VOL 12

1 7847

amount of moisture retained by sediment samples and roughly indicative of the texture of the sediment. The finer the grain size and sometimes the greater the amount of organic material, the more moisture will usually be retained. Sieved grain size is a much more accurate determination of the sediment sizes present, as can be seen by comparing data in Tables IV.1-3.

Percent Volatile Solids

Percent Volatile Solids (VS%) is a measure of the amount of carbonaceous material in sediments that can be driven off by combustion in a furnace. The mean and maximum amount of volatile solids increased in October 1991 over those of recent years except 1985, as is indicated in Table IV.6. The highest value, 16.84 ppm, occurred in October 1985 at the Ballona Creek mouth, Station 1, and was almost equaled by 16.12 ppm at Station 22 in October 1991 after several years of lower peaks. Ranges were lower in 1977 and 1978 (Soule and Oguri, 1988).

Percent Total Organic Carbon

Percent Total Organic Carbon (TOC%) is a more advanced measure of the amount of material derived from plant and animal sources. Total organic carbon increased, as did VS%, in October 1991, although levels were higher in 1985 and 1989. The peak value of 10.10 ppm was at Station 1 in October 1985, higher than the 1977-1978 levels.

Oxygen Demand

Immediate Oxygen Demand (IOD) (in mg/kg) is related to the amount of oxygen utilized during exposure of a sample to an oxidizing agent for a limited time, usually 15 minutes; it is a measure of inorganic and organic content, as is Chemical Oxygen Demand (COD). The latter is measured over a longer time, usually two hours in the presence of a strong oxidizer, usually potassium dichromate in sulfuric acid. These measures give a relative value of the amount of oxygen removed from the water column by bacterial action and/or chemical reaction upon exposure of the sediments to oxidation by resuspension, or from changes in chemistry due to transition from a freshwater to seawater environment. Sediments are low in oxygen, or without it (anoxic) below the surface of the benthos. This measure is a very important factor in dredging because resuspension of anoxic sediments in the water column can cause removal of dissolved oxygen, depleting the amount available for fish and other organisms. IOD and COD are also related to Biochemical Demand (BOD) in the water column, discussed in Chapter II.

The IOD levels in the marina have decreased by an order of magnitude since the 1977-1978 surveys. This probably has improved the oxygen levels under stressed conditions such as summer temperature maxima. The peak IODs were 5,010 ppm in March 1977 at Station 5 and 4,590 ppm at Station 8 in March 1978. Although the peaks increased between 1990-1991, the increase was from 374 to 557 ppm, well below the earlier maxima (Soule and Oguri, 1980,1988).

The COD maximum peaked in 1989 at Station 12, but the 1991 maximum value was the second highest since 1985. This occurred at Station 22, which has been highest in COD, TVS and TOC since measurements were begun there in 1990. Such a result is not unexpected since a large amount of organic debris is usually present in Oxford Street basin. Station 10, which receives flow from that basin, was highest in IOD and second highest in TOC and COD. The mean COD increased from 57,010 ppm in October 1990 to 67,100 ppm in May 1991, concomitant with a large increase at Station 3, indicative of the influx and deposition of sediments there. The mean decreased to 59,900 ppm in October 1991, in spite of the extreme value of 188,300 ppm at Station 22. Station 8 showed an increase from 34,130 ppm in October 1990 to 60,500 ppm in May 1991 and to 68,600 ppm in October 1991. This may have been related to the demise of the seagrass bed there, although other, oxygen demanding parameters such as oil and grease have changed as well.

Oil and Grease

The range in oil and grease levels was slightly higher in October 1991 than those of the previous two years (Table IV.6), with a range of 1,080 ppm to 8,700 ppm; however the maxima were higher in 1985, 1987 and 1989, years in which Station 22 was not included. In October 1991, Stations 22 and 10 had the highest levels, followed by Stations 8 and 4. The mean for the marina was higher than the October 1990 mean but decreased from the May 1991 level (Soule et al., 1992). The variations from year to year suggest that oil and grease levels have not changed appreciably since the 1970s. Some oil may occur in the marina because natural oil seeps were a part of the bay and wetlands areas prior to construction of the marina, and may still be active enough to cause some emissions.

