applies

One of the following practices or procedures shall be used whenever the off-site drainage area is less than 50 percent of the on-site drainage area to that system. A special exception may be given, at the discretion of the local plan approval agency, where site conditions make this procedure impossible.

Method of Temporary Diversion

1. Construction of a sediment trap or basin below a permanent storm drain outfall. Temporarily divert storm flow into the basin or trap constructed below permanent outfall channel.
2. In-line diversion of storm drain at an inlet or manhole, achieved by installing a pipe stub in the side of a manhole or inlet and temporarily blocking the permanent outfall pipe from that structure. A temporary outfall ditch or pipe may be used to convey storm flow from the stub to a sediment trap or basin. This method may be used just above a permanent outfall or prior to connecting into an existing storm drain system.
3. Delay completion of the permanent storm drain outfall and temporarily divert storm flow into a sediment basin or trap. Earth dike, swale or design diversion is used, depending on the drainage area, to direct flow into a sediment basin or trap. The basin or trap should be constructed to one side of the proposed permanent storm drain location whenever possible.
4. Installation of a stormwater management basin early in the construction sequence. Install temporary measures to allow use as a sediment basin. Since these structures are designed to receive storm drain outfalls, diversion should not be necessary.

Completion and Disposition

When the areas contributing sediment to the system have been stabilized, procedures can be taken to restore the system to its planned use.

The following removal and restoration procedure is recommended:

1. Flush the storm drain system to remove any accumulated sediment.
2. Remove the sediment control devices, such as traps, basins, dikes, swales, etc.
3. For sites where an inlet was modified, brick shut the temporary pipe stub and open the permanent outfall pipe.
4. Establish permanent stabilized outfall channel as noted on the plans.
5. Restore the area to grades shown on the plan and stabilize with vegetative measures.
6. For basins that will be converted to stormwater management, remove the accumulated sediment, open the low flow orifice, and seed all disturbed areas to permanent vegetation.

VOL 12

6060

STANDARD AND SPECIFICATIONS FOR WATER BAR

Definition

A ridge or ridge and channel constructed diagonally across a sloping road or utility right-of-way that is subject to erosion.

Purpose

To limit the accumulation of erosive volumes of water by diverting surface runoff at predesigned intervals.

Conditions Where Practice Applies

Where runoff protection is needed to prevent erosion on sloping access right-of-ways or either long, narrow sloping areas generally less than 100 feet in width.

Design Criteria

Design computations are not required.

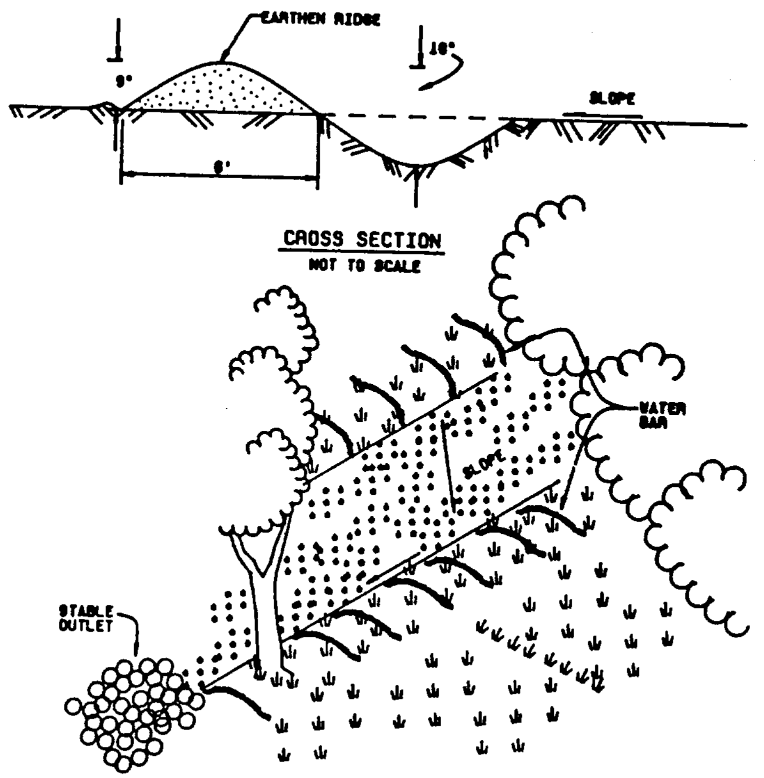
1. The design height shall be a minimum of 18 inches measured from channel bottom to ridge top.
2. The side slopes shall be 2:1 or flatter; a minimum of 4:1 where vehicles cross.
3. The base width of the ridge shall be six feet minimum.
4. The spacing of the water bars shall be as follows:

Slope (%)	Spacing (ft)
<5	125
5 to 10	100
10 to 20	75
20 to 35	50
> 35	25

5. The positive grade shall not exceed 2%. A crossing angle of approximately 60 degrees is preferred.
6. Water bars should have stable outlets, either natural or constructed. Site spacing may need to be adjusted for field conditions to use the most suitable areas for water disposal.

See figure 5A.4 on page 5A.10 for details.

Figure 5A.4
Water Bar Details



CONSTRUCTION SPECIFICATIONS

1. INSTALL THE WATER BAR AS SOON AS THE RIGHT OF WAY IS CLEARED AND GRADED.
2. DISK OR STRIP THE SOD FROM THE BASE FOR THE CONSTRUCTED RIDGE BEFORE PLACING FILL.
3. TRACK THE RIDGE TO COMPACT IT TO THE DESIGN CROSS SECTION.
4. THE OUTLET SHALL BE LOCATED ON AN UNDISTURBED AREA. FIELD SPACING WILL BE ADJUSTED TO USE THE MOST STABLE OUTLET AREAS. OUTLET PROTECTION WILL BE PROVIDED WHEN NATURAL AREAS ARE NOT ADEQUATE.
5. VEHICLE CROSSING SHALL BE STABILIZED WITH GRAVEL. EXPOSED AREAS SHALL BE IMMEDIATELY SEEDED AND MULCHED.
6. PERIODICALLY INSPECT WATER BARS FOR EROSION DAMAGE AND SEDIMENT. CHECK OUTLET AREAS AND MAKE REPAIRS AS NEEDED TO RESTORE OPERATION.

U.S. DEPARTMENT OF AGRICULTURE SOIL CONSERVATION SERVICE SYRACUSE, NEW YORK	WATER BARS	STANDARD SYMBOL — WB —

STANDARD AND SPECIFICATIONS
FOR
LEVEL SPREADER

Definition

A non-erosive outlet for concentrated runoff constructed to disperse flow uniformly across the a slope.

Purpose

To convert concentrated flow to sheet flow and release it uniformly over a stabilized area.

Conditions Where Practice Applies

Where sediment-free storm runoff can be released in sheet flow down a stabilized slope without causing erosion; where a level lip can be constructed without filling; where the area below the level lip is uniform with a slope of 10% or less and the runoff will not re-concentrate after release; and where no traffic will be allowed over spreader.

Design Criteria

The design capacity shall be determined by estimating the peak flow from the 10 year storm. The drainage area shall be restricted to limit the maximum flows into the spreader to 30 cfs. The level spreader shall have the following minimum dimensions:

Design Flow (cfs)	Minimum Entrance Width (ft.)	Depth (ft.)	End Width (ft.)	Length (ft.)
0-10	10	0.5	3	10
10-20	16	0.6	3	20
20-30	24	0.7	3	30

A transition section 20 feet in length shall be constructed from the width of the diversion or channel to the width of the spreader to ensure uniform outflow. This last transition section will blend the diversion grade to zero grade at the beginning of the spreader.

Construct the level lip in undisturbed soil to a uniform height and zero grade over the length of the spreader. Protect the lip with an erosion resistant material or mat to prevent erosion and allow vegetation to become established.

The outlet area should be a generally smooth, well vegetated area no steeper than 10 percent.

See figure 5A.5 on page 5A.12 for details.

0-10	10	0.5	10
10-20	16	0.6	20
20-30	24	0.7	30

CONSTRUCTION SPECIFICATIONS

1. THE MATTING SHOULD BE A MINIMUM OF 4FT. WIDE EXTENDING 6 INCHES OVER THE LIP AND BURIED 6 INCHES DEEP IN A VERTICAL TRENCH ON THE LOWER EDGE. THE UPPER EDGE SHOULD BUTT AGAINST SMOOTHLY CUT SOD AND BE SECURELY HELD IN PLACE WITH CLOSELY SPACED HEAVY DUTY WIRE STAPLES AT LEAST 12 INCHES IN LENGTH.
2. ENSURE THAT THE LIP IS LEVEL TO UNIFORMLY SPREAD DISCHARGE.
3. THE LIP SHALL BE CONSTRUCTED ON UNDISTURBED SOIL NOT FILL.
4. A 20 FOOT TRANSITION SECTION WILL BE CONSTRUCTED FROM THE DIVERSION CHANNEL TO THE SPREADER TO SMOOTHLY BLEND THE DIFFERENT DIMENSION AND GRADES.
5. THE RUNOFF DISCHARGE WILL BE OUTLETED ONTO A STABLIZED VEGETATED SLOPE NOT EXCEEDING 10%.
6. SEED AND MULCH THE DISTURBED AREA IMMEDIATELY AFTER CONSTRUCTION.

STANDARD AND SPECIFICATIONS FOR PIPE SLOPE DRAIN

Definition

A temporary structure placed from the top of a slope to the bottom of a slope.

Purpose

The purpose of the structure is to convey surface runoff down slopes without causing erosion.

Conditions Where Practice Applies

Pipe slope drains are used where concentrated flow of surface runoff must be conveyed down a slope in order to prevent erosion. The maximum allowable drainage area shall be 5 acres.

Design Criteria

See Figures 5A.6 and 5A.7 on pages 5A.14 and 5A.15 for details.

General

Size	Pipe/Tubing Diameter (in).	Maximum Drainage Area (Ac)
PSD-12	12	0.5
PSD-18	18	1.5
PSD-21	21	2.5
PSD-24	24	3.5
PSD-30	30	5.0

Inlet

The minimum height of the earth dike at the entrance to the pipe slope drain shall be the diameter of the pipe (D) plus 12 inches.

Outlet

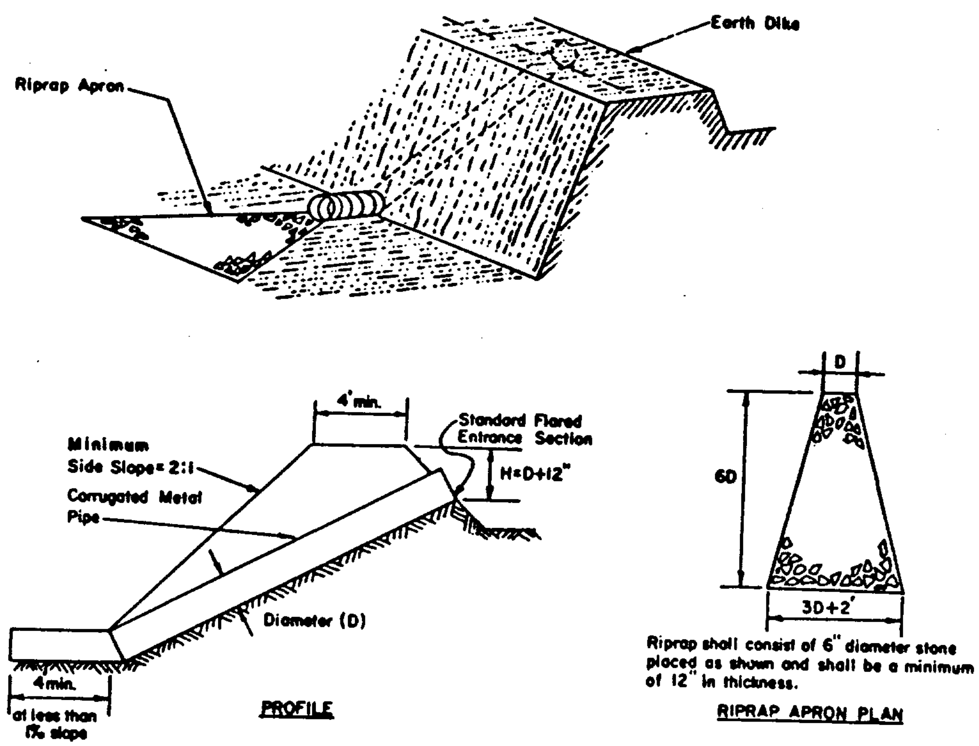
The pipe slope drain shall outlet into a sediment trapping device when the drainage area is disturbed. A riprap apron shall be installed below the pipe outlet where clean water is being discharged into a stabilized area.

Construction Specifications

1. The pipe slope drain shall have a slope of 3 percent or steeper.
2. The top of the earth dike over the inlet pipe and those dikes carrying water to the pipe shall be at least one (1) foot higher at all points than the top of the inlet pipe.
3. Corrugated metal pipe or equivalent shall be used with watertight connecting bands.
4. A flared end section shall be attached to the inlet end of pipe with a watertight connection.
5. The soil around and under the pipe and end section shall be hand tamped in 4 in. lifts to the top of the earth dike.
6. Where flexible tubing is used, it shall be the same diameter as the inlet pipe and shall be constructed of a durable material with hold down grommets spaced 10 ft. on centers.
7. The flexible tubing shall be securely fastened to the corrugated metal pipe with metal strapping or watertight connecting collars.
8. The flexible tubing shall be securely anchored to the slope by staking at the grommets provided.
9. Where a pipe slope drain outlets into a sediment trapping device, it shall discharge at the riser crest or weir elevation.
10. A riprap apron shall be used below the pipe outlet where clean water is being discharged into a stabilized area. See Figures 5A.6 and 5A.7.
11. Inspection and any needed maintenance shall be performed after each storm.

VOL 12

Figure 5A.6
Pipe Slope Drain - Rigid



Note: Size designation is: PSD-Pipe Diam.
(ex., PSD-12= Pipe Slope Drain with 12" diameter pipe)

CONSTRUCTION SPECIFICATIONS

1. THE PIPE SLOPE DRAIN SHALL HAVE A SLOPE OF 3% OR STEEPER.
2. TOP OF THE EARTH DIKE OVER THE INLET PIPE AND ALL DIKES CARRYING WATER TO THE PIPE SHALL BE AT LEAST ONE FOOT HIGHER THAN THE TOP OF THE PIPE.
3. ADD 0.3 FOOT TO DIKE HEIGHT FOR SETTLEMENT.
4. SOIL AROUND AND UNDER THE SLOPE PIPE SHALL BE HAND TAMPED IN 4 INCH LIFTS.
5. THE PIPE SHALL BE CORRUGATED METAL PIPE WITH WATERTIGHT 12 INCH CONNECTING BANDS OR FLANGE CONNECTIONS.
6. RIP-RAP TO BE 6 INCHES IN A LAYER AT LEAST 12 INCHES THICKNESS AND PRESSED INTO THE SOIL.
7. PERIODIC INSPECTION AND REQUIRED MAINTENANCE MUST BE PROVIDED AFTER EACH RAIN EVENT.

Maximum Drainage Area: 5 Acres

U.S. DEPARTMENT OF AGRICULTURE SOIL CONSERVATION SERVICE SYRACUSE, NEW YORK	PIPE SLOPE DRAIN	STANDARD SYMBOL PSD

STANDARD AND SPECIFICATIONS FOR STRAW BALE DIKE

Definition

A temporary barrier of straw or similar material used to intercept sediment laden runoff from small drainage areas of disturbed soil.

Purpose

The purpose of a bale dike is to reduce runoff velocity and effect deposition of the transported sediment load. Straw bale dikes have an estimated design life of three (3) months.

Conditions Where Practice Applies

The straw bale dike is used where:

1. No other practice is feasible.
2. There is no concentration of water in a channel or other drainage way above the barrier.
3. Erosion would occur in the form of sheet erosion.
4. Length of slope above the straw bale dike does not exceed these limits.

Constructed Slope	Percent Slope	Slope Length (ft.)
2:1	50	25
2 -1/2:1	40	50
3:1	33	75
3-1/2:1	30	100
4:1	25	125

Where slope gradient changes through the drainage area, steepness refers to the steepest slope section contributing to the straw bale dike.

The practice may also be used for a single family lot if the slope is less than 15 percent. The contributing drainage area in this instance shall be less than one acre and the length of slope above the dike shall be less than 200 feet.

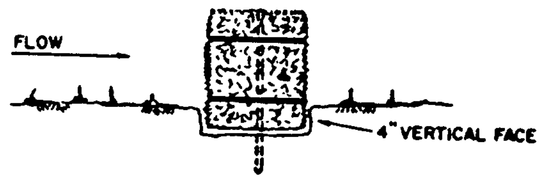
Design Criteria

A design is not required. All bales shall be placed on the contour with cut edge of bale adhering to the ground. See Figure 5A.8 on page 5A.18 or details.

VOL 12

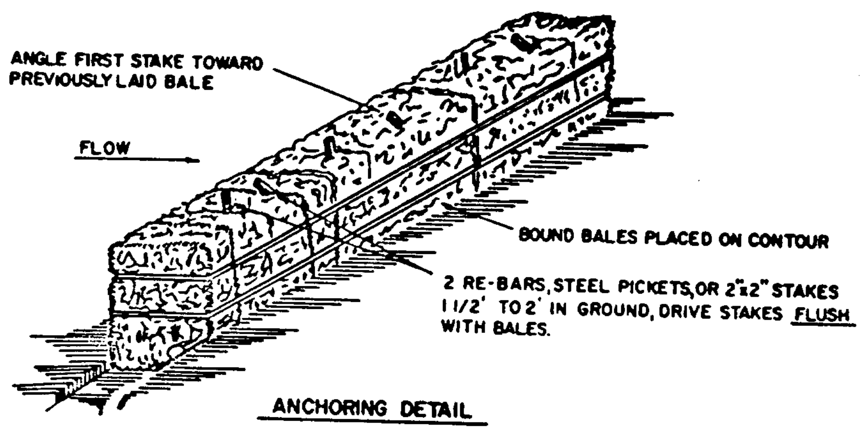
6069

Figure 5A.8
Straw Bale Dike Details



BEDDING DETAIL

DRAINAGE AREA NO MORE THAN 1/4 ac. PER 100 FEET OF STRAW BALE DIKE FOR SLOPES LESS THAN 25%



ANCHORING DETAIL

CONSTRUCTION SPECIFICATIONS

1. BALES SHALL BE PLACED AT THE TOE OF A SLOPE OR ON THE CONTOUR AND IN A ROW WITH ENDS TIGHTLY ABUTTING THE ADJACENT BALES.
2. EACH BALE SHALL BE EMBEDDED IN THE SOIL A MINIMUM OF (4) INCHES, AND PLACED SO THE BINDINGS ARE HORIZONTAL.
3. BALES SHALL BE SECURELY ANCHORED IN PLACE BY EITHER TWO STAKES OR RE-BARS DRIVEN THROUGH THE BALE. THE FIRST STAKE IN EACH BALE SHALL BE DRIVEN TOWARD THE PREVIOUSLY LAID BALE AT AN ANGLE TO FORCE THE BALES TOGETHER. STAKES SHALL BE DRIVEN FLUSH WITH THE BALE.
4. INSPECTION SHALL BE FREQUENT AND REPAIR REPLACEMENT SHALL BE MADE PROMPTLY AS NEEDED.
5. BALES SHALL BE REMOVED WHEN THEY HAVE SERVED THEIR USEFULNESS SO AS NOT TO BLOCK OR IMPEDE STORM FLOW OR DRAINAGE.

U. S. DEPARTMENT OF AGRICULTURE SOIL CONSERVATION SERVICE SYRACUSE, NEW YORK	STRAW BALE DIKE	STANDARD SYMBOL SBD

STANDARD AND SPECIFICATIONS FOR SILT FENCE

Definition

A temporary barrier of geotextile fabric (filter cloth) used to intercept sediment laden runoff from small drainage areas of disturbed soil.

Purpose

The purpose of a silt fence is to reduce runoff velocity and effect deposition of transported sediment load. Limits imposed by ultraviolet stability of the fabric will dictate the maximum period the silt fence may be used.

Conditions Where Practice Applies

A silt fence may be used subject to the following conditions:

1. Maximum allowable slope lengths contributing runoff to a silt fence are:

Slope Steepness	Maximum Slope Length (Ft)
2:1	50
3:1	75
4:1	125
5:1	175
Flatter than 5:1	200

2. Maximum drainage area for overland flow to a silt fence shall not exceed 1/2 acre per 100 feet of fence; and
3. Erosion would occur in the form of sheet erosion; and
4. There is no concentration of water flowing to the barrier.

Design Criteria

Design computations are not required. All silt fences shall be placed as close to the area as possible, and the area below the fence must be undisturbed or stabilized.

A detail of the silt fence shall be shown on the plan, and contain the following minimum requirements:

1. The type, size, and spacing of fence posts.
2. The size of woven wire support fences.
3. The type of filter cloth used.
4. The method of anchoring the filter cloth.
5. The method of fastening the filter cloth to the fencing support.

Where ends of filter cloth come together, they shall be overlapped, folded and stapled to prevent sediment bypass. See Figure 5A.9 on page 5A.20 for details.

Criteria for Silt Fence Materials

1. Silt Fence Fabric: The fabric shall meet the following specifications unless otherwise approved by the appropriate erosion and sediment control plan approval authority. Such approval shall not constitute statewide acceptance. Statewide acceptability shall depend on in field and/or laboratory observations and evaluations.

Fabric Properties	Minimum Acceptable Value	Test Method
Grab Tensile Strength (lbs)	90	ASTM D1682
Elongation at Failure (%)	50	ASTM D1682
Mullen Burst Strength (PSI)	190	ASTM D3786
Puncture Strength (lbs)	40	ASTM D751 (modified)
Slurry Flow Rate (gal/min/sf)	0.3	
Equivalent Opening Size	40-80	US Std Sieve CW-02215
Ultraviolet Radiation Stability (%)	90	ASTM G-26

2. Fence Posts (for fabricated units): The length shall be a minimum of 36 inches long. Wood posts will be of sound quality hardwood with a minimum cross sectional area of 3.0 square inches. Steel posts will be standard T and U section weighing not less than 1.00 pound per linear foot.
3. Wire Fence (for fabricated units): Wire fencing shall be a minimum 14-1/2 gage with a maximum 6 in. mesh opening, or as approved.
4. Prefabricated Units: Envirofence or approved equal may be used in lieu of the above method providing the unit is installed per details shown in Figure 5A.9.

6072

STANDARD AND SPECIFICATIONS FOR CHECK DAM

Definition

Small temporary stone dams constructed across a drainageway.

Purpose

To reduce erosion in a drainage channel by restricting the velocity of flow in the channel.

Condition Where Practice Applies

This practice is used as a temporary or emergency measure to limit erosion by reducing flow in small open channels that are degrading or subject to erosion; and where permanent stabilization is impractical due to short period of usefulness and time constraints of construction.

Design Criteria

Drainage Area: Maximum drainage area above the check dam shall not exceed two (2) acres.

Height: Not greater than 2 feet. Center shall be maintained 9 inches lower than abutments at natural ground elevation.

Side Slopes: Shall be 2:1 or flatter

Spacing: The check dams shall be spaced as necessary in the channel so that the crest of the downstream dam is at the elevation of the toe of the upstream dam.

Stone Size: Use graded stone 2 to 15 inches in size (NYS - DOT Light Stone Fill meets these requirements).

The overflow of the check dams will be stabilized to resist erosion that might be caused by the check dam. See Figure 5A.10 on page 5A.22 for details.

Maintenance

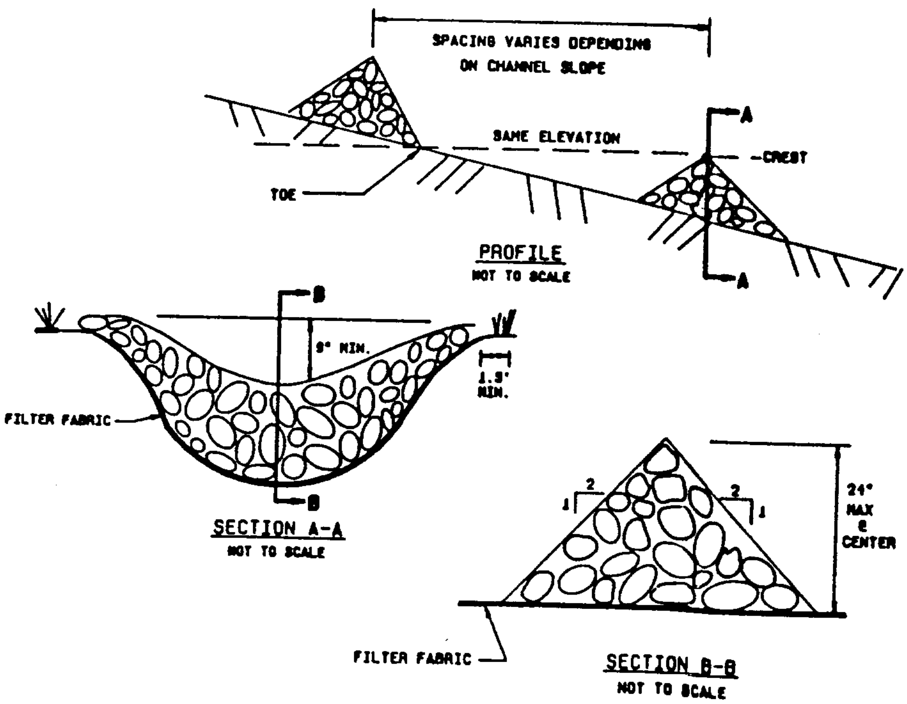
The check dams should be inspected after each runoff event. Correct all damage immediately. If significant erosion has occurred between structures a liner of stone or other suitable material should be installed in that portion of the channel.

Remove sediment accumulated behind the dam as needed to allow channel to drain through the stone check dam and prevent large flows from carrying sediment over the dam. Replace stones as needed to maintain the design cross section of the structures.

VOL 12

6073

Figure 5A.10
Check Dam Details



CONSTRUCTION SPECIFICATIONS

1. STONE WILL BE PLACED ON A FILTER FABRIC FOUNDATION TO THE LINES, GRADES AND LOCATIONS SHOWN IN THE PLAN.
2. SET SPACING OF CHECK DAMS TO ASSUME THAT THE ELEVATIONS OF THE CREST OF THE DOWNSTREAM DAM IS AT THE SAME ELEVATION OF THE TOE OF THE UPSTREAM DAM.
3. EXTEND THE STONE A MINIMUM OF 1.5 FEET BEYOND THE DITCH BANKS TO PREVENT CUTTING AROUND THE DAM.
4. PROTECT THE CHANNEL DOWNSTREAM OF THE LOWEST CHECK DAM FROM SCOUR AND EROSION WITH STONE OR LINER AS APPROPRIATE.
5. ENSURE THAT CHANNEL APPURTENANCES SUCH AS CULVERT ENTRANCES BELOW CHECK DAMS ARE NOT SUBJECT TO DAMAGE OR BLOCKAGE FROM DISPLACED STONES.

MAXIMUM DRAINAGE AREA 2 ACRES.

VOL 12

6074

R0039382

STANDARD AND SPECIFICATIONS FOR ROCK DAM

Definition

A rock embankment located to capture sediment.

Purpose

To retain sediment on the construction site and prevent sedimentation in off site water bodies.

Conditions Where Practice Applies

The rock dam may be used instead of the standard sediment basin with barrel and riser. The rock dam is preferred when it is difficult to construct a stable, earthen embankment and rock materials are readily available. The site should be accessible for periodic sediment removal. This rock dam should not be located in a live stream. The top of the dam will serve as the overflow outlet. The inside of the dam will be faced with smaller stone to reduce the rate of seepage so a sediment pool forms during runoff events.

Design Criteria

Drainage Area: The drainage area for this off stream structure is limited to 50 acres.

Location: The location of the dam should:

- provide a large area to trap sediment
- interrupt runoff from disturbed areas
- be accessible to remove sediment
- not interfere with construction activities

Storage Volume: The storage volume behind the dam should be at least 1,800 cubic feet based on the amount of disturbed area draining to the dam. This volume is measured one foot below the top of dam.

Dam Section:

Top Width	5 feet minimum @ crest
Side Slopes	2:1 upstream slope 3:1 downstream slope
Height	8' max to spillway crest

Length of Crest: The crest length should be designed to carry the 10 yr. peak runoff with a flow depth of 1 foot and 1 foot of freeboard.

Rock at the abutments should extend at least 2 feet above the spillway and be at least 2 feet thick. These rock abutments should extend at least one foot above the downstream slope to prevent abutment scour. A rock apron at least 1.5 feet thick should extend downstream from the toe of the dam a distance equal to the height of the dam to protect the outlet area from scour.

Rock Fill: The rockfill should be well graded, hard, erosion resistant stone with a minimum d_{50} size of 9 inches. A "key trench" lined with geotextile filter fabric should be installed in the soil foundation under the rockfill. The filter fabric must extend from the key trench to the downstream edge of the apron and abutments to prevent soil movement and piping under the dam.

The upstream face of the dam should be covered with a fine gravel (NYS-DOT #1 washed stone or equal) a minimum 1 foot thick to reduce the drainage rate.

Trapping Efficiency: To obtain maximum trapping efficiency, design for a long detention period. Usually a minimum of eight (8) hours before the basin is completely drained. Maximize the length of travel of sediment laden water from the inlet to the drain. Achieve a surface area equal to 0.01 acres per cfs (inflow) based on the 10-year storm.

See Figure 5A.11 on page 5A.24 for details.

Maintenance

Check the basin area after each rainfall event. Remove sediment and restore original volume when sediment accumulates to one-half the design volume. Check the structure for erosion, piping, and rock displacement after each significant event and replace immediately.

Remove the structure and any sediment immediately after the construction area has been permanently stabilized. All water should be removed from the basin prior to the removal of the rock dam. Sediment should be placed in designated disposal areas and not allowed to flow into streams or drainageways during structure removal.

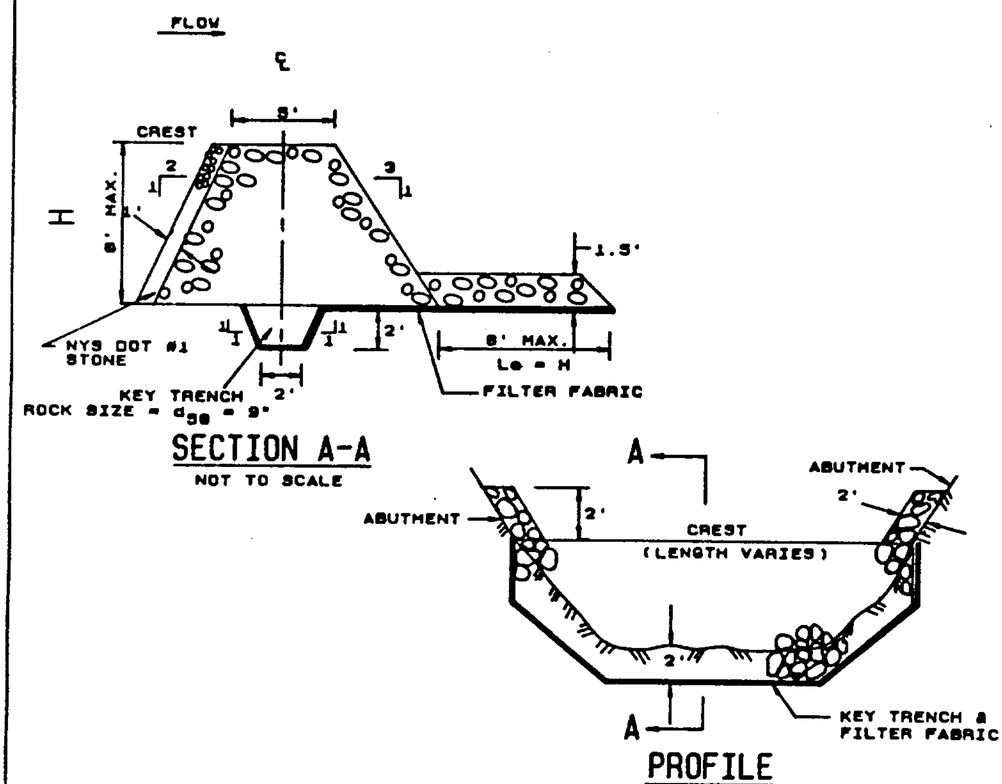
VOL 12

6075

VOL 12

6076

Figure 5A.11
Rock Dam Details



MAXIMUM DRAINAGE AREA: 50 ACRES

CONSTRUCTION SPECIFICATIONS

1. THE AREA UNDER THE ROCK DAM SHALL BE CLEARED AND STRIPPED OF ROOTS AND OTHER OBJECTIONABLE MATERIAL. THE RESERVOIR SHALL BE CLEARED AS NEEDED TO FACILITATE SEDIMENT REMOVAL.
2. DIMENSIONS SHOWN ARE MINIMUM. TRENCH SHALL BE EXCAVATED FROM ABUTMENT TO ABUTMENT ON THE DAM CENTERLINE. FILTER FABRIC SHALL BE PLACED FROM UPSTREAM EDGE OF KEYTRENCH TO DOWNSTREAM EDGE OF APRON. JOINTS WILL LAP A MINIMUM OF 1 FT. WITH UPSTREAM STRIP ON TOP.
3. CONSTRUCT THE ROCK EMBANKMENT TO THE DIMENSIONS SHOWN ON THE DRAWING. ROCK ABUTMENTS SHALL BE MAINTAINED 2 FT. ABOVE THE CREST.
4. THE ROCK DAM SHALL BE CONSTRUCTED PRIOR TO CLEARING THE BASIN AREA. STABLIZE ALL DISTURBED AREAS, EXCEPT THE BASIN AREA, WITH TEMPORARY SEEDING.
5. FENCES AND WARNING SIGNS SHOULD BE PLACED AS APPROPRIATE.

U.S. DEPARTMENT OF AGRICULTURE SOIL CONSERVATION SERVICE SYRACUSE, NEW YORK	ROCK DAM	STANDARD SYMBOL

STANDARD AND SPECIFICATIONS FOR STORM DRAIN INLET PROTECTION

Definition

A permeable barrier installed around inlets in the form of a fence, berm or excavation around an opening, thereby reducing sediment content of sediment laden water.

Purpose

To prevent sediment laden water from entering a storm drain system through inlets.

Conditions Where Practice Applies

This practice shall be used where the drainage area to an inlet is disturbed, it is not possible to temporarily divert the storm drain outfall into a trapping device and watertight blocking of inlets is not advisable. It is not to be used in place of sediment trapping devices. This may be used in conjunction with storm drain diversion to help prevent siltation of pipes installed with low slope angle.

Types of Storm Drain Inlet Practices

There are five (5) specific types of storm drain inlet protection practices that vary according to their function, location, drainage area and availability of materials:

I. Excavated Drop Inlet Protection
II. Fabric Drop Inlet Protection
III. Stone & Block Drop Inlet Protection
IV. Sod Drop Inlet Protection
V. Curb Drop Inlet Protection

Design Criteria

Drainage Area - The drainage area for storm drain inlets should be in accordance with the specific type of inlet used. (Type I through Type V).

Type I - Excavated Drop Inlet Protection

Limit the drainage area to the inlet device to 1 acre. Excavated side slopes shall be no steeper than 2:1. The minimum depth shall be 1 foot and the maximum depth 2 feet as measured from the crest of the inlet structure. Shape the excavated basin to fit conditions with the longest dimension oriented toward the longest inflow area to provide maximum trap efficiency. The capacity of the excavated basin should be established to contain 900 cubic feet per acre of disturbed area. Weep holes, protected by the fabric and stone, should be provided for draining the temporary pool.

Inspect and clean the excavated basin after every storm. Sediment should be removed when 50 percent of the storage volume is achieved. This material should be incorporated in the site in a stabilized manner.

See details for Excavated Drop Inlet Protection in Figure 5A.12 on page 5A.27.

Type II - Fabric Drop Inlet Protection

Limit the drainage area to 1 acre per inlet device. Land area slope immediately surrounding this device should not exceed 1 percent. The maximum height of the fabric above the inlet crest shall not exceed 1.5 feet.

The top of the barrier should be maintained to allow overflow to drop into the drop inlet and not bypass the inlet to unprotected lower areas. Support stakes for fabric shall be a minimum of 3 feet long, spaced a maximum 3 feet apart. They should be driven close to the inlet so any overflow drops into the inlet and not on the unprotected soil. Improved performance and sediment storage volume can be obtained by excavating the area.

Inspect the fabric barrier after each rain event and make repairs as needed. Remove sediment from the pool area as necessary with care not to undercut or damage the filter fabric. Upon stabilization of the drainage area remove all materials and unstable sediment and dispose of properly. Bring the adjacent area of the drop inlet to grade, smooth and compact and stabilize in the appropriate manner to the site.

See Figure 5A.13 for Details for Filter Fabric Drop Inlet Protection on page 5A.28.

Type III - Stone and Block Drop Inlet Protection

Limit the drainage area to 1 acre at the drop inlet. The stone barrier should have a minimum height of 1 foot and a maximum height of 2 feet. Do not use mortar. The height should be limited to prevent excess ponding and bypass flow.

Recess the first course of blocks at least 2 inches below the crest opening of the storm drain for lateral support. Subsequent courses can be supported laterally if needed by placing a 2x4 inch wood stud through the block openings perpendicular to the course. The bottom row should have a few blocks oriented so flow can drain through the block to dewater the basin area.

The stone should be placed just below the top of the blocks on slopes of 2:1 or flatter. Place hardware cloth or wire mesh with 1/2 inch openings over all block openings to hold stone in place.

As an optional design, the concrete blocks may be omitted and the entire structure constructed of stone, ringing the outlet ("doughnut"). The stone should be kept at a 3:1 slope toward the inlet to keep it from being washed into the inlet. A level area 1 foot wide and four inches below the crest will further prevent wash. Stone on the slope toward the inlet should be at least 3 inches in size for stability and 1 inch or smaller away from the inlet to control flow rate. The elevation of the top of the stone crest must be maintained 6 inches lower than the ground elevation downslope from the inlet to insure that all storm flows pass over the stone into the storm drain and not past the structure. Temporary diking should be used as necessary to prevent bypass flow.

The barrier should be inspected after each rain event and repairs made where needed. Remove sediment as necessary to provide for accurate storage volume for subsequent rains. Upon stabilization of contributing drainage area remove all materials and any unstable soil and dispose of properly. Bring the disturbed area to proper grade, smooth, compact and stabilize in a manner appropriate to the site.

See Figure 5A.14 for Details for Stone and Block Drop Inlet Protection on page 5A.29.

Type IV - Sod Drop Inlet Protection

The drainage area should be limited to 2 acres and the velocity over the sod kept below 5 feet per second. Place the sod to form a turf mat completely covering the soil surface for a minimum distance of 4 feet from each side of the drop inlet where runoff will enter. The slope of the sodden area should not exceed 4:1. (This can be a permanent practice).

During the first 4 weeks, water sod as often as necessary to maintain moist soil to a depth of 2 inches. Maintain a grass height of a least 2 inches with no more than 1/3 the shoot height (grass leaf) removed in any mowing. Apply fertilizer and lime as necessary to maintain the desired growth and sod density.

See figure 5A.15 Details for Sod Drop Inlet Protection on page 5A.30.

Type V - Curb Drop Inlet Protection

The drainage area should be limited to 1 acre at the drop inlet. The wire mesh must be of sufficient strength to support the filter fabric and stone with the water fully impounded against it. Stone is to be 2 inches in size and clean. The filter fabric must be of a type approved for this purpose with an equivalent opening size (EOS) of 40-85. The protective structure will be constructed to extend beyond the inlet 2 feet in both directions. Assure that storm flow does not bypass the inlet by installing temporary dikes directing flow into the inlet.

The structure should be inspected after every storm event. Any sediment should be removed and disposed of on the site. Any stone missing should be replaced. Check materials for proper anchorage and secure as necessary.

See Figure 5A.16 for Details for Curb Drop Inlet Protection on page 5A.31.

STANDARD AND SPECIFICATIONS FOR SEDIMENT TRAP

Definition

A temporary sediment control device formed by excavation and/or embankment to intercept sediment laden runoff and to retain the sediment.

Purpose

The purpose of the structure is to intercept sediment laden runoff and trap the sediment in order to protect drainage ways, properties, and right-of-way below the sediment trap from sedimentation.

Conditions Where Practice Applies

A sediment trap is usually installed in a drainage way, at a storm drain inlet, or other points of discharge from a disturbed area.

Sediment traps should not be used to artificially break up a natural drainage area into smaller sections where a larger device (sediment basin) would be better suited.

Design Criteria

If any of the design criteria presented here cannot be met, see Standard and Specifications for Sediment Basin on page 5A.47.

Drainage Area

The drainage area for sediment traps shall be in accordance with the specific type of sediment trap used (Type I through VI).

Location

Sediment traps shall be located so that they can be installed prior to grading or filling in the drainage area they are to protect. Traps must not be located any closer than 20 feet from a proposed building foundation if the trap is to function during building construction. Locate traps to obtain maximum storage benefit from the terrain, for ease of cleanout and disposal of the trapped sediment.

Trap Size

The volume of a sediment trap as measured at the elevation of the crest of the outlet shall be at least 1800 cubic feet per acre of drainage area. The volume of a constructed trap shall be calculated using standard mathematical procedures. The volume of a natural sediment trap may be approximated by the equation; Volume (cu. ft.) = 0.4 x surface area (sq. ft.) x maximum depth (ft.).

Trap Cleanout

Sediment shall be removed and the trap restored to the original dimensions when the sediment has accumulated to 1/2 of the design depth of the trap. Sediment removed from the trap shall be deposited in a protected area and in such a manner that it will not erode.

Embankment

All embankments for sediment traps shall not exceed five (5) feet in height as measured at the low point of the original ground along the centerline of the embankment. Embankments shall have a minimum four (4) foot wide top and side slopes of 2:1 or flatter. The embankment shall be compacted by traversing with equipment while it is being constructed.

The elevation of the top of any dike directing water to any sediment trap will equal or exceed the maximum height of the outlet structure along the entire length of the trap.

Excavation

All excavation operations shall be carried out in such a manner that erosion and water pollution shall be minimal. Excavated portions of sediment traps shall have 1:1 or flatter slopes.

Outlet

The outlet shall be designed, constructed and maintained in such a manner that sediment does not leave the trap and that erosion at or below the outlet does not occur.

Sediment traps must outlet onto stabilized (preferably undisturbed) ground, into a watercourse, stabilized channel, or into a storm drain system.

Trap Details Needed on Erosion and Sediment Control Plans

There is no standard symbol for a sediment trap. Each trap shall be delineated on the plans in such manner that it will not be confused with any other features. Each trap on a plan shall indicate all the information necessary to properly construct and maintain the structure. If the drawings are such that this information cannot be delineated on the drawings, then a table shall be developed. If a table is developed, then each trap on a plan shall have a number and the numbers shall be consecutive.

The following information shall be shown for each trap in a summary table form on the plans.

1. Trap number
2. Type of trap
3. Drainage area
4. Storage required
5. Storage provided (if applicable)
6. Outlet length or pipe sizes
7. Storage depth below outlet or cleanout elevation
8. Embankment height and elevation (if applicable)

Type of Sediment Traps

There are six (6) specific types of sediment traps which vary according to their function, location or drainage area.

I. Pipe Outlet Sediment Trap
II. Grass Outlet Sediment Trap
III. Storm Inlet Sediment Trap
IV. Swale Sediment Trap
V. Stone Outlet Sediment Trap
VI. Riprap Outlet Sediment Trap

I. Pipe Outlet Sediment Trap

A Pipe Outlet Sediment Trap consists of a trap formed by embankment or excavation. The outlet for the trap is through a perforated riser and a pipe through the embankment. The outlet pipe and riser shall be made of corrugated metal. The top of the embankment shall be at least 1 1/2 feet above the crest of the riser. The top 2/3 of the riser shall be perforated with one (1) inch nominal diameter holes or slits spaced six (6) inches vertically and horizontally placed in the concave portion of the corrugated pipe.

No holes or slits will be allowed within six (6) inches of the top of the horizontal barrel. All pipe connections shall be watertight. The riser shall be wrapped with 1/2 to 1/4 inch hardware clothwire then wrapped with filter cloth (Mirafi lOOX, Poly Filter GB or a filter cloth with an equivalent sieve size between #40-80) and secured with strapping or connecting band at the top and bottom of the cloth. The cloth shall cover an area at least six (6) inches above the highest hole and six (6) inches below the lowest hole. The top of the riser pipe shall not be covered with filter cloth. The riser shall have a base with sufficient weight to prevent flotation of the riser. Two approved bases are:

1. A concrete base 12 in. thick with the riser embedded 9 in. into the concrete base, or
2. One quarter inch, minimum, thick steel plate attached to the riser by a continuous weld around the circumference of the riser to form a watertight connection. The plate shall have 2.5 feet of stone, gravel, or earth placed on it to prevent flotation. In either case, each side of the square base measurement shall be the riser diameter plus 24 inches.

Pipe outlet sediment traps shall be limited to a five (5) acres maximum drainage area. Pipe outlet sediment traps may be interchangeable in the field with stone outlet or riprap sediment traps provided that these sediment traps are constructed in accordance with the detail and specifications for that trap.

Select pipe diameter from the following table:

Minimum Sizes Barrel Diameter[1] (in.)	Riser Diameter[1] (in.)	Maximum Drainage Area (ac.)
12	15	1
15	18	2
18	21	3
21	24	4
21	27	5

[1] Barrel diameter may be same size as riser diameter.

See details for Pipe Outlet Sediment Trap ST-I in Figure 5A.17 (1) and 5A.17 (2) on pages 5A.36 and 5A.37.

II. Grass Outlet Sediment Trap

A Grass Outlet Sediment Trap consists of a trap formed by excavating the earth to create a holding area. The trap has a discharge point over natural existing grass. The outlet length (feet) shall be equal to four (4) times the drainage area (acres) and a minimum length of four (4) feet. The outlet shall be free of any restrictions to flow. The outlet lip must remain undisturbed and level. The volume of this trap shall be computed at the elevation of the crest of the outlet. Grass outlet sediment traps shall be limited to a five (5) acre maximum drainage area.

See Details for Grass Outlet Sediment Trap ST-II in Figure 5A.18 on page 5A.38.

III. Storm Inlet Sediment Trap

A Storm Inlet Sediment Trap consists of a basin formed by excavation on natural ground that discharges through an opening in a storm drain inlet structure. This opening can either be the inlet opening or a temporary opening made by omitting bricks or blocks in the inlet.

A yard drain inlet or an inlet in the median strip of a dual highway could use the inlet opening for the tap outlet. The trap should be out of the roadway so as not to interfere with future compaction or construction. Placing the trap on the opposite side of the opening and diverting water from the roadway to the trap is one means of doing this. Storm inlet sediment traps shall be limited to a three (3) acre maximum drainage area. The volume of this trap is measured at the elevation of the crest of the outlet (invert of the inlet opening).

VOL 12

6086

See Details for Storm Inlet Sediment Trap ST-III in Figure 5A.19 on page 5A.39.

IV. Swale Sediment Trap

A Swale Sediment Trap consists of a trap formed by over excavating a swale or a drainage ditch. The outlet of the swale sediment trap is controlled by the invert of the downstream swale. Swale sediment traps are placed in surface drain ditches just before the runoff water leaves the property, enters a watercourse at the end of cut sections, or immediately preceding ditch inlets or stabilized outlets. Often a section of concrete liner is left out to construct the swale trap in that section. Once the contributory drainage area is stabilized, the trap may be removed and the swale or ditch reconstructed. The swale sediment trap shall be used only where no other device is feasible. The swale sediment trap shall be limited to a maximum drainage area of two (2) acres. The volume of this trap shall be computed at the elevation of the invert of the outlet.

See Details for Swale Sediment Trap ST-IV in Figure 5A.20 on Page 5A.40.

V. Stone Outlet Sediment Trap

A Stone Outlet Sediment Trap consists of a trap formed by an embankment or excavation. The outlet of this trap is over a stone section placed on level ground. The minimum length (feet) of the outlet shall be equal to four (4) times the drainage area (acres).

Required storage shall be 1,800 cubic feet per acre of drainage area.

The outlet crest (top of stone in weir section) shall be level, at least one (1) foot below top of embankment and no more than one (1) foot above ground beneath the outlet. Stone used in the outlet shall be small riprap (4 in. x 8 in.). To provide more efficient trapping effect, a layer of filter cloth should be embedded one (1) foot back into the upstream face of the outlet stone or a one (1) foot thick layer of two (2) inch or finer aggregate shall be placed on the upstream face of the outlet.

Stone Outlet Sediment Traps may be interchangeable in the field with pipe or riprap outlet sediment traps provided they are constructed in accordance with the detail and specifications for those traps. Stone outlet sediment traps shall be limited to a five (5) acre maximum drainage area.

See Details for Outlet Sediment Trap ST-V in Figure 5A.21 on page 5A.41.

VI. Riprap Outlet Sediment Trap

A Riprap Outlet Sediment Trap consists of a trap formed by an excavation and embankment. The outlet for this trap shall be through a partially excavated channel lined with riprap. This outlet channel shall discharge onto a stabilized area or to a stable watercourse. The riprap outlet sediment trap may be used for drainage areas of up to a maximum of 15 acres.

Design Criteria for Riprap Outlet Sediment Trap

1. The total contributing drainage area (disturbed or undisturbed either on or off the developing property) shall not exceed 15 acres.
2. The storage needs for this trap shall be computed using 1800 cubic feet of required storage for each acre of drainage area. The storage volume provided can be figured by computing the volume of storage area available behind the outlet structure up to an elevation of one (1) foot below the level weir crest.
3. The maximum height of embankment shall not exceed five (5) feet.
4. The elevation of the top of any dike directing water to a riprap outlet sediment trap will equal or exceed the minimum elevation of the embankment along the entire length of this trap.

See Details for Riprap Outlet Sediment Trap ST-VI on Figure 5A.22 on page 5A.42.

Optional Dewatering Methods

Optional dewatering devices may be designed for use with sediment traps. Included are two methods which may be used. See Figure 5A.23 on page 5A.44 for details.

Pipe Outlet Sediment Trap: ST-I - Construction Specifications

CONSTRUCTION SPECIFICATION FOR PIPE OUTLET TRAP: ST-1

1. AREA UNDER EMBANKMENT SHALL BE CLEARED, GRUBBED AND STRIPPED OF ANY VEGETATION AND ROOT MAT. THE POOL AREA SHALL BE CLEARED.
2. THE FILL MATERIAL FOR THE EMBANKMENT SHALL BE FREE OF ROOTS OR OTHER WOODY VEGETATION AS WELL AS OVER-SIZED STONES, ROCKS, ORGANIC MATERIAL, OR OTHER OBJECTIONABLE MATERIAL. THE EMBANKMENT SHALL BE COMPACTED BY TRAVERSING WITH EQUIPMENT WHILE IT IS BEING CONSTRUCTED.
3. VOLUME OF SEDIMENT STORAGE SHALL BE 1800 CUBIC FEET PER ACRE OF CONTRIBUTORY DRAINAGE.
4. SEDIMENT SHALL BE REMOVED AND TRAP RESTORED TO ITS ORIGINAL DIMENSIONS WHEN THE SEDIMENT HAS ACCUMULATED TO 1/2 THE DESIGN DEPTH OF THE TRAP. REMOVED SEDIMENT SHALL BE DEPOSITED IN A SUITABLE AREA AND IN SUCH A MANNER THAT IT WILL NOT ERODE.
5. THE STRUCTURE SHALL BE INSPECTED AFTER EACH RAIN AND REPAIRS MADE AS NEEDED.
6. CONSTRUCTION OPERATIONS SHALL BE CARRIED OUT IN SUCH A MANNER THAT EROSION AND WATER POLLUTION ARE MINIMIZED.
7. THE STRUCTURE SHALL BE REMOVED AND AREA STABILIZED WHEN THE DRAINAGE AREA HAS BEEN PROPERLY STABILIZED.
8. ALL FILL SLOPES SHALL BE 2:1 OR FLATTER; CUT SLOPES 1:1 OR FLATTER.
9. ALL PIPE CONNECTIONS SHALL BE WATERTIGHT.
10. THE TOP 2/3 OF THE RISER SHALL BE PERFORATED WITH ONE (1) INCH DIAMETER HOLES OR SLITS SPACED SIX (6) INCHES VERTICALLY AND HORIZONTALLY AND PLACED IN THE CONCAVE PORTION OF PIPE. NO HOLES WILL BE ALLOWED WITHIN SIX (6) INCHES OF THE HORIZONTAL BARREL.
11. THE RISER SHALL BE WRAPPED WITH 1/4 TO 1/2 INCH HARDWARE CLOTH WIRE THEN WRAPPED WITH FILTER CLOTH (HAVING AN EQUIVALENT SIEVE SIZE OF 40-80). THE FILTER CLOTH SHALL EXTEND SIX (6) INCHES ABOVE THE HIGHEST HOLE AND SIX (6) INCHES BELOW THE LOWEST HOLE. WHERE ENDS OF FILTER CLOTH COME TOGETHER, THEY SHALL BE OVER-LAPPED, FOLDED AND STAPLED TO PREVENT BYPASS.
12. STRAPS OR CONNECTING BANDS SHALL BE USED TO HOLD THE FILTER CLOTH AND WIRE FABRIC IN PLACE. THEY SHALL BE PLACED AT THE TOP AND BOTTOM OF THE CLOTH.
13. FILL MATERIAL AROUND THE PIPE SPILLWAY SHALL BE HAND COMPACTED IN FOUR (4) INCH LAYERS. A MINIMUM OF TWO (2) FEET OF HAND COMPACTED BACKFILL SHALL BE PLACED OVER THE PIPE SPILLWAY BEFORE CROSSING IT WITH CONSTRUCTION EQUIPMENT.
14. THE RISER SHALL BE ANCHORED WITH EITHER A CONCRETE BASE OR STEEL PLATE BASE TO PREVENT FLOTATION. FOR CONCRETE BASED THE DEPTH SHALL BE 12 INCHES WITH THE RISER EMBEDDED NINE (9) INCHES. A 1/4 INCH MINIMUM THICKNESS STEEL PLATE SHALL BE ATTACHED TO THE RISER BY A CONTINUOUS WELD AROUND THE BOTTOM TO FORM A WATERTIGHT CONNECTION AND THEN PLACE TWO (2) FEET OF STONE, GRAVEL, OR TAMPED EARTH ON THE PLATER.

Riprap Outlet Sediment Trap: ST-VI - Construction Specifications

CONSTRUCTION SPECIFICATION FOR RIPRAP OUTLET SEDIMENT TRAP = ST-VI

1. THE AREA UNDER EMBANKMENT SHALL BE CLEARED, GRUBBED AND STRIPPED OF ANY VEGETATION AND ROOT MAT. THE POOL AREA SHALL BE CLEARED.
2. THE FILL MATERIAL FOR THE EMBANKMENT SHALL BE FREE OF ROOTS OR OTHER WOODY VEGETATION AS WELL AS OVER-SIZED STONES, ROCKS, ORGANIC MATERIAL OR OTHER OBJECTIONABLE MATERIAL. THE EMBANKMENT SHALL BE COMPACTED BY TRAVERSING WITH EQUIPMENT WHILE IT IS BEING CONSTRUCTED. MAXIMUM HEIGHT OF EMBANKMENT SHALL BE FIVE (5) FEET, MEASURED AT CENTERLINE OF EMBANKMENT.
3. ALL FILL SLOPES SHALL BE 2:1 OR FLATTER, CUT SLOPES 1:1 OR FLATTER.
4. ELEVATION OF THE TOP OF ANY DIKE DIRECTING WATER INTO TRAP MUST EQUAL OR EXCEED THE HEIGHT OF EMBANKMENT.
5. STORAGE AREA PROVIDED SHALL BE FIGURED BY COMPUTING THE VOLUME AVAILABLE BEHIND THE OUTLET CHANNEL UP TO AN ELEVATION OF ONE (1) FOOT BELOW THE LEVEL WEIR CREST.
6. FILTER CLOTH SHALL BE PLACED OVER THE BOTTOM AND SIDES OF THE OUTLET CHANNEL PRIOR TO PLACEMENT OF STONE. SECTIONS OF FABRIC MUST OVERLAP AT LEAST ONE (1) FOOT WITH SECTION NEAREST THE ENTRANCE PLACED ON TOP. FABRIC SHALL BE EMBEDDED AT LEAST SIX (6) INCHES INTO EXISTING GROUND AT ENTRANCE OF OUTLET CHANNEL.
7. STONE USED IN THE OUTLET CHANNEL SHALL BE FOUR (4) TO EIGHT (8) INCHES (RIPRAP). TO PROVIDE A FILTERING EFFECT, A LAYER OF FILTER CLOTH SHALL BE EMBEDDED ONE (1) FOOT WITH SECTION NEAREST ENTRANCE PLACED ON TOP. FABRIC SHALL BE EMBEDDED AT LEAST SIX (6) INCHES INTO EXISTING GROUND AT ENTRANCE OF OUTLET CHANNEL.
8. SEDIMENT SHALL BE REMOVED AND TRAP RESTORED TO ITS ORIGINAL DIMENSIONS WHEN SEDIMENT HAS ACCUMULATED TO 1/2 THE DESIGN DEPTH OF THE TRAP. REMOVED SEDIMENT SHALL BE DEPOSITED IN A SUITABLE AREA AND IN SUCH A MANNER THAT IT WILL NOT ERODE.
9. THE STRUCTURE SHALL BE INSPECTED AFTER EACH RAIN AND REPAIRED AS NEEDED.
10. CONSTRUCTION OPERATIONS SHALL BE CARRIED OUT IN SUCH A MANNER THAT EROSION AND WATER POLLUTION ARE MINIMIZED.
11. THE STRUCTURE SHALL BE REMOVED AND THE AREA STABILIZED WHEN DRAINAGE AREA HAS BEEN PROPERLY STABILIZED.
12. DRAINAGE AREA FOR THIS PRACTICE IS LIMITED TO 15 ACRES OR LESS.

STANDARD AND SPECIFICATIONS FOR PORTABLE SEDIMENT TANK

Definition

A sediment tank is a compartmented tank container through which sediment laden water is pumped to trap and retain the sediment.

Purpose

To trap and retain sediment prior to pumping the water to drainageways, adjoining properities, and rights-of-way below the sediment tank site.

Conditions Where Practice Applies

A sediment tank is to be used on sites where excavations are deep, and space is limited, such as urban construction, where direct discharge of sediment laden water to stream and storm drainage systems is to be avoided.

Design Criteria

Location

The sediment tank shall be located for ease of clean-out and disposal of the trapped sediment, and to minimize the interference with construction activities and pedestrian traffic.

Tank Size

The following formula should be used in determining the storage volume of the sediment tank; pump discharge (G.P.M.) x 16 = Cubic Foot Storage

An example of a typical sediment tank is shown on Figure 5A.24 on page 5A.46. Other container designs can be used if the storage volume is adequate and approval is obtained from the local approving agency.

VOL 12

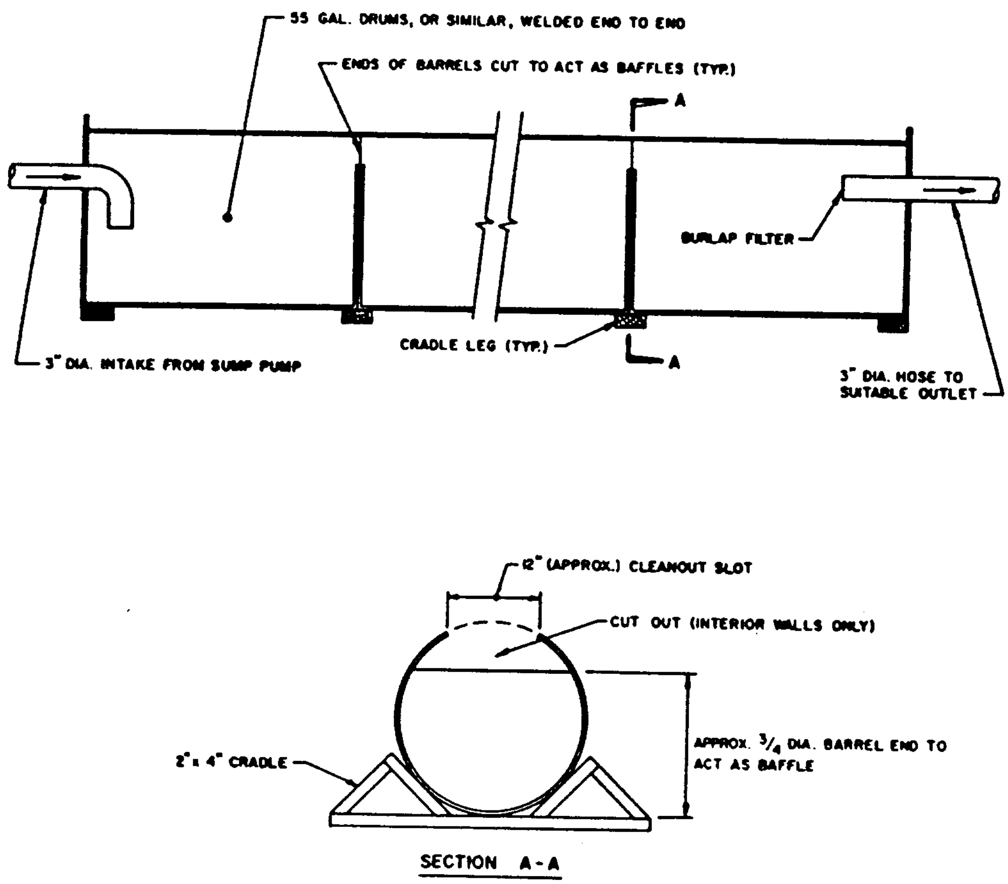
6097

R0039405

VOL 12

Figure 5A.24
Portable Sediment Tank

PORTABLE SEDIMENT TANK



CONSTRUCTION NOTES

1. CLEAN OUT THE SEDIMENT TANK WHEN ONE THIRD (1/3) FILLED WITH SILT.
2. STEEL DRUMS ARE USED AS AN EXAMPLE DUE TO THEIR READY AVAILABILITY ANY TANKS MAY BE USED, PROVINDING THAT THE VOLUME REQUIREMENTS ARE MET.
3. ALL SEDIMENT COLLECTED IN THE TANK SHALL BE DISPOSED OF IN A SEDIMENT TRAPPING DEVICE OR AS APPROVED BY THE INSPECTOR.

6098

STANDARD AND SPECIFICATIONS FOR SEDIMENT BASIN

Definition

A temporary barrier or dam constructed across a drainage way or at other suitable locations to intercept sediment laden runoff and to trap and retain the sediment.

Scope

This standard applies to the installation of temporary sediment basins on sites where: (a) failure of the structure would not result in loss of life, damage to homes or buildings, or interruption of use or service of public roads or utilities; (b) the drainage area does not exceed 100 acres; and (c) the basin is to be removed within 36 months after the beginning of construction of the basin.

Permanent (to function more than 36 months) sediment basins, or temporary basins exceeding the classification requirements for class 1 and 2, or structures that temporarily function as a sediment basin but are intended for use as a permanent pool shall be classified as permanent structures and shall conform to criteria appropriate for permanent structures. These structures shall be designed and constructed to conform to SCS Standard and Specification No. 378 for Ponds in the National Handbook of Conservation Practices. The total volume of permanent sediment basins shall equal or exceed the capacity requirements for temporary basins contained herein.

Standard sediment basin designs can be used for drainage area of 10 or 20 acres. See Figures 5A.25 and 5A.26 on pages 5A.55 and 5A.56 for details.

Classification of Temporary Sediment Basins

For the purpose of this standard, temporary sediment basins are classified as follows:

Class	1	2
Max. Drainage Area (acres)	100	100
Max. Height[1] of Dam (ft.)	10	15
Min. Embankment Top Width (ft)	8	10
Embankment Side Slopes	2:1 or Flatter	2 1/2:1 or Flatter
Anti-Seep Collar Required	Yes	Yes

[1] Height is measured from the low point of original ground along the centerline of dam to the top of the dam.

Purpose

The purpose of a sediment basin is to intercept sediment laden runoff and reduce the amount of sediment leaving the disturbed area in order to protect drainage ways, properties, and rights-of-way below the sediment basin.

Conditions Where Practice Applies

A sediment basis is appropriate where physical site conditions or land ownership restrictions preclude the installation of other erosion control measures to adequately control runoff, erosion, and sedimentation. It may be used below construction operations which expose critical areas to soil erosion. The basin shall be maintained until the disturbed area is protected against erosion by permanent stabilization.

Design Criteria

Compliance with Laws and Regulations

Design and construction shall comply with state and local laws, ordinances, rules and regulations.

Location

The sediment basin should be located to obtain the maximum storage benefit from the terrain and for ease of cleanout of the trapped sediment. It should be located to minimize interference with construction activities and construction of utilities. Whenever possible, sediment basins should be located so that storm drains may outfall or be diverted into the basin. Do not locate basins in perennial streams.

Size of the Basin

The sediment storage volume of the basin, as measured from the bottom of the basin to the elevation of the crest of the principal spillway shall be at least 1,800 cubic feet per acre of distrubed area draining to the basin. This 1,800 cubic feet is equivalent to 1/2 inch of sediment per acre of drainage area. where possible, the entire drainage area is used for this computation, rather than the distrubed area above, to maximize trapping efficiency.

Sediment basins shall be cleaned out when the volume remaining as described above is reduced by sedimentation to 900 cubic feet per acre of drainage area (50 percent full), except in no case shall the sediment level be permitted to build up higher than one foot below the principal spillway crest. At this elevation cleanout shall be performed to restore the original design volume to the sediment basin.

The elevation corresponding to the maximum allowable sediment level shall be determined and shall be stated in the design data as a distance below the top of the riser and shall be clearly marked on the riser.

The basin dimensions necessary to obtain the required basin volume as stated above shall be clearly shown on the plans to facilitate plan review, construction and inspection.

Shape of the Basin

It is recommended that the designer of a sediment basin strive to incorporate the following features:

1. Length to width ratio greater than 2:1, where length is the distance between the inlet and outlet.
2. A wedge shape with the inlet located at the narrow end.

Spillway Design

Runoff shall be computed by the method outlined in Chapter 2, Estimating Runoff, Engineering Field Manual for Conservation Practices available in the Soil Conservation Service offices, Section 10 of this manual, or by TR-55, Urban Hydrology for Small Watersheds. Runoff computations shall be based upon the worst soil cover conditions expected to prevail in the contributing drainage area during the anticipated effective life of the structure. The combined capacities of the principal and emergency spillway shall be sufficient to pass the peak rate of runoff from a ten year frequency storm.

1. Principal spillway: A spillway consisting of a vertical pipe or box type riser joined (watertight connection) to a pipe (barrel) which shall extend through the embankment and outlet beyond the downstream toe of the fill. The minimum capacity of the principal spillway shall be 0.2 cfs per acre of drainage area when the water surface is at the emergency spillway crest elevation. For those basins with no emergency spillway, the principal spillway shall have the capacity to handle the peak flow from a ten year frequency rainfall event. The minimum size of the barrel shall be 8 inches in diameter. See Figures 5A.27, 5A.28 and 5A.29 on pages 5A.57, 5A.58 and 5A.59 for principal spillway sizes and capacities.

   A. Crest elevation: When used in combination with an emergency spill way, the crest elevation of the riser shall be a minimum one foot below the elevation of the control section of the emergency spillway.

   B. Watertight riser and barrel assembly: The riser and all pipe connection shall be completely watertight except for the inlet opening at the top or a dewatering opening and shall not have any other holes, leaks, rips or perforations in it.

   C. Dewatering the basin: There are two stages of dewatering the basin: (1) the detention pool which is below the crest of the riser and above the surface of the trapped sediment; and (2) the sediment itself which will have a high water content to the point of being "soupy".

      1) Individual dewatering methods may be dictated by the intended use of the basin, i.e., sediment, flyash, or other special materials, that are to be trapped and retained within the basin. If a dewatering device is needed it shall be included in the sediment basin plans submitted for approval and shall be installed during construction of the basin.

      Dewatering shall be done in such a manner as to remove the relatively clean water without removing any of the sediment that has settled out and without removing any appreciable quantities of floating debris. Dewatering sediments trapped in a basin are often advantageous to the developer or contractor. Relatively dry material can be handled with on-site equipment rather than the expensive draglines often needed to handle wet (undewatered) sediments. Usually, the detention pool may be dewatered by a siphon installed on the riser, mechanical pumping, and surface or subsurface drains. For details on these methods of dewatering, see Figure 5A.30 on page 5A.60.

      2) Dewatering the sediment is not required but some local ordinances may require some methods to dewater the basin and facilitate the cleanout process. One very successful means of doing this is by use of a dewatering device.

   D. Anti-vortex device and trash rack: An anti-vortex device and trash rack shall be securely installed on top of the riser and shall be the concentric type as shown in Figure 5A.31 on pages 5A.61 and 5A.62.

   E. Base: The riser shall have a base attached with a watertight connection and shall have sufficient weight to prevent flotation of the riser. Two approved bases for risers ten feet or less in height are: 1) a concrete base 18 in. thick with the riser embedded 9 in. in the base, and 2) a 1/4 in. minimum thickness steel plate attached to the riser by a continuous weld around the circumference of the riser to form a watertight connection. The plate shall have 2.5 feet of stone, gravel, or compacted earth placed on it to prevent flotation. In either case, each side of the square base shall be twice the riser diameter.

   For risers greater than ten feet high computations shall be made to design a base which will prevent flotation. The minimum factor of safety shall be 1.20 (Downward forces = 1.20 x upward forces). See Figure 5A.32 on page 5A.63 for details.

VOL 12 6100

F. Anti-Seep Collars: Anti-seep collars shall be installed around all conduits through earth fills of impoundment structures according to the following criteria:

1) Collars shall be placed to increase the seepage length along the conduit by a minimum of 15 percent of the pipe length located within the saturation zone.

2) Collar spacing shall be between 5 and 14 times the vertical projection of each collar.

3) All collars shall be placed within the saturation zone.

4) The assumed normal saturation zone (phreatic line) shall be determined by projecting a line at a slope of 4 horizontal to 1 vertical from the point where the normal water (riser crest) elevation touches the upstream slope of the fill to a point where this line intersects the invert of the pipe conduit. All fill located within this line may be assumed as saturated.

When anti-seep collars are used, the equation for revised seepage length becomes:

$$2(N)(P) = 1.15(L_s) \text{ or } N = (0.075)(L_s)/P$$

Where: L_s = Saturated length is length, in feet, of pipe between riser and intersection of phreatic line and pipe invert.

N = number of anti-seep collars.

P = vertical projection of collar from pipe, in feet.

5) All anti-seep collars and their connections shall be watertight.

See Figure 5A.33 on pages 5A.64 and 5A.65 for anti-seep collar design and Figure 5A.34 on page 5A.66 for construction details.

G. Outlet: An outlet shall be provided, including a means of conveying the discharge in an erosion free manner to an existing stable channel. Where discharge occurs at the property line, drainage easements will be obtained in accordance with local ordinances. Adequate notes and references will be shown on the erosion and sediment control plan.

Protection against scour at the discharge end of the pipe spillway shall be provided. Measures may include impact basin, riprap, revetment, excavated plunge pools, or other approved methods. See Standard and Specifications for Rock Outlet Protection, page 5B.21.

2. Emergency Spillways: The entire flow area of the emergency spillway shall be constructed in undisturbed ground (not fill). The emergency spillway cross-section shall be trapezoidal with a minimum bottom width of eight feet. This spillway channel shall have a straight control section of at least 20 feet in length; and a straight outlet section for a minimum distance equal to 25 feet.

A. Capacity: The minimum capacity of the emergency spillway shall be that required to pass the peak rate of runoff from the 10 year 24-hour frequency storm, less any reduction due to flow in the pipe spillway. Emergency spillway dimensions may be determined by using the method described in Figure 5A.35 on page 5A.67.

B. Velocities: The velocity of flow in the exit channel shall not exceed 5 feet per second for vegetated channels. For channels with erosion protection other than vegetation, velocities shall be within the non-erosive range for the type of protection used.

C. Erosion Protection: Erosion protection shall be provided for by vegetation as prescribed in this publication or by other suitable means such as riprap, asphalt or concrete.

D. Freeboard: Freeboard is the difference between the design high water elevation in the emergency spillway and the top of the settled embankment. If there is no emergency spillway it is the difference between the water surface elevation required to pass the design flow through the pipe and the top of the settled embankment. Freeboard shall be at least one foot.

Embankment Cross-Section

Class 1 Basins: The minimum top width shall be eight feet. The side slopes shall not be steeper than 2:1.

Class 2 Basins: The minimum top width shall be ten feet. The side slopes shall not be steeper than 2 1/2:1.

Entrance of Runoff Into Basin

Points of entrance of surface runoff into excavated sediment basins shall be protected to prevent erosion. Considerable care should be given to the major points of inflow into basins. In many cases the difference in elevation of the inflow and the bottom of the basin is considerable, thus creating a potential for severe gullying and sediment generation. Often a riprap drop at major points of inflow would eliminate gullying and sediment generation.

Diversions, grade stabilization structures or other water control devices shall be installed as necessary to insure direction of runoff and protect points of entry into the basin. Points of entry should be located so as to insure

VOL 12

6/01

maximum travel distance of entering runoff to point of exit (the riser) from the basin.

Disposal

The sediment basin plans shall indicate the method(s) of disposing of the sediment removed from the basin. The sediment shall be placed in such a manner that it will not erode from the site. The sediment shall not be deposited downstream from the basin, adjacent to a stream or floodplain. Disposal sites will be covered by an approved sediment control plan.

The sediment basis plans shall also show the method of disposing of the sediment basin after the drainage area is stabilized, and shall include the stabilization of the sediment basin site. Water contained within the storage area shall be removed from the basin by pumping, cutting the top of the riser, or other appropriate method prior to removing or breaching the embankment. Sediment shall not be allowed to flush into a stream or drainage way.

Safety

Sediment basins are attractive to children and can be very dangerous. Local ordinances and regulations must be adhered to regarding health and safety. The developer or owner shall check with local building officials on applicable safety requirements. If fencing of sediment basins is required, the location of and type of fence shall be shown on the plans.

Construction Specifications

Site Preparation

Areas under the embankment shall be cleared, grubbed, and stripped of topsoil to remove trees, vegetation, roots or other objectionable material. In order to facilitate cleanout and restoration, the pool area (measured at the top of the pipe spillway) will be cleared of all brush, trees, and other objectionable materials.

Cutoff-Trench

A cutoff trench shall be excavated along the centerline of earth fill embankments. The minimum depth shall be two feet. The cutoff trench shall extend up both abutments to the riser crest elevation. The minimum bottom width shall be four feet, but wide enough to permit operation of excavation and compaction equipment. The side slopes shall be no steeper than 1:1. Compaction requirements shall be the same as those for embankment. The trench shall be dewatered during the backfilling/compaction operations.

Embankment

The fill material shall be taken from approved areas shown on the plans. It shall be clean mineral soil free of roots, woody vegetation, oversized stones, rocks, or other objectionable material. Relatively pervious materials such as said or gravel (Unified Soil Classes GW, GP, SW & SP) shall not be placed in the embankment. Areas on which fill is to be placed shall be scarified prior to placement of fill. The fill material shall contain sufficient moisture so that it can be formed by hand into a ball without crumbling. If water can be squeezed out of a ball, it is too wet for proper compaction. Fill material shall be placed six inch to eight inch thick continuous layers over the entire length of the fill. Compaction shall be obtained by routing and hauling the construction equipment over the fill so that the entire surface of each layer of the fill is traversed by at least one wheel or tread track of the equipment or by the use of a compactor. The embankment shall be constructed to an elevation 10 percent higher than the design height to allow for settlement.

Pipe Spillway

The riser shall be securely attached to the barrel or barrel stub by welding the full circumference making a watertight structural connection. The barrel stub must be attached to the riser at the same percent (angle) of grade as the outlet conduit. The connection between the riser and the riser base shall be watertight. All connections between barrel sections must be achieved by approved watertight bank assemblies (See Figure 5A.36 on page 5A.69 for details). The barrel and riser shall be placed on a firm, smooth foundation of impervious soil. Pervious materials such as sand, gravel, or crushed stone shall not be used as backfill around the pipe or anti-seep collars. The fill material around the pipe spillway shall be placed in four inch layers and compacted under and around the pipe to at least the same density as the adjacent embankment.

A minimum depth of two feet of hand compacted backfill shall be placed over the pipe spillway before crossing it with construction equipment. Steel base plates on risers shall have at least 2 1/2 feet of compacted earth, stone or gravel placed over it to prevent flotation.

Emergency Spillway

The emergency spillway shall be installed in undisturbed ground. The achievement of planned elevations, grades, design width, entrance and exit channel slopes are critical to the successful operation of the emergency spillway and must be constructed within a tolerance of +/- 0.2.

Vegetative Treatment

Stabilize the embankment and emergency spillway in accordance with the appropriate vegetative standard and specification immediately following construction. In no case shall the embankment remain unstabilized for more than seven (7) days.

VOL 12

6/02

Erosion and Pollution Control

Construction operations shall be carried out in such a manner that erosion and water pollution will be minimized. State and local laws shall be complied with concerning pollution abatement.

Safety

State and local requirements shall be met concerning fencing and signs, warning the public of hazards of soft sediment and floodwater.

Maintenance

1. Repair all damages caused by soil erosion and construction equipment at or before the end of each working day.
2. Sediment shall be removed from the basin when it reaches the specified distance below the top of the riser. This sediment shall be placed in such a manner that it will not erode from the site. The sediment shall not be deposited downstream from the embankment, adjacent to a stream or floodplain.

Final Disposal

When temporary structures have served their intended purpose and the contributing drainage area has been properly stabilized, the embankment and resulting sediment deposits are to be leveled or otherwise disposed of in accordance with the approved sediment control plan. The proposed use of a sediment basin site will often dictate final disposition of the basis and any sediment contained therein. If the site is scheduled for future construction, then the basin material and trapped sediments must be removed, safely disposed of, and backfilled with a structural fill.

When the basin area is to remain open space the pond may be pumped dry, graded and back filled.

Information to be Submitted

Sediment Basin designs and construction plans submitted for review to a local Soil and Water Conservation District, or other agency shall include the following:

1. Specific location of the basin.
2. Plan view of the storage basin and emergency spillway, showing existing and proposed contours.
3. Cross section of dam, principal spillway and emergency spillway and profile of emergency spillway.
4. Details of pipe connections, riser to pipe connections, riser base, anti-seep collars, trash rack cleanout elevation and anti-vortex device.
5. Runoff calculations for 10 year frequency storm, if required.
6. Storage Computation
   A. Total required
   B. Total available
   C. Level of sediment at which cleanout shall be required; to be stated as a distance from the riser crest to the sediment surface.
7. Calculations showing design of pipe and emergency spillway.

Note: Items 5 through 7 above may be submitted using the design data sheet on pages 5A.52 through 5A.55.

TEMPORARY SEDIMENT BASIN DESIGN DATA SHEET INSTRUCTIONS FOR USE OF FORM

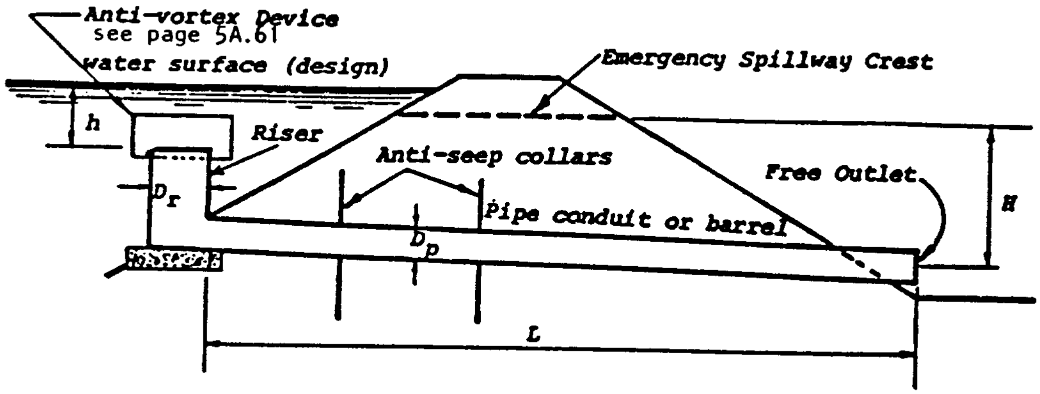
1. Minimum required detention volume is 67 cubic yards per acre from each acre of drainage area. Values larger than 67 cubic yards per acre may be used for greater protection. Compute volume using entire drainage area although only part may be disturbed.
2. The volume of a naturally shaped (no excavation in basin) basin may be approximated by the formula $V = (0.4)(A)(d)$, where V is in cubic feet, A is the surface area of the basin, in square feet, and d is the maximum depth of the basin, in feet. Volume may be computed from contour information or other suitable methods.
3. If volume of basin is not adequate for required storage, excavate to obtain the required volume.
4. The method described in Section 10 - TR-55 or the SCS Engineering Field Manual for Conservation Practices, Chapter 2, are the preferred methods for runoff computation. If rational method is used to compute runoff, obtain appropriate values for "I" and "C", depending on watershed conditions during development.
5. Required discharge from pipe spillway equals 0.2 cfs/ac. times total drainage area. (This is equivalent to a uniform runoff of 5 in. per 24 hours). The pipe shall be designed to carry Q_p if site conditions preclude installation of an emergency spillway to protect the structure.
6. Determine value of "H" from field conditions; "H" is interval between the centerline of the outlet pipe and the emergency spillway crest or if there is no emergency spillway, to the design high water.
7. See Pipe Spillway Design Charts, Figures 5A.28 and 5A.29 on pages 5A.58 and 5A.59.
8. See Riser Inflow Curves, Figure 5A.27 on page 5A.57.
9. See Trash Rack and Anti-Vortex Device Design, Figures 5A.31 on page 5A.61.
10. Compute Q_{es} by subtracting actual flow carried by the pipe spillway from the total inflow, Q_p.
11. Use appropriate tables to obtain values of H_p, bottom width, and actual Q_{es}. If no emergency spillway is to be used, so state, giving reason(s).
12. See Anti-Seep Collar Design.
13. Fill in design elevations. The emergency spillway crest must be set no closer to riser crest than value of h which causes pipe spillway to carry the minimum required Q. Therefore, the elevation difference between spillways shall be equal to the value of h, or one foot, whichever is greater. Design high water is the elevation of the emergency spillway crest plus the value of Hp, or if there is no emergency spillway, it is the elevation of the riser crest plus h required to handle the 10 year storm. Minimum top of dam elevation requires 1.0 ft. of freeboard above design high water.

VOL 12

6/05

R0039413

PIPE SPILLWAY DESIGN



H = Head on pipe spillway (pipe flow), ft. (centerline of outlet to emergency spillway crest or to design high water if no emergency spillway)

h = Head over riser crest, ft.

L = Length of pipe in ft.

D_p = Diameter of pipe conduit (barrel)

Dr = Diameter of riser

To use charts for pipe spillway design:

- Enter chart, Figures 5A.28 and 5A.29 on pages 5A.58 and 5A.59 with H and required discharge.
- Find diameter of pipe conduit that provides equal or greater discharge
- Enter chart, Figure 5A.27 on page 5A.57 with actual pipe discharge. Read across to select smallest riser that provides discharge within weir flow portion of rating curve. Read down to find corresponding h required.

Example:

Given: Q (required) = 5.8 cfs, L = 60 ft., H = 9 ft. to centerline of pipe = Free outlet

Find: Pipe size, actual Q and size of riser

Q of 12 in. pipe = 6.0 cfs x (correction factor) 1.07 = 6.4 cfs from the Pipe Flow Chart

From Riser Inflow Curves (Figure 5A.27 on page 5A.57), smallest riser = 18 in. (@ h = 0.6)

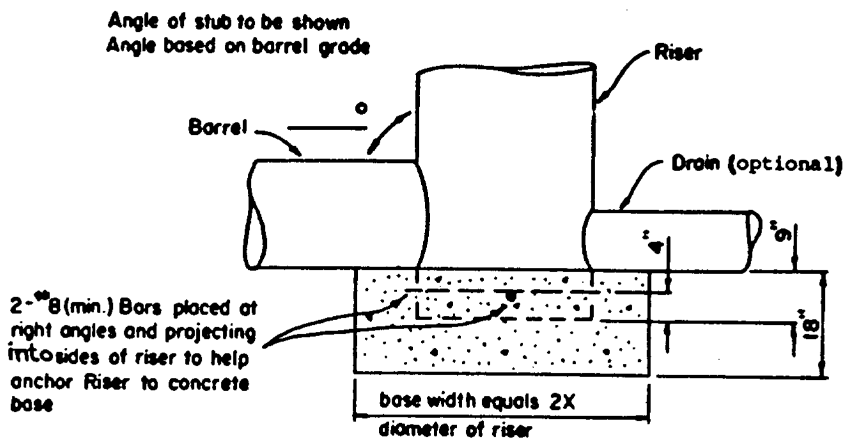
Note: The criteria for sizing the cylinder is that the area between the inside of the cylinder and the outside of the riser is equal to or greater than the area inside the riser. Therefore, the above table is invalid for use with concrete pipe risers.

Figure 5A.32
Riser Base Details



RISER BASE DETAIL

NOTES:

1. The concrete base shall be poured in such a manner to insure that the concrete fills the bottom of the riser to the invert of the outlet pipe to prevent the riser from breaking away from the base.

2. With aluminum or aluminized pipe, the embedded section must be painted with zinc chromate or equivalent.

3. Riser baser may be sized as computed using floatation with a factor of safety of 1.2.

Figure 5A.33 (1)
Anti-Seep Collar Design

This procedure provides the anti-seep collar dimensions for only temporary sediment basins to increase the seepage length by 15% for various pipe slopes, embankment slopes and riser heights.

The first step in designing anti-seep collars is to determine the length of pipe within the saturated zone of the embankment. This can be done graphically or by the following equation, assuming that the upstream slope of the embankment intersects the invert of the pipe at its upstream end. (See embankment-invert intersection on the drawing below:

$$L_s = y\,(z + 4)\left[1 + \frac{\text{pipe slope}}{0.25-\text{pipe slope}}\right]$$

Where: L_s = length of pipe in the saturated zone (ft.)

y = distance in feet from upstream invert of pipe to highest normal water level expected to occur during the life of the structure, usually the top of the riser.

z = slope of upstream embankment as a ratio of z ft. horizontal to one ft. vertical.

pipe slope = slope of pipe in feet per foot.

This procedure is based on the approximation of the phreatic line as shown in the drawing below:

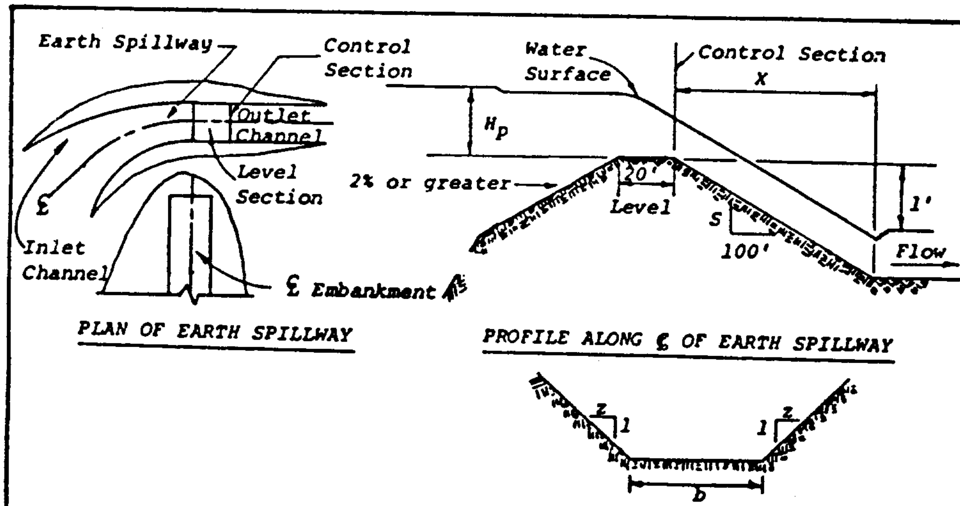
Figure 5A.35 (1)
Design Data for Earth Spillways



PLAN OF EARTH SPILLWAY

PROFILE ALONG ℄ OF EARTH SPILLWAY

CROSS SECTION OF EARTH SPILLWAY AT CONTROL SECTION

LEGEND

n = Manning's Coefficient of Roughness.
H_p = Difference in Elevation between Crest of Earth Spillway at the Control Section and Water Surface in Reservoir, in feet.
b = Bottom Width of Earth Spillway at the Control Section, in feet.
Q = Total Discharge, in cfs.
V = Velocity, in feet per second, that will exist in Channel below Control Section, at Design Q, if constructed to slope (S) that is shown.
S = Flattest Slope (S), in %, allowable for Channel below Control Section.
X = Minimum Length of Channel below Control Section, in feet.
z = Side Slope Ratio.

NOTES:

1) For a given H_p a decrease in the exit slope from S as given in the table decreases spillway discharge but increasing the exit slope from S does not increase discharge. If an exit slope (S_e) steeper than S is used, then velocity (V_e) in the exit channel will increase according to the following relationship:

$$V_e = V\left(\frac{S_e}{S}\right)^{0.3}$$

2) Data to right of heavy vertical lines on drawings should be used with caution, as the resulting sections will be either poorly proportioned or have velocities in excess of 6 ft/sec.

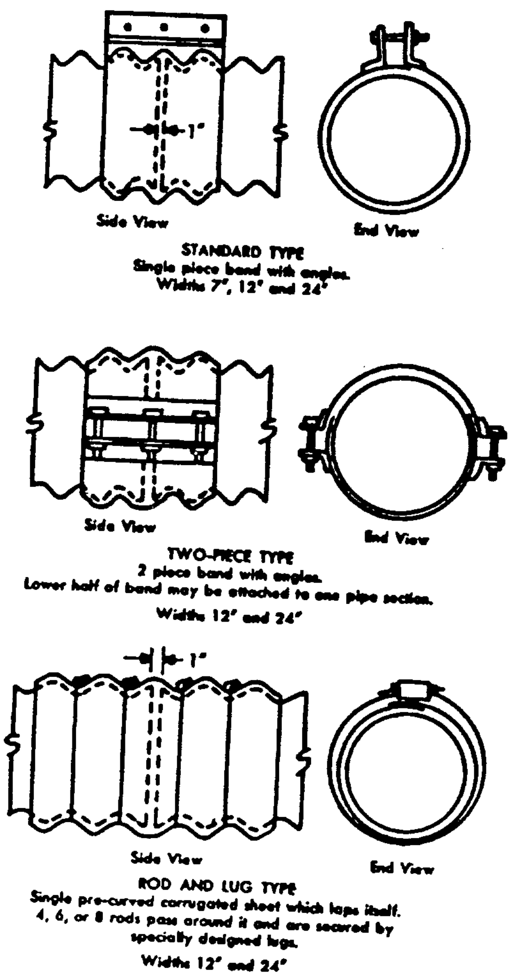
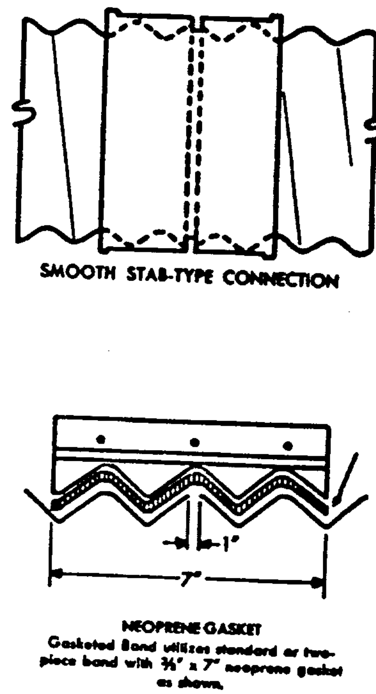
Figure 5A.36
Corrugated Steel Pipe Couplers





Note: Under no circumstance will the dimple (universal) connector be acceptable for use in any sediment control or stormwater management structure.

(All connector bands require neoprene gaskets.)

Procedure for Determining or Altering Sediment Basin Shape

As specified in the Standard and Specification, the pool area at the elevation of crest of the principal spillway shall have a length to width ratio of at least 2.0 to 1. The purpose of this requirement is to minimize the "short circuiting" effect of the sediment laden inflow to the riser and thereby increase the effectiveness of the sediment basin. The purpose of this procedure is to prescribe the parameters, procedures and methods of determining and modifying the shape of the basin.

The length of the flow path (L) is the distance from the point of inflow to the riser (outflow point). The point of inflow is the point that the stream enters the normal pool (pool level at the riser crest elevation). The pool area (A) is the area of the normal pool. The effective width (W_e) is found by the equation:

$$We = A/L \text{ and } L:W \text{ ratio} = L/W_e$$

In the event there is more than one inflow point, any inflow point which conveys more than 30 percent of the total peak inflow rate shall meet the length to width ratio criteria.

The required basin shape may be obtained by proper site selection, by excavation or by constructing a baffle in the basin. The purpose of the baffle is to increase the effective flow length from the inflow point to the riser. Baffles shall be placed midway between the inflow point and the riser. The baffle length shall be as required to provide the minimum 2:1 length width ratio. The effective length (L_e) shall be the shortest distance the water must flow from the inflow point around the end of the baffle to the outflow point. Then:

$$W_e = A/L_e \text{ and } L:W \text{ ratio} = L_e/W_e$$

Three examples are shown on the following page. Note that for the special case in example C the water is allowed to go around both ends of the baffle and the effective length, $L_e = L_1 + L_2$. Otherwise, the length to width ratio computations are the same as shown above. This special case procedure for computing Le is allowable only when the two flow paths are equal, i.e., when $L_1 = L_2$. A baffle detail is also shown in Figure 5A.37 on page 5A.71.

STANDARD AND SPECIFICATIONS FOR STABILIZED CONSTRUCTION ENTRANCE

Definition

A stabilized pad of aggregate underlain with filter cloth located at any point where traffic will be entering or leaving a construction site to or from a public right-of-way, street, alley, sidewalk or parking area.

Purpose

The purpose of stabilized construction entrance is to reduce or eliminate the tracking of sediment onto public rights-of-way or streets.

Conditions Where Practice Applies

A stabilized construction entrance shall be used at all points of construction ingress and egress.

Design Criteria

See Figure 5A.38 on page 5A.74 for details.

Aggregate Size: Use 2 in. stone, or reclaimed or recycled concrete equivalent.

Thickness: Not less than six (6) inches.

Width: 12 foot minimum but not less than the full width of points where ingress or egress occurs. 24 foot minimum if there is only one access to the site.

Length: As required, but not less than 50 feet (except on a single residence lot where a 30 foot minimum would apply).

Filter cloth: To be placed over the entire area to be covered with aggregate. Filter cloth will not be required on a single family residence lot. Piping of surface water under entrance shall be provided as required. If piping is impossible, a mountable berm with 5:1 slopes will be permitted.

Criteria for Filter Cloth

The filter cloth shall be woven or nonwoven fabric consisting only of continuous chain polymeric filaments or yarns of polyester. The fabric shall be inert to commonly encountered chemicals, hydro-carbons, mildew, rot resistant, and conform to the fabric properties as shown:

Fabric Properties[3]	Light Duty[1] Roads Grade Subgrade	Heavy Duty[2] Haul Roads Rough Graded	Test Method
Grab Tensile Strength (lbs)	200	220	ASTM D1682
Elongation at Failure (%)	50	60	ASTM D1682
Mullen Brust Strength (lbs)	190	430	ASTM D3786
Puncture Strength (lbs)	40	125	ASTM D751 modified
Equivalent	40-80	40-80	US Std Sieve
Openning Size			CW-02215
Aggregate Depth (in)	6	10	–

[1] Light Duty Road: Area sites that have been graded to subgrade and where most travel would be single axle vehicles and an occasional multi-axle truck. Acceptable materials are Trevira Spunbond 1115, Mirafi IOOX, Typar 3401, or equivalent.

[2] Heavy Duty Road: Area sites with only rough grading, and where most travel would be multi-axle vehicles. Acceptable materials are Trevira Spunbond 1135, Miraft 600X, or equivalent.

[3] Fabrics not meeting these specifications may be used only when design procedure and supporting documentation are supplied to determine aggregate depth and fabric strength.

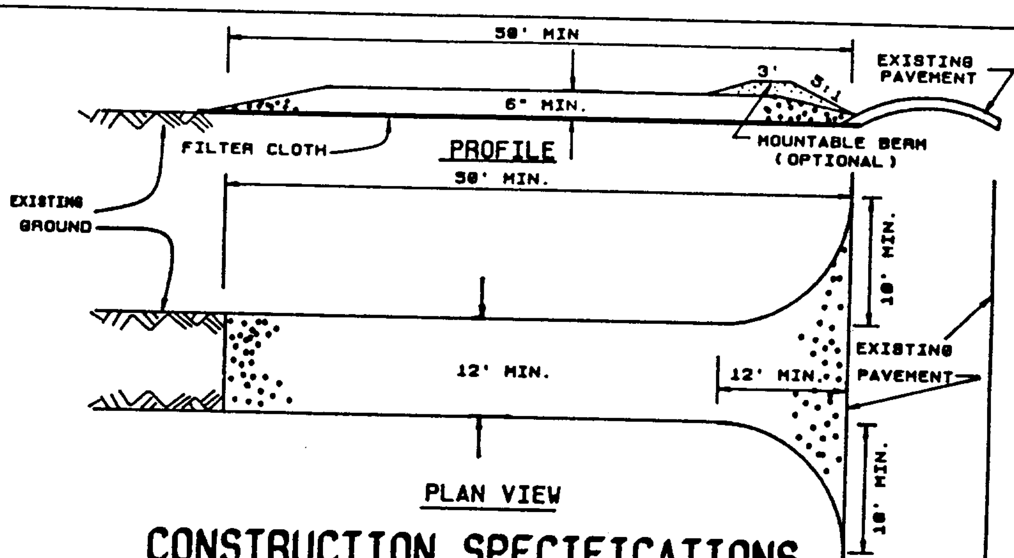
Maintenance

The entrance shall be maintained in a condition which will prevent tracking of sediment onto public rights-of-way or streets. This may require periodic top dressing with additional aggregate. All sediment spilled, dropped, or washed onto public rights-of-way must be removed immediately.

When necessary, wheels must be cleaned to remove sediment prior to entrance onto public rights-of-way. When washing is required, it shall be done on an area stabilized with aggregate which drains into an approved sediment trapping device. All sediment shall be prevented from entering storm drains, ditches, or watercourses.

VOL 12

Figure 5A.38
Stabilized Construction Entrance Details



CONSTRUCTION SPECIFICATIONS

1. STONE SIZE - USE 2" STONE, OR RECLAIMED OR RECYCLED CONCRETE EQUIVALENT.

2. LENGTH - NOT LESS THAN 50 FEET (EXCEPT ON A SINGLE RESIDENCE LOT WHERE A 30 FOOT MINIMUM LENGTH WOULD APPLY).

3. THICKNESS - NOT LESS THAN SIX (6) INCHES.

4. WIDTH - TWELVE (12) FOOT MINIMUM, BUT NOT LESS THAN THE FULL WIDTH AT POINTS WHERE INGRESS OR EGRESS OCCURS. TWENTY-FOUR (24) FOOT IF SINGLE ENTRANCE TO SITE.

5. FILTER CLOTH - WILL BE PLACED OVER THE ENTIRE AREA PRIOR TO PLACING OF STONE.

6. SURFACE WATER - ALL SURFACE WATER FLOWING OR DIVERTED TOWARD CONSTRUCTION ENTRANCES SHALL BE PIPED ACROSS THE ENTRANCE. IF PIPING IS IMPRACTICAL, A MOUNTABLE BERM WITH 5:1 SLOPES WILL BE PERMITTED.

7. MAINTENANCE - THE ENTRANCE SHALL BE MAINTAINED IN A CONDITION WHICH WILL PREVENT TRACKING OR FLOWING OF SEDIMENT ONTO PUBLIC RIGHTS-OF-WAY. ALL SEDIMENT SPILLED, DROPPED, WASHED OR TRACTED ONTO PUBLIC RIGHTS-OF-WAY MUST BE REMOVED IMMEDIATELY.

8. WHEN WASHING IS REQUIRED, IT SHALL BE DONE ON AN AREA STABILIZED WITH STONE AND WHICH DRAINS INTO AN APPROVED SEDIMENT TRAPPING DEVICE.

9. PERIODIC INSPECTION AND NEEDED MAINTENANCE SHALL BE PROVIDED AFTER EACH RAIN.

STANDARD AND SPECIFICATIONS FOR CONSTRUCTION ROAD STABILIZATION

Definition

The stabilization of temporary construction access routes, on-site vehicle transportation routes and construction parking areas.

Purpose

To control erosion on temporary construction routes and parking areas.

Condition Where Practice Applies

All traffic routes and parking areas for temporary use by construction traffic.

Design Criteria

Construction roads should be located to reduce erosion potential, minimize impact on existing site resources and maintain operations in a safe manner. Highly erosive soils, wet or rocky areas, and steep slopes should be avoided. Roads should be routed where seasonal water tables are deeper than 18 inches. Surface runoff and control should be in accordance with other standards.

Road Grade - A maximum grade of 12% is recommended, although grades up to 15% are possible for short distances.

Road Width - 14 foot minimum for one-way traffic or 24 foot minimum for two-way traffic

Side Slope of Road Embankment - 2:1 or flatter

Ditch capacity - On site roadside ditch and culvert capacities shall be the 10 yr. peak runoff.

Stone surface - Use a 6-inch course of NYS DOT base course or equivalent as specified in NYS - Standards and Specifications for Highways.

Construction Specifications

1. Clear and strip roadbed and parking areas of all vegetation, roots, and other objectionable material.
2. Locate parking areas on naturally flat areas as available. Keep grades sufficient for drainage but not more than 2 to 3%.
3. Provide surface drainage and divert excess runoff to stabilized areas.
4. Maintain cut and fill slopes to 2:1 or flatter and stabilize with vegetation as soon as grading is accomplished.
5. Spread 6-inch course of crushed stone evenly over the full width of the road smooth to avoid depressions.
6. Provide appropriate sediment control measures to prevent offsite sedimentation.

Maintenance

Inspect construction roads and parking areas periodically for condition of surface. Topdress with new gravel as needed. Check ditches for erosion and sedimentation after rainfall events. Maintain vegetation in a healthy, vigorous condition. Areas producing sediment should be treated immediately.

VOL 12

6128

STANDARD AND SPECIFICATIONS FOR TEMPORARY ACCESS WATERWAY CROSSING

V O L 1 2

6 / 2 9

Definition

A temporary access waterway crossing is a structure placed across a waterway to provide access for construction purposes for a period of less than one year. Temporary access crossings shall not be utilized to maintain traffic for the general public.

Purpose

The purpose of the temporary access waterway crossing is to provide safe, environmentally sound access across a waterway for construction equipment by establishing minimum standards and specifications for the design, construction, maintenance, and removal of the structure. Temporary access waterway crossings are necessary to prevent construction equipment from damaging the waterway, blocking fish migration, and tracking sediment and other pollutants into the waterway. This standard and specification may represent a channel constriction thus the temporary nature of waterway access crossings must be stressed. They should be planned to be in service for the shortest practical period of time and removed as soon as their function is completed.

Conditions Where Practice Applies

The following standard and specification for temporary access waterway crossings are applicable in non-tidal waterways. These standard and specifications provide designs based on waterway geometry rather than the drainage area contributing to the point of crossing.

The principal consideration for development of the standard and specifications is concern for erosion and sediment control. Structural utility and safety must also be considered when designing temporary access waterway crossings to withstand expected loads.

The three types of standard temporary access waterway crossings are bridges, culverts, and fords.

General Requirements

1. In-Stream Excavation: In-Stream excavation shall be limited to only that necessary to allow installation of the standard methods as presented in Subsection "Temporary Access Waterway Crossing Methods."
2. Elimination of Fish Migration Barriers: Of the three basic methods presented in Subsection "Temporary Access Waterway Crossing Methods", bridges pose the least potential for creating barriers to aquatic migration. The construction of any specific crossing method as presented in Subsection "Temporary Access Waterway Crossing Methods", shall not cause a significant water level difference between the upstream and downstream water surface elevations. Fish spawning or migration within waterways is from October 1 to April 30 for water classified for trout and from March 15 to June 15 for other streams.
3. Crossing Alignment: The temporary waterway crossing shall be at right angles to the stream. Where approach conditions dictate, the crossing may vary 15 degrees from a line drawn perpendicular to the centerline of the stream at the intended crossing location.
4. Road Approaches: The centerline of both roadway approaches shall coincide with the crossing alignment centerline for a minimum distance of 50 feet from each bank of the waterway being crossed. If physical or right-of-way restraints preclude the 50 feet minimum, a shorter distance may be provided. All fill materials associated with the roadway approach shall be limited to a maximum height of 2 feet above the existing flood plain elevation.
5. Surface Water Diverting Structure: A water diverting structure such as a swale shall be constructed (across the roadway on both roadway approaches) 50 feet (maximum) on either side of the waterway crossing. This will prevent roadway surface runoff from directly entering the waterway. The 50 feet is measured from the top of the waterway bank. Design criteria for this diverting structure shall be in accordance with the "Standard and Specification" for the individual design standard of choice. If the roadway approach is constructed with a reverse grade away from the waterway, a separate diverting structure is not required.
6. Road Width: All crossings shall have one traffic lane. The minimum width shall be 12 feet with a maximum width of 20 feet.
7. Time of Operation: All temporary crossings shall be removed within 14 calendar days after the structure is no longer needed. Unless prior written approval is obtained, all structures shall be removed within one year from the date of the installation.
8. Materials

   A. Aggregate: There shall be no earth or soil materials used for construction within the waterway channel. New York State Department of Transportation specifications coarse aggregate designation No. 4 (3/4" to 4") also referenced as AASHTO designation No. 1 shall be the minimum acceptable aggregate size for temporary crossings. Larger aggregates will be allowed.

B. Filter Cloth: Filter cloth is a fabric consisting of either woven or nonwoven plastic, polypropylene, or nylon used to distribute the load, retain fines, allow increased drainage of the aggregate and reduce mixing of the aggregate with the subgrade soil. Filter cloths such as Mirafi, Typar, Adva Filter, Polyfilter X, or approved equivalent shall be used, as required by the specific method.

Temporary Access Waterway Crossing Methods

The following criteria for erosion and sediment control shall be considered when selecting a specific temporary access waterway crossing standard method:

1. Site aesthetics: Select a standard design method that will least disrupt the existing terrain of the stream reach. Consider the effort that will be required to restore the area after the temporary crossing is removed.
2. Site location: Locate the temporary crossing where there will be the least disturbance to the soils of the existing waterway banks. When possible locate the crossing at a point receiving minimal surface runoff.
3. Physical site constraints: The physical constraints of a site may preclude the selection of one or more of the standard methods.
4. Time of year: The time of year may preclude the selection of one or more of the standard methods due to fish spawning or migration restrictions.
5. Vehicular loads and traffic patterns: Vehicular loads, traffic patterns, and frequency of crossings should be considered in choosing a specific method.
6. Maintenance of crossing: The standard methods will require various amounts of maintenance. The bridge method should require the least maintenance whereas the ford method will probably require more intensive maintenance.
7. Removal of the structure: Ease of removal and subsequent damage to the waterway should be primary factors in considering the choice of a standard method.

Temporary Access Bridge (Figure 5A.39 on page 5A.82)

A temporary access bridge is a structure made of wood, metal, or other materials which provides access across a stream or waterway.

Considerations

1. Preferred Method. This is the preferred method for temporary access waterway crossings. Normally, bridge construction causes the least disturbance to the waterway bed and banks when compared to the other access waterway crossings.
2. Most bridges can be quickly removed and reused.
3. Temporary access bridges pose the least chance for interference with fish migration when compared to the other temporary access waterway crossings.
4. Restrictions and Permits: A permit from the New York State department of Environmental Conservation, Division of Regulatory Affairs, Regional Permit Administrator, will be needed to install and remove temporary access culverts in streams with a classification of C(T) and higher. Installation and removal may not be permitted during the period of time from the start of trout spawning until the eggs have hatched. In some instances, restrictions may also be applied to bass spawning waters.

Construction Specifications

1. Restriction: Construction, use, or removal of a temporary access bridge will not normally have any time of year restrictions since construction, use or removal should not affect the stream or its banks.
2. Bridge Placement: A temporary bridge structure shall be constructed at or above bank elevation to prevent the entrapment of floating materials and debris.
3. Abutments: Abutments shall be placed parallel to and on stable banks.
4. Bridge Span: Bridges shall be constructed to span the entire channel. If the channel width exceeds 8 feet (as measured from top-of-bank to top-of-bank) then a footing, pier or bridge support may be constructed within the waterway. One additional footing, pier or bridge support will be permitted for each additional 8 foot width of the channel. However, no footing, pier or bridge support will be permitted within the channel for waterways less than 8 feet wide.
5. Stringers: Stringers shall either be logs, sawn timber, prestressed concrete beams, metal beams, or other approved materials.
6. Deck Material: Decking shall be of sufficient strength to support the anticipated load. All decking members shall be placed perpendicular to the stringers, butted tightly, and securely fastened to the stringers. Decking materials must be butted tightly to prevent any soil material tracked onto the bridge from falling into the waterway below.
7. Run Planks (optional): Run planking shall be securely fastened to the length of the span. One run plank shall be provided for each track of the equipment wheels.

Although run planks are optional, they may be necessary to properly distribute loads.

8. Curbs or Fenders: Curbs or fenders may be installed along the outer sides of the deck. Curbs or fenders are an option which will provide additional safety.

9. Bridge Anchors: Bridges shall be securely anchored at only one end using steel cable or chain. Anchoring at only one end will prevent channel obstruction in the event that floodwaters float the bridge. Acceptable anchors are large trees, large boulders, or driven steel anchors. Anchoring shall be sufficient to prevent the bridge from floating downstream and possibly causing an obstruction to the flow.

10. Stabilization: All areas disturbed during installation shall be stabilized within 14 calendar days of that disturbance in accordance with the Standard and Specifications for Critical Area Seeding on page 3.3.

Bridge Maintenance Requirements

1. Inspection: Periodic inspection shall be performed by the user to ensure that the bridge, streambed and stream banks are maintained and not damaged.
2. Maintenance: Maintenance shall be performed, as needed to ensure that the structure compiles with the standard and specifications. This shall include removal and disposal of any trapped sediment or debris. Sediment shall be disposed of outside of the flood plain and stabilized.

Bridge Removal and Clean-Up Requirements

1. Removal: When the temporary bridge is no longer needed, all structures including abutments and other bridging materials shall be removed within 14 calendar days. In all cases, the bridge materials shall be removed within one year of installation.
2. Final Clean-Up: Final clean-up shall consist of removal of the temporary bridge from the waterway, protection of banks from erosion, and removal of all construction materials. All removed materials shall be stored outside the waterway flood plain.
3. Method: Removal of the bridge and clean-up of the area shall be accomplished without construction equipment working in the waterway channel.
4. Final Stabilization: All areas disturbed during removal shall be stabilized within 14 calendar days of that disturbance in accordance with the Standard and Specifications for Critical Area Seedings on page 3.3.

Temporary Access Culvert (Figure 5A.40 on page 5A.83)

A temporary access culvert is a structure consisting of a section(s) of circular pipe, pipe arches, or oval pipes of reinforcing concrete, corrugated metal, or structural plate, which is used to convey flowing water through the crossing.

Considerations

1. Temporary culverts are used where a) the channel is too wide for normal bridge construction, b) anticipated loading may prove unsafe for single span bridges, or c) access is not needed from bank to bank.
2. This temporary waterway crossing method is normally preferred over a ford type of crossing, since disturbance to the waterway is only during construction and removal of the culvert.
3. Temporary culverts can be salvaged and reused.

Construction Specifications

1. Restrictions and Permits: A permit from the New York State department of Environmental Conservation, Division of Regulatory Affairs, Regional Permit Administrator, will be needed to install and remove temporary access culverts in streams with a classification of C(T) and higher. Installation and removal may not be permitted during the period of time from the start of trout spawning until the eggs have hatched. In some instances, restrictions may also be applied to bass spawning waters.

   Critical periods are as follows:

   Rainbow Trout: Early spring to early summer (March 15 - July 1)[1]

   Brook and Brown Trout: Early fall to late spring (Oct. 1 - June 1)[1]

   Bass: Late spring to midsummer (May 15 - July 30)[1]

[1] Dates cover Statewide application. Locally, the period may be shorter.

2. Culvert Strength: All culverts shall be strong enough to support their cross sectional area under maximum expected loads.
3. Culvert Size: The size of the culvert pipe shall be the largest pipe diameter that will fit into the existing channel without major excavation of the waterway channel or without major approach fills. If a channel width exceeds 3 feet, additional pipes may be used until the cross sectional area of the pipes is greater than 60 percent of the cross sectional area of the existing channel. The minimum size culvert that may be used is 12 inch diameter pipe.
4. Culvert Length: The culvert(s) shall extend a minimum of one foot beyond the upstream and downstream toe of the aggregate placed around the culvert. In no case shall the culvert exceed 40 feet in length.

VOL 12

6/3/1

5. Filter Cloth: Filter cloth shall be placed on the streambed and streambanks prior to placement of the pipe culvert(s) and aggregate. The filter cloth shall cover the streambed and extend a minimum six inches and a maximum one foot beyond the end of the culvert and bedding material. Filter cloth reduces settlement and improves crossing stability.

6. Culvert Placement: The invert elevation of the culvert shall be installed on the natural streambed grade to minimize interference with fish migration (free passage of fish).

7. Culvert Protection: The culvert(s) shall be covered with a minimum of one foot of aggregate. If multiple culverts are used they shall be separated by at least 12 in. of compacted aggregate fill. At the minimum, the bedding and fill material used in the construction of the temporary access culvert crossings shall conform with the aggregate requirements cited in the General Requirements subsection.

8. Stabilization: All areas disturbed during culvert installation shall be stabilized within 14 calendar days of the disturbance in accordance with the Standard for "Critical Area Stabilization With Permanent Seeding."

Culvert Maintenance Requirements

1. Inspection: Periodic inspection shall be performed to ensure that the culverts, streambed, and streambanks are not damaged, and that sediment is not entering the stream or blocking fish passage or migration.

2. Maintenance: Maintenance shall be performed, as needed in a timely manner to ensure that structures are in compliance with this standard and specification. This shall include removal and disposal of any trapped sediment or debris. Sediment shall be disposed of and stabilized outside the waterway flood plain.

Culvert Removal and Clean-Up Requirements

1. Removal: When the crossing has served its purpose, all structures including culverts, bedding and filter cloth materials shall be removed within 14 calendar days. In all cases, the culvert materials shall be removed within one year of installation. No structure shall be removed during the spawning season (March 15 through June 15).

2. Final Clean-up: Final clean-up shall consist of removal of the temporary structure from the waterway, removal of all construction materials, restoration of original stream channel cross section, and protection of the streambanks from erosion. Removed material shall be stored outside of the waterway flood plain.

3. Method: Removal of the structure and clean-up of the area shall be accomplished without construction equipment working in the waterway channel.

4. Final Stabilization: All areas disturbed during culvert removal shall be stabilized within 14 calendar days of the disturbance in accordance with the Standard for "Critical Area Stabilization with Permanent Seeding."

Temporary Access Ford (Figure 5A.41 on page 5A.84)

A temporary access ford is a shallow structure placed in the bottom of a waterway over which the water flows while still allowing traffic to cross the waterway.

Considerations

Temporary fords may be used when the streambanks are less than four (4) feet above the invert of the stream, and the streambed is armored with naturally occurring bedrock, or can be protected with an aggregate layer in conformance with these specifications.

Construction Specifications

1. Restrictions and Permits: A permit from New York State department of Environmental Conservation, Division of Regulatory Affairs, Regional Permit Administrator, will be needed to install, use, and remove temporary fords in streams with a classification of C(T) or higher. Installation, use and removal may not be permitted during the period of time from the start of trout spawning until the eggs have hatched. In some instances, restrictions may also be applied to bass spawning waters.

   Current periods are as follows:

   Rainbow Trout: Early spring to early summer (March 15 - July 1)[1]

   Brook and Brown Trout: Early fall to late spring (Oct. 1 - June 1)[1]

   Bass: Late spring to midsummer (May 15 - July 30)[1]

[1] Dates cover Statewide application. Locally, the period may be shorter.

2. The approaches to the structure shall consist of stone pads constructed to comply with the aggregate requirements of the General Requirements subsection.

   The entire ford approach (where banks were cut) shall be covered with filter cloth and protected with aggregate to a depth of four (4) inches.

3. Fords shall be prohibited when the stream banks are four (4) feet or more in height above the invert of the stream.

VOL 12

6/32

4. The approach roads at the cut banks shall be no steeper than 5:1. Spoil material from the banks shall be stored out of the flood plain and stabilized.

5. One layer of filter cloth shall be placed on the streambed, streambanks and road approaches prior to placing the bedding material on the stream channel or approaches. The filter cloth will be a minimum of six (6) inches and a maximum one foot beyond bedding material.

6. The bedding material shall be coarse aggregate or gabion mattresses filled with coarse aggregate.

7. Aggregate used in ford construction shall meet the minimum requirements of the General Requirements subsection.

8. All fords shall be constructed to minimize the blockage of stream flow and shall allow free flow over the ford. The placing of any material in the waterway bed will cause some upstream ponding. The depth of this ponding will be equivalent to the depth of the material placed within the stream and therefore should be kept to a minimum height. However, in no case will the bedding material be placed deeper than 12 inches or one-half (1/2) the height of the existing banks whichever is smaller.

9. Stabilization: All areas disturbed during ford installation shall be stabilized within 14 calendar days of that disturbance in accordance with the Standard and Specifications for Critical Area Seeding on page 3.3.

10. Ford Removal and Clean-Up Requirements

A. Removal: When the temporary structure has served its purpose, excess material used for this structure need not be removed. Care should be taken so that any aggregate left does not create an impoundment or restrict fish passage.

B. Final Clean-Up: Final clean-up shall consist of removal of excess temporary ford materials from the waterway. All materials shall be stored outside the waterway flood plain.

C. Method: Clean up shall be accomplished without construction equipment working in the stream channel.

D. Approach Disposition: The approach slopes of the cut banks shall not be backfilled.

E. Final Stabilization: All areas disturbed during ford removal shall be stabilized within 14 calendar days of that disturbance in accordance with the Standard and Specifications for Critical Area Seeding on page 3.3.

NOTE: Any temporary access crossing shall conform to the technical requirements of this Standard and Specifications as well as any specific requirement imposed by the New York State Department of Environmental Conservation.

STANDARD AND SPECIFICATIONS FOR DUST CONTROL

Definition

The control of dust resulting from land-disturbing activities.

Purpose

To prevent surface and air movement of dust from disturbed soil surfaces that may cause off-site damage, health hazards, and traffic safety problems.

Conditions Where Practice Applies

On construction roads, access points, and other disturbed areas subject to surface dust movement and dust blowing where off-site damage may occur if dust is not controlled.

Design Criteria

Construction operations should be scheduled to minimize the amount of area disturbed at one time. Buffer areas of vegetation should be left where practical. Temporary or permanent stabilization measures should be installed. No specific design criteria is given; see construction specifications below for common methods of dust control.

Construction Specifications

Vegetative Cover - For disturbed areas not subject to traffic; vegetation provides the most practical method of dust control (see section 3).

Mulch (including gravel mulch) - Mulch offers a fast effective means of controlling dust.

Spray adhesives - Examples of spray adhesives for use on mineral soils are shown in the following table:

Material	Water Dilution	Type of Nozzle	Apply Gallons/Acre
Acrylic polymer	9:1	coarse spray	500
Latex emulsion	12.5:1	fine spray	235
Resin in water	4:1	fine spray	300

Water quality should be considered when materials are selected for dust control.

Sprinkling - The site may be sprayed until the surface is wet. This is especially effective on haul roads and access routes.

Stone used for construction roads is also effective for dust control.

Barriers - a fence or similar barrier can control air currents at intervals equal to fifteen times the barrier height. Preserve existing wind barrier vegetation as much as practical.

Maintenance

Maintain dust control measures through dry weather periods until all disturbed areas are stabilized.

STANDARD AND SPECIFICATIONS FOR SUMP PIT

Definition

A temporary pit which is constructed to trap and filter water for pumping to a suitable discharge area.

Purpose

To remove excessive water from excavations.

Conditions Where Practice Applies

Sump pits are constructed when water collects during the excavation phase of construction. This practice is particularly useful in urban areas during excavation for building foundations.

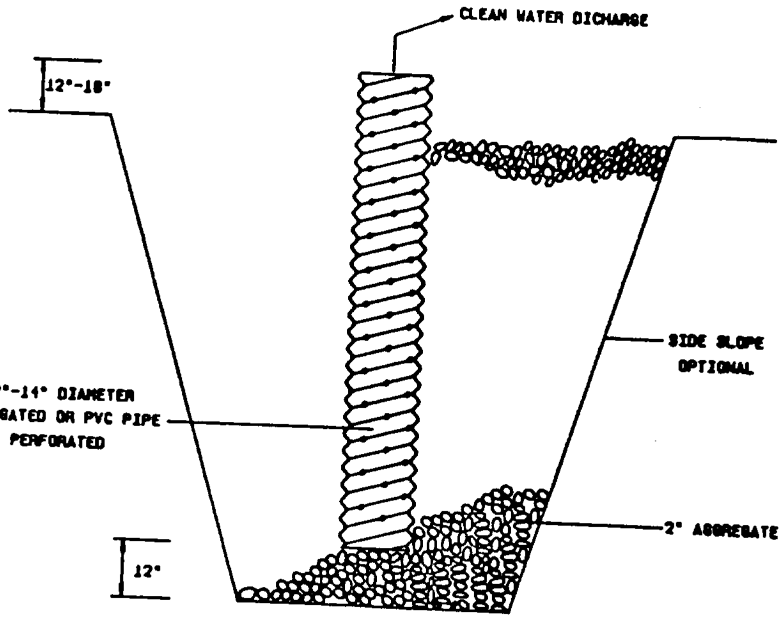
Design Criteria

The number of sump pits and their locations shall be determined by the contractor. A design is not required but construction should conform to the general criteria outlined on Figure 5A.42 on page 5A.88.

A perforated vertical standpipe is placed in the center of the pit to collect filtered water. Water is then pumped from the center of the pipe to a suitable discharge area.

Discharge of water pumped from the standpipe should be to a sediment trap, sediment basin or stabilized area. If water from the sump pit will be pumped directly to a storm drain system, filter cloth (Mirafi 100 X, Poly Filter GB or a filter cloth with an equivalent sieve size between 40-80) should be wrapped around the standpipe to ensure clean water discharge. It is recommended that 1/4 to 1/2 inch hardware cloth be wrapped around and secured to the standpipe prior to attaching the filter cloth. This will increase the rate of water seepage into the standpipe.

Figure 5A.42
Sump Pit Details



CONSTRUCTION SPECIFICATIONS

1. PIT DIMENSIONS ARE OPTIONAL.
2. THE STANDPIPE SHOULD BE CONSTRUCTED BY PERFORATING A 12"-24" DIAMETER CORREGATED OR PVC PIPE.
3. A BASE OF 2" AGGREGATE SHOULD BE PLACED IN THE PIT TO A DEPTH OF 12". AFTER INSTALLING THE STANDPIPE, THE PIT SURROUNDING THE STANDPIPE SHOULD THEN BE BACKFILLED WITH 2" AGGREGATE.
4. THE STAND PIPE SHOULD EXTEND 12"-18" ABOVE THE LIP OF THE PIT.
5. IF DISCHARGE WILL BE PUMPED DIRECTLY TO A STORM DRAINAGE SYSTEM, THE STANDPIPE SHOULD BE WRAPPED WITH FILTERCLOTH BEFORE INSTALLATION.

   IF DESIRED, 1/4"-1/2" HARDWARE CLOTH MAY BE PLACED AROUND THE STANDPIPE, PRIOR TO ATTACHING THE FILTERCLOTH. THIS WILL INCREASE THE RATE OF WATER SEEPAGE INTO THE PIPE.

STANDARD AND SPECIFICATIONS FOR DIVERSION

Definition

A drainage way of parabolic or trapezoidal cross-section with a supporting ridge on the lower side that is constructed across the slope.

Purpose

The purpose of a diversion is to intercept and convey runoff to stable outlets at non-erosive velocities.

Conditions Where Practice Applies

Diversions are used where:

1. Runoff from higher areas is or has potential for damaging properties causing erosion, or interfering with or preventing the establishment of vegetation on lower areas.
2. Surface and/or shallow subsurface flow is damaging sloping upland.
3. The length of slopes needs to be reduced so that soil loss will be reduced to a minimum.

Diversions are only applicable below stabilized or protected areas. Avoid establishment on slopes greater than fifteen percent. Diversions should be used with caution on soils subject to slippage. Construction of diversions shall be in compliance with state drainage and water laws.

Design Criteria

Location

Diversion location shall be determined by considering outlet conditions topography, land use, soil type, length of slope, seep planes (when seepage is a problem), and the development layout.

Capacity

Peak rates of runoff values used in determining the capacity requirements shall be as outlined in Chapter 2, Estimating Runoff, Engineering Field Manual for Conservation Practices, Section 10 of this manual or by TR-55, Urban Hydrology for Small Watersheds.

The constructed diversion shall have capacity to carry, as a minimum, the peak discharge from a ten year frequency rainfall event with freeboard of not less than 0.3 of a foot.

Diversions designed to protect homes, schools, industrial buildings, roads, parking lots, and comparable high risk areas, and those designed to function in connection with other structures, shall have sufficient capacity to carry peak runoff expected from a storm frequency consistent with the hazard involved.

Cross Section

The diversion channel shall be parabolic or trapezoidal in shape. Parabolic Diversion design charts are provided in Figures 5B.2 through 5B.7 on pages 5B.4 to 5B.9. The diversion shall be designed to have stable side slopes. The side slopes shall not be steeper than 2:1 and shall be flat enough to insure ease of maintenance of the diversion and its protective vegetative cover.

The ridge shall have a minimum width of four feet at the design water elevation; a minimum of 0.3 of a foot freeboard and a reasonable settlement factor shall be provided.

Velocity and Grade

The permissible velocity for the specified method of stabilization will determine the maximum grade. Maximum permissible velocities of flow for the stated conditions of stabilization shall be as shown in Table 5B.1 on page 5B.2 of this standard.

Diversions are not usually applicable below high sediment producing areas unless land treatment practices or structural measures, designed to prevent damaging accumulations of sediment in the channels are installed with or before the diversions.

Outlets

Each diversion must have an adequate outlet. The outlet may be a grassed waterway, vegetated or paved area, grade stabilization structure, stable watercourse, or subsurface drain outlet. In all cases the outlet must convey runoff to a point where outflow will not cause damage. Vegetated outlets shall be installed before diversion construction, if needed, to insure establishment of vegetative cover in the outlet channel.

The design elevation of the water surface in the diversion shall not be lower than the design elevation of the water surface in the outlet at their junction when both are operating at design flow.

Stabilization

Diversions shall be stabilized in accordance with the appropriate Standard and Specification for Vegetative Practices (Section 3).

Construction Specifications

See Figure 5B.1 on page 5B.3 for details.

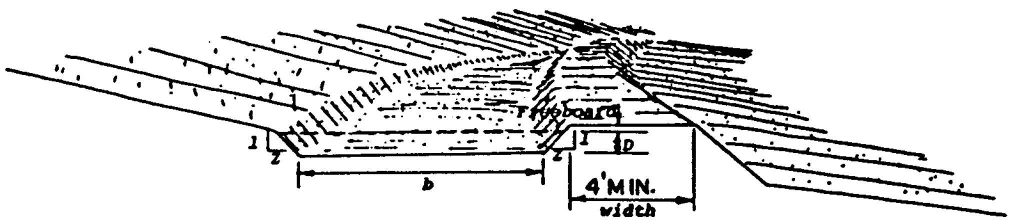
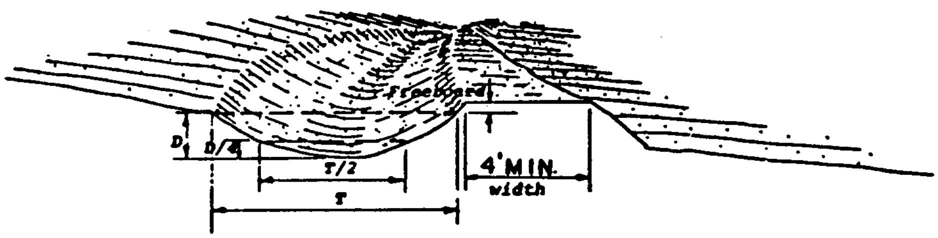
DIVERSION



TRAPEZOIDAL CROSS-SECTION



PARABOLIC CROSS-SECTION

Construction Specifications

1. All trees, brush, stumps, obstructions, and other objectionable material shall be removed and disposed of so as not to interfere with the proper functioning of the diversion.
2. The diversion shall be excavated or shaped to line, grade, and cross section as required to meet the criteria specified herein, and be free of irregularities which will impede normal flow.
3. Fills shall be compacted as needed to prevent unequal settlement that would cause damage in the completed diversion.
4. All earth removed and not needed in construction shall be spread or disposed of so that it will not interfere with the functioning of the diversion.
5. Stabilization shall be done according to the appropriate Standard and Specifications for Vegetative Practices.
   A. For design velocities of less than 3.5 ft. per sec., seeding and mulching may be used for the establishment of the vegetation. It is recommended that, when conditions permit, temporary diversions or other means be used to prevent water from entering the diversion during the establishment of the vegetation.
   B. For design velocities of more than 3.5 ft. per sec., the diversion shall be stabilized with sod, with seeding protected by jute or excelsior matting or with seeding and mulching including temporary diversion of water until the vegetation is established. See the Standard and Specifications for Protective Materials.

T = Top width, Retardance "C"
D = Flow depth, Retardance "C"
V_1 = Permissible velocity, Retardance "D"
V_2 = Velocity, Retardance "C"

T and D are the dimensions required to carry the design flow. Add freeboard and allowance for settlement as necessary.

STANDARD AND SPECIFICATIONS FOR GRASSED WATERWAY

Definition

A natural or man-made channel of parabolic or trapezoidal cross-section that is below adjacent ground level and is stabilized by suitable vegetation. The flow channel is normally wide and shallow and conveys the runoff down the slope.

Purpose

The purpose of a grassed waterway is to convey runoff without causing damage by erosion.

Conditions Where Practice Applies

Grass waterways are used where added vegetative protection is needed to control erosion resulting from concentrated runoff.

Design Criteria

Capacity

The minimum capacity shall be that required to confine the peak rate of runoff expected from a 10 year frequency rainfall event or a higher frequency corresponding to the hazard involved. This requirement for confinement may be waived on slopes of less than one (1) percent where out-of-bank flow will not cause erosion or property damage.

Peak rates of runoff values used in determining the capacity requirements shall be as outlined in Chapter 2, Estimating Runoff, Engineering Field Manual for Conservation Practices, Section 10 of this manual or by TR-55, Urban Hydrology for Small Watersheds.

Where there is base flow, it shall be handled by a stone center, subsurface drain, or other suitable means since sustained wetness usually prevents adequate vegetative cover. The cross-sectional area of the stone center or subsurface drain size to be provided shall be determined by using a flow rate of 0.1 cfs/acre or by actual measurement of the maximum base flow.

Velocity

Maximum permissible velocities (1) of flow shall not exceed the values shown:

Slope	Channel Lining	Permissible Velocity[1] (ft/sec.)
0-5%	Reed canarygrass	5
	Tall fescue	
	Kentucky bluegrass	
0-5% (cont'd)	Grass-legume mixture	4
	Red fescue	2.5
	Redtop	
	Sericea lespedeza	
	Annual lespedeza	
	Small grains	
5-10%	Reed canarygrass	4
	Tall fescue	
	Kentucky bluegrass	
	Grass-legume mixture	3

[1] For highly erodible soils, permissible velocities should be decreased 25%. An erodibility factor (K) greater than 0.35 would indicate a highly erodible soil. Erodibility factors (K factors) for New York soils are listed on the Soils 5 forms available in each SCS office.

Cross Section

The design water surface elevation of a grassed waterway receiving water from diversions or other tributary channels shall be equal to or less than the design water surface elevation in the diversion or other tributary channels.

The top width of parabolic waterways shall not exceed 30 feet and the bottom width of trapezoidal waterways shall not exceed 15 feet unless multiple or divided waterways, stone center, or other means are provided to control meandering of low flows.

Structural Measures

In cases where grade or erosion problems exist, special control measures may be needed such as stone centers, drop structures, or grade stabilization measures. Where needed, these measures will be supported by adequate design computations. For typical cross sections of waterways with riprap sections or stone centers, refer to Figure 5B.8 on page 5B.13.

The design procedures for parabolic and trapezoidal channels are available in the SCS Engineering Field Manual for Conservation Practices; Figure 5B.9 on page 5B.14 also provides a design chart for parabolic waterway.

Outlets

Each waterway shall have a stable outlet. The outlet may be another waterway, a stabilized open channel, grade stabilization structure, etc. In all cases, the outlet must discharge in such a manner as not to cause erosion. Outlets shall be constructed and stabilized prior to the operation of the waterway.

Stabilization

Waterways shall be stabilized in accordance with the appropriate vegetative stabilization standard and specifications.

Construction Specifications

See Figure 5B.10 on page 5B.15 for details

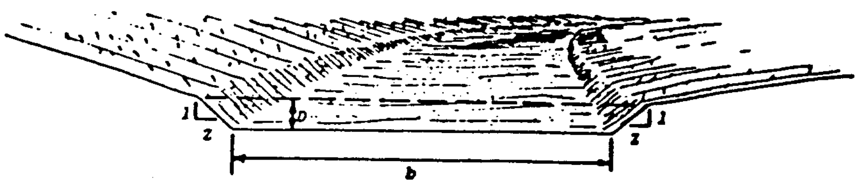
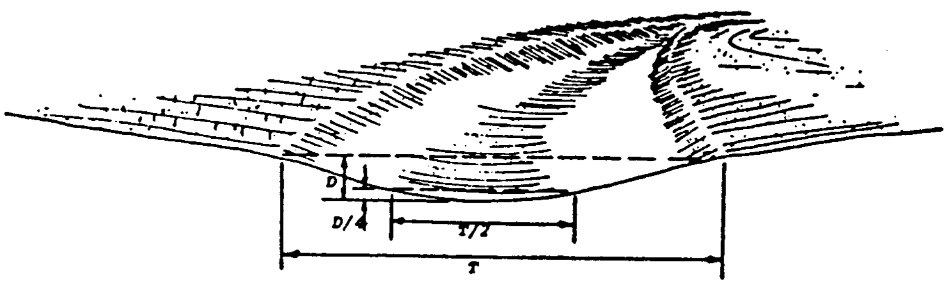
GRASSED WATERWAY



TRAPEZOIDAL CROSS-SECTION



PARABOLIC CROSS-SECTION

Construction Specifications

1. All trees, brush, stumps, obstructions, and other objectionable material shall be removed and disposed of so as not to interfere with the proper functioning of the waterway.
2. The waterway shall be excavated or shaped to line, grade, and cross section as required to meet the criteria specified herein, and be free of bank projections or other irregularities which will impede normal flow.
3. Fills shall be compacted as needed to prevent unequal settlement that would cause damage in the complete waterway.
4. All earth removed and not needed in construction shall be spread or disposed of so that it will not interfere with the functioning of the waterway.
5. Stabilization shall be done according to the appropriate Standard and Specifications for Vegetative Practices.
   A. For design velocities of less than 3.5 ft. per sec., seeding and mulching may be used for the establishment of the vegetation. It is recommended that, when conditions permit, temporary diversions or other means should be used to prevent water from entering the waterway during the establishment of the vegetation.
   B. For design velocities of more than 3.5 ft. per sec., the waterway shall be stabilized with sod, with seeding protected by jute or excelsior matting or with seeding and mulching including temporary diversion of the water until the vegetation is established.
   C. Structural - Vegetative Protection
      (1) Subsurface drain for base flow shall be constructed as shown on the Standard Drawing and as specified in the Standard and Specifications for Subsurface Drain.

VOL 12

STANDARD AND SPECIFICATIONS FOR LINED WATERWAY OR OUTLET

Definition

A waterway or outlet with a lining of concrete, stone, or other permanent material. The lined section extends up the side slopes to the designed depth. The earth above the permanent lining may be vegetated or otherwise protected.

Purpose

To provide for the disposal of concentrated runoff without damage from erosion or flooding where grassed waterways would be inadequate due to high velocities.

Scope

This standard applies to waterways or outlets with linings of cast-in-place concrete, flagstone mortared in place, rock riprap, gabions or similar permanent linings. It does not apply to irrigation ditch and canal linings, grassed waterways with stone centers or small lined sections to carry prolonged low flows, or to reinforced concrete channels. The maximum capacity of the waterway flowing at design depth shall not exceed 100 cubic feet per second.

Conditions Where Practice Applies

This practice applies where the following or similar conditions exist:

1. Concentrated runoff is such that a lining is required to control erosion.
2. Steep grades, wetness, prolonged base flow, seepage, or piping would cause erosion.
3. The location is such that damage from use by people or animals precludes use of vegetated waterways or outlets.
4. Soils are highly erosive or other soil and climate conditions preclude using vegetation.
5. High value property or adjacent facilities warrant the extra cost to contain design runoff in a limited space.

Design Criteria

Capacity

1. The minimum capacity shall be adequate to carry the peak rate of runoff from a 10 year, 24-hour storm. Velocity shall be computed using Manning's equation with a coefficient of roughness "n" as follows:

Lined Material	"n"
Concrete (Type):	
Trowel Finish	0.015
Float Finis	0.019
Gunite	0.019
Flagstone	0.022
Riprap	Determine from Fig. 5B.11 on page 5B.19
Gabion	0.030

2. Riprap and filter (bedding) shall be designed in accordance with criteria set forth in the National Cooperative Highway Research Program Report 108, available from the University Microfilm International, 300 N. Ree Road, Ann Arbor, Michigan 48016, Publication No. PB-00839; or the Hydraulic Engineering Circular No. 11, prepared by the U.S. Bureau of Public Roads, available from Federal Highway Administration, 400 7th Street, S.W., Washington, D.C. 20590, HNG-31, or the procedure in the Soil Conservation Service's Engineering Field Manual, Chapter 16.

Velocity

1. Maximum design velocity shall be as shown below. Except for short transition sections, flow with a channel gradient within the range of 0.7 to 1.3 of this flow's critical slope must be avoided unless the channel is straight. Velocities exceeding critical will be restricted to straight reaches.

Design Flow Depth (ft.)	Maximum Velocity (ft./sec.)
0.0 - 0.5	25
0.5 - 1.0	15
Greater than 1.0	10

2. Waterways or outlets with velocities exceeding critical shall discharge into an energy dissipator to reduce velocity to less than critical, or to a velocity the downstream soil and vegetative conditions will allow.

Cross Section

The cross section shall be triangular, parabolic, or trapezoidal. Monolithic concrete or gabions may be rectangular.

Freeboard

The minimum freeboard for lined waterways or outlets shall be 0.25 feet above design high water in areas where erosion resistant vegetation cannot be grown adjacent to the paved side slopes. No freeboard is required where good vegetation can be grown and is maintained.

6/62

Side Slope

Steepest permissible side slopes, horizontal to vertical will be as follows:

1. Non-Reinforced Concrete
   Hand-placed, formed concrete
   Height of lining, 1.5 ft. or less.................... Vertical
   Hand placed screened concrete or mortared in-place flagstone
   Height of lining, less than 2 ft........................1 to 1
   Height of lining, more than 2 ft...................... 2 to 1
2. Slip form concrete:
   Height of lining, less than 3 ft.........................1 to 1
3. Rock Riprap...2 to 1
4. Gabions .... Vertical
5. Pre-cast Concrete Sections.......................... Vertical

Lining Thickness

Minimum lining thickness shall be as follows:

1. Concrete.................4 in. (In most problem areas, shall be 5 in. with welded wire fabric reinforcing.)

2. Rock Riprap......1.5 x maximum stone size plus thickness of filter or bedding.

3. Flagstone.............4 in. including mortar bed.

Related Structures

Side inlets, drop structures, and energy dissipators shall meet the hydraulic and structural requirement of the site.

Filters or Bedding

Filters or bedding to prevent piping, reduce uplift pressure, and collect water will be used as required and will be designed in accordance with sound engineering principles. Weep holes and drains will be provided as needed.

Concrete

Concrete used for lining shall be so proportioned that it is plastic enough for thorough consolidation and stiff enough to stay in place on side slopes. A dense product will be required. A mix that can be certified as suitable to produce a minimum strength of at least 3,000 pounds per square inch will be required. Cement used shall be Portland Cement, Type I, II, IV, or V. Aggregate used shall have a maximum diameter of 1 1/2 inches.

Weep holes should be provided in concrete footings and retaining walls to allow free drainage of water. Pipe used for weep holes shall be non-corrosive.

Mortar

Mortar used for mortared in-place flagstone shall consist of a mix of cement, sand, and water with a water/cement ratio of not more than 6 gallons of water per bag of cement.

Contraction Joints

Contraction joints in concrete linings, where required, shall be formed transversely to a depth of about one third the thickness of the lining at a uniform spacing in the range of 10 to 15 feet.

Rock Riprap or Flagstone

Stone used for riprap or gabions shall be dense and hard enough to withstand exposure to air, water, freezing and thawing. Flagstone shall be flat for ease of placement and have the strength to resist exposure and breaking.

Cutoff

Cutoff walls shall be used at the beginning and ending of concrete lining, and for rock riprap lining shall be keyed into the channel bottom and at both ends of the lining.

Construction Specifications

1. The foundation area shall be cleared of trees, stumps, roots, sod, loose rock, or other objectionable material.
2. The cross-section shall be excavated to the neat lines and grades as shown on the plans. Over-excavated areas shall be backfilled with moist soil compacted to the density of the surrounding material.
3. No abrupt deviations from design grade or horizontal alignment shall be permitted.
4. Concrete linings shall be placed to the thickness shown on the plans and finished in a workmanlike manner. Adequate precautions shall be taken to protect freshly placed concrete from freezing or extremely high temperatures, to insure proper curing.
5. Filter bedding, and rock riprap shall be placed to line and grade in the manner specified.
6. Construction operation shall be done in such a manner that erosion, air and water pollution will be minimized and held within legal limits. The completed job shall present a workmanlike appearance. All disturbed areas shall be vegetated or otherwise protected against soil erosion.

Maintenance

Pavement or lining should be maintained as built to prevent undermining and deterioration. Trees should be removed next to pavements, as roots can cause uplift damage.

Vegetation next to pavement should be maintained in good condition to prevent scouring if the pavement is overtopped. See Standard and Specifications for Critical Area Seeding on page 3.3.

STANDARD AND SPECIFICATIONS FOR ROCK OUTLET PROTECTION

Definition

A section of rock protection placed at the outlet end of the culverts, conduits or channels.

Purpose

The purpose of the rock outlet protection is to reduce the depth, velocity, and energy of water, such that the flow will not erode the receiving downstream reach.

Scope

This standard applies to the planning, design, and construction of rock riprap and gabions for protection of downstream areas. It does not apply to rock lining of channels or streams.

Conditions Where Practice Applies

This practice applies where discharge velocities and energies at the outlets of culverts, conduits or channels are sufficient to erode the next downstream reach. This applies to:

1. Culvert outlets of all types.
2. Pipe conduits from all sediment basins, dry storm water ponds, and permanent type ponds.
3. New channels constructed as outlets for culverts and conduits.

Design Criteria

The design of rock outlet protection depends entirely on the location. Pipe outlets at the top of cuts or on slopes steeper than 10 percent, cannot be protected by rock aprons or riprap sections due to reconcentration of flows and high velocities encountered after the flow leaves the apron.

Many counties and state agencies have regulations and design procedures already established for dimensions, type and size of materials, and locations where outlet protection is required. Where these requirements exist, they shall be followed.

Tailwater depth

The depth of tailwater immediately below the pipe outlet must be determined for the design capacity of the pipe. If the tailwater depth is less than half the diameter of the outlet pipe and the receiving stream is wide enough to accept divergence of the flow, it shall be classified as a Minimum Tailwater Condition; see Figure 5B.14 on page 5B.26 as an example. If the tailwater depth is greater than half the pipe diameter and the receiving stream will continue to confine the flow, it shall be classified as a Maximum Tailwater Condition; see Figures 5B.15 and 5B.16 on pages 5B.27 and 5B.28 as an example. Pipes which outlet onto flat areas with no defined channel may be assumed to have a Minimum Tailwater Condition; see Figure 5B.14 on page 5B.26 as an example.

Apron Size

The apron length and width shall be determined from the curves according to the tailwater conditions:

Minimum Tailwater - Use Figure 5B.12 on page 5B.24
Maximum Tailwater - Use Figure 5B.13 on page 5B.25

If the pipe discharges directly into a well defined channel, the apron shall extend across the channel bottom and up the channel banks to an elevation one foot above the maximum tailwater depth or to the top of the bank, whichever is less.

The upstream end of the apron, adjacent to the pipe shall have a width two (2) times the diameter of the outlet pipe, or conform to pipe end section if used.

Bottom Grade

The outlet protection apron shall be constructed with no slope along its length. There shall be no overfall at the end of the apron. The elevation of the downstream end of the apron shall be equal to the elevation of the receiving channel or adjacent ground.

Alignment

The outlet protection apron shall be located so that there are no bends in the horizontal alignment.

Materials

The outlet protection may be done using rock riprap, grouted riprap or gabions.

Riprap shall be composed of a well graded mixture of stone size so that 50 percent of the pieces, by weight, shall be larger than the d_{50} size determined by using the charts. A well graded mixture as used herein is defined as a mixture composed primarily of larger stone sizes but with a sufficient mixture of other sizes to fill the smaller voids between the stones. The diameter of the largest stone size in such a mixture shall be 1.5 times the d_{50} size.

Thickness

The minimum thickness of the riprap layer shall be 1.5 times the maximum stone diameter for d_{50} of 15 inches or less; and 1.2 times the maximum stone size for d_{50} greater than 15 inches. The following chart lists some examples:

D_{50} (inches)	d_{max} (inches)	Mimimum Blanket Thickness (inches)
4	6	9
6	9	14
9	14	20
12	18	27
15	22	32
18	27	32
21	32	38
24	36	43

Stone Quality

Stone for riprap shall consist of field stone or rough unhewn quarry stone. The stone shall be hard and angular and of a quality that will not disintegrate on exposure to water or weathering. The specific gravity of the individual stones shall be at least 2.5.

Recycled concrete equivalent may be used provided it has a density of at least 150 pounds per cubic foot, and does not have any exposed steel or reinforcing bars.

Filter

A filter is a layer of material placed between the riprap and the underlying soil surface to prevent soil movement into and through the riprap. Riprap shall have a filter placed under it in all cases.

A filter can be of two general forms: A gravel layer or a plastic filter cloth. The plastic filter cloth can be woven or non-woven monofilament yarns, and shall meet these base requirements: thickness 20-60 mils, grab strength 90-120 lbs; and shall conform to ASTM D-1777 and ASTM D-1682.

Gravel filter blanket when used shall be designed by comparing particle sizes of the overlying material and the base material. Design criteria are available in Standard and Specification for Riprap Slope Protection, page 5B.55.

Gabions

Gabions shall be made of hexagonal triple twist mesh with heavily galvanized steel wire. The maximum linear dimension of the mesh opening shall not exceed 4 1/2 inches and the area of the mesh opening shall not exceed 10 square inches.

Gabions shall be fabricated in such a manner that the sides, ends, and lid can be assembled at the construction site into a rectangular basket of the specified sizes. Gabions shall be of single unit construction and shall be installed according to manufacturers recommendations.

The area on which the gabion is to be installed shall be graded as shown on the drawings. Foundation conditions shall be the same as for placing rock riprap and filter cloth shall be placed under all gabions. Where required, a key may be needed to prevent undermining of the main gabion structure.

Maintenance

Once a riprap outlet has been installed, the maintenance needs are very low. It should be inspected after high flows to see if scour beneath the riprap has occurred, or any stones have been dislodged. Repairs should be made immediately.

Design Procedure

1. Investigate the downstream channel to assure that non-erosive velocities can be maintained.
2. Determine the tailwater condition at the outlet to establish which curve to use.
3. Enter the appropriate chart with the depth of flow and discharge velocity to determine the riprap size and apron length required. It is noted that references to pipe diameters in the charts are based on full flow. For other than full pipe flow, the parameters of depth of flow and velocity must be used.
4. Calculate apron width at the downstream end if a flared section is to be employed.

Examples

Example 1: Pipe Flow (full) with discharge to unconfined section.

Given: A circular conduit flowing full.

Q = 280 cfs, diam. = 66 in., tailwater (surface) is 2 ft. above pipe invert (minimum tailwater condition).

Find: Read d_{50} = 1.2 and apron length (L_a) = 38 ft.

Apron width = diam. + L_a = 5B.5 + 38 = 43.5 ft.

Use: d_{50} = 15", d_{max} = 22", blanket thickness = 32"

Example 2: Box Flow (partial) with high tailwater

Given: A box conduit discharging under partial flow conditions. A concrete box 5.5 ft. x 10 ft. flowing 5.0 ft. deep,

Q = 600 cfs and tailwater surface is 5 ft. above invert (max. tailwater condition).

Since this is not full pipe flow and does not directly fit the nomograph assumptions, it is necessary to compute the

VOL 12

6/67

velocity in the conduit and then substitute the depth of flow as a diameter to find a discharge equal to full flow for that diameter, in this case 60 inches.

Compute velocity:

$$V = (Q/A) = (600/(5)(10)) = 12 \text{ fps}$$

Then substituting:

$$Q = \frac{\pi D^2}{4} \times V = \frac{3.14\,(5\text{ ft})^2}{4} \times 12 \text{ fps} = 236 \text{ cfs}$$

At the intersection of the curve d = 60 in. and Q = 236 cfs, read d_{50} = 0.4 ft.

Then reading the d = 60 in. curve, read apron length (L_a) = 40 ft.

Apron width, W = conduit width + (0.04)(L_a) = 10 + (0.4)(40) = 26 ft.

Example 3: Open Channel Flow with Discharge to Unconfined Section

Given: A trapezoidal concrete channel 5 ft. wide with 2:1 side slopes is flowing 2 ft. deep, Q = 180 cfs (velocity = 10 fps) and the tailwater surface downstream is 0.8 ft. (minimum tailwater condition).

Find: Using similar principles as Example 1, compute equivalent discharge for a 2-foot circular pipe flowing full at 10 feet per second.

Velocity:

$$Q = \frac{\pi\,(2\text{ft})^2}{4} \times 10 \text{ fps} = 31.4 \text{ cfs}$$

At intersection of the curve, d = 24 in. and Q = 32 cfs, read d_{50} = 0.6 ft.

Then reading the d = 24 in. curve, read apron length (L_a) = 20 ft.

Apron width, W = bottom width of channel + L_a = 5 + 20 = 25 ft.

Example 4: Pipe flow (partial) with discharge to a confined section

Given: A 48 in. pipe is discharging with a depth of 3 ft., Q = 100 cfs, and discharge velocity of 10 fps (established from partial flow analysis) to a confined trapezoidal channel with a 2 ft. bottom, 2:1 side slopes, n = .04, and grade of 0.6%.

Calculation of the downstream channel (by Manning's Equation) indicates a normal depth of 3.1 ft. and normal velocity of 3.9 fps.

Since the receiving channel is confined, the maximum tailwater condition controls.

Find: discharge using above principles:

$$Q = \frac{\pi\,(3\text{ft})^2}{4} \times 10 \text{ fps} = 71 \text{ cfs}$$

At the intersection of d = 36 in. and Q = 71 cfs, read d_{50} = 0.3 ft.

Reading the d = 36" curve, read apron length (L_a) = 30 ft.

Since the maximum flow depth in this reach is 3.1 ft., that is the minimum depth of riprap to be maintained for the entire length.

Construction Specifications

1. The subgrade for the filter, riprap or gabion shall be prepared to the required lines and grades. Any fill required in the subgrade shall be compacted to a density of approximately that of the surrounding undisturbed material.
2. The rock or gravel shall conform to the specified grading limits when installed respectively in the riprap or filter.
3. Filter cloth shall be protected from punching, cutting or tearing. Any damage other than an occasional small hole shall be repaired by placing another piece of cloth over the damaged part or by completely replacing the cloth. All overlaps whether for repairs or for joining two pieces of cloth shall be a minimum of one foot.
4. Stone for the riprap or gabion outlets may be placed by equipment. Both shall each be constructed to the full course thickness in one operation and in such a manner as to avoid displacement of underlying materials. The stone for riprap or gabion outlets shall be delivered and placed in a manner that will insure that it is reasonably homogenous with the smaller stones and spalls filling the voids between the larger stones. Riprap shall be placed in a manner to prevent damage to the filter blanket or filter cloth. Hand placement will be required to the extent necessary to prevent damage to the permanent works.

STANDARD AND SPECIFICATIONS FOR GRADE STABILIZATION STRUCTURE

Definition

A structure to stabilize the grade or to control head cutting in natural or artificial channels.

Scope

This standard applies to all types of grade stabilization structures. It does not apply to storm sewers or their component parts.

Purpose

Grade stabilization structures are used to reduce or prevent excessive erosion by reduction of velocities and grade in the watercourse or by providing channel linings or structures that can withstand the higher velocities.

Conditions Where Practice Applies

This practice applies to sites where the capability of earth and vegetative measures is exceeded in the safe handling of water at permissible velocities, where excessive grades or overfall conditions are encountered or where water is to be lowered structurally from one elevation to another. These structures should generally be planned and installed along with or as a part of other conservation practices in an overall surface water disposal system.

Design Criteria

Compliance with Laws and Regulations

Design and construction shall be in compliance with state and local laws and regulations. Such compliance is the responsibility of the landowner or developer.

General

Designs and specifications shall be prepared for each structure on an individual job basis depending on its purpose, site conditions and the basic criteria of the conservation practice with which the structure is planned. Typical structures are as follows:

1. Channel linings of concrete, asphalt, half round metal pipe or other suitable lining materials. These linings should generally be used where channel velocities exceed safe velocities for vegetated channels due to increased grade or a change in channel cross section or where durability of vegetative lining is adversely affected by seasonal changes. Adequate protection will be provided to prevent erosion or scour of both ends of the channel lining.
2. Overfall structures of concrete, metal, rock riprap or other suitable material is used to lower water from one elevation to another. These structures are applicable where it is desirable to drop the watercourse elevation over a very short horizontal distance. Adequate protection will be provided to prevent erosion or scour upstream, downstream and along sides of overfall structures. Structures should be located on straight sections of channel with a minimum of 100 feet of straight channel each way.
3. Pipe drops of metal pipe with suitable inlet and outlet structures. The inlet structure may consist of a vertical section of pipe or similar material, an embankment or a combination of both. The outlet structure will provide adequate protection against erosion or scour at the pipe outlet.

Capacity

Structures which are designed to operate in conjunction with other erosion control practices shall have as a minimum capacity equal to the bankfull capacity of the channel delivering water to the structures. The minimum design capacity for structures that are not designed to perform in conjunction with other practices shall be that required to handle the peak rate of flow from a 10 year, 24 hour frequency storm or bankfull, whichever is greater. Peak rates of runoff used in determining the capacity requirements shall be determined as outlined in Chapter 2, Estimating Runoff, Engineering Field Manual for Conservation Practices, Section 10 in this manual or by TR-55, Urban Hydrology for Small Watersheds.

Set the rest of the structure at an elevation that will stabilize the grade of the upstream channel. The outlet should be set at an elevation to assure stability. Outlet velocities should be kept within the allowable limits for the receiving stream. Structural drop spillways need to include a foundation drainage system to reduce hydrostatic loads.

Structures which involve the retarding of floodwater or the impoundment of water shall be designed using the criteria set forth in the guidelines for Ponds or Floodwater Retarding Structures, whichever is applicable.

Construction Specifications

Structures shall be installed according to lines and grades shown on the plan. The foundation for structures shall be cleared of all undesirable materials prior to the installation of the structure. Materials used in construction shall be of a permanency commensurate with the design frequency and life expectancy of the practice. Earthfill, when used as a part of the structure, shall be placed in 4 inch lifts and hand compacted within 2 feet of the structure.