Phosphate

Phosphate is found on the natural environment as orthophosphate (PO_4) in sediments, in water and in organic compounds of all living organisms. Phosphate contamination increased above the 1970s levels in the surveys from October 1984 to February 1987 but since then it has decreased by three orders of magnitude presumably due to the decrease or removal of phosphate in detergents. It is commonly introduced into receiving waters from treated or untreated sewage effluent, from fertilizer in runoff and from decay of organic matter. The range in October 1991 was the lowest it has been, at <1-43.50 ppm, perhaps reflecting the control of sewage overflows up Ballona Creek. The reason for the maximum to appear in Basin B, Station 6, is unclear since it is not usually one of the heavily contaminated sites.

Organic Nitrogen

Organic nitrogen (Org-N) levels ranged from 334 to 4,910 ppm in October 1991, a range similar to that in 1989 but lower than that in 1985 (Table IV.6). In contrast to levels on October 1990 and May 1991, levels were much lower at Stations 12, 1, and 13 (Table IV.5) in October 1991 after the dry season. Mean Org-N was higher than it was in October 1990 but lower than the high May 1991 value (Soule et al., 1992). Org-N maximum values have exceeded those of the 1977-1978 period throughout all 1980s and 1990s surveys.

Sulfide

Sulfide is a measure of the breakdown of organic matter, characterized by the odor of rotten eggs due to release of hydrogen sulfide gas, and is an indicator of anoxic sediments. As reported by Soule et al., (1992) sulfide was below the limits of detection at Stations 4, 5, 6, 7, 8, and 9 in October 1990 before the spring rainstorms, but levels were among the highest in May 1991 at Stations 4-8 and 11 after the rains. In October 1991, levels had dropped throughout the marina, but Stations 5, 6 and 7 retained sulfide levels only a little lower than those found in May. This may be part of the reason why the benthic populations have been poor at those stations, and fish almost nonexistent at Station 5. Apparently material flushed from the basins is accumulating in mid-channel under anoxic conditions rather than being carried out to sea. However, the peak sulfide level was two to three orders of magnitude lower in the 1990s than in 1977.

TRACE METAL CONTAMINATION

The data for trace metal contamination in October 1991 for all stations is presented in Table IV.5, and the distribution of the various metals is illustrated in Figures IV.10 through IV.20. In Table IV.6, ranges of metal contamination are compared from 1985 through 1991. With a few exceptions, there were increases in the mean value of metals from October 1990 to May 1991, following the rainy season; October 1991 mean levels were higher than in October 1990 but lower than those in May 1991, indicative of some dry weather flushing.

The National Oceanographic and Atmospheric Administration (NOAA) examined published literature and unpublished data on toxicity of trace metals (Long and Morgan, 1990), developing a system of evaluating toxicity based on background levels, sediment-water equilibrium partitioning, spiked sediment bioassays, and the co-occurrence of fauna and contaminants in the field. They developed ranges of toxicity as follows: From threshold to the tenth percentile of effects is called the Effects Range-Low (ER-L), followed by the Effects Range-Medium (ER-M) and an Apparent Effects Threshold (AET). NOAA is currently updating these ranges with a much enlarged data base, but the ranges are not changing appreciably as a result of the new data according to E.R. Long (pers. comm.)

Table IV.7 tabulates the published NOAA ranges and also those developed by the National Research Council (NRC, 1989), based on data from EPA, the U.S. Geological Survey and other sources. The ranges in marina trace metal values are compared with these criteria.

Arsenic

The maximum for arsenic decreased from 13.80 ppm in October 1990 to 10.54 ppm in May 1991 and to 5.51 ppm in October 1991, rather than showing an increase in the May maximum as did other parameters. The mean for the marina decreased from 8.00 ppm to 3.96 ppm during that period (Soule et al., 1992), which may be considered a beneficial trend, although arsenic levels have not approached the ER-L value of 33 ppm since surveys began in 1977. Most values may in fact be below background levels in the Southern California Bight which were estimated by Mearns et al (1991) to be about 10 ppm.