Seeding, fertilizing and mulching shall conform to the recommendation specification in Section 3.

Construction operations shall be carried out in such a manner that erosion and air and water pollution will be minimized. State and local laws concerning pollution abatement shall be complied with.

Locate emergency bypass areas so floods in excess of structural capacity enters the channel far enough downstream so as not to cause damage to the structure.

Maintenance

Once properly installed, the maintenance for the grade stabilization structure should be minimal. Inspect the structure periodically and after major storm events. Check fill for piping or extreme settlement. Ensure a good vegetative cover. Check the channel for scour or debris and loss of rock from aprons. Repair or replace failing structures immediately.

VOL 12

6/7/5

STANDARD AND SPECIFICATIONS
FOR
PAVED FLUME

Definition

A small concrete-lined channel to convey water on a relatively steep slope.

Purpose

To convey concentrated runoff safely down the face of a cut or fill slope without causing erosion.

Condition Where Practice Applies

Where concentrated storm runoff must be conveyed down a cut or fill slope as part of a permanent erosion control system. Paved flumes serve as stable outlets for diversions, drainage channels, or natural drainageways that are located above relatively steep slopes. Paved flumes should be used on slopes of 1:5 to 1 or flatter.

Design Criteria

Capacity - Minimum capacity should be the 10 year frequency storm. Freeboard or enough bypass capacity should be provided to safeguard the structure from peak flows expected for the life of the structure.

Slope - The slope should not be steeper than 1.5:1 (67%).

Cutoff Walls - Install cutoff walls at the beginning and end of paved flumes. The cutoff should extend a minimum of 18 inches into the soil and across the full width of the flume and be 6 inches thick. Cutoff walls should be reinforced with #3 reinforcing bars (3/8") placed on a 6 inch grid in the center of the wall.

Anchor Lugs - Space anchor lugs a minimum of 10 feet on centers for the length of the flume. They will extend the width of the flume, extend 1 foot into subsoil, be a minimum of 6 inches thick and reinforced with #3 reinforcing bars placed on a 6 inch grid.

Concrete - Minimum strength of design mix shall 3000 psi. Concrete thickness shall be a minimum of 6 inches reinforced with #3 reinforcing bars. Mix shall be dense, durable, and stiff enough to stay in place on steep slopes and sufficiently plastic for consolidation. Concrete mix should include an air-entraining admixture to resist freeze-thaw cycles.

Cross Section - Flumes shall have minimum depth of 1 foot with 1.5:1 side slopes. Bottom widths shall be based on maximum flow capacity. Chutes will be maintained in a straight alignment because of supercritical flow velocities.

Drainage filters - Use a drainage filter with all paved flumes to prevent piping and reduce uplift pressures. Size of the filter material will be dependent on the soil material the flume is located in.

Inlet section - Design the inlet to the following minimum dimensions: side walls 2 feet high, length 6 feet, width equal to the flume channel bottom, and side slopes the same as the flume channel side slopes.

Outlet section - Outlets must be protected from erosion. Usually an energy dissipator is used to reduce the high chute velocities to lower non erosive velocities. Rock riprap should be placed at the end of the dissipator to spread flow evenly to the receiving channel.

See figure 5B.17 on page 5B.33 for examples of outlet structures.

Invert - Precast concrete sections may be used in lieu of cast in place concrete. These sections should be designed at the joint to be overlapped to prevent displacement between sections. Joint sealing compound should be used to prevent migration of soil through a joint. Cutoff walls and anchor lugs should be cast in the appropriate sections to accomodate the design criteria.

Small Flumes - Where the drainage area is 10 acres or less the design dimensions for concrete flumes may be selected from those shown in the following table:

	Drainage Area (Acres)	
	5	10
Min Bottom Width	4	8
Min Inlet Depth (ft)	2	2
Min Channel Depth (ft)	1.3	1.3
Max Channel Slope	1.5:1	1.5:1
Max Side Slope	1.5:1	1.5:1

See figure 5B.18 on page 5B.34 for details.

Construction Specifications

1. The subgrade shall be constructed to the lines and grades shown on the plans. Remove all unsuitable material and replace them if necessary with compacted stable fill materials. Shape subgrade to uniform surface. Where concrete is poured directly on subsoil maintain it in a moist condition.

VOL 12

6176

2. On fill slopes the soil adjacent to the chute for a minimum of 5 feet must be well compacted.

3. Where drainage filters are placed under the structure the concrete will not be poured on the filter. A plastic liner, a minimum of 4 mils thick, will be placed to prevent contamination of filter layer.

4. Place concrete for the flume to the thickness shown on the plans and finish according to details. Protect freshly poured concrete from extreme temperatures (hot or cold) and ensure proper curing.

5. Form, reinforce, and pour together cutoff walls, anchor lugs and channel linings. Provide traverse joints to control cracking at 20 foot intervals. Joints can be formed by using a 1/8 inch thick removable template or by sawing to a minimum depth of 1 inch. Flumes longer than 50 feet shall have preformed expansion joints installed.

6. Immediately after construction, all disturbed areas will be final graded and seeded.

Maintenance

Inspect flumes after each rainfall until all areas adjoining the flume are permanently stabilized. Repair all damage immediately. Inspect outlet and rock riprap to assure presence and stability. Any missing components should be immediately replaced.

CONSTRUCTION SPECIFICATIONS

1. SUBGRADE SHALL BE CONSTRUCTED TO THE LINES AND GRADES SHOWN ON THE PLANS. REMOVE ALL UNSUITABLE MATERIAL AND REPLACE THEM IF NECESSARY WITH COMPACTED STABLE FILL MATERIALS. SHAPE SUBGRADE TO UNIFORM SURFACE. WHERE CONCRETE IS POURED DIRECTLY ON SUBSOIL MAINTAIN IT IN A MOIST CONDITION.
2. ON FILL SLOPES THE SOIL ADJACENT TO THE CHUTE FOR A MINIMUM OF 5 FEET MUST BE WELL COMPACTED.
3. WHERE DRAINAGE FILTERS ARE PLACED UNDER THE STRUCTURE THE CONCRETE WILL NOT BE POURED ON THE FILTER. A PLASTIC LINER, MINIMUM 4 MILS THICK, WILL BE PLACED TO PREVENT CONTAMINATION OF THE FILTER LAYER.
4. PLACE CONCRETE FOR THE FLUME TO THE THICKNESS SHOWN ON THE PLANS AND FINISH ACCORDING TO DETAILS. PROTECT FRESHLY POURED CONCRETE FROM EXTREME TEMPERATURES (HOT OR COLD) AND ENSURE PROPER CURING.
5. FORM, REINFORCE, AND POUR TOGETHER CUTOFF WALLS, ANCHOR LUGS AND CHANNEL LININGS. PROVIDE TRAVERSE JOINTS TO CONTROL CRACKING AT 20 FOOT INTERVALS. JOINTS CAN BE FORMED BY USING A 1/8 INCH THICK REMOVABLE TEMPLATE OR BY SAWING TO A MINIMUM DEPTH OF 1 INCH. FLUMES LONGER THAN 50 FEET SHALL HAVE PERFORMED EXPANSION JOINTS INSTALLED.
6. IMMEDIATELY AFTER CONSTRUCTION, ALL DISTURBED AREAS WILL BE FINAL GRADED AND SEEDED.
7. MAINTENANCE - INSPECT FLUMES AFTER EACH RAINFALL UNTIL ALL AREAS ADJOINING THE FLUME ARE PERMANENTLY STABILIZED. REPAIR ALL DAMAGE IMMEDIATELY. INSPECT OUTLET AND ROCK RIPRAP TO ASSURE PRESENCE AND STABILITY. ANY MISSING COMPONENTS SHOULD BE IMMEDIATELY REPLACED.

R0039487

STANDARD AND SPECIFICATIONS FOR STRUCTURAL STREAMBANK PROTECTION

Definition

Stabilization of eroding streambanks by the use of designed structural measures.

Purpose

To protect exposed or eroded streambanks from the erosive forces of flowing water.

Condition Where Practice Applies

Generally applicable where flow velocities exceed 6 feet per second or where vegetative streambank protection is inappropriate. Necessary where excessive runoff or construction activities creates an erosive condition on a streambank.

Design Criteria

Since each channel is unique, measures for structural streambank should be installed according to a design based on specific site conditions.

Develop designs according to the following principles:

Make protective measures compatible with other channel modifications planned or being carried out in the channel reaches.

Use the design velocity of the peak discharge of the 10-year storm or bankfull discharge, whichever is less. Structural measures should be capable of withstanding greater flows without serious damage.

Ensure that the channel bottom is stable or stabilized by structural means before installing any permanent bank protection.

Streambank protection should begin at a stable location and end at a stable point along the bank.

Changes in alignment should not be done without a complete analysis of effects on the rest of the stream system for both environmental and stability effects.

Provisions should be made to maintain and improve fish and wildlife habitat.

Ensure that all requirements of state law and all permit requirements of local, state and federal agencies are met.

Construction Specifications

Riprap - Riprap is the most commonly used material to structurally stabilize a streambank.

1. Bank slope - slopes shall be graded to 2:1 or flatter prior to placing bedding, filter fabric or riprap.
2. Filter - filters should be placed between the base bank material and the riprap and meet the requirements of criteria listed in the Standards and Specifications for Riprap Slope Protection, page 5B.55.
3. Gradation - The gradation of the riprap is dependent on the velocity expected against the bank for the design conditions. Once the velocity is known gradation can be selected from the gradations below. The riprap should extend 2 feet below the channel bottom and be keyed into the bank both at the upstream end and downstream end of the proposed work or reach.

See Figure 5B.19 on page 5B.37 for details.

Gabions - Design and install gabions according to manufacturers recommendations. Since these are rectangular, rock-filled wire baskets they are somewhat flexible in armoring channel bottoms and banks. They can withstand significantly higher velocities for the size stone they contain due to the basket structure. They also stack vertically to act as a retaining wall for constrained areas (figure 5B.20).

Gabions should not be used in streams that carry a bedload that can abrade the wire causing separation and failure.

Reinforced Concrete - May be used to armor eroding sections of streambank by constructing walls, bulk heads, or bank linings. Provide positive drainage behind these structures to relieve uplift pressures.

Grid pavers - Modular concrete units with or without void areas can be used to stabilize streambanks. Units with void areas can allow the establishment of vegetation. These structures may be obtained in a variety of shapes (figure 5B.20) or they may be formed and poured in place. Maintain design and installation in accordance with manufacturers instructions.

Revetment - Structural support or armoring to protect an embankment from erosion. Riprap and gabions are commonly used. Also used is a hollow fabric mattress with cells that receive a concrete mixture, (ie. Fabriform). Any revetment should be installed to a depth below the anticipated

VOL 12

6/80

channel degradation and into the channel bed as necessary to provide stability.

Modular Pre-Cast Units - Interlocking modular precast units of different sizes, shapes, heights and depths have been developed for a wide variety of applications. These serve in the same manner as gabions. They provide verticality in tight areas as well as durability. Many types are available with textured surfaces. They also act as gravity retaining walls. They should be designed and installed in accordance with the manufacturers recommendations (figure 5B.20).

All areas disturbed by construction should be stabilized as soon as the structural measures are complete.

Maintenance

Check stabilized streambank sections after every high-water event, and make any needed repairs immediately to prevent any further damage or unraveling of the existing work.

STANDARD AND SPECIFICATIONS FOR DEBRIS BASIN

Definition

A barrier or dam constructed across a waterway or at other suitable locations to form a basin for catching and storing sediment and other waterborne debris.

Scope

This standard covers the installation of debris basins on sites where: (1) failure of the structure would not result in loss of life or interruption of use or service of public utilities; (2) the drainage area does not exceed 200 acres; and (3) the water surface area at the crest of the emergency spillway does not exceed 5 acres. For the purpose of this standard, debris basins are classified according to the following table:

Class	Maximum Drainage Area(Ac)	Maximum Height[1] of Dam(ft)	Emergency Spillway Required	Design Storm Frequency
1[2]	20	5	No	--
2	20	10	Yes	10 yrs.
3	200	20	Yes	25 yrs.

[1] Height is measured from the low point of original ground along the centerline of dam to the top of dam for Class 1 and to crest of emergency spillway for Classes 2 and 3.

[2] Class 1 basins are to be used only where site conditions are such that it is impractical to construct an emergency spillway in undisturbed ground.

Purpose

To provide a permanent or temporary means of trapping and storing sediment from eroding areas in order to protect properties or stream channels below the installation from damage by excessive sedimentation and debris.

Conditions Where Practice Applies

Where physical conditions or land ownership preclude the treatment of the sediment source by the installation of erosion control measures to reduce runoff and erosion. It may also be used as a permanent or temporary measure during grading and development of areas above. If it is a temporary structure, it may be removed once the development is complete and the area is permanently protected against erosion by vegetative or mechanical means.

Design Criteria

The capacity of the debris basin to the elevation of the crest of the principal spillway is to equal the volume of the expected sediment yield from the unprotected portions of the drainage area during the planned useful life of the structure. The minimum volume of sediment in acre feet per year can be determined for various drainage areas under construction from curves on Figure 5B.21 on page 5B.42. Values of iso-erodents for a specific area or state can be obtained from Figure 8.1, "Average Annual Iso-Erodent Values" on page 8.3. Also, an example of sediment capacity determined by computing an equation is given in Section 6, Guidelines for Estimating Sediment Yields for Urban Construction Areas.

<u>Spillway Design</u>

Runoff will be computed by the method outlined in Chapter 2, Estimating Runoff "Engineering Field Manual for Conservation Practices" or Section 10. Runoff computations should be based upon the soil cover conditions expected to prevail during the construction period of the development.

For Class 2 basins, the combined capacities of the principal and emergency spillways will be sufficient to pass the peak rate of runoff from a 10 year frequency storm after adjusting for flood routing (method shown in SCS Engineering Field Manual may be used).

For Class 3 basins, the combined capacities of the pipe and emergency spillways will be sufficient to pass the peak rate of runoff from a 25 year frequency storm.

<u>Pipe Spillway</u>

The pipe spillway will consist of a vertical pipe box type riser jointed to a conduit which will extend through the embankment and outlet beyond the downstream toe of the fill. The minimum diameter of the conduit will be 8 inches. The riser will be perforated to provide for a gradual drawdown after each storm event. The minimum average capacity of the principal spillway will be sufficient to discharge 5 inches of runoff from the drainage area in 24 hours (0.21 cfs per acre of drainage area). The riser of the principal spillway shall be a cross-sectional area at least 1.3 times that of the barrel.

1. Crest Elevation: The crest elevation of the riser shall be at least 3 feet below the crest elevation of the embankment.

2. Perforated: Metal pipe risers shall be perforated with 1-1/2 inch diameter holes spaced 8 inches vertically and 10-12 inches horizontally around the pipe. Box type risers shall be ported or have some means for complete drainage of the sediment pool within a 5 day period following storm inflows.

3. Anti-vortex device: An anti-vortex device shall be installed on the top of the riser.

4. Base: The riser shall have a base attached with a watertight connection. The base shall have sufficient weight to prevent flotation of the riser.

5. Trash rack: An approved trash rack shall be firmly attached to the top of the riser if the pipe spillway conveys 25 percent or more of the peak rate or runoff from the design storm.

6. Anti-seep collars: Anti-seep collars shall be installed around the pipe conduit within the normal saturation zone when any of the following conditions exist:

   A. The settled height of dam exceeds 15 ft.

   B. The conduit is of smooth pipe larger than 8 inches in diameter.

   C. The conduit is of corrugated metal pipe larger than 12 inches in diameter.

   The anti-seep collars and their connections to the pipe shall be watertight. The maximum spacing shall be approximately 14 times the minimum projection of the collar measured perpendicular to the pipe.

7. Outlet protection: Protection against scour at the discharge end of the pipe spillway shall be provided. Protective measures may include structures of the impact basin type, rock riprap, paving, revetment, excavation of plunge pool or use of other approved methods.

Emergency spillway

Class 2 and 3 basins: An emergency spillway shall be excavated in undisturbed ground wherever site conditions permit. The emergency spillway cross section shall be trapezoidal with a minimum bottom width of 8 feet.

Class 1 basins: The embankment may be used as an emergency spillway. In these cases, the downstream slope of the embankment shall be 5:1 or flatter and the embankment must be immediately protected against erosion by means such as sodding, rock riprap, asphalt coating or other approved methods.

1. Capacity: The minimum capacity of the emergency spillway shall be that required to pass the peak rate of runoff from the design storm, less any reduction due to flow in the pipe spillway. Emergency spillway dimensions can be determined by using the method outlined in Chapter 11 of "Engineering Field Manual for Conservation Practices."

2. Velocities: The maximum allowable velocity of flow in the exit channel shall be 6 feet per second for vegetated channels. For channels with erosion protection other than vegetation, velocities shall be in the safe range for the type of protection used.

3. Erosion protection: Provide for erosion protection by vegetation or by other suitable means such as rock riprap, asphalt, concrete, etc.

4. Freeboard: Freeboard is the difference between the design flow elevation in the emergency spillway and the top of the settled embankment. The minimum freeboard for Class 2 and Class 3 basins shall be 1 foot.

Embankment (Earth Fill)

Class 1 basins: The minimum top width shall be 10 feet. The upstream slope shall be no steeper than 3:1. The downstream slope shall be no steeper than 5:1.

Class 2 basins: The minimum top width shall be 8 feet. The combined upstream and downstream side slopes shall not be less than 5:1 with neither slope steeper than 2-1/2:1.

Class 3 basins: The minimum top width shall be 10 feet. Side slopes shall be no steeper than 2-1/2:1.

Embankment (other than Earth Fill)

Class 1 basins only: The embankment may be constructed of the following materials:

1. Pressure treated timber crib - rock filled.
2. Precast reinforced concrete crib - rock filled.
3. Gabions.

When the above material is used for the embankment, a principal spillway is not required; however, the dam shall be pervious to allow for drainage during time of low inflow. Basins constructed of the above materials should be used only when the sediment to be trapped is coarse grained material such as GW or GP material (Unified Soil Classification System).

Construction Specifications

Site Preparation

Areas under the embankment and any structural works shall be cleared, grubbed and the topsoil stripped to remove trees, vegetation, roots, and other objectionable material. In order to facilitate cleanout and restoration, the pool area will be cleared of all brush and excess trees.

Cutoff Trench

A cutoff trench shall be excavated along the centerline of dam on earth fill embankments to a depth of at least 1.0 foot into a layer of slowly permeable material. The minimum depth shall be 2 feet. The cutoff trench shall extend up both abutments to the riser crest elevation. The minimum bottom width shall be 4 feet, but wide enough to permit operation of compaction equipment. The side slopes shall be no steeper than 1:1. Compaction requirements shall be the same as those for embankment. The trench shall be kept free from standing water during the backfilling operations.

Embankment

The fill material shall be taken from approved designated borrow areas. It shall be free of roots, woody vegetation, oversized stones, rocks or other objectionable material. Areas on which fill is to be placed shall be scarified prior to placement of fill. The fill material should contain sufficient moisture so that it can be formed into a ball without crumbling. If water can be squeezed out of the ball, it is too wet for proper compaction.

Fill material will be placed in 6 to 9 inch layers and shall be continuous over the entire length of the fill. Compaction will be obtained by routing the hauling equipment over the fill so that the entire surface of the fill is traversed by at least one track width of the equipment or compaction shall be achieved by the use of a compactor. The embankment shall be constructed to an elevation 10 percent higher than the design height to allow for settlement if compaction is obtained with hauling equipment. If compactors are used for compaction, the overbuild may be reduced to 5 percent.

Pipe Spillway

The riser shall be solidly attached to the barrel and all connections shall be watertight. The barrel and riser shall be placed on a firm foundation. The fill material around the pipe spillway will be placed in 4 inch layers and compacted to at least the same density as the adjacent embankment.

Emergency Spillway (Class 2 and 3 basins)

The emergency spillway shall be installed in undisturbed earth unless specified otherwise in the plan. The lines and grades must conform to those shown on the plans as nearly as skillful operation of the excavating equipment will permit.

Embankment (other than Earth Fill)

The rock used to fill cribbing or gabions will be hard and durable and of an approved size and gradation.

Erosion and Pollution Control

Construction operations will be carried out in such a manner that erosion and water pollution will be minimized. State and local laws concerning pollution abatement shall be complied with.

Safety

State requirements shall be met concerning fencing and signs warning the public of hazards of soft sediment and floodwater.

Seeding

Seeding, fertilizing and mulching shall conform to the recommendations in Section 3, Vegetative Measures for Erosion and Sediment Control in Urban Areas, of this manual.

Final Disposal

In the case of temporary structures, when the intended purpose has been accomplished and the drainage area properly stabilized, the embankment and resulting silt deposits are to be leveled or otherwise disposed of in accordance with the plan.

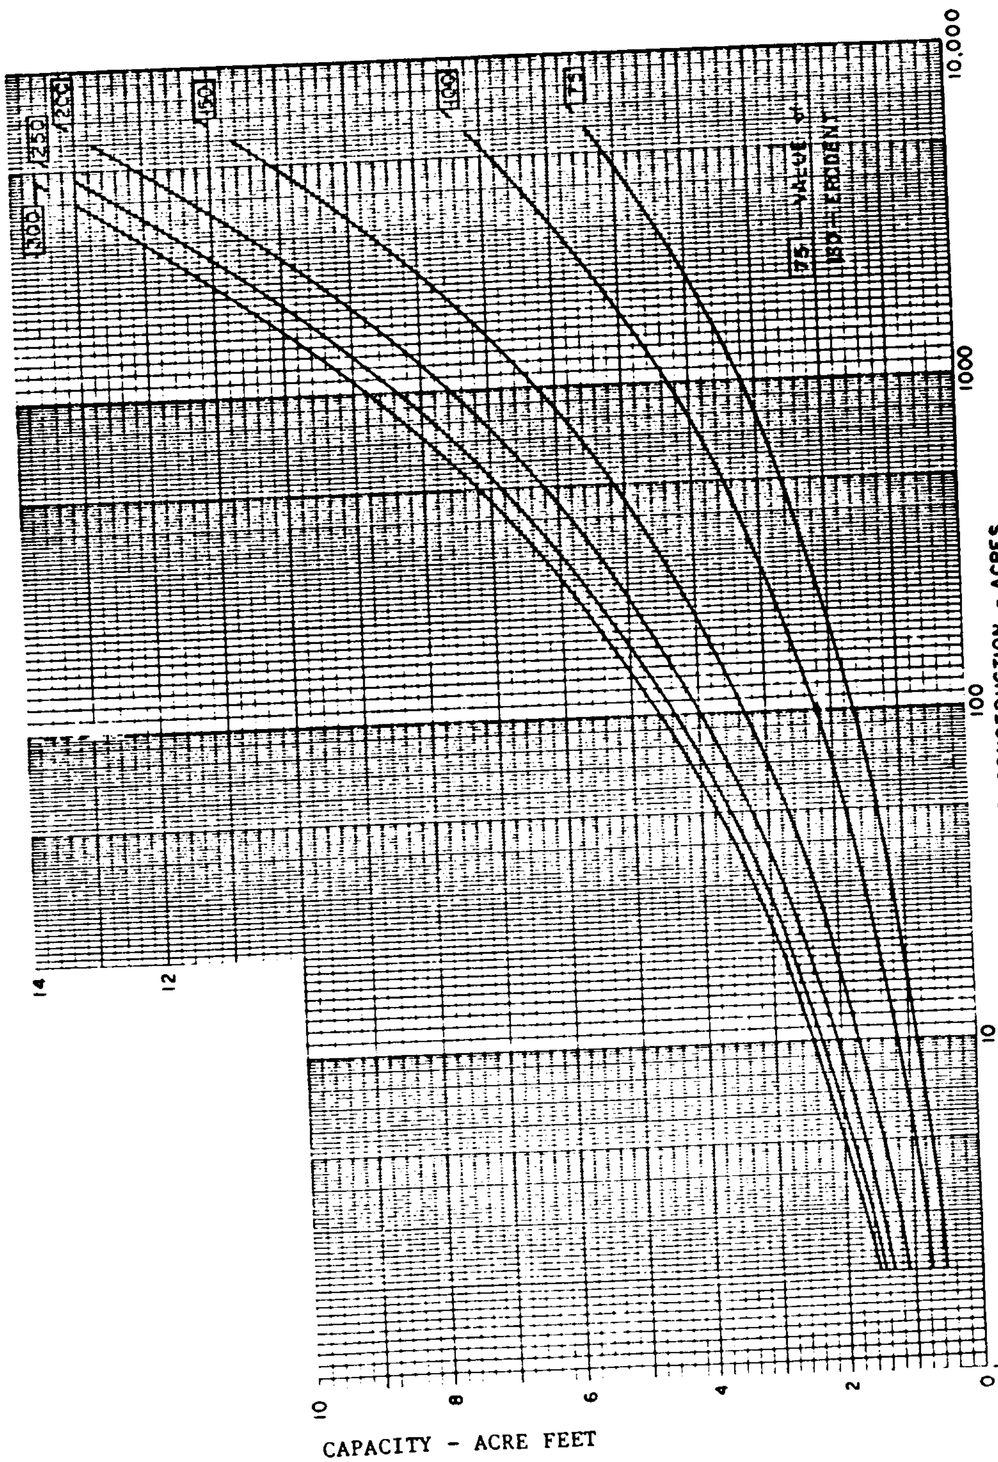
One-Year Debris Basin Sediment Capacity



VOL 12

6-187

R0039495

STANDARD AND SPECIFICATIONS FOR SUBSURFACE DRAIN

Definition

A conduit, such as tile, pipe or tubing, installed beneath the ground surface which intercepts, collects, and/or conveys drainage water.

Purpose

A subsurface drain may serve one or more of the following purposes:

1. Improve the environment for vegetative growth by regulating the water table and groundwater flow.
2. Intercept and prevent water movement into a wet area.
3. Relieve artesian pressures.
4. Remove surface runoff.
5. Provide internal drainage of slopes to improve their stability and reduce erosion.
6. Provide internal drainage behind bulkheads, retaining walls, etc.
7. Replace existing subsurface drains that are interrupted or destroyed by construction operations.
8. Provide subsurface drainage for dry storm water management structures.
9. Improve dewatering of sediment in sediment basins. (See Standard and Specification for Sediment Basins on page 5A.47).

Conditions Where Practice Applies

Subsurface drains are used in areas having a high water table or where subsurface drainage is required. The soil shall have enough depth and permeability to permit installation of an effective system. This standard does not apply to storm drainage systems or foundation drains.

An outlet for the drainage system shall be available, either by gravity flow or by pumping. The outlet shall be adequate for the quantity of water to be discharged without causing damage above or below the point of discharge and shall comply with all state and local laws.

Design Criteria

The design and installation shall be based on adequate surveys and on-site soils investigations.

Required Capacity of Drains

The required capacity shall be determined by one or more of the following:

1. Where sub-surface drainage is to be uniform over an area through a systematic pattern of drains, a drainage coefficient of 1 inch to be removed in 24 hours shall be used; see Drain Charts, Figures 5B.22 through 5B.24 on pages 5B.46 to 5B.48.
2. Where sub-subsurface drainage is to be by a random interceptor system, a minimum inflow rate of 0.5 cfs per 1,000 feet of line shall be used to determine the required capacity. If actual field tests and measurements of flow amounts are available, they may be used for determining capacity.

   For interceptor subsurface drains on sloping land, increase the inflow rate as follows:

Land Slope	Increase Inflow Rate By
2-5 percent	10 percent
5-12 percent	20 percent
Over 12 percent	30 percent

3. Additional design capacity must be provided if surface water is allowed to enter the system.

Size of Subsurface Drain

The size of subsurface drains shall be determined from drain charts found on Figures 5B.22 through 5B.24 on pages 5B.46 to 5B.48. All subsurface drains shall have a nominal diameter which equals or exceeds four (4) inches.

Depth and Spacing

The minimum depth of cover of subsurface drains shall be 24 inches where possible. The minimum depth of cover may be reduced to 15 inches where it is not possible to attain the 24 inch depth and where the drain is not subject to equipment loading or frost action. Roots from some types of vegetation can plug drains as the drains get closer to the surface.

The spacing of drain laterals will be dependent on the permeability of the soil, the depth of installation of the drains and degree of drainage required. Generally, drains installed 36 inches deep and spaced 50 feet center-to-center will be adequate. For more specific information see the New York Drainage Guide.

Minimum Velocity and Grade

The minimum grade for subsurface drains shall be 0.10 percent. Where surface water enters the system a velocity of not less than 2 feet per second shall be used to establish the minimum grades. Provisions shall be made for preventing debris or sediment from entering the system by means of filters or collection and periodic removal of sediment from installed traps.

Materials for Subsurface Drains

Acceptable subsurface drain materials include perforated, continuous closed joint conduits of polyethylene plastic, concrete, corrugated metal, asbestos cement, bituminized fiber, polyvinyl chloride and clay tile.

The conduit shall meet strength and durability requirements of the site.

Loading

The allowable loads on subsurface drain conduits shall be based on the trench and bedding conditions specified for the job. A factor of safety of not less than 1.5 shall be used in computing the maximum allowable depth of cover for a particular type of conduit.

Envelopes and Envelope Materials

Envelopes shall be used around subsurface drains for proper bedding and to provide better flow into the conduit. Not less than three inches of envelope material shall be used for sand/gravel envelopes. Where necessary to improve the characteristics of flow of groundwater into the conduit, more envelope material may be required.

Where county regulations do not allow sand/gravel envelopes, but require a special type and size of envelope material, they shall be followed.

Envelope material shall be placed to the height of the uppermost seepage strata. Behind bulkheads and retaining walls, it shall go to within twelve inches of the top of the structure. This standard does not cover the design of filter materials where needed.

Materials used for envelopes shall not contain materials which will cause an accumulation of sediment in the conduit or render the envelope unsuitable for bedding of the conduit. Envelope materials shall consist of either filter cloth or sand/gravel material, which shall pass a 1 1/2 inch sieve, 90 to 100 percent shall pass a 3/4 inch sieve, and not more than 10 percent shall pass a No. 60 sieve.

Filter cloth envelope can be either woven or nonwoven monofilament yarns and shall have a sieve opening ranging from 40 to 80. The envelope shall be placed in such manner that once the conduit is installed, it shall completely encase the conduit.

The conduit shall be placed and bedded in a sand/gravel envelope. A minimum of three inches depth of envelope materials shall be placed on the bottom of a conventional trench. The conduit shall be placed on this and the trench completely filled with envelope material to minimum depth of 3 inches above the conduit.

Soft or yielding soils under the drain shall be stabilized where required and lines protected from settlement by adding gravel or other suitable material to the trench, by placing the conduit on plank or other rigid support, or by using long sections of perforated or watertight pipe with adequate strength to insure satisfactory subsurface drain performance.

Use of Heavy Duty Corrugated Plastic Drainage Tubing

Heavy duty corrugated drainage tubing shall be specified where rocky or gravelly soils are expected to be encountered during installation operations. The quality of tubing will also be specified when cover over this tubing is expected to exceed 24 inches for 4, 5, 6, or 8 inch tubing. Larger size tubing designs will be handled on an individual job basis.

Auxiliary Structure and Subsurface Drain Protection

The outlet shall be protected against erosion and undermining of the conduit, against damaging periods of submergence and against entry of rodents or other animals into the subsurface drain. An animal guard shall be installed on the outlet end of the pipe. A swinging animal guard shall be used if surface water enters the pipe.

A continuous 10 foot section of corrugated metal, cast iron, polyvinyl chloride or steel pipe without perforations shall be used at the outlet end of the line and shall outlet 1.0 foot above the normal elevation of low flow in the outlet ditch or above mean high tide in tidal areas. No envelope material shall be used around the 10 foot section of pipe. Two-thirds of the pipe shall be buried in the ditch bank and the cantilevered section shall extend to a point above the toe of the ditch side slope. If not possible, the side slope shall be protected from erosion.

Conduits under roadways and embankments shall be watertight and designed to withstand the expected loads.

Where surface water is to be admitted to subsurface drains, inlets shall be designed to exclude debris and prevent sediment from entering the conduit. Lines flowing under pressure shall be designed to withstand the resulting pressures and velocity of flow. Surface waterways shall be used where feasible.

The upper end of each subsurface drain line shall be capped with a tight fitting cap of the same material as the conduit or other durable material unless connected to a structure.

Construction Specifications

1. Deformed, warped, or otherwise damaged pipe or tubing shall not be used.
2. All subsurface drains shall be laid to a uniform line and covered with envelope material. The pipe or tubing

VOL 12

6/89

shall be laid with the perforations down and oriented symmetrically about the vertical center line. Connections will be made with manufactured functions comparable in strength with the specified pipe or tubing unless otherwise specified. The method of placement and bedding shall be as specified on the drawing.

3. Envelope material shall consist of filter cloth or a sand/gravel (which shall pass the 1 1/2 inch sieve, 90 to 100 percent shall pass 3/4 inch sieve, and not more than 10 percent shall pass the No. 60 sieve).
4. The upper end of each subsurface drain line shall be capped with a tight fittings cap of the same material as the conduit or other durable material unless connected to a structure.
5. A continuous 10 foot section of corrugated metal, cast iron, polyvinyl chloride or steel pipe without perforations shall be used at the outlet end of the line. No envelope material shall be used around the 10 foot section of pipe. An animal guard shall be installed on the outlet end of the pipe.
6. Earth backfill material shall be placed in the trench in such a manner that displacement of the drain will not occur.
7. Where surface water is entering the system, the pipe outlet section of the system shall contain a swing type trash and animal guard.

STANDARD AND SPECIFICATIONS FOR LAND GRADING

VOL 12

6/94

Definition

Reshaping of the existing land surface in accordance with a plan as determined by engineering survey and layout.

Purpose

The purpose of a land grading specification is to provide for erosion control and vegetative establishment on those areas where the existing land surface is to be reshaped by grading according to plan.

Design Criteria

The grading plan should be based upon the incorporation of building designs and street layouts that fit and utilize existing topography and desirable natural surrounding to avoid extreme grade modifications. Information submitted must provide sufficient topographic surveys and soil investigations to determine limitations that must be imposed on the grading operation related to slope stability, effect on adjacent properties and drainage patterns, measures for drainage and water removal and vegetative treatment, etc.

Many counties have regulations and design procedures already established for land grading and cut and fill slopes. Where these requirement exist, they shall be followed.

The plan must show existing and proposed contours of the area(s) to be graded. The plan shall also include practices for erosion control, slope stabilization, safe disposal of runoff water and drainage, such as waterways, lined ditches, reverse slope benches (include grade and cross section), grade stabilization structures, retaining walls, and surface and subsurface drains. The plan shall also include phasing of these practices. The following shall be incorporated into the plan:

1. Provisions shall be made to safely conduct surface runoff to storm drains, protected outlets or to stable water courses to insure that surface runoff will not damage slopes or other graded areas; see standards and specifications for Grassed Waterway, Diversion, Grade Stabilization Structure.
2. Cut and fill slopes that are to be stabilized with grasses shall not be steeper than 2:1. when slopes exceed 2:1 special design and stabilization consideration are required and shall be adequately shown on the plans. (Note: Where the slope is to be mowed the slope should be no steeper than 3:1 although 4:1 is preferred because of safety factors related to mowing steep slopes.)
3. Reverse slope benches or diversion shall be provided whenever the vertical interval (height) of any 2:1 slope exceeds 20 feet; for 3:1 slope it shall be increased to 30 feet and for 4:1 to 40 feet. Benches shall be located to divide the slope face as equally as possible and shall convey the water to a stable outlet. Soils, seeps, rock outcrops, etc., shall also be taken into consideration when designing benches.
   A. Benches shall be a minimum of six feet wide to provide for ease of maintenance.
   B. Benches shall be designed with a reverse slope of 6:1 or flatter to the toe of the upper slope and with a minimum of one foot in depth. Bench gradient to the outlet shall be between 2 percent and 3 percent, unless accompanied by appropriate design and computations.
   C. The flow length within a bench shall not exceed 800 feet unless accompanied by appropriate design and computations; see Standard and Specifications for Diversion on page 5B.1.
4. Surface water shall be diverted from the face of all cut and/or fill slopes by the use of diversions, ditches and swales or conveyed downslope by the use of a designed structure, except where:
   A. The face of the slope is or shall be stabilized and the face of all graded slopes shall be protected from surface runoff until they are stabilized.
   B. The face of the slope shall not be subject to any concentrated flows of surface water such as from natural drainage ways, graded swales, downspouts, etc.
   C. The face of the slope will be protected by special erosion control materials, sod, gravel, riprap or other stabilization method.
5. Cut slopes occurring in ripable rock shall be serrated as shown in Figure 5B.25 on page 5B.51. The serrations shall be made with conventional equipment as the excavation is made. Each step or serration shall be constructed on the contour and will have steps cut at nominal two foot intervals with nominal three foot horizontal shelves. These steps will vary depending on the slope ratio or the cut slope. The nominal slope line is 1-1/2:1. These steps will weather and act to hold moisture, lime, fertilizer and seed thus producing a much quicker and longer lived vegetative cover and better slope stabilization. Overland flow shall be diverted from the top of all serrated cut slopes and carried to a suitable outlet.

6. Subsurface drainage shall be provided where necessary to intercept seepage that would otherwise adversely affect slope stability or create excessively wet site conditions.

7. Slopes shall not be created so close to property lines as to endanger adjoining properties without adequately protecting such properties against sedimentation, erosion, slippage, settlement, subsidence or other related damages.

8. Fill material shall be free of brush, rubbish, rocks, logs, stumps, building debris, and other objectionable material. It should be free of stones over two (2) inches in diameter where compacted by hand or mechanical tampers or over eight (8) inches in diameter where compacted by rollers or other equipment. Frozen material shall not be placed in the fill nor shall the fill material be placed on a frozen foundation.

9. Stockpiles, borrow areas and spoil shall be shown on the plans and shall be subject to the provisions of this Standard and Specifications.

10. All disturbed areas shall be stabilized structurally or vegetatively in compliance with the Standard and Specifications for Critical Area Treatment in Section 3.

Construction Specifications

See Figure 5B.26 on page 5B.52 for details.

1. All graded or disturbed areas including slopes shall be protected during clearing and construction in accordance with the erosion and sediment control plan until they are adequately stabilized.

2. All erosion and sediment control practices and measures shall be constructed, applied and maintained in accordance with the sediment control plan and the "New York Guidelines for Urban Erosion and Sediment Control."

3. Topsoil required for the establishment of vegetation shall be stockpiled in amount necessary to complete finished grading of all exposed areas.

4. Areas to be filled shall be cleared, grubbed and stripped of topsoil to remove trees, vegetation, roots or other objectionable material.

5. Areas which are to be topsoiled shall be scarified to a minimum depth of three inches prior to placement of topsoil.

6. All fills shall be compacted as required to reduce erosion, slippage, settlement, subsidence or other related problems. Fill intended to support buildings, structures and conduits, etc., shall be compacted in accordance with local requirements or codes.

7. All fill shall be placed and compacted in layers not to exceed 8 inches in thickness.

8. Except for approved landfills or nonstructural fills, fill material shall be free of brush, rubbish, rocks, logs, stumps, building debris and other objectionable materials that would interfere with or prevent construction of satisfactory fills.

9. Frozen material or soft, mucky or highly compressible materials shall not be incorporated into fill slopes or structural fills.

10. Fill shall not be placed on frozen foundation.

11. All benches shall be kept free of sediment during all phases of development.

12. Seeps or springs encountered during construction shall be handled in accordance with the Standard and Specification for Subsurface Drain on page 5B.43 or other approved methods.

13. All graded areas shall be permanently stabilized immediately following finished grading.

14. Stockpiles, borrow areas, and spoil areas shall be shown on the plans and shall be subject to the provisions of this Standard and Specifications.

Construction Specifications

1. All graded or disturbed areas including slopes shall be protected during clearing and construction in accordance with the approved sediment control plan until they are permanently stabilized.
2. All sediment control practices and measures shall be constructed, applied and maintained in accordance with the approved sediment control plan and the "Standards and Specifications for Soil Erosion and Sediment Control in Developing Areas".
3. Topsoil required for the establishment of vegetation shall be stockpiled in amount necessary to complete finished grading of all exposed areas.
4. Areas to be filled shall be cleared, grubbed and stripped of topsoil to remove trees, vegetation, roots or other objectionable material.
5. Areas which are to be topsoiled shall be scarified to a minimum depth of three inches prior to placement of topsoil.
6. All fills shall be compacted as required to reduce erosion, slippage, settlement, subsidence or other related problems. Fill intended to support buildings, structures and conduits, etc., shall be compacted in accordance with local requirements or codes.
7. All fill to be placed and compacted in layers not to exceed 8 inches in thickness.
8. Except for approved landfills, fill material shall be free of brush, rubbish, rocks, logs, stumps, building debris and other objectionable materials that would interfere with or prevent construction of satisfactory fills.
9. Frozen materials or soft, mucky or highly compressible materials shall not be incorporated into fills.
10. Fill shall not be placed on a frozen foundation.
11. All benches shall be kept free of sediment during all phases of development.
12. Seeps or springs encountered during construction shall be handled in accordance with the Standard and Specifications for Subsurface Drain or other approved method.
13. All graded areas shall be permanently stabilized immediately following finished grading.
14. Stockpiles, borrow areas and spoil areas shall be shown on the plans and shall be subject to the provisions of this Standard and Specifications.

U.S. DEPARTMENT OF AGRICULTURE SOIL CONSERVATION SERVICE SYRACUSE, NEW YORK	LANDGRADING DETAILS	STANDARD SYMBOL

STANDARD AND SPECIFICATIONS FOR SURFACE ROUGHENING

Definition

Roughening a bare soil surface with horizontal grooves running across the slope, stair-stepping, or tracking with construction equipment.

Purpose

To aid the establishment of vegetative cover from seed, to reduce runoff velocity and increase infiltration, and to reduce erosion and provide for trapping of sediment.

Conditions Where Practice Applies

All construction slopes require surface roughening to facilitate stabilization with vegetation, particularly slopes steeper than 3:1.

Design Criteria

There are many different methods to achieve a roughened soil surface on a slope. No specific design criteria is required. However, the selection of the appropriate method depends on the type of slope. Methods include tracking, grooving and stair-stepping. Steepness, mowing requirements, a cut or fill slope operation are all factors considered in choosing a roughening method.

Construction Specifications

A. <u>Cut slope, No mowing</u>

1. Stair-step grade or groove cut slopes with a gradient steeper than 3:1. (figure 5B.27).
2. Use stair-step grading on any erodible material soft enough to be ripped with a bulldozer. Slopes of soft rock with some soil are particularly suited to stair-step grading.
3. Make the vertical cut distance less than the horizontal distance, and slightly slope the horizontal position of the "step" to the vertical wall.
4. Do not make vertical cuts more than 2 feet in soft materials or 3 feet in rocky materials.

Grooving uses machinery to create a series of ridges and depressions that run across the slope on the contour. Groove using any appropriate implement that can be safely operated on the slope, such as disks, tillers, spring harrows, or the teeth of a front end loader bucket. Do not make the grooves less than 3 inches deep or more than 15 inches apart.

B. <u>Fill slope, No Mowing</u>

1. Place fill to create slopes with a gradient steeper than 3:1 in lifts 9 inches or less and properly compacted. Ensure the face of the slope consists of loose, uncompacted fill 4 to 6 inches deep. Use grooving as described above to roughen the slope, if necessary.
2. Do not blade or scrape the final slope face.

C. <u>Cuts/Fills, Mowed Maintenance</u>

1. Make mowed slopes no steeper than 3:1.
2. Roughen these areas to shallow grooves by normal tilling, disking, harrowing, or use of cultipacker-seeder. Make the final pass of such tillage equipment on the contour.
3. Make grooves at least 1 inch deep and a maximum of 10 inches apart.
4. Excessive roughness is undesirable where mowing is planned.

Tracking should be used primarily in sandy soils to avoid undue compaction of the soil surface. Tracking is generally not as effective as the other roughening methods described. (It has been used as a method to track down mulch). Operate tracked machinery up and down the slope to leave horizontal depressions in the soil. Do not back-blade during the final grading operation.

STANDARD AND SPECIFICATIONS FOR RIPRAP SLOPE PROTECTION

Definition

A layer of stone designed to protect and stabilize areas subject to erosion.

Purpose

To protect the soil surface from erosive forces and/or improve the stability of soil slopes that are subject to seepage or have poor soil structure.

Conditions Where Practice Applies

Riprap is used for cut and fill slopes subject to seepage, erosion, or weathering, particularly where conditions prohibit the establishment of vegetation. Riprap is also used for channel side slopes and bottoms, streambanks and grade sills, on shorelines subject to erosion, and at inlets and outlets to culverts, bridges, slope drains, grade stabilization structures and storm drains.

Design Criteria

Gradation - Riprap should be a well-graded mixture with 50% by weight larger than the specified design size. The diameter of the largest stone size in such a mixture should be 1.5 times the d50 size with smaller sizes grading down to 1 inch. The designer should determine the riprap size that will be stable for design conditions. Having determined the stone size, the designer should select the size or sizes that equal or exceed that minimum size based on riprap gradations commercially available in the area.

Thickness - The minimum layer thickness should be 1.5 times the maximum stone diameter, but in no case less than 6 inches.

Quality - Stone for riprap should be hard, durable field or quarry materials. They should be angular and not subject to breaking down when exposed to water or weathering. The specific gravity should be at least 2.5.

Size - The sizes of stones used for riprap protection are determined by purpose and specific site conditions:

1. Slope Stabilization - Riprap stone for slope stabilization not subject to flowing water or wave action should be sized for the proposed grade. The gradient of the slope to be stabilized should be less than the natural angle of repose of the stone selected. Angles of repose of riprap stones may be estimated from figure 5B.28.

   Riprap used for surface stabilization of slopes does not add significant resistance to sliding or slope failure and should not be considered a retaining wall. Slopes approaching 1.5:1 may require special stability analysis. The inherent stability of the soil must be satisfactory before riprap is used for surface stabilization.

2. Outlet Protection - Design criteria for sizing stone and determining dimensions of riprap aprons are presented in Standards and Specifications for Rock Outlet Protection.

3. Streambank Protection - Design criteria for sizing stone for stability of channel bank are presented in Standard and Specifications for Structural Streambank Protection.

Filter Blanket - A filter blanket is a layer of material placed between the riprap and the underlying soil to prevent soil movement into or through the riprap. A suitable filter may consist of a well-graded gravel or sand-gravel layer or a synthetic filter fabric manufactured for this purpose. The design of a gravel filter blanket is based on the ratio of particle size in the overlying filter material to that of the base material in accordance with the criteria below. Multiple layers may be designed to effect a proper filter if necessary.

A gravel filter blanket should have the following relationship for a stable design:

$$\frac{d_{15}\text{ filter}}{d_{85}\text{ base}} \leq 5$$

$$5 < \frac{d_{15}\text{ filter}}{d_{50}\text{ base}} \leq 40$$

and

$$\frac{d_{50}\text{ filter}}{d_{50}\text{ base}} \leq 40$$

Filter refers to the overlying material while base refers to the underlying material. These relationship must hold between the base and filter and the filter and riprap to prevent migration of material. In some cases more than one filter may be needed. Each filter layer should be a minimum of 6 inches thick.

A synthetic filter fabric may be used with or in place of gravel filters. The following particle size relationships should exist:

1. Filter fabric covering a base containing 50% or less by weight of fine particles (#200 sieve size):

a. $$\frac{d_{85}\text{ base (mm)}}{\text{EOS}^{*}\text{filter fabric (mm)}} > 1$$

VOL 12

6200

b. total open area of filter fabric should not exceed 36%

2. Filter fabric covering other soils:

a. EOS is no larger than 0.21 mm (#70 sieve size)

b. total open area of filter fabric should not exceed 10%.

*EOS - Equivalent opening size compared to a U.S. standard sieve size.

No filter fabric should have less than 4% open area or an EOS less than U.S. Standard Sieve #100 (0.15 mm). The permeability of the fabric must be greater than that of the soil. The fabric may be made of woven or nonwoven monofilament yarns and should meet the following minimum requirements:

thickness 20-60 mils

grab strength 90-120 lbs.

conform to ASTM D-1682 or ASTM D-177

Filter blankets should always be provided where seepage is significant or where flow velocity and duration of flow or turbulence may cause underlying soil particles to move through the riprap.

Construction Specifications

Subgrade Preparation - Prepare the subgrade for riprap and filter to the required lines and grades shown on the plans. Compact any fill required in the subgrade to a density approximating that of the undisturbed material or overfill depressions with riprap. Remove brush, trees, stumps, and other objectionable material. Cut the subgrade sufficiently deep so that the finished grade of the riprap will be at the elevation of the surrounding area. Channels should be excavated sufficiently to allow placement of the riprap in a manner such that the finished inside dimensions and grade of the riprap meet design specifications.

Sand and gravel filter blanket - Place the filter blanket immediately after the ground foundation is prepared. For gravel, spread filter stone in a uniform layer to the specified depth. Where more than one layer of filter material is used, spread the layers with minimal mixing.

Synthetic filter fabric - Place the cloth directly on the prepared foundation. Overlap the edges by at least 2 feet, and space the anchor pins every 3 feet along the overlap. Bury the upper and lower ends of the cloth a minimum of 12 inches below ground. Take precautions not to damage the cloth by dropping the riprap. If damage occurs remove the riprap and repair the sheet by adding another layer of filter fabric with a minimum overlap of 12 inches around the damaged area. Where large stones are to be place, a 4 inch layer of fine sand or gravel is recommended to protect the filter cloth.

Stone placement - Placement of the riprap should follow immediately after placement of the filter. Place riprap so that it forms a dense, well-graded mass of stone with a minimum of voids. The desired distribution of stones throughout the mass may be obtained by selective loading at the quarry and controlled dumping during final placement. Place riprap to its full thickness in one operation. Do not place riprap by dumping through chutes or other methods that cause segregation of stone sizes. Be careful not to dislodge the underlying base or filter when placing the stones.

The toe of the riprap should be keyed into a stable foundation at its base as shown in figure 5B.29. The toe should be excavated to a depth of 2.0 feet. The design thickness of the riprap should extend a minimum of 3 feet horizontally from the slope. The finished slope should be free of pockets of small stone or clusters of large stones. Hand placing may be necessary to achieve proper distribution of stone sizes to produce a relatively smooth, uniform surface. The finished grade of the riprap should blend with the surrounding area.

Maintenance

Riprap should be inspected periodically for scour or dislodged stones. Control weed and brush growth as needed.

STANDARD AND SPECIFICATIONS FOR RETAINING WALLS

Definition

A structural wall constructed and located to prevent soil movement.

Purpose

To retain soil in place and prevent slope failures and movement of material down steep slopes.

Conditions Where Practice Applies

A retaining wall may be used where site constraints won't allow slope shaping and seeding to stabilize an area. Slope areas that demonstrate seepage problems or experience erosive conditions at the toe can utilize retaining walls to help stabilize these areas. Retaining walls can be built from mortared block or stone, cast-in-place concrete, railroad ties, gabions, and more recently, precast concrete modular units that form a gravity retaining wall (see figure 5B.30). These precast units allow for ease and quickness of installation while their granular backfill provides drainage. Selection of materials and type of wall should be based on hazard potential, load conditions, soil parameters, groundwater conditions, site constraints and aesthetics.

Design Criteria

The design of any retaining wall structure must address the aspects of foundation bearing capacity, sliding, overturning, drainage and loading systems. These are complex systems and all but the smallest retaining walls should be designed by a licensed engineer.

Bearing Capacity - A minimum factor of safety of 1.5 should be maintained as the ratio of the ultimate bearing capacity to the designed unit loading. Spread footers and other methods may be used to meet factor requirements.

Sliding - A minimum factor of 2.0 should be maintained against sliding. This factor is usually reduced to 1.5 when passive pressures on the front of the wall are ignored.

Overturning - A minimum factor of safety of 1.5 should be used as the ratio of the resisting moment (that which tends to keep the wall in place) to the overturning moment.

Drainage - Unless adequate provisions are made to control both surface and groundwater behind the retaining wall, a substantial increase in active pressures tending to slide or overturn the wall will result. When backfill is sloped down to a retaining wall surface drainage should be provided. Drainage systems with adequate outlets should be provided behind retaining walls that are placed in cohesive soils. Drains should be graded or protected by filters so soil material will not move through the drainfill.

Load systems - Several different loads or combination of loads need to be considered when designing a retaining wall. The minimum load is the level backfill that the wall is being constructed to retain. Its unit weight will vary depending on its composition.

Additional loads such as line loads, surcharge loads or slope fills will add to make the composite design load system for the wall.

Construction Specifications

Concrete Walls

1. Foundation will be prepared by excavating to the lines and grades shown on the drawings and removing all objectionable material.
2. Subgrade will be compacted and kept moist at least 2 hours prior to placement of concrete.
3. Steel reinforcing will be in accordance with the schedule on the drawings and kept free of rust, scale or dirt.
4. Exposed edges will be chamfered 3/4 inches.
5. Drainfill will meet the gradations shown on the drawings.
6. Weep holes will be provided as drain outlets as shown on the drawings.
7. Concrete will be poured and cured in accordance with ACI specifications.

Precast Units

1. Foundation will be prepared by excavating to the lines and grades shown on the drawings.
2. Subgrade will be compacted and trimmed to receive the leveling beam.
3. Precast units will be placed in accordance with the manufacturers recommendation.
4. Granular fill placed in the precast bins shall be placed in 3 foot lifts, leveled off and compacted with a plate vibrator.

Gabions

1. Foundation will be prepared by excavating to the lines and grades shown on the drawings.

2. Subgrade will be compacted and leveled to receive first layer of gabions. The first row will be keyed into the existing grade at the toe, a minimum of 1.5 feet.
3. Gabions will be placed according to the manufacturers recommendations.
4. They will be filled with stone or crushed rock from 4 to 8 inches in diameter.
5. In corrosive environments, gabion wire should be coated with PVC.

Maintenance

Once in place a retaining wall should require little maintenance. They should be inspected annually for signs of tipping, clogged drains or soil subsidence. If such conditions exist they should be corrected immediately.

Example Erosion and Sediment Control Plan

Introduction

What follows is an example erosion and sedimentation control plan based on one from the files of the State of North Carolina. The site is located in the Piedmont region. The plan was modified to demonstrate the application of a variety of erosion and sedimentation control practices.

This example plan was developed in detail for instructive purposes. The specific number of maps, practices, drawings, specifications, and calculations required depends on the size and complexity of the development. The designer should select the most practical and effective practices to control erosion and prevent sediment from leaving the site. The plan should be organized and presented in a clear, concise manner. Sufficient design and background information should be included to facilitate review by erosion control personnel. Construction details should be precise and clear for use by an experienced general contractor.

An acceptable erosion and sedimentation control plan must contain:

1. brief narrative
2. construction schedule
3. maintenance plan
4. vicinity map
5. site topo map
6. site development plan
7. erosion and sedimentation control plan drawing
8. detail drawings and specifications
9. vegetative plan

Although this example is from North Carolina, its organization, analysis and detail are appropriate in all locations. The original content of the example was retained for continuity. Regarding practices selected, refer to the flow charts in Section 2 to correlate with the control groups. In the example, the temporary diversion equate to New York's earth dike. Supporting calculations for these practices are not included to maintain the size of this publication. However, the criteria in each of the practice standards in the appropriate sections, will guide the user in their design.

Narrative

Project Description

The purpose of the project is to construct two large commercial buildings with associated paved roads and parking area. Another building will be added in the future. Approximately 6 acres will be disturbed during this construction period. The site is 11.1 acres located in Granville County, 2 miles north of Deal, NC, off Terri Road (see Vicinity Map).

Site Description

The site has rolling topography with slopes generally 4 to 6%. Slopes steepen to 10 to 20% in the northwest portion of the property where a small, healed-over gully serves as the principal drainageway for the site. The site is now covered with volunteer heavy, woody vegetation, predominately pines, 15 to 20 ft high. There is no evidence of significant erosion under present site conditions. The old drainage gully indicates severe erosion potential and receives flow from 5 acres of woods off-site. There is one large oak tree, located in the western central portion of the property, and a buffer area, fronting Terri Road, that will be protected during construction.

Adjacent Property

Land use in the vicinity is commercial/industrial. The land immediately to the west and south has been developed for industrial use. Areas to the north and east are undeveloped and heavily wooded, primarily in volunteer pine. Hocutt Creek, the off-site outlet for runoff discharge, is presently a well-stabilized, gently flowing perennial stream. Sediment control measures will be taken to prevent damage to Hocutt Creek. Approximately 5 acres of wooded area to the east contribute runoff into the construction area.

Soils

The soil in the project area is mapped as Creedmoor sandy loam in B and C slope classes. Creedmoor soils are considered moderately well to somewhat poorly drained with permeability rates greater than 6 inches/hour at the surface but less than 0.1 inches/hour in the subsoil. The subsurface is pale brownstone loam, 6 inches thick. The subsoil consists of a pale brown and brownish yellow sandy clay loam ranging from light gray clay, 36 inches thick. Below 36 inches is a layer of fine sandy loam to 77 inches. The soil erodibility factor (K value) ranges from 0.20 at the surface to 0.37 in the subsoil.

Due to the soil permeability of the subsoil that will be exposed during grading, a surface wetness problem with high runoff is anticipated following significant rainfall events. No groundwater problem is expected. The tight clay in the subsoil will make vegetation difficult to establish. A small amount of topsoil exists on-site and will be stockpiled for use in landscaping.

VOL 12

624

Planned Erosion and Sedimentation Control Practices

1. **Sediment Basin:** A sediment basin will be constructed in the northwest corner of the property. All water from disturbed areas, about 6 acres, will be directed to the basin before leaving the site. (Note: The undisturbed areas to the east and north could have been diverted, but this was not proposed because it would have required clearing to the property line to build the diversion and the required outlet structure.) See pages 6.11-6.13 for details.

2. **Temporary Gravel Construction Entrance/Exit:** A temporary gravel construction entrance will be installed near the northwest corner of the property. During wet weather it may be necessary to wash vehicle tires at this location. The entrance will be graded so that runoff water will be directed to an inlet protection structure and away from the steep fill area to the north. See page 6.13 for specifications.

3. **Temporary Block and Gravel Drop Inlet Protection:** A temporary block and gravel drop inlet protection will be installed at the drop inlet located on the south side of the construction entrance. Runoff from the device will be directed into the sediment basin. (Note: The presence of this device reduces the sediment load on the sediment basin and provides sediment protection for the pipe. In addition, sediment removal at this point is more convenient than from the basin.) See page 6.14 for specifications.

4. **Temporary Diversion:** Temporary diversions will be constructed above the 3:1 cut slopes south of Buildings A and B to prevent surface runoff from eroding these banks. (Note: Sediment-free water may be diverted away from the project sediment basin.) A temporary diversion will be constructed near the middle of the disturbed area to break up this long, potentially erosive slope should the grading operation be temporarily discontinued. A temporary diversion dike will be constructed along the top edge of the fill slope at the end of each day during the filling operation to protect the fill slope. This temporary diversion will outlet to the existing undisturbed channel near the north edge of the construction site and/or to the temporary inlet protection device at the construction entrance as the fill elevation increases. See page 6.15 for specifications.

5. **Level Spreader:** A level spreader will serve as the outlet for the diversion east of Building A and south of Building B. The area below the spreader is relatively smooth and heavily vegetated with a slope of approximately 4%. See page 6.16 for specifications.

6. **Tree Preservation and Protection:** A minimum 2.0 ft. high protective fence will be erected around a large oak tree at the dripline to prevent damage during construction. Sediment fence materials may be used for this purpose. See page 6.17 for specifications.

7. **Land Grading:** Heavy grading will be required on approximately 6 acres. The flatter slope after grading will reduce the overall erosion potential of the site. The buildings will be located on the higher cut areas, and the access road and open landscaped areas will be located on fill areas. See pages 6.17-6.18 for specifications.

All cut slopes will be 3:1 or flatter to avoid instability due to wetness, provide fill material, give an open area around the buildings, and allow vegetated slopes to be mowed. Cut slopes will be fine graded immediately after rough grading; the surface will be disked and vegetated according to the Vegetation Plan (pages 6.30-6.32).

Fill slopes will be 2:1 with fill depths as much as 12 to 15 ft. Fill will be placed in layers not to exceed 9 inches in depth and compacted. (Note: Fills of this depth should have detailed compaction specifications in the general construction contract. These specifications are not part of the erosion and sedimentation control plan.)

The fill slope in the north portion of the property is the most vulnerable area to erosion on the site. Fill slopes will be 2:1 with fill depths as much as 12 to 15 ft. Fill will be placed in layers not to exceed 9 inches in depth and compacted.

VOL 12 6215

(Note: Fills of this depth should have detailed compaction specifications in the general construction contract. These specifications are not part of the erosion and sedimentation control plan.)

The fill slope in the north portion of the property is the most vulnerable area to erosion on the site. Temporary diversions will be maintained at the top of this fill slope at all times, and the filling operation will be graded to prevent overflow to the north. Filling will be done as a continuous operation until final grade is reached. The paved road located on the fill will be sloped to the south and will function as a permanent diversion. The area adjacent to the roads and parking area will be graded to conduct runoff to the road culverts. Runoff water from the buildings will be guttered to the vegetated channels. The finished slope face to the north will not be back-bladed. The top 2 to 6 inches will be left in a loose and roughened condition. Plantings will be protected with mulch, as specified in the Vegetation Plan.

A minimum 15-ft undisturbed buffer zone will be maintained around the perimeter of the disturbed area. (NOTE: This will reduce water and wind erosion, help contain sediment, reduce dust, and reduce final landscaping costs.)

8. **Temporary Sediment Trap:** A small sediment trap will be constructed at the intersection of the existing road ditch and channel number 3 to protect the road ditch. Approximately 2 acres of disturbed area will drain into this trap. See pages 6.19-6.20 for specifications.

9. **Sediment Fence:** A sediment fence will be constructed around the topsoil stockpile and along the channel berm adjacent to the deep cut area as necessary to prevent sediment from entering the channels. See pages 6.20-6.21 for specifications.

10. **Sod Drop Inlet Protection:** Permanent sod drop inlet protection will replace the temporary block and gravel structure when the contributing drainage area has been permanently seeded and mulched. See pages 6.21-6.22 for specifications.

11. **Grass-Lined Channel:** Grass-lined channels with temporary straw-net liners will be constructed around Buildings A and B to collect and convey site water to the project's sediment basin. See pages 6.22-6.24 for specifications.

Should the disturbed areas adjoining the channels not be stabilized at the time the channels are vegetated, a sediment fence will be installed adjacent to the channel to prevent channel siltation.

12. **Riprap-Lined and Paved Channels:** A riprap channel will be constructed in the old gully along the north side of the property starting in the northwest corner after all other construction is complete. This channel will replace the old gully as the principal outlet from the site. See pages 6.25-6.26 for specifications.

13. **Construction Road Stabilization:** As soon as final grade is reached on the entrance road, the subgrade will be sloped to drain to the south and stabilized with a 6-inch course of NC DOT standard ABC stone. The parking area and its entrance road will also be stabilized with ABC stone to prevent erosion and dust during the construction of the buildings prior to paving. See pages 6.26-6.27 for specifications.

14. **Outlet Stabilization Structure:** A riprap apron will be located at the outlet of the three culverts to prevent scour. See pages 6.27-6.28 for specifications.

15. **Surface Roughening:** The 3:1 cut slopes will be lightly roughened by disking just prior to vegetating, and the surface 4 to 6 inches of the 2:1 fill slopes will be left in a loose condition and grooved on the contour. See page 6.29 for specifications.

16. **Surface stabilization**: will be accomplished with vegetation and mulch as specified in the vegetation plan. One large oak tree southwest of Building A and a buffer area between the parking lot and Terri Road will be preserved. Roadway and parking lot base courses will be installed as soon as finished grade is reached.

17. **Dust control**: is not expected to be a problem due to the small area of exposure, the undisturbed perimeter of trees around the site, and the relatively short time of exposure (not to exceed 9 months). Should excessive dust be generated, it will be controlled by sprinkling.

VOL 12

6217

Construction Schedule

1. Obtain plan approval and other applicable permits.
2. Flag the work limits and mark the oak tree and buffer area for protection.
3. Hold preconstruction conference at least one week prior to starting construction.
4. Install sediment basin as the first construction activity.
5. Install storm drain with block and gravel inlet protection at construction entrance/exit.
6. Install temporary gravel construction entrance/exit.
7. Construct temporary diversions above proposed building sites. Install level spreader and sediment trap and vegetate disturbed areas.
8. Complete site clearing except for the old gully channel in the northwest portion of the site. This area will be cleared during last construction phase for the installation of the riprap liner.
9. Clear waste disposal area in the northeast corner of property, only as needed.
10. Rough grade site, stockpile topsoil, construct channels, install culverts and outlet protection, and install sediment fence as needed. Maintain diversions along top of fill slope daily. NOTE: A temporary diversion will be constructed across the middle of the graded area to reduce slope length and the bare areas mulched should grading be discontinued fort more than 3 weeks.
11. Finish the slopes around buildings as soon as rough grading is complete. Leave the surface slightly roughened and vegetate and mulch immediately.
12. Complete final grading for roads and parking and stabilize with gravel.
13. Complete final grading for buildings.
14. Complete final grading of grounds, topsoil critical areas, and permanently vegetate, landscape, and mulch.
15. Install riprap outlet channel and extend riprap to the pipe outlet under entrance road.
16. All erosion and sediment control practices will be inspected weekly and after rainfall events. Needed repairs will be made immediately.
17. After the site is stabilized, remove all temporary measures and install permanent vegetation on the disturbed areas.
18. Estimated time before final stabilization--9 months.

VOL 12

Maintenance Plan

1. All erosion and sediment control practices will be checked for stability and operation following every runoff-producing rainfall but in no case less than once every week. Any needed repairs will be made immediately to maintain all practices as designed.

2. The sediment basin will be cleaned out when the level of sediment reaches 2.0 ft below the top of the riser. Gravel will be cleaned or replaced when the sediment pool no longer drains properly.

3. Sediment will be removed from the sediment trap and block and gravel inlet protection device when storage capacity has been approximately 50% filled. Gravel will be cleaned or replaced when the sediment pool no longer drains properly.

4. Sediment will be removed from behind the sediment fence when it becomes about 0.5 ft deep at the fence. The sediment fence will be repaired as necessary to maintain a barrier.

5. All seeded areas will be fertilized, reseeded as necessary, and mulched according to specifications in the vegetative plan to maintain a vigorous, dense vegetative cover.

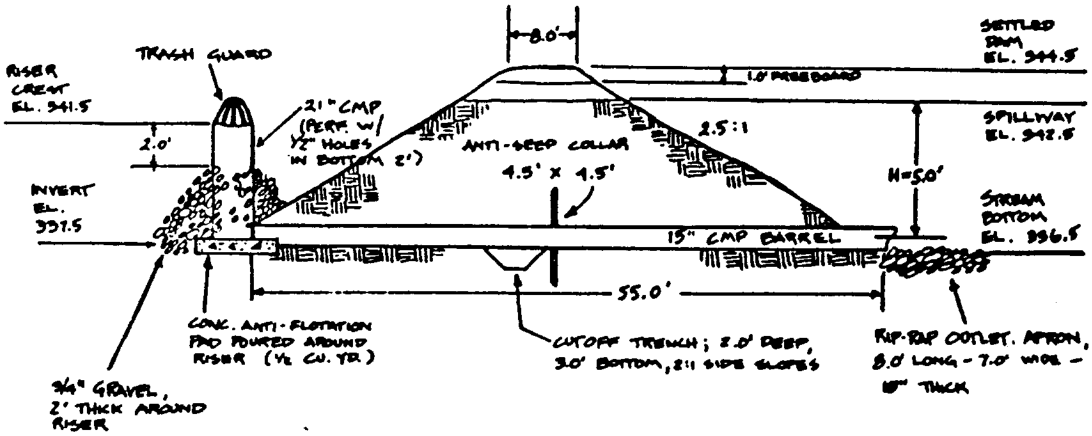
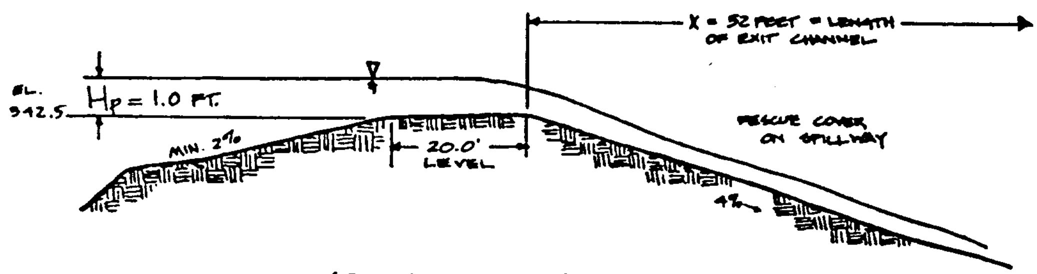
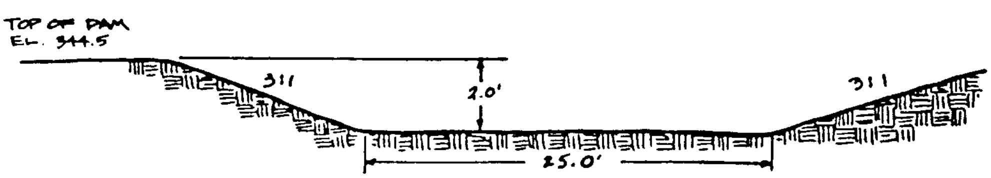
DETAIL DRAWINGS AND SPECIFICATIONS

1. SEDIMENT BASIN





SPILLWAY PROFILE



SPILLWAY: CROSS SECTION AT CONTROL SECTION

(1.) CONSTRUCTION SPECIFICATIONS:

1. CLEAR AND GRUB FOUNDATION FOR EMBANKMENT AND EXCAVATE THE AREA FOR THE RIPRAP OUTLET PAD. AREA TO BE 8.0' LONG, 7.0' WIDE AND 1.5' DEEP. (NOTE: THIS EXCAVATION WILL SERVE AS A SEDIMENT TRAP WHILE STRUCTURE IS BEING BUILT.)

2. EXCAVATE CUTOFF TRENCH ALONG EMBANKMENT CENTERLINE AND UP ABUTMENTS TO ELEVATION 544.0 AS SHOWN. KEEP TRENCH DRY WHEN BACKFILLING AND COMPACTING.

3. USE SEDIMENT POOL AREA AS SOURCE OF FILL MATERIAL FOR THE DAM. MATERIAL SHOULD BE CLEAN MINERAL SOIL, FREE OF ROOTS, WOODY MATERIAL, ROCKS OR OTHER OBJECTIONABLE MATERIAL. SCARIFY FOUNDATION AND PLACE FILL IN LAYERS NOT TO EXCEED 8" OVER THE ENTIRE LENGTH OF DAM. COMPACT BY HEAVY WHEEL EQUIPM NT. THE ENTIRE SURFACE OF EACH LAYER MUST BE TRAVERSED BY AT LEAST ONE WHEEL OF THE COMPACTION EQUIPMENT. THE FILL MATERIAL MUST BE MOIST BUT NOT SO WET THAT WATER CAN BE SQUEEZED FROM IT.

4. PERFORATE 24" CMP RISER WITH ½" HOLES SPACED 3" APART IN EACH OUTSIDE VALLEY TO WITHIN 2.0' OF THE TOP. SECURE TRASH RACK TO RISER TOP. MAXIMUM OPENING BETWEEN BARS OF RACK NOT TO EXCEED 3".

5. SECURELY ATTACH THE RISER TO THE BARREL AND ALL OTHER PIPE JOINTS WITH ROD AND LUG CONNECTOR BANDS WITH RUBBER GASKETS TO ASSURE WATER TIGHTNESS. PLACE THE BARREL AND RISER ON A SMOOTH, FIRM FOUNDATION. PLACE FILL AROUND THE PIPE IN 4" LAYERS AND HAND COMPACT. TAKE CARE NOT TO RAISE THE PIPE FROM FIRM CONTACT WITH ITS FOUNDATION WHEN COMPACTING UNDER PIPE HAUNCHES.

6. SECURE ONE STANDARD CORRUGATED METAL ANTI-SEEP COLLAR AROUND BARREL. MAKE SURE CONNECTION IS WATERTIGHT. HAND COMPACT AROUND ANTI-SEEP COLLAR.

7. PLACE A MINIMUM OF 2 FT. OF HAND COMPACTED BACKFILL OVER PIPE BEFORE CROSSING IT WITH CONSTRUCTION EQUIPMENT.

8. ANCHOR RISER IN PLACE WITH 1/2 YD³ CONCRETE PAD POURED AROUND RISER.

9. PLACE 3/4" GRAVEL (D.O.T. #5 WASHED STONE) OVER THE PERFORATED HOLES APPROXIMATELY 2" THICK.

10. INSTALL EMERGENCY SPILLWAY IN UNDISTURBED SOIL TO THE LINES AND GRADES SHOWN IN DRAWINGS.

VOL 12

6227

11. PLACE CLASS A EROSION CONTROL STONE OVER FILTER FABRIC ON LEVEL GRADE FOR RIPRAP APRON AT PIPE OUTLET. TOP OF RIPRAP TO BE SAME ELEVATION AS OUTLET CHANNEL BOTTOM. NO OVERFALL.

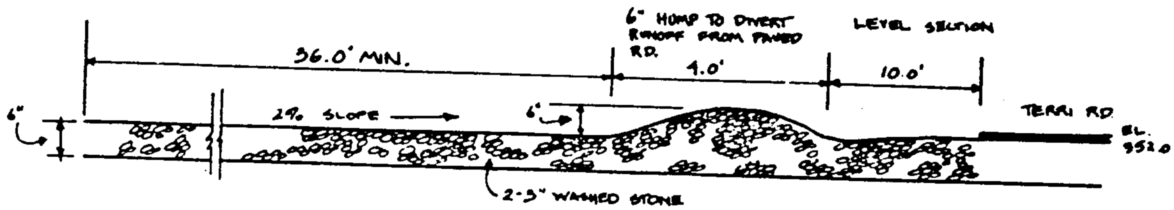
12. CLEAR SEDIMENT POOL AREA TO ELEVATION 341.5 AFTER THE EMBANKMENT IS COMPLETE.

13. VEGETATE ALL DISTURBED AREAS (EXCEPT THE SEDIMENT POOL) IN ACCORDANCE WITH THE VEGETATIVE PLAN.

14. SEDIMENT TO BE REMOVED FROM BASIN WHEN THE LEVEL IS WITHIN 2.0' OF THE TOP OF THE RISER. (SAME LEVEL AS TOP OF GRAVEL.)

VOL 12

2. TEMPORARY GRAVEL CONSTRUCTION ENTRANCE



GRAVEL ENTRANCE / EXIT : WIDTH — 15.0', FLARED TO 25.0' AT ROAD
LENGTH — 50.0'
GRADE — 2.0%

(2.) CONSTRUCTION SPECIFICATIONS

1. CLEAR THE ENTRANCE / EXIT AREA OF ALL VEGETATION, ROOTS, AND OTHER OBJECTIONABLE MATERIAL.

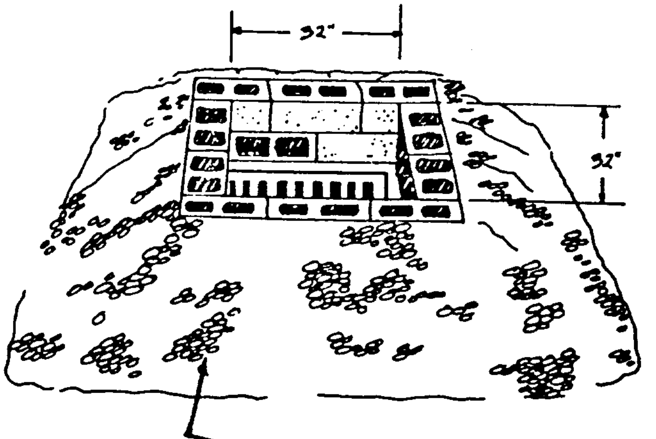
2. GRADE THE ROAD FOUNDATION SO THAT THE ENTRANCE / EXIT WILL HAVE A CROSS SLOPE TO THE SOUTH AND ALL RUNOFF WILL DRAIN TO THE BLOCK AND GRAVEL DROP INLET PROTECTION STRUCTURE.

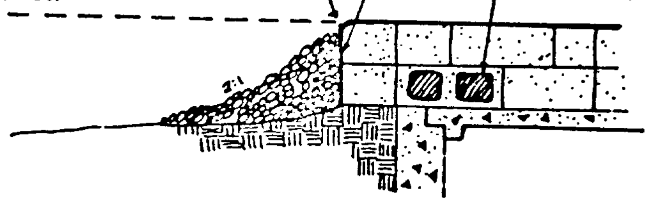
3. PLACE STONE TO THE DIMENSIONS, GRADE AND ELEVATION SHOWN.

4. USE WASHED STONE 2" TO 3" IN SIZE.

NOTE : MAINTAIN THE GRAVEL PAD IN A CONDITION TO PREVENT MUD OR SEDIMENT FROM LEAVING THE SITE. SHOULD MUD BE TRACKED OR WASHED ONTO TERRI ROAD, IT MUST BE REMOVED IMMEDIATELY.

3. TEMPORARY BLOCK AND GRAVEL DROP INLET PROTECTION





(3.) CONSTRUCTION SPECIFICATIONS

1. LAY CONCRETE BLOCKS ON FIRM, SMOOTH FOUNDATION EXCAVATED 3" BELOW STORM DRAIN TOP. PLACE BLOCKS AGAINST DRAIN INLET FOR LATERAL SUPPORT.

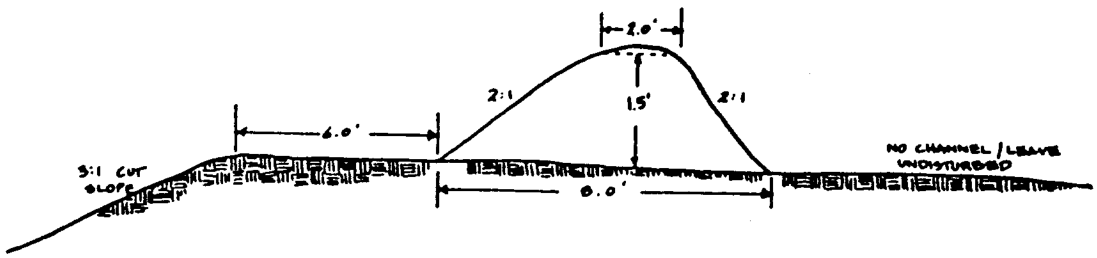
2. PLACE AT LEAST ONE CONCRETE BLOCK ON ITS SIDE IN EACH BOTTOM ROW OF BLOCKS.

3. PLACE WIRE MESH WITH ½" OPENINGS OVER ALL BLOCK OPENINGS USED FOR DRAINAGE.

4. USE D.O.T. #57 WASHED STONE TO REDUCE FLOW RATE BUT ALLOW DRAINAGE. PLACE STONE ON 2:1 SLOPE TO WITHIN 3" OF TOP OF BLOCK.

5. ANY SOIL LEFT EXPOSED BETWEEN THE BLOCK AND CONCRETE DRAIN INLET SHOULD BE FILLED WITH 3" DIAMETER STONE TO PREVENT WASHING WHEN WATER FLOWS OVER BLOCKS INTO DRAIN.

4. TEMPORARY DIVERSIONS



TYPICAL X-SECTION DIVERSION #1 & #2

DIVERSION #1 — GRADE = 2%
LENGTH = 450'

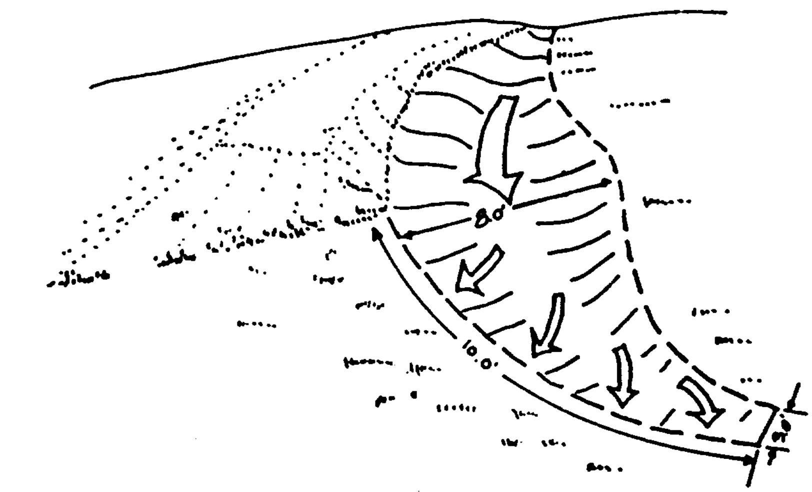
DIVERSION #2 — GRADE = 0.5%
LENGTH = 400'

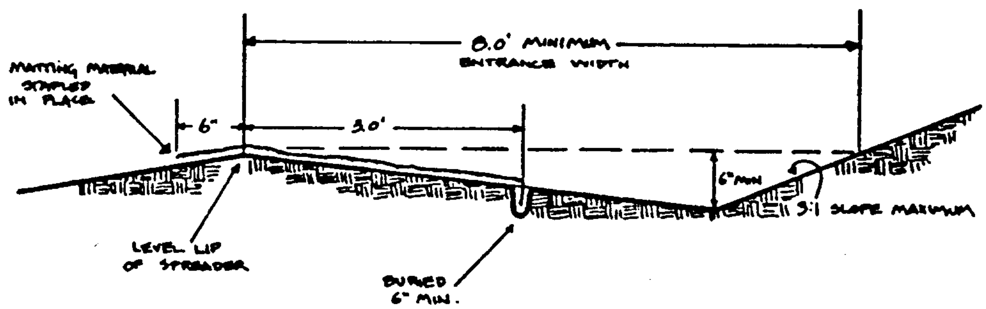
(4.) CONSTRUCTION SPECIFICATIONS

1. REMOVE ALL TREES, BRUSH & STUMPS FROM DIVERSION FOUNDATION.
2. CONSTRUCT RIDGE TO FULL DIMENSIONS SHOWN — ALLOW 10% FOR SETTLING.
3. COMPACT RIDGE BY WHEELS OF CONSTRUCTION EQUIPMENT.
4. ENSURE THAT THE TOP OF THE DIVERSION IS ON DESIGN GRADE OR HIGHER AT ALL POINTS.
5. SEED AND MULCH IMMEDIATELY AFTER CONSTRUCTION. SEE VEGETATIVE PLAN.

6230

5. LEVEL SPREADER





CROSS SECTION

(5.) CONSTRUCTION SPECIFICATIONS

1. FIBERGLASS MATTING, 4.0 FT. WIDE, SHOULD EXTEND 6" OVER THE LEVEL LIP AND BE BURIED 6" DEEP AT THE LOWER EDGE.

2. ENSURE THAT THE SPREADER LIP IS LEVEL THROUGHOUT ITS LENGTH.

3. CONSTRUCT THE LEVEL SPREADER ON UNDISTURBED SOIL (NOT ON FILL.)

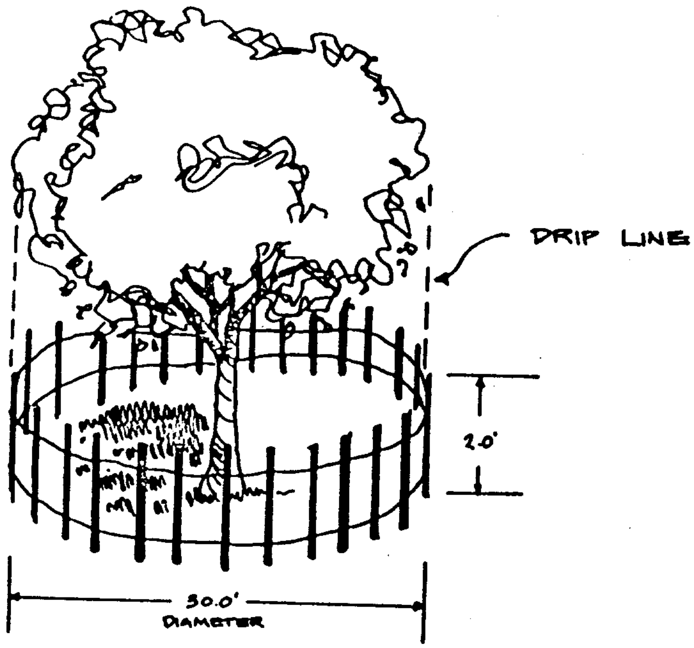
4. CONSTRUCT A TRANSITION SECTION FROM THE DIVERSION TO BLEND SMOOTHLY TO THE WIDTH AND DEPTH OF THE SPREADER.

5. IMMEDIATELY AFTER CONSTRUCTION, APPROPRIATELY SEED AND MULCH THE ENTIRE DISTURBED AREA OF THE SPREADER. SEE VEGETATIVE PLAN.

VOL 12

6231

6. TREE PRESERVATION & PROTECTION



NOTE: SEDIMENT FENCE MATERIAL MAY BE USED TO BUILD FENCE.

• DRIVE STAKES FIRMLY INTO GROUND – AT LEAST 12"

7. LAND GRADING

1. FINISHED LAND SURFACES WILL BE GRADED AS SHOWN ON SITE DEVELOPMENT PLAN.
2. CUT SLOPES WILL BE 3:1 OR FLATTER FOR MAINTENANCE BY MOWING AND ROUGHENED FOR VEGETATIVE ESTABLISHMENT.
3. THE HIGH FILL SLOPE ON THE NORTH WILL NOT BE STEEPER THAN 2:1 AND ROUGHENED BY GROOVING ACROSS THE SLOPE.
4. TOPSOIL WILL BE REMOVED FROM AREAS TO BE GRADED AND FILLED AND IT WILL BE STOCKPILED IN LOCATIONS SHOWN.
5. AREAS TO BE FILLED WILL BE CLEARED AND GRUBBED.
6. FILL WILL BE PLACED IN LAYERS NOT TO EXCEED 9" AND COMPACTED AS REQUIRED IN THE SPECIFICATIONS FOR THE DEVELOPMENT PLAN (NOT A PART OF SEDIMENT CONTROL PLAN.)

VOL 12

6232

VOL 12

6233

7. FROZEN MATERIAL OR SOFT, HIGHLY COMPRESSIBLE MATERIAL WILL NOT BE USED AS FILL.

8. FILL WILL NOT BE PLACED ON A FROZEN SURFACE.

9. ROAD AND PARKING SURFACES WILL BE SLOPED AS SHOWN ON SITE DEVELOPMENT PLAN TO CONTROL RUNOFF.

10. LAND ADJOINING PAVED AREAS WILL BE SLOPED NO STEEPER THAN 6:1 AND GRADED TO DRAIN AS SHOWN.

11. SURFACE RUNOFF FROM BUILDINGS WILL BE COLLECTED IN GUTTERS AND PIPED TO CHANNELS 1, 2, 3 AND 4.

12. DIVERSIONS WILL BE INSTALLED ABOVE CUT SLOPES PRIOR TO LAND CLEARING AND GRADING.

13. A DIVERSION WILL BE MAINTAINED AT ALL TIMES ABOVE THE FILL SLOPE TO PREVENT OVERFLOW ON THIS STEEP AREA.

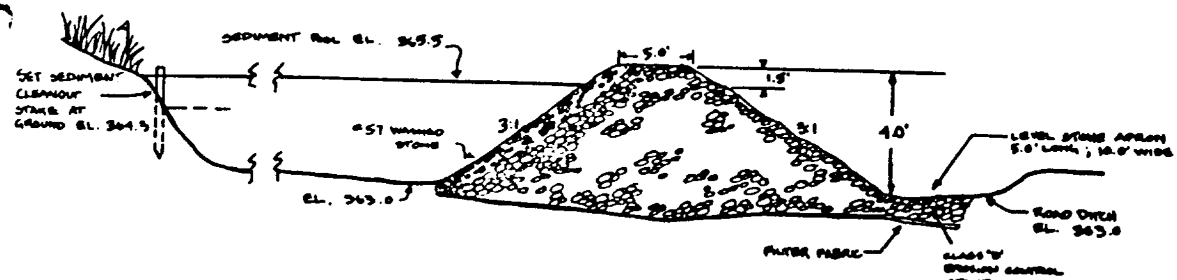
14. CUTTING AND FILLING WILL BE DONE AS A CONTINUOUS OPERATION UNTIL FINAL GRADE IS REACHED. SHOULD GRADING BE TEMPORARILY DISCONTINUED, A TEMPORARY DIVERSION WILL BE CONSTRUCTED ACROSS THE MIDDLE OF THE DISTURBED AREA TO BREAK UP THE LONG SLOPE TO THE NORTH.

15. AS SOON AS FINAL GRADES ARE REACHED THE GRADED AREAS WILL BE STABILIZED IN ACCORDANCE WITH THE VEGETATIVE PLAN.

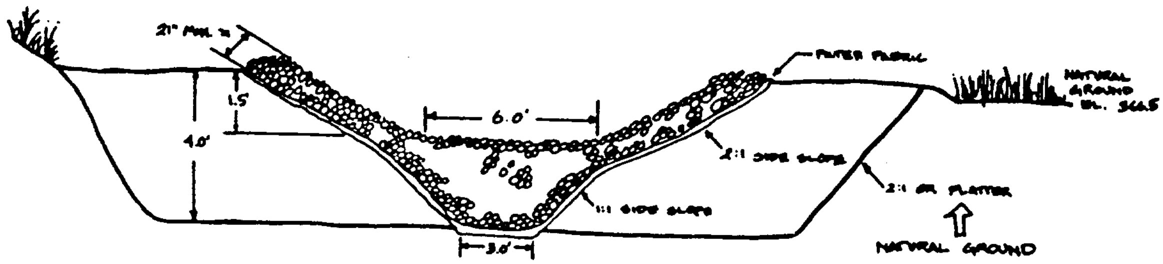
16. AN UNDISTURBED AREA WILL BE LEFT AS A BUFFER AROUND THE ENTIRE GRADED SITE EXCEPT AT ROAD ENTRANCE AND CHANNEL #3 OUTLET.

17. WHEN THE DEVELOPED SITE HAS BEEN PROPERLY STABILIZED, ALL THE TEMPORARY SEDIMENT AND EROSION CONTROL MEASURES WILL BE REMOVED, THE DISTURBED AREA GRADED TO BLEND WITH THE SURROUNDING AREA, AND VEGETATED.

8. TEMPORARY SEDIMENT TRAP



CROSS SECTION



STONE SECTION

(8.) CONSTRUCTION SPECIFICATIONS

1. CLEAR, GRUB AND STRIP THE AREA UNDER THE EMBANKMENT OF ALL VEGETATION AND ROOT MAT.
2. CLEAR POND AREA BELOW ELEVATION 365.5
3. USE FILL MATERIAL FREE OF ROOTS, WOODY VEGETATION AND ORGANIC MATTER. PLACE FILL IN LIFTS NOT TO EXCEED 9" AND MACHINE COMPACT.
4. CONSTRUCT DAM AND STONE SPILLWAY TO DIMENSIONS, SLOPES AND ELEVATIONS SHOWN.
5. ENSURE THAT THE SPILLWAY CREST IS LEVEL AND AT LEAST 1.5' BELOW THE TOP OF THE DAM AT ALL POINTS.
6. STONE USED FOR SPILLWAY SECTION — CLASS "B" EROSION CONTROL STONE.

VOL 12

6234

R0039542

7. STONE USED ON INSIDE SPILLWAY FACE TO CONTROL DRAINAGE — D.O.T. # 57 WASHED STONE.

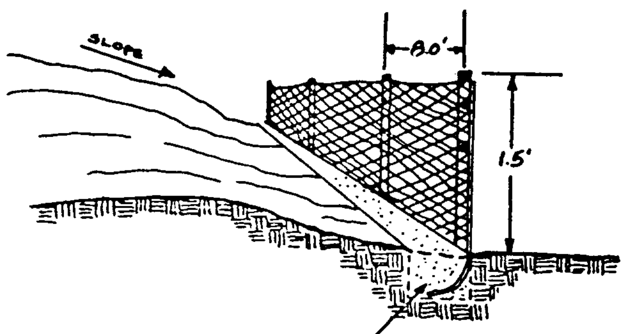
8. EXTEND STONE OUTLET SECTION TO VEGETATED ROAD DITCH ON ZERO GRADE WITH TOP ELEVATION OF STONE LEVEL WITH BOTTOM OF DRAIN.

9. ENSURE THAT THE TOP OF THE DAM AT ALL POINTS IS 0.5' ABOVE NATURAL SURROUNDING GROUND.

10. STABILIZE THE EMBANKMENT AND ALL DISTURBED AREA ABOVE THE SEDIMENT POOL AS SHOWN IN THE VEGETATION PLAN.

VOL 12

9. SEDIMENT FENCE



6235

(9.) CONSTRUCTION SPECIFICATIONS

1. CONSTRUCT SEDIMENT FENCE ON LOW SIDE OF TOPSOIL STOCKPILE TO PREVENT SEDIMENT FROM BEING WASHED INTO THE DRAINAGE SYSTEM. FENCE TO EXTEND AROUND APPROXIMATELY 70% OF THE PERIMETER OF THE STOCKPILE.

2. LOCATE POSTS DOWNSLOPE OF FABRIC TO HELP SUPPORT FENCING.

R0039543

3. BURY TOE OF FENCE APPROXIMATELY 8" DEEP TO PREVENT UNDERCUTTING

4. WHEN JOINTS ARE NECESSARY, SECURELY FASTEN THE FABRIC AT A SUPPORT POST WITH OVERLAP TO THE NEXT POST.

5. FILTER FABRIC TO BE OF NYLON, POLYESTER, PROPYLENE OR ETHYLENE YARN WITH EXTRA STRENGTH — 50 LB/LIN. IN. (MINIMUM) — AND WITH A FLOW RATE OF AT LEAST 0.3 GAL./FT² / MINUTE. FABRIC SHOULD CONTAIN ULTRAVIOLET RAY INHIBITORS AND STABILIZERS.

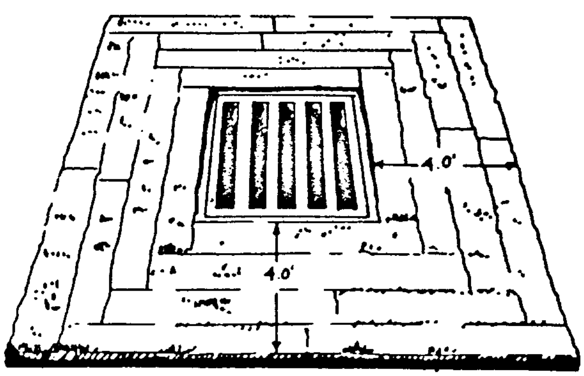
6. POST TO BE 4" DIAMETER PINE WITH A MIMUMUM LENGTH OF 4' FEET.

NOTE: IF HIGH CUT SLOPES ADJOINING CHANNELS 1, 2, AND 3 ARE NOT ADEQUATELY STABILIZED BEFORE CHANNEL IS CONSTRUCTED, A SEDIMENT FENCE SHOULD BE LOCATED ON THE CHANNEL BERM TO PREVENT SEDIMENT FROM ENTERING THE CHANNEL SYSTEM. THE FENCE SHOULD BE INSTALLED AS SHOWN ABOVE ALONG THE ENTIRE UNSTABLE AREA ADJOINING THE CHANNEL.

VOL 12

10. SOD DROP INLET PROTECTION

AFTER THE CONTRIBUTING DRAINAGE AREA HAS BEEN PERMANENTLY STABILIZED, THE BLOCK AND GRAVEL STRUCTURE WILL BE REMOVED AND PERMANENT SOD LAID AROUND THE DROP INLET.



FOUR 1-FOOT WIDE STRIPS OF TALL FESCUE SOD ON EACH SIDE OF THE DROP INLET

6236

R0039544

(10.) CONSTRUCTION SPECIFICATIONS

1. RAKE SOIL SURFACE TO BREAK GROUND CRUST ; LEAVE SURFACE UNIFORM AND WATER LIGHTLY.
2. LAY SOD IN A STAGGERED PATTERN AS SHOWN WITH STRIPS BUTTED TIGHTLY AGAINST EACH OTHER.
3. BUTTING — ANGLED ENDS CAUSED BY CUTTING MUST BE MATCHED CORRECTLY.
4. ROLL SOD TO PROVIDE FIRM SOIL CONTACT.
5. IRRIGATE UNTIL SOIL IS WET TO ABOUT 4" BELOW THE SOD.
6. KEEP SOD MOIST UNTIL SOD TAKES ROOT.

3. GROOVE ON CONTOUR — GROOVES APPROX. 3" DEEP + 12" APART.
4. VEGETATE IMMEDIATELY AFTER GROOVING.

B. — 3:1 CUT SLOPE

1. GROOVE BY DISCING TO EVEN SURFACE FOR MAINTENANCE BY MOWING.
2. GROOVES APPROX. 1" - 2" DEEP AND 10" APART.
3. VEGETATE IMMEDIATBLY AFTER DISCING. SEE VEGETATIVE PLAN.

VOL 12

6244

R0039552

VEGETATIVE PLAN

Seedbed Preparation (SP)

SP-1 Fill slopes 3:1 or steeper to be seeded with a hydraulic seeder (permanent seedings)

1) Leave the last 4-6 inches of fill loose and uncompacted, allowing rocks, roots, large clods and other debris to remain on the slope.

2) Roughen slope faces by making grooves 2-3 inches deep, perpendicular to the slope.

3) Spread lime evenly over slopes at rates recommended by soil tests.

SP-2 Fill slopes 3:1 or steeper (temporary seedings)

1) Leave a loose, uncompacted surface. Remove large clods, rocks, and debris which might hold netting above the surface.

2) Spread lime and fertilizer evenly at rates recommended by soil tests.

3) Incorporate amendments by roughening or grooving soil surface on the contour.

SP-3 High-maintenance turf

1) Remove rocks and debris that could interfere with tillage and the production of a uniform seedbed.

2) Apply lime and fertilizer at rates recommended by soil tests; spread evenly and incorporate to a depth of 2-4" with a farm disk or chisel plow.

3) Loosen the subgrade immediately prior to spreading topsoil by disking or scarifying to a depth of at least 2 inches.

4) Spread topsoil to a depth of 2-4 inches and cultipack.

5) Disk or harrow and rake to produce a uniform and well-pulverized surface.

6) Loosen surface just prior to applying seed.

SP-4 Gentle or flat slopes where topsoil is not used.

1) Remove rocks and debris.

2) Apply lime and fertilizer at rates recommended by soil tests; spread evenly and incorporate into the top 6" with a disk, chisel plow, or rotary tiller.

3) Break up large clods and rake into a loose, uniform seedbed.

4) Rake to loosen surface just prior to applying seed.

VOL 12

6245

Seeding Methods (SM)

SM-1 Fill slopes steeper than 3:1 (permanent seedings)

Use hydraulic seeding equipment to apply seed and fertilizer, a wood fiber mulch at 45 lb/1,000 ft^2, and mulch tackifer.

SM-2 Gentle to flat slopes or temporary seedings

1) Broadcast seed at the recommended rate with a cyclone seeder, drop spreader, or cultipacker seeder.

2) Rake seed into the soil and lightly pack to establish good contact.

Mulch (MU)

MU-1 Steep slopes (3:1 or greater)

In mid-summer, late fall or winter, apply 100 lb/1,000 ft^2 grain straw, cover with netting and staple to the slope. In spring or early fall use 45 lb/1,000 ft^2 wood fiber in a hydroseeder slurry.

MU-2 High-maintenance vegetation and temporary seedings

Apply 90 lb/1,000 ft^2 (4000 lb/acre) grain straw and tack with 0.1 gal/yd^2 asphalt (11 gal/1,000 ft^2).

MU-3 Grass-lined channels

Install excelsior mat in the channel, extend up the channel banks to the highest calculated depth of flow, and secure according to manufacturer's specifications.

On channel shoulders, apply 100 lb/1,000 ft^2 grain straw and anchor with 0.1 gal/yd^2 (11 gal/1,000 ft^2) asphalt.

Maintenance (MA)

MA-1 Refertilize in late winter or early spring the following year. Mow as desired.

MA-2 Keep mowed to a height of 2-4 inches. Fertilize with 40 lb/acre (1 lb/1,000 ft^2) nitrogen in winter and again the following fall.

MA-3 Inspect and repair mulch and lining. Refertilize in late winter of the following year with 150 lb/acre 10-10-10 (3.5 lb/1,000 ft^2). Mow regularly to a height of 3-4 inches.

MA-4 Topdress with 10-10-10 fertilizer if growth is not fully adequate.

MA-5 Topdress with 50 lb/acre (1 lb/ 1,000 ft^2) nitrogen in March. If cover is needed through the following summer, overseed with 50 lb/acre Kobe lespedeza.

VOL 12

Maintaining Vegetative Measures

Maintaining vegetation for soil protection or other uses is needed to keep the system functioning. Proper maintenance defers or prevents impairment of plant cover. It is usually less costly to carry on a maintenance program than it is to make repairs after prolonged neglect.

Maintenance should occur on a regular basis, consistent with favorable plant growth, soil and climatic conditions. This involves regular seasonal work for mowing, fertilizing, liming, watering, pruning, fire controls, weed and pest control, reseeding and timely repairs. It also requires prompt removal of debris, protection of vegetation from unintended uses or traffic and special attention to critical areas. Well maintained vegetation provides a comfortable margin of reserve that will carry through emergencies. A preventive maintenance program anticipates requirements and accomplishes work when it can be done with the least effort and expense.

The degree of preventive maintenance depends upon the category of vegetation and land: improved, semi-improved and unimproved grounds. Greater maintenance is required for improved grounds than unimproved grounds. Regardless of the category, vegetative cover requires a certain degree of management or the desired function of the vegetation will be defeated.

Mowing is a recurring practice and its intensity depends upon the function of the ground cover. On improved areas, such as lawns, certain recreation fields and picnic areas, mowing will be frequent. On semi-improved areas, mowing will be less frequent. On unimproved areas, mowing may occur once every three years as required to eliminate invading woody vegetation.

The application of fertilizer will follow a like pattern. On improved areas, fertilizer amounts should be in sufficient quantities to keep cover healthy and vigorous without over stimulation of growth. On semi-improved grounds, the rate of fertilizer application is usually about 1/2 the rate applied on improved areas. Unimproved areas should receive limited fertilizer applications as required to produce enough growth to prevent undue erosion.

Lime should be applied to maintain the desired level of soil reaction. On improved grounds, amounts of lime may be applied to maintain the optimum pH range. On semi-improved and unimproved areas, the pH may be maintained at a lower level than optimum.

Weeds and brush frequently invade grass cover as a direct result of inadequate maintenance. Amount of weeds or brush that can be tolerated in any protective planting depends upon the land category and its intended use. On improved areas few or no weeds or undesirable brush should be tolerated. This tolerance may become proportionately greater as land category declines. Drainageways are subject to rapid infestation of weeds and woody plants. These should be eradicated or cut back since they often reduce drainageway efficiency. Control of weeds or brush is accomplished by using herbicides, mechanical methods, soil sterilants and, perhaps, selective removal by hand.

Pest and disease control requirements are usually more intensive on improved areas. Most insects, such as grubs, army worms, beetles and ants, feed on grass roots, stems and leaves and may cause considerable damage in a short period of time if not controlled early. Rodents, such as field mice, moles, and woodchucks, may damage vegetation and create hazards by burrowing and throwing up mounds on earthen structures. Insects and rodents should be kept under reasonable control.

Diseases of herbaceous and woody plants are usually of minor importance where adapted species have been used and reasonably good management is practiced.Trees that have been destroyed by disease or seriously damaged by insects should be removed. Removal of such trees is essential because diseases and insect infestations will likely spread to other plants.

Dry vegetation constitutes a fire hazard. The taller the vegetation, the greater the hazard. Herbaceous vegetation on improved ground may be less subject to serious fire since it is kept well mowed and probably well watered. Tree and shrub areas on improved ground also undergo fairly intensive management. Debris, such as fallen trees and branches, is usually removed without undue delay and litter is occasionally cleared away. These practices reduce fire hazards considerably. On unimproved grounds, vegetation is usually allowed to grow tall. Mowing and removing residue on occasion may help prevent fires in such areas. In g-neral, grass fires in New York State are not critical. Judicious care, consistent with land category and purpose of vegetation usually will help prevent fires.

Temporary seedings should be inspected every 30 days. Areas damaged should be reseeded and remulched.

Protective coverings and their anchoring methods should be inspected to determine whether or not the cover is in place at the proper density and properly anchored. Where commercially available netting of either paper and plastic or jute mesh is applied, check for damage by vandalism, fire or loss of anchoring. All areas should be inspected to determine if rilling is occurring beneath the protective cover. Where this is occurring, the area should be regraded and recovered.

VOL 12

6 2 5 1

Maintaining Structural Measures

Structural measures must be maintained to be effective. In general, these measures must be periodically inspected to insure structural integrity, detect vandalism damage, and for cleaning and repair whenever necessary. During construction, all structures should be inspected weekly and after every rain. After construction, inspections should be made at least semi-annually and after every heavy rain.

An improperly applied control measure, or one that is not properly maintained, invites failure and can create more damage than if no measures had been taken. One excellent time to check on the performance of all project control measures is during a rainstorm. The experience gained by this type of inspection is valuable to both the contractor and the project inspection team.

A comprehensive program should be outlined for the use of those who have maintenance responsibility. Maintenance items should include, but not be limited to, those shown for each of the following measures.

Sediment Basins

The most obvious maintenance required for these structures is the requirement for periodic cleanout. Cleanout may be done after one foot of silt is deposited or, in instances where proper hydraulics can be maintained, as much as 50 percent of capacity may be filled before cleanout is necessary.

Temporary pool outlets constructed of filter fabric covered stone should be inspected for tears in the fabric or clogging of the filter cloth with silt or debris. Silt can be removed from woven filter cloth with a stiff brush.

Embankments must be inspected for cracks, excessive seepage, rodents and undesirable vegetative growth. The principal and emergency spillways must be cleaned of obstructions and inspected for structural integrity. The outlets below the spillways must be inspected for erosion and obstructions to flow removed.

Diversions and Channels

The various types of temporary and permanent diversions and channels perform similar functions and must be maintained to insure that they perform satisfactorily. The channel cross-section must be inspected to insure that the side slopes remain stable. Check for points of scour, rodent holes, and breaches. The channel bottom must be inspected for erosion or excessive scour, deposition of sediment or other obstructions. If the channels are lined, the linings should be checked for structural integrity. Cracking, spalling, or other physical deterioration of the lining must be repaired. Inlets and outlets are to be checked to insure that they remain adequate, show no sign of erosion or loss of structural integrity.

Grade Stabilization Structures

Temporary structural measures of reducing velocities include barriers of hay or straw bales, brush or brush and fabric, and fabric and fence. Permanent check dams of timber, timber and stone, concrete or sheet piling are also utilized. In all instances it is important that the structure: (1) maintain its integrity, (2) is not by passed by an erosion channel, and (3) does not develop excessive scour at its base or excess sediment at its top.

Lined Waterway or Outlet

Channel linings other than vegetation must be inspected for undermining, cracking, spalling, plugging of weep holes, and channel obstructions. Inlets and outlets should be inspected for scour and obstructions.

Lining of channel sidewalls and floor by stone, concrete or fabric are common stabilization practices. Temporary channels may be lined by fabric or plastic which should be properly anchored. Check anchoring and inspect the fabric or plastic for tears. Permanent linings must be inspected for integrity, protection replaced where necessary and the channel cleared of debris and obstructions. Inlet and outlet areas should be checked for scour.

Traffic Control

Where markers or fencing are utilized for traffic control, inspect periodically to insure that they are properly placed, and functioning properly. Traffic must be kept off all structural erosion control measures at all times. Where traffic must cross a structural measure, a crossing should be constructed.

Pollution Control During Construction

Inspect to insure that dust control measures are utilized, where necessary. All maintenance work on equipment should be done in a safe area. Maintenance items such as cans, boxes, and cartridges should be stored in a suitable building. Following use, all such items should be disposed of in a safe manner and at a suitable site.

GUIDELINES FOR ESTIMATING SEDIMENT YIELDS FOR URBAN CONSTRUCTION AREAS

1. An approximation of the quantities of sediment yield resulting from uncontrolled urban construction activities can be made by use of an equation. The values thus obtained can be useful in estimating the sediment capacity requirements needed for desilting basins or sediment traps.

2. The equation does not provide for quantities of sediment contributed through bedload movement. Volumes of bedload sediment are assumed to be equal to the quantity of suspended sediment carried through the structure outlet; therefore, the trap efficiency of the structure is not computed.

3. The results obtained by use of the equation may be applied generally in New York State only after an adjustment is made to reflect the variation in rainfall and erosion potential of soils within the region.

   To accomplish this, iso-erodent values for various areas are obtained from Figure 8-1[1]. Correction values to be used in the equation for different iso-erodent values are given in Table 8.1.

   Also, the average value of 60 pounds per cubic foot of submerged sediment is used in converting tons to acre feet for sediment storage design purposes (60 pounds per cubic foot equals 1320 tons per acre foot).

Table 8-1

Iso-Erodent Value	Correction Factor Used in Equation
300	1.56
250	1.47
200	1.34
150	1.12
125	0.94
100	0.76
75	0.57

4. The equation was derived from a limited amount of data obtained by short term measurements. Therefore, it is considered to be of a tentative nature and subject to change.

   The equation relates sediment yield to the area under construction as follows:

   $$V = ((C \times A)/1320) \times (222{,}000/A)^{0.715}$$

   Where: V = acre feet, required sediment storage per year.

   A = uncontrolled drainage area under construction expressed in square miles.

   C = iso-erodent correction factor.

Example:

Given: Drainage area of a site under construction equals 0.5 square miles (320 acres). For areas within the range of iso-erodent value 100, the correction for use in equation is 0.76 (see Table 6.1)

Equation is:

$$V = ((C \times A)/1320) \times (222{,}000/A)^{0.715}$$
$$= ((0.76 \times 0.5)/1320) \times (222{,}000/0.5)^{0.715}$$
$$= 0.000288 \times (444{,}000)^{0.715}$$
$$= 0.000288 \times 10{,}898$$
$$= 3.14 \text{ acre-feet}$$

The present form of the equation is designed for use within the general area of New York State. One of the factors in this equation is limited to a range of conditions generally predominating in this area and another factor is limited to a specific condition.

The factors referred to are "C" and "1320" in the portion of the equation represented by the term (CA/1320).

The factor "1320" represents tons per acre foot of sediment having an average dry weight of 60 pounds per cubic foot.

Figure 8.2, page 8.4 is useful in determining the appropriate tons per acre foot factor for use in the equation according to various dry unit weights of sediments.

For example in an area where the average dry weight of sediments is 50 pounds per cubic foot, the factor used in the equation would be 1080 tons per acre foot.

The following sources of information and data were used in analyzing sediment yield from urban construction areas. The data include yields from housing developments, industrial and commercial sites, and highway construction areas:

BENEFIT-COST GUIDELINES

Analyzing Benefits and Costs

Benefit-Cost Analysis is a technique to determine whether the measure will result in more benefits than it will cost.

For the purposes of making a benefit-cost analysis, the time period associated with erosion and sedimentation is considered to extend from the first disturbance of the land up to the time of establishing effective erosion control.

Ascribing Effects to Treatment Measures

The generally accepted basis for attributing effects of treatment measures on a comparable basis is the "with" and "without" approach. The approach compares the expected difference in damages between what is expected if no controls are used and what is expected if a measure is installed. The total difference in expected damage is the estimated benefit of the measure.

Sediment damages may be related to (1) deposition of eroded materials on flood plains, in channels, reservoirs, residences, utilities and other properties that require the removal and disposition of materials, and the repairing of damaged facilities and (2) swamping damage which adversely affects existing features or limits potential improvement of land caused by a rise in the ground water table or by impairing surface drainage.

Sediment resulting from construction sites could be deposited along a stream and cause individual landowners to pay for its removal. Sediment could also destroy aesthetic values of a stream (clean water vs muddy water) and adversely impact on stream fisheries and micro-organisms.

In municipal and industrial uses where water is pumped directly from a river or reservoir, slugs of sediment associated with excessive rainfall may pose severe water quality problems. Turbidity may be increased, necessitating increased treatment which raises the cost of operations. Sediment may also be deposited in storm drains, reducing their ability to control flooding. This increases flood damage and requires the cleanout of sediment from the storm drain systems.

Pricing Treatment Measures and Benefits

Prices applied should reflect values expected to prevail at the time of occurrence. Current prices are used for installation costs of treatment measures. Projected normalized prices (based on past prices and trends) should be used for estimating future values (benefits, operations and maintenance costs and replacement costs) for permanent type measures only.

Period of Analysis and Evaluation

The period of analysis in years should equal the economic life (need for a measure) or the physical life of treatment measures, whichever is less. The benefits considered over the evaluation period include those accruing over the period.

The annual costs of permanent measures chargeable to the evaluation period include the amortized installation costs and the future annual operation, maintenance and replacement costs necessary to provide the benefits over the evaluation period. The amortization rate should be based of prevailing local interest rates at the time of installation.

Appraisal of Damages and Treatment Costs

Many people are affected by the damages resulting from erosion and sedimentation. Also, many persons are benefited by its prevention, reduction or mitigation.

Costs will be incurred to: (1) install treatment measures; or (2) correct damages; or (3) a combination of the two.

Treatment Measures

Treatment measures on developing sites are frequently temporary - generally lasting only one or two construction seasons. Benefits and costs for temporary measures can be compared directly using current prices.

Permanent measures are planned to trap sediment and control erosion and runoff during and beyond the construction period. The prevention of sediment damages can be accomplished by either or both of two methods:

1. Stabilizing sediment source areas by applying conservation erosion control measures.
2. Trapping sediment before it leaves the construction area.

Some of the potential benefits from preventing downstream sediment transport and deposition include:

1. Prevention or reduction in cost of removal and disposition of sediment from properties.
2. Prevention or reduction in damage to property.
3. Prevention of water quality impairment.

Some permanent measures may be retained to provide long-term benefits.

For example, a sediment basin may be cleaned out after construction is finished and utilized for aesthetics, recreation or fish.

VOL 12

6267

R0039575

Benefits and costs for permanent measures need to be converted by discounting and amortizing to average annual figures for comparison.

Benefit-Cost Analysis

A simple equation for determining the benefits of controlling sediment is:

$$B = (S \times Y) - [C + (S \times Y)(1.00 - P)]$$

Where: B = Benefits in dollars.

S = Cubic yards of sediment expected to move off the site if no control measures are applied.

Y = Cost in dollars per yard to recover and dispose of sediment that has moved off the site.

C = Estimated cost of temporary measures to be installed.

P = Estimated effectiveness of proposed measures expressed as a decimal.

Example

This example illustrates the methodology of a benefit-cost analysis:

Given: A construction site of 78 acres, which without erosion control measures will yield about 5 acre feet or 8,000 cubic yards of sediment (S) to the lower end of the site. There is a channel with several culverts located below the site and it is assumed all the sediment would be deposited in it. It would be necessary to remove all the additional sediment in order to maintain the capacity of the channel and avoid increased hazard to flooding. The cost of removing and disposing the sediment is estimated at $2.00 per cubic yard (Y).

With temporary erosion control measures, including a sediment basin, in place during the one year construction period, sediment delivered to the channel will be reduced 90 percent (P). The cost of the measures would be as follows, (no amortization is required since costs and benefits are incurred in a similar one year period):

1. Land grading measures $2,000
2. Temporary sediment basin............... $3,000

a. Construction..........$1,500
b. Maintenance..........$1,000
c. Restoration............$500

Total Cost (C).........$5,000

The "without treatment" condition reveals damages in the form of costs to remove sediment. Benefit (costs saved) are derived by subtracting the sediment removal costs under the "with treatment" condition.

1. Without treatment condition
   8,000 cu. yd.(S) x $2.00/cu. yd.(Y) = $16,000(SxY)
2. With treatment condition
   a. Costs (C) described above = ...$5,000
      will control 7,200 cu. yd. (SxP) of the sediment
   b. Removal costs for remaining 800 cu.yd.
      800 x $2.00 = ...$1,600
   c. Total = $6,600
3. Benefits
   $16,000 - $6,600 = ...$9,400 (B)

Using the formula directly, the computations show the same results:

$$B = (S \times Y) - [c + (S \times Y)(1.00 - P)]$$

$$B = (\$8,000 \times 2.00) - [(\$5,000 + (8,000 \times 2.00)(1.00 - 0.90)]$$

$$B = (\$16,000) - (\$5,000 + 1,600)$$

$$B = (\$16,000) - (\$6,600)$$

$$B = \$9,400$$

In this example, the more economical approach would be to install treatment measures rather than correct damages at a later date. A third alternative would be "do nothing" which would result in a higher flood damage hazard that would need evaluation under a more sophisticated analytical model. **Also, in this simple example, water quality issues were not included although society in general, places a value on such issues.**

ESTIMATING URBAN RUNOFF

INTRODUCTION

The increased amount of erosion occurring with the conversion of rural land to urban greatly depends on the amount of runoff that occurs. This section addresses what influences runoff and how the volume and rate of runoff is determined. The method and most of the material is reprinted from Urban Hydrology for Small Watersheds[1], TR-55, Soil Conservation Service, June 1986.

FACTORS AFFECTING RUNOFF

Rainfall

Precipitation, whether it occurs as rain or snow, is the potential source of water that may run off the surface of small watersheds. The extent of the storm and the distribution of rainfall during the storm are two major factors which affect the peak rate of runoff.

The storm distribution can be thought of as a measure of how the rate of rainfall (intensity) varies within a given time interval. For example, in a given 24-hour period, a certain amount of precipitation may have been measured. However, this precipitation may have occurred over the entire 24-hour period or in just one hour. These two situations represent two entirely different storm distributions.

The size of the storm is often described by the length of time over which precipitation occurs, the total amount of precipitation occurring and how often this same storm might be expected to occur (frequency). Thus a 10-year, 24 hour storm can be thought of as a storm producing the amount of rain in 24 hours with a 10% chance of occurrence in a year. One day (24 hour) rainfall maps are listed as Exhibit 10.1 at the end of this section for 2, 5, 10, 25, 50 and 100 year frequencies.

Antecedent Moisture Condition

The runoff from a given storm is affected by the existing soil moisture content resulting from the amount of precipitation occurring during the preceding five days (antecedent moisture condition).

Watershed Area

The watershed area or area draining water to the point of interest is usually determined from a topographic map or scaled areal photograph accompanied by a field review locating manmade features that have diverted the flow of water.

Soils

In general, the higher the rate of infiltration, the lower the quantity of stormwater runoff. Fine-textured soils such as clay produce a higher rate of runoff than do coarse-textured soils such as sand. Sites having clay soils may require the construction of more elaborate drainage systems than sites having sandy soils. Exhibit 10.2 contains a list of soils found in New York State and their respective hydrologic soil group.

Surface Cover

The type of cover and its condition affects runoff volume through its influence on the infiltration rate of the soil. Fallow land yields more runoff than forested or grass land for a given soil type.

The foliage and its litter maintain the soil's infiltration potential by preventing the sealing of the soil surface from the impact of the raindrops. Some of the raindrops are maintained on the surface of the foliage, increasing their chance of being evaporated back to the atmosphere. Some of the intercepted moisture is so long draining from the plant down to the soil that it is withheld from the initial period of runoff. Foliage also transpires moisture into the atmosphere thereby creating a moisture deficiency in the soil which must be replaced by rainfall before runoff occurs. Vegetation, including ground litter, forms numerous barriers along the path of the water flowing over the surface of the land which slows the water down and reduces its peak rate of runoff.

Covering areas with impervious material reduces surface storage and infiltration and thus increases the amount of runoff.

Time Parameters

Time is the parameter that is used to distribute the runoff into a hydrograph. The time is based on the velocities of flow through segments of the watershed. The slope of the land in the watershed is a major factor in determining the velocity. Two major parameters are time of concentration (T_c) and travel time of flow through the segments (T_t).

Storage in the Watershed

On very flat surfaces where ponding or swampy areas occur throughout the watershed, a considerable amount of the surface runoff may be retained in temporary storage, thus reducing the rate at which runoff will occur. Storage areas may be created to reduce the rate of runoff in an urbanizing area. These can be effective sediment traps as well as flood detention structures if left permanently in the watershed.

VOL 12

6276

METHODS OF DETERMINING RUNOFF

Many different methods of computing runoff have been developed. Some of the methods and limitations of each are listed below.

1. The Rational Method establishes an empirical formula, Q = CiA, for computing peak rates of runoff that is commonly used in urban areas. "Q" is the peak runoff rate in cfs, "C" is a runoff coefficient, "i" is the average rainfall intensity in in./hr. and "A" is the drainage area in acres. It is useful for estimating runoff on relatively small areas such as roof tops, parking lots, or others. According to Practices in Detention of Urban Stormwater[2], American Public Works Association Special Report # 43, "use of the rational equation should be limited to drainage areas of less than 20 acres." However, some practitioners totally deplore use of the Rational Method even on the smallest of drainage areas. The most serious drawback of the Rational Method is that it gives only peak discharge and provides no information on the time distribution of the storm runoff. Furthermore the choice of "C" and Time of Concentration "T_c" when choosing "i" in the Rational Method is more an art of judgment than a precise account of the antecedent moisture or a real distribution of rainfall intensity[3]. Modifications of the Rational Method have similar limitations.

2. Computer Program for Project Formulation-Hydrology,[4] SCS-TR-20, utilizes hydrologic soil-cover complexes to determine runoff volumes and unit hydrographs to determine peak rates of discharge. Factors included in the method are 24-hour rainfall amount, a given rainfall distribution, runoff curve numbers, time of concentration, travel time, and drainage area. This procedure probably should not be used for drainage areas more than 20 square miles. It is very useful for large drainage basins especially when there are a series of structures or several tributaries to be studied.

3. The SCS Engineering Field Manual, Chapter 2 procedures for determining peak discharge, is valid for small rural watersheds. The time of concentration for the non-urbanized area is estimated using a formula based on flow length, runoff curve number and average watershed slope. Chapter 2 procedures are applicable to drainage areas that range from 1 to 2000 acres. Tables, figures, exhibits and worksheets are included for a quick and reliable way to estimate peak discharge and runoff for a range of rainfall amounts, soil types, land use and cover conditions.

4. The SCS-TR-55 tabular method is an approximation of the more detailed SCS-TR-20 method. The tabular method can be used for watersheds where hydrographs are needed to measure non-homogeneous runoff, i.e., the watershed is divided into subareas. It is especially applicable for measuring the effects of changed land use in a part of a watershed. It can also be used to determine the effects of structures and combinations of structures, including channel modifications, at different locations in a watershed. The tabular method should not be used when large changes in the curve number occur among subareas within a watershed and when runoff volumes are less than about 1.5 inches for curve numbers less than 60.

For most watershed conditions, however, this procedure is adequate to determine the effects of urbanization on peak rates of discharge for subareas with "T_c" less than two hours.

5. The SCS-TR-55 Graphical Peak Discharge Method calculates peak discharge from hydrograph analyses using TR-20 Computer Program for Project Formulation. This method demonstrates a procedure for estimating depth and peak rates of runoff from small watersheds. The watershed must be hydrologically homogeneous, that is land use, soils, and cover are distributed uniformly throughout the watershed. The time of concentration for the watershed is estimated using the computed flow velocities for the sheet flow, shallow concentrated flow and channel flow. These values may range from 0.1 to 10 hours. This method was selected for inclusion in this manual to use in designing erosion and sediment control measures.

VOL 12 6277

SCS RUNOFF CURVE NUMBER METHOD

The SCS Runoff Curve Number (CN) method is described in detail in Nation Engineering Handbook - Chapter 4[5], (NEH-4). The SCS runoff equation is

$$Q = \frac{(P-I_a)^2}{(P-I_a)+S} \qquad \text{[Eq. 10.1]}$$

where

Q = runoff (in),

P = rainfall (in),

S = potential maximum retention after runoff begins (in), and

I_a = initial abstraction (in).

Initial abstraction (I_a) is all losses before runoff begins. It includes water retained in surface depressions, water intercepted by vegetation, evaporation, and infiltration. I_a is highly variable but generally is correlated with soil and cover parameters. Through studies of many small agricultural watersheds, I_a was found to be approximated by the following empirical equation:

$$I_a = 0.2S \qquad \text{[Eq. 10.2]}$$

By removing I_a as an independent parameter, this approximation allows use of a combination of S and P to produce a unique runoff amount. Substituting equation 10.2 into equation 10.1 gives

$$Q = \frac{(P-0.2S)^2}{(P+0.8S)} \qquad \text{[Eq. 10.3]}$$

S is related to the soil and cover conditions of the watershed through the CN. CN has a range of 0 to 100, and S is related to CN by

$$S = \frac{1000}{CN} - 10 \qquad \text{[Eq. 10.4]}$$

Figure 10.1 on Page 10.4 and Table 10.1 on Page 10.3 solve equations 10.3 and 10.4 for a range of CN's and rainfall.

VOL 12

6279

FACTORS CONSIDERED IN ESTIMATING RUNOFF CURVE NUMBERS

The major factors that determine CN are the hydrologic soil group (HSG), cover type, treatment, hydrologic condition, and antecedent runoff condition (ARC). Another factor considered is whether impervious areas outlet directly to the drainage system (connected) or whether the flow spreads over pervious areas before entering the drainage system (unconnected). Figure 10.2 on Page 10.6 is provided to aid in selecting the appropriate figure or table for determining curve numbers.

CN's in Tables 10.2a, 10.2b and 10.2c on Pages 10.7, 10.8 and 10.9 respectively represent average antecedent runoff condition for urban, cultivated agricultural, other agricultural, and arid and semiarid rangeland uses. Tables 10.2 starting on Page 10.7 assume impervious areas are directly connected. The following sections explain how to determine CN's and how to modify them for urban conditions.

Hydrologic soil groups

Infiltration rates of soils vary widely and are affected by subsurface permeability as well as surface intake rates. Soils are classified into four HSG's (A, B, C and D) according to their minimum infiltration rate, which is obtained for bare soil after prolonged wetting. Exhibit 10.2 on page 10.33 of this manual defines the four groups and provides a list of most of the soils in New York State and their group classification. The soils in the area of interest may be identified from a county soil survey report, which can be obtained from local SCS offices or soil and water conservation district offices, see Section 13.

Most urban areas are only partially covered by impervious surfaces; the soil remains an important factor in runoff estimates. Urbanization has a greater effect on runoff in watersheds with soils having high infiltration rates (sands and gravels) than in watersheds predominantly of silts and clays, which generally have low infiltration rates.

Any disturbance of a soil profile can significantly change its infiltration characteristics. With urbanization, native soil profiles may be mixed or removed or fill material from other areas may be introduced. Therefore, a method based on soil texture is given in Exhibit 10.2 for determining the HSG classification for disturbed soils.

Cover Type

Tables 10.2 starting on Page 10.7 address most cover types such as vegetation, bare soil, and impervious surfaces. There are a number of methods for determining cover type. The most common are field reconnaissance, aerial photographs, and land use maps.

Treatment

Treatment is a cover type modifier (used only in Table 10.2b on Page 10.8) to describe the management of cultivated agricultural lands. It includes mechanical practices, such as contouring and terracing, and management practices, such as crop rotations and reduced or no tillage.

Hydrologic Condition

Hydrologic condition indicates the effects of cover type and treatment on infiltration and runoff and is generally estimated from density of plant and residue cover on sample areas. Good hydrologic condition indicates that the soil usually has a low runoff potential for that specific hydrologic soil group, cover type, and treatment. Some factors to consider in estimating the effect of cover on infiltration and runoff are (a) canopy or density of lawns, crops, or other vegetative areas; (b) amount of year-round cover; (c) amount of grass or close-seeded legumes in rotations; (d) percent of residue cover; and (e) degree of surface roughness.

Antecedent Runoff Condition

The index of runoff potential before a storm event is the antecedent runoff condition (ARC). ARC is an attempt to account for the variation in CN at a site from storm to storm. CN for the average ARC at a site is the median value as taken from sample rainfall and runoff data. The CN's in Tables 10.2 starting on page 10.7 are for the average ARC, which is primarily used for design applications. See the SCS NEH-4 and Rallison and Miller[6] for more detailed discussion of storm-to-storm variation and a demonstration of upper and lower enveloping curves.

Urban Impervious Area Modifications

Several factors, such as the percentage of impervious area and the means of conveying runoff from impervious areas to the drainage system, should be considered in computing CN for urban areas[7]. For example, do the impervious areas connect directly to the drainage system, or do they outlet onto lawns or other pervious areas where infiltration can occur?

Connected Impervious Areas

An impervious area is considered connected if runoff from it flows directly into the drainage system. It is also considered connected if runoff from it occurs as concentrated shallow flow that runs over a pervious area and then into a drainage system.

Urban CN's, Table 10.2a on page 10.7, were developed for typical land use relationships based on specific assumed percentages of impervious area. These CN values were developed on the assumptions that (a) pervious urban

Table 10.2a - Runoff Curve Numbers for Urban Areas[1]

(Reprinted from: 210-VI-TR-55, Second Ed., June 1986)

Cover Description		Curve numbers for hydrologic soil group			
Cover type and hydrologic condition	Average percent impervious area[2]	A	B	C	D
Fully developed urban areas (vegetation established)					
Open space (lawns, parks, golf courses, cemeteries, etc)[3]:					
Poor condition (grass cover < 50%)		68	79	86	89
Fair condition (grass cover 50% to 75%)		49	69	79	84
Good condition (grass cover > 75%)		39	61	74	80
Impervious areas					
Paved: parking lots, roofs, driveways, etc. (excluding right-of-way]		98	98	98	98
Streets and roads:					
Paved: curbs and storm sewers (excluding right of way)		98	98	98	98
Paved; open ditches (including right-of-way)		83	89	92	98
Gravel (including right-of-way)		76	85	89	91
Dirt (including right-of-way)		72	82	87	89
Western desert urban areas:					
Natural desert landscape (pervious areas only)[4]		63	77	85	88
Artificial desert landscaping (impervious weed barrier, desert shrub with a 1 to 2 inch sand or gravel mulch and basin boarders)		96	96	96	96
Urban districts:					
Commercial and business	85	89	92	94	95
Industrial	72	81	88	91	93
Residential districts by average lot size:					
1/8 acre or less (town houses]	65	77	85	90	92
1/4 acre	38	61	75	83	87
1/3 acre	30	57	72	81	86
1/2 acre	25	54	70	80	85
1 acre	20	51	68	79	84
2 acres	12	46	65	77	82
Developing urban areas					
Newly graded areas (pervious areas only, no vegetation)[5]		77	86	91	94
Idle lands (CN's are determined using cover types similar to those in Table 10.2c).					

1Average runoff condition and $I_a = 0.2S$

[2]The average percent impervious area shown was used to develop composite CN's. Other assumptions are as follows: impervious areas are directly connected to the drainage system, impervious areas have a CN of 98, and pervious area are considered equivalent to open space in good hydrologic condition. CN's for other combinations of conditions may be computed using Figure 8.3 or 8.4.

[3]CN's shown are equivalent to those of pasture. Composite CN's may be computed for other combinations of open space cover type.

[4]Composite CN's for natural desert landscaping should be computed using Figure 8.3 or 8.4 based on the impervious area percentage (CN = 98) and the pervious area CN. The pervious area CN's are assumed equivalent to desert shrub in poor hydrologic condition.

[5]Composite CN's to use for the design of temporary measures during grading and construction should be computed using figure 8.3 or 8.4 based on the degree of development (impervious area percentage) and the CN's for newly graded pervious areas.

		Good	51	67	76	80

[1]Average runoff condition, and Ia = 0.2S.

[2]Crop residue cover applies only if residue is on at least 5% of the surface throughout the year.

[3]Hydrologic condition is based on combination of factors that affect infiltration and runoff, including (a) density and canopy of vegetative areas, (b) amount of year-round cover, (c) amount of grass or close-seeded legumes in rotation, (d) percent of residue cover on the land surface (good-20%), and (e) degree of surface roughness.

Poor: Factors impair infiltration and tend to increase runoff.

Good: Factors encourage average and better than average infiltration and tend to decrease runoff.

[1]Average runoff condition, and $I_a = 0.2S$.

[2]Poor: < 50% ground cover or heavily grazed with no mulch.

Fair: 50 to 75% ground cover and not heavily grazed.

Good: > 75% ground cover and lightly or only occasionally grazed.

[3]Poor: <50% ground cover.

Fair: 50 to 75% ground cover.

Good: > 75% ground cover.

[4]Actual curve number is less than 30; use CN = 30 for runoff computations.

[5]CN's shown were computed for areas with 50% woods and 50% grass (pasture) cover. Other combinations of conditions may be computed from the CN's for woods and pasture.

[6]Poor: Forest litter, small trees, and brush are destroyed by heavy grazing or regular burning.

Fair: Woods are grazed but not burned, and some forest litter covers the soil.

Good: Woods are protected from grazing, and litter and brush adequately cover the soil.

VOL 12

6284

areas are equivalent to pasture in good hydrologic condition and (b) impervious areas have a CN of 98 and are directly connected to the drainage system. Some assumed percentages of impervious area are shown in Table 10.2a on page 10.7.

If all of the impervious area is directly connected to the drainage system, but the impervious area percentages or the pervious land use assumptions in Table 10.2a on page 10.7 are not applicable, use Figure 10.3 on page 10.10 to compute a composite CN. For example, Table 10.2a on page 10.7 gives a CN of 70 for a 1/2-acre lot in hydrologic soil group B, with an assumed impervious area of 25 percent. However, if the lot has 20 percent impervious area and a pervious area CN of 61, the composite CN obtained from Figure 10.3 on page 10.10 is 68. The CN difference between 70 and 68 reflects the difference in percent impervious area.

Unconnected Impervious Areas

Runoff from these area is spread over a pervious area as sheet flow. To determine CN when all or part of the impervious area is not directly connected to the drainage system, (1) use Figure 10.4 on page 10.11 if total impervious area is less than 30 percent or (2) use Figure 10.3 on page 10.10 if the total impervious area is equal to or greater than 30 percent, because the absorptive capacity of the remaining pervious areas will not significantly affect runoff.

When impervious area is less than 30 percent, obtain the composite CN by entering the right half of Figure 10.4 on page 10.11 with the percentage of total impervious area and the ratio of total unconnected impervious area to total impervious area. Then move left to the appropriate pervious CN and read down to find the composite CN. For example, for a 1/2-acre lot with 20 percent total impervious area (75 percent of which is unconnected) and a pervious CN of 61, the composite CN from Figure 10.4 on page 10.11 is 66. If all of the impervious area is connected, the resulting CN (from Figure 10.3 on page 10.10) would be 68.

Runoff Determination

When CN and the amount of rainfall have been determined for the watershed, determine runoff by using Figure 10.1 on page 10.4, Table 10.1 on page 10.3, or equations 10.3 and 10.4. The runoff is usually rounded to the nearest hundredth of an inch.

Limitations

- Curve numbers describe average conditions that are useful for design purposes. If the rainfall event used is a historical storm, the modeling accuracy decreases.
- Use the runoff curve number equation with caution when recreating specific features of an actual storm. The equation does not contain an expression for time and, therefore, does not account for rainfall duration or intensity.
- The user should understand the assumption reflected in the initial abstraction term (I_a) and should ascertain that the assumption applies to the situation. I_a, which consists of interception, initial infiltration, surface depression storage, evapotranspiration, and other factors, was generalized as 0.2S based on data from agricultural watersheds (S is the potential maximum retention after runoff begins). This approximation can be especially important in an urban application because the combination of impervious areas with pervious areas can imply a significant initial loss that may not take place. The opposite effect, a greater initial loss, can occur if the impervious areas have surface depressions that store some runoff. To use a relationship other than I_a = 0.2S, one must redevelop equation 10.3, Figure 10.1 on page 10.4, Table 10.1 on page 10.3 and Tables 10.2 on pages 10.7 to 10.9 by using the original rainfall-runoff data to establish new S or CN relationships for each cover and hydrologic soil group.
- Runoff from snowmelt or rain or frozen ground cannot be estimated using these procedures.
- The CN procedure is less accurate when runoff is less than 0.5 inch. As a good check, use another procedure to determine runoff.
- The SCS runoff procedures apply only to direct surface runoff: do not overlook large sources of subsurface flow or high ground water levels that contribute to runoff. These conditions are often related to HSG A soils and forest areas that have

been assigned relatively low CN's in Tables 10.2 on page 10.7 to 10.9. Good judgment and experience based on stream gage records are needed to adjust CN's as conditions warrant.

- When the weighted CN is less than 40, use another procedure to determine runoff.

Examples

Four examples illustrate the procedure for computing runoff curve number (CN) and runoff (Q) in inches. Worksheet 2, Figure 10.5 on page 10.13, is provided to assist TR-55 users. Figures 10.6 through Figure 10.9 on pages 10.14 through 10.17 respectively represent the use of Worksheet 2 for each example. All four examples are based on the same watershed and the same storm event.

The watershed covers 250 acres in Broome County, New York. Seventy percent (175 acres) is a Mardin soil, which is in hydrologic soil group C. Thirty percent (75 acres) is a Tioga soil, which is in group B. The event is a 25 year frequency, 24-hour storm with a total rainfall of 5.5 inches.

Cover type and conditions in the watershed are different for each example. The examples, therefore, illustrate how to compute CN and Q for various situations of proposed, planned, or present development.

Example 1

The present cover type is pasture in good hydrologic condition. See Figure 10.6 on page 10.14 for Worksheet 2 information.

Example 2

Seventy percent (175 acres) of the watershed, consisting of all the Tioga soil and 100 acres of the Mardin soil, is 1/2-acre residential lots with lawns in good hydrologic condition. The rest of the watershed is scattered open space in good hydrologic condition. See Figure 10.7 on page 10.15.

Example 3

This example is the same as example 2, except that the 1/2-acre lots have a total impervious area of 35 percent. For these lots, the pervious area is lawns in good hydrologic condition. Since the impervious area percentage differs from the percentage assumed in Table 10.2, use Figure 10.3 on page 10.10 to compute CN. See Figure 10.8 on page 10.16.

Example 4

This example is also based on example 2, except that 50 percent of the impervious area associated with the 1/2 acre lots on the Mardin soil is "unconnected," that is, it is not directly connected to the drainage system. For these lots, the pervious area CN (lawn, good condition) is 74 and the impervious area is 25 percent. Use Figure 10.4 on page 10.11 to compute the CN for these lots. CN's for the 1/2-acre lots on Tioga soil and the open space on Mardin soil are the same as those in example 2. See Figure 10.9 on page 10.17.

VOL 12

6292

R0039600

Time of Concentration and Travel Time

Travel time (T_t) is the time it takes water to travel from one location to another in a watershed. T_t is a component of time of concentration (T_c) which is the time for runoff to travel from the hydraulically most distant point of the watershed to a point of interest within the watershed. T_c is computed by summing all the travel times for consecutive components of the drainage conveyance system.

T_c influences the shape and the peak of the runoff hydrograph. Urbanization usually decreases T_c, thereby increasing the peak discharge. But T_c can be increased as a result of (a) ponding behind small or inadequate drainage systems, including storm drain inlets and road culverts, or (b) reduction of land slope through grading.

Factors Affecting Time of Concentration and Travel Time

Surface Roughness

One of the most significant effects of urban development on flow velocity is less retardance to flow. That is, undeveloped areas with very slow and shallow overland flow through vegetation become modified by urban development: the flow is then delivered to streets, gutters, and storm sewers that transport runoff downstream more rapidly. Travel time through the watershed is generally decreased.

Channel Shape And Flow Patterns

In small non-urban watersheds, much of the travel time results from overland flow in upstream areas. Typically, urbanization reduces overland flow lengths by conveying storm runoff into a channel as soon as possible. Since channel design have efficient hydraulic characteristics, runoff flow velocity increases and travel time decreases.

Slope

Slopes may be increased or decreased by urbanization, depending on the extent of site grading or the extent to which storm sewers and street ditches are used in the design of the water management system. Slope will tend to increase when channels are straightened and decrease when overland flow is directed through storm sewers, street gutters, and diversions.

Computation of Travel Time and Time of Concentration

Water moves through a watershed as sheet flow, shallow concentrated flow, open channel flow, or some combination of these. The type that occurs is a function of the conveyance system and is best determined by field inspection.

Travel time (T_t) is the ratio of flow length to flow velocity:

$$T_t = \frac{L}{3600\,V} \qquad \text{[Eq. 10.4]}$$

where

T_t = travel time (hr),

L = flow length (ft),

V = average velocity (ft/s), and

3600 = conversion factor from seconds to hours

Time of concentration (T_c) is the sum of T_t values for the various consecutive flow segments:

$$T_c = T_{t1} + T_{t2} + \ldots T_{tm} \qquad \text{[Eq. 10.5]}$$

where

T_c = time of concentration (hr) and

m = number of flow segments.

Sheet Flow

Sheet flow is flow over plane surfaces. It usually occurs in the headwater of streams. With sheet flow, the friction value (Manning's n) is an effective roughness coefficient that includes the effect of raindrop impact; drag over the plane surface; obstacles such as litter, crop ridges, and rocks; and erosion and transportation of sediment. These n values are for very shallow flow depths of about 0.1 foot or so. Table 10.3 on page 10.19 gives Manning's n values for sheet flow for various surface conditions.

For sheet flow of less than 300 feet, use Manning's kinematic solution[H] to compute T_t:

$$T_t = \frac{0.007\,(nL)^{0.8}}{(P_2)^{0.5}\,s^{0.4}} \qquad \text{[Eq. 10.6]}$$

where

T_t = travel time (hr),

n = Manning's roughness coefficient, Table 10.3 on page 10.19

L = flow length (ft),

P_2 = 2 year, 24 hour rainfall (in), and

s = slope of hydraulic grade line (land slope, ft/ft).

This simplified form of Manning's kinematic solution is based on the following:

(1) shallow steady uniform flow,

Residue cover >20%	0.17
Grass:	
Short grass prarie	0.15
Dense grasses[2]	0.24
Bermudagrass	0.41
Range (natural)	0.13
Woods:[3]	
Light underbrush	0.40
Dense underbrush	0.80

[1]The values are a composite of information compiled by Engman (1980).

[2]Includes species such as weeping lovegrass, bluegrass, buffalo grass, blue grama grass, and native grass mixtures.

[3]When selecting n consider cover to a height of about 0.1 ft. This is the only part of the plant cover that will obstruct sheet flow.

(2) constant intensity of rainfall excess (that part of a rain available for runoff),

(3) rainfall duration of 24 hours, and

(4) minor effect of infiltration on travel time.

Rainfall depth can be obtained from Exhibit 10.1 at the end of this chapter.

Shallow Concentrated Flow

After a maximum of 300 feet, sheet flow usually becomes shallow concentrated flow. The average velocity for this flow can be determined from Figure 10.10 on page 10.20, in which average velocity is a function of watercourse slope and type of channel. Tillage can affect the direction of shallow concentrated flow. Flow may not always be directly down the watershed slope if tillage runs across the slope.

After determining average velocity in Figure 10.10 on page 10.20, use equation 10.4 to estimate travel time for the shallow concentrated flow segment.

Open Channels

Open channels are assumed to begin where surveyed cross section information has been obtained, where channels are visible on aerial photographs, or where blue lines (indicating streams) appear on United States Geological Survey (USGS) quadrangle sheets. Manning's equation or water surface profile information can be used to estimate average flow velocity. Average flow velocity is usually determined for bank-full elevation.

Manning's equation is

$$V = \frac{1.49\, r^{2/3} s^{1/2}}{n} \qquad \text{[Eq. 10.7]}$$

where

- V = average velocity (ft/sec),
- r = hydraulic radius (ft) and is equal to a/p_w,
- a = cross sectional flow area (ft^2),
- p_w = wetted perimeter (ft),
- s = slope of the hydraulic grade line (channel slope, ft/ft), and
- n = Manning's roughness coefficient for open channel flow.

Manning's "n" values for open channel flow can be obtained from standard textbooks[9]. After average velocity is computed using equation 10.7, T_t for the channel segment can be estimated using equation 10.4.

Reservoirs or Lakes

Sometimes it is necessary to estimate the velocity of flow through a reservoir or lake at the outlet of a watershed to determine travel time. This travel time is normally very small and can be assumed as zero.

Limitations

- Manning's kinematic solution should not be used for sheet flow longer than 300 feet. Equation 10.6 was developed for use with the four standard rainfall intensity-duration relationships.
- In watersheds with storm sewers, carefully identify the appropriate hydraulic flow path to estimate T_c. Storm sewers generally handle only a small portion of a large event. The rest of the peak flow travels by streets, lawns, and so on, to the outlet. Consult a standard hydraulics textbook to determine average velocity in pipes for either pressure or nonpressure flow.
- The minimum T_c used is 0.1 hour.
- A culvert or bridge can act as a reservoir outlet if there is significant storage behind it. The procedures in TR-55 can be used to determine the peak flow upstream of the culvert. Detailed storage routing procedures should be used to determine the outlet through the culvert.
- Figure 10.11 on page 10.22 provides Worksheet 3 for calculating Time of Concentration (T_c) or travel time (T_t).

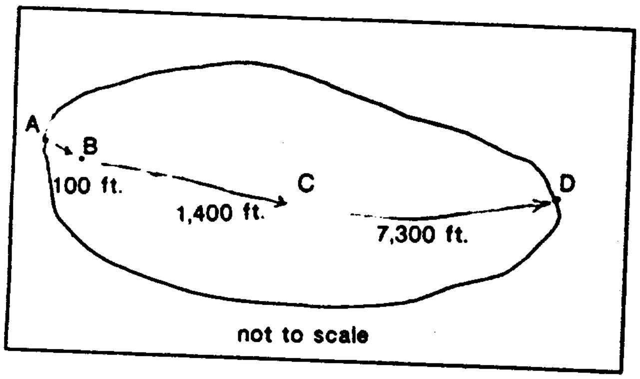
Example

Example 5

The sketch below shows a watershed in Broome County, New York. The problem is to compute T_c at the outlet of the watershed (point D). The 2-year 24-hour rainfall depth is 2.8 inches.

All three points occur from the hydraulically most distant point (A) to the point of interest (D). To compute T_c, first determine T_t for each segment from the following information:



Segment AB: Sheet flow; dense grass; slope (s) = 0.01 ft/ft; and length (L) = 100 ft.

Segment BC: Shallow concentrated flow; unpaved; s = 0.01 ft/ft; and L = 1400 ft.

Segment CD: Channel flow; Manning's n = .05; flow area (a) = 27 ft^2; wetted perimeter (pw) = 28.2 ft; s = 0.005 ft/ft; and L = 7300 ft.

See Figure 10.12 on page 10.23 for the computations made on worksheet 3 for Example 5.

Graphical Peak Discharge Method

The Graphical method was developed from hydrograph analyses using TR-20, "Computer Program for Project Formulation-Hydrology". The peak discharge equation used is:

$$q_p = q_u A_m Q F_p \qquad \text{[Eq. 10.8]}$$

where

- q_p = peak discharge (cfs);
- q_u = unit peak discharge (csm/in);
- A_m = drainage area (mi^2);
- Q = runoff (in); and
- F_p = pond and swamp adjustment factor.

The input requirements for the Graphical method are as follows:

(1) T_c (hr),

(2) drainage area (mi^2),

(3) appropriate rainfall distribution (I, IA, II, or III),

(4) 24-hour rainfall (in), and

(5) CN.

If pond and swamp areas are spread throughout the watershed and are not considered in the T_c computation, an adjustment for pond and swamp areas is also needed.

Peak Discharge Computation

For a selected rainfall frequency, the 24-hour rainfall (P) is obtained from Exhibit 10.1 at the end of this chapter. CN and total runoff (Q) for the watershed were computed earlier. The CN is used to determine the initial abstraction (I_a) from Table 10.4 on page 10.24. I_a/P is then computed.

If the computed I_a/P ratio is outside the range shown in Figures 10.16 and 10.17 on pages 10.28 and 10.29 respectively for the rainfall distribution of interest, then the limiting value should be used. If the ratio falls between the limiting values, use linear interpolation. Figure 10.13 on page 10.24 illustrates the sensitivity of I_a/P to CN and P.

Peak discharge per square mile per inch of runoff (q_u) is obtained from Figures 10.16 and 10.17 by using T_c, rainfall distribution type, and I_a/P ratio. The pond and swamp adjustment factor is obtained from Table 10.5 on page 10.25 (rounded to the nearest Table value). Use Worksheet 4, Figure 10.14 on page 10.26, to aid in computing the peak discharge using the Graphical method.

Figure 10.13 - Variation of I_a/P for P and CN

69	0.899		

Table 10.5 - Adjustment factor (F_p) for pond and swamp areas that are spread throughout the watershed	
Percentage of pond and swamp areas	Fp
0.0	1.00
0.2	0.97
1.0	0.87
3.0	0.75
5.0	0.72

Limitations

- The Graphical method provides a determination of peak discharge only. If a hydrograph is needed or watershed subdivision is required, use the Tabular Hydrograph method in Technical Release #55. Use TR-20 if the watershed is very complex or a higher degree of accuracy is required.
- The watershed must be hydrologically homogeneous, that is, describable by one CN. Land use, soils, and cover are distributed uniformly throughout the watershed.
- The watershed may have only one main stream or, if more than one, the branches must have nearly equal T_c's.
- The method cannot perform valley or reservoir routing.
- The F_p factor can be applied only for ponds or swamps that are not in the T_c flow path.
- Accuracy of peak discharge estimated by this method will be reduced if I_a/P values are used that are outside the range given in Figures 10.16 and 10.17. The limiting I_a/P values are recommended for use.
- This method should only be used if the weighted CN is greater than 40.
- When this method is used to develop estimates of peak discharge for both present and developed conditions of a watershed, use the same procedure for estimating T_c.
- T_c values with this method may range from 0.1 to 10 hours.

Example

Example 6

Compute the 25-year peak discharge for the 250-acre watershed described in examples 2 and 5. Figure 10.15 on page 10.27 shows how Worksheet 4 is used to compute q_p as 248 cfs.

SCS Hydrologic Soil Groups - New York

Soils are classified into hydrologic soil groups (HSG's) to indicate the minimum rate of infiltration obtained for bare soil after prolonged wetting. The HSG's; which are A, B, C, and D; are one element used in determining runoff curve numbers.

The infiltration rate is the rate at which water enters the soil at the soil surface. It is controlled by surface conditions. HSG also indicates the transmission rate-the rate at which the water moves within the soil. This rate is controlled by the soil profile. Approximate numerical ranges for transmission rates shown in the HSG definitions were first published by Musgrave. The four groups are defined by SCS soil scientists as follows:

Group A soils have low runoff potential and high infiltration rates even when thoroughly wetted. They consist chiefly of deep, well to excessively drained sands or gravels and have a high rate of water transmission (greater than 0.30 in/hr).

Group B soils have moderate infiltration rates when thoroughly wetted and consist chiefly of moderately deep to deep, moderately well to well drained soils with moderately fine to moderately coarse textures.

These soils have a moderate rate of water transmission (0.15-0.30 in/hr).

Group C soils have low infiltration rates when thoroughly wetted and consist chiefly of soils with a layer that impedes downward movement of water and soils with moderately fine to fine texture. These soils have a low rate of water transmission (0.05-0.15 in/hr).

Group D soils have high runoff potential. They have very low infiltration rates when thoroughly wetted and consist chiefly of clay soils with a high swelling potential, soils with a high permanent water table, soils with a claypan or clay layer at or near the surface, and shallow soils over nearly impervious material. These soils have a very low rate of water transmission (0-0.5 in/hr).

Disturbed Soil Profiles

As a result of urbanization, the soil profile may be considerably altered and the listed group classification may no longer apply. In these circumstances, use the following to determine HSG according to the texture of the new surface soil, provided that significant compaction has not occurred[10]:

HSG	*Soil textures*
A	Sand, loamy sand, or sandy loam
B	Silt loam or loam
C	Sandy clay loam
D	Clay loam, silty clay loam, sandy clay, silty clay, or clay

Drainage and Group D Soils

Some soils in the list are in group D because of a high water table that creates a drainage problem. Once these soils are effectively drained, they are placed in a different group. For example, Adrian soil is classified as A/D. This indicates that the drained Adrian soil is in group A and the undrained soil is in group D.

MEMORANDUM

TO: **Regional Water Engineers, Bureau Directors, Section Chiefs**
FROM: **Salvatore Pagano - Director, Division of Water**
SUBJECT: **Division of Water Technical and Operational Guidance Series (5.1.10)**

EROSION AND SEDIMENT CONTROL GUIDELINES FOR NEW DEVELOPMENT
(Originator: Philip M. DeGaetano)

6318

I. PURPOSE

To provide soil erosion and sediment control guidelines to regional water staff involved in the review of land development projects. These guidelines are to be used in conjunction with the **Stormwater Management Guidelines** (TOGS 5.1.8) in reviewing proposed development projects.

II. DISCUSSION

Sediment in runoff from construction sites can have a significant effect on the quality of downstream waters. It is of such concern that it has been highlighted as a source category to be addressed by the EPA regulations on stormwater management. It is also identified as a significant source category in the State Nonpoint Source Assessment Report.

The potential effects of increased sediment are varied:

> "Sediment may destroy fish habitat through blanketing of fish spawning and feeding areas and elimination of certain food organisms, directly impact fish through gill abrasion and fin rot, and reduce sunlight penetration, thereby impairing photosynthesis of aquatic plants. Suspended sediment decreases recreational values, reduces fishery habitat, adds to the mechanical wear of water supply pumps and distribution systems, and adds to treatment costs for water supplies. Nutrients and toxic substances attached to sediment particles are transported to waterbodies and may

enter aquatic food chains, cause fish toxicity problems, contribute to algal blooms, impair recreational uses, and degrade the water as a drinking water source."[1]

The following guidelines are designed for consideration by both government officials and project sponsors in the preparation and review of erosion and sediment control plans for a land development project. If implemented properly, the guidelines herein will assist in achieving the following water and natural resource management objectives.

- reduce the erosion potential from a development or construction project;
- decrease nonpoint source pollution and water quality degradation;
- maintain stream channels for their biological functions, as well as for drainage, through reduced sediment deposition.

The U.S. Environmental Protection Agency has recently adopted stormwater management regulations which will be implemented through the National Pollutant Discharge Elimination System (NPDES). Consequently, the N.Y. State Pollutant Discharge Elimination System (SPDES) program may be used in this state to implement the new federal regulations. The regulations contain provisions which require control of erosion from certain land development projects. However, the federal stormwater management program is not fully operational at this time.

Until the stormwater permit system is operational, it would be appropriate to use the authority of the State Environmental Quality Review Act (SEQRA) to apply the erosion and sediment control guidelines which make up this TOGS for all land development projects and construction activities when it is determined that soil erosion and sedimentation is a relevant area of environmental concern or when it is determined that soil erosion and sedimentation, if not controlled, may have a significant effect on the environment. Upon such determination, an erosion and sediment control plan should be prepared. The following are examples of projects where soil erosion and sedimentation are common relevant areas of environmental concern.

1. land clearing or land grading projects involving five or more acres;
2. residential development consisting of five or more dwelling units, unless each dwelling unit is on a lot of two or more acres;
3. industrial and/or commercial projects which result in an impervious surface of one or more acres;
4. site preparation on slopes which exceed 1½ ft. of vertical rise to 10 ft. of horizontal distance (or site preparation in areas of severe erosion potential where such areas have been mapped);
5. site preparation within 100 ft. of a wetland;
6. site preparation within 100 ft. of any watercourse;
7. excavating or filing which exceeds a total of 100 cu. yds. of material within any parcel or any contiguous parcels.

---

1 Nonpoint Source Management Program. January, 1990.

VOL 12

6319

Pursuant to the consistency requirements of the New York State Nonpoint Source Management Program as authorized under Section 319 of the Federal Clean Water Act of 1987, and pursuant to Presidential Executive Order 12372 requiring intergovernmental review of federal programs, the erosion and sediment control guidelines herein should be applied to all eligible federal agencies which either undertake development projects in the State or assist development projects through funding.

III. GUIDANCE

It is the policy of the Division of Water that an erosion and sediment control plan be prepared for all projects for which soil erosion and sedimentation has been identified as a relevant area of environmental concern, or, for which if it is not controlled, it may have a significant effect on the environment. The plan should be prepared and submitted as part of the SEQR process.