Cadmium

Cadmium is widely used in electroplating, paint pigments, plastics and batteries. Point source control and waste treatment have reduced emissions to local waters. In the bight, the background level is estimated to be 0.4 ppm (Mearns et al., 1991). Cadmium was marginally lower in the 1970s, but the highest value recorded of 34 ppm in October 1987 at Station 13 represents by far the highest, and probably was the result of illegal dumping or erosion of contaminated terrestrial sediment (Station 22 was not being sampled at that time). The ER-L of 5.0 ppm was not reached at any station in October 1991; the range was from below the limits of detection to 3.00 ppm, with a mean of 1.00 ppm. The highest value of 3.00 ppm was found at Station 22 in Oxford Street basin, indicating terrestrial input.

Chromium

While chromium is a common component in the earth's crust, its use in metal finishing and many industrial processes has introduced it into urban effluents and runoff. Minute quantities of chromium are necessary to form certain enzymes in some invertebrates and in mammalian physiology and as oxygen carrying blood pigments. The background

* Units are in Effects Range-Low (ER-L), Effects Range-Medium (ER-M), Apparent Effects Threshold (AET) (Long and Morgan, 1990 for NOAA) and National Research Council (NRC) EPA Threshold Toxic Levels. In ppm. (NSD = Not sufficient data).

level in the bight is estimated at 5 to 40 ppm by Mearns et al. (1991). The mean chromium value in the marina was 38.43 ppm in October 1991, very similar to the 38.35 ppm in October 1990 but lower than the 46.76 ppm of May 1991. The maximum values declined from 129 ppm in March 1977 to level off at about 70 ppm until the decline in October 1991 to 57.90 ppm. This is an encouraging trend.

Copper

Copper is another trace metal necessary to living organisms in minute amounts. It is bioaccumulated by some molluscs and crustaceans but is not bioamplified in the food chain. Copper is toxic in larger trace quantities, particularly to invertebrate larvae, and is one of the oldest substances used in antifouling compounds. Concentrations in coastal sediments depend on depth and sediment grain size, and the coastal background level is about 10 ppm (Mearns et al., 1991). The mean copper level increased from 145.29 ppm in October 1990 to 169.85 ppm in May 1991 and to 187.49 ppm in October 1991, the highest mean of all the 1984-1991 surveys; the highest maximum was in October 1991 at 410 ppm at Station 8. All stations except Stations 12, 1, and 2 exceeded the ER-L and Stations 8, 9, 10, and 11 exceed the ER-M and AET. The increase in copper might be due to increased use in antifouling paint because of the ban on tributyltin (TBT).

Iron

There is no ER-L or ER-M for iron in marine sediments and no data base indicating toxicity. In micro amounts it is essential to living organisms. Levels in the marina increased to a peak of 71,500 ppm at Station 7 in 1990 and decreased to 63,200 at Station 11 in October 1991, but this is higher than any other peak values.

Lead

Lead is of serious concern in urban areas where it is a prominent airborne pollutant. It is not required in trace quantities by organisms and causes acute and chronic illnesses, either from inhalation or ingestion. Lead concentrations in non-urban coastal areas range from 2.4 to 29 ppm whereas median levels in bays and harbors have ranged from 8 to 994 ppm (Mearns et al., 1991). Marina del Rey has some of the highest levels, exceeded only by the area of the Newport Bay shipyards.

The minimum level of lead increased from 7.95 ppm in October 1990 to 41.3 ppm in May 1991 and to 62.2 ppm in October 1991. In the same period the maximum rose from 325 ppm to 575 ppm after the rains, and decreased to 487 ppm during dry weather. By far the largest quantity was in the Oxford Street basin, at Stations 22, 13, and at Station 10 in the marina, which indicates the terrestrial source for high lead levels. The highest mean level, 169 ppm, was in 1985 and the lowest in 1988 with 99.98 ppm, before Station 22 was added in 1990. The mean in May 1991 was 168 ppm after the rains, decreasing to 151.58 in October 1991, and the mean for all periods, 1984-1991 is 144.67 ppm.