The attached guidelines were developed to aid persons in preparing and reviewing erosion and sediment control plans. They provide guidance on sound management practices, but are not fixed and inflexible rules to be applied in reviewing erosion control plans without considering the particular facts and circumstances of a particular project.

It should be noted that some communities may have duly adopted erosion control requirements, and that they should be consulted and complied with. In the absence of such requirements, Regional Water staff are encouraged to consult the management practices described in this guidance where appropriate to encourage their use by county and local agencies and by developers and consultants involved in preparing and reviewing development plans and proposed projects. To the fullest extent practicable, Regional Water staff should seek the assistance of County Soil and Water Conservation District sta'f during the review of erosion and sediment control plans.

VOL 12

EROSION AND SEDIMENT CONTROL GUIDELINES FOR NEW DEVELOPMENT

A. Existing vegetation on a project site should be retained and protected as much as possible to minimize soil loss on a project site and to minimize erosion control costs.

B. Sediment control practices/measures, where necessary, should be designed to protect the natural character of rivers, streams, lakes, coastal waters or other waterbodies on-site and minimize erosion and sedimentation off-site from the start of land disturbance activities to establishment of permanent stabilization.

1. The off-site impacts of erosion and sedimentation related to land clearing, grading and construction activities should not be any greater during and following land disturbance activities than under pre-development conditions.

2. Pursuant to Part 700 et seq. of Title 6, Chapter X of NYCRR:

   a. toxic and other deleterious substances shall not be discharged in amounts that will adversely affect the taste, color or odor thereof, or impair the waters of the state for their best (classified) usages,

   b. suspended, colloidal and settleable solids shall not be discharged in amounts that causes substantial visible contrast to natural conditions, or causes deposition or impairs the waters for their best (classified) usages.

This means that stream reaches on-site and downstream of construction areas should not have substantial visible contrast relative to color, taste, odor, turbidity and sediment deposition from the reaches upstream of the construction area. Impacts such as these which result from construction or developmental activities are a violation of Part 700 water quality standards and may be subject to enforcement actions.

C. Erosion and sediment control measures should be constructed in accordance with an erosion and sediment control plan. The plan should:

1. describe the temporary and permanent structural and vegetative measures that will be used to control erosion and sedimentation for each stage of the project from land clearing to the finished stage.

2. provide a map showing the location of erosion and sediment control measures.

3. provide dimensional details of proposed erosion and sediment control facilities as well as calculations used in the siting and sizing sediment basins. (Guidance for performing calculations can be obtained in the reference cited in Section E.8.)

4. identify temporary erosion and sediment control facilities which will be converted to permanent stormwater management facilities.

5. provide an implementation schedule for staging temporary and permanent erosion and sediment control facilities.

6321

6. provide a maintenance schedule for soil erosion and sediment control facilities and describe maintenance activities to be performed.

D. Erosion and sediment control measures should be constructed prior to beginning any other land disturbances. The devices should not be removed until the disturbed land areas are stabilized.

E. Specify guidance.

1. Exposure Restrictions: No more than 5 acres of unprotected soil should be exposed at any one time. Previous earthwork should be stabilized in accord with approved design standards and specifications referenced in Section E.8 before additional area is exposed. (Site factors including topography, soil erosion potential, proximity to wetlands and water courses may require limiting the amount of raw earth that can be exposed at any one time to less than 5 acres.)

2. Grading: Perimeter grading should blend with adjoining properties.

3. Vegetative Protection: Where protection of trees and/or other vegetation is required, the location of the site to be protected should be shown on the erosion control plan. The method of protecting vegetation during construction should conform to the design criteria referenced in Section E.8.

4. Drainage control.

a. Surface runoff that is relatively clean and sediment free should be diverted or otherwise prevented from flowing through areas of construction activity on the project site. This will greatly reduce sediment loading in surface runoff.

b. A fill associated with an approved temporary sediment control structure or permanent stormwater management structure, should not be created which causes water to pond off-site on adjacent property, without first having obtained ownership or permanent easement for such use from the owner of the off-site or adjacent property.

c. Natural drainage channels should not be altered or relocated without the proper approvals. Pursuant to Article 15 of the Environmental Conservation Law, a protected stream and the bed and banks thereof should not be altered or relocated without the approval of the Department of Environmental Conservation.[2]

d. Runoff from any land disturbing activity should not be discharged or have the potential to be discharged off-site or into storm drains or into watercourses unless such discharge is directed through a properly designed, installed and maintained structure, such as a sediment trap, to retain sediment on-site. Accumulated sediment should be removed when 60% of the storage capacity of the sediment retention structure is filled with sediment.

e. For finished grading, adequate gradients should be provided so as to prevent water from standing on the surface of lawns for more than 24 hours after the end of a rainfall, except in a swale flow area which may drain as long as 48 hours after the end of rainfall.

---

2 A natural drainage channel refers to a swale, water course in a gully, or a protected or unprotectd stream. Natural drainage channels should not be altered or relocated on adjacent properties without first having obtained ownership or a permanent easement for the altered or relocated drainage channel from the owner of the off-site or adjacent property.

VOL 12

6322

f. Permanent swales or other points of concentrated water flow should be stabilized with sod, rip-rap, paving, or covered with a approved erosion control matting as provided for in the design criteria referenced in Section E.8.

g. Surface flows over cut and fill slopes should be controlled as provided for in the design criteria for vegetating waterways referenced in Section E.8.

5. Timing.

a. Except as noted below, all sites should be seeded and stabilized with erosion control materials, such as straw mulch, jute mesh, or excelsior within 15 days of final grading. If construction has been suspended, or sections completed, areas should be seeded immediately and stabilized with erosion control materials. Maintenance should be performed as necessary to ensure continued stabilization.

i. For active construction areas such as borrow or stockpile areas, roadway improvements, and areas within 50 ft. of a building under construction, a perimeter sediment control system consisting, for example, of silt fencing or hay bales, should be installed and maintained to contain soil.

ii. On cut side of roads, ditches should be stabilized immediately with rock rip-rap or other non-erodible liners, or where appropriate, vegetative measures such as sod. When seeding is approved, an anchor mulch should be used and soil should be limed and fertilized in accord with recommendations referenced in Section E.8.

iii. Permanent seeding should optimally be undertaken in the spring from March 21 through May 20, and in late summer and early fall from August 25 to October 15. During the peak summer months and in the fall after October 15 when seeding is found to be impracticable, an appropriate mulch should be applied. Permanent seeding may be undertaken during summer if plans provide for adequate watering of the seedbed.

iv. All slopes steeper than 3:1 (h:v), as well as basin or trap embankments, and perimeter dikes should, upon completion, be immediately stabilized with sod, seed and anchored straw mulch, or other approved stabilization measures. Areas outside of the perimeter sediment control system should not be disturbed. Maintenance should be performed as necessary to ensure continued stabilization.

b. Temporary sediment trapping devices should be removed within thirty (30) calendar days following establishment of permanent stabilization in all contributory drainage araes. Stormwater management structures used temporarily for sediment control should be converted to the permanent configuration within this time period as well.

6. Stream protection.

a. The bed and banks of all on-site and off-site streams that may be impacted by land clearing, grading, and construction activities should be protected to prevent stream, river, lake or coastal sedimentation, streambank erosion, stream enlargement and degradation or loss of

VOL 12

6323

fisheries habitat. Measures for protecting the bed and/or banks of a stream may include, for example, gabion baskets, rip-rap, log cribbing, and vegetative measures. [3]

b. Where temporary work roads or haul roads cross stream channels, adequate waterway openings must be constructed using spans, culverts, washed rock backfill or other acceptable, clean methods that will ensure that road construction and use do not result in turbidity and sediment downstream. All stream crossing activities and appurtenances shall be in compliance with a permit issued pursuant to Article 15 of the Environmental Conservation Law, where applicable, and should be carried out in conformance with guidelines in DEC'S Stream Corridor Management manual. [4]

7. Maintenance.

a. An erosion control plan for a project site should identify maintenance requirements for erosion and sediment control practices utilized, and it should provide a maintenance schedule. All erosion and sediment control measures should be inspected periodically and maintained in conformance with the schedule so as to ensure they remain in effective operating condition until such times as they are removed.

b. All points of construction ingress and egress should be protected to prevent the deposition of materials onto traversed public thoroughfare(s) either by installing and maintaining a stabilized construction entrance, or by washing all vehicle wheels in a safe disposal area. All materials deposited onto public thoroughfare(s) should be removed immediately. Proper precautions should be taken to ensure that materials deposited onto public thoroughfares are removed so that they do not enter catch basins, storm sewers, or combined sewers.

c. Accumulated sediment should be removed when 60% of the storage capacity of the retention structure is filled with sediment.

8. Design specifications.

Designs, standards and specifications for controlling erosion and sedimentation are found in the following publication and should be identified and shown in the erosion control plan:

> Empire State Chapter, Soil & Water Conservation Society, New York Guidelines for Urban Erosion and Sediment Control, Syracuse. March 1988.

---

3 Whenever possible, vegetative streambank stabilization practices are recommended over structural practices such as rip-rap and gabion linings which may unnecessarily alter the existing stream ecosystem.

4 New York State Department of Environmental Conservation, "Stream Corridor Management: A Basic Reference Manual," Albany, 1986.

APPENDIX B
HOW TO USE THE UNIVERSAL SOIL LOSS EQUATION IN URBANIZING AREAS

To predict soil losses on construction sites, the equation used is:

A = R or (EI) x KLS

Where:

A is the computed soil loss per acre in tons. This quantity may be converted to cubic yards by using conversion factors shown in Table B.1.

R is the rainfall intensity factor which is a measure of the erosive force of rainfall. EI is also used as a designation of rainfall intensity. R refers to the average annual rainfall erosion index. The EI factor is the rainfall erosion index for a part of a year, "probability" storm or for the magnitude of a single storm. The R value for urban areas is the same as that assigned to work units for agricultural lands. This value should be used in predicting annual soil losses on construction sites.

Table B.2 contains EI values of key cities in the New York area for soil loss probabilities other than the average annual losses. These may be used to further characterize soil loss hazards. For example, in Syracuse, New York, the annual average R value is 100. Table B.2 shows that the value of R will equal or exceed 129 in 20% of the years. This is 129 x 100 or 1.29 times the average value.

Soil losses from individual storms may also be computed. For example, Table B.2 shows that a 10 year rain in Syracuse has an erosion index of 61 or more. This means that the soil losses from this one storm may be 61% of the soil losses occurring during an entire average year.

K is the soil erodibility factor. In construction work, B and C soil horizons are mostly involved. Lists of K factors for A, B, and C horizons are shown in Table B.3. (This table includes only representative soils and their K values. For more complete listings of soils, contact the local SCS office.)

Limited research data show that infiltration rates and erosion losses from compacted[1] fills do not differ greatly from those on "cuts," when slopes and surface materials are the same. Loose fills may lose less soil and water than compacted fills. Since research has not yet determined the rates of soil loss on loose fills, the same K values that are used for B and C horizons on cuts or compacted fills may be used for loose fills.

L is the slope length factor

S is the slope gradient factor

These two factors are closely interrelated and have been computed into one combined value known as the LS value. These combined values are shown in Table B.4. Two other factors in the Universal Equation, namely P and C, are not used on urbanized lands though they are used on agricultural lands. These factors are concerned mostly with contouring, contour strip-cropping, crop rotations, stages of crop growth, tillage and harvesting methods which have little or no relation to urbanized lands.

The Universal Soil Loss Equation is designed to estimate soil losses by sheet erosion only. Construction sites are also subject to rill and gully erosion. The losses from rilling and gullying are in addition to losses from sheet erosion and, therefore, must be taken into account for determining total losses on a given site.

One method of measuring rill erosion is by using the Alutin Rill Erosion Method. This procedure is fairly accurate up to losses of 100 tons per acre. Greater losses than this generally fall into the category of gullying and these are computed by measuring the cut area in cubic yards. (See Appendix C for estimating soil losses by rilling.)

A major difference between the above mentioned methods of computing soil losses is that the Universal Soil Loss Equation can be used for estimating soil losses before and after they occur, while losses from rilling and gullying can be computed only after the erosion occurs.

The following are examples showing how the Universal Soil Loss Equation is used for estimating soil losses:

Assume Syracuse, New York, as the locale of a construction site. The disturbed site is 50 acres in size, with an average gradient of 8% and an average slope length of 500 feet. The soil is a Schoharie silt loam with a K value of 0.28 in both the B and C horizons. (The K value is obtained from Table B.3.) The LS value is 2.2 and is obtained from Table B.4.

1. Compute soil losses from this unprotected surface for a 12 month period. The average annual rainfall erosion index (R) is 100.

[1] Compaction in this section of the guidelines refers to that which occurs from normal grading and hauling operations.

A = RKLS = 100 x 0.28 x 2.2 x 50 acres = 3,080 tons or 2,679 cubic yards. (Latter computation obtained by using conversion factor of 0.87 shown in Table B.1.)

2. Compute soil losses from this unprotected surface for a 3 month period (June, July, August). The EI value for this period is 59. This value is obtained as follows:

   Refer to the erosion index distribution curve applicable to Syracuse, New York, Figure B.1. The EI reading for June 1 is 17% and for September 1 is 76%. The percent of average annual index for this period is 76% - 17% or 59%. Since the annual erosion index for this location is 100, the EI value for the 3 month period is 59% of 100 or 59.

   A = (EI) KLS = 59 x 0.28 x 2.2 x 50 acres = approximately 1,817 tons or 1,581 cubic yards.

3. Compute soil losses for the 1 year out of 5 when the rainfall intensity (R) will increase from the average annual R of 100 to an R of 129. (Latter value from Table B.2.)

   A = RKLS or 129 x 0.28 x 2.2 x 50 acres = approximately 3,973 tons or 3,456 cubic yards.

4. Compute soil losses for the 1 year out of 20 when the rainfall intensity (R) will increase from the normal average annual value of 100 to an annual value of 197. (Latter value from Table B.2.)

   A = RKLS = 197 x 0.28 x 2.2 x 50 acres = approximately 6,068 tons or about 5,279 cubic yards.

5. Compute soil losses from the expected magnitude of a single storm that may occur once in 5 years. The EI value of this storm is 38. (Obtained from Table B2.2.)

   A = EI x KLS = 38 x 0.28 x 2.2 x 50 acres = approximately 1,166 tons or about 1,014 cubic yards.

6. Compute soil losses from the expected magnitude of a single storm that may occur once in 10 years. The EI value of this storm is 61. (Obtained from Table B.2.)

   A = EI x KLS = 61 x 0.28 x 2.2 x 50 acres = approximately 1,879 tons or about 1,635 cubic yards.

7. Compute soil losses from the expected magnitude of a single storm that may occur once in 20 years. The EI value of this storm is 65. (Obtained from Table B.2.)

   A = EI x KLS = 65 x 0.28 x 2.2 x 50 acres = approximately 2,002 tons or about 1,742 cubic yards.

<u>Slope Length (L) and Gradient (S)</u>

Slope length is defined as the distance from the point of origin of overland flow to either of the following: (1) the point where the slope decreases to the extent that significant deposition begins or (2) the point where runoff enters a well defined channel. Field slopes are often either convex (steepening substantially toward the lower end) or concave (flattening toward the lower end). When the lower end of the slope is steeper than the upper end, the gradient of the steeper segment should be used with the overall slope length to enter the slope effect chart (Table B.4). On a concave slope, deposition may occur on the lower end of the field such as in a deep depression or channel. In such cases, the appropriate length and gradient are those of that segment of the slope that is above the channel or point of deposition.

NOTE: Sediment yields are difficult to relate quantitatively to soil losses from a given construction site. Sediment yield is commonly expressed by $D_r = (S + /S_e) \times 100$. S + is total sediment passing a measuring station, S_e is loss estimated by the Universal Soil Loss Equation or other means and D_r is the sediment yield ratio in percentage. Research is sparse on this problem, but sediment yield rates range mostly from 10 to 70 percent, depending upon topographic characteristics and size of drainage areas.

Refer to Sections 5 and 8 for procedures in computing sediment storage capacities of debris basins.

[3] K values of the A horizons were taken from "K and T Factors of Soil Series Mapped in the Northeast Region", January 1970, USDA, SCS.

[4] K values of the fine earth fraction of the B and C horizons were determined by using the "Soil Erodibility Nomograph", W.H. Wishmeier, ARS-SWC, Purdue University, 2-1-71. (See Figure B.3.) The K values for the fine earth fraction were then adjusted for coarse fragment content and bulk density based on the following criteria: 15 to 35 percent coarse fragments; decrease K value 1/3. Greater than 35 percent coarse fragments; decrease K value 1/2. Bulk density greater than 2g/cc or 125 lbs./cu. ft.; decrease K value 1/10.

Table B.5
Guide to Classification of Vegetal Covers in Waterways and Channels as to Degree of Retardness

Retardance and Cover	Stand	Condition and Height
Retardance A		
Reed canarygrass	Excellent	Tall (Average 36")
Tall fescue	Excellent	Tall (Average 36")
Smooth bromegrass	Excellent	Tall (Average 36")
Switchgrass	Excellent	Tall (Average 36")
Retardance B		
Alfalfa	Good	Uncut (Average 11" tall)
Tall fescue	Good	Average (20" tall)
Smooth bromegrass	Good	Average (20" tall)
Switchgrass	Good	Average (20" tall)
Red fescue	Good	Uncut (Average 16" tall)
Kentucky bluegrass	Good	Uncut (Average 16" tall)
Redtop	Good	Average (22" tall)
Retardance C		
Kentucky bluegrass	Good	Headed (6 to 12")
Grass-legume mixture (orchardgrass, ryegrass and birdsfoot trefoil)	Good	Uncut (6 to 8")
Red fescue	Good	Headed (6 to 12")
Retardance D		
Kentucky bluegrass	Good	Cut to 2.5"
Grass-legume mixture	Good	Uncut, 4"
Red fescue	Good	Cut to 2.5"

Retardance is the degree of resistance to flow by vegetation. Retardance "A" is high, while retardance

APPENDIX C
FIELD MEASUREMENT OF RILL EROSION IN TONS PER ACRE

The method explained below for measuring rill erosion in tons per acre is known as the Alutin Rill Erosion Method. This procedure accounts for 80 percent of lysimeter measures that involve losses of 5 to 100 tons per acre. Losses greater than 100 tons per acre are usually beyond the realm of rilling

The basic formula used in this calculation is:

Tons Per Acre Soil Loss = sum of cross section of rills in square inches along a measured lineal distance of 14.0 feet across the slope.

The procedure for field measuring rill erosion that is generally accepted is as follows:

Step 1 -- Pace off or measure a lineal distance of 42 or 84 feet across the slope.

Step 2 -- Measure in inches the width and depth of each rill along the chosen distance.

Step 3 -- Multiply each width and depth reading to obtain the area in square inches.

Step 4 -- Add all products of readings along chosen distance.

Step 5 -- Divide this sum by 3 if a 42 foot distance was selected and by 6 if 84 feet was chosen. The result is tons of soil loss per acre.

EXAMPLE:

Width (in.) x	Depth (in.) =	Area in square inches
3	3	9
2	3	6
3	6	18
4	6	24
3	5	15
5	6	30
		102

For a chosen distance of 42 feet, the soil loss in tons per acre = 102/3 = 34.

APPENDIX D
EXCERPTS FROM EROSION AND SEDIMENT CONTROL ORDINANCES

NEW YORK, ROCKLAND COUNTY: Resolution Concerning Site Drainage Erosion and Sedimentation

RESOLUTION No. 414 - RESOLUTION CONCERNING SITE DRAINAGE EROSION AND SEDIMENTATION

WHEREAS, There have been several inquiries concerning the appropriateness of the further clarification and guidelines in the establishment of grades, contours, drainage and ground cover concerning developments with in the Town of Orangetown; and

WHEREAS, The Rockland County Soil and Water Conservation District has recommended certain standards and guidelines be adopted by the various municipalities within the County of Rockland; and

WHEREAS, Pursuant to Section 21-7 of the Land Development Regulations of the Town of Orangetown and other related sections, the Planning Board has jurisdiction over the review of all plans, plats and control over the plans for the development of subdivisions; and

WHEREAS, It is the desire of the Town Board to provide further guidelines to the Planning Board for the review of subdivisions, now, there fore be it

RESOLVED, That the Planning Board adopt the following guidelines in the review of all subdivisions submitted to it for consideration:

1. Three (3) sets of plans for the control of drainage, erosion and sedimentation shall be submitted to the Planning Board, or its duly authorized representative, at the time the final drawings or construction plans are submitted. These plans shall bear the approval of the Soil and Water Conservation District that the proposed measures to provide drainage and erosion and sedimentation control are adequate.

2. Measures to provide the control of drainage, erosion and sedimentation shall be described and provided for in the construction plans and the estimated cost of accomplishing said measures shall be included in the performance bond. In addition, thereto, the landowner shall be required to provide a cash escrow guarantee to be held by the Town) in an amount determined by the Planning Board or its duly authorized representative, which would insure the Town that emergency measures could be taken by the Town at the landowner's expense due to the nonconformance or negligence of the landowner in his construction program.

3. During the construction phase consultive technical assistance will be furnished, if necessary, by the Planning Board or its duly authorized representative of the Soil and Water Conservation District.

   The Planning Board or its duly authorized representative shall enforce compliance with the approved plans.

4. The Planning Board or its duly authorized representative shall make a continuing review and evaluation of the methods used and the overall effectiveness of the drainage and erosion and sedimentation control program.

   The following control measures should be used for effective control of drainage and erosion and sediment:

   a. The smallest practical area of land should be exposed at any one time during construction.
   b. When land is exposed during construction, the exposure should be kept to the shortest practical period of time.
   c. Where necessary, temporary vegetation and/or mulching should be used to protect areas exposed during construction.
   d. Sediment basins (debris basins, desilting basins, or silt traps) should be installed and maintained to remove sediment from runoff waters and protect land undergoing change.
   e. Provisions should be made to effectively accommodate the increased runoff caused by changed soil and surface conditions during and after construction.
   f. The permanent final vegetation and structures should be installed as soon as practical in the construction.
   g. The development plan should be fitted to the topography and soils so as to create the least erosion potential.
   h. Wherever feasible, natural vegetation should be retained and protected, and be it

RESOLVED Further, That the Office of Building, Zoning and Planning Administration and Enforcement shall be responsible for the inspection and enforcement of any decisions rendered by the Planning Board in connection with these guidelines.

VOL 12 6340

SECTION 404. Drainage System, Flood Hazards and Erosion Control

A. Drainage Systems

Adequate and comprehensive drainage systems shall be provided to convey the storm water runoff originating within and outside the subdivision in accordance with the natural direction of runoff for the total upland watershed area affecting the subdivision. Such drainage systems shall have sufficient capacity to accommodate the potential future runoff based upon the probable land use and ultimate development of the total watershed area upland of the subdivision.

In general, the preservation of natural watercourses is preferable to the construction of drainage channels, and wherever practicable such natural watercourses should be preserved. Attention is called to the possibilities of using easements for natural watercourses to satisfy the open space requirements of "average density" developments under the Zoning Ordinance. Storm sewers and subdivision drainage facilities shall be based upon a design flow with a minimum return interval of 10 years. The design of natural watercourse channels shall depend upon the drainage are according to the following table.

DESIGN RETURN INTERVALS FOR NATURAL WATERCOURSES

Drainage Area	Recurrence Interval
Above 20 square miles	100 years
Between 4 and 20 square miles	50 years
Less than 4 square miles	25 years

B. Flood Hazard Prevention

Flood hazard prevention shall include the control of soil erosion of land surface and drainage channels and the prevention of inundation and excessive ground water seepage by comprehensive site grading and the establishment of adequate elevations of buildings, building openings and roadways above the observed, anticipated or computed water levels of storm sewers, streams, channels, flood plains, detention basins and swales.

Particular attention shall be paid to development in the vicinity of West Creek and its flood plain; and no alteration of the existing characteristics of this area shall take place without the specific approval of the Town Engineer as to the adequacy of the protective measures taken, if any, and the effects of such development on upstream and downstream reaches of the watercourse and adjacent properties.

C. Erosion Control

In order to ensure that the land can be developed without danger to health or peril from fire, flood or other menace, the Planning Board shall require the developer to follow certain erosion control practices as it deems necessary. Both the Planning Board and the developer shall consult with the Town Engineer, as required, and the Town Engineer shall determine whether or not the required procedures are being put into practice. Such procedures may include:

1. Exposing the smallest practical area of land at any one time during development.
2. Provision of temporary vegetation and/or mulching to protect critical areas
3. Provision of adequate drainage facilities to accommodate effectively the increased runoff caused by changed soil and surface conditions during and after development.
4. Fitting of the development plan to the topography and soils so as to minimize the erosion potential.
5. Retention and protection of natural vegetation wherever possible.
6. Installation of permanent final vegetation and structures as soon as practicable.
7. Provision of adequate protective measures when slopes in excess of 10% are graded; and minimizing such steep grading.

MARYLAND, MONTGOMERY COUNTY: Sediment Control Ordinance

(Amendment to the Subdivision Ordinance, Chapter 104, as Codified in 1965 Montgomery County (Maryland) Code, Adopted April 21, 1957.)

A new subsection is added to Section 104-24 Preliminary Subdivision Plan - Approval Procedure to be known as Section 104-24 (i) as follows:

(i) Sediment Control (adopted 6/27/67). The approval of all preliminary plans and extensions of previously approved plans shall include provisions for erosion and sediment control, in accordance with the Montgomery County Sediment Control Program, adopted by the County Council, June 29, 1965.

VOL 12 6341

(1) The Board, in its consideration of each preliminary plan or extension of previously approved plan, shall condition its approval upon the execution by the subdivider of erosion and sediment control measures to be specified by the Board after receiving recommendations from the Montgomery Soil Conservation District.

(2) One copy of each approved preliminary plan or extension of previously approved plan shall be referred to the Montgomery Soil Conservation District for review and recommendations as to adequate erosion and sediment control measures to prevent damage to other properties.

(3) The installation and maintenance of the specified erosion and sediment control measures shall be accomplished in accordance with the procedures for Public Works Agreement as specified in Section 104-26(g) and in accordance with standards and specifications on file with the Montgomery Soil Conservation District.

(4) Permits for clearing and grading prior to the recordation of plats shall be obtained from the Department of Public Works subject to the granting of temporary easements and other conditions deemed necessary by the Department in order to inspect and enforce the performance of the specified erosion and sediment control measures provided for in subsection (1) above.

(5) In the event the subdivision proceeds to clear and grade prior to recording of plats, without satisfying the conditions specified under Section 4, the Board may revoke the approval of the preliminary plan or extension of previously approved plan.

Amend Article I, Section 23-2, General Requirements (of subdivision plans), by the addition of a new paragraph to be known as 23-2(1) to read as follows:

(1) Erosion and Sediment Control Measures

Adequate controls of erosion and sediment control methods shall be provided prior to any clearing, grading or construction.

Amend Section 23-8, Preliminary Plats - Preparation, by the addition of a new paragraph to be known as 23-8(g) to read as follows: (Preliminary plats shall include a)

(g) Statement that erosion and sediment control methods shall be provided prior to any clearing, grading or construction.

Amend Article 2 of Chapter 23 by the addition of a new paragraph to Section 23-12, Final Plats - Approval, to be known as 23-12(c) to read as follows: (Plats shall be approved only if)

(c) Plans and specifications for the control of erosion and sedimentation, if such controls are deemed necessary, have been submitted and approved by the Director of Public Works or his agent. This approval shall be concurrent with the approval of the aforesaid plans and specifications and become a part thereof.

MARYLAND - STATE-WIDE HOUSE BILL NO. 1151 (1970): Sediment Control

Section 3. And be it further enacted, the new Sections 105 through 110 inclusive be and they are hereby added to Article 96A of the Annotated Code of Maryland (1957 Edition, 1961 Replacement Volume and 1969 Cumulative Supplement), title "Water Resources," to follow immediately after Section 104 therefore and to be under the new subtitle "Sediment Control" and to read as follows:

105: The General Assembly of the State of Maryland hereby determines and finds that the lands and waters comprising the watersheds of the State are great natural assets and resources; that as a result of erosion and sediment deposition on lands and in waters within the watersheds of the State, said waters are being polluted and despoiled to such a degree that fish, marine life and recreational use of the waters are being adversely affected. In order to protect the natural resources of the State, the Secretary of Natural Resources is directed to adopt criteria and procedures to be used by the counties and the local Soil Conservation Districts to implement soil and shore erosion control programs. Such procedures may provide for the review and approval of major grading, sediment and erosion control plans by the Department of Natural Resources.

106: (A) Before land is cleared, graded, transported or otherwise disturbed for purposes including, but not limited to the construction of buildings, the mining of minerals, the development of golf courses and the construction of roads and streets by any private person, partnership, corporation, municipal corporation, county or state agency within the State of Maryland, the proposed earth change shall first be submitted to and approved by the appropriate Soil Conservation District. Land clearing, soil movement and construction shall be carried out in accordance with the written recommendations of the said Soil Conservation Districts regarding the control of erosion and siltation and the elimination of pollution.

(B) In Prince George's and Montgomery Counties, the Washington Suburban Sanitary Commission shall, after consultation with and advice of the Soil Conservation Districts of the two counties and the Depart-

VOL 12

6342

ment of Natural Resources, prepare and adopt regulations for erosion and siltation control requirements for utility construction, with the regulations to be adopted and enforced as are other regulations of the Commission pursuant to the authority conferred upon it by other laws. The provisions of this subsection shall not apply until erosion and siltation control requirements for utility construction have been approved by the Soil Conservation Districts in each county.

(C) The Department of Natural Resources shall assist the Soil Conservation Districts in the preparation of a unified sediment control program and in the implementation of said program pursuant to this subtitle. Furthermore, nothing in this subtitle shall affect the responsibilities of the Department of Water Resources under Article 96A of the Annotated Code of Maryland (1964 Replacement Volume and 1969 Supplement).

(D) Notwithstanding the provisions of this section, the Department of Natural Resources shall review and approve all land clearing, soil movement and construction activity undertaken by any agency of the State government.

107: The provisions of this subtitle shall not apply to agricultural land management practices, the construction of agricultural structures or to the construction of single family residences and/or their accessory buildings on lots of two acres or more. Regardless of planning, zoning or subdivision controls, no permits shall be issued by any county or municipality for grading or for the construction of any building, other than those matters exempted above, unless such grading or construction is in accordance with plans approved as provided in this subtitle.

108: (A) The counties and municipalities shall have the power and authority to issue grading and building permits as otherwise provided by law. No grading or building permits shall be issued until the developer submits a grading and sediment control plan designed by a professional engineer registered in the State of Maryland, approved by the appropriate Soil Conservation District and the developer certifies that all land clearing, construction and development will be done pursuant to the said plan. Criteria for sediment control and for referral of an applicant to the appropriate Soil Conservation District and the Department of Natural Resources. The county agency responsible for on-site inspection and enforcement of the provisions of this subheading shall make a final inspection and forward its report to the appropriate Soil Conservation District. Notice of violation of the provisions of this subtitle shall be filed with the Department of Natural Resources as well as with the appropriate county agency.

(B) Each county shall adopt grading and building ordinances, or portion thereof, which are necessary to carry out the provisions of this subtitle. The Department of Natural Resources and the appropriate Soil Conservation District shall assist the several counties in the development of such ordinances or necessary portions thereof. The provisions of this subsection shall be carried out prior to March 1, 1971. Prior to March 1, 1971, established ordinances and procedures shall be used by the counties to carry out the provisions of this subtitle.

109: Any violation of this subheading shall be deemed a misdemeanor, and the person, partnership or corporation who is found guilty of such violation shall be subject to a fine not exceeding five thousand dollars ($5,000) or one year's imprisonment for each and every violation. Any agency whose approval is required under this subheading or any person in interest may seek an injunction against any person, partnership or corporation, whether public or private, violating or threatening violation of any provisions of this subheading.

110: For the purposes of this subheading, the Bureau of Public Works or similar municipal agency is empowered and directed to act in the place of the appropriate Soil Conservation District in municipalities which are not within a Soil Conservation District.

MARYLAND, PRINCE GEORGE'S COUNTY: Procedure for Incorporating Erosion and Sediment Control in Subdivision Plans

Under this sediment control program, the following procedures are provided to assist landowners, developers and engineers in the inclusion of required erosion and sediment control measures in the planning and construction of subdivisions.

Prior to preparation and submission of a preliminary plan, but after completion of the topographic survey, a developer may seek technical assistance from staff members of the Soil Conservation District or the Prince George's County Planning Board regarding erosion and sediment control measures.

Preliminary Subdivision Plan Stage

Under existing procedures, developers submit plans to the Prince George's County Planning Board. The Planning Board staff, then on the basis of size, topography, erosion hazards and other factors relating to sedimentation, determines which plans will be submitted to the Soil Conservation District for review of erosion and sediment control measures. It so indicates on the copies referred to other agencies. Soil Conservation District technical assistance in developing needed erosion and sediment control measures will be furnished on request at this stage.

After all reviews are completed, the planning staff submits the plan to the Prince George's County Planning Board with recommendations, including any sediment control requirements deemed necessary. The Board may give conditional approval of the plan, subject to the requirements being carried out by the developer.

Construction Stage

Consultive technical assistance in establishing the planned erosion and sediment control measures is furnished by the Soil Conservation District on request of the builders, developers and their engineers, consistent with current operating policies and available resources at the time the work is to be done.

Article 22: Grading and Erosion Control to the Building Code

Section 2200.0 Purpose

The purpose of this article is to safeguard life, limb, property and public welfare by establishing minimum requirements for grading, drainage and erosion control of land within Prince George's County, Maryland, and to establish procedures by which these requirements are to be administered and enforced.

Section 2205.0 Application

A written application in form prescribed by the Building Official shall be required for each permit. Plans and specifications shall be submitted with each application for a grading permit, unless specifically not required by the Building Official.

(11) Site development plan showing elevations, dimensions, location, extent and the slope of all proposed grading, load bearing fill, buildings, parking areas, and driveways; all clearly indicated.

(12) The area in square yards of the total site minus that area to remain undisturbed and currently having an effective erosion resistant ground cover or surface.

(13) The planned area of the development, or of each subdivision thereof, the development sequence of such subdivision and the time of exposure of each area prior to completion of effective temporary and/or permanent erosion and sediment control measures.

(14) Adequate plans of all drainage provisions, retaining walls, cribbing, planting, antierosion devices or other protective devices to be constructed in connection with or as part of the proposed work, together with a map showing the drainage area of land tributary to the site and calculated runoff from the area served by all drains.

Section 2207.0 Soils Report

The Building Official shall, if load bearing fill is proposed, and may otherwise require a soils investigation to correlate surface and subsurface conditions with the proposed grading plan. The results of the investigation shall be presented in a report by a Soil Engineer which shall include but need not be limited to: data regarding the nature, distribution and supporting ability of existing soils and rock on the site, conclusions and recommendations for grading requirements and erosion control, including recommendations to insure stable soil conditions and ground water control as applicable. The Building Official may require such supplemental reports and date as he deems necessary. Recommendations included in such reports and approved by the Building Official shall be incorporated in the grading plan or specifications.

Section 2212.0 Conditions of Approval

In granting any permit pursuant to this article, the Building Official may impose such conditions as may be reasonably necessary to prevent creation of nuisance or unreasonable hazard to persons or to public or private property. Such conditions may include but need not be limited to: (1) The granting (or securing from others) and recordation in County Land Records, easements for drainage facilities, including the acceptance of their discharge on the property of others and for the maintenance of slopes or antierosion facilities.

(2) Adequate control of dust by watering or other control methods acceptable to the Building Official and in conformance with applicable air pollution ordinances.

(3) Improvement of any existing grading, ground surface or drainage conditions on the site to meet the standards required under this article for new grading, drainage and erosion control.

Section 2214.0 Responsibility of Permittee

Notwithstanding, other conditions or provisions of the permit, or the minimum standards set forth in this article, the Permittee is responsible for the prevention of damage to the adjacent property. No person shall grade on land in any manner, or so close to the property line as to endanger or damage any adjoining public street, sidewalk, alley or any other public or private property without supporting and protecting such property from settling, cracking, erosion, sediment or other damage or personal injury which might result.

VOL 12

6344

Section 2220.2 Inspection

After commencing initial grading operation, the Permittee shall request inspections at the following stages in the development of the site, or of each subdivision thereof:

(1) Upon completion of stripping, the stockpiling of topsoil and disposal of all unsuitable material; but prior to beginning any other preparation of the ground.

(2) Upon completion of preparation of ground to receive fill, but prior to beginning any placement.

(3) Upon completion of rough grading, but prior to placing top soil, permanent drainage or other site development improvements and ground covers.

(4) Upon completion of final grading; permanent drainage and erosion control facilities, including established ground covers and planting; and all other work of the permit.

Section 2225.0 Maintenance

In implementation of the Sediment Control Program for Prince George's County, as adopted by the Board of County Commissioners on June 20, 1967, all grading plans and specifications accompanying grading and/or combined grading and building permits shall include provisions for both interim (temporary) and ultimate (permanent) erosion and sediment control.

2228.1 - The design, installation and maintenance of erosion and sediment control measures shall be accomplished in accordance with guide standards adopted by Prince George's County Soil Conservation District on file with the Prince George's County Department of Inspections and Permits.

2228.2 - All graded surfaces, with particular emphasis on the face of all cut and fill slopes, shall be seeded, sodded and/or planted or otherwise protected from erosion as soon as practicable; and shall be watered, tended and maintained until growth is well established at time of completion and final inspection.

Section 2229.0 Preparation of Ground

2229.3 - Natural and/or existing slopes exceeding five (5) horizontal to one (1) vertical shall be benched or continuously stepped into competent materials prior to placing all classes of fill.

2229.4 - Fills toeing out on natural slopes steeper than four (4) horizontal to one (1) vertical shall not be made unless approved by the Building Official after receipt of a report by a Soil Engineer certifying that he has investigated the property, made soil tests and that in his opinion such steeper slopes will safely support the proposed fill.

2229.5 - All trees in areas of grade change shall be removed unless protected with suitable tree wells.

Section 2237.0 Drainage

The following provisions apply to a conveyance and disposal of stormwater runoff.

2237.1 - All drainage facilities shall be designed to convey surface water in such a manner to prevent detrimental erosion, overflow or ponding to the nearest practical street, storm drain or other watercourse in accordance with such applicable design criteria, standards and procedures as contained herein or otherwise required by the Prince George's County Public Works Department and by the Washington Suburban Sanitary Commission.

2237.2 - The ponding of water shall not be permitted above cut or fill slopes or on drainage terraces, nor shall water be impounded on adjacent property. Adequate drainage facilities shall be provided to prevent such ponding.

2237.3 - Erosion Control - The Permittee and the Owner shall make adequate provisions to prevent any surface waters from materially damaging the face of any excavation or fill. All slopes shall be temporarily and/or permanently protected from surface water runoff from above by interceptor and diversion berms, swales, brow or berm ditches and shall be sodded, seeded and/or planted; unless upon the recommendation of the Prince George's Soil Conservation District, the Building Official determines such treatment is unnecessary and specifically waives this requirement.

2237.5 Facilities and Improvements - All drainage terraces, interceptor and diversion berms, swales and brow or berm ditches shall be designed and constructed and, when required, shall be piped or paved or otherwise improved to the satisfaction of the Building Official. Drainage discharging into natural watercourses may require that such natural ground be protected from erosion by an adequate amount of riprap or other measures.

2237.6 Drainage Terraces - Cut and fill slopes in excess of thirty (30) feet but not more than sixty (60) feet in vertical heights shall be terraced at approximate mid-height. Terraces in slopes with a vertical height greater than sixty (60) feet shall be made at equal vertical intervals not more than thirty (30) feet apart. Drainage terraces shall be a minimum of five (5) feet wide with a minimum invert gradient of one percent (1%) if sodded or one half percent (1/2%) if paved; and must convey water to a safe disposal area.

EROSION AND SEDIMENT CONTROL PLAN REVIEW CHECKLIST

LEGEND FOR REVIEW CHECKLIST

AS = ALTERNATIVES SUGGESTED	A = ADEQUATE	INC = INCOMPLETE
R = REQUESTED, NOT SUBMITTED	NA = NOT APPLICABL	NC = NOT CHECKED

PROJECT NAME:______________________ SITE LOCATION:______________________

APPLICANT'S NAME & ADDRESS:______________________ ______________________

THE DISTRICT HAS REVIEWED THE SUBJECT PROPOSAL AND SUGGESTS THE FOLLOWING ITEMS BE REVISED TO PROVIDE THE PROPER SOIL EROSION, SEDIMENT, AND STORMWATER CONTROLS CONSISTENT WITH THE SUBJECT TOPOGRAPHY. TECHNICAL REVIEW SUPPLIED BY THE SOIL CONSERVATION SERVICE

PLANS - GENERAL

______1. Scope of plan clearly delineated and noted in title block

______2. Vicinity map with scale and north arrow.

______3. Legend, scales, north arrow for plan view.

______4. Existing and proposed topography shown, contours labeled and spot elevations at critical areas.

______5. Typical designs on plan review drawings shown for necessary diversion berms, interceptor drains and outlets, level spreaders, storm drain inlet protectors, grassed waterways, etc.

______6. Limit of 100 year floodplain delineated on plan.

______7. Existing and proposed improvements and utilities.

______8. The total disturbed area delineated on site plan:

______ a. Indicate the total acreage to be paved, roofed, sodded, seeded, etc.

______ b. Delineate all areas to be stabilized vegetatively by seeding, sodding, or ground covers.

______ c. Greenbelt areas are clearly delineated.

______9. Standard General Notes.

_____10. Scale.

_____11. Sequence of operations.

_____12. Stock pile area designated or referenced.

_____13. Property boundaries indicated, and easements as needed.

_____14. Street profiles.

_____15. Composite drainage area map for plans requiring more than one sheet, with sediment control measures shown in their approximate locations.

SOILS INFORMATION

_____16. Detailed soils Map attached or overlaid on plan map with interpretations.

_____17. Deep soil pit logs attached and exact location shown on plan map for all proposed dry and diffusion wells, and septic systems.

EROSION AND SEDIMENT CONTROL PLAN REVIEW CHECKLIST - Page 2

SOIL EROSION AND SEDIMENT CONTROL

_____18. Permanent Dikes (perimeter, diversion, interceptor)

- _____a. Practice meets purpose and design criteria.
- _____b. Positive drainage is maintained, and contributing drainage area shown
- _____c. Outlet to sediment trapping device or onto stable outlet
- _____d. Points of vehicular crossings shown and stabilized (mountable berm).
- _____e. Standard detail and construction specifications

_____19. Temporary Swales (interceptor, perimeter).

- _____a. Practice meets purpose and design criteria.
- _____b. Contributing drainage area shown.
- _____c. Channel grade exceeding ____% slope properly stabilized.
- _____d. Adequate outlet or discharge condition.
- _____e. Provisions for traffic crossing shown on plan.
- _____f. Standard detail and construction specifications

_____20. Traps (Rip-rap, earth, pipe, and storm inlet).

- _____a. Practice meets purpose and design criteria
- _____b. Contributing drainage area delineated on plan.
- _____c. Trap sized by largest drainage area (existing or developed) to trap.
- _____d. Type and size of outlet structure.
- _____e. Outlet conditions.
- _____f. Plan view of trap and storage area (drawn to scale with bottom dimensioned
- _____g. Volume calculations.
- _____h. Bottom, crest and clean-out (at 50% trap efficiency) elevations.
- _____i. Standard detail and construction specifications

_____21. Straw Bale Dike and Silt Fence

- _____a. Meets purpose and design criteria
- _____b. Controlled slope less than 100 feet
- _____c. Drainage area less than 1 acre per 100 feet of dike or fence. (for sheet erosion only)
- _____d. Standard detail and construction specifications

_____22. Grade Stabilization Structure (flume, pipe, slope drain, etc.)

- _____a. Meets purpose and design criteria
- _____b. Pipe drain size noted
- _____c. Contributing drainage area shown
- _____d. Standard detail and construction specifications

_____23. Permanent Structural Practices or Sediment Control Measures Exceeding the Design Criteria of the Standard detail.

- _____a. Practice meets purpose and design
- _____b. Drainage area map
- _____c. Runoff calculations
- _____d. Calculations for size, velocity, and Q
- _____e. Standard detail with dimensions and construction specifications

_____24. Provisions for protecting cut and fill slopes from surface runoff

VOL 12

6348

_____25. Site Grading

- _____a. Maximum created slope of 2 foot horiz. to 1 foot vert.
- _____b. Slopes requiring regular maintenance will be no steeper than 3 foot deep.
- _____c. Details of cut and fill slopes shown

_____26. Seeding Specification and Notes

- _____a. Seedbed Preparation
- _____b. Permanent seeding (mix and rate) - includes method of application.
- _____c. Temporary seeding (mix and rates) - includes method of application
- _____d. Mulching (includes anchoring method)
- _____e. Sod (type and installation)
- _____f. Fertilizer (amount and type)
- _____g. Lime (amount and type)
- _____h. Seeding dates (temporary and Permanent - to cover entire year).

_____27. Storm inlets adequately protected (detail required)

_____28. Stabilized construction entrances shown on plan (detail required)

_____29. Provisions for sediment and erosion control of areas disturbed for storm drain and utility construction.

_____30. Storm Drainage

- _____a. Drainage area map and computations
- _____b. Plan and profile indicating pipe size, type, slope, Q, structures, and inlet (type), top and invert elevations
- _____c. Proposed outlet protection dimensions and computations.
- _____d. Constructed outfall ditch or swale cross-section and flow computations for depth and velocity
- _____e. Profile of outfall sufficient to show natural gradient of accepting channel or conduit.
- _____f. Outlet protection of 0% slope for minimum required distance

_____31. Riprap and Gabions

- _____a. Median stone size and minimum depth of treated section shown on plan.
- _____b. Riprap placed upon approved filter cloth
- _____c. Cross-section detail of treated areas

_____32. Permit notification from other agencies

_____33. Storm Water Management referred to:________________ Date:

GLOSSARY

SECTION 12
GLOSSARY

The list of terms that follows is representative of those used by soil conservationists, soil scientists, engineers, developers, contractors, planners, etc. The terms are in common use in conservation matters.

ACCESS ROAD - A road or vehicular travel way constructed to provide needed access.

ACRE-FOOT - The volume of water that will cover 1 acre to a depth of 1 foot.

AESTHETIC VALUE - The increase in value of a property derived from such intangible factors as its inherent attractiveness, its access to attractive views, or its general appeal to the sense of beauty of the owner or purchaser.

A-HORIZON - The organic material and leached minerals in the uppermost layer of soil.

AMORTIZATION - To repay a debt in a sequence of equal payments. Part of each payment is used to pay the interest due at the time it is made, and the balance is applied to the reduction of the principal.

ANGLE OF REPOSE - Angle between the horizontal and the maximum slope that a soil assumes through natural processes.

ANTECEDENT MOISTURE CONDITION (AMC) - The degree of wetness of a watershed at the beginning of a storm.

APRON - A floor or lining to protect a surface from erosion; for example, the pavement below chutes, spillways, or at the toes of dams.

ASSESSED VALUE - The value placed on property for taxation purposes.

ASSOCIATED COSTS - A term commonly used in water resource development projects. These costs include the value of goods and services needed over and above project costs to make the immediate products or services of a project available for use or sale.

BASE FLOW - The stream discharge from groundwater runoff.

BEDDING - The process of laying a drain or other conduit in its trench and tamping earth around the conduit to form its bed. The manner of bedding may be specified to conform to the earth load and conduit strength.

BEDLOAD - The sediment that moves by sliding, rolling, or bounding on or very near the streambed; sediment moved mainly by tractive or gravitational forces or both, but at velocities less than the surrounding flow.

B-HORIZON - The intermediate layer of clays and oxides in a soil below the A-horizon; also called the zone of accumulation.

BENCH MARK (economics) - Data for a specific time period that is used as a base for comparative purposes with comparable data.

(engineering) - A point of reference in elevation surveys.

BERM - A shelf that breaks the continuity of a slope.

BLIND - Placement of loose soil around a tile or conduit to prevent damage or misalignment when the trench is backfilled. Allows water to flow more freely to the tile.

BLIND DRAIN - A type of drain consisting of an excavated trench refilled with pervious materials, such as coarse sand, gravel or crushed stone, where water percolates through the voids and flows toward an outlet. Often referred to as a French drain because of its initial development and widespread use in France.

BLIND INLET - Inlet to a drain in which entrance of water is by percolation rather than open flow channels.

BRUSH LAYERING - The embedment of green branches of shrub or tree species, perpendicular to the slope, on successive horizontal rows or contours.

BRUSH-MATTING - A mulch of hardwood brush fastened down with stakes and wire.

cfs. - Abbreviation for cubic feet per second. A unit of water flow.

CAPITAL RECOVERY PERIOD - The period of time required for the net returns from an outlay of capital to equal the investment.

CAPITALIZED COST - The first cost of an asset plus the present value of all renewals expected within the planning horizon.

CHANNEL - A natural stream that conveys water; a ditch or channel excavated for the flow of water.

CHANNEL IMPROVEMENT - The improvement of the flow characteristics of a channel by clearing, excavation, realignment, lining, or other means in order to increase its capacity. Sometimes used to connote channel stabilization.

VOL 12

6351

CHANNEL STABILIZATION - Erosion prevention and stabilization of velocity distribution in a channel using jetties, drops, revetments, vegetation, and other measures.

COMPACTION - To unite firmly; the act or process of becoming compact, usually applied in geology to the changing of loose sediments into hard, firm rock. With respect to construction work with soils, engineering compaction is any process by which the soil grains are rearranged to decrease void space and bring them into closer contact with one another, thereby increasing the weight of solid material per cubic foot.

CONDUIT - Any channel intended for the conveyance of water, whether open or closed.

CONIFER - A tree belonging to the order Coniferae, usually evergreen, with cones and needle-shaped or scale-like leaves and producing wood known commercially as "soft wood."

CONSERVATION - The protection, improvement, and use of natural resources according to principles that will assure their highest economic or social benefits.

CONSERVATION DISTRICT - A public organization created under state enabling law as a special purpose district to develop and carry out a program of soil, water, and related resource conservation, use, and development within its boundaries, usually a subdivision of state government with a local governing body and always with limited authorities. Often called a soil conservation district or a soil and water conservation district.

CONTOUR - 1. An imaginary line on the surface of the earth connecting points of the same elevation.

2. A line drawn on a map connecting points of the same elevation.

CONTOUR INTERVAL - The vertical distance between contour lines.

CONTOUR MAP - A map that shows the shape of the surface features of the ground by the use of contours.

CONTOUR WATTLING - The packing of lengths of bundles of twigs or whips into a continuous length partially buried across a slope at regular contour intervals and supported on the downhill slide by stakes.

CREST - 1. The top of a dam, dike, spillway, or weir, frequently restricted to the overflow portion.

2. The summit of a wave or peak of a flood.

CRITICAL SITE - A sediment producing, highly erodible, or severely eroded area or site.

CRITICAL VELOCITY - Velocity at which a given discharge changes from tranquil to rapid flow; that velocity in open channels for which the specific energy (sum of the depth and velocity head) is a minimum for a given discharge.

CROSS-SECTION - A drawing that shows the features that would be exposed by a vertical cut through a man-made or natural structure.

CROWN (forestry) - The upper part of a tree, including the branches and foliage.

CUBIC FOOT PER SECOND - Rate of fluid flow at which 1 cubic foot of fluid passes a measuring point in 1 second. (Abbr. cfs.) (Syn. Second-foot; CUSEC.) See cfs.

CUT - Portion of land surface or area from which earth has been removed or will be removed by excavation; the depth below original ground surface to excavated surface.

CUT-AND-FILL - Process of earth moving by excavating part of an area and using the excavated material for adjacent embankment or fill areas.

CUTOFF - 1. Wall, collar, or other structure, such as a trench, filled with relatively impervious material intended to reduce seepage of water through porous strata.

2. In river hydraulics, the new and shorter channel formed either naturally or artificially when a stream cuts through the neck of a band.

DEBRIS DAM - A barrier built across a stream channel to retain rock, sand, gravel, silt, or other material.

DEBRIS GUARD - Screen or grate at the intake of a channel, drainage, or pump structure for the purpose of stopping debris.

DECIDUOUS PLANT - A plant that sheds all its leaves every year at a certain season.

DEGRADATION - To wear down by erosion, especially through stream action.

DEPOSIT - Material left in a new position by a natural transporting agent, such as water, wind, ice, or gravity, or by the activity of man.

DESIGN STANDARDS - Standards of construction governing the size, shape, and relationship of spaces in any structure which will control soil erosion and sedimentation.

DESIGN STORM - A given rainfall amount, areal distribution, and time distribution, used to estimate runoff. The rainfall amount is for a given frequency (25-year, 50-year, etc.).

DESILTING AREA - An area of grass, shrubs, or other vegetation used for inducing deposition of silt and other debris from flowing water, located above a stock tank, pond, field, or other area needing protection from sediment accumulation. See Filter Strip.

DETENTION DAM - A dam constructed for the purpose of temporary storage of streamflow or surface runoff and for releasing the stored water at controlled rates.

DIKE - An embankment to confine or control water, especially one built along the banks of a river to prevent overflow of lowlands; a levee.

DISCHARGE - Rate of flow, specifically fluid flow; a volume of fluid passing a point per unit time, commonly expressed as cubic feet per second, million gallons per day, gallons per minutes, or cubic meters per second.

DISCHARGE FORMULA (hydraulics) - A formula to calculate rate of flow of fluid in a conduit or through an opening. For steady flow discharge, $Q = AV$, wherein Q is rate of flow, A is cross sectional area, and V is mean velocity. Common units are cubic feet per second, square feet, and feet per second, respectively. To calculate the mean velocity, V, for uniform flow in pipes or open channels, see Manning's formula.

DIVERSION - Channel constructed across the slope for the purpose of intercepting surface runoff; changing the accustomed course of all or part of a stream. See Terrace.

DIVERSION TERRACE - Diversions, which differ from terraces in that they consist of individually designed channels across a hillside, may be used to protect bottomland from hillside runoff or may be needed above a terrace system for protection against runoff from an un-terraced area. They may also divert water out of active gullies, protect farm buildings from runoff, reduce the number of waterways, and are sometimes used in connection with strip cropping to shorten the length of slope so that the strips can effectively control erosion. See Terrace.

DRAINAGE - The removal of excess surface water or groundwater from land by means of surface or subsurface drains.

DRAINAGE AREA - The area draining into a stream at a given point. The area may be of different sizes for surface runoff, subsurface flow and base flow, but generally the surface runoff area is used as the drainage area. See watershed.

DRAINAGE DISTRICT - A cooperative, self-governing public corporation created under state law to finance, construct, operate, and maintain a drainage system involving a group of land holding.

DROP-INLET SPILLWAY - Overfall structure in which the water drops through a vertical riser connected to a discharge conduit.

DROP SPILLWAY - Overfall structure in which the water drops over a vertical wall onto an apron at a lower elevation.

DROP STRUCTURE - A structure for dropping water to a lower level and dissipating its surplus energy; a fall. A drop may be vertical or inclined.

EFFLUENT - 1. The discharge or outflow of water from ground or subsurface storage.

2. The fluids discharged from domestic, industrial, and municipal waste collection systems or treatment facilities.

EROSION - 1. The wearing away of the land surface by running water, wind, ice, or other geological agents, including such processes as gravitational creep.

2. Detachment and movement of soil or rock fragments by water, wind, ice, or gravity. The following terms are used to describe different types of water erosion:

a. **GULLY EROSION** - The erosion process whereby water accumulates in narrow channels and, over short periods, removes the soil from this narrow area to considerable depths, ranging from 1 to 2 feet to as much as 75 to 100 feet.

b. **RILL EROSION** - An erosion process in which numerous small channels only several inches deep are formed; occurs mainly on recently cultivated soils. See Rill.

c. **SHEET EROSION** - The removal of a fairly uniform layer of soil from the land surface by runoff water.

EUTROPHICATION - A means of aging of lakes whereby aquatic plants are abundant and waters are deficient in oxygen. The process is usually accelerated by enrichment of waters with surface runoff containing nitrogen and phosphorus.

EVAPOTRANSPIRATION (ET) - Plant transpiration plus evaporation from the soil. Difficult to determine separately, therefore used as a unit for study.

FALLOW - Cropland kept free of vegetation during the growing season. May be a normal part of the cropping system for weed control, water conservation, soil conditioning, etc.

FILTER STRIP - Strip of permanent vegetation above ponds, diversion terraces,and other structures to retard flow of runoff water, causing deposition of transported material, thereby reducing sediment flow. See Desilting Area.

FINISHED GRADE - The final grade or elevation of the ground surface conforming to the approved grading plan.

VOL 12

6353

FLOOD FRINGE - That portion of the floodplain subject only to shallow inundation and low velocity flow of floodwater.

FLOODPLAIN - A level surface of stratified alluvium on either side of a stream which is built up by silt and sand carried out of the main channel and submerged during times of flood.

FLOODPLAIN MANAGEMENT - The wise use of floodplains so as to reduce human suffering and property damage resulting from floods and to lessen the need for expensive flood control structures, such as dams and reservoirs.

FLOODWAY - That portion of the floodplain required to store and discharge floodwaters without causing significant damaging or potentially damaging increases in flood heights and velocities.

FREEBOARD (hydraulics) - Vertical distance between the maximum water surface elevation anticipated in design and the top of restraining banks or structures provided to prevent overtopping because of unforeseen conditions.

FREQUENCY - An expression or measure of how often a hydrologic event of given size or magnitude should, on the average, be equaled or exceeded. For example, a 50-year frequency flood should be equaled or exceeded in size, on the average, only once in 50 years. In drought or deficiency studies it usually defines how many years will, on the average, be equal to or less than a given size or magnitude.

FUNCTIONAL PLAN - A plan for one element or closely related elements of a comprehensive plan, for example, transportation, recreation, and open spaces. Such plans, of necessity, should be closely related to the land use plan. Plans that fall short of considering all elements of a comprehensive plan may be considered as functional plans. Thus, resource conservation and development plans and watershed project plans should be considered as functional plans.

GABION - A galvanized wire basket filled with stone used for structural purposes. When fastened together used as retaining walls, revetments, slope protection and similar structures.

GRADE STABILIZATION STRUCTURE - A structure for the purpose of stabilizing the grade of a gully or other watercourse, thereby preventing further head-cutting or lowering of the channel grade.

GRASSED WATERWAY - A natural or constructed waterway, usually broad and shallow, covered with erosion resistant grasses, used to conduct surface water from cropland.

GRAVEL ENVELOPE - Selected aggregate placed around the screened pipe section of well casing or a subsurface drain to facilitate the entry of water into the well or drain.

GRAVEL FILTER - Graded sand and gravel aggregate placed around a drain or well screen to prevent the movement of fine materials from the aquifer into the drain or well.

GULLY - A channel or miniature valley cut by concentrated runoff but through which water commonly flows only during and immediately after heavy rains or during the melting of snow. A gully may be dendritic or branching or it may be linear, rather long, narrow, and of uniform width. The distinction between gully and rill is one of depth. A gully is sufficiently deep that it would not be obliterated by normal tillage operations, whereas a rill is of lesser depth and would be smoothed by ordinary farm tillage.

HARDPAN - A hardened soil layer in the lower A or in the B horizon caused by cementation of soil particles with organic matter or with materials such as silica, sesquioxides, or calcium carbonate. The hardness does not change appreciably with changes in moisture content, and pieces of the hard layer do not slake in water.

HIGHWAY EROSION CONTROL - The prevention and control of erosion in ditches, at cross drains, and on fills and road banks within a highway right-of-way. Includes vegetative practices and structural practices.

HOOD INLET - Entrance to a closed conduit that has been shaped to induce full flow at minimum water surface elevation.

HORIZONS, MINERAL SOIL -

A horizons are surface layers.

B horizons are subsoil horizons [1]; They are designated as follows:

B alone indicates some residual transformation or change in place, such as color.

Bt indicates accumulations of translocated clay. Bx indicates a B horizon with fragipan characteristics such as firmness, brittleness and high density.

C horizons are substrata layer [1]; they consist of mineral material like or unlike the material from which the A & B horizons have formed and have been little affected by soil forming process. They are designated as follows:

C alone indicates material like the material from which the A & B horizons have formed.

Cx indicates a C horizon of material like that of the A & B horizons but has the firm, brittle and dense characteristics of a fragipan.

[1] Roman numerals are prefixed to the appropriate horizon designations such as IIB, IIbt, IIBx, and IIC or IICS when it is necessary to number a series of layers of unlike or contrasting material from the sur-

face downward. Claverack is an example in which the A & B horizons have formed in sand and the underlying material is contrasting silty clay that is indicated as a IIC horizon.

HYDRAULIC GRADE LINE - In a closed conduit, a line joining the elevations to which water could stand in risers or vertical pipes connected to the conduit at their lower end and open at their upper end. In open channel flow, the hydraulic grade line is the free water surface.

HYDROGRAPH - A graph showing variation in stage (depth) or discharge of a stream of water over a period of time.

HYDROLOGIC SOIL COVER COMPLEX - A combination of a hydrologic soil group and a type of cover.

HYDROLOGIC SOIL GROUP - A group of soils having the same runoff potential under similar storm and cover conditions.

HYDROLOGY - The science that deals with the occurrence and behavior of water in the atmosphere, on the ground and under the ground. Rainfall intensities, rainfall interception by trees, effects of crop rotation on runoff, floods, droughts and the flow of springs and wells, are some of the topics studied by a hydrologist.

HYDROSEEDING - The dissemination of seed hydraulically in a water medium; mulch, lime, and fertilizer can be incorporated into the sprayed mixture.

IMPERVIOUS SOIL - A soil through which water, air, or roots cannot penetrate. No soil is impervious to water and air all the time.

IMPOUNDMENT - Generally, an artificial collection or storage of water, as a reservoir, pit, dugout, sump, etc. See Reservoir.

INDUSTRIAL PARK - A tract of land, the control and administration of which are vested in a single body, suitable for industrial use because of location, topography, proper zoning, availability of utilities, and accessibility to transportation.

INFILTRATION - Rainfall minus interception, evaporation, and surface runoff. The part of rainfall that enters the soil.

INFILTRATION RATE - A soil characteristic determining or describing the maximum rate at which water can enter the soil under specified conditions, including the presence of an excess of water. See Infiltration Velocity.

INITIAL ABSTRACTION (I_a) - When considering surface runoff, I_a is all the rainfall before runoff begins. When considering direct runoff, I_a consists of interception, evaporation and the soil-water storage that must be exhausted before direct runoff may begin.

INOCULATION (OF SEEDS) - The addition of nitrogen fixing bacteria (inoculant) to legume seeds or to the soil in which the seeds are to be planted; the bacteria take free nitrogen from the air and make it available to the seeds.

INTERCEPTION - Precipitation retained on plant or plant residue surfaces and finally absorbed, evaporated, or sublimated. That which flows down the plant to the ground is called "steamflow" and not counted as true interception.

INTERMITTENT STREAM - A stream or portion of a stream that flows only in direct response to precipitation. It receives little or no water from springs and no long term continued supply from melting snow or other sources. It is dry for a large part of the year, ordinarily more than 3 months.

ISO-ERODENT VALUE - A term used to correlate areas of equally erosive average annual rainfall.

LANDSCAPE - All the natural features, such as fields, hills, forests, water, etc., that distinguish one part of the earth's surface from another part, usually that portion of land or territory which the eye can comprehend in a single view, including all of its natural characteristics.

LIME, AGRICULTURAL - A soil amendment consisting principally of calcium carbonate but including magnesium carbonate and perhaps other materials, used to furnish calcium and magnesium as essential elements for the growth of plants and to neutralize soil acidity.

LINING - A protective covering over all or part of the perimeter of a reservoir or a conduit to prevent seepage losses, withstand pressure, resist erosion, and reduce friction or otherwise improve conditions of flow.

LIVE STAKING - Securing vegetative cover for control of erosion and shallow sliding by means of willow or poplar cuttings that root easily and grow rapidly under certain conditions.

MANNING'S FORMULA (hydraulics) - A formula used to predict the velocity of water flow in an open channel or pipeline:

$$V = ((1.486)(r^{2/3})(s^{1/2}))/n$$

where:

V = the mean velocity of flow in feet per second; r = the hydraulic radius;

s = the slope of the energy gradient or for assumed uniform flow the slope of the channel in feet per foot; and

n = the roughness coefficient or retardance factor of the channel lining.

MUCK SOIL - 1. An organic soil in which the organic matter is well decomposed (USA usage).

2. A soil containing 20 to 50 percent organic matter.

MULCH - A natural or artificial layer of plant residue or other materials, such as sand or paper, on the soil surface.

NETTING - Plastic, paper, or cotton material used to hold mulch on the soil surface.

OUTLET - Point of water disposal from a stream, river, lake, tidewater, or artificial drain.

PARTICLE SIZE CLASSES FOR FAMILY GROUPINGS (as used in the Soil Classification System of the National Cooperative Soil Survey in the United States) - Various particle size classes are applied to arbitrary control sections that vary according to the depth of the soil, presence or absence of argillic horizons, depth to paralithic or lithic contacts, fragipans, horizons. No single set of particle size classes is appropriate as a family grouping for all kinds of soil. The classification tabulated below provides a choice of several particle size classes.

1. Sandy-Skeletal - More than 35 percent, by volume, coarser than 2 millimeters, with enough fines to fill interstices larger than 1 millimeter; fraction less than 2 millimeters is as defined for the sandy class.

2. Loamy-Skeletal - More than 35 percent, by volume, coarser than 2 millimeters, with enough fines to fill interstices larger than 1 millimeter; fraction less than 2 millimeters is as defined for loamy classes.

3. Sandy - Sands, except very fine sand, and loamy sands, except loamy very fine sand.

4a. Coarse-Loamy - With less than 18 percent clay and more than 15 percent coarser than very fine sand (including coarse fragments up to 7.5 centimeters).

b. Fine-Loamy - With more than 18 percent clay but less than 35 percent clay and more than 15 percent coarser than very fine sand (including coarse fragments up to 7.5 centimeters).

c. Coarse-Silty - With less than 18 percent clay and less than 15 percent coarser than very fine sand (including coarse fragments up to 7.5 centimeters).

d. Fine-Silty - With more than 18 percent clay and less than 35 percent clay and less than 15 percent coarser than very fine sand (including coarse fragments up to 7.5 centimeters).

5a. Fine - With more than 35 percent clay but less than 60 percent clay.

b. Very-Fine - With more than 60 percent clay.

PEAK FLOW - The maximum instantaneous flow of water from a given storm condition at a specific location.

PEAT - Dark brown residual material produced by the partial decomposition and disintegration of plants that grow in wet places.

PERMEABILITY - The quality of a soil horizon that enables water or air to move through it. Terms used to describe permeability are as follows: very slow, slow, moderately slow, moderate, moderately rapid, rapid, and very rapid.

pH - A numerical measure of the acidity or alkalinity of a soil; neutral soil has a pH of 7; all pH values below 7 are acid, and all above 7 are alkaline.

PLANNED UNIT DEVELOPMENT - A zoning classification permitting flexibility of site design by combining building types and uses in ways that would be prohibited by traditional zoning standards.

PLAT OF SURVEY - A scaled drawing identifying a parcel of real estate, prepared by a registered surveyor, including a legal description of the property and the dimensions of the physical improvements.

RAINFALL INTENSITY - The rate at which rain is falling at any given instant, usually expressed in inches per hour.

RETARDANCE (vegetation) - The characteristic of the vegetative lining of a channel that tends to restrict and impede flow relative to a perfectly smooth channel.

RETENTION - The amount of precipitation on a drainage area that does not escape as runoff. It is the difference between total precipitation and total runoff.

RETURN FLOW - That portion of the water diverted from a stream which finds its way back to the stream channel either as surface or underground flow.

REVETMENT - Facing of stone or other material, either permanent or temporary, placed along the edge of a stream to stabilize the bank and to protect it from the erosive action of the stream.

RIPARIAN RIGHTS - The rights of an owner whose land abuts water. They differ from state to state and often depend on whether the water is a river, lake, or ocean. See Water Rights.

RIPRAP - Broken rock, cobbles, or boulders placed on earth surfaces, such as the face of a dam or the bank of a stream, for protection against the action of water (waves); also applied to brush or pole mattresses, or brush and stone, or other similar materials used for soil erosion control.

RUNOFF - That portion of the precipitation on a drainage area that is discharged from the area in stream channels. Types include surface runoff, groundwater runoff, or seepage.

RUNOFF CURVE NUMBER (CN) - A parameter combining the effects of soils, watershed characteristics and land use. This parameter represents the hydrologic soil cover complex of the watershed.

SCALPING - Removal of sod or other vegetation in spots or strips.

SCARIFY - To abrade, scratch, or modify the surface; for example, to scratch the impervious seed coat of hard seed or to break the surface of the soil with a narrow-bladed implement.

SEDIMENT - Solid material, both mineral and organic, that is in suspension, is being transported, or has been moved from its site of origin by air, water, gravity, or ice and has come to rest on the earth's surface either above or below sea level.

SEDIMENT BASIN - A basin or pond designed to store a calculated amount of sediment being transported on the site.

SEDIMENT DISCHARGE - The quantity of sediment, measured in dry weight or by volume, transported through a stream cross-section in a given time. Sediment discharge consists of both suspended load and bedload.

SEEDBED - The soil prepared by natural or artificial means to promote the germination of seed and the growth of seedlings.

SEEPAGE - 1. Water escaping through or emerging from the ground along an extensive line or surface as contrasted with a spring where the water emerges from a localized spot.

2. The process by which water percolates through the soil.

3. (percolation) The slow movement of gravitational water through the soil.

SETTLING BASIN - An enlargement in the channel of a stream to permit the settling of debris carried in suspension.

SHRINK-SWELL POTENTIAL - The susceptibility of soil to volume change due to loss or gain in moisture content.

SHRUB - A woody perennial plant differing from a perennial herb by its more woody stems and from a tree by its low stature and habit of branching from the base. There is no definite line between herbs and shrubs or between shrubs and trees; all possible intergradations occur.

SIDE SLOPES (engineering) - The slope of the sides of a canal, dam, or embankment. It is customary to name the horizontal distance first, as 0.5 to 1, or frequently, 1-1/2:1, meaning a horizontal distance of 1.5 feet to 1 foot vertical.

SITE ANALYSIS - Evaluation of the qualities and drawbacks of a site by comparison with those aspects of other comparable sites.

SOIL EROSION AND SEDIMENTATION CONTROL PLAN - A plan which fully indicates the necessary land protection and structural measures, including a schedule of the timing of their installation, which will effectively minimize soil erosion and sediment yields.

SOIL STRUCTURE - The arrangement of primary soil particles into compound particles or clusters that are separated from adjoining aggregates and have properties unlike those of an equal mass of unaggregated soil particles. The principal forms of soil structure are: platy (laminated), prismatic (vertical axis of aggregates longer than horizontal), columnar (prisms with rounded tops), blocky (angular or subangular), and granular. Structureless soils are: (1) single grain (each grain by itself, as in dune sand), or (2) massive (the particles adhering together without any regular cleavage, as in many claypans and hardpans).

SOIL SURVEY - Survey showing soil type and composition.

SOIL TEXTURE - The relative proportions of the various soil separates in a soil as described by the classes of soil texture shown in Figure 1. The textural classes may be modified by the addition of suitable adjectives when coarse fragments are present in substantial amounts; for example, gravelly silt loam. (For other modifications, see coarse fragments.) Sand, loamy sand, and sandy loam are further subdivided on the basis of the proportions of the various sand separates present.

SPILLWAY - An open or closed channel, or both, used to convey excess water from a reservoir. It may contain gates, either manually or automatically controlled, to regulate the discharge of excess water.

SPOIL - Soil or rock material excavated from a canal, basin, or similar construction.

STAGE (hydraulics) - The variable water surface or the water surface elevation above any chosen datum. See Gage Height; Gaging Station.

STATE SOIL AND WATER CONSERVATION COMMITTEE, COMMISSION, OR BOARD - The state agency established by state soil conservation district enabling legislation to assist with the administration of the provisions of the state soil conservation districts law. The official title may vary from the above as new or amended state laws are made.

STILLING BASIN - An open structure or excavation at the foot of an overfall, chute, drop, or spillway to reduce the energy of the descending stream.

STREAMBANKS - The usual boundaries, not the flood boundaries, of a stream channel. Right and left banks are named facing downstream.

STRATA CAPACITY - The maximum amount of material a stream is able to transport.

STREAM LOAD - Quantity of solid and dissolved material carried by a stream. See Sediment Load.

STORMWATER MANAGEMENT - Runoff water safely conveyed or temporarily stored and released at an allowable rate to minimize erosion and flooding.

STRIPPING - Denuding vacant or untouched land of its present vegetative cover and topsoil.

SUBGRADE - The soil prepared and compacted to support a structure or a pavement system.

SUBSOIL - The B horizons of soils with distinct profiles. In soils with weak profile development, the subsoil can be defined as the soil below the plowed soil (or its equivalent of surface soil), in which roots normally grow. Although a common term, it cannot be defined accurately.

SUMP - Pit, tank, or reservoir in which water is collected for withdrawal or stored.

SUSPENDED LOAD - The fine sediment kept in suspension in a stream because the settling velocity is lower than the upward velocity of the current.

SWALE - A linear, but flattish depression in the ground surface which conveys drainage water but offers no impediment to traffic, as do ditches or gutters.

TERRACE - An embankment or combination of an embankment and channel constructed across a slope to control erosion by diverting or storing surface runoff instead of permitting it to flow uninterrupted down the slope. Terraces or terrace systems may be classified by their alignment, gradient, outlet, and cross-section. Alignment is parallel or non-parallel. Gradient may be level, uniformly graded, or variably graded. Grade is often incorporated to permit paralleling the terraces. Outlets may be soil infiltration only, vegetated waterways, tile outlets, or combinations of these. Cross-sections may be narrow base, broad base, bench, steep backslope, flat channel, or channel.

TIME OF CONCENTRATION - Time required for water to flow from the most remote point of a watershed, in a hydraulic sense, to the outlet.

TIMING SCHEDULE - A construction progress schedule showing the proposed dates of commencement and completion of each of the various subdivisions of work as shown and called for in the approved plans and specifications.

TOPOGRAPHIC MAP - A schematic drawing of prominent landforms indicated by conventional symbols such as hachures or contour lines.

TOPSOIL - The uppermost layers of soil containing organic material and suited for plant survival and growth.

TRAP EFFICIENCY - The capability of a reservoir to trap sediment.

TRAVEL TIME - The time for water to travel from one location to another in a watershed. A travel time is part of a component of time of concentration (T_c).

TRIBUTARY - Secondary or branch of a stream, drain, or other channel that contributes flow to the primary or main channel.

UNIFIED SOIL CLASSIFICATION SYSTEM (engineering) - A classification system based on the identification of soils according to their particle size, gradation, plasticity index, and liquid limit.

UNIT HYDROGRAPH - A discharge hydrograph coming from one inch of direct runoff distributed uniformly over the watershed, with the direct runoff generated at a uniform rate during the given storm duration. A watershed may have 1-hour, 2-hour, etc. unit hydrographs.

WATER QUALITY STANDARDS - Minimum requirements of purity of water for various uses; for example, water for agricultural use in irrigation systems should not exceed specific levels of sodium bicarbonates, pH, total dissolved salts, etc.

WATER RIGHTS - The legal rights to the use of water. They consist of riparian rights and those acquired by appropriation and prescription. Riparian rights are those rights to use and control water by virtue of ownership of the bank or banks. Appropriated rights are those acquired by an individual to the exclusive use of water, based strictly on priority of appropriation and application of the water to beneficial use and without limitation of the place of use to riparian land. Prescribed rights are those to which legal title is acquired by long possession and use without protest of other parties.

WATERSHED - The area contributing direct runoff to a stream. Usually it is assumed that base flow in the stream also comes from the same area. However, the ground water watershed may be larger or smaller.

WATER TABLE - The upper surface of groundwater or that level below which the soil is saturated with water; locus of points in soil water at which the hydraulic pressure is equal to atmospheric pressure.

WATERWAY - A natural course or constructed channel for the flow of water.

WATTLE - A group or bundle of twigs, whips or withes.

WEEP-HOLES (engineering) - Openings left in retaining walls, aprons, linings, or foundations to permit drainage and reduce pressure.

ZONING (rural) - A means by which governmental authority is used to promote the proper use of land under certain circumstances. This power traditionally resides in the state, and the power to regulate land uses by zoning is usually delegated to minor units of government, such as towns, municipalities, and counties, through an enabling act that specifies powers granted and the conditions under which these are to be exercised.

ZONING ORDINANCE - The exercise of police power for the purpose of carrying out the land use plan of an area. It may also include regulations to effect control of the size and height of buildings, population density, and use of buildings; for example, residential, commercial, industrial, etc.

INTRODUCTION

Erosion is the wearing away of the land surface through the forces of wind and water. Sedimentation is the transport and delivery of eroded soil particles. Erosion represents a major conservation problem in New York. The combined efforts of the Soil Conservation Service and New York's 57 Soil and Water Conservation Districts over the past half century have produced great accomplishments toward the reduction of erosion and sedimentation. These efforts must continue and even intensify if we are to continue to protect and conserve our valuable soil resource. Increased public awareness has resulted in thousands of New York landowners establishing conservation plans and applying practices to protect their land from erosion and enhance water quality by reducing the amount of nutrients, pesticides and sediment moving from eroding areas.

This publication is focused specifically on one type of erosion, namely critical erosion. A critical erosion area is one which is eroding at an accelerated rate and producing large quantities of sediment. The critical erosion area frequently creates a hazard to life and limb, or threatens private property or a public utility. Examples of critical erosion areas include rapidly eroding cropland, construction sites, streambanks, roadbanks, logging roads, skid trails, ditch and channel banks, surface mined land, sandblows and dunes, denuded and gullied areas, and landfills.

The most cost-effective way to control erosion is to establish appropriate vegetative cover. The type of cover depends upon the needs and characteristics of each individual site. This guide provides specific data for treating critical erosion areas. Topics covered include planning considerations, the techniques of seeding and planting, a description of various plant materials, recommendations for selected areas, special site considerations, tabular data for grasses and legumes, trees and shrubs, mulches, fish and wildlife benefits from stabilizing vegetation and additional suggested reference material.

Chapter 1: PLANNING CONSIDERATIONS

Factors to Consider

Each critical erosion area is a unique site requiring the consideration of many factors toward resolving the erosion problem. The various factors to be considered in planning a solution for each area include soil types and condition, water management, land use, geology, existing vegetation, present and proposed use of the site, climate, shade tolerance, and the overall environment of the area.

Soils

Soil is the medium in which seeds germinate and roots grow. The condition of the soil may well determine the success or failure of seedings or plantings. Often, removal of topsoil leaves a subsoil layer remaining as the material to be seeded or planted. This material is typically infertile, poor in structure and aggregation, low in organic matter, and may be very acid. In many cases, the subsoil is highly susceptible to erosion due to slow water intake and rapid runoff. Applications of organic matter, manure, lime, and appropriate commercial fertilizers are usually necessary to assist in overcoming these limiting conditions.

Where topsoil has been removed, four inches or more of loamy topsoil applied to the site before seeding enhances establishment of ground cover and minimizes maintenance.

For detailed information about soil characteristics, a recent soil map prepared as part of the National Cooperative Soil Survey will be helpful. Soil properties relating to plant growth and engineering are outlined in the soil survey reports. Copies of maps and reports are available from Soil and Water Conservation District offices, the Soil Conservation Service, and Cornell Cooperative Extension.

Water Management

In many instances a critical erosion area exists due to the action of water, either from surface runoff as a result of rainfall or snow melt, or surface flow in the form

VOL 12

6375

of seeps, or poor drainage, which keeps the soil saturated for a long duration. Proper water management is necessary in all three instances.

Where surface runoff is a problem, water can be directed away from the area by means of a shallow ditch known as a diversion. The diversion is constructed at a point on site where it will intercept runoff water and carry it to a safe outlet that will not adversely impact the area or the environment.

Seeps and poor drainage can keep soil saturated, create slumping, and make it difficult to establish adequate vegetation. These can be alleviated through surface and/or subsurface drainage measures. In most instances, this consists of installing perforated tile which intercepts and collects this subsurface water and directs it away from the problem area.

Land Use

The land use of the area surrounding the critical erosion site must be taken into consideration when planning the critical area treatment. Conservation plantings should be considered based on their size and appearance at maximum growth and development to determine whether or not they are appropriate for the particular site and its planned use.

Conservation plantings which enhance and blend with the surroundings are preferred. As an example, plantings which would be ideal for a rural or forested environment may not fit in an urban setting. Likewise, plantings which provide habitat enhancement for various species of fish and wildlife may not be applicable to an urban area. However the primary objective is effective erosion control, while in some cases aesthetics may be secondary.

Geology

When planning a solution for any critical erosion area, site geology, which includes both the overburden soil and underlying bedrock should be taken into consideration. Of primary importance is the existence of unstructured bedrock at a shallow depth which can have considerable impact on the establishment of vegetation. In most instances, a detailed review of the soil survey will provide sufficient information on site geology and any geologic limitations.

Existing Vegetation

Existing vegetation can provide a dual role in planning a solution for a critical erosion area. The vegetation currently on the site can provide clues as to the types of plantings that can be expected to grow and flourish.

Second, the existing vegetation may be both desirable and aesthetically pleasing. Planning considerations may involve incorporating this vegetation into the overall site design.

Present and Proposed Use

In determining the suitable plant species for any critical erosion area, consideration must be given to the current use of the site and in particular the future use, especially if the use will change. If recreation will be involved or the site is adjacent to an urban area, species which will tolerate human or vehicular traffic without suffering substantial damage should be chosen. If fish or wildlife habitat is desired, plant species should be selected which will be of benefit for food and/or cover.

Climate

Climatological variations should be considered in selecting plant species for a site. Factors such as amount of rainfall, and particularly in New York, wide fluctuations in temperature are of prime importance in determining which species of vegetation will flourish. Tolerance of species to substantial snow cover is also an important consideration in certain areas of the state. Refer to *Figure 1 Plant Hardiness Zones*, from USDA Plant Hardiness Zone Map, Misc. Publication No. 1475, 1990.

Shade Tolerance

If the critical erosion area to be seeded is in woodland, shade tolerance becomes critical to the success of the planting. The tolerance of each species to be used should be verified.

Overall Environment

The overall environment of a critical erosion area brings together all of the factors discussed up to this point. Planning for a critical erosion area should attempt to identify, and as much as possible, utilize the environment of the area. A site, when properly planned and established, should blend with the overall surroundings. It should not stand out as something unusual or visually displeasing.

Site Preparation

Where equipment will travel over the site during planting or for maintenance after establishment, slopes should be no steeper than 3:1. They should be benched to allow for maintenance. Leave existing trees and shrubs where desirable, and protect from injury and soil compaction to a distance of two times the canopy radius.

Install any necessary water control measures such as:

- diversions
- waterways or outlets
- surface drains
- subsurface (tile) drains
- bench terraces

Respread topsoil over the area when construction is completed if topsoil has been stripped off and stockpiled.

Test the soil to determine need for lime and/or fertilizer. If sandy or gravelly, determine percent of fines.

Remove all surface debris such as stones (greater than 2"), tree stumps, etc. depending on maintenance requirements of the area.

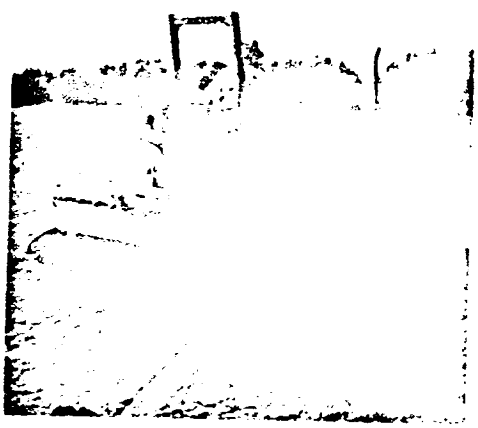
Chapter 2: TECHNIQUES OF SEEDING AND PLANTING



Drill - Seeding using offset packer wheels to cover seed and firm seedbed.

Seedbed Preparation

The surface should be scarified to a depth of at least two inches with a disk or other suitable implement. In some situations, such as drainage ditch banks, scarification can be excluded if lime, fertilizer and seed are applied to the roughened surface within 24 hours after digging. Sandy and gravelly sites seldom require scarification. On some small areas, direct seeding is possible without scarifying the slope. This is primarily on cool, moist slopes as in the Adirondack Mountains.

Apply lime, fertilizer, or manure. Mix them into the surface soil to a depth of at least two inches. If lime and fertilizer are applied by hydroseeder, incorporation into the soil is not practical. Both manure and soils should be analyzed for nutrient content. When results are available, nutrients should be applied according to nutrient needs of the erosion control cover. *Note:* Scarification and lime/fertilizer applications may be combined steps.

Application Rates

The following are suggested application rates for permanent seedings:

- Apply the amount of lime needed to attain a pH of at least 6.0 if legumes are included in the seeding mixture. If only grasses are to be seeded, a pH of 5.5 is acceptable.

VOL 12

6379

- Apply at least 30 pounds of nitrogen and 60 pounds each of phosphorus and potassium (600 pounds of 5-10-10 or equivalent) per acre.[1] Nitrogen application can be eliminated if 10 tons of manure per acre are applied.

Note: Lime, fertilizer and manure are most effective when worked into the soil surface.

Manure applications to sites should be recommended only after an evaluation of any potential water quality hazards. When available, manure may be applied to critical areas before seeding.[2] Work it into the soil if practical, especially on waterways and spillways. Manure helps to improve soil structure by adding organic matter.

Seed Specifications

Certified seed or sod of proven cultivars provides best results. Legumes should be scarified if necessary, and inoculated with the proper strain of nitrogen-fixing bacteria immediately before seeding. Use only plant cultivars adapted to local climatic conditions. *Note:* Quantity of seed does not compensate for poor quality.

Refer to *Descriptions of Grass and Legume Species* and *Tables 1A* and *1B* which contain information on plant characteristics, adaptation, use, suitability and level of maintenance required. Suggested seeding rates and seed mixtures for specified uses are shown in *Tables 2* and *3* for permanent seedings, and in *Table 4* for temporary seedings.

Time Of Seeding

Cool season plants are those which begin growth in cool seasons (spring/fall) and normally set seed in June/July. Frequently, cool season plants become dormant when temperatures persist above 85° Fahrenheit and moisture is limited. Kentucky bluegrass, red fescue and reed canarygrass are examples.

Warm season plants are those which begin growth slowly in the spring, produce a rapid flush of growth during the heat of the summer and set seed in the fall. Many warm season plants are sensitive to frost. In the fall frost may kill top growth. In the spring growth initiates from the base of the plant. Examples of warm season plants are switchgrass, lovegrass, and bluestems.

Timeliness of plantings may also be crucial. For example, a fall seeding of cool season grasses on a warm, droughty, sandy site may be successful. However, a spring seeding may fail.

1 Pounds of nutrients based on elemental N, P_2O_5 and K_2O.

2 Do not use manure when birdsfoot trefoil is planned for use.

Cool Season Mixtures

Good results are usually attained from seedings or plantings that are established in the spring before May 20 or in late summer after August 15. Spring seeding of legumes is recommended, however, late summer seedings prior to September 1 can also be made. When crownvetch is seeded in late summer at least 35 percent of the seed should be hard seed (un-scarified) to provide additional germination in the spring.

Temporary seedings of annual ryegrass, spring oats, or a combination of them may be made any time during the early or mid-spring season. Sudangrass or annual ryegrass may be used for late spring and summer seedings. Annual ryegrass or winter grains may be used for late summer and fall temporary seedings.

Temporary seedings of spring grains and annual ryegrass may be made in August. Permanent seedings of perennial grasses and/or legumes may then be overseeded in the spring. For other temporary seedings, where regrowth is desired in the spring, winter hardy grains or perennial ryegrass may be seeded in August or early September.

If seedings or plantings are made during dry periods (May 15-August 10), irrigation may be necessary to insure a successful seeding. Irrigation generally is not recommended on steep slopes.

Warm Season Mixtures

Seed should be planted on droughty, sandy or gravelly sites as early in the spring as possible and prior to May 1. On sites where soils have a high percentage of fines (greater than 15% silt and clay) plant by June 1. April or early May seedings are frequently more successful than late May seedings.

Seeding Or Planting

Proper seeding and planting techniques are important to insure successful plantings on critical areas. The slope of the land, soil texture, moisture regime and plant species all need to be evaluated before selecting the most appropriate system and equipment.

Drill

A grass drill (not a grain drill) or a cultipacker-seeder are the best methods of seeding. But the preferred method will depend on slope and conditions of the planting site. Grasses must be planted no more than 1/4 to 1/2 inch deep. If the drill does not have a packer attachment, a packer/roller should be trailed behind the drill.

Tracking

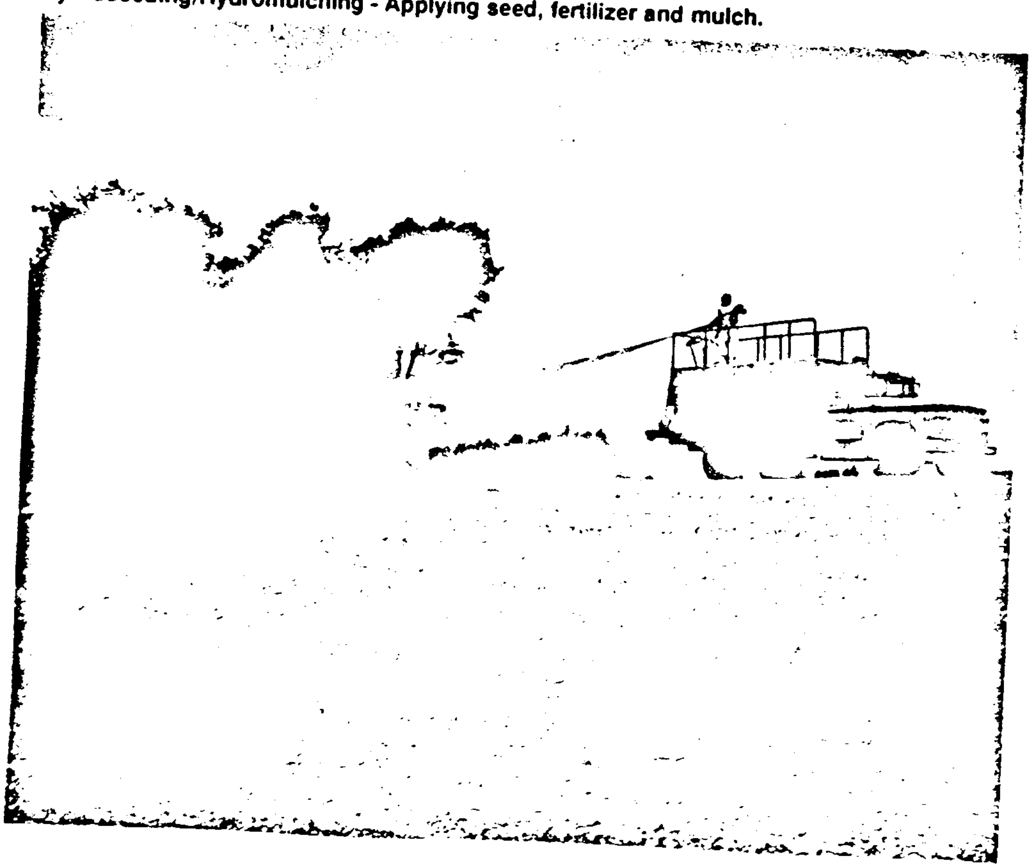
On steep slopes or where drilling is not feasible, broadcasting and tracking with a bulldozer is an alternative method. Tracking is performed by running a dozer up and down the slope, offsetting each pass so that the entire area is covered with tracks. This technique is especially valuable on droughty sites and wherever flatpea or warm season grasses are used.

Hydroseeder

This method is best for steep, inaccessible areas where a drill or other mechanized equipment is difficult or impossible to use. When applying seed, lime, fertilizer or mulch materials with the hydroseeder, do not use more than 100-150 pounds of solids per 100 gallons of water.

When legume seed is to be included in a slurry mixture containing fertilizer, the amount of inoculant added to the tank should be four times the rate prescribed by the inoculant manufacturer. A low solution pH is detrimental to the legume inoculant. If inoculant is in a seed, fertilizer, and lime slurry, it should be used within 3-4 hours, or a fresh supply of inoculant should be added. If there are

Hydroseeding/Hydromulching - Applying seed, fertilizer and mulch.



no legumes in the seed mixture, the seed may be mixed in a slurry with the lime and fertilizer. Hydrated lime should not be used if seed is to be mixed into the slurry.

Broadcast

Seed may be broadcast by using a whirlwind or cyclone seeder, or by hand. If spread by hand, seed may be mixed with sawdust to help achieve an even distribution. This is helpful for seeding small quantities of very small or light seeded species such as redtop, lovegrass, or little bluestem.

One half of the seed should be applied by walking in one direction, the other one half by walking at 90 degrees to the first direction. This yields a much more uniform seeding with fewer "missed" areas. Incorporate seed by cultipacking or raking, or tracking with a bulldozer.

Frost seeding is a technique which promotes seed incorporation by the frost action of daily freezing and thawing. This takes advantage of the frost cracks in the soil by broadcasting seed from February through April when snow is not present. Some of the seed will move into the frost cracks as the ground repeatedly freezes and thaws. Success depends greatly on timing. Round seeds work better than light fluffy seeds when using this technique.

Sprigging

This is done by planting a shoot, root, or sprout of a plant. It is a costly method, but may be necessary to establish some plants on critical erosion areas.

Sprigging should be done in the early spring, just before the time that normal plant growth begins. Lime and fertilizer should be applied in accordance with the needs of the species to be planted.

Sodding

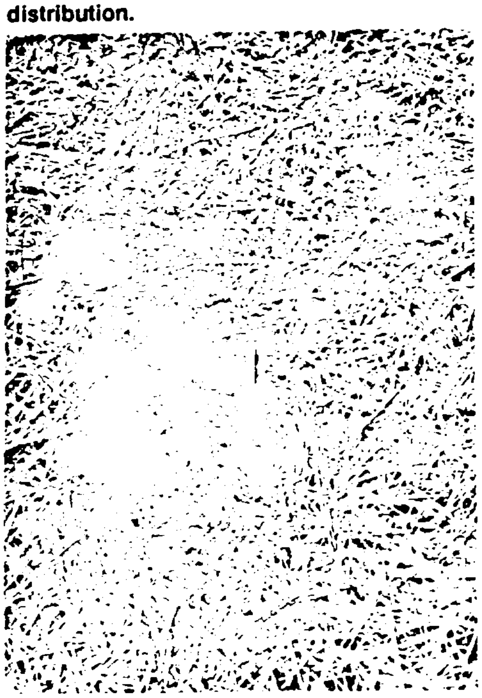
This consists of covering an area with sections of sod in order to provide quick soil protection. Select a dense sod containing suitable varieties for the site to be sodded. Sod must be free of problem weeds. Use "certified" varieties of grasses. Additionally, sod should be at least one year old, but not older than 3 years. The sod should be placed within 12 hours of cutting.

Lay strips of sod across the slope, beginning at the bottom. Strips may be anchored using 6-12 inch wire staples that are spaced 2 feet apart along the up-hill edge of the sod strip. Stagger joints and make sure the ends are butted up tightly. Roll the sod after placement to improve contact with the soil surface. Irrigate after rolling and during dry periods.

Maintenance

In spring of the second year of new seedings apply 300 - 400 lbs/ac of 5-10-10 of fertilizer or equivalent. When seedings or plantings consist of only grasses, an application of nitrogen fertilizer should be applied annually at the rate of 40 pounds per acre, or approximately 1 pound per 1000 square feet. Where legumes are included in the planting, nitrogen applications are usually not necessary nor recommended. If nitrogen applications are made they can be injurious to the legume. Obtain a soil test and apply phosphorus and potassium as tests indicate.

Mulching - Proper mulch rate and uniform distribution.



Mulching

Mulching is a very important step in establishing vegetation on critical areas. A mulch cover will help hold moisture, protect soil from erosion, hold seed in place, and keep soil temperatures more constant. Mulch reduces the "frost heaving" of small plants during the early spring freeze/thaw periods. It should be applied uniformly by mechanical means or by hand. Some bare soil should still be visible through the mulch.

Hay, straw or other fibrous mulches are the best for newly seeded areas. Some mulches are subject to blowing and must be kept moist or "tied" down. Mulch materials may also be used alone as a temporary ground cover measure for reducing soil erosion.

Hydromulching

Hydromulching is a process by which water and various combinations of seed, fertilizer, ground limestone, inoculants, wood cellulose and even compatible insecticides and fungicides are mixed in a tank to form a slurry. The slurry is maintained by continuous agitation until used. The material is sprayed over the area to be seeded, under high pressure. Wood cellulose mulch is suitable for use only in a slurry. It cannot be used for dry applications.

Dry straw or hay materials may be applied using a straw chopper or bedding chopper. Rotating blades chop the hay or straw and a blower propels the mulch

Strawmulching machine.

out a spout directed towards the area being mulched. Hay or straw frequently requires anchoring to prevent the mulch from being blown away. See *Table 5* for guide to mulching materials, rates and uses, and *Table 6* for mulch anchoring.

Planning Considerations

1. Consider mulching equipment availability, i.e.: hydromulchers, straw mulchers, etc. Some mulch materials require specialized equipment to apply a product properly.

2. Prior to mulching, install the necessary temporary or permanent water erosion control (structural) practices and drainage systems within or adjacent to the area to be mulched.

3. Slope, grade and smooth the site if conventional equipment is to be used in applying and anchoring the mulch.

4. Remove all undesirable stones and other debris depending on anticipated land use.

5. Compacted or crusted soil surface should be loosened to at least two inches by disking or other suitable methods.

6. When mulching new seedings, apply mulch immediately after seeding, the same day as seeding or within 48 hours. Do not mulch if germination is occurring.

Mulching Materials

1. Select from *Table 5*, the type of mulch and application rate that will best meet the need and availability of material.

2. If required, select the anchoring method from *Table 6* that will work best.

3. The best combination of mulching material for critical areas is straw (small grain) mulch applied at 2 tons/acre (90 lbs/1,000 sq. ft.). Anchor the straw mulch with wood fiber mulch (hydromulch) at 750 lbs/acre (17-20 lbs/1,000 sq. ft.). The wood fiber mulch must be applied through a hydroseeder immediately after straw mulching.

Chapter 3: SELECTION AND DESCRIPTION OF PLANT MATERIALS

Trees and Shrubs

Many trees and shrubs (woody and herbaceous) are useful in protecting soil surfaces against wind and water erosion. Some trees and shrubs can also be used as soil stabilizers. Furthermore, they serve a number of environmental and engineering functions such as acoustical control, atmospheric purification, traffic control, glare reduction and reflection control. They also serve as climatological controls and provide aesthetic values through screening and space articulation.

Species Selection

The first, and most important step is proper selection of plant materials. Each site must be evaluated for soil and water conditions, climatic adaptability of the plant, and expected plant growth rate. It is advisable to consult with extension horticulturists, arborists, nursery people, or foresters in selecting plants that are suited for local conditions.

Important considerations when selecting trees or shrubs:

- Select only short species of shrubs when planting under utility wires.
- Avoid planting directly over or near water, gas, oil and sewer lines or buried telephone and power cables.
- Plant trees away from buildings to avoid contact at maturity.
- The form, beauty, color, ultimate size, hardiness, shade tolerance, water needs and soil preference of trees and shrubs must be considered.

When erosion or sediment control is not of primary concern, critical areas may be stabilized with rugged, fast growing trees and shrubs. Once established, they have a good record of taking care of themselves. In some cases, it may be desirable to use trees and shrubs as screening plants to shield sites such as gravel pits from public view. These plants should be given the best attention at planting by providing them with good soil, water and mulch. It is particularly necessary that the plants be checked and watered as needed during the first two growing seasons to promote rapid growth.

Quality planting stock should be used. Normally one or two year old deciduous seedlings and three or four year old coniferous transplants, when properly produced and handled, will meet the requirements. Larger specimen plants may be used if immediate landscape values are a consideration, but the costs will be considerably higher. Stock should be kept cool and moist until planted. Competing vegetation, if significant, should be destroyed or suppressed prior to planting by scalping (clearing) a small area where the plant is to be placed.

Dormant stock should be planted in the spring by May 15 or in the fall from August 15 through October 15.

Of the plants suggested in *Table 7*, the fastest growing trees are the poplars, willows, elms and pines, in that order. Of the shrubs, the fastest growing are forsythia, tall hedge buckthorn, and mock-orange. Shrub and tree recommendations for various soil conditions are also listed in *Table 7*.

Planting

Some erosion control shrubs are planted as bare-root seedlings, or in the case of willows and dogwood, hardwood cuttings or rooted cuttings can be used.

Hardwood cuttings should be a minimum of 3/8 inch diameter and 8-12 inches long. Cuttings are planted so that only the upper most bud is exposed. Along streams, plant on 2 foot centers beginning at the normal water level and plant two or three rows. Normally the area is overseeded with a grass mix immediately after planting. Refer to *Table 3* for selecting an appropriate seed mixture.

Nursery grown trees and shrubs have a much better chance of survival than plants dug from wild stands. Nursery stock has a root ball wrapped with burlap, plastic or wire or has been grown in a container. Deciduous trees with trunk diameters less than three inches may be planted anytime the soil is workable, but must be mulched and watered. Roots must be kept moist until planting by watering or heeling in.

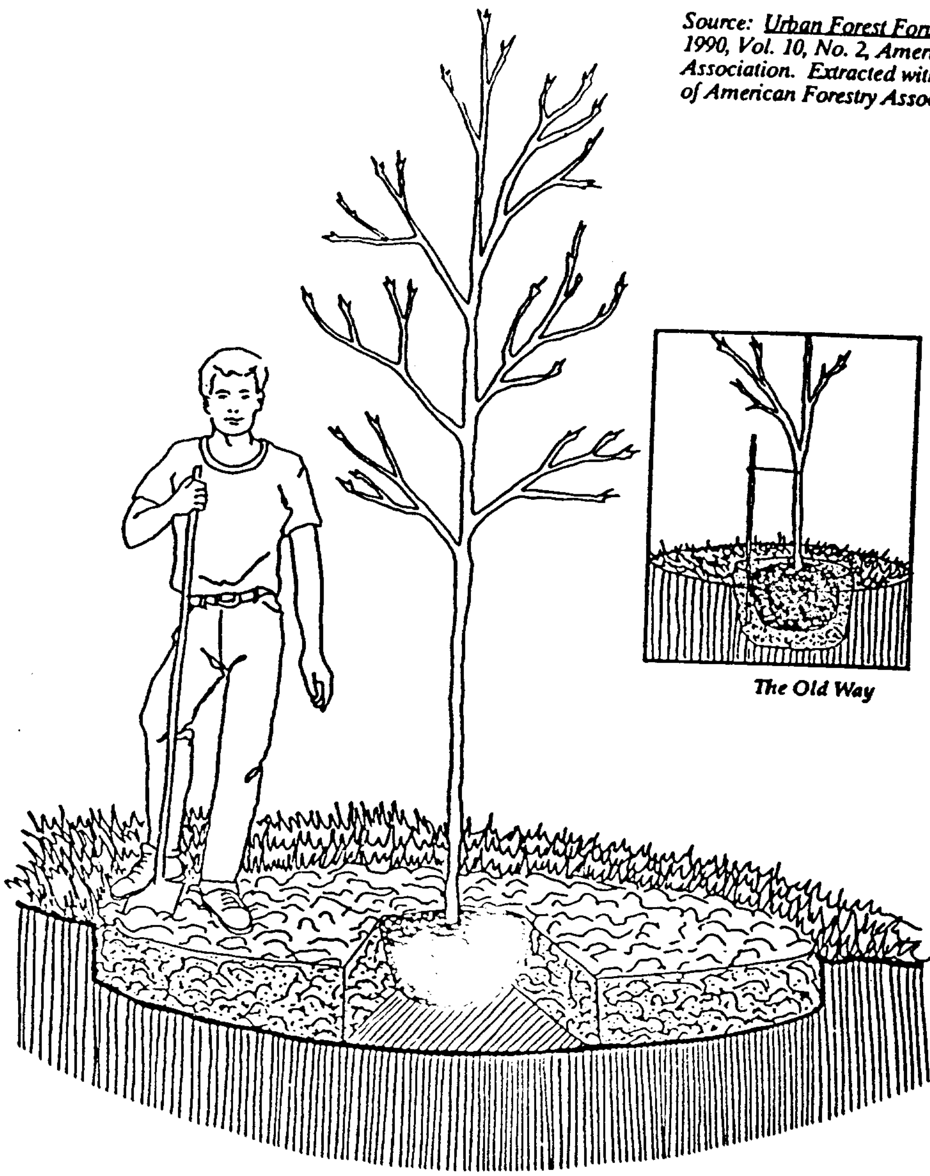
Proper spacing, planting depth and soil mixtures are also important considerations. New planting procedures are recommended by the American Forestry Association. See *Figure 2 - New Tree Planting Procedures* on the next page for details.

Fertilizing and Watering

Erosion control shrubs which are planted as bare-root seedlings or cuttings should not be fertilized during the planting year. They are not usually watered except at time of planting or during drought.

Figure 2: New Tree Planting Procedure

Source: Urban Forest Forum, April/May 1990, Vol. 10, No. 2, American Forestry Association. Extracted with permission of American Forestry Association.



The new method of tree planting will result in better survival and growth than the old method. Grass competition and soil compaction are two of the most common factors in poor performance. The New Method: Prepare a planting area five times the diameter of the root ball or container. Use a rototiller and/or spades to loosen and mix the soil to a depth of about 12 inches. Organic matter (well decomposed) can be added. Dig a hole in the center to set the tree, so that the root ball will rest on solid ground. Backfill around the root area, pressing the soil but not packing it. Mulch the entire prepared area with 2 to 4 inches of bark, wood chips, decomposed sawdust, or leaves. Reference the article for a full explanation.

The amount of fertilizer applied to other landscape plants will depend upon soil fertility and growth desired. Generally, shrubs should be fertilized in spring before growth starts. If soil temperatures are at least 40 degrees Fahrenheit, roots can absorb nutrients.

Deciduous shrubs should be fertilized the second year with one-quarter pound of a 5-10-5 fertilizer per plant (or 25 lbs. per 1,000 sq. ft. for block planting) or the equivalent. A slow release fertilizer is preferred. Evergreens should be fertilized at half the rate.

Trees are fertilized according to size. Use one pound of 5-10-5 per inch of trunk diameter for trees up to three inches in diameter. Broadcast fertilizer over the soil near the dripline of the tree branches.

Valuable trees and shrubs should be watered for two to three growing seasons after transplanting. A three to four inch mound of soil around the planting hole will provide a reservoir area for water to soak into the rooting zone. During dry periods, trees should receive about two inches of water at two to three week intervals.

Protection

Broken branches and roots should be pruned at planting time. Severe pruning is not needed on nursery-grown plants.

Trees may need to be secured with stakes and guy wires during the establishment period, usually one or two growing seasons. If wire is used, pad it with rubber hose to protect the bark.

Mulching

Mulches conserve soil moisture, insulate the soil and smother weeds. Wood chips and bark mulches are generally the preferred mulch material; straw and hay are attractive to rodents. Several fabric materials are available. Use according to manufacturer's recommendations. See *Mulching* section in *Chapter 2* for more information.

Inspection

The planting should be inspected after the first and second growing seasons. Replanting and repairs should be scheduled as needed.

Descriptions Of Grass And Legume Species

The following narrative describes the important individual characteristics, qualities and tolerances of plants recommended for use in vegetative stabilization of critical erosion areas. It is intended to point out specific traits which can be used to an advantage in revegetative work.

American beachgrass - *Ammophila breviligulata:* Beachgrass is the primary dune building plant for coastal sands. This cool season grass is extensively rhizomatous in sandy soils, and readily grows up through new deposition layers. It is planted vegetatively with dormant culms (stems) that can be obtained from coastal nurseries. Beachgrass and other sand colonizing plants are very intolerant of foot or vehicular traffic.

Big bluestem - *Andropogon gerardi* and little bluestem- *Schizachyrium scoparium:* Warm season bunch grasses have dense deep root systems and grow in large clumps. Under favorable conditions big bluestem grows up to 7 feet tall and little bluestem to 3 feet tall. Both are very drought tolerant even on soils with a very low percentage of silt and clay.

Birdsfoot trefoil - *Lotus corniculatus:* A winter hardy, perennial legume adapted to both well and poorly drained soils. Under favorable conditions trefoil will spread by reseeding. Trefoil is tolerant of medium acid soils, but grows more vigorously if such sites are limed to a pH of 6.0 - 6.5.

Canada bluegrass - *Poa compressa:* This rhizomatous perennial is slow starting and is seldom used alone. It is shade and drought tolerant. It can also be used to an advantage under conditions too dry or not otherwise entirely favorable to Kentucky bluegrass.

Caucasian bluestem - *Bothriochloa caucasicus:* This is an introduced warm season grass from Eurasia. In mixtures with native warm season grasses, Caucasian provides faster cover. It is only marginally hardy in New York and may winter kill, providing room for the native grasses.

Creeping foxtail - *Alopecurus arundinaceus:* This foxtail is a perennial, cool season grass that is not related to the weedy foxtails. Creeping foxtail is tolerant of wet soils and cold temperatures and is very vigorous once established. The small light seed does not flow in planting machinery and must be broadcast.

Creeping red fescue - *Festuca rubra (subsp. commutata):* This fescue is a cool season grass that spreads by underground stems or rhizomes. It is adapted to a wide range of soil types, tolerant of dry sites and valuable for its shade tolerance. It is a short grass used for low maintenance areas or general purpose turf.

Crownvetch - *Coronilla varia:* Crownvetch is a winter hardy, perennial legume that develops dense growth on well or moderately well drained soils. It spreads by underground stems and is self seeding. The seedlings will grow in moderately acid sites, but they will do better if the area is limed to a pH of 5.5 to 6.0.

Deertongue - *Panicum clandestinum:* Deertongue is a native perennial, warm season grass which normally reaches a height of up to 3 feet. It spreads slowly by rhizomes and seed. It is the most acid-tolerant of the grasses described. In droughty and low-fertility areas, deer-tongue can be used also. It does not persist as well as other warm season grasses on some sandy sites.

Flatpea - *Lathyrus sylvestris:* Flatpea is a perennial, deeply tap rooted legume with long vine-like stems capable of climbing to a height of eight feet. It is not adapted to wet sites, but will persist on moderately well drained to droughty soils. Seedlings are slow to develop, however once established, plants are vigorous and form a thick vegetative ground cover which resists encroachment by other plants.

Kentucky bluegrass - *Poa pratensis:* Kentucky bluegrass grows best on well drained, fertile soils. It establishes slowly but spreads by rhizomes to make an excellent, smooth turf. During hot, dry weather the plant goes dormant. It is used both as lawn and pasture grass.

Perennial ryegrass - *Lolium perenne:* This is a bunch grass having very rapid seedling growth. It tolerates fairly wet soils but can stand only short periods of flooding. It's used to provide quick protective cover on exposed soils, but does not withstand hot, dry weather or severe winters. Diploid cultivars are recommended for critical area seedings. New tetraploid cultivars are not as winter hardy.

Redtop - *Agrostis gigantea (A. alba):* This grass tolerates acid soils and droughty to poorly drained conditions. It emerges very quickly to form protective cover. Redtop is low growing and has a creeping growth habit. Although vigorous in the seedling stages, redtop does not seriously compete with slower growing cool season species. The reseeding habit and rhizomatous character of the roots make it a good plant for erosion control.

Reed canarygrass - *Phalaris arundinacea:* It will grow on poorly or well drained soils, and is tolerant of both flooding and drought. It spreads by scaly rhizomes which can also be used for vegetative propagation. The stems are coarse and the leaves are broad. Seed germinates slowly and loses viability after one year of storage. Use only fresh seed grown the previous season. Spring plantings are recommended. Avoid using reed canarygrass on slow moving waterways as the grass will retard water flow and eventually clog the waterway.

Sand lovegrass - *Eragrostis trichodes:* This species is commonly used in the plains area. Sand lovegrass is slower to establish than weeping lovegrass, but persists longer. This species is extremely small seeded.

Smooth bromegrass - *Bromus inermis:* This winter hardy forage grass spreads by rhizomes to form a coarse dense sod. It's tolerant of heat and drought. It grows on diverse types of soil, but is not tolerant of poorly drained areas. It has good seedling vigor, but is slow to establish a sod. The large, light seed is difficult to plant mechanically.

Switchgrass - *Panicum virgatum:* This perennial, warm season grass has short rhizomes and coarse stems. It has good seedling vigor and is widely adapted to soils which are moderately well drained to droughty. It will tolerate extremely acid soils, pH 4.0 to 4.5 and is the most widely used native warm season grass.

Tall fescue - *Festuca arundinacea:* It is a very widely adapted grass. Most seed sources are infected with a non-visible fungus which actually helps the plant compete under adverse conditions, but reduces forage quality. Tall fescue tolerates poor drainage and can survive winter flooding. It will grow on acid, alkaline or saline soils. Although considered a bunch grass, some tall fescue spreads slowly by short rhizomes. It produces a coarse, tough turf that resists traffic when seeded at heavy rates.

Weeping lovegrass - *Eragrostis curvula:* This warm season bunch grass has rapid first year growth. It spreads by tillering so that individual plants may be 12-15 inches in diameter in 2 to 3 years. Excellent growth can be obtained on low-fertility soils. Plants often winter kill in New York and New England but can be used as an annual.

White clover - *Trifolium repens:* Both standard and ladino types are readily adopted to most cool season grass mixtures. Clover adds nitrogen fixing capability which is beneficial to overall grass vigor on critical sites.

Wildflowers - Many species: Many species of wildflowers (forbs) are available for use on critical areas. Wildflowers can have a very positive impact with the public, and also serve to attract birds. Most seed companies which deal in wildflowers have mixes tailored to the Northeast, and some have mixtures for wet or dry soils.

Two cultivars selected for use in the Northeast are 'Golden Jubilee' black-eyed susan and 'Lancer' perennial pea. Both are adapted to most well drained soils. Perennial pea adds color to flatpea and crownvetch seedings.

Chapter 4: RECOMMENDATIONS FOR SELECTED AREAS

Construction Sites, Rights-of-Way, Capped Landfills

There are several important principles to be considered in vegetative control of erosion and sedimentation on construction sites including:

- Soils should not be exposed for more than about 15 days unless construction is to resume within 30 days. If construction is suspended for some reason, areas should be seeded and/or mulched without delay.
- Carefully select plant species adapted to the site and the purpose for which they are to be used.
- Do not burn or otherwise remove the protective vegetative litter from the site. Bare areas are vulnerable to erosion.
- Grade to a slope that allows for ease in planting and maintenance.
- Stockpile topsoil for use on the areas that need it for establishing vegetation.
- Limit removal of vegetation to the smallest possible area to accomplish construction needs.
- If the site is to be broadcast seeded, it should be done while the bulldozers are still on the area to provide tracking services.
- Guidelines for controlling erosion and sedimentation are available from New York State Department of Environmental Conservation.

Droughty Sites, Sand and Gravel Pits

Grade and shape site as needed. The amount and kind of grading required will vary with the planned use. For example, a recreation area development may require grading for access roads, trails, picnic or camp sites, etc. A wildlife area development may need only minor reshaping of steep banks to facilitate vegetation. Proper planning of operations during excavation of material can greatly reduce the amount of reshaping required for satisfactory establishment of vegetation.

Regardless of planned use, all banks should be reshaped to a maximum slope of 2:1. On some types of soil material, the banks should be no steeper than 3:1. If equipment is to travel on the slopes when revegetating, they should not exceed 3:1. Select seed mix based on the percent fines (silt and clay fraction by weight) passing a # 200 mesh sieve. If less than 16%, use warm season grasses only. If 16-20%, use warm season grasses or perennial legume mixes. If 21%, or higher, cool season grass legume mixtures can be used.

Dikes, Levees, Dams, Pond Banks, Terraces, Diversions or Other Earth Works

Select plant species that are adapted to the site. If the site is to be mowed regularly, grasses such as Kentucky bluegrass and creeping red fescue should be seeded.

Roadbanks

Old roadbanks should be scarified or regraded if rilled or gullied. This may be accomplished using a drag chain, disk or chisel, brush rake or a dozer. Lime and fertilizer should be applied after scarification.

New roadbanks should be limed and fertilized, seeded, and mulched as soon as possible after earth work is completed. If not seeded within 24 hours after construction, scarify the surface before seeding.

Rural Homesites

There are usually areas that can be seeded immediately following the completion of clearing and shaping of the site. Cover should be established on all areas that lie outside of those needed for construction activities. This will help reduce erosion and sedimentation. Lime, fertilizer, and seed should be applied as soon as possible after each work site is completed. If this is done, scarification of the seedbed may not be necessary.

Industrial Areas

During the development of industrial areas there are many places that should be protected by vegetative cover. Areas where construction activities will not take place should be vegetated as soon as possible after the earth work is completed. Species requiring little or no maintenance can be used on many of these areas.

Rights-of-Way (ROW)

Woody plant suppression is a secondary goal of many right-of-way plantings. Flatpea and crownvetch are the most successful plants for this purpose. Neither species is tolerant of poorly drained soils. On poorly drained sites reed canarygrass is the best choice. Flatpea and/or crownvetch should be planted as the final grading and smoothing are completed to promote good soil-seed contact. This is most important and will enable the rapid establishment of a stand which can

VOL 12

6394

suppress woody plants. Shade tolerance might also be a concern through wooded sites. If the canopy creates 50% shade cover or more, crownvetch may not grow vigorously or provide adequate woody plant suppression. Flatpea remains vigorous with a minimum of 3-4 hours of direct sunlight.

Capped Landfills

Landfills are often capped with an impervious layer specified in the closure plan. Then 20"- 24" of coarse sandy material may be applied as a growth media. Even when better material is used, droughty conditions often result due to the limited rooting depth to the impervious layer or high concentrations of methane. Warm season grasses are often the best species for these sites. They have extensive fibrous root systems and better water/nutrient use efficiency than do cool season grasses.

Streambanks

The following discussion and methods are provided as a guide in analyzing the problem, and the measures that can be used in its control. Except for minor site corrections where simple measures can be employed, the complexity of planning and construction require the assistance of an engineer.

Type of Planting

Straight stream sections and the inside of curved sections should be stabilized by seeding, or by planting shrubs on properly sloped banks above the normal water line. Shrubs are best suited to swift, steep-sided gravelly streams, especially those subject to ice-scour. Herbaceous plants are best suited to slower streams having low or gently sloping banks.

The outside bank of curved channel sections should be stabilized by using structural control (riprapping, gabions, cribbing, etc.) at the toe of the slope, and by planting shrubs on properly sloped banks above the installed structural measures.

For critical sections where surface runoff water cannot be diverted, sodding or seeding protected by jute netting or similar erosion control fabric should be used.

Topsoil

When soil conditions are particularly adverse for herbaceous vegetation, topsoil should be spread to a depth of four inches or more and then incorporated into the surface.

Mulching

Seeded side slopes should be mulched. Where streambanks are steeper than 2:1 or higher than ten feet, the mulch should be anchored.

Seeding Mixtures

Refer to the seeding mixture numbers found in *Tables 2* and *3*.

VOL 12

6395

Shrub Species and Arrangement

Top of Bank: Bayberry, coralberry, 'Streamco' purpleosier willow, or 'Bankers' dwarf willow spaced 4' x 4' to 6' x 6'.

Average Annual High Water Line: 'Streamco' purpleosier willow, or 'Bankers' dwarf willow spaced 3' x 3' to 4' x 4' (approximately 65-120 shrubs per 1,000 sq. ft.).

Normal Water Line: 'Streamco' purpleosier willow or 'Bankers' dwarf willow spaced 2' x 2' (approximately 240 shrubs per 1,000 sq. ft.), single row of 'Ruby' redosier dogwood or silky dogwood - spaced 2' apart in the row, or riprap. On sections where riprapping is not required, the silky dogwood would be planted just above the normal water line.

Preparing Cuttings: Woody cuttings, of the shrubs mentioned above, can be purchased from commercial nurseries or taken from native sources in the area during late winter before the leaves come out. To do this, take the cuttings from the latest growth, which is the new wood that grew during the previous season. The cuttings should be taken from 8-12 inches long, and from 3/8 to 1/2 inch in diameter. Be sure to use a sharp knife or pruning shears to avoid bruising the bark. Each cutting should have at least three healthy buds on it. Since the ends may dry out, make the cuts at least one inch away from the highest and lowest buds. Keep the cuttings cold and moist and plant them as soon as possible. Being careful not to injure the buds, plant the cuttings with the buds pointed up. The top bud should be at ground level or slightly above.

Large Streambanks

The problem of stabilizing the banks of large streams is complex. It does not lend itself to precise design, and the success of a given project is dependent upon the judgement, experience and skill of the designer.

Salt or Other Toxic Sites

When dealing with leachable toxics in sites, it is important to minimize disturbance of the surface. The surface may have been leached out since the last deposition of the toxic substance. Disturbance will bring higher concentrations back to the surface. This may prevent vegetating the site until the surface has leached the toxic material below the root zone.

Biotechnical Slope Stabilization

These critical erosion areas often require a combination of engineering and plant material treatments. Expensive structural engineering can sometimes be reduced by using woody plants which provide improved slope stability. An in-depth discussion of these techniques is found in "*Biotechnical Slope Protection* *and Erosion Control*" by Gray and Leiser, or *Chapter 18* of the *SCS Engineering Field Manual.*

Biotechnical slope stabilization is a series of techniques, all of which use plants in combination with engineering to protect slopes from soil movement and erosion. The principles are not new, and were utilized by the Soil Conservation Service on the Winooski River in Vermont 40 years ago. The resurgence in interest is for two reasons:

- Cost savings is considerable when compared to structural engineering practices used alone to correct critical erosion problems.
- Aesthetic cover provided by plants is often preferred over rock or concrete.

Wattles or Live Fascines

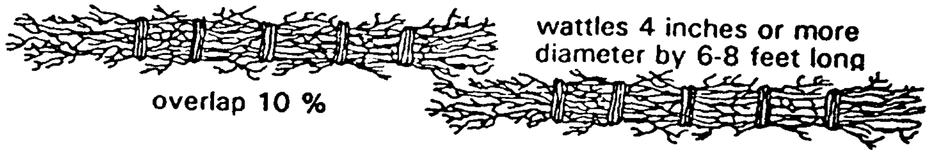
The primary procedure uses bundles of willow or dogwood whips about four inches in diameter and seven feet long. The bundles are referred to as "wattles" or "live fascines." The wattles are placed across the slope on the contours at three to five foot elevation intervals. Shallow trenches are dug and the wattles are placed in them, staked down, and covered with soil. The wattles sprout roots and stems along their length creating a continuous barrier to sloughing, etc. Wattles can be installed with hand labor. Refer to *Figure 3* on next page for details.

Brush Matting

A second technique is called brush matting. This system is used where major

Streambank stabilization - Planting willow wattles to modify flow along the bank.

Figure 3. Wattling or live-fascine installation



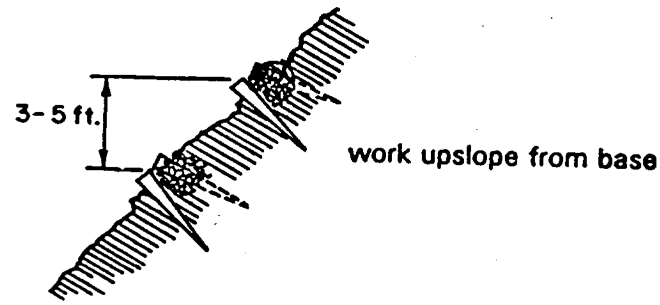


Figure 4. Brush matting installation

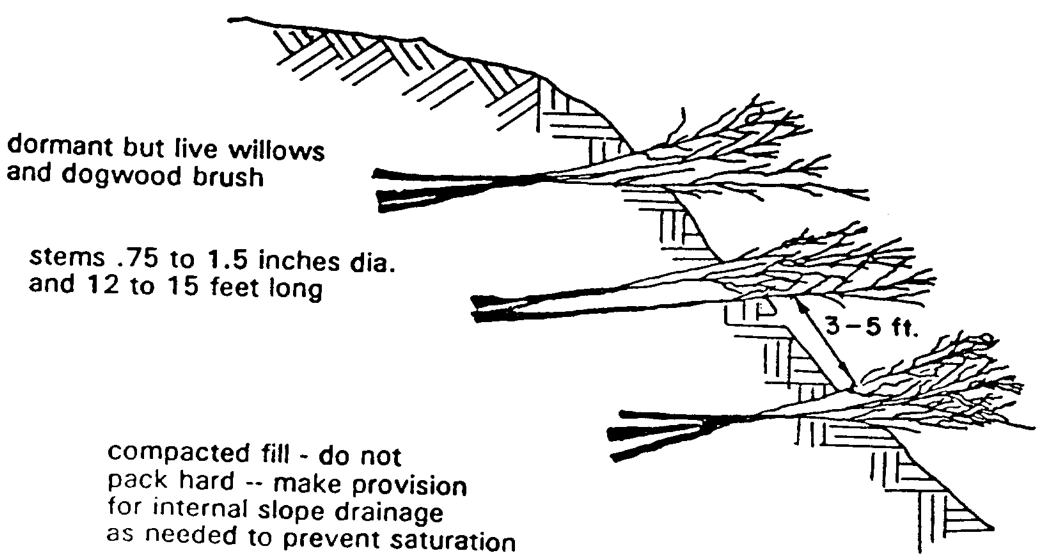

VOL 12

63998

R0039706

reconstruction of a slope is needed, and it requires a bulldozer and/or a backhoe. It also requires a much greater volume of vegetation than does wattling. Starting at the base of the slope a pad is constructed on the contour. A layer of brush is placed on the pad, with butt ends into the hillside and tops out. A thin layer of soil is spread over the brush, then a second and third brush layer is applied also with soil between. Then a three to five foot layer of soil is placed on top and the process is repeated, working up the slope. About three to five feet of brush tops remains protruding out from the slope at each lift. See *Figure 4.*

For these techniques to be effective, the wattles and brush matting must consist of species which will root rapidly and grow. Non-rooting species (most shrubs) will fail. 'Streamco' and 'Bankers' willows have been tested and work very well for biotechnical slope stabilization. After the slope is stable, many other woody plants will invade and may dominate the site causing it to blend in with local vegetation. It is strongly recommended that the assistance of someone experienced in these techniques should be involved during the planning phase.

Lake Frontage

Erosion control of lake shoreline can be extremely difficult, especially where bluffs occur along the Great Lakes or other large lakes. Before a course of action is selected, consult with specialists from: Sea Grant, Cornell Cooperative Extension, County Soil and Water Conservation District, USDA Soil Conservation Service, or US Army Corp of Engineers.

When vegetative solutions are feasible, 'Cape' American beachgrass is the most commonly used plant on unconsolidated sands or gravels.

Filter Strips

Filter strips are extremely useful in preventing sediment from reaching water courses. Strips of grass or grass/legume should be a minimum of 20 feet wide for sediment trapping. *In table 3,* Seed mixture #2 or #5 is suggested. Mixture #2 should be used on soils of well to moderately well drained. Mixture #5 may be used on soils of poorly to very poorly drained classes.

Insufficient documentation is currently available on nutrient absorption by plants within filter strips. However, actively growing grasses are effective nutrient users. When nutrients are to be filtered, manage the filter strips to keep the plant in a vegetative growth stage. Mowing and removing the forage prior to seed head production will be the best practice to keep the grass vigorously growing.

Sandblows and Dunes

Few plants will stabilize eroding, sandy areas. American beachgrass has been successful in many situations. It is necessary to plant culms of this grass. As the beachgrass begins to stabilize the sand, other plants can be established. Keep people and vehicles off planted areas.

When planting or sprigging beachgrass, the best planting time is in early spring before May 15. Plant sprigs containing 3 stems (culms) about 8" deep at a spacing of 18" apart in rows. Rows should be staggered 18" apart. A 12" x 12" spacing will stabilize an area faster and should be considered when patching blowout areas.

Cape American beachgrass on sand and gravel bank two months after planting.

Fertilize the planted area with 10-10-10 fertilizer or equivalent, at a rate of 400 pounds per acre at planting time. Follow this with 40 pounds per acre of nitrogen after spring growth begins, and repeat annually until an adequate plant cover is established.

Temporary Stabilization of Sandblows and Dunes

Two temporary stabilization techniques may be used. One uses brush placed with butts windward. Start by placing brush on the leeward side and working toward the windward side. Overlap butts with tops to provide a shingling effect. A second approach uses snowfence. Place the fencing material at right angles to the prevailing wind.

Permanent Stabilization of Sandblows and Dunes

Vegetative stabilization is done by planting culms of 'Cape' American beachgrass. A planting unit of beachgrass consists of three healthy culms. Planting should be done between March 1 and April 15. Culms will be planted 8 to 9 inches deep. Culms may be purchased commercially or dug locally during the planting season. The stems should be cut back to 15 inches before or after digging. They may be stored by heeling-in, or storing at 28 to 32 degrees Fahrenheit.

An alternative, less expensive method is to plant the beachgrass in bands. These bands should be spaced 20 to 40 feet

VOL 12

6400

apart. The bands should consist of at least two parallel rows spaced approximately 18 inches by 18 inches. The closer band spacing should be used on the prevailing wind side of dunes.

On inland windblown areas, use 20 foot spacing between double rows of American beachgrass. Bands should be perpendicular to damaging wind direction. Fertilizer should be applied to the planted bands as discussed above.

Shrub and tree plantings may be combined with beachgrass on coastal and inland sites. Where this is the intent, the woody species are planted 1 to 3 years after the beachgrass is put on the site. Some compatible trees and shrubs are:

Inland Area Species:
- *American holly*
- *Scotch pine*
- *Pitch pine*
- *'Arnot' bristly locust*
- *Bayberry*
- *Rugosa rose*

Coastal Area Species:
- *American holly*
- *Beach plum*
- *Bayberry*
- *Rugosa rose*
- *'Emerald Sea' shore juniper*

WINDBREAKS

An often overlooked possibility for vegetating critical areas is to provide additional benefits of wind, snow, sight, noise, and dust control. Minimal maintenance of the barriers is desirable, so plants must be selected with an eye toward adaptation as well as effectiveness. Guiding principles for windbreaks include:

- Windbreaks are most effective at downwind distances of less than 10 times the height of the trees.
- Two row windbreaks often provide acceptable performance; visual screens can be single row plantings.
- Noise barriers increase in effectiveness as their distance to the noise source is reduced.
- Visual screens are most successful with evergreens providing year-round benefits, but a partial screen can be achieved faster with poplars or other fast growing deciduous species.
- Snow control plantings should be placed on the windward side at least 50 feet from the locations to be protected. Snow will accumulate upwind of, in, and downwind of the windbreak. Care should be exercised to avoid snow accumulation on inappropriate locations.
- Species selection and placement are critical to avoid interfering with septic and drainage systems. Utilities such as water, gas, and electric lines should also be avoided.
- Gaps in the windbreak/screen should be filled with replacement trees as soon as possible.

Wildlife And Fish Benefits

Some species of wildlife will benefit from the stabilization of critically eroding areas regardless of type of plants used. Proper planning of critical area plantings can result in additional wildlife benefits.

Wildlife

Nearly all plants provide some wildlife cover but some are better than others. Wildlife are selective in the plants they use for food. Whenever possible, select plants that provide both food and cover for the wildlife species for which habitat improvement is intended. Refer to *Table 9 "Wildlife and Fish Benefits of Stabilizing Plants"* for food and cover value of various plants.

Most species of wildlife, with the exception of field nesting songbirds, require hardwood shrubs and/or trees for food, escape, roosting or loafing cover. Many species prefer evergreens for winter cover. For a description of the types and amounts of the habitat elements that are needed by the individual wildlife species for minimum and optimum habitat, refer to the *USDA Soil Conservation Service (SCS) Field Office Technical Guide - Standards and Specifications for Wildlife Upland Habitat Management or Wildlife Wetland Habitat Management.*

Steep slopes (over 3:1) are not as desirable for ground nesting birds as are flatter slopes. Level areas are best. If seeding large areas for general wildlife benefits it is best to add 1/4 to 1/2 acre or larger clumps of wildlife shrubs and evergreens totaling not more than 5 acres or 1/4 of the area, whichever is larger.

Exposed soil areas to be planted to trees and/or shrubs should be stabilized by seeding mixture 22 or 23 from *Table 3* before or at the time the shrubs and/or trees are planted. Only the aisles should be seeded to grass. Maintenance mowing should be performed after July 15 to minimize loss of nesting birds.

Fish

Fish benefit from stabilized streambanks. Controlled upland erosion reduces sediment reaching streams that may smother fish eggs. Shade provided by overhanging grasses, shrubs and trees help cool the water. Stems and roots protruding into the water also provide cover for fish. Small shrubs, such as 'Ruby' redosier dogwood, alder, and 'Streamco' purpleosier willow will provide some shade to small streams when planted on the bank, particularly on north or south flowing streams.

On larger streams, and streams flowing east or west, shade trees like boxelder maple, sycamore and red or silver maple are needed to provide shade over the water. These large trees should be planted on top of the streambank 8 to 10 feet from the edge.

Care should be taken in planing woody plant establishment so that fishermen are not excluded from the entire bank.

TABLE 3
PERMANENT SEEDING MIXTURE RECOMMENDATIONS BY RATE AND SITE ADAPTATION

Seed as early as possible in the spring and no later than June 1. Late summer/early fall seedings can also be done between August 15 - September 15. These late season seedings are not recommended for mixes 12, 15a, 15b, 18 and 19.

SEED MIXTURE	Variety	Rate in lbs/ac (lbs/1000 ft2)	SOIL-SITE ADAPTATION		
			Excessively Drained	Well to Mod Well Drained	Poorly To Very Poorly Drained
1.Ky. bluegrass*	Adelphi/Baron	20 (.5)	-	X	-
Creeping red	Ensylva	20 (.5			
fescue, or		5 (.1)

24. Wildflower Mix	misc.	various	x	x	x

VOL 12

6409

TABLE 3 (cont.)

* Wildflowers (#24) may be seeded with these mixtures.
** Reed canarygrass. Use only seed with germination rate of 70% or better that has been tested within past 4 or 5 months.
*** (PLS) Pure Live Seed. Warm season grass seed is sold and planted on the basis of pure live seeds (PLS). An adjustment is made to the bulk weight of seed to compensate for inert material and dead seed.

Pure live seed may be calculated when the percent germination and the percent purity is known.

1. Convert % germination and purity to decimal form.

2. PLS factor = germ X purity.

3. Pounds of seed needed = $\frac{\text{seeding rate in pure live seed}}{\text{PLS Factor}}$

EXAMPLE: Want to seed little bluestem at
2 PLS pounds/acre
seed lot has purity of 65%
germination of 80%

so PLS factor = .65 x .80 = .52

Pounds of Seed needed = $\frac{2}{.52}$ = 3.8 pounds

**** Vegetative culms or stems are used as propagates (not seed). Three culms are typically planted per planting hole.

TABLE 4

TEMPORARY SOIL AND WATER CONSERVATION
SEEDING MIXTURES

SEED	LBS./ACRE	LBS./1000 Sq. Ft.
For Spring Seedings:		
a) Annual ryegrass	30	.7
b) Spring oats	80 (2 1/2bu)	2.00
c) Annual ryegrass	15	.35
and		
Spring oats	64 (2 bu)	1.50
d) Perennial ryegrass	30	.7
For Late Spring & Summer Seedings:		
a) Sudangrass	40 (1.0 bu)	.90
b) Annual ryegrass	30	.7
c) Perennial ryegrass	30	.7
For Late Summer & Fall Seedings:		
a) Annual ryegrass (Common)	30	.7
b) Winter rye (Aroostook)	112 (2 bu)	2.50
c) Winter wheat	120 (2 bu)	2.75
d) Perennial ryegrass (Pennfine)	30	.7

TABLE 5 - GUIDE TO MULCH MATERIALS, RATES AND USES

Mulch Material	Quality Standards	Application Rates per 1000 Sq. Ft.	Application Rates per Acre	Depth of Application	Remarks
Sawdust green, or composted	Free from objectionable coarse material	83-500 cu. ft.	--	1-7"	Most effective as a mulch around ornamentals, small fruits & other nursery stock. Requires 30-35 lbs. N/ton to prevent N deficiency while decaying mulch. One cu. ft. weighs 25 lbs
Wood Chips or Shavings	Green or air-dried. Free of objectionable coarse materials	500-900 lbs.	10-20 tons	2-7"	Has about the same use and application as sawdust, but requires less N/ton (10-12 lbs.). Resistant to wind blowing. Decomposes slowly.
Wood Excelsior	Green or airdried burred wood fibers	90 lbs. (1 bale)	2 tons	--	Decomposes slowly Subject to some wind blowing. Packaged. in 80-90 lbs. bales.
Wood Fiber Cellulose (Partly digested wood fibers)	Made from natural wood usually with green dye & dispersing agent added.	50 lbs.	2000 lbs.	--	Apply with hydromulcher. No tie-down required. Less erosion control provided than 2t hay or straw.
Compost or Manure	Well shredded, free of excessive coarse materials	400-600 lbs.	8-10 tons	--	Use straw manure where erosion control is needed. May create problem with weeds. Excellent moisture conserver. Resistant to wind blowing.

TABLE 5 - GUIDE TO MULCH MATERIALS, RATES AND USES (Cont.)

Mulch Material	Quality Standards	Application Rates per 1000 Sq. Ft.	per Acre	Depth of Application	Remarks
Cornstalks, shredded or chopped	Air-dried, shredded into 8" to 12" lengths	150-300 lbs.	4-6 tons	--	Effective for erosion control, relatively slow to decompose. Excellent for mulch on crop fields. Resistant to wind blowing.
Gravel, Crushed Stone or Slag	Washed; Size 2B or 3A - 1 1/2"	9 cu. yds.	--	3"	Excellent mulch for short slopes and around woody plants and ornamentals. Use 2B where subject to foot traffic.(Approx. 2000 lbs./cu.yd.). Frequently used over black plastic for better weed control.
Hay or Straw	Air-dried; free of undesirable seeds & coarse materials	90-100 lbs.2-3 bales	2 T 100-120 bales	cover about 90% surface	Use straw where mulch is maintained for more than three months. Subject to wind blowing unless anchored. Most commonly used mulching material. Best micro environment for germinating seeds.
Peat Moss	Dried, compressed free of coarse	200-400 cu. ft.	1/2-1	2"-4"	Most effective as a mulch around ornamentals. Subject to wind blowing unless kept wet. 100 lbs. bales (6 cu. ft.). Excellent moisture holding capacity.

TABLE 5 - GUIDE TO MULCH MATERIALS, RATES AND USES (Cont.)

Mulch Material	Quality Standards	Application Rates per 1000 Sq. Ft.	per Acre	Depth of Application	Remarks
Jute Twisted Yarn	Undyed, unbleached plain weave Warp 78 ends/yd Weft 41 ends/yd 60-90 lbs/roll	48" x 50 yds or 48" x 75 yds	--	--	Use without additional mulch. Tie down as per manufacturing specification.
Excelsior Wood Fiber Mats	Interlocking web of excelsior fibers with photodegradable plastic netting	48"x100" 2 sided plastic 48"x180" 1 sided plastic	--	--	Use without additional mulch. Excellent for seeding establishment. Tie down as per manufacturers specifications. Approx. 72 lbs/roll for excelsior with plastic on both sides. Use two sided plastic for center - plastic for centerline of waterways.
Glass Fiber	1/4" thick, 7/16" dia., holes on 1" centers; 56 lb. rolls.	72"x30 yds.	--	--	Use without additional mulch. Tie down with T bars as per manufacturers specifications.
Plastic	2-4 mils	Variable	--	--	Use black for weed control. Effective moisture conservation and weed control for small fruits and ornamentals.
Filter Fabrics	Woven or Spun	Variable	--	--	--
Straw or coconut fiber or combination	photodegradable plastic net on one or two sides.	most are 6.5 ft x 83.5 ft	81 rolls	--	Designed to tolerate higher velocity water flow, centerlines of waterways. 60 sq. yds. per roll.

TABLE 6: MULCH ANCHORING GUIDE

Anchoring Method or Material	Kind Of Mulch To Be Anchored	How To Apply
A. Manual 1. Peg and twine	Hay or straw	After mulching, divide areas into block approx. 1 sq. yd. in size. Drive 4-6 pegs per block to within 2" to 3" of soil surface. Secure mulch to surface by stretching twine between pegs in criss-cross pattern on each block. Secure twine around each peg with 2 or more turns. Drive pegs flush with soil where mowing and maintenance is planned.
2. Mulch netting	Hay or straw	Staple the light-weight paper, jute, wood fiber, or plastic nettings to soil surface according to manufacturer's recommendations. Should be biodegradable. Most products are not suitable for foot traffic.
3. Soil & stones	Plastic	Plow a single furrow along edge of area to be covered with plastic, fold about 6" of plastic into the furrow and plow furrow slice back over plastic. Use stones to hold plastic down in other places as needed.
4. Cut-in	Hay or straw	Cut mulch into soil surface with square edged spade. Make cuts in contour rows spaced 18" apart. Most successful on contour in sandy soils.
B. Mechanical 1. Asphalt spray (emulsion)	Compost, wood chips wood shavings, hay or straw	Apply with suitable spray equipment using the following rates: asphalt emulsion: on slopes use200 gal/ac, on level, use 150 gal/ac; liquid asphalt: (rapid, medium, or slow setting) 0.10 gallons per sq/yd. 400 gal/ac.
2. Wood cellulose fiber	Hay or straw	Apply with hydroseeder immediately after mulching. Use 750 lbs wood fiber per acre. Some products contain an adhesive material.
3. Pick chain	Hay or straw manure compost	Use on slopes steeper than 3:1. Pull across slopes with suitable power equipment.
4. Mulch anchoring tool or disk	Hay or straw, manure/mostly straw	Apply mulch and use a mulch anchoring tool. When a disk (smooth) is used, set in straight position and pull across slope with suitable power equipment. Mulch material should be "tucked" into soil surface about 3".
5. Chemical	Hay or straw	Apply Terra Tack AR 120 lbs/ac in 480 gal. of water or Aerospray 70 (60 gal/ac) according to manufacturer's instructions. Avoid application during rain. A 24 hour curing period and a soil temperature higher than 45° F are required.

Point Source Controls: The Potomac River Cleanup

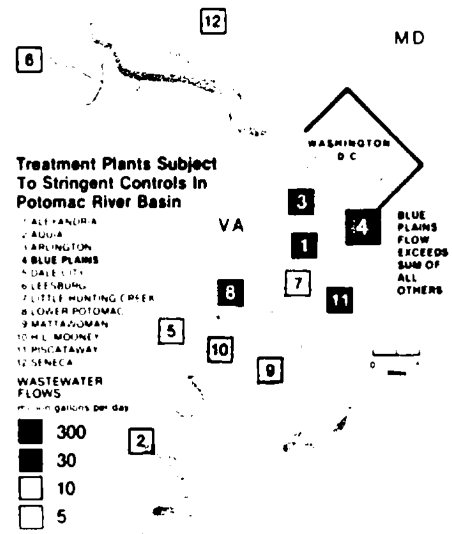
Restoring a river through cooperation and consensus

WASHINGTON METROPOLITAN AREA

Characteristics
- 14,670 square mile drainage basin has approximately 100 tributaries.
- Large quantities (averaging 456 million gallons/day) of treated effluent are released from the Washington, D.C. area.
- Approximately 3 million of the basin's 4 million residents live in the Washington metropolitan area which is adjacent to the estuary; population is projected to increase 20 percent by 2000

Resources
- The river is a major spawning area for anadromous and semi-anadromous fish species, e.g., shad, perch, and striped bass.
- 1985 commercial finfish landings were valued at over $2 million.
- Recreational activities include sport fishing and boating
- Municipal water supply withdrawals averaged approximately 370 million gallons per day (in 1985).

Issues
- Municipal treatment plants are the only major point-source loading
- Nutrient loadings encouraged algal blooms, which have led to low oxygen levels, fishkills, and changes to the ecosystem.
- Estuary cleanup has required a concerted cooperative effort among the Washington region's principal local jurisdictions.



Introduction

In the late 1960's, local, State, and Federal officials began a coordinated and sustained effort to clean up the Potomac River.

Historically, the Upper Potomac River Estuary had suffered from severely degraded water quality. Noxious odors, large mats of floating algae, blue-green algae, depleted oxygen concentrations, and turbid water were frequent conditions. Pollution-sensitive fish (such as large-mouthed bass) and submerged aquatic vegetation had largely disappeared from the river. Bacterial contamination and viruses prevented safe water contact recreation.

Efforts by scientists and local, State, and Federal officials in the past 20 years to implement and upgrade point source controls, however, have dramatically reversed the trend of declining water quality. The States of Maryland and Virginia and the District of Columbia implemented stringent point source discharge limits based on analysis of the upper estuary's assimilative capacity and the capabilities of wastewater treatment technology. These actions have reduced biochemical oxygen demand (BOD) and phosphorus discharges to the upper estuary by 95 percent. Algal blooms are now infrequent, and submerged aquatic vegetation and many species of sportfish have reappeared in the river. Potomac River area residents now benefit from commercial and recreational river uses.

Overview and Characteristics of the Problem

The Potomac River drainage area encompasses portions of the States of Pennsylvania, Virginia, West Virginia, the District of Columbia, and Maryland. About 95 percent of the land in the basin is forested or in agriculture. In sharp contrast, the upper estuary, which extends 54 miles from the northwest boundary of Washington, D.C. to Maryland Point, is highly urbanized. The upper estuary receives the largest volume of flow from treated wastewater discharges. Industrial discharges are insignificant.

The Potomac supports two critical water uses in the Washington area. As a major water supply, the free-flowing part of the river provides about 75 percent of metropolitan Washington's drinking water. The Potomac is also profoundly important to the area as a recreational and aesthetic resource. The river supports boating, fishing, and, in some areas, swimming. Hundreds of miles of parkland border the Potomac, including the Washington, D.C. Tidal Basin, site of several major memorials and tourist attractions.

For much of this century the Potomac has suffered from pollution stresses. During the 1950's it was described as an open cesspool. Rapid development of the Washington metropolitan region was a major factor in the river's decline. Between 1940 and the early 1970's, population growth repeatedly outstripped sewage treatment plant capacity, despite expansions intended to meet demands for years to come. Raw or partially treated sewage was regularly discharged into the Potomac as a consequence of overloaded plants and inadequate sewer capacity.

Of the 11 major treatment plants that serve the Washington metropolitan area, the Blue Plains facility is the largest point source to the estuary. This regional plant, managed by the District of Columbia, serves the city and some of suburban Maryland and Virginia. In 1985, the Blue Plains plant discharged about 309 million gallons a day directly to the estuary—about 65 to 70 percent of the entire wastewater load for the year.

Chronology of the Cleanup Effort

In the late 1950's conferees at the first Federal-State Potomac Enforcement Conference meetings, convened by the U.S. Public Health Service to address water quality problems, recommended secondary wastewater treatment. By 1965, however, water quality in the Potomac had worsened because rapid population growth and accompanying increases in sewage flows had outstripped plant capacities. President Lyndon B. Johnson called national attention to the Potomac when he proposed making it a model for a national water quality improvement campaign. Following his appeal, Congress passed the Water Quality Act of 1965, which required States to establish water quality standards. Jurisdictions in the Washington metropolitan area agreed to adopt a fishable-swimmable standard.

The Federal-State Potomac Enforcement Conference was reconvened in 1969. Conferees developed discharge limits based on an assessment of the estuary's assimilative capacity and available treatment technology. Conferee recommendations, which were strenuously debated, pushed treatment technologies to their limits. Nevertheless, the recommendations were formally accepted in 1970 by the District of Columbia, Maryland, Virginia, and local jurisdictions through the Memorandum of Understanding (MOU) on the Washington Regional Water Pollution Control Plan. upgrades to the Blue Plains regional wastewater treatment plant, allocated capacity for the plant to the District of Columbia and its suburban users, and proposed a schedule for siting and constructing another regional plant to absorb the anticipated increases in treatment demands on the Blue Plains facility.

What appeared to be a workable intermunicipal framework for addressing Potomac pollution problems quickly broke down as the population continued to grow and sewage flows to Blue Plains exceeded jurisdictional flow allocations. Threats of lawsuits to enforce these allocations led to a new agreement in 1971 for interim treatment at Blue Plains. In addition, building moratoria established to restrict sewage treatment demands were not strictly enforced, and demand for treatment continued to grow. Thus, in 1973, the Commonwealth of Virginia filed suit against the Washington Suburban Sanitary Commission (the agency responsible for sewage in the suburban Maryland counties and at that time the prime source of the excess flows). Fairfax County, Va., the District of Columbia, and the Federal government joined the suit.

The parties to the suit ultimately reached an agreement in 1974, the basis for a consent decree that, among other things, limited the amount of sewage each jurisdiction could send to Blue Plains. It also established a formula for jurisdictions using the plant to take responsibility for sludge disposal. A key feature of the decree, lacking in previous agreements, was accountability. Violations, including delays, would constitute a contempt of court and would be punishable.

Throughout the 1970's new treatment technologies were installed and plants constructed and expanded. Potomac water quality began to improve. The upgrading of treatment plants, however, exacerbated an old problem. Advanced waste treatment processes produced substantially larger quantities of sludge than secondary treatment alone had. Difficulties in locating sludge disposal sites led to legal actions in which the District of Columbia sued Maryland's Washington Suburban Sanitary Commission to force disposal of sludge as agreed in the 1974 consent decree.

Anxious to overcome the interjurisdictional squabbling and court battles of the 1970's, representatives from area jurisdictions and treatment plant operators began to form standing committees to negotiate agreements, monitor progress, resolve differences, and plan for future needs on a regular basis. The first and most prominent committee was made up of chief administrative officers (CAO's) representing the principal Blue Plains user jurisdictions and agencies. This committee, known as the Blue Plains CAO's, was organized in 1980 under the auspices of the Metropolitan Washington Council of Governments, which provided neutral grounds for meeting and support staff.

The Blue Plains CAO's Committee undertook the reworking of the wide array of existing agreements, some of which dated back to the 1950's. Committee staff worked diligently, and at one stage met weekly for municipal agreement for managing sewage treatment and sludge disposal through 2010. An informal but important ground rule that has been credited with promoting agreement was the commitment of all participants to stay on at certain critical meetings until the issues at hand had been fully resolved.

The resulting Blue Plains Intermunicipal Agreement was signed by area jurisdictions in September 1985. In addition to sewage and sludge management, the agreement formalized annual funding support to a coordinated program for monitoring and tracking Potomac water quality. This program, managed by the Metropolitan Council of Governments, provides a common and comprehensive data base to enable a scientific approach to water quality planning and decision-making. Another important component of the agreement included the specification of conditions that would regulate or stop a user's commitments for system extensions if its sewage flows exceeded its allocated capacity at Blue Plains. The lack of such a provision in earlier agreements had been a significant problem during the 1970's.

Another important group, the Potomac Studies Policy Committee, was formed in 1985 to develop consensus positions of common interest to the Washington area wastewater treatment community. The policy committee evaluates technical issues associated with Washington area water quality management programs and standards. It addresses estuary-wide problems and the contribution of upstream Potomac pollution loading sources that affect regional water quality, and provides a unified voice for negotiating with water quality regulators. The policy committee strives to achieve balance between treatment technology, costs to users, and water quality standards.

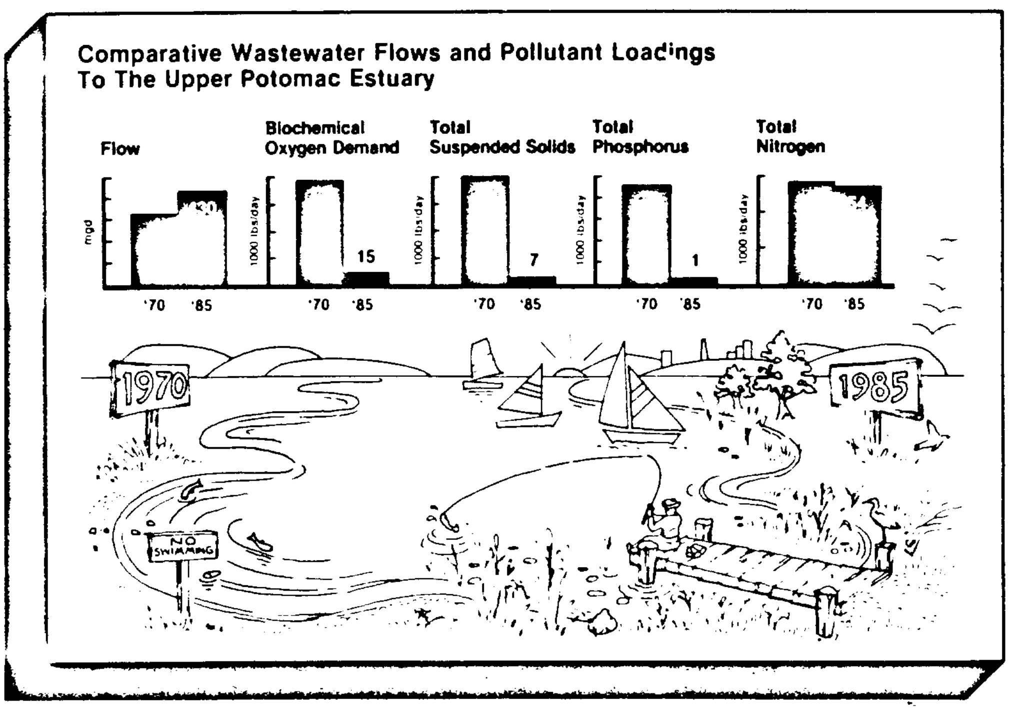
The Blue Plains and Potomac Studies Policy Committees have proven themselves to be valuable forums for ongoing resolution of regional water quality concerns and issues, preventing the crisis atmosphere that pervaded the preceding decade. Participants are pleased with the cooperation achieved between local jurisdictions and wastewater treatment plant operators thus far and are optimistic that it will continue.

Financing

The success of the Potomac cleanup to date has been hard won, taking over 20 years of sustained effort and more than $1 billion investment in capital facility improvements. The 1972 Federal Water Pollution Control Act's Construction Grants Program covered 75 percent of plant construction, expansion, and upgrading costs. Remaining funds came from local government expenditures and State grant programs. The annual operating costs to meet plant discharge requirements now exceed $100 million per year at the Washington region's principal discharges. These costs are financed through local user fees.

Results

Although the original goal, established in the late 1960's, of obtaining fishable-swimmable conditions year-round in the upper estuary remains to be fully real-



ized, significant improvements in Potomac water quality have been made. The improvement in the upper estuary has, in turn, contributed to dramatic improvement in the lower estuary.

Reductions of nearly 95 percent in biochemical oxygen demand and total phosphorus point source discharges highlight the accomplishments.This has been achieved through stringent nutrient limits for municipal wastewater discharges. For example, the current effluent phosphorus limit for Blue Plains is 0.18 mg/L. Effluent limits assigned to Washington area treatment plants could be met only by upgrading secondary treatment plants to advanced waste treatment facilities, which use additional filtration, nutrient removal processes, and chlorination. Improvements to other facilities have also enhanced water quality in the basin. The improvements included increases in sewer transmission and wastewater treatment plant capacities, and improved operational procedures to substantially reduce the incidence of wet weather overflows. Most of the Washington metropolitan area's sewer system is now connected to advanced waste treatment facilities, either on-line or under construction. The Blue Plains plant is one of the largest advanced waste treatment plants in the United States.

Signs of a healthy river that were missing from the estuary during the 1950's and 1960's are now reappearing. Submerged aquatic vegetation and accompanying desirable species of fish and wildlife have returned in abundance to many portions of the river. At the same time, the growth of nuisance blue-green algae has been greatly reduced.

As river water quality has improved, commercial and recreational activities along the river have also reemerged. The waterfront now provides an attractive location for parks, recreational facilities, and restaurants. Boating and fishing are common along the urban stretch of the estuary.

Other sources of pollution have increased in relative significance as Washington area point source loads have been cut. Discharges of nutrients, biochemical oxygen demand, and sediment loadings from upstream point sources, nonpoint sources, and nutrient releases and oxygen demand from river bottom sediments all contribute to pollutant loading inputs to the upper estuary.