All stations exceeded the ER-L of 35 ppm, and all stations except Stations 1, 2, 6 and 7 exceeded the ER-M of 110 ppm, but only Station 22 exceeded the AET of 300 ppm. In spite of the drop in lead use in gasoline in the 1980s, the lowest maximum was in October 1988 and the maxima have increased since then, exceeding 1977-1978 maxima. The range of variation, however, may be so great that the general level is stable. The extremes in maxima were 88.8 and 359 ppm in 1977-1978.

<u>Manganese</u>

There are no ER-l and ER-M values for manganese, and it is not considered to be a problem as a contaminant. Manganese, like iron, is essential to living organisms in micro quantities. The peak value of 340 ppm was found at Station 13 in October 1987, but the peak values seem generally to lie in a range of 260 to 285 ppm while the minimum had been quite varied.

<u>Mercury</u>

Mercury is a common trace element in the earth's crust, and has been extensively mined in California. The background level is estimated to be 0.05 ppm (Mearns et al,. 1991). Mercury is extremely toxic in the methylmercury form, but formation of

VOL 12 1 7855

methylmercury is dependent on a number of factors, including temperature, and the presence of organic compounds, sulfide and fresh water.

The range in October 1991 was from below the limits of detection (<0.09) to 0.94 ppm, with the maximum being lower than it has been since 1977. Levels at all stations except Stations 12, 1, 2, and 13 were above the ER-L of 0.15 ppm, but none were above the ER-M of 1.0 ppm. This can, however, be considered a positive trend.

Nickel

The principal sources of nickel in marine sediments are from steel alloys and plating works, although nickel is a natural element in the environment. The range in the marina for October 1991 was 8.02 to 32.0 ppm; this was the highest minimum since October 1987 but the lowest maximum of all the surveys performed. The peak nickel value was 145 ppm in March 1978. The ER-L is 30 ppm, which was slightly exceeded only at Stations 9 and 10, and did not approach the ER-M of 50 ppm. This is also a positive trend for improvement.

Tin

Toxicity of tin and organotins, especially tributyltin (TBT) in water has been well documented, being toxic in parts per trillion concentrations to larvae of some molluscan species (reviewed in Soule and Oguri, 1988). Long and Morgan did not establish an ER-L or ER-M for TBT in sediments because of inadequacy of the data base, including lack of standardized methods of analysis which make comparisons difficult. There is at present no documentation of toxicity in sediments. Bioassays of seawater spiked with TBT indicated that concentrations of TBT in sea water were toxic at much lower levels than normally at much higher concentrations.

The range concentrations in sediments have ranged from below the limits of detection to a peak of 1,070 ppm in October 1987, declining to a peak of 5.57 ppm in October 1988 and thereafter being between 0.4 and 0.53 ppm.

Zinc

Zinc is an essential element in trace quantities and is ubiquitous in the natural environment. Zinc enters the marine environment as airborne particulates, in runoff, or in municipal effluents. Levels at all except Station 1 exceeded the ER-L of 120 in October 1991, and six stations exceeded the ER-M and AET (Table IV.7). Peak levels have varied between about 400 ppm to 660 ppm, with the highest occurring in October 1987; in October 1991 the peak was 491 ppm, rising to 640 ppm in May 1991 and dropping slightly to 624 ppm in October 1991. Mean levels of zinc have varied from 267.92 ppm in October 1984 down to 206.25 ppm in October 1988, rising to 279 ppm in May 1991, following the rains, and declining to 259 ppm by October 1991. The mean f all surveys in 1984-1991 is 248.88 ppm.