The participants in the Potomac cleanup program have turned their attention to meeting the new challenges. The existing regional monitoring network and data base are already being used, and the 1970 Memorandum of Understanding has been revised and reaffirmed. The regional framework developed to confront point source removal is providing a ready forum for addressing emerging issues.

While some pollution problems remain, further progress will require improved wastewater treatment at smaller facilities upstream and downstream of the Washington, D.C. region. Implementation of effective nonpoint source controls, particularly for agricultural nonpoint source loadings, will also be needed.

Lessons Learned

The latest round of Potomac River cleanup activities has taken two decades to reach its current level of success. The effort has been difficult, but it has worked. Its success was due to people who insisted on more than the status quo. They invested in technologies required to meet stringent effluent limits to protect the estuary. They strove for cooperative agreements and held others to them, going to court when necessary. It took technical talent – the scientists who developed the models and analyzed the data, the treatment plant operators and engineers who implemented the requirements. It took money – a combined local, State, and Federal investment exceeding $1 billion in capital facilities, and user fees of over $100 million a year in plant operation costs. Most important, the cleanup succeeded because of the initiative, cooperation, and sustained commitment of local agencies to hammer out and implement the interjurisdictional agreements necessary to make it work.

Improving conditions in the Potomac required an enormous effort to overcome resistance to building moratoria, legal suits, press coverage, and a charged atmosphere among the participants. Ultimately, however, a high level of cooperation among local governments and the regulatory agencies led to the dramatic improvement in water quality conditions that area residents now enjoy. Through the efforts and battles along the way, a strong and lasting framework for cooperation has evolved.

The Potomac's cleanup was facilitated under the regional policy and technical committee structure which evolved in the 1980's to track progress and evaluate future water quality management needs. This structure has proven quite effective as a forum for developing consensus positions on regional water quality management issues and programs. It derives its strength and continuity through a collective local government commitment to the support of a centralized technical staff, data base, and reporting function dedicated to the assessment and resolution of Potomac water quality issues.

But for all the achievements, the greatest lesson from the Potomac's experience may be that strategies for pollution control must be flexible and continually evolving. New problems and questions have emerged as a result of regional successes in reducing point source loadings. For example, environmentally sound and cost-effective sludge management programs, acceptable to both regulatory agencies and local communities, must be found and agreed upon. Area decisionmakers and residents must evaluate to what extent they are willing to protect area water quality and identify the most cost-effective, practical, and acceptable management programs.

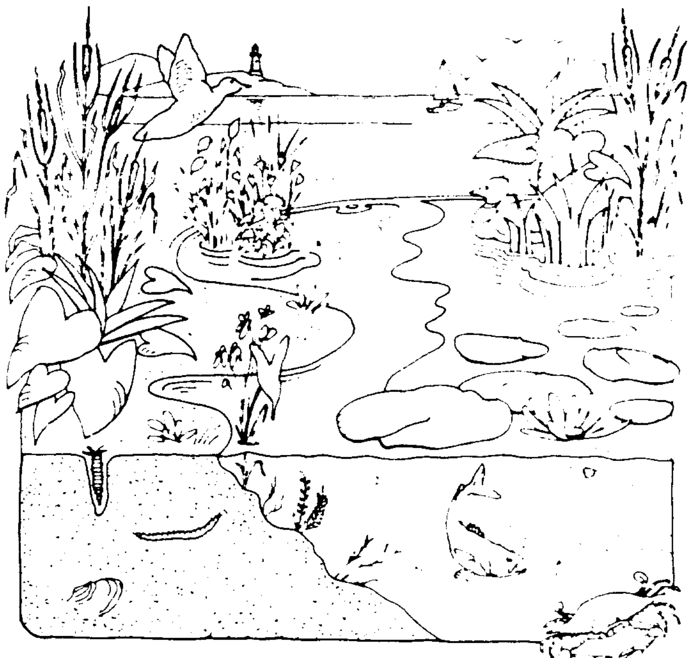
Saving Bays and Estuaries: A Handbook of Tactics

Introduction

VOL 12



Estuaries—where rivers meet the sea, and fresh water mixes with salt—are among the earth's richest and most productive habitats. They serve as the principal spawning grounds and nurseries for at least two-thirds of our Nation's commercial fisheries, provide irreplaceable recreational and aesthetic enjoyment, and are home to valuable and diverse species of fish, shellfish, and wildlife.

They are also home to people. Already, 70 percent of the U.S. population lives within 50 miles of a coastline, and that number is growing. But with people comes pollution, and our estuaries are clearly in trouble, threatened by toxic and bacterial contamination, sewage discharges and agricultural runoff, oxygen-depleted waters, and loss of fish and wildlife habitat.

Learning Through The National Estuary Program

There are no easy answers to these problems, but we have learned some lessons. One is that estuaries are complex ecological systems with subtle dependencies among many species and habitats. If conditions change in one area, they will also change in others. In estuaries, there are very few purely local effects.

We've also learned that conventional, "end-of-pipe" pollution controls are not enough. Agricultural runoff and other nonpoint sources contribute pesticides and excess phosphorus and nitrogen to bays hundreds of miles away; the wind carries in toxics that contaminate bottom sediments in otherwise pristine waters. Yet how do we regulate homeowners who put too much fertilizer on their lawns? How does one State control air pollutants coming from another State on the other side of the country?

Finally, we've learned that saving our estuaries and

6430

R0039738

EPA

Strategies for Protecti..g

coastal waters is a long-term process. It will demand heavy commitments of time, money, and support from everyone who affects or uses or benefits from their resources. Just as important, it will require a fresh approach to solving environmental problems, one that recognizes we are dealing with integrated ecosystems, not clusters of isolated problems.

EPA's National Estuary Program provides an opportunity to apply these hard-won lessons. Under the law, its mission is to protect and enhance water quality and living resources in estuaries by helping States to develop and carry out basin-wide, comprehensive programs to conserve and manage their estuarine resources.

This handbook shares some of the experience gained in this process in estuary programs throughout the country and demonstrates many innovative tactics for

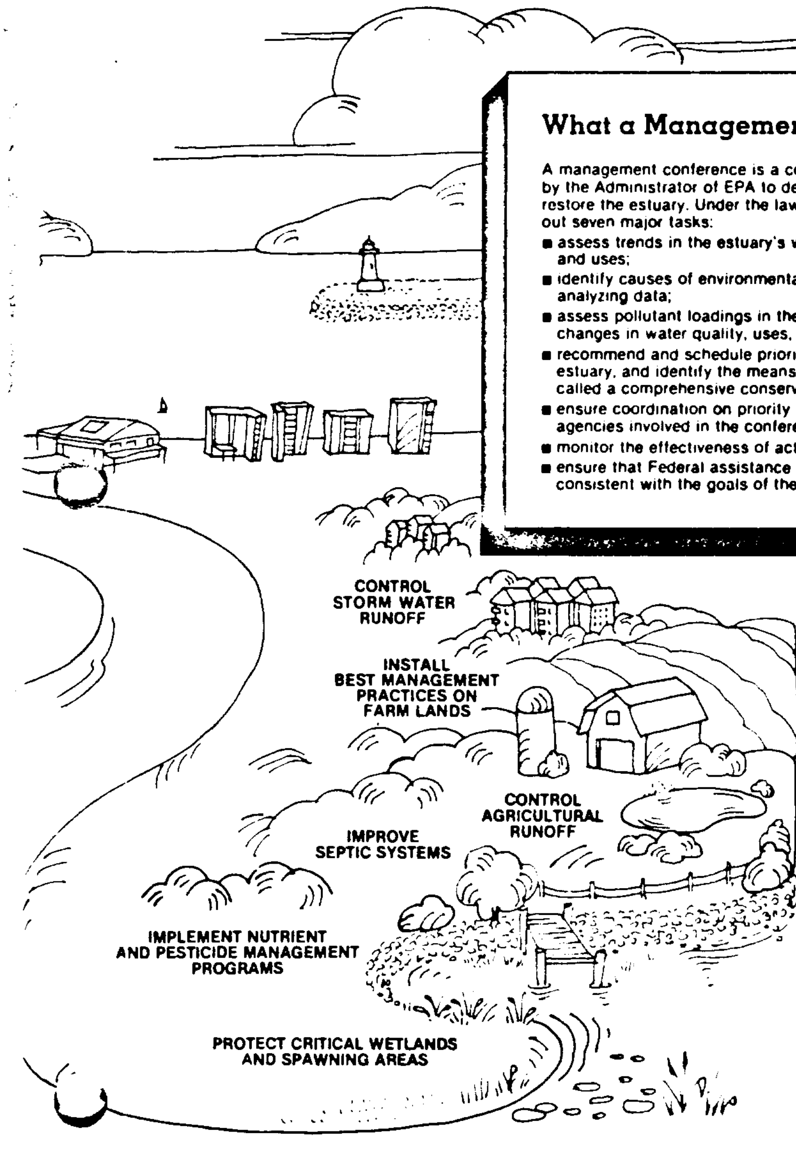
Bays and Estuaries



What a Management Conference Does

A management conference is a committee convened for a specific estuary by the Administrator of EPA to decide what actions to take to protect or restore the estuary. Under the law, a management conference must carry out seven major tasks:

- assess trends in the estuary's water quality, natural resources, and uses;
- identify causes of environmental problems by collecting and analyzing data;
- assess pollutant loadings in the estuary and relate them to observed changes in water quality, uses, and natural resources;
- recommend and schedule priority actions to restore and maintain the estuary, and identify the means to carry out these actions (this is called a comprehensive conservation and management plan);
- ensure coordination on priority actions among Federal, State, and local agencies involved in the conference;
- monitor the effectiveness of actions taken under the plan; and
- ensure that Federal assistance and development programs are consistent with the goals of the plan.

dealing with major estuarine and coastal problems. Three ecosystem management areas are covered: water and sediment quality; living resources; and land and water resources. Other areas of interest include technical support and financial resources.

The case study format is designed to present information clearly and quickly, and also identifies sources of additional information. We encourage readers to use the handbook along with the *Estuary Program Primer*, a manual for establishing and managing estuary programs, and hope that these case studies will alert managers to innovative management tools and help them avoid costly mistakes. We also hope that users will find new ways to apply the lessons presented in these case studies and that participants in other programs will share their experiences. We plan to expand the handbook as new approaches and lessons emerge with experience.

The National Estuary Program welcomes comments and suggestions for additions to this handbook. For more information contact:

EPA

The National Estuary Program

The purpose of the National Estuary Program is to identify nationally significant estuaries, protect and improve their water quality, and enhance their living resources. Estuaries are to achieve these goals through collaborative efforts called *comprehensive conservation and management plans (CCMPs)*; development of CCMPs is carried out by oversight committees called *management conferences*.

The legislation that established the National Estuary Program named 11 estuaries to receive priority consideration to be in the program. These are Albemarle/Pamlico Sounds, Long Island Sound, Buzzards Bay, Narragansett Bay, Puget Sound, San Francisco Bay, Galveston Bay, Sarasota Bay, Delaware Bay, Delaware Inland Bays, and New York-New Jersey Harbor. Santa Monica Bay was added to this list in the Fiscal Year 1988 Appropriations Act.

The Administrator of EPA selects estuaries for the program in response to nominations by State governors, or at the Agency's initiative in the case of interstate estuaries. Estuaries are selected based on their potential to address issues of significant national concern, as well as their demonstrated institutional, financial, and political commitment to carry out protective actions. Once an estuary is selected, the Administrator formally convenes a management conference.

Management conferences provide a framework for interest groups to work together to develop comprehensive plans and timetables (the CCMPs) to protect and restore the estuary and coastal areas. Conference members must include citizen and user interest groups, scientists, government officials, and resource managers from Federal, State, and local agencies.

Representatives from these groups sit on an oversight committee that serves as the formal management conference and oversees development of the CCMP. Other technical, policy, and citizen advisory committees may provide supplemental advice and help. This committee structure approach was first developed in the Chesapeake Bay and Great Lakes programs and has worked very well. We expect it will work equally well for other estuary and near coastal water programs.

A Phosphorus Strategy for the Great Lakes

Improving water quality through intergovernmental agreements

UNITED STATES/CANADA

Characteristics

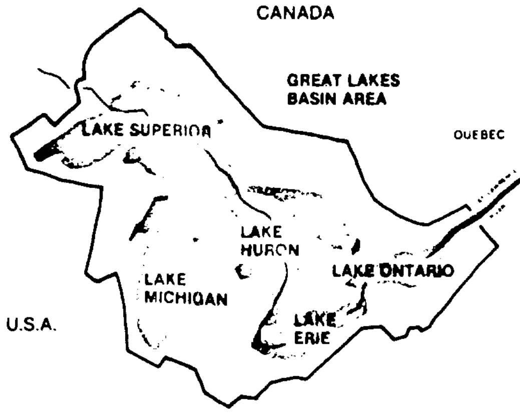
- The largest freshwater bodies in the world, the Great Lakes comprise:
  - 20 percent of the earth's fresh surface water.
  - 95 percent of North America's fresh surface water.
  - 6 billion gallons of water discharged per hour via the St. Lawrence River.
- Retention times for water in the lakes range from less than 3 years to over 200 years.

Resources

- The Great Lakes are the center of U.S. heavy industry.
- $155 billion of economic activity occurs annually.
- $3 billion in recreational activity occurs annually.
- 24 million Americans depend on the lakes for drinking water.

Issues

- Loss of commercial fishing continues.
- Aesthetics and recreation are impaired.
- Drinking water resources are affected.
- Public health risks from food consumption continue.



Introduction

Recognizing the importance of the Great Lakes, the U.S. and Canadian governments have operated a long-term intergovernmental program to control direct and indirect sources of pollution, monitor conditions, and assess trends in the water quality and biological health of the lakes. By the late 1960's the effects of years of pollution in the Great Lakes were alarming, particularly in Lake Erie and Lake Ontario. Eutrophication – a natural process of nutrient enrichment and silting – was accelerated by high levels of phosphorus entering the lake. As a result, oxygen depletion was widespread and many previously abundant fish species and other aquatic organisms were virtually eliminated.

By setting pollution control goals that the two countries could agree on, the Great Lakes Water Quality Agreements of 1972 and 1978 have guided a successful cleanup and restored a viable fishery for the world's largest freshwater system. These joint initiatives address conventional pollutants (such as plant growth-inducing nutrients) as well as toxic contaminants entering the lakes from land-based activities. The nutrient control aspects of the program are discussed here.

Overview and Characteristics of the Problem

The Great Lakes contain 95 percent of the fresh surface water in North America. This vast resource supports commercial and recreational fisheries, water supply, shipping, and aesthetic enjoyment. The five Great Lakes, their interconnecting channels, and the St. Lawrence River outlet to the Atlantic Ocean are integral components of the U.S. and Canadian economies. The Great Lakes basin supports one fifth of all American industry. Over $180 billion in annual economic activity is based on the Great Lakes: the Canadian portion of the Great Lakes Basin accounts for $27 billion in economic activity; the U.S. portion accounts for $155 billion.

VOL 12

6434

In the past 170 years, the population of the Great Lakes basin has increased more than a hundredfold. Today, the basin is home to nearly 37 million people, comprising a third of the Canadian population and a seventh of the American population. This growth was accompanied by increasing point and nonpoint source pollutant inputs to the ecosystem. By the 1930's, the impacts of these pollutants were becoming apparent in the biological, physical, and chemical components of the Great Lakes ecosystem. Commercial fish species (lake trout, blue pike, whitefish, sauger, and lake herring) declined sharply; the once-abundant mayfly disappeared from western Lake Erie, Green Bay, and Saginaw Bay; and populations of opossum shrimp vanished from Lake Erie. Algal production, however, not only increased, but shifted from predominately free-floating forms valuable as food for fish fry toward more troublesome species typical of elevated nutrient conditions. Long-term changes in both open-lake and near-shore water chemistry reflected eutrophic conditions from nutrient enrichment.

The dramatic changes in fish communities and other aquatic organisms were directly linked to decreased oxygen levels. Linkages were particularly well documented in western Lake Erie, Green Bay, and Saginaw Bay. In the central basin of Lake Erie, for example, roughly 70 percent of the bottom waters developed pronounced oxygen deficits each year.

Program Development

The institutional framework for the Great Lakes cleanup was actually established in 1909 by a Boundary Water Treaty between the United States and Canada. The treaty established the International Joint Commission, which was asked in 1964 by the U.S. and Canadian governments to study the water quality conditions in Lakes Erie and Ontario (the "Lower Lakes") and the St. Lawrence River. In 1970, the commission reported its findings:

- Lake Erie (and particularly the Western Basin) was already in an advanced state of eutrophication, and the eutrophication of Lake Ontario was accelerated. In both cases, current and historic nutrient loadings were at fault.
- Phosphorus is the only nutrient required for growth whose level can be effectively controlled with current technology such as widespread improvements in existing municipal and industrial wastewater treatment plants.
- The major phosphorus source to the lakes is municipal sewage; agricultural runoff and industrial wastes are the only significant nonsewage phosphorus sources.
- Detergents contribute 70 percent of U.S. and 50 percent of Canadian sewage phosphorus.

Based on these findings, the commission recommended that the Governments of Canada and the United States enter into agreement on an integrated phosphorus control program, to include

1. An immediate reduction in detergent phosphorus content (to a minimum practicable level) followed by the complete replacement of detergent phosphorus with environmentally less harmful materials, by December 31, 1972;

2. An 80 percent reduction in nondetergent residual phosphorus in municipal and industrial waste effluents discharging to Lakes Erie and Ontario and the international portion of the St. Lawrence River by 1975, with subsequent reductions to the maximum extent possible by economically feasible processes; and

3. General reductions in agricultural inputs of phosphorus to Lakes Erie and Ontario and the international portion of the St. Lawrence River.

KEY COMPONENTS OF NUTRIENT CONTROL STRATEGY

- PHOSPHATE DETERGENT BAN
- AGRICULTURAL NONPOINT SOURCE CONTROLS
- STRINGENT MUNICIPAL AND INDUSTRIAL POINT SOURCE CONTROLS

The findings and recommendations of the commission indicated the severity of the problem, the need for major pollution control actions, and the need for broad political support. To meet these needs, it was determined that an international agreement must be forged to implement a binational cleanup effort. As a result, the first Great Lakes Water Quality Agreement was signed by the United States and Canada on April 15, 1972, agreeing to the need for a phosphorus reduction program based on commission findings.

Then during the mid-1970's additional modeling work was completed, which

- Quantified how much phosphorus entered the system from point, nonpoint, and atmospheric sources and determined how many tons of phosphorus reduction per year would be needed to meet the target reduction in each lake;
- Set target phosphorus concentrations for each lake to achieve a healthy ecosystem.

Using these modeling tools, a new agreement was signed in 1978 that

- Allocated these phosphorus reduction requirements to each country, and
- Determined how many tons of phosphorus reduction per year would be needed to meet the target concentration for each lake.

Control Program

Point source controls, especially on municipal wastewater treatment plants, provided the basic thrust of the phosphorus reduction program. A treatment level of 1 mg/L phosphorus in treatment plant effluent was established for all plants of 1 million gallons per day or greater capacity under the 1978 agreement. Reaching this level required plants to use advanced wastewater treatment. It was also recognized that effluent controls alone would not meet the goals, and additional reductions from agricultural nonpoint controls and phosphate detergent bans would be necessary.

VOL 12

6435

Although great progress occurred during the 1970's, the 1983 update of the Great Lakes Water Quality Agreement mandated development of U.S. and Canadian Phosphorus Management Plans. The U.S. plan, submitted in 1986, states that if nonpoint source controls do not achieve the necessary additional reductions in total phosphorus loadings (to be determined in a scheduled 1988 progress review), municipal treatment plants will be required to meet effluent phosphorus levels below the current 1 mg/L limit. The plan further states that the water-quality based controls mandated in the Clean Water Act will be implemented if the combined effect of advanced wastewater treatment and nonpoint source control do not meet the in-lake phosphorus concentrations required by the agreement.

Responsible Authorities and Financing

In the United States, the primary implementing agencies are the U.S. EPA and the eight States bordering the Great Lakes. The Great Lakes National Program Office was established within EPA to monitor the progress and effectiveness of U.S. efforts toward achieving the goals of the agreement, as well as to provide technical and management assistance to States, counties, and local jurisdictions in implementing the agreement. In Canada, primary responsibility for implementing the agreement rests with Environment Canada and Ontario's Ministry of the Environment.

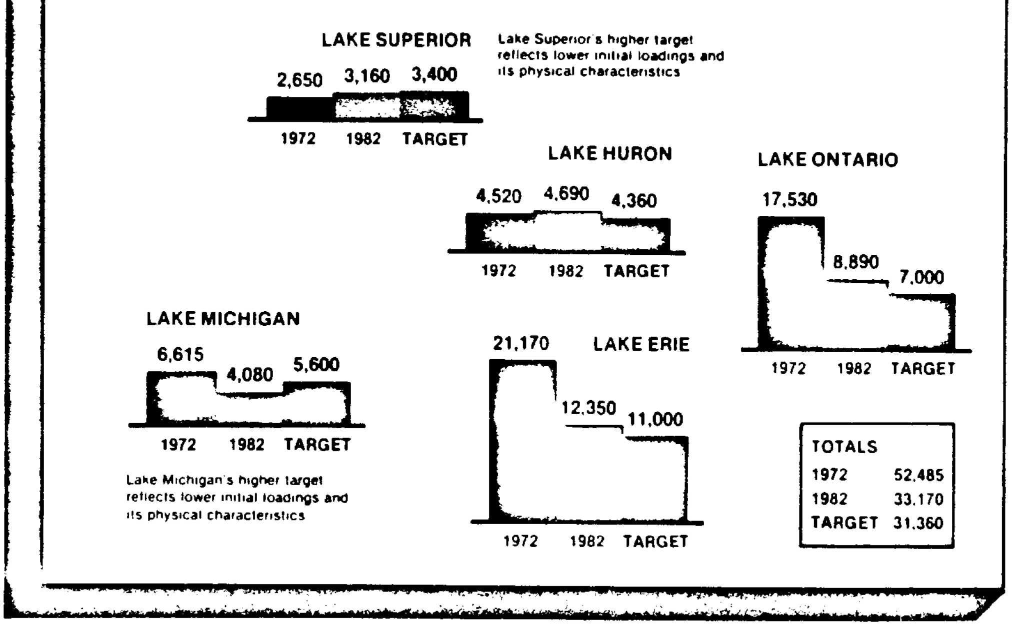
In the United States, new NPDES discharge permits were issued for essentially all major point source dischargers in the 1974-1975 period. EPA tracked these permits with a compliance monitoring system to flag frequent or large violations. Compliance with the permitting system was high, but Federal and State-level administrative enforcement (violation notices, compliance orders, etc.) was also a major factor in the program's success in achieving phosphorus load reductions from point sources.

Nonpoint control programs have centered on controlling soil erosion. A variety of programs conducted by USDA entities (Soil Conservation Service, the Agricultural Stabilization and Conservation Service, Forest Service, Farmers Home Administration, and the Cooperative Extension Service) to promote soil conservation and erosion control have proven useful. Several Federal/State/local cooperative demonstration projects have been conducted to test farm management practices, such as conservation tillage. A major field test of conservation tillage for phosphorus control was funded through EPA's Great Lakes Program Office (under section 108 of the Clean Water Act) in 31 counties in Indiana, Ohio, and Michigan.

Results

Since 1972, over 1,000 municipal treatment plants have been constructed or upgraded. At the same time, in-

Progress in Meeting Phosphorus Targets (In metric tons / year)



fluent phosphorus loads to these and other plants were reduced through broad enactment of legislation to control phosphorus in household detergents. As a result, most municipal wastewater point sources of over 1 million gallons a day capacity have now achieved or exceeded the 1 mg/L effluent phosphorus limit and the average point source phosphorus load reduction goals of the agreement are being attained. As a result of the phosphorus control provisions of the agreement, significant decreases in phosphorus levels are reported in all the Great Lakes. Excepting certain localized areas, the Upper Lakes (Superior, Huron and Michigan) are no longer overenriched. In the Lower Lakes, Lake Ontario exhibits reduced overall phosphorus concentrations and diminished algal biomass. In Lake Erie, the levels of free-floating microscopic plants in the open water have decreased and shifted toward species found in balanced-nutrient systems. U.S. phosphorus loadings to Lake Erie from municipal treatment plants decreased by 62 percent from 1972 to 1978, and by 1982 the load had dropped to only 16 percent of the 1972 level. Within five years of the 1972 agreement, 64 percent of the municipal treatment plants and 76 percent of the industries on the U.S. side were in compliance with the point source limits established to meet the goals of the agreement. The corresponding Canadian figures were 89 percent and 50 percent, respectively. To date, more than $7.5 billion have been spent or obligated in the United States and Canada for municipal sewage construction in the Great Lakes basin (resulting in an 80-90 percent reduction in municipal phosphorus loads), with another $1 billion from local governments and industries. In the United States, the majority of this money has been spent through the section 201 Construction Grants Program, under the Clean Water Act.

Lessons Learned

A principal reason for the success of the Great Lakes phosphorus control initiative was the degree of commitment made to its objectives at the highest levels of the affected governments. This commitment was backed with Federal legislation and a multibillion dollar grant program.

Another reason for the program's success was the commitment of the government to continual response. Within two years of the International Joint Commission's 1970 report, a point source control program was in effect; within five years, enforceable point source limits for all major municipal and industrial discharges were in effect. Although many technical questions were unanswered in 1972, responsible governmental officials on both sides of the basin decided that sufficient information existed to support a coordinated, programmatic response. Further scientific research on problem definition and understanding has continued in parallel with, and with the financial support of, the overall phosphorus control program.

The Great Lakes Water Quality Agreement provides the legal basis for nutrient management of the Great Lakes ecosystem. Under the authority of the agreement, the Great Lakes National Program Office reviews major municipal and industrial point source discharge permits for adherence to the phosphorus management goals of the agreement. This unique feature ensures that local dischargers conform to the terms of the agreement.

A Comprehensive Source Control Program for Protecting Shellfish Waters

Citizen action preserves shellfish resources

TILLAMOOK BAY, OREGON

Characteristics
- The basin has five individual watersheds containing 363,520 acres:
  - -89 percent forestland
  - -6 percent agricultural land with intensive dairy farming adjacent to the bay.
- Annual precipitation averages from 90 to 150 inches

Resources
- Tillamook Bay is the most productive oyster and clam growing water in Oregon.
- Lowland areas are used intensively for dairy farming.
- Recreational activities (e.g., boating, fishing) attract more than a million tourists each year.

Issues
- Concentrated livestock wastes and the region's wet weather create severe runoff problems and contaminated conditions.

FECAL COLIFORM REDUCTIONS IN TILLAMOOK RIVERS

RIVER	% REDUCTION
KILCHIS	30%
MIAMI	78%
TRASK	62%
TILLAMOOK	58%
WILSON	53%

Introduction

The State of Oregon has implemented a program to protect the shellfish in Tillamook Bay from recurring incidents of bacterial contamination. Tillamook Bay is Oregon's most productive oyster and clam growing area—80 percent of the State's commercially harvested oysters come from its waters. The State program, which has been supported by Federal agencies and local governments, focuses on controlling point and nonpoint pollution sources.

The lowland areas surrounding the bay are neither highly industrialized nor densely populated overall. Several small towns exist, but most of the land is devoted to intense dairy farming. Runoff from agricultural operations in combination with sewage treatment discharges from the local towns had created the bacterial contamination problems in Tillamook Bay. High fecal coliform contamination threatened shellfish harvesting and the local economy.

The Oregon Department of Environmental Quality and others addressed the problem by implementing best management practices on the dairy farms and upgrading local sewage treatment plants to control bacterial pollution. These actions have kept the bay open for safe shellfish harvesting.

Overview of Bay Characteristics and Problems

Tillamook Bay drainage basin is located 60 miles west of Portland on the northern Oregon coast. Five major rivers drain 97 percent of the basin and discharge to Tillamook Bay. Most of the bay is shallow. At high tide the bay's average depth is just 6 feet; at extreme low tide, water is confined mostly to the narrow channels. Ninety percent of the basin is steep, mountainous, forested terrain and sparsely populated. Eight percent of the land area is relatively flat and devoted to agriculture and population centers.

Shellfishing in Tillamook Bay includes recreational and commercial clamming, and commercial oyster harvesting. Annual harvest approaches 600,000 pounds of clams and 175,000 pounds of oysters. The bay and its tributaries support a good finfishery for salmonid species (chinook, silver chum, salmon, and steelhead). Because of the popularity of the northern Oregon coast, many tourists camp, fish, and bike along the bay.

In the lowlands, 118 farms with nearly 20,000 cattle line the lower portion of the Tillamook watershed. Approximately 13,000 people live in the bay basin. A little less than half the population is served by sewers; the remainder uses on-site sewage systems. Together, the presence of concentrated livestock wastes (280,000 tons of manure per year) and the region's wet weather (average rainfall 90-150 inches per year) created severe problems of bacterial pollution via runoff.

Following moderate to large storms, fecal coliform counts were often high in the bay. Coliform bacteria reside in the intestinal tract of warm-blooded animals; their abundant presence in water indicates significant fecal contamination. In addition, when fecal coliform counts are high, other more harmful bacteria and pathogens from warm-blooded animals may also be present. These high bacterial counts are the basis for closing the bay to shellfish harvesting. The bacterial problem created a serious human health hazard and threatened an important industry.

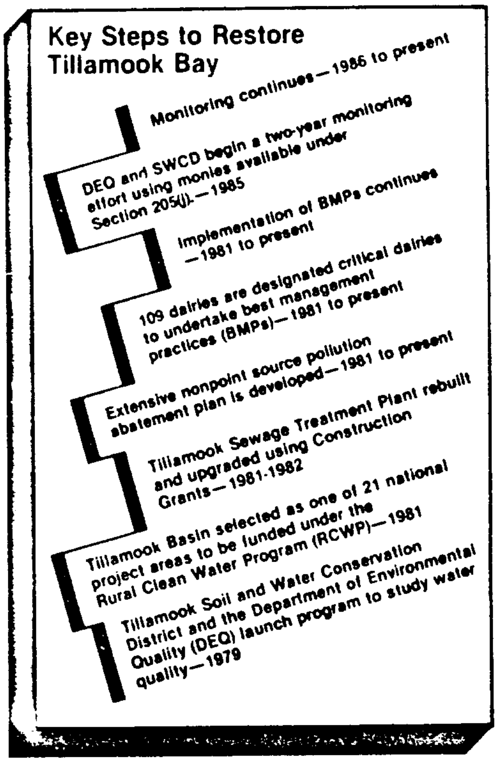
Problem Characterization

In 1979, a program between the Tillamook Soil and Water Conservation District and the Oregon Department of Environmental Quality was set up to monitor water quality in the bay. This program included a review of existing data and collection of additional water quality data. Using information gathered during the initial study, the Department of Environmental Quality conducted a project to specifically identify the sources, extent, and dynamics of fecal pollution occurring in the bay and its watershed. During the investigation six major potential fecal sources were examined: (1) sewage treatment plants, (2) recreation, (3) forestry activities, (4) industries, (5) agricultural operations, and (6) on-site subsurface sewage disposal systems. A comprehensive Tillamook Bay Fecal Waste Management Plan was developed for protecting the shellfish resource.

The study concluded that fecal coliform bacteria detected in the bay originated from farms (manure), poor sewage treatment plants in the river subbasins, and inadequate subsurface drainage. Of these, the study identified malfunctioning sewage treatment plants and dairy operations as the primary sources.

Process

The Tillamook study was conducted through a combined effort of Federal, State, and local government officials and the cooperation of the local dairy industry. Local citizens were actively involved throughout the study and development of a management plan. A group of citizens met regularly to review the data col-



lected and analyzed by the Department. These same people also worked cooperatively with the Department and the Soil Conservation Service to develop the management options for controlling the problem. Dairymen working with the Soil Conservation Service helped develop the solutions to the dairy problems. County and State sanitarians developed control strategies for the septic tank problems. Sewage treatment plant owners and operators developed the strategy for minimizing impacts from their plants.

Meetings as well as phone calls and personal contacts with the study team have involved the public in the policymaking process. Implementation of the management plan was rendered less controversial and more effective because the local citizens knew why a control plan was necessary and were able to communicate their concerns and contribute their suggestions from the beginning. A local coordinating committee, including both State and local officials, continues to meet regularly to discuss the progress of the program. The County Extension Service also organizes important interagency meetings (EPA, FDA, DEQ). The Extension Service conducts a comprehensive educational and information program, including media releases, talks to civic groups, and tours. These tours are often for other farmers from outside the county who are interested in the practices being used in the Tillamook area.

Management Plan Development and Implementation

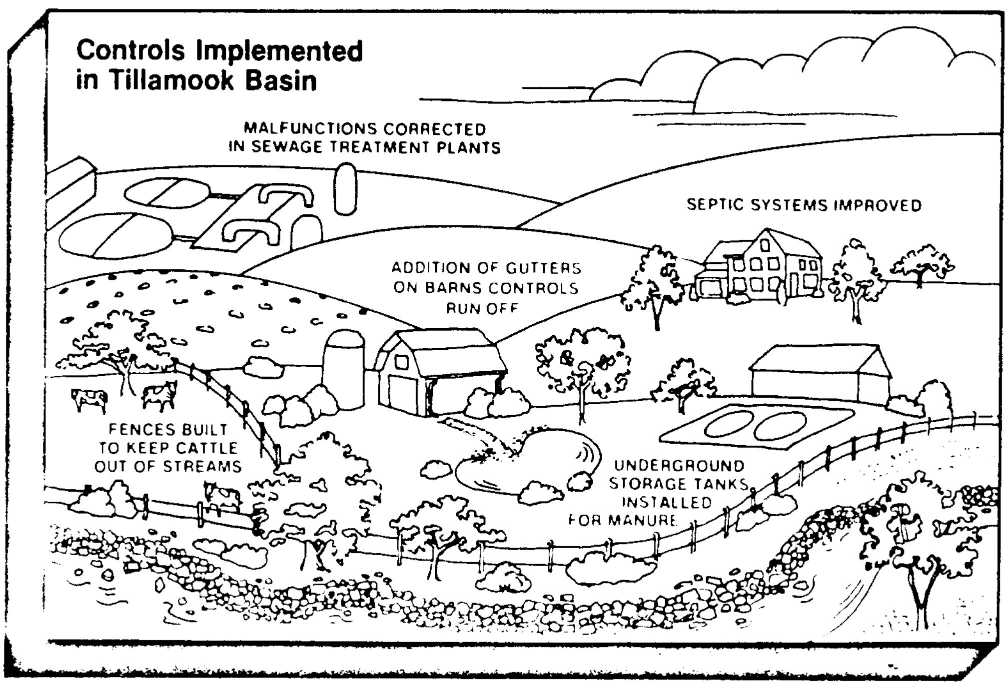
Interested citizens and the Department of Environmental Quality developed three management options to control shellfish contamination: (1) closing the bay to harvesting of shellfish until the problem corrected itself; (2) initiating new types of corrective actions aimed at reducing the pollution potential of the identified fecal sources and developing harvesting criteria for the bay; or (3) strengthening existing pollutant control programs and developing harvesting criteria for the bay. The last option was chosen because it was the most cost-effective and did not negatively impact the shellfish industry, which already had self-imposed limited harvesting during critical runoff periods.

Recognizing the need for immediate action to protect the public health and the long-term nature of the cleanup, the Department adopted a standard procedure for determining when to open or close the bay to shellfish harvesting. This procedure relied on five criteria that were developed by the Department of Environmental Quality and State Health Department. Any one of these criteria could be used to close shellfish beds for 5 to 10 days. The bay is automatically closed when a sewage treatment plant bypass or malfunction occurs, during high river flow, and during periods of frequent rainfall.

Since the dairy waste was considered to be one of the most pervasive problems, the Soil and Water Conservation District and the dairy community developed an extensive cleanup plan to address the animal waste problem. The strategy relied on two principles: (1) prevent rainwater and clean surface water from coming into contact with manure, and (2) when this is not possible, prevent contaminated surface water from reaching the streams or the bay. To implement the plan, 109 dairy farms were designated as critical dairies. To achieve the goal of a 70 percent reduction in fecal coliform loading, all critical dairies were encouraged to undertake best management practices (BMP's). Each farmer developed individual farm water quality plans. Each plan addressed the water quality problems of that farm, best management practices that would be used to alleviate them, and a 3- to 10-year schedule for implementing the practices.

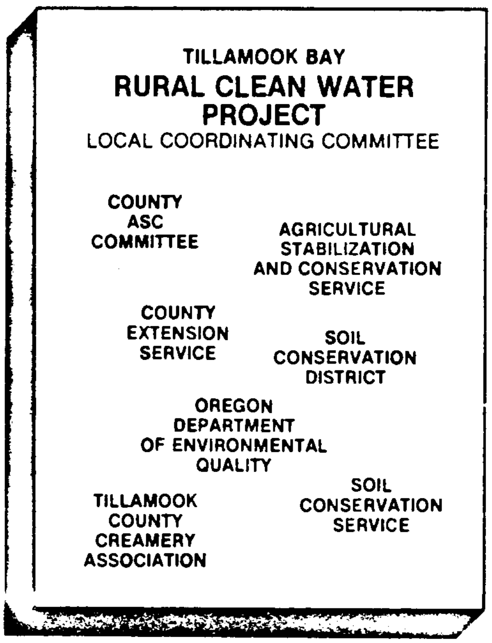
To ensure that the most critical sources were treated first, each farm was ranked based on factors such as the distance of confinement areas to open water, the acreage of poorly drained soils where manure is spread, the number of cattle per acre, and the farm's location in the watershed and floodplain. The BMP's applied by farmers included installing solid and liquid manure storage facilities, roofing animal manure accumulation areas, erecting streambank fencing, and managing roof water.

The other critical problem identified in the plan, sewage waste, was addressed by the Department of Environmental Quality. Sewage treatment levels were determined to be adequate, but malfunctioning equip-



ment problems did occasionally occur. To rectify the problem, alarms and shutdown devices were installed at the sewage treatment plant. The Fecal Waste Management Plan instituted procedures to notify health officials of malfunctions so that shellfish beds could be closed. In addition, many failing septic systems have been eliminated as a pollution source by the expansion of a municipal sewer line.

The Fecal Waste Management Plan and Bay closure criteria were adopted by local and State agencies in July 1981. The criteria were implemented in 1982. Currently, the closure criteria are being re-evaluated based on continuing fecal coliform monitoring results.



Responsible Authorities and Financing

Funding for the program came from a variety of sources. The Tillamook Bay bacteria and water quality management plan study were originally funded by U.S. EPA 208 funds. Upgrades to the Tillamook sewage treatment plant were financed through EPA construction grants. The nonpoint cleanup effort was funded through USDA's Rural Clean Water Program, which provided a cost-share of up to 75 percent of the landowners' costs. The local Agricultural Stabilization and Conservation Service has received more than $4 million through this program to assist dairy owners in the implementation of BMP's. The farmers have also committed more than $3 million of their own money to support this effort. In 1986, the Department of Environmental Quality and the Soil and Water Conservation District began a new monitoring program funded by U.S. EPA 205(j) funds to assess the effectiveness of the management plan.

Results

Water quality and fecal contamination levels are improving basinwide from cleanup activities. Although implementation is not yet complete, the project has been able to show significant water quality improvements in both the rivers and the bay. In 1985 bay closures were invoked less frequently, and employment in Tillamook's oyster industry was the highest since 1952. Industries and dairy farming are still open for business.

Best management practices are working and water quality conditions are approaching desirable levels. Work on the farms is 45 to 50 percent complete. Recent water quality data analysis shows that fecal coliform contamination of the bay has already been significantly reduced between 1980 and 1985. Based upon the projected level of BMP implementation and the decline of fecal coliform concentration already observed, it appears that by 1991 Tillamook Bay will routinely meet shellfish water quality standards, although unusual weather conditions could cause a temporary problem.

Lessons Learned

Continued improvement of the water quality is expected for Tillamook Bay and its tributaries. With the knowledge of who, how, and when sources of pollution operate and discharge in a watershed and bay, point and nonpoint source discharges can be controlled to protect a shellfish industry.

The success of the plan is attributable to a number of factors:

- The County Extension Service Soil and Water Conservation District, the Agricultural Stabilization and Conservation Service, Soil Conservation Service, and the Creamery Association worked together closely from the beginning of the program. These agencies worked cooperatively to create strong public involvement. The involvement of local citizens throughout all phases of the project fostered local pride in the accomplishments and, more important, fostered a pride in the livability of the Tillamook area.
- Cost-sharing money became available and was adequate to show immediate progress.
- The project was very closely tied to an important resource, which made the community highly interested.
- The solutions were fairly easy to develop and implement.

Strategies for the Preservation of an Estuarine Watershed

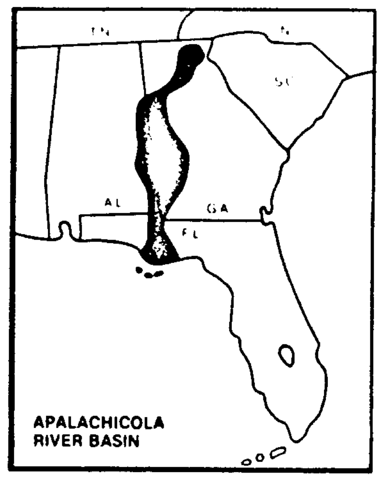
Preserving watersheds through land purchases and protective designations

APALACHICOLA BAY, FLORIDA

Characteristics
- The estuary covers approximately 210 square miles.
- The basin drains 19,600 square miles in Alabama, Georgia, and Florida, with 12 percent of the basin in Florida.
- The Apalachicola River is the largest river in Florida in terms of flow.
- Forty percent of the Apalachicola Bay is suitable for growing oysters.

Resources
- The bay produces 90 percent of the Florida oyster harvest, and 10 percent of the national harvest.
- The bay is a major spawning ground for blue crab and shrimp.
- Annual seafood landings in Franklin County (which surrounds the main estuary) are valued in excess of $14 million.
- The upper basin is an area of unusual biological diversity.

Issues
- The pollution and proposed dredging projects threatened the bay's productive seafood industry.
- Protection and preservation of the river and bay floodplain and sensitive areas around the bay became a priority of the State and local authorities.
- Maintenance of existing flow from northern States was threatened.



Introduction

The Apalachicola River basin may be the most protected estuarine system in the United States. For over 10 years the State of Florida, in conjunction with Federal and local authorities, has taken a variety of actions to preserve the relatively pristine Apalachicola drainage basin. The protection of the unique natural resources of the Apalachicola system has been accomplished by three major types of actions including (1) land acquisition, (2) establishment of protective designations, and (3) basin management. Extensive research to document the ecology of the Apalachicola Bay system helped focus basin management actions.

The Apalachicola River is formed by the convergence of the Chattahoochee and Flint Rivers, which originate in northern Georgia. The river drains into Apalachicola Bay which produces 90 percent of the State's oyster harvest; is a major spawning ground for blue crab and shrimp; and also provides a finfish (spot, croaker, and sea trout) harvest. In the early 1970's the Apalachicola system was threatened by proposed navigation projects that would substantially modify the river's hydrodynamics, clear-cutting in the lower basin that would increase sediment and nutrient loads, development pressures, and poor sewage treatment.

Overview of Bay Characteristics and Problems

The Apalachicola estuary is located on the Gulf Coast of Florida at the mouth of the Apalachicola-Chattahoochee-Flint (ACF) River system. The estuary is a relatively shallow lagoon and barrier island system. It has an average depth between 6 and 9 feet, and covers approximately 210 square miles. The waters of the ACF basin are used for diverse purposes, including commercial and recreational fishing; commercial navigation; recreation; hydropower; municipal, industrial, and agricultural water supply; sewage effluent discharge; and fish propagation.

The major urban areas are in Georgia and Alabama, whereas the Florida portion of the basin is sparsely populated. The six Florida counties adjacent to the basin have low population densities of 30 people per square mile and are predominately forest.

In the early 1970's, periodic closings of the oyster beds in Apalachicola Bay threatened the viability of the local seafood economy. The sewage treatment plant often discharged raw sewage to Apalachicola Bay. At the same time, the Corps of Engineers proposed constructing four dams in the Apalachicola River. Concerns about the freshwater retention incorporated in these proposals increased the interest of the local citizens. Proposed land development for the area added to these concerns.

Major Components of the Program

Protection efforts focused on land acquisition, protective designations, basin management, and research.

Land Acquisition

Public land acquisition has proven to be a cornerstone of the effort to protect the Apalachicola ecosystem. Over 100,000 acres of land have been purchased for a variety of purposes.There are currently two State land acquisition programs active in the region: the State's Conservation and Recreation Lands Program (CARL), and the Save Our Rivers Program.

These programs have purchased lands along the river floodplain, the lower portion of the river, the bay front, and nearby islands.

In CARL, the State has purchased 14,475 acres for $6.4 million. Under Save Our Rivers, the State purchased over 35,000 acres of bottomland hardwood swamp for $10.3 million and is negotiating for the purchase of 42,000 more acres of floodplain. An additional 31,863 acres were acquired through an earlier program at a cost of $22.8 million. Additional acquisitions around the bay have a high ranking on the current CARL list. The Florida Department of Natural Resources is responsible for the selection and negotiations for land acquisition; however, all final purchases must be approved by a six-member interagency committee that includes the Governor and his cabinet.

Protective Designations

State, Federal, and international protective designations have also been instrumental in protecting the river and bay. Each of these designations serves a different role in protecting the system. Together, they have drawn attention to the system, which has impacted permit, treatment, and land use decisions. The primary designations used have been Aquatic Preserve, Outstanding Florida Water (OFW), National Estuarine Research Reserve (Sanctuary), Area of Critical State Concern, and International Biosphere Reserve.

Basin Management

An effort to manage the basin as a system was proposed by the Northwest Florida Management District in 1976, but received no support. In 1979, when the Apalachicola estuary was declared a National Estuarine Sanctuary, a requirement for basinwide management was connected to the release of Federal funds.

In 1982, interest in systemwide management of the basin was revived by the Department of Environmental Regulation. In 1983, an interstate Memorandum of Understanding (MOU) was signed by Florida, Georgia, and Alabama to develop a basinwide drought management plan, a water management strategy for the system, and a navigation maintenance plan.

Major Protective Designations

Outstanding Florida Water

The majority of the Florida portion of the basin is designated as Outstanding Florida Water. This designation prevents a permanent point source discharge from degrading the receiving water. The OFW designation imposes reduced allowances for waste disposal and assimilation. It restricts new long-term pollutant discharges such as sewage, industrial effluent, dredging, and filling. OFW restrictions help to ensure that recreational and ecological integrity of the area are preserved.

National Estuarine Research Reserve

Through the Office of Coastal Zone Management the lower Apalachicola River and Bay was designated as a National Estuarine Sanctuary, now known as National Estuarine Research Reserve. The Apalachicola Reserve is the largest in the country: 193,758 acres, or twice the size of the other 17 reserves combined. The Apalachicola Reserve includes floodplain, fresh and saltwater marshes, open water, and barrier islands. Through this program Federal and State funds are used for land acquisition, research, and education. The Apalachicola National Estuarine Reserve Advisory Council (ANERAC), an 11-member board, serves as a forum for coordination among local interests, State environmental agencies, and the Federal government. The Estuarine Research Reserve plays a key role in the effort to use scientific understanding to manage the resource.

Area of Critical State Concern

The Apalachicola Bay area was designated an Area of Critical State Concern through the Apalachicola Bay Area Protection Act. This designation allows for State oversight and control of government decisions and ordinances. The intent of the act is (1) to protect the water quality of the bay area, (2) to financially assist Franklin County and its municipalities in upgrading and expanding their sewage systems, (3) to monitor activities in the area to ensure resource protection, and (4) to educate the residents of the area in order to preserve its natural resources. The act also puts the Resource Planning and Management Committee in an advisory role to support Franklin County in enacting land development regulations related to stormwater systems, correct onsite sewage treatment systems, and develop a map of pollution-sensitive segments of the critical shoreline. Since its designation the county has imposed an ordinance which provides a buffer between land development and the estuary. The Apalachicola Bay Area Protection Act also provided money to upgrade the municipal sewage system in Apalachicola.

Aquatic Preserve

The estuary was designated an aquatic preserve in 1975. This designation requires the State to develop a management plan to ensure the long-term protection of the aquatic resource.

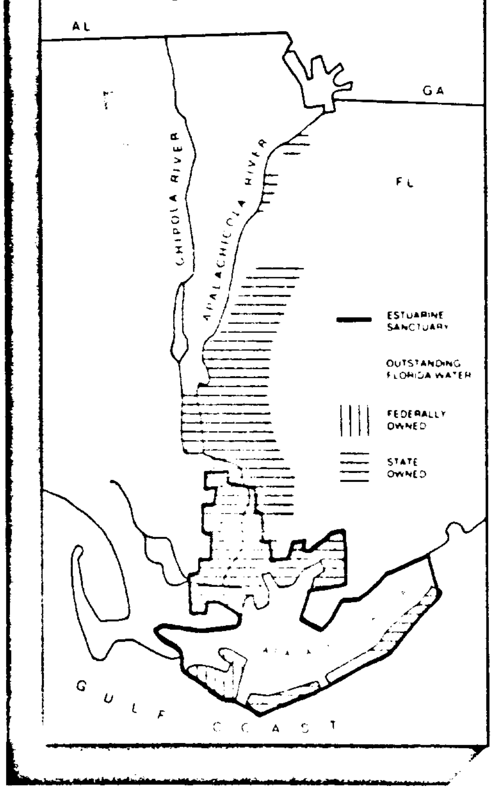
International Biosphere Reserve

This international recognition for the area by the United Nations was received in 1984.

In 1983, the Governor appointed an Apalachicola Task Force to work under the Coastal Zone Interagency Management Committee (IMC) to deal with the problem of frequent closing of the bay to oystering because of sewage. The task force membership includes the Department of Community Affairs, the Department of Health and Rehabilitative Services, Department of Commerce, Department of Natural Resources, and the Department of Environmental Regulation. This task force was instrumental in developing the Apalachicola Bay Protection Act of 1985, which designated the region as an Area of Critical State Concern.

The Navigation Maintenance Plan helped resolve a 10-year-old disagreement between Florida, which resisted year-round use of the river channel on environmental grounds, and Alabama, Georgia, and the Corps of Engineers, which felt Florida's resistance was suppressing the regional economy. The plan allowed navigation if no further degradation of the environment occurred. Some proposed structural modifications were abandoned and maintenance practices revised to meet this goal. The Corps finally judged that, without the structural modifications, flow was not sufficient for year-round use in most years.

Area Designated for Protection



Responsible Authorities and Financing

Major funding and consistent research support have come from the Florida Sea Grant College (National Oceanic and Atmospheric Administration) and Franklin County Board of Commissioners. Supplementary funding has been provided by private industry as well as by State and Federal agencies.

Many of the initiatives to protect the system originated in the Florida Department of Environmental Regulation. In 1979, the Department hired a staff person dedicated to coordinating and resolving problems impacting the river and bay system. After a year, funding for this position was covered by a grant from the Office of Coastal Zone Management until 1985 when the position was made permanent by the Apalachicola Bay Protection Act. Through this position the Department has helped initiate a comprehensive program to manage and protect the system. Money for the CARL Program comes from taxes on minerals, oil and gas, and possibly from real estate taxes in the near future. This money is put into a trust fund for land acquisitions and drawn on as needed. An estimated $40 million in revenue will be put into the CARL program this year.

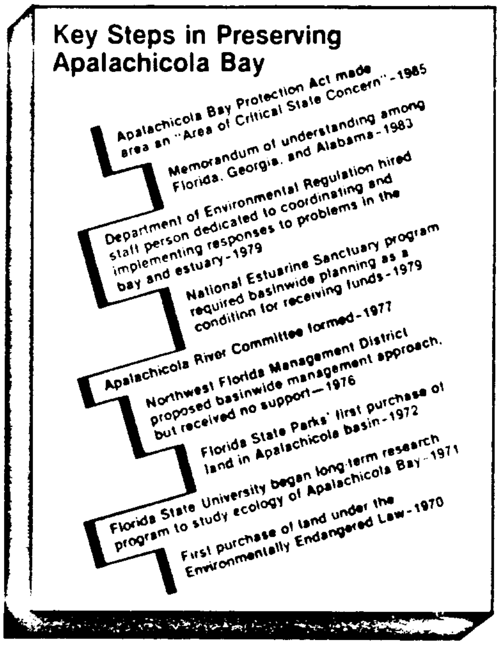
Process

In the early 1970's a broad-based effort to protect the Apalachicola ecosystem was undertaken because the people of Franklin County recognized the need for a management program to protect this resource.

In 1972, a field monitoring program began in Apalachicola Bay to gather scientific information for the purpose of applying it to practical problems. Scientists from Florida State University, United States Geological Service, Fresh Water Fish and Game Commission, Department of Environmental Regulation, and many others have investigated biological, chemical, and physical characteristics of the river and bay. Major contributions for this research have come from Florida Sea Grant College (National Oceanic and Atmospheric Administration) and the Franklin County Board of Commissioners. This monitoring project has continued for over 10 years and continues today.

Local efforts to protect the area have included adoption of county-wide zoning regulations in the 1970's and a comprehensive plan in 1981 in Franklin County. The State and the Northwest Florida Management District efforts have included land acquisitions, a number of protective designations, and a resource planning and a management committee.

A critical factor influencing long-term protection of the resource is communication and coordination among all involved parties. Over the past decade, the State has made a considerable effort to involve local county commissioners, developers, the scientific community, and the public in the decisionmaking process. In 1977, the Apalachicola River Committee was formed to bring the Departments of Environmental Regulation



and Natural Resources and other State and local agencies together to strengthen local planning efforts through the provisions of data and technical assistance. Representatives on the committee included the six counties bordering the river, and State and Federal resource agencies. It was chaired by the Apalachee Regional Planning Council. The committee was especially concerned with navigation issues and since Florida law required local government approval of dredging permits, the committee wielded some power.

In conjunction with the Memorandum of Understanding adopted by the three States and the Corps in 1983, an Interim Coordinating Committee consisting of representatives of each State and the Corps was established. This committee was responsible for dealing with interstate water management and navigation issues and was intended to terminate after three years. However, since the arrangement has worked well, all parties agreed to continue the committee as the Interstate Coordinating Committee. The final Navigation Maintenance Plan (NMP) adopted by this committee included a provision requiring that before any measures listed in the NMP are implemented in Florida, public meetings would be held in the affected areas to provide information and to receive public input.

Results

Efforts to date have left hope and optimism that the foundation exists for the Apalachicola system to be protected over the long term. Continued work is necessary, however, and results are contingent upon the involvement and acceptance of the effort by local government and citizens.

To date the State has purchased over 85,000 acres in the basin. At least 40 percent of floodplain is publicly owned and by the end of 1987 it is hoped that almost 90 percent of the wetlands in the Apalachicola floodplain will be publicly owned. Efforts to acquire more land in the Apalachicola basin will continue, but it is uncertain how much additional land will be purchased. By the end of the land acquisition program the State hopes to have the floodplain of the river intact and in public ownership.

Protective designations have brought significant attention to the system and have provided some measure of protection to the area. These designations, however, can lull the public into a false sense of security. For example, many people mistakenly believed the Estuarine Reserve would impose strict limits and controls on anything and everything that would harm the estuary. The Reserve actually has no authority to regulate development, but instead promotes research and education.

Perhaps most important, all parties are interested in continuing and expanding efforts to protect the system. Several State agencies have full-time staff specifically assigned to working on the system, as does the Florida Defenders of the Environment.

Lessons Learned

The Apalachicola experience shows that a river basin can be managed and protected. Litigation, acquisition, the State permitting process, the education of local citizens, planning and management, and public pressure have all played major roles in this effort. The combined efforts of local, State, Federal, and university programs in the Apalachicola River basin have been extremely important.

The education of all concerned parties has been a key to the program's success. There has been little turnover among State and Federal agency staff, with many having five to 10 years experience working on the system. Consequently, many have become quite knowledgeable about the system. And, after dealing with resource management issues in the basin for the past 10 to 15 years, county officials have also gained an appreciation for the system's ecology and have integrated this to some extent into the decisionmaking process.

Maryland's Critical Area Program

Managing aquatic resources by controlling land-based activities

CHESAPEAKE BAY

Characteristics

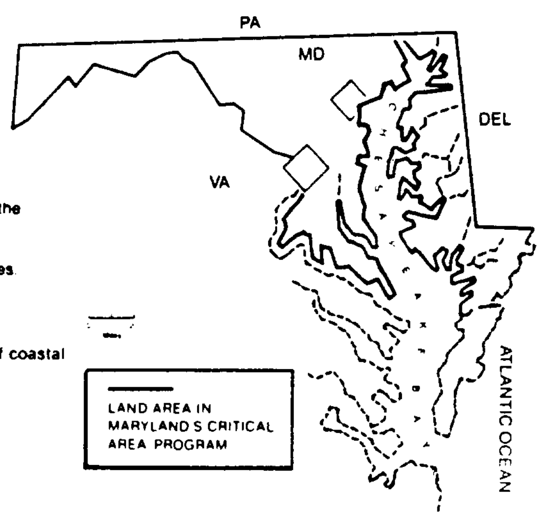
- The area includes 2,900 miles of shoreline and 614,000 acres of land.
- Land usage includes:
  - -35 percent tidal wetlands
  - -25 percent agricultural lands
  - -28 percent forest
  - -12 percent developed area.

Resources

- Over 200 species of finfish and shellfish inhabit the bay at some point in their life cycle.
- Bay produces 50 percent of blue crabs and 33 percent of oysters harvested in the United States.
- Canada geese, ducks, and other migratory waterfowl find winter habitat in the bay area.

Issues

- Development is increasing in the critical area of coastal counties at twice the rate outside critical area.
- Loss of wildlife habitat is a continuing problem.
- Nonpoint source pollution has been identified as major problem.
- Fish and shellfish resources are declining.



Introduction

The Critical Area Law focuses on land-based activities as a source of problems in Chesapeake Bay water quality. It is a program designed to balance the pressure for new development while checking its potential to increase the amounts of pollutants entering the bay from disturbed areas. Equally important, the Critical Area Law emphasizes the need to preserve the bay area's richly diverse habitats for fish, wildlife, and plants and to use its resources wisely.

Historically, the Chesapeake Bay has provided generous harvests of high quality seafood, abundant water-based recreation, deep international shipping lanes supporting Maryland and Virginia's industrial base, and a haven for wildlife. Rapid population growth and development and associated pollutant and sediment loads have threatened the bay's water quality, natural habitats, shoreline, and commercial integrity.

In the early 1980's, subsequent to the release of the Chesapeake Bay Program's research findings, concern for the bay was high – as demonstrated by the passage of 34 legislative and budget measures in the State of Maryland for bay cleanup. The Bay Critical Area Law was a major component of this initiative.

Overview of Bay Characteristics and Problems

Located on the Atlantic coastal plain, the Chesapeake Bay drains over 150 rivers in a 64,000 square mile area. The lands surrounding the bay support diverse uses: farming, forestry, industry, recreation, urban and suburban development, and unique natural habitats. Since the 1950's, these lands have developed rapidly. In fact, in Maryland, 17 percent of new coastal county development has occurred on only 9 percent of the available land area – within 1,000 feet of shoreline.

The health of the bay has been declining. Evidence includes decreased stocks of bay anadromous fish species and degraded water quality, particularly in the upper Chesapeake Bay and tidal estuaries. In these areas, increased nutrients have lowered available oxygen for fish and aquatic life; sediment has

VOL 12
6446

decreased available light for submerged aquatic vegetation and shipping lanes and other channels; and toxic substances have reduced species diversity.

The Chesapeake Bay Critical Area Law

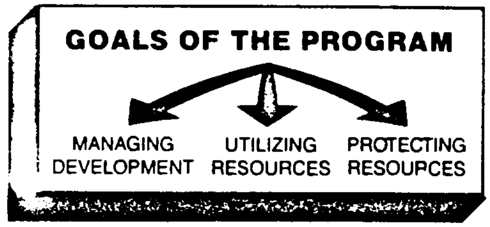
By passing the Chesapeake Bay Critical Area Law, the Maryland General Assembly recognized that land uses near the water's edge have important consequences for water quality and wildlife habitat. The law

- Identified lands within 1,000 feet of mean high water or landward of tidal wetlands as a "Critical Area";
- Defined goals to reduce the impact of development on water quality as well as on fish, wildlife, and plant habitats;
- Created an intergovernmental framework for: comprehensive land use planning and habitat protection.

The law also established a commission of 25 members to develop criteria for implementing the program. The criteria established three broad categories for land use. The law requires local jurisdictions to develop programs to manage lands in the three categories as specified by the characteristics and criteria developed by the commission. The management of these lands is to include measures to address land cover and impervious surfaces; buffer areas; setbacks; open space, water access, and recreation areas; and timber harvesting. Each jurisdiction must submit its program to the Critical Area commission for review.

Goals

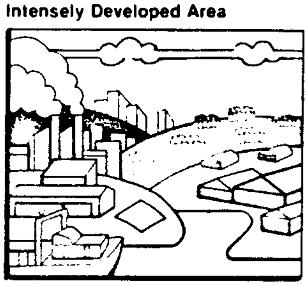
The implementation criteria, which were drafted by the commission with substantial public contribution and approved by the State General Assembly, address three resource management issues: development, resource utilization, and resource protection.



Managing Development. The commission designated three broad land use categories: Intensely Developed, Limited Development, and Resource Conservation Areas. In general, the rationale was to direct new growth in the Critical Area to already built-up areas because this would minimize the impact of growth on protective land uses and natural habitat. In the Limited Development Area, the existing pattern of development could continue, but the commission developed criteria, often in the form of performance standards, so that impacts to water quality and natural habitats would be

Characteristics of Land Classifications in Critical Area, and Criteria for Management

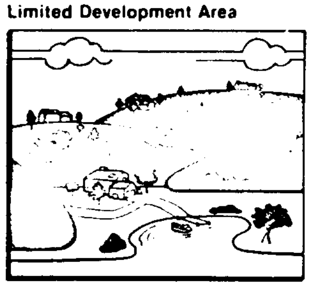
Intensely Developed Area



Characteristics
- Dense residential, institutional, commercial, or industrial uses
- 4 or more dwelling units per acre
- Public sewer and water serving 3 or more housing units per acre

Applicable Criteria
- Reduce pollutant loadings by at least 10% from predevelopment loads
- Reduce nonpoint impacts to streams and tidal waters from redevelopment
- Protect remaining wildlife and fish habitats

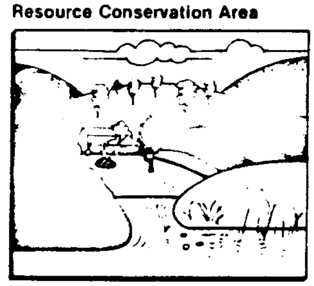
Limited Development Area



Characteristics
- 1 dwelling unit per 5 acres up to 4 per acre
- Areas with public sewer, or water, or both
- Mixture of land usage—not dominated by agriculture, wetlands, forest, or open space

Applicable Criteria
- Replace cleared forest land on an acre-for-acre basis
- Restrict removal of existing forest land to 20% when development occurs
- Restrict impervious areas to 15% of the land area being developed
- Encourage clustering of dwelling units to conserve natural habitats

Resource Conservation Area



Characteristics
- Housing density of less than 1 dwelling unit per five acres
- No public sewer or water
- Primarily open fields, wetlands, forest, and agriculture

Applicable Criteria
- Limit residential development to an overall density not to exceed 1 dwelling unit per 20 acres
- Encourage agriculture and forestry

minimal. The Limited Development Area was defined to include areas containing the protective land uses and natural habitats. The commission then considered the question of how to accommodate some development in the Resource Conservation Areas but still maintain such uses.

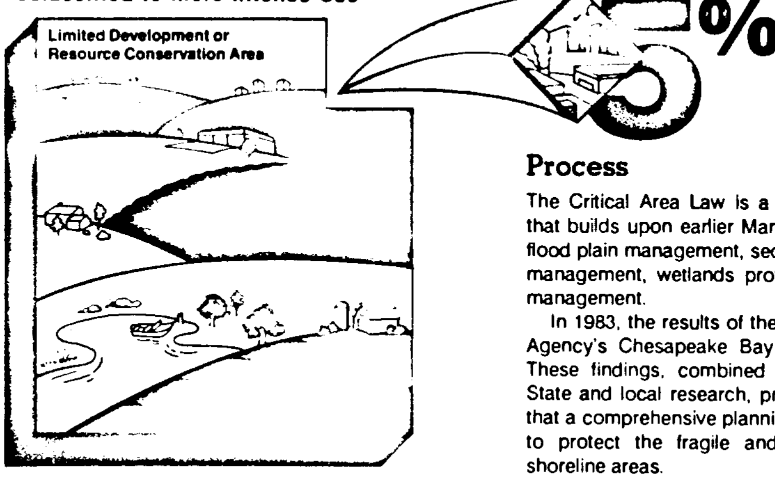
The law required local jurisdictions to assign their lands in the critical area to one of three categories by December 1985.

The criteria also allow for development of pre-existing lots and subdivisions through grandfather provisions and for expansion of development. Intensely Developed Areas and Limited Development Areas may be expanded by up to 5 percent of a county's land area, excluding the acreage in tidal wetlands or federally owned property from the formula. No more than one-half of this allocated expansion may occur directly in the Resource Conservation Area.

Utilizing Resources. The law also calls for improved management of forests, agriculture, and water-dependent facilities within the Critical Area. Specific requirements are

- Commercial tree harvest operations affecting one or more acres per year must have a forest management plan; limitations are imposed on timber harvesting within 1,000 feet of mean high water of the bay or perennial tributary streams;

Only 5% of Land May Be Reclassified to More Intense Use



- Soil conservation and water management plans and implementation of best management practices are required within five years on agricultural lands;
- A 25-foot filter strip must be established along tidal waters and streams until a soil conservation plan is implemented;
- Feeding or watering of livestock is prohibited within 50 feet of the water's edge; and
- New development within 100 feet of shoreline except in water-dependent communities, and new marinas are prohibited in Resource Conservation Areas.

Protecting Resources. The last component of the Critical Area Program provides for protection of nontidal wetlands, threatened and endangered species, species in need of conservation, and plant and wildlife habitat. These habitat and wildlife protection measures require local jurisdictions to

- Inventory and protect fish spawning grounds, threatened and endangered species habitat, colonial water bird nesting sites, historic waterfowl staging and concentration areas, and forest-interior-dwelling bird habitat;
- Create wildlife corridor systems to ensure that any new development in the Critical Area will preserve existing habitats;
- Establish a minimum 25-foot buffer zone around nontidal wetlands to prevent any future habitat modification; and
- Establish a minimum 100-foot naturally vegetated buffer strip around the bay in all nondeveloped areas.

Responsible Authorities and Financing

Implementation of the Critical Area Program is based on a well-defined State/local government partnership. Each of 60 local jurisdictions (16 counties and 44 municipalities) is to develop its own program to implement the Critical Area criteria. The commission performs an oversight function to ensure that these plans meet the stated goals of the criteria and coordinates implementation among the local jurisdictions. The operation of the commission and development of local plans are financed through general State revenues. The State provided funds to develop the maps and local programs.

Process

The Critical Area Law is a comprehensive approach that builds upon earlier Maryland programs, including flood plain management, sediment control, stormwater management, wetlands protection, and coastal zone management.

In 1983, the results of the Environmental Protection Agency's Chesapeake Bay Program were released. These findings, combined with facts uncovered by State and local research, provided powerful evidence that a comprehensive planning approach was required to protect the fragile and economically important shoreline areas.

Following this report, the Governor of Maryland created an interdepartmental task force to respond to the findings of the bay study. The Critical Area Program was one of the legislative and budgetary measures proposed by the task force. Local government participated early in the drafting process through the Maryland Association of Counties and the Maryland Municipal League. Committees of the Maryland General Assembly also reviewed the bill frequently throughout the drafting process. The bill was enacted on June 1, 1984.

From its early stages, the bill's intent was to maintain local planning authority. The enacted legislation provides for both a carefully defined local implementation process and comprehensive State oversight. The membership of the Critical Area Commission was important in developing the criteria, and local jurisdiction played a strong role. Of 25 members, 11 are residents, elected officials, or appointed officials of coastal counties; 8 members represent the commercial, recreational, and environmental interests of the bay. Only six commission members are from State agencies. All members are appointed by the Governor, with State Senate approval. The commission's executive director is selected by the commission chairperson.

Prior to drafting the criteria, the commission held seven public hearings during December 1984, at locations around Maryland's bay coastline, to enable local citizens and bay interest groups to voice their opinions.

Throughout the criteria development process, the commission continued to conduct formal meetings and public hearings. Commission members and staff also made numerous appearances before General Assembly committees, spoke at meetings organized by the many interest groups concerned with bay issues, and conducted television and radio interviews.

Following a final series of nine public hearings during July 1985 to review the proposed criteria, the commission substantially modified the criteria to address public concerns. The revised criteria were signed into law on May 13, 1986, 22 months after enactment of the Critical Area Law. These criteria are now guiding local jurisdictions in their development of Critical Area land use plans.

Program Status

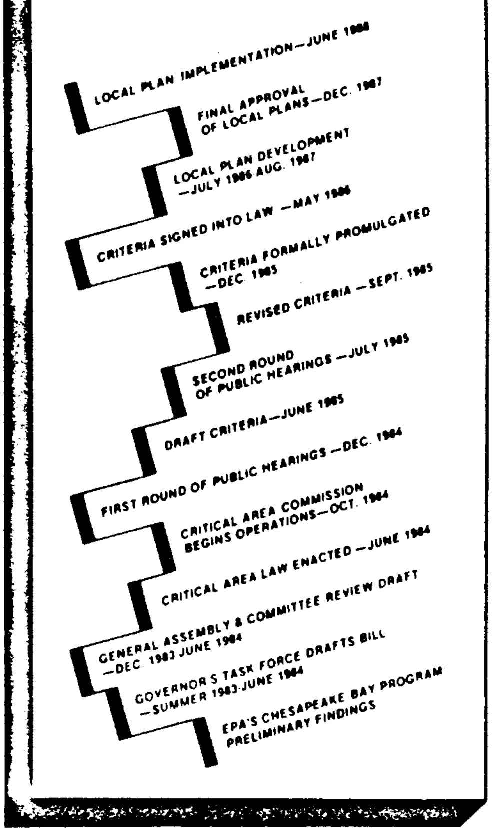
Local jurisdictions are developing program plans and amending their zoning ordinances as needed to meet Program goals. Final approval of all local plans is expected shortly.

The positive results of this process can be seen in local jurisdictions now working together to develop coordinated plans and continued support by citizens at their local government levels. Perhaps as important is the increased contact between State agencies and local jurisdictions – particularly the small jurisdictions – which has improved intergovernmental relations.

Lessons Learned

The Critical Area Program – the Critical Area Law, the commission, and the criteria – is a reality. It demonstrates that support for managing coastal development can be generated; that comprehensive State-level land use restrictions, typically fraught with controversy, can be established; and that a process of local implementation complemented by State oversight can be defined.

Origin and Development of the Critical Area Program



The active involvement of local officials and the public, the clear definition of respective State and local roles, and the protection of local planning authority were fundamental to this program's success.

The Critical Area Program may still face areas of resistance. If fully implemented, however, the program will fairly balance diverse interests and preserve the essential rights of local jurisdictions. By bringing local interests together with State regulators, a strong program was devised to protect the recovery of the bay. For Maryland, a State-level response worked; elsewhere a multi-county or multi-State program might be appropriate to protect estuarine environments.

For further information on this program, contact Dr. Sarah Taylor or Dr. Kevin Sullivan, Maryland Critical Area Commission, Annapolis, MD; or Mark Alderson, EPA Project Manager, Washington, DC.

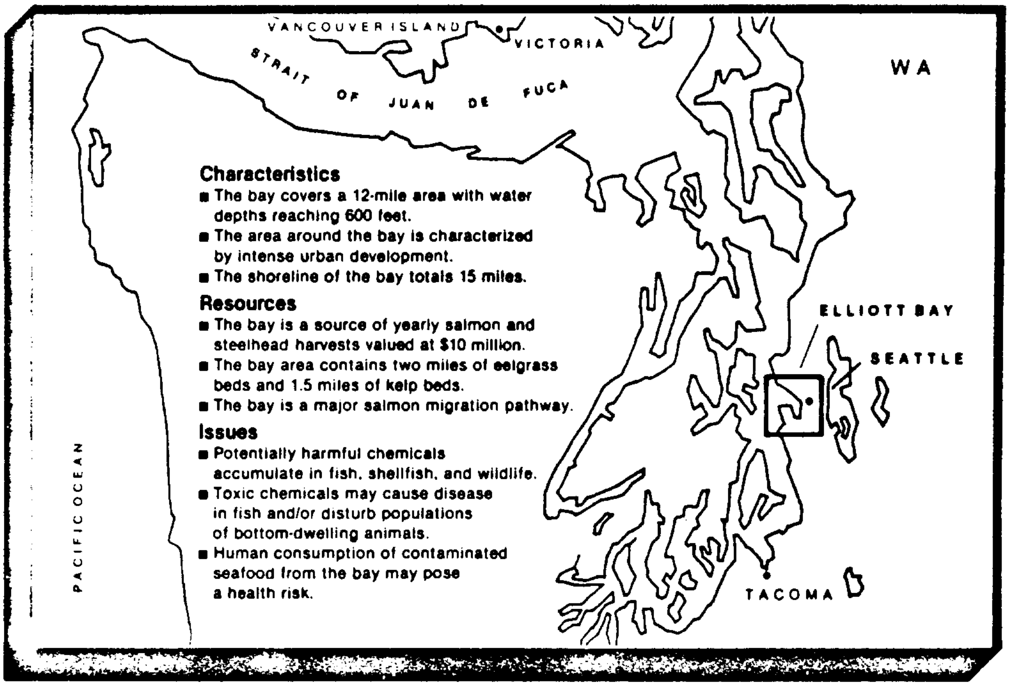
An Action Plan for Containing and Reducing Pollutants

Controlling toxic contamination in an urban bay through special enforcement teams and interagency coordination

ELLIOTT BAY, WASHINGTON STATE



Introduction

The Elliott Bay Toxic Action Program is an important part of a much larger effort to minimize toxic contamination in Puget Sound and protect its resources. Focused on the problems of an urban bay, its goal is to control toxic substances at their sources, particularly those toxics contaminating the bottom sediments of Elliott Bay and the Duwamish River. It does this by coordinating the authorities of various governmental agencies to revise discharge permits, enforce hazardous materials regulations, and clean up contaminated sites.

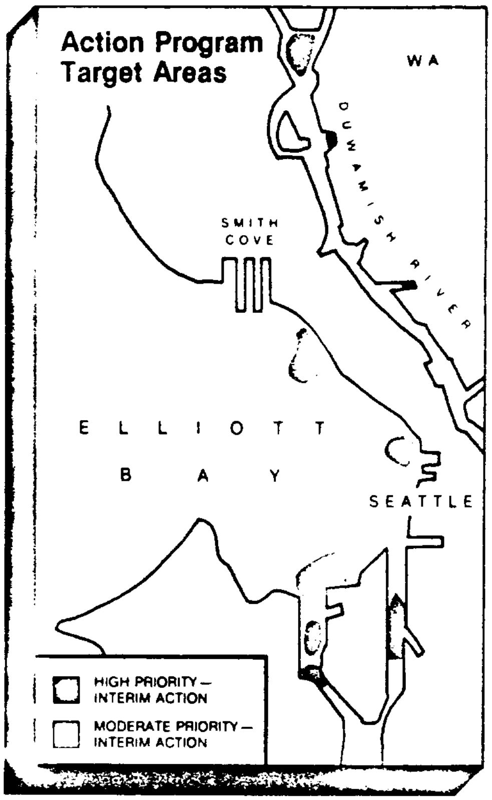
To target these regulatory authorities more effectively, the program relies on a strike force called EBAT--the Elliott Bay Action Team. This special enforcement and compliance team conducts field inspections and follow-up monitoring to ensure that required control actions are actually implemented. Other important components of the program include an interagency work group and a citizens advisory committee.

The Elliott Bay program, by coordinating and targeting various activities, has provided a model for interagency cooperation and management of site-specific toxic contamination.

Overview of Elliott Bay and Its Toxic Contamination Problems

Located on the eastern shore of central Puget Sound near Seattle, Elliott Bay covers a 12 square-mile area

R0039758



with water depths of up to 600 feet. The bay's drainage basin is extensively developed, and the bay itself receives major industrial and sewage discharges.

Among the living resources of the bay are salmon, flounder, shrimp, squid, and various clam species.

During the 1970s, the U.S. Environmental Protection Agency (EPA), the Municipality of Metropolitan Seattle (Metro), and the National Oceanic and Atmospheric Administration (NOAA) found harmful levels of toxic chemicals in sediments on the bottom of Elliott Bay and the Duwamish River, including potential carcinogens such as polychlorinated biphenyls (PCBs) and polynuclear aromatic hydrocarbons (PAHs), as well as toxic metals such as arsenic and lead. In addition, up to 16 percent of bottomfish caught in contaminated areas have liver tumors, and bottom-dwelling animal populations have dropped overall in the same areas.

Studies have shown that chemical contamination, along with overfishing and habitat destruction, may contribute to declines in some fishery resources. Moreover, NOAA researchers have recently demonstrated that some of the contaminant load discharged from the Duwamish River could move to the main basin of Puget Sound. If pollution is not curtailed, the effects of contamination could become widespread.

Elliott Bay Toxics Action Program

The focus of the Elliott Bay Toxics Action program is to control the sources of toxic contaminants by coordinating compliance and enforcement efforts among Federal, State, and local agencies. Ordinarily, activities such as field investigations, permit and site inspections, and hazardous substance control or cleanup programs are handled under different authorities by separate agencies. Integrating these activities under the "umbrella" of the program increases their effectiveness and provides a framework for identifying priority sites, choosing source controls, appointing appropriate agencies for enforcing controls, and developing a timetable for putting control programs into place.

A key element in this program is EBAT, a special enforcement and compliance team that includes staff from the Washington State Department of Ecology. EBAT was created in September 1985 to carry out site inspections, identify pollutant sources, revise discharge permits as necessary, develop alternative regulatory responses, and help dischargers develop cost-effective solutions to pollution problems. In cases where responsible parties fail to solve pollution problems or do not comply with discharge requirements, EBAT also has authority to take enforcement actions, such as administrative orders and monetary penalties.