CONCLUSIONS: NONMETALLIC CONTAMINANTS AND TRACE METALS

Of the non-metallic contaminants, there has been improvement in Immediate Oxygen Demand, phosphate, and sulfide in the marina, while volatile solids, Chemical Oxygen Demand, and Organic-Nitrogen have worsened somewhat.

Among the trace metals, levels of arsenic, cadmium and chromium have not been a problem, remaining below the ER-L levels in all surveys and have shown declines in the most recent surveys. The maxima for tin as tributyltin have declined dramatically, by more than three orders of magnitude since October 1987. Levels of nickel have declined to where only Stations 9 and 10 exceed the ER-L slightly. Contamination with copper, lead and zinc has fluctuated over a considerable range during the 1984-1991 surveys, but we conclude that zinc and lead have not changed appreciably except following large rainfall periods. The lowest means for the series for lead and zinc were in October 1988, while the lowest mean for copper was in October 1985. The mean for copper increased in May 1991 after the rains but continued to increase in the dry season to the highest mean of the series. This suggests that copper may have increased both from rainfall runoff and/or from increased antifouling use in the marina. The low frequency of sampling and number of samples precludes more precise indication of sources and trends. Copper, lead and zinc are substances that must be controlled to improve conditions in the marina benthos.

PESTICIDES AND CHLORINATED HYDROCARBONS

INTRODUCTION

A few pesticides have been prominent contaminants in Marina del Rey, existing in quantities sufficient to have affected the presence/absence of some species by inhibition of reproduction or by exerting chronic effects on distribution and growth of mature organisms. Pesticide analysis has been conducted in all sediment surveys since 1984, but only DDTs were analyzed in the 1977 baseline studies due to technology limitations. Aldrin, BHCs, Lindane, Endrin, Toxaphene, Heptachlor and Heptachlor Epoxide have been absent from all 1984-1991 surveys. Dieldrin has not been found since October 1987; production was halted in the U.S. in the 1970s, but it continued to be imported until 1985, and all use was banned in the U.S. in 1987. Although the DDTs have been banned since the early 1970s and Chlordane since the early 1980s, they have persisted in Marina del Rey, as they have in local coastal waters, exerting a variety of effects on the local fauna.

RESULTS

Station Rankings

Stations in the marina have been ranked according to the total pesticides and chlorinated hydrocarbons in sediments sampled in October 1991. In Table IV.8, the total scores are tabulated for October 1989 and 1990, May 1991 and October 1991. Because of typographical errors in the previous report (Table IV.11, in Soule et al., 1992) a few of the total pesticide and chlorinated hydrocarbon totals were changed but the only ranking changed was that of Station 8 which moved from low to medium low. Table IV.8 incorporates the corrected data and compares it with the October 1991 data.

The outstanding difference in the October 1991 results was the disappearance of the chlorinated hydrocarbon Aroclors 1254 and 1260, which first appeared in our surveys in October 1988. Aroclor levels were highest in the October 1989 survey, and those totals have been included in Table IV.8 for comparison. Figure IV.21 illustrates the absence of Aroclors in 1988, followed by the dramatic maximum reached in October 1989, the decrease

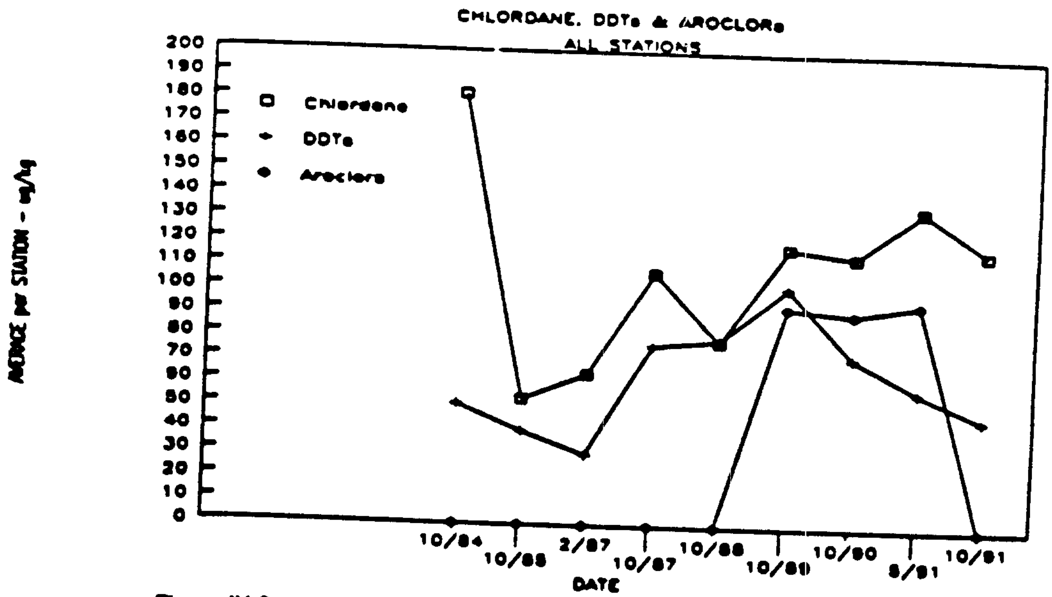

Figure IV.21. Average Chlordane, DDTs and Aroclor PCBs in sediments from all stations, October 1984 through October 1991.

Chlordane is the principal component of the non-DDT pesticides; there was 11.0 ppb of Dieldrin in October 1985 and 32.5 ppb in February 1987; but it was undetected thereafter. The maxima in PCBs coincided with high Chlordane levels in 1989 and 1990, increasing potential for ecological impact. PCBs were below limits of detection in October 1991.

---

in May 1991, and the disappearance of Aroclors by October 1991.

Extreme variation in contaminant loading according to the flushing characteristics of particular stations can be noted in rankings in Table IV.8. Station 12 was in the highest group in October 1989, dropped to medium low in October 1990, rose to medium high on May 1991 and decreased again to medium low in October 1991. Station 1, nearer the bay, was in the lowest category in October 1989, rose to moderate ranking in October 1990 and to the high category in May 1991, after which it dropped back to the low ranking. Station 2, at the sandbar, had the highest total pesticides and chlorinated hydrocarbons ever recorded in the marina in October 1989, and while the total decreased to 473 ppb, or 42 percent of that in

October 1990, the total remained in the high category and had increased to 541 ppb by October 1991, indicating dry weather accumulation at the sandbar.

Station 22, at the inner end of Oxford Street basin, was not a sampling station in October 1989, but took top ranking when it was added in October 1990. It dropped to the next lowest in May 1991 after the rains but rebounded to the medium high ranking in October 1991. Station 13, at the outer end of Oxford Street basin functioned inversely to Station 22, moving from low to medium high and back to low in the same period. Stations 10 and 11 had relatively high totals from October 1989 through May 1991, after which both dropped to the low category. In contrast, these two stations stayed in the high category for trace metals and non-metallic contaminants during the October 1990-1991 period, illustrating the differences in the behavior of the pesticides, related perhaps to differences in sources, solubilities and/or complexing with sediments.

Station 3, which was the cleanest in total pesticides and chlorated hydrocarbons in October 1989 and 1990, jumped to the high category in May 1991 and continued to remain in that position, indicative either of input from Ballona Lagoon and the surrounding terrestrial area or spreading of accumulation behind the sandbar, or both. In non-metallic contaminants (Table IV.4) and trace metals, Station 3 had the lowest rank in October 1990 but rose to medium high in May 1991 and remained there through October 1991.

Seven stations were included in the low category of pesticides and chlorinated hydrocarbons in October 1991, the largest number of sites in recent years, but no stations reached the lows below 30 ppb that occurred in 1989 and 1990.

Toxic Effects

NOAA determined the Effects Range-Low (ER-L), Effects Range-Medium (ER-M), and Apparent Effects Threshold (AET) by extensive data analysis (Long and Morgan, 1990), while the National Research Council (NRC) has provided other estimates of effects levels. The NOAA data on pesticides are not as extensive in some cases as they are for trace metals.