In addition to EBAT, two other programs are important to the Elliott Bay Toxic Action Program. These are the Interagency Work Group and the Citizens Advisory Committee.

The Interagency Work Group is the mechanism through which the various agencies integrate their efforts. Chaired by a member of the Department of Ecology, the work group is more broadly based than EBAT. Its role is to coordinate program activities among agencies; circulate technical data and reports from related projects; report on plans and ongoing corrective actions; review work plans, progress, and technical results; and agree on future corrective actions and schedules.

The Citizens Advisory Committee (CAC) is also broad-based. It includes representatives of environmental groups, community organizations, business and industry, and resource users such as sport and commercial fishermen. Its role is to review program objec-

VOL 12

6451

tives and proposed actions; identify public concerns and issues relevant to action plans; and disseminate information to members of organizations represented on the committee.

Products of the Elliott Bay Toxics Action program are reviewed by the EPA regional office in Seattle, Washington.

Process

The Elliott Bay Toxic Action program evolved from earlier water-quality programs carried out by Metro and the Department of Ecology, although its current organization began with funding by the U.S. EPA early in 1985. At that time, the work group and CAC were established. Together with EPA, they worked to issue a draft report identifying problems in the bay and river, and proposing a sampling and analysis program. This report was the basis of an Interim Action Plan issued in October 1985.

During the same period, Metro and the Department of Ecology established and funded EBAT to carry out field sampling and laboratory analysis. Over 1,000 samples of sediment and biota were analyzed between October 1985 and June 1987. Along with a slide show and periodic press releases, these sampling results helped to publicize and gather support for the Elliott Bay program.

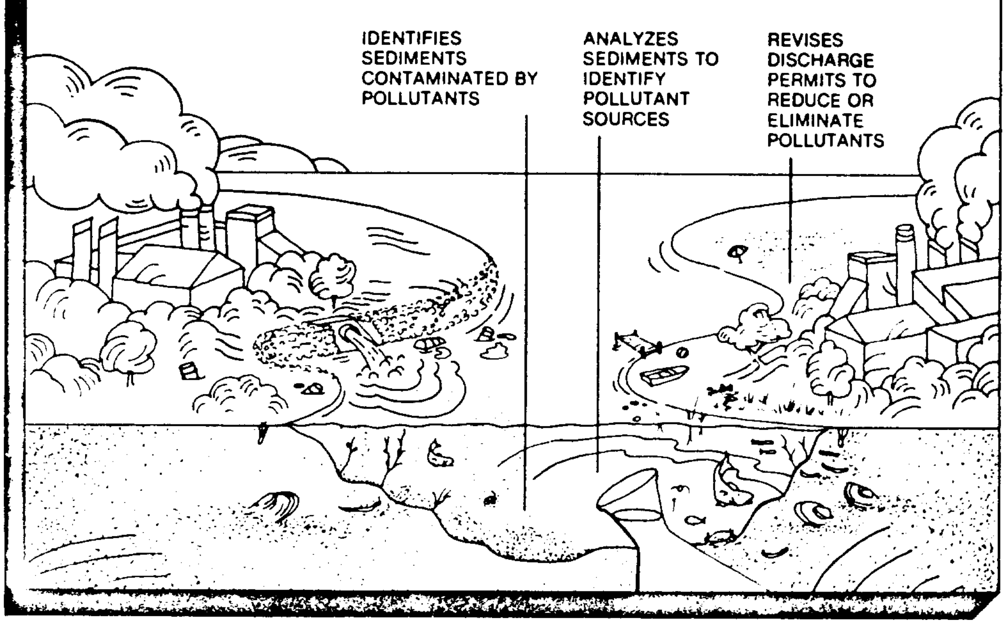
The samples collected are still being studied for evidence of chemical contamination and biological effects. Data from these studies and from continuing EBAT findings will help to redefine problem areas and identify additional pollutant sources.

Results

Since 1985, the Elliott Bay program has identified 42 unpermitted discharges and 15 contaminated upland sites; developed permits incorporating best management practices (BMPs) for shipyards; cleaned up two upland sites and negotiated the cleanup of 12 more.

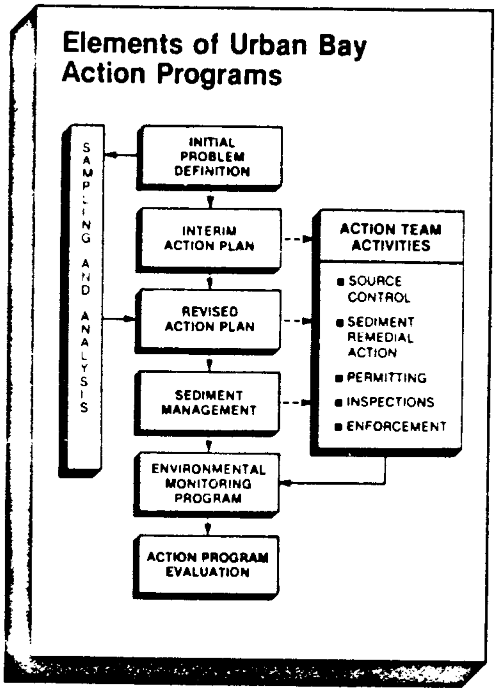
In addition, EBAT has conducted more than 221 inspections at 124 sites. These inspections have led to termination of some discharges or wastewater reuse in-

What EBAT Does



VOL 12 6452

R0039760



stead of discharge; rerouting of discharges to sanitary sewer systems; modification of existing discharge permits or development of new ones; and enforcement actions against noncomplying facilities, including 36 Notices of Violation, 22 Administrative Orders, and 28 levies of monetary penalties.

Lessons Learned

The experience of the Elliott Bay program demonstrates that a successful urban bay program must include several key elements:

- It must involve citizens, the regulated community, other governmental agencies, resource managers, and scientists in the decisionmaking process.
- It must focus on specific problem areas.
- It should use field inspections and personal contact with facility managers to encourage cooperation and find innovative, cost-effective solutions to identified problems.
- It should use a special task force to focus and carry out coordinated enforcement activities. EBAT, for example, was effective in dealing with localized toxic hot spots because it had sufficient regulatory authority and funding to carry out field inspections and enforcement actions.

The Elliott Bay program also demonstrates the importance of developing pollution control plans based on input from relevant governmental and regulatory agencies. In addition, it shows that wide-ranging public involvement is essential if regulatory actions are to be perceived as both necessary and fair.

Other factors that will affect the long-term success of the program include the development of toxics limitations and tests, issuance of permits for discharges from combined sewer overflows and storm drains, and continued interaction with other efforts in the Puget Sound area. All urban bay action programs can benefit from the sampling activities and source controls required under these programs.

Compensatory Mitigation to Protect Critical Fishery Habitats

Protecting fish and wildlife while allowing development

PUGET SOUND/WASHINGTON

Characteristics

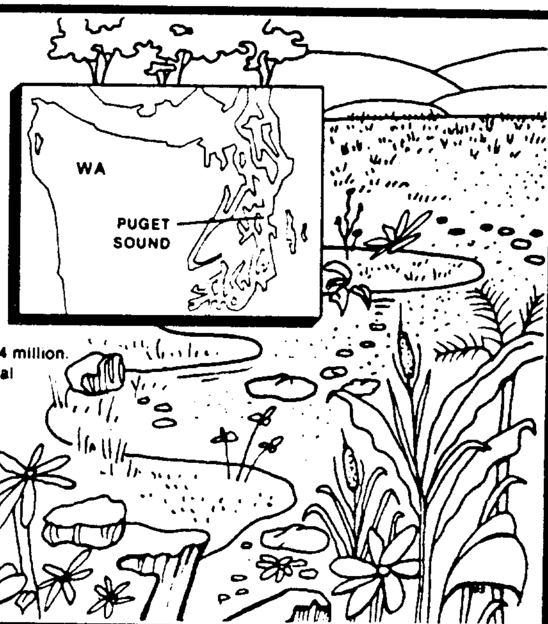
- Puget Sound is a classic, deep fjord with rocky shoreline and steep, jagged cliffs adjacent to the shoreline.
- The basin has nine watersheds containing over 10 million acres:
  - -82 percent forestland
  - -9 percent urban
  - -6 percent farmland
  - -3 percent rural, non-farmland
- Intertidal wetlands are limited due to shoreline configuration, but the nine watersheds support numerous other wetlands systems important to the ecology of the region.

Resources

- The estimated value of fisheries in 1984 was $74 million.
- Nearshore and intertidal wetlands provide critical habitat for economically important species.

Issues

- The Puget Sound area has already lost most of the major wetlands that existed at the mouths of some of the region's major rivers.
- Remaining estuarine wetlands occupy areas under severe pressure for development because of increasing population.
- Critical habitats must be protected without unduly restricting development.



Introduction

Wetlands are extremely important as fish and wildlife habitats and as buffer zones that trap nutrients and sediments and regulate flooding. Yet because of their proximity to the water, and frequent location in highly populated areas, wetlands are increasingly being lost to development. To stem such losses in the Puget Sound area, local officials have adopted a permitting strategy of wetlands replacement known as compensatory mitigation. The goal of the strategy is to prevent the net loss of critical fish and wildlife habitats by requiring the replacement of wetlands lost to the impacts of shoreline development. Because it is very difficult to reproduce adequately the size, diversity, and complexity of natural wetlands ecosystems, however, compensatory mitigation for the most part is allowed only in areas already disturbed by human uses and only if impairment or destruction of habitat is unavoidable.

Experience has also shown that mitigation projects require careful design, area preparation and planting, and follow-up. To ensure better projects, agencies are now requiring developers to prove the technical feasibility of their proposed compensation techniques; a questionable methodology may be grounds for permit denial. In fact, many developers already have recognized that good design is in their own interests, and that each well- executed project makes it more likely that other mitigation proposals will be accepted by permitting authorities.

Compensatory mitigation as a management tool was rare before 1980, but its use has increased in recent years. In Puget Sound, the mitigation programs have al-

VOL 12

6454

ready taught some important lessons that serve as valuable guides for programs elsewhere in the United States.

Overview of Characteristics and Problems

Puget Sound is a deep, fjord-like estuary connected with the Pacific Ocean through the Strait of Juan de Fuca. The shoreline consists of bluffs and beaches formed during the retreat of glaciers and modified by erosion and deposition. This geology means that many wetlands occupy areas that are also considered highly suitable for development.

The result is that over half of the Sound's wetlands have been lost to development in the last 100 years, and the pressure to build up shoreline areas continues to increase. Many of these areas are important fish and shellfish habitats, as well as resting and feeding spaces for a broad variety of resident and migratory birds. For the most part, these critical habitats are being protected through existing regulatory programs in the state. Compensatory mitigation has been proposed as a way to channel pressures away from pristine or critical habitats by allowing development in areas already affected by human activities.

Program Evolution and Responsibilities

The concept of mitigation was first established at the federal level as part of the Fish and Wildlife Coordination Act, but rarely was used for estuarine areas until the National Environmental Policy Act (NEPA) was passed in 1969. The concept was reaffirmed in the Clean Water Act of 1977 and again in the NEPA modifications of 1978. These three statutes govern federal involvement in proposed shoreline development projects.

The lead federal agency is the U.S. Corps of Engineers, which has authority to issue dredging and filling permits. However, this authority is limited somewhat by the U.S. Environmental Protection Agency's authority to review final permits and to prohibit, condition, or restrict permits in any site that may be unacceptably affected. The U.S. Fish and Wildlife Service and the National Marine Fisheries Service also influence the Corps' permitting considerations.

Within the State of Washington, coordinated management of shoreline development began with the passage of the Shoreline Management Act of 1971. The Washington Department of Ecology administers the Act, but other state agencies involved include the Department of Fisheries, the Department of Wildlife, and the Department of Natural Resources.

Developing a Mitigation Plan

For permits involving mitigation, the Corps begins the process by convening meetings at which development proposals and mitigation plans can be reviewed and modified. These meetings are attended by potential developers, representatives of involved government agencies, resource managers, and representatives of Indian tribes dependent on fisheries and other wetland resources.

Although the formal review process begins when a developer applies to the Corps for a permit to develop shoreline and associated wetlands, the Corps prefers to hold preapplication meetings where interested parties can resolve as many issues as possible before formal application is made. A primary goal of the permit review meetings is to provide a forum to raise potential environmental impacts and discuss methods of reducing or avoiding them. Another goal is to agree on appropriate mitigation strategies for those impacts that cannot be avoided.

Most resource agencies in Puget Sound have adopted a goal of "no net loss of in-kind habitat," the aim being to maintain the number and variety of specific habitats. Developers find the one-to-one tradeoff easy to understand and difficult to challenge—if their project will cause habitat loss, they must replace the lost habitat with an equivalent amount of the same kind of habitat, preferably as near as possible to the original site.

In practice, however, adequate replacement often requires two-to-one mitigation to offset adverse effects. At the same time, mitigation techniques are still so new that even one-to-one replacement is seldom achieved. For these reasons, local officials have been extremely conservative in using compensatory mitigation to resolve development/preservation conflicts. Most have chosen to rely instead on avoiding adverse impacts in the first place.

Elements of Successful Plans

Despite the difficulties in implementation, some shoreline development has been allowed using compensatory mitigation as a condition of the permits. To enforce these permits, the Corps must follow criteria that determine whether a proposed plan is feasible. Since 1982, mitigation criteria increasingly have been included in the permit itself. Desirable components of a mitigation plan include:

- baseline data characterizing the extent and value of critical habitats and the abundance and distribution of key species;
- mitigation goals laying out the specific goals and objectives of the mitigation actions;
- detailed work plans describing and specifying mitigation techniques, including maintenance requirements and relevant deadlines;
- performance standards to be used to measure whether mitigation goals are being met;
- monitoring plans describing schedules for collecting data to track mitigation progress;
- contingency plans describing corrective actions if proposed mitigation techniques are inadequate; and
- performance bonds ensuring commitment to fulfill mitigation actions, monitoring, and contingency measures.

Results

Mitigation projects in Puget Sound have taken place chiefly around the cities of Seattle and Tacoma. Most have included plans to modify substrate or create shoreline areas to replace lost habitat. Less-used techniques include transplanting eelgrass and creating marshes.

The U.S. Fish and Wildlife Service has evaluated 20 recently begun or proposed projects in Puget Sound for the completeness of their mitigation plans. The sites for replacement habitat ranged in size from 0.05 acres to 24 acres, and included use of all four techniques. Every mitigation plan in this study provided detailed work plans and monitoring plans, and more than half also included baseline information and contingency plans. However, most of the plans lacked environmental goals, performance standards, and performance bonds.

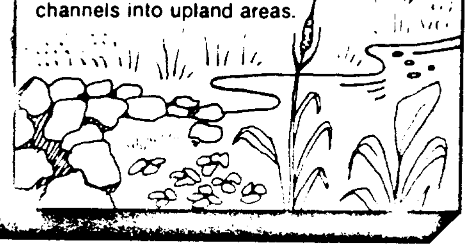
Common Mitigation Techniques Used in Puget Sound

SUBSTRATE MODIFICATION
Manipulation of substrate composition or relief by placement of boulders, cobble, gravel, or fine sand.

SHORELINE CREATION
Construction of shallow-water habitat by excavating upland areas or by filling areas of deeper water.

EELGRASS TRANSPLANTATION
Creation of eelgrass meadows by transplanting.

MARSH CREATION
Construction of marsh habitat by planting emergent aquatic vegetation or excavating channels into upland areas.



These findings reflect the problems Puget Sound agencies have experienced in measuring the success of mitigation projects. Objective evaluations depend on clearly defined environmental goals and performance standards, and these are the elements most often missing from plans. In addition, the lack of standardized monitoring protocols hinders interpretation of collected data, as does the lack of interagency coordination in tracking projects.

A development project for the Port of Tacoma illustrates some of the techniques and problems encountered in the use of compensatory mitigation. In this case, port officials needed to fill in a portion of wetland that serves a critical habitat for the prey of juvenile salmon. To mitigate the effects of this habitat loss, they created a six-acre marsh about half a mile upstream on the Puyallup River by excavating and contouring existing upland areas, connecting the modified area to the Puyallup River, and planting some 50,000 shoots of a hardy marsh plant called Lyngby's sedge. Monitoring after a year showed that:

- the density of Lyngby's sedge had increased by 400 percent.
- other species of marsh grasses were establishing themselves among the Lyngby's sedge;
- densities of invertebrates important as salmon prey had increased substantially;
- juveniles of four different salmon species were remaining in the marsh for several days to feed on the increased prey; and
- other species of fish were also using the marsh.

These data seemed to indicate that the marsh was largely successful in the first year, although an unforeseen problem arose. Sedimentation in the Puyallup River was so high that dredged channels were filling in rapidly, with some channels losing a foot of depth during the year. To correct the problem, these channels are being modified to reduce the effects of sedimentation.

Lessons Learned

The projects in Puget Sound have demonstrated the need for thorough planning. While developers have cooperated well in developing work plans and monitoring plans, the effectiveness of mitigation projects conducted so far is clouded by the lack of clear environmental goals and performance standards. At a minimum, mitigation plans should include baseline data, environmental goals, work plans, performance standards, monitoring plans, contingency plans, and performance bonds.

More importantly, the Puget Sound experience shows the need for tight interagency coordination. Mitigation projects typically involve multiple agencies, each concerned with slightly different issues. Unless they agree at the outset on the basic goals mitigation is expected to achieve, project oversight is fragmented and serious concerns get lost between the cracks. Such agreement could also help establish common, interagency criteria to specify feasible mitigation plans, and the inclusion of such criteria in each permit. Agencies could also agree to standardized monitoring protocols and project tracking systems.

Several other lessons have emerged from the Puget Sound projects, including:

- the value of preapplication meetings in identifying and resolving potential issues at an early stage;
- the recognition that, while the goal of "no net loss of in-kind habitats" is desirable, in practice, it requires a greater than one-to-one replacement ratio; and
- the value of locating mitigation projects as near as possible to the original habitat site.

But the most important lesson from the Puget Sound experience is that compensatory mitigation is not a panacea. Strict replacement is extremely difficult to achieve, and most mitigation plans seek simply to maintain fish and wildlife habitat, rather than to replace the full spectrum of wetlands values.

Compensatory mitigation may prove to be a promising management tool in Puget Sound for protecting critical habitats, but the success of mitigation techniques have yet to be proven.

For further information, contact Kirvil Skinnarland, Puget Sound Water Quality Authority, Seattle, WA; or Michael Rylko, US EPA, Seattle, WA; or Mark Alderson, US EPA, Washington, DC.

National Estuary Program

Special Area Management Plan for Salt Pond Protection

Water quality and resource protection through local planning

RHODE ISLAND

Characteristics

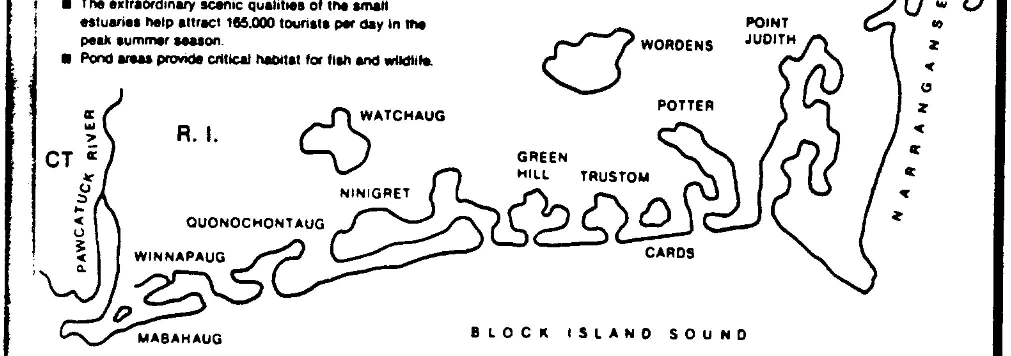
- Nine shallow coastal lagoons are of widely varying size
- A 38 square mile area is included in narrow pond watershed region.
- Land usage as of 1987 includes: wetland, 9 percent; private open land, 45 percent; public open space, 11 percent; developed area, 25 percent; agricultural area, 7 percent; other, 3 percent.

Resources

- The ponds serve as spawning grounds and nurseries for flounder, oysters, scallops, and clams.
- The extraordinary scenic qualities of the small estuaries help attract 165,000 tourists per day in the peak summer season.
- Pond areas provide critical habitat for fish and wildlife.

Issues

- Population is projected to quadruple by the year 2000 unless restrictive zoning is imposed.
- Groundwater contamination from septic systems causes seasonal algae blooms and threatens potable water quality.
- Bacterial contamination has curtailed shellfishing.
- Construction of permanent breachways in larger ponds has changed the salinity regimes.
- Erosion, coupled with misguided development, are endangering existing buildings and natural habitat.



Introduction

Local efforts to protect Rhode Island's ecologically important salt pond region have led to a unique planning partnership among the state's Coastal Resources Management Council, a number of local governments, the University of Rhode Island's Coastal Resources Center, and active citizen groups. This partnership has brought together the technical expertise and local implementation necessary to protect the water quality, habitat, and aquatic resources of a vulnerable coastal lagoon system.

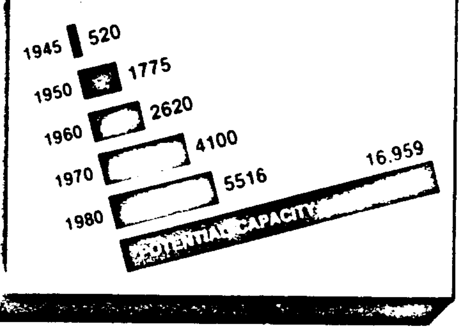
Overview of Salt Pond Characteristics and Problems

Known locally as Salt Ponds, Rhode Island's nine coastal lagoons are separated from the ocean only by a narrow strip of inlet-pierced barrier islands. The ponds have long supported commercial and recreational fisheries, and their associated wetlands provide critical habitat for waterfowl and aquatic species. The area also supports a major tourist industry based on recreational boating, swimming, and canoeing, and its attractive small fishing villages, farms, and old summer colonies have made it the state's most rapidly developing region. This rapid development, however, has brought with it problems that threaten to degrade the environmental quality of the salt ponds, including problems such as groundwater contamination, algae blooms, bacterial contamination of shellfish beds, sedimentation, and changes in fish and shellfish populations.

Developing a Management Initiative for the Salt Ponds

Local concerns were already aroused as the condition of the Salt Ponds worsened. In 1980, however, the

Number of Households in Salt Ponds Area IN THOUSANDS



Coastal Resources Center at the University of Rhode Island published an ecological history of the ponds that traced three centuries of pond use and abuse. The resulting outcry spurred a major research effort at the University of Rhode Island to determine the ecological health of the ponds, assess causes of problems, and determine trends in siltation, aquatic resources, and water quality.

The research verified that human activities were causing much of the ecological degradation in the Salt Ponds. Septic systems located in unsuitable sandy soils were often overloaded or malfunctioning, contaminating groundwater with bacteria and high nitrogen levels. This groundwater was entering the Salt Ponds, where it harmed shellfish habitat, promoted algae blooms, and depleted oxygen in the water. Excess nitrogen also was entering the pond system from fertilizers, stormwater runoff, and animal wastes. In addition, shore breachways had upset estuarine ecology by accelerating sedimentation and altering the circulation patterns and salinity mixtures important to key fish and shellfish species.

These findings clearly called for a broad, ecosystem approach to problem management. Under the auspices of Rhode Island's Coastal Zone Management and Sea Grant programs (both funded through the National Oceanographic and Atmospheric Administration), the Coastal Resources Center convened a Salt Pond Advisory Committee to help develop a Special Area Management (SAM) plan for the ponds. (SAM plans are developed under the Coastal Zone Management Program to provide special protection for designated geographic areas.) Members of the committee included representatives of state agencies, area towns, and local citizen groups who jointly developed and recommended a plan for addressing pond problems. Key issues addressed by the plan included water quality protection, breachway management and sediment controls, fisheries productivity, storm hazards, and land use. The plan also called for a comprehensive approach to management and decisionmaking by requiring that proposals for major developments be reviewed jointly and early on by all concerned local, state, and federal agencies.

After a series of public meetings , Rhode Island adopted the plan in 1984 for implementation by the state's Coastal Resources Management Council. At that point, the Salt Ponds Advisory Committee was replaced by an Action Committee of state agency staff and appointed members from each town. The committee complements the state's regulatory authority by developing nonregulatory initiatives and management strategies, as well as by providing an educational forum for the SAM plan.

The committee has also generated public interest and support for protective actions. The "Pondwatchers" citizen monitoring program, for example, has trained more than 40 volunteers to scientifically monitor water quality conditions in the ponds. Their findings have been used to complement the state's monitoring efforts, detect illegal outfalls, and support decisions on zoning, wastewater management, and shellfish bed closures. Publicized pondwatcher events have built support for the Salt Ponds, and the volunteers themselves have become strong advocates of resource protection initiatives.

The Pondwatchers

Program

- Over 40 trained volunteers monitor water quality conditions in seven ponds every other week from spring through mid-autumn.
- Citizens learn scientifically valid techniques of field sampling and analysis.
- A quarterly newsletter distributed to volunteers summarizes sampling results and tracks pertinent issues.

Outcome

- Pondwatchers have consistently obtained credible water quality data.
- Results have supported local wastewater management and zoning decisions and State policy decisions regarding shellfishing closures and resource management.
- Sampling stations and collection schedules complement State Department of Environmental Management's monitoring efforts, which are severely limited by budget and personnel constraints. At Department's request, Pondwatchers have expanded monitoring efforts to detect illegal outfalls to Salt Ponds. The State is considering a similar volunteer monitoring program for freshwater lakes and reservoirs around the State.
- Frequent press coverage of Pondwatchers' events in the Salt Pond region help build support for the Salt Ponds.
- Associations of Pondwatchers have become vocal advocates of resource protection initiatives.

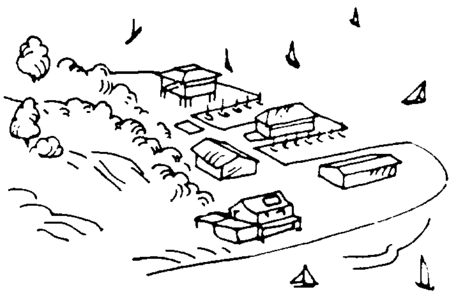
VOL 12

6460

Special Area Management Plan Features

Water Quality Protection

- Development of a coordinated permit procedure among management authorities designed to address flaws in the fragmented permitting process and promote consistent, timely agency responses based on a holistic ecosystem evaluation format.
- Use of land use classifications, density controls, and buffer strips to protect groundwater sources and critical areas.
- Strict limitations on extending infrastructure services such as public water and sewer service into undeveloped areas. Extensions are encouraged in overdeveloped sections.
- Use of denitrification units as part of a septic system maintenance, pumping, and upgrading program.
- Controls on pollution from point sources of runoff using drainage swales, and from petroleum storage tanks and offshore oil spills.
- Installation of sewage pump-out facilities at marinas.

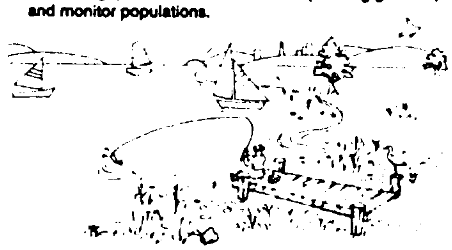


Breachway Management and Sedimentation Controls

- Specific restrictions on navigational dredging and inlet stabilization in designated pond areas, and on dredged material disposal.
- Delineation of compatible improvements to pond facilities.
- Remedial dredging to restore beneficial water circulation and flow conditions; installation of sediment catch basins and tidal gates.

Fish and Fisheries

- Appointment of fisheries stewards for the ponds.
- Establishment of management measures to prevent overfishing, protect brood stocks and spawning grounds, and monitor populations.



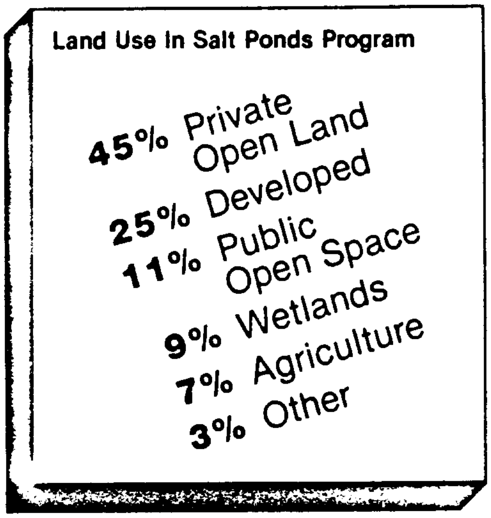
Intensifying Use

- Expansion of public access to beaches, boat launches, and recreational fishing areas; expansion of parks and campgrounds.
- Protection of open space and agricultural resources.
- Preservation and promotion of historic sites.

Storm Hazards

- Establishment of strict construction standards in floodzones, including special reconstruction provisions in areas susceptible to flooding.
- Restrictions on filling, removing, grading or restoration of shoreline features.
- Preparation of a regional post-storm restoration plan.

R0039768



Responsible Authorities and Financing

Funding for research and public education has come primarily through Rhode Island's Sea Grant and Coastal Resources Management programs; implementation of SAM recommendations is supported by the towns and by pass-through funds from the Coastal Resources Management Council.

Results

The SAM plan approach—targeting a specific geographic area for comprehensive planning and providing technical expertise for local decision-makers—is providing an effective framework for protecting the Salt Ponds from inappropriate development. Plan implementation has led to a coordinated review process for proposed development and has supported major initiatives to control runoff and upgrade local septic systems. Other protections introduced by the SAM plan include land-use controls such as limits on new public water/sewer service in undeveloped areas and buffer strips to protect groundwater sources and critical areas; breachway management such as restrictions on navigational dredging and disposal and restoration of pond circulation and flow conditions; fisheries management measures such as fishing limits and brood stock and spawning protections; and storm damage controls such as beachfront construction standards and building limitations.

Equally important, the plan has forged promising institutional links between technical experts and local decisionmakers.

Lessons Learned

The Salt Ponds SAM plan works because the causes, effects, and sources of pollution are clearly identified, and its goals well defined and based on an ecosystem management approach. The implementation of the SAM plan has shown that a partnership of local officials, technical experts, and citizens can effectively address difficult issues of resource use and development. It has also demonstrated that local officials can benefit from and use scientific information in the process of making environmental decisions. Finally, the Salt Ponds experience shows that a strong public participation and educational effort helps establish the firm local support and commitment needed to carry out the plan.

Remaining issues to be resolved include ensuring adequate financial support and consistent local support for appropriate planning, permitting, and enforcement.

COASTAL NONPOINT POLLUTION CONTROL PROGRAM

Program Development and Approval Guidance

January 1993

29

START

6462 F

FOREWORD

As part of the Coastal Zone Act Reauthorization Amendments of 1990, Congress enacted a new Section 6217 entitled "Protecting Coastal Waters". This provision requires states with coastal zone management programs that have received Federal approval under section 306 of the Coastal Zone Management Act (CZMA), to develop and implement Coastal Nonpoint Pollution Control Programs. These coastal nonpoint programs are to be used to control sources of nonpoint pollution which impact coastal water quality.

Section 6217 requires coastal states to submit their coastal nonpoint programs to the National Oceanic and Atmospheric Administration (NOAA) and the Environmental Protection Agency (EPA) for approval. Failure to submit an approvable program will result in a state losing a portion of its Federal funding under section 306 of the CZMA and section 319 of the Clean Water Act.

This document, developed by NOAA and EPA, contains guidance for states in developing and implementing their coastal nonpoint programs. It describes the requirements that must be met, including: the geographic scope of the program; the pollutant sources to be addressed; the types of management measures used; the establishment of critical areas; technical assistance, public participation, and administrative coordination; and, the process for program submission and Federal approval. The document also contains the criteria by which NOAA and EPA will review the states' submissions.

This document should be used in conjunction with the Guidance Specifying Management Measures for Sources of Nonpoint Pollution in Coastal Waters published by EPA in January 1993. Copies of that document can be obtained from EPA, 401 M ST, SW, Washington D.C. 20460.

EXECUTIVE SUMMARY

This document is the National Oceanic and Atmospheric Administration's (NOAA) and the Environmental Protection Agency's (EPA) *Coastal Nonpoint Pollution Control Program: Program Development and Approval Guidance* for state Coastal Nonpoint Pollution Control Programs (coastal nonpoint programs) developed under section 6217 of the Coastal Zone Act Reauthorization Amendments of 1990 (CZARA). This document should be read in conjunction with EPA's *Guidance Specifying Management Measures for Sources of Nonpoint Pollution in Coastal Waters*, which is discussed below.

Section 6217 requires states to establish coastal nonpoint programs, which must be approved by both NOAA and EPA. Once approved, the coastal nonpoint programs will be implemented through changes to the state nonpoint source pollution program approved by EPA under section 319 of the Clean Water Act (CWA) and through changes to the state coastal zone management program approved by NOAA under section 306 of the Coastal Zone Management Act (CZMA). Beginning in fiscal year 1996, states that fail to submit an approvable coastal nonpoint program to NOAA and EPA face statutory reductions in Federal funds awarded under both section 306 of the CZMA and section 319 of the CWA.

The statute and legislative history indicate that the central purpose of section 6217 is to strengthen the links between Federal and state coastal zone management and water quality programs in order to enhance state and local efforts to manage land use activities that degrade coastal waters and coastal habitats. This is to be accomplished primarily through the implementation of: (1) management measures in conformity with guidance published by EPA under section 6217(g) of CZARA, and (2) additional state-developed management measures as necessary to achieve and maintain applicable water quality standards.

This Program Development and Approval Guidance sets forth NOAA's and EPA's interpretation of the statutory requirements for the state coastal nonpoint programs, and is intended to assist states in developing approvable programs. The document first provides an overview of the legislative goals and requirements of section 6217. It then provides a description of the criteria that NOAA and EPA will use when reviewing coastal nonpoint programs for approval based on NOAA's and EPA's interpretation of CZARA's requirements. Finally, it discusses the program approval process established by NOAA and EPA. A decision by NOAA and EPA to approve or disapprove a state's program will be made on the basis of the applicable laws and regulations as applied to the specific facts presented by the program.

VOL 12

The following is a summary of the requirements for state coastal nonpoint programs.

6217(g) Guidance Management Measures and Additional Management Measures

The statute requires state programs to provide for the implementation of management measures in conformity with EPA's (g) guidance and for additional management measures for land uses and critical coastal areas adjacent to impaired or threatened coastal waters. Implementation of these additional management measures in combination with the basic (g) management measures must be designed so as to attain and maintain applicable water quality standards under section 303 of the CWA including protecting designated uses. (Section 6217(b)(1) and (2)).

In order to meet these requirements, states will need to include the following elements in their coastal nonpoint programs.

6217(g) Guidance Management Measures

- An identification of those nonpoint source categories and subcategories that impact coastal waters for which applicable (g) guidance management measures will be implemented. States must include a description of and justification for any exclusions from (g) guidance measures. These exclusions are limited to sources within a category (e.g., agriculture) or subcategory (e.g., confined animal facilities) which, individually or cumulatively, do not significantly impact coastal waters.

- A description of the (g) guidance management measures to be implemented, and the technical documentation for any alternative measures selected by the state for implementation in lieu of those in the (g) guidance.

- A description of the procedures that the state will use to ensure implementation of the management measures, including operation and maintenance practices, inspection procedures, certification procedures, and monitoring.

Additional Management Measures

- An identification of land uses and critical coastal areas that will require additional management measures.

- A description of state-developed additional management measures to be implemented to meet water quality standards and protect designated uses.

6467

Implementation of All Management Measures

- A description of a state program that ensures implementation of both the (g) guidance management measures and the additional management measures, including: designation of a lead state agency for each source category and/or subcategory, a description of the legal authorities to implement the management measures (i.e., enforceable policies and mechanisms), and a description of how the lead agency will implement the program.

- A schedule for full implementation of the (g) guidance management measures within three years of Federal approval and full implementation of additional management measures within eight years of Federal approval. The latter includes a two year period for evaluating the implementation of the (g) measures, and three years to implement the necessary additional measures. New activities will be subject to the applicable management measure requirements at the time of Federal approval.

6217 Management Area and Coastal Zone Boundary Modification

The statute requires each state to include a proposal to modify its coastal zone boundary as the coastal management agency deems necessary to implement NOAA's boundary recommendation.

NOAA has conducted its initial review of each state's coastal boundary. Based on this review, NOAA will make its recommendation to the states on the area to be included in the coastal nonpoint program (i.e., the section 6217 management area) in early 1993. NOAA and EPA expect that states will respond either by modifying the coastal zone boundary to implement NOAA's recommendation or by identifying other authorities that exist or will be established, as necessary, to implement the coastal nonpoint program outside the state's current coastal zone boundary but within the 6217 management area.

Enforceable Policies and Mechanisms

Section 306(d)(16) of the CZMA requires state coastal zone management programs to contain enforceable policies and mechanisms to implement the applicable requirements of the coastal nonpoint programs.

In order to satisfy this requirement, states will need to adopt, at a minimum, enforceable policies and mechanisms to implement the (g) guidance management measures and the additional management measures. These enforceable policies and mechanisms may be state and local regulatory controls, and/or non-regulatory incentive programs combined with state enforcement authority.

Program Coordination

The statute requires the coastal nonpoint programs to be coordinated closely with existing Clean Water Act programs and with approved state coastal zone management plans. In addition, the statute requires the establishment of coordination mechanisms among state agencies and between state and local officials responsible for land use programs and permitting, water quality permitting and enforcement, habitat protection, and public health and safety.

NOAA and EPA expect state coastal nonpoint programs to be well coordinated with all relevant Federal, state and local programs including those administered by EPA, NOAA and U.S. Department of Agriculture (USDA). In addition, states should establish mechanisms to coordinate the relevant state and local programs through joint project reviews, memoranda of agreement, or other mechanisms. Where possible, these mechanisms should build upon existing coordination procedures.

Technical Assistance

The statute requires states to provide technical and other assistance to local governments and the public for implementing the additional management measures.

NOAA and EPA expect states to identify those portions of the coastal nonpoint programs that are to be implemented by local governments and to include a program to provide technical and other assistance to local governments and the public in the state coastal nonpoint program.

Public Participation

The statute requires states to provide opportunities for public participation in all aspects of the coastal nonpoint program.

NOAA and EPA expect that the public will be involved early in the process of developing the coastal nonpoint program. The state must also provide an opportunity for public comment on the final coastal nonpoint program prior to submission of the program to NOAA and EPA, and an opportunity to participate in the implementation of the program.

VOL 12

Program Submission and Approval

States must submit their coastal nonpoint programs to NOAA and EPA for approval within 30 months of the publication of final management measures guidance (i.e., July 1995). When a state coastal nonpoint program receives final Federal approval, it will be incorporated automatically into the state's coastal management and nonpoint programs. NOAA and EPA have established a voluntary threshold review process to assist states in the development of their programs.

Federal Support for State Coastal Nonpoint Programs

NOAA is authorized under section 6217(f) of CZARA to provide funds to state coastal management agencies to develop coastal nonpoint programs. In addition, funds may be available under section 319 of the CWA to implement coastal nonpoint programs. NOAA and EPA will also work with the states to identify other sources of funds to develop and implement the state programs.

VOL 12

PROGRAM DEVELOPMENT AND APPROVAL GUIDANCE

I. PURPOSE AND INTRODUCTION

Water quality remains one of the most important environmental problems facing the United States. In coastal areas, beach closures, prohibitions on harvesting shellfish, and loss of biological productivity in coastal habitats are evidence of water quality impairment. Based on an assessment of 75% of United States estuarine waters, current best estimates are that 35% of these waters are impaired and 10% are threatened.

Coastal waters are affected by both point and nonpoint sources of pollution, with the latter a significant and, in many cases, the dominant form of pollution in a given water body. While great strides in controlling point sources of pollution have been made since the passage of the Federal Water Pollution Control Act in 1972, nonpoint source pollution remains a major problem in many coastal areas. The leading nonpoint contributors to estuarine waters are urban runoff (including certain construction activities and onsite disposal systems) and agriculture. Other significant nonpoint contributors in some coastal watersheds include silviculture, marinas, and hydromodification. In addition, the loss and degradation of wetlands and riparian areas has adversely impacted coastal water quality.

Congress enacted section 6217 of the Coastal Zone Act Reauthorization Amendments of 1990 (CZARA) in November 1990 to help address the problem of nonpoint source pollution in coastal waters.[1] (A copy of this statute is found in Appendix A.) Section 6217 requires that coastal states with federally approved coastal management programs develop Coastal Nonpoint Pollution Control Programs (hereafter, coastal nonpoint programs).[2] The legislative history indicates that the central purpose of section 6217 is to strengthen the links between Federal and state coastal zone management and water quality programs in order to enhance state and local efforts to manage land use activities that degrade coastal waters and coastal habitats.[3] The state coastal zone management agency designated under section 306 of the Coastal Zone Management Act (CZMA) and nonpoint source management agency designated under section 319 of the Clean Water Act (CWA) will have a dual and co-equal role and responsibility in developing and implementing the coastal nonpoint program.

6471

[1] Section 6217 does not amend the CWA or the CZMA, but rather contains independent provisions.

[2] The term "state" refers to states, territories and commonwealths having coastal management programs approved under section 306 of the Coastal Zone Management Act.

[3] As defined in section 304 (10) of CZARA and used in this guidance, "land use" includes water uses.

Although nonpoint source pollution is a significant source of pollution in coastal waters, the legislative history states that "the new program will not and ought not bear the full burden of restoring and maintaining coastal water quality, but will operate instead in conjunction with controls on point sources established under the Clean Water Act and associated programs." Therefore, state coastal nonpoint programs under section 6217 are required only to address nonpoint source pollution, and are expected to address, at a minimum, the major sources of nonpoint pollution specified in the (g) guidance.[4]

Thus, a state does not need to provide in its coastal nonpoint program for the implementation of the management measures developed by EPA under section 6217(g) of CZARA for activities that are clearly regulated as point source discharges.[5] However, in the interest of consistency and comprehensiveness, each state may choose to apply the (g) management measures to both point and nonpoint sources throughout the state's section 6217 management area, as long as the specific NPDES requirements are also met for those sources subject to NPDES permitting requirements.

Section 6217 envisions a two-tiered management approach for the control of nonpoint sources of pollution. To receive Federal approval, the state coastal nonpoint program must ensure: (1) the implementation, at a minimum, of management measures in conformity with the guidance developed under section 6217(g) by EPA, in consultation with NOAA and other Federal agencies, to protect coastal waters generally, and (2) the implementation of additional management measures applicable to land and water uses and critical coastal areas identified by the state pursuant to section 6217(b)(1) and (2) so as to attain and maintain applicable water quality standards under section 303 of the CWA and to protect designated uses.[6]

The purpose of the first tier is to protect coastal waters generally, and therefore, is not tied to specific water quality problems. The state must provide for the implementation

---

4 Historically, there have been overlaps and ambiguities among programs addressing nonpoint and point sources of pollution. Some of these overlaps, such as those which occur with the National Pollution Discharge Elimination System (NPDES) stormwater permit program (under section 402(p) of the CWA), are discussed in more detail in Appendix B. Many of the techniques and practices used to control point sources, such as channelized urban stormwater, are equally applicable to nonpoint sources, and vice versa. Nevertheless, the programs do not have identical requirements. Certain NPDES requirements may go beyond the management measures specified in the (g) guidance.

5 For simplicity, the guidance containing these management measures, which was published by EPA in January, 1993, will be referred to as the "(g) guidance" in this document. A list of the management measures included in this guidance is provided as Appendix C.

6 In addition to addressing the contribution of pollution through runoff from the land, the state coastal nonpoint program should also consider the infiltration of pollutants into ground water which can result in the pollution of surface waters.

of these management measures in conformity with the (g) guidance which includes management measures for the following categories of nonpoint pollution sources: agricultural runoff; urban runoff; silvicultural runoff; hydromodification, shoreline erosion, and dams; and marinas. In addition, the (g) guidance includes management measures for wetlands protection, riparian areas, and vegetated filter strips, which are effective for several different source categories.

If the general level of protection provided by the first management tier is insufficient to enable coastal waters to meet water quality standards and protect designated uses, then the state must implement the second tier which consists of additional management measures. The purpose of the second tier is to restore coastal waters and, in the case of the critical areas, to protect against future pollution problems.

This document, developed by the National Oceanic and Atmospheric Administration (NOAA) and the Environmental Protection Agency (EPA), contains guidance for developing and implementing coastal nonpoint programs. The first section of this guidance introduces the coastal nonpoint program. The second section provides an overview of the statute's requirements. The third section discusses the specific program requirements, including requirements for coordination with other programs; the geographic scope of the coastal nonpoint program and coastal zone boundary review; implementation of management measures in conformity with EPA's (g) guidance and additional state-developed management measures; technical assistance; public participation; administrative coordination; and enforceable policies and mechanisms. The final section describes EPA's and NOAA's process for review and approval of coastal nonpoint programs submitted by the states, and the schedule for state implementation of the program.

VOL 12

6474

II. OVERVIEW OF STATUTORY REQUIREMENTS AND PROGRAM APPROVAL PROCESS

Congress enacted CZARA section 6217, entitled "Protecting Coastal Waters," to address the impacts of nonpoint source pollution on coastal water quality.[7] Section 6217(a) requires each state with a federally approved coastal zone management program under section 306 of the CZMA to develop and submit to NOAA and EPA a coastal nonpoint program for approval. The statute states that the purpose of this new state program "shall be to develop and implement management measures for nonpoint source pollution to restore and protect coastal waters, working in close conjunction with other State and local authorities."

NOAA and EPA do not expect states to develop and implement stand-alone coastal nonpoint programs, but rather expect that states will develop and implement the coastal nonpoint program through changes to the approved state nonpoint source management program and to the approved state coastal zone management program developed under section 306 of the CZMA, as amended.

All states and territories have EPA-approved nonpoint source management programs or portions of programs and are currently receiving section 319 grants to assist them in implementing the approved programs. Currently, there are 29 federally approved state and territorial coastal zone management programs developed and approved pursuant to the CZMA (see Appendix D).

II.A. Statutory Requirements

Under section 6217, coastal nonpoint programs must contain a number of elements in order to be approvable by NOAA and EPA. The state programs must:

1. be closely coordinated with existing state and local water quality plans and programs developed pursuant to sections 208, 303, 319 and 320 of the CWA, and with state coastal zone management programs.

2. provide for the implementation, at a minimum, of management measures in conformity with the guidance published under section 6217(g) to protect coastal waters generally (discussed in section II.B).

3. provide for the implementation and continuing revision from time to time of additional management measures that are necessary to attain and maintain applicable water quality standards and protect designated uses with respect to:

[7] This section has been codified at 16 U.S.C. § 1455b.

R0039782

a. land uses which, individually or cumulatively, may cause or contribute significantly to a degradation of (a) coastal waters not presently attaining or maintaining applicable water quality standards or protecting designated uses, or (b) coastal waters that are threatened by reasonably foreseeable increases in pollution loadings from new or expanding sources; and

b. critical coastal areas adjacent to coastal waters which are failing to attain or maintain water quality standards or which are threatened by reasonably foreseeable increases in pollution loadings.

4. provide for technical and other assistance to local governments and the public to implement additional management measures.

5. provide opportunities for public participation in all aspects of the program.

6. establish mechanisms to improve coordination among state agencies and between state and local officials responsible for land use programs and permitting, water quality permitting and enforcement, habitat protection, and public health and safety.

7. propose to modify state coastal zone boundaries as the state determines is necessary to implement NOAA recommendations under section 6217(e), which are based on findings that modifications to the inland boundary of a state coastal zone are necessary to more effectively manage land and water uses to protect coastal waters.

This guidance discusses these requirements in greater detail in section III and explains NOAA's and EPA's expectations for state coastal nonpoint programs.

In addition to the provisions of section 6217, CZARA amended section 306 of the CZMA to require that, before approving a coastal zone management program submitted by a coastal state, NOAA shall find that, "...the management program contains enforceable policies and mechanisms to implement the applicable requirements of the Coastal Nonpoint Pollution Control Program of the State required by section 6217...." (section 306(d)(16)). States with federally approved coastal management programs must demonstrate compliance with section 306(d)(16) in order to receive final approval of their coastal nonpoint programs.

The statute requires that states submit their coastal nonpoint programs to NOAA and EPA 30 months after EPA publishes final (g) guidance. The final (g) guidance was published in January 1993; therefore, coastal states must submit their coastal nonpoint programs to NOAA and EPA for approval in July 1995.

II.B. Section 6217(g) Management Measures Guidance

Section 6217(g) requires that EPA, in consultation with NOAA, the U.S. Fish and Wildlife Service, and other Federal agencies publish "guidance for specifying management measures for sources of nonpoint pollution in coastal waters." Management measures are defined in section 6217(g)(5) as:

> "*economically achievable measures for the control of the addition of pollutants from existing and new categories and classes of nonpoint sources of pollution, which reflect the greatest degree of pollutant reduction achievable through the application of the best available nonpoint pollution control practices, technologies, processes, siting criteria, operating methods, or other alternatives.*"

As provided by section 6217(g)(2), the management measures guidance includes:

> (A) "a description of a range of methods, measures, or practices, including structural and nonstructural controls and operation and maintenance procedures, that constitute each measure;
>
> (B) a description of the categories and subcategories of activities and locations for which each measure may be suitable;
>
> (C) an identification of the individual pollutants or categories or classes of pollutants that may be controlled by the measures and the water quality effects of the measures;
>
> (D) quantitative estimates of the pollution reduction effects and costs of the measures;
>
> (E) a description of the factors which should be taken into account in adapting the measures to specific sites or locations; and
>
> (F) any necessary monitoring techniques to accompany the measures to assess over time the success of the measures in reducing pollution loads and improving water quality."

The (g) guidance provides a basis for the state coastal nonpoint programs.

II.C. Procedures for Program Development and Approval

NOAA and EPA have prepared this program development and approval guidance to assist states in developing approvable coastal nonpoint programs. The states are encouraged to consult with NOAA and EPA as they develop specific program elements. NOAA and EPA have established a voluntary threshold review process to assist states in the development of their programs. This process is discussed in more detail in section IV.B.

NOAA and EPA will jointly review the state program within six months after submission. Because of the inseparable nature of the land use and water quality portions of the coastal nonpoint programs in achieving the statutory goals, NOAA and EPA have determined as a matter of policy that neither agency will grant approval to a state's coastal nonpoint program until the program meets the Federal approval requirements as determined by both agencies.

If a coastal state fails to submit an approvable program within 30 months after publication of the (g) guidance, NOAA and EPA will reduce Federal grant dollars to the state under the coastal zone management and nonpoint source management programs as required by section 6217(c)(3) and (4). The penalty provisions begin in Fiscal Year 1996 with a 10% reduction in funding under both programs, increasing to 15% in FY 1997, 20% in FY 1998, and 30% in FY 1999 and each fiscal year thereafter. In the case of the coastal zone management program, the penalty is based upon the grants otherwise available to a state in the current fiscal year. In the case of the section 319 nonpoint source management program, the penalty is based on the grant amount awarded to the state for the preceding fiscal year.

Under certain limited circumstances, a state may request a conditional approval of its coastal nonpoint program. If a state is granted conditional approval of its program, the penalty provisions of section 6217 will be suspended during the conditional approval period if the state continues to make progress on the workplan and to meet the milestones agreed to with NOAA and EPA as part of the conditional approval. (See discussion of conditional approval in section IV.C.)

II.D. Federal Support for State Coastal Nonpoint Programs

NOAA is authorized under section 6217(f) of the CZARA to provide funds to the designated state coastal management agency to develop its coastal nonpoint program. The Federal funds may not exceed 50% of the cost of developing the program, and the state share of costs must be paid from non-Federal sources. NOAA has published separate guidance on application procedures and allocations. Since funds will be limited, state coastal agencies are encouraged to work closely with state nonpoint source agencies and other appropriate Federal, state, regional and local agencies to develop their coastal nonpoint programs. Funds under section 319(h) of the CWA are available for program implementation.

NOAA and EPA will consider using additional financial incentives and/or disincentives to encourage states to develop effective coastal nonpoint programs within the statutory deadline.

III. SPECIFIC COASTAL NONPOINT PROGRAM REQUIREMENTS

State coastal nonpoint pollution programs must contain a number of components mandated by section 6217. The following section discusses these statutory requirements and the minimum criteria that the state coastal nonpoint program needs to meet to obtain Federal approval.

III.A. Coordination with Existing State Programs

The statute requires that state coastal nonpoint programs be closely coordinated with state and local water quality plans and programs under sections 208, 303, 319, and 320 of the CWA, and with state coastal zone programs. (Section 6217(a)(2)). Some of these programs are discussed in Appendix E. This requirement is necessary to ensure that the new coastal nonpoint program can be integrated into existing state programs upon approval.

During the program development process, NOAA and EPA expect state coastal zone management and nonpoint source agencies to involve the relevant Federal, state, regional and local programs. A number of states already closely coordinate the activities of these programs through their existing coastal zone management and state nonpoint programs. States should develop their coastal nonpoint programs to complement and strengthen existing coastal management and nonpoint source authorities, while minimizing unnecessary duplication or conflicts at the Federal, state or local levels. Components of existing programs that meet the requirements of section 6217 should be incorporated into the states' coastal nonpoint programs.

III.B. Coastal Zone Boundaries and 6217 Management Area

As directed by section 6217(a), the geographic scope of each coastal nonpoint program must be sufficient to ensure implementation of management measures to "restore and protect coastal waters." Section 6217(e), which requires NOAA to conduct a review of each state's coastal zone boundary, refines the focus to require NOAA to determine the geographic area encompassing the land and water uses having a "significant" impact on a state's coastal waters. A significant impact can occur from both the individual and cumulative effects of land and water uses. NOAA and EPA will not approve a state coastal nonpoint program whose geographic scope does not encompass such uses because a program that does not control the significant land and water uses cannot be expected to "restore and protect coastal waters".

Section 6217(e) requires that NOAA, in consultation with EPA, review each state's existing state coastal zone boundary established under the CZMA, and recommend any modification to that boundary needed to effectively manage land and water uses to protect coastal waters. Specifically, the statute directs NOAA, in consultation with EPA, to evaluate whether each state coastal zone boundary extends inland to the extent necessary to control nonpoint source pollution from land and water uses that have a significant impact on a state's coastal waters. See section 6217(e)(1). If NOAA, in consultation with EPA, finds that boundary modifications are necessary for a state to more effectively manage land and water uses to protect coastal waters, then NOAA shall recommend appropriate modifications. See section 6217(e)(2).

Although expressed in terms of a recommendation that a state modify its coastal zone boundary, NOAA's recommendation also defines what NOAA and EPA believe should be the geographic scope of that state's coastal nonpoint program, i.e., "the 6217 management area". A state program need not adopt the exact 6217 management area recommended by NOAA if the state can demonstrate that a smaller geographic area would be adequate to restore and protect coastal waters. Absent such a demonstration, however, NOAA and EPA expect the geographic scope of the coastal nonpoint program to correspond to NOAA's recommendation.

To provide a basis for its recommendation, NOAA conducted a review of states' existing coastal zone boundaries and provided each state with an analysis of its boundary. In conducting this review, NOAA, in consultation with EPA, compared indicators of nonpoint source pollution potential within coastal zone boundaries, and within coastal watersheds. Coastal watersheds were selected because watersheds provide a logical physical unit when dealing with nonpoint source pollution. To provide a uniform framework for evaluation, the review was based on the national hydrologic unit classification system developed by the U.S. Geological Survey (USGS). For purposes of this review, coastal watersheds were defined as the USGS Cataloging Units adjacent to the shore and extending inland along estuaries to include the USGS Cataloging Units that encompass the head of tide.

Within each state, NOAA evaluated each watershed that drains into coastal waters, whether or not that watershed is encompassed within a state's existing coastal zone. Based on nationally available data, NOAA determined for each watershed whether significant indicators of nonpoint pollution potential were present within four analysis areas: (1) the existing coastal zone, (2) the coastal watershed, (3) the area inland of the coastal watershed within the state's borders, and (4) the area beyond the state borders that drain into coastal waters. NOAA has focused on significant indicators of nonpoint source pollution in compliance with section 6217(e) which directs NOAA to evaluate whether the coastal zone extends inland "to the extent necessary to control land and water uses that have a significant impact on coastal waters of the State." (Section 6217(e)(1)).

Based on the review of each coastal watershed, NOAA will develop a preliminary assessment of the appropriate geographic scope of the state's program, i.e., the 6217 management area, and will make a corresponding recommendation for modification to the state's coastal zone boundary. Where the coastal watershed appears to capture most of the significant indicators of nonpoint pollution potential, NOAA will recommend the coastal watershed as the 6217 management area. Where significant indicators of nonpoint source pollution are present inland of the coastal watershed, NOAA will recommend that the 6217 management area extend inland of the coastal watershed.[8]

Finally, in coastal watersheds where an area less than the coastal watershed captures most of the significant indicators of nonpoint source pollution, especially where the existing coastal boundary closely aligns with the coastal watershed, NOAA will recommend that lesser area as the 6217 management area. In no case will NOAA recommend an area less than the existing coastal zone as the 6217 management area.

The geographic scope of the coastal nonpoint program must be based on the impact of land and water uses on coastal waters. NOAA's boundary recommendation will specify a 6217 management area to guide states during program development.[9] In response to this recommendation, states are encouraged to undertake their own analysis of their coastal watersheds. At the time of program submission, a state may propose an alternative 6217 management area, in which case the state must demonstrate to NOAA's and EPA's satisfaction that the management area extends as far as necessary to control sources of nonpoint pollution that, individually or cumulatively, significantly impact the state's coastal waters. NOAA and EPA will evaluate the adequacy of the state's proposed 6217 management area as part of the program review and approval process. Specific criteria for this evaluation are being developed by NOAA and will be published separately.

A state is expected to demonstrate authority to manage the final 6217 management area in one of two ways. First, a state may demonstrate that its coastal zone boundary has been modified to encompass the entire 6217 management area. If the state coastal zone management agency lacks authority to modify the boundary, the coastal nonpoint program must contain recommendations to the appropriate state authority for changes to the coastal zone boundary. Because there is no assurance that the coastal zone boundary will be modified as proposed, NOAA and EPA also expect a state to demonstrate that it

---

[8] The nature of the underlying data makes it infeasible for NOAA to recommend a specific distance beyond the coastal watershed. States will be expected to examine these watersheds during program development to analyze indicators of nonpoint pollution and to determine the inland extent of the 6217 management area.

[9] Section 6217(b)(7) requires that each state program contain a proposed or recommended coastal zone boundary modification as necessary to implement the NOAA recommendation.

VOL 12 6481

R0039789

has the necessary authorities, including enforceable policies and mechanisms, to ensure implementation of the coastal nonpoint program within the 6217 management area.

Second, because the modification of a state's coastal zone boundary necessarily has other implications besides nonpoint source pollution control, a state may choose not to alter its coastal zone boundary. Areas outside the coastal zone, but within the 6217 management area, would be managed with other state authorities networked into the coastal nonpoint program. Although changing the coastal zone boundary to address NOAA's recommendation may be preferable because it would provide the clearest delineation of the geographic scope of the coastal nonpoint program, the statute does not make this a prerequisite for Federal approval. If the state's 6217 management area extends beyond the state's existing coastal zone boundary, the state must also show that it has the necessary authorities, including enforceable policies and mechanisms, to ensure the implementation of the program's management measures with the 6217 management area.[10]

III.C. Implementation of Management Measures In Conformity with Section 6217(g) Guidance

For program approval, each coastal nonpoint program must "provide for the implementation, at a minimum, of management measures in conformity with the guidance published under subsection (g), to protect coastal waters generally..."(section 6217(b)). In developing the (g) guidance, EPA focused on the significant categories and sources of nonpoint pollution identified in state section 319 nonpoint source assessments. The categories of nonpoint sources addressed in the (g) guidance are: agricultural runoff; urban runoff (including developing and developed areas); silvicultural (forestry) runoff; hydromodification, including shoreline erosion, and dams; and marinas. In addition, the (g) guidance includes management measures for wetlands protection, riparian areas and vegetated filter strips, which apply to a number of sources. A number of specific source subcategories are also discussed in detail in the (g) guidance.

In order to satisfy the statutory requirement to provide for implementation of management measures in conformity with the (g) guidance, state programs must:

1. Identify nonpoint source categories or subcategories that will be addressed;
2. Identify management measures to be implemented for those categories and subcategories; and,
3. Describe the process by which the state will ensure the implementation of the management measures.

[10] In addition, a state may choose to utilize a combination of the two approaches described above.

VOL 12

6482

These elements are discussed in more detail in the following sections.

In its coastal nonpoint program document, a state must respond to each of the (g) management measures by either: (1) providing for the implementation of that measure or an alternative as effective as the (g) measure; or (2) justifying why the management measure is not included in the program. This justification must be based on the exclusion of certain nonpoint categories or subcategories using the process described in section III.C.1.

III.C.1. Identification of sources to be addressed

For program approval, states must provide for the implementation of management measures for each of the nonpoint source categories (e.g., agriculture) and subcategories (e.g., confined animal facilities) identified in the (g) guidance to protect coastal waters generally. States must also provide for the implementation of management measures specified for wetlands and riparian area protection. In addition, a state may include management measures for sources not identified in the (g) guidance (e.g., mining operations not subject to permitting under section 402 of the CWA), if the state determines such management measures are necessary to protect coastal waters generally.

NOAA and EPA may allow a state to exclude some categories, subcategories or sources from the requirements of its coastal nonpoint program. An exclusion may occur under two scenarios: (1) if a nonpoint source category or subcategory is neither present nor reasonably anticipated in the 6217 management area, or (2) if a state can demonstrate that a category, subcategory or particular source of nonpoint pollution does not and is not reasonably expected to, individually or cumulatively, present significant adverse effects to living coastal resources or human health.

Under the first scenario, a state can exclude one or more nonpoint source categories or subcategories in coastal watersheds or parts of coastal watersheds. To do so, a state must clearly demonstrate that each of those nonpoint source categories or subcategories is neither present nor reasonably anticipated in such areas. If such a demonstration is made, the state need not develop and provide for the implementation of management measures for those nonpoint source categories or subcategories. For example, if a state does not have and does not foresee the establishment of an animal feeding operation in the 6217 management area, it need not develop a program to control such operations. It should be noted, however, that when the exclusion applies only to a portion of the area or a particular coastal watershed, the state must still provide for the implementation of the management measures in all other portions of the 6217 management area where the categories or subcategories are present or anticipated.

Under the second scenario, states may exclude certain sources within retained categories and subcategories. To do so, the state must adequately demonstrate that those sources, individually and cumulatively, do not and are not reasonably expected to present significant adverse effects to living coastal resources or human health. Factors that may be considered to exclude such sources include, but are not limited to:

- pollutant loadings or estimates of loadings from the sources;
- intensity of land use; and
- ecological and human health risk associated with the source.

In general, this second type of exclusion is designed to exclude sources that are present in the 6217 management area but that, individually or cumulatively, do not and are not reasonably expected to cause significant adverse effects to living coastal resources or human health. In determining the significance of adverse effects, states should consider both direct and indirect adverse effects. An example of a source that may be excluded under this approach could include an on-site disposal system located a considerable distance from surface coastal waters and above the groundwater table.

NOAA and EPA wish to emphasize the limited applicability of this second type of exclusion. For this reason, NOAA and EPA have expressly placed the burden upon the states to demonstrate that any excluded sources will not and are not reasonably expected to present adverse effects to living coastal resources or human health, and that the application of the (g) measures to the remaining sources will protect coastal waters generally.

For either type of exclusion, states must submit a description and documentation of the data and rationale relied upon for excluding the sources. The documentation should include information contained in existing state water quality assessments (including those developed under sections 305(b) and 319 of the CWA), other information sources listed in Section III.D., and existing data (or modelling results) that indicate the insignificance of the loadings or hydrologic impacts caused by sources that the state proposes to exclude.

EPA and NOAA will review the states' submissions, including the adequacy of the assessments, to determine whether the category or subcategory needs to be addressed by the coastal nonpoint program. The issue of assessment adequacy may be discussed through the threshold review process. In addition, NOAA and EPA will, at a state's request, consider proposed exclusions during the threshold review process discussed in section IV.B.

In the "Applicability" section of many management measures in the (g) guidance, EPA has already established minimum sizes below which the measures do not apply (e.g., marinas with less than 10 slips) based on economic achievability analysis. In such cases, state programs should address all sources above those minimum levels, except where a state can document, as described above, that a less stringent level in a particular geographic area will still allow protection of coastal waters generally.

It should be noted that sources excluded from the (g) measures implementation nevertheless may be subject to additional management measures discussed in section III.D.

III.C.2. Identification of management measures to be implemented

For program approval, states must specify the management measures that will be implemented to address each category or subcategory of sources identified through the process in section III.C.1 of this guidance document. Section 6217(b) requires state management measures to be in conformity with those measures specified in the (g) guidance. A state management measure is "in conformity with" those specified in the (g) guidance if it is identical to, or is demonstrated to be as effective as, the (g) guidance measures.

In order to accommodate variabilities relating to source, location and climate, or other local conditions that could affect the implementation of the (g) guidance management measures, the (g) guidance also lists a number of practices that can be used to implement each management measure. States have considerable flexibility in choosing management practices to achieve the management measures and are not restricted to specifying or implementing the practices described in the (g) guidance. The practices or system of practices chosen, however, must ensure the effective implementation of the management measures. For program approval, the coastal nonpoint program must describe the process the state will use to select practices that will result in the effective implementation of the (g) guidance management measures.

Selection of Alternative Management Measures

In developing management measures in conformity with the (g) guidance, states may select "alternative management measures" under two conditions: (1) states have conditions that make the 6217(g) measures inapplicable or unsuitable, or (2) other measures that equal or exceed the effectiveness of the 6217(g) measures already exist or are scheduled to be implemented under existing state laws or programs. The use of alternative management measures in these situations is supported not only by the statute, which acknowledges that the (g) measures may be adapted to specific sites or locations (section 6217(g)(2)(E)), but also by the legislative history which directs NOAA and EPA to accord states flexibility in selecting management measures.

States may use these alternative measures instead of the (g) measures in their coastal nonpoint programs only if they can demonstrate that such alternatives are as effective in controlling nonpoint pollution as the measures specified in the (g) guidance. For program approval, a state electing to specify an alternative management measure for implementation will need to demonstrate that the alternative is at least as effective as the (g) guidance management measure it intends to replace. States should use the best available information to make this showing.

Management measure effectiveness can be evaluated or described in many ways: pollutant loading, pollutant loading reductions, pollutant concentration in discharge, peak concentration reductions, mean concentration reductions, habitat impacts (including impacts resulting from changes in flow), impacts to fisheries, impacts to macroinvertebrates, wildlife impacts, effects on support of designated uses, direct impacts to the water resource of concern, the extent to which the source is actively managed, or other factors. States may use any combination of these factors to demonstrate the effectiveness of alternative management measures.

For approval of an alternative management measure, the state will need to demonstrate that the alternative management measure (or a combination of measures or a series of measures applied over time) is as effective as the measure set forth in the (g) guidance when applied in the specific state or local area. For example, when management measures in the (g) guidance specify certain storm events, design criteria or pollutant reduction levels, the alternative management measures must specify similar storm events, design criteria or pollutant reduction levels. In addition, the state will need to demonstrate that the operation and maintenance procedures for the alternative are feasible and adequate to maintain a level of pollution control as effective as the (g) guidance measure over the lifetime of the measure. In choosing an alternative management measure, states should take into account possible adverse impacts of these alternative measures on other coastal resources such as ground water or wetlands.

In support of its alternative management measure, a state will need to identify the procedures used to evaluate the measure and the results of that evaluation, and provide specific technical documentation of the evaluation as part of their coastal nonpoint programs. In general, information used to document that an alternative management measure is as effective as a (g) guidance measure should be comparable in scope and depth to that provided in EPA'S (g) guidance. States must support the evaluation of alternative management measures with appropriate technical documentation. Although sources such as "refereed" technical journals are preferred, other publications, such as Federal and state technical guides, are acceptable. Fliers, fact sheets, and other general public materials generally are not adequate sources of information without additional supporting information.

In addition, or as an alternative to relying on written studies, the state may wish to convene a technical review group consisting of experts knowledgeable in the subject area covered by the management measure. This may be especially useful where the state is interested in pursuing innovative approaches. The technical review group should provide a report describing the evaluation procedure that was used to assess the effectiveness of the alternative management measure. The report should be submitted to NOAA and EPA as part of the program review process. EPA and NOAA will, at the state's request, consider proposed alternative management measures during the threshold review process and/or approval process discussed in section IV.

Innovative Market-Oriented Incentive Mechanisms

EPA and NOAA are interested in encouraging states to propose innovative market-oriented incentive mechanisms to implement the (g) measures or alternative management measures at lower costs. An important example of incentive mechanisms that could serve to lower substantially the costs of obtaining a given level of loadings reductions is the trading of pollution reduction credits.

Trading programs are proving to be a successful and cost-effective approach under the Clean Air Act for reducing air pollutant emissions. Several case studies in North Carolina, Colorado, and Wisconsin show that the trading of pollution credits holds considerable promise for reducing water pollutant loadings as well, particularly nutrients. See Appendix H for short descriptions of these cases. Appendix H also presents several brief summaries of relevant technical publications. These publications indicate that pollutant trading programs may hold potential for achieving substantial cost savings while attaining pollution reductions equivalent to those established by the (g) measures guidance.

Conceptually, sources with low control costs would make trading arrangements directly with sources facing high control costs. The low-cost sources would undertake additional abatement efforts in exchange for financial compensation from the high-cost sources. Sources with higher abatement costs would undertake less control efforts, while acquiring additional reductions from other lower cost sources. Increased loadings from the high-cost sources would be offset by the additional abatement efforts of low-cost sources, so that the total loadings would be the same as if no trading occurred. In this manner, the private incentives of polluters would be harnessed for public purposes. Thus, more pollution abatement would be undertaken where it was cheapest, and less would be undertaken where it was costly, reducing the overall cost while achieving the same overall level of control. Such a trading scheme can minimize the total cost of achieving the required reduction in loadings.

EPA and NOAA encourage states to propose innovative approaches such as the theoretical case outlined above and as described in Appendix H. Any such proposal, of course, must be consistent with the requirements of CZARA. At a minimum, in order for EPA and NOAA to approve a market-based proposal as achieving implementation of particular (g) measures, states would need to demonstrate that the proposal would result in expected pollutant reductions equalling or exceeding those that otherwise would be achieved in the same watershed if each participant separately implemented the (g) measures. Finally, as with the implementation of any management measure, a trading program would also need to meet the requirements for enforceable policies and mechanisms described in section III.H.

States may consider trading schemes which involve trading of pollution credits among nonpoint and point sources as well as among nonpoint sources alone. States may also consider trading among sources inside and outside of the geographic area subject to the (g) measures guidance, as long as such sources are within the same watershed. States may also consider trading arrangements involving different pollutants (such as nutrients) with similar environmental effects, to the extent that the state demonstrates that any net environmental benefit is expected to result from the trading program. However, these trading schemes should take into account uncertainties such as those associated with measurements or predictions of pollutant loadings of a pollutant from the array of sources involved. States should consider whether trading ratios should be established to account for such uncertainties.

The likelihood of success of trading programs can be increased if states carefully define the responsibilities of sources involved. Trading programs should provide assurance that the validity of trading agreements will be preserved. Trades between sources are most promising if they shift the responsibility for the agreed-to controls entirely from the buyer to the seller, who would then be subject to the enforceable policies and mechanisms referenced above. If buyers are required to adopt additional controls when sellers fail to implement agreed-to controls, then trading programs are less likely to succeed. Similarly, trades are most promising if they are based only on the validity of the agreement, and not on the success of the controls agreed to by the seller. Otherwise, the risks to buyers of trading -- that is, having to pay twice -- may prevent many trades and undermine the effectiveness of a trading program.

EPA and NOAA encourage states to focus on minimizing the costs of transacting trades. Delays and uncertainty in arranging specific trades, as well as direct application fees, can serve to raise the costs of transacting trades, to hinder trades, and to lower the likelihood that such trades will reduce compliance costs. Similarly, arbitrary requirements that trades substantially reduce net expected pollutant loadings can serve to raise transaction costs and deter trades. Finally, states should establish guidelines for sources to follow in arranging trades. Such guidelines should help reduce unnecessary delays, avoid any later invalidation of trades, and lower transaction costs by increasing the likelihood that trades will be approved in advance.

When proposing a trading program to control nonpoint sources, a state would need to determine from EPA's (g) measures guidance and other sources the pollutant loading reductions that must be achieved from a group of sources within a watershed over a specified period, such as a season or a year. This establishes the baseline that the trade would need to achieve. For example, implementing the (g) guidance control measures on a dairy farm of given characteristics could be expected to reduce nutrient loadings by a certain amount. Each source would be required to reduce loadings by the necessary amount, by implementing controls on-site, or off-site through appropriate trading arrangements. Sources that believe their costs of achieving the necessary loading reductions are high could finance incremental controls at other sources with lower costs, expecting such trades to be approved. Compliance would be ascertained through demonstration that the necessary loadings reductions are achieved either on-site by implementing control measures, or off-site through appropriate trading arrangements, consistent with enforceable policies and mechanisms established elsewhere by the state in its coastal nonpoint program.

Multiple Management Measures

Section 6217(g)(5) of CZARA requires that management measures be economically achievable. In its economic achievability analysis, EPA estimated costs of selected combinations of multiple management measures applicable to sources. EPA focused its analysis on those cases which it believes are most likely to occur. Multiple measures which EPA concluded are economically achievable include (1) erosion control, confined animal feedlots, and grazing management measures, (2) combination of all forestry measures, (3) new development requirements such as stormwater, erosion and sediment control, and septic tanks, (4) all marina requirements; and (5) municipality requirements such as stormwater, erosion and sediment control, bridge maintenance, salt storage, street sweeping, wetlands protection, stream stabilization, and dam-related expenses.

EPA and NOAA recognize that it is impossible to determine economic achievability for all possible combinations of management measures. For example, a dairy farm might be responsible for control of discharge from animal feedlots, grazing, erosion, streambank stabilization, and wetlands preservation. In this case, EPA has found that a combination of management measures for erosion, feedlots and grazing are economically achievable, but not in combination with wetlands protection and streambank stabilization. In situations where EPA has not considered a specific combination of management measures in its economic achievability analysis, states may be granted flexibility to re-examine whether a particular combination of multiple management measures is economically achievable for a group of sources. If, in its program submission or in subsequent revisions, a state finds that EPA did not consider the economic achievability of multiple management measures that apply to a group of sources when added together, the state may propose a fresh determination of management measures applicable to that group of sources. When making these determinations, states will need to meet the requirements of CZARA, including section 6217(g), which defines management measures as reflecting the greatest degree of pollutant reduction economically achievable. States may take into account direct and indirect costs and may consider incremental costs relative to incremental reductions in loadings.

III.C.3. Description of the implementation process and authorities

For program approval, the state will need to provide detailed information on how it will ensure implementation of the management measures in conformity with the (g) guidance. This information should be provided for each nonpoint source category or subcategory as identified in section III.C.1.

At a minimum, for each category and subcategory, the state coastal nonpoint program will:

a. Describe the scope, structure, and coverage of the state implementation program.

b. Describe the organization, structure and authorities of the state or local agency or agencies that will have responsibility for administering the implementation program, including:

i. an identification of the designated lead agency for the program addressing each category or subcategory. If the designated lead agency is not the section 319 or coastal zone management agency, the description must specify how the lead agency and its authorities have been incorporated into the coastal nonpoint program.

ii. a description of how the lead agency expects to implement the program including, for example, the number of staff and general responsibilities, cost of the program and potential funding sources.

c. Include a schedule for each nonpoint source category or subcategory with milestones for achieving full implementation of the management measures within three years as described in section IV.D.

d. Identify enforceable policies and mechanisms to ensure that each management measure identified in the coastal nonpoint program is implemented in accordance

VOL 12

6490

R0039798

with section III.H. of this guidance. States must submit copies of the appropriate legislative and administrative documents to demonstrate that authorities exist to support implementation of the management measures. Furthermore, if the enforcement authority will not be exercised directly by the state coastal zone management or section 319 agency, the state coastal nonpoint program must include provisions to ensure that the governmental body with the statutory authority exercises that authority as set forth in the state's coastal nonpoint program. States must submit documentation such as memoranda of understanding, executive orders or administrative directives which embody agreements to ensure this conformity. These authorities must be incorporated into the coastal nonpoint program.

e. Describe mechanisms to improve coordination among state agencies and among state and local officials responsible for land use programs and permitting, water quality permitting and enforcement, habitat protection, and public health and safety as required by section 6217(b)(6). States will need to include copies of any memoranda of agreement or provisions for joint project review. (See discussion in section III.G.)

f. Describe a process to identify practices to achieve the management measures.

g. Describe activities to ensure continuing performance and long term effectiveness of the measure through proper operation and maintenance. States should follow the operation and maintenance programs described in the (g) guidance or, where the state has developed its own measures, describe the operation and maintenance requirements for the alternative measures. Activities to monitor implementation and enforcement should include a program for the comprehensive survey of sources that are required to implement the management measure, and a program for periodic inspections of sources.

h. Describe state activities to monitor the effectiveness of the (g) measures based on accepted water quality monitoring protocols such as those described in Chapter 8 of the (g) guidance.

States may meet any of these requirements by: (1) identifying existing program activities currently being implemented effectively under state coastal zone management programs, state nonpoint source management programs, or by other state programs; (2) providing the information discussed above for the existing programs; (3) developing new enforceable policies, as necessary; and (4) incorporating these programs into the new coastal nonpoint program.

III.D. Requirements for Implementation of Additional Management Measures

For program approval, state coastal nonpoint programs must provide for the implementation of "additional management measures" where coastal water quality is impaired or threatened even after the implementation of the management measures specified in the (g) guidance. See Section 6217(b).[11] These additional measures apply both to existing land and water uses that are found to cause or contribute to water quality impairment and to new or substantially expanding land uses within critical coastal areas adjacent to impaired or threatened coastal waters. Specific statutory requirements for implementation of additional management measures can be found in sections 6217(b)(1), (2) and (3) of CZARA.