In Table IV.9, the effects levels are compared with the ranges of pesticides and

Table IV.9. Concentrations of metals in sediments producing biological effects in October 1991 compared with levels in Marina del Rey in October 1990 and May 1991.*

chlorinated hydrocarbons in the marina for October 1990, May 1991 and October 1991, along with stations which exceed the various levels. The ranges for surveys from 1985 to 1991 are listed in Table IV.10. Complete data for October 1990, with corrections, and October 1991 are presented in Tables IV.11 and 12.

<u>Chlordane</u>

Chlordane is an insecticide persistent in the marine environment which has been used extensively in termite control and was supposedly banned in 1988. However, the substance seems to continue to enter the marina. The behavior of Aroclors, also persistent chemicals, which were introduced between October 1988 and October 1989 and disappeared (were below the limits of detection) by October 1991 after having been very high, is indicative that flushing does occur. However Chlordane (Figure 22) has not similarly been eliminated as would be expected if its use has really been discontinued, although leaching or seepage from wood structures may be occurring. Station 2 again showed the peak value, decreasing from the maximum of 630 ppm in October 1989, when Aroclors also peaked at Station 2. Chlordane decreased to 410 ppb at Station 2 in October 1990 and to 360 ppb by May 1991, but increased to 436 ppb in October 1991. The level was second highest at Station 22 in October, as it was in October 1990, and third at Station 3, suggesting major terrestrial sources such as drainage into Oxford Street basin and the Ballona Lagoon area. Station 3 may receive Chlordane from Ballona Lagoon and also be the major source that deposited at Station 2.

The ER-L for Chlordane is 0.5 ppb, the ER-M is 6 ppb, the AET is tentatively given as 2 ppb and the NRC limit is 20 ppb. All survey stations exceed these limits for Chlordane, which had a low value of 31 ppb, the highest minimum in recent surveys.

<u>DDTs</u>

DDT was formulated just prior to World War II and its use for malaria control stimulated application as an insecticide in a wide variety of habitats, causing its entry into marine ecosystems. DDT continued to be manufactured locally by the Montrose Chemical

Not Detected: <10.0, Toxaphene, Aroclor 1016, 1221, 1232, 1242, 1248 1254, 1260; <4.0 o.p'DDT, o.p'DDD; <2.0, Alpha BHC, Beta BHC, Endrin.

Company until 1982, even though its use in the United States was banned in 1972 after it was demonstrated that it interfered with calcium metabolism and caused thinning of bird eggshells, leading to reproductive failure. The carcinogenicity and toxicity of DDTs are open to question. In the 1950s waste residues were dumped in quantity in the Catalina Channel from barges, and large amounts passed through the Los Angeles County sewer system, causing deposition along the Palos Verdes shelf (Chartrand et al., 1985; Mearns et al., 1991).

Sources in the marina are unknown, but the highest levels of DDT, DDD and DDE were at Stations 2 and 3 in October 1991, although there has been a variety of stations with the maximum levels (Table IV.10). Sources of non-degraded p.p'DDT are not known, although new DDT may be finding its way into the marina, or DDT that has been buried and not biodegraded but was perhaps recently uncovered in terrestrial excavations may have been carried into the marina via storm drains. The range increased from below the limits of detection (<ND 4.0) to 29 ppb in October 1990 to <ND 4.0 to 48 ppb in October 1991, although the means were similar at 18.23 and 18.4 ppb; the mean had been reduced to 8.8 ppb in May 1991 following the spring rains. All stations exceeded the p.p'DDT ER-L of 1 ppb except Stations 1 and 13 and also exceeded the ER-M, AET and NRC concentrations for effects in October 1991. Figure 23 shows the distribution in October 1991.

For p.p'DDD, the October 1991 (Figure 24) range was <ND 4.0 to 23 ppb, with a higher maximum than in May 1991 but considerably lower than the 100 ppb of October 1990. All except Stations 6, 8, 10 and 13 exceeded the ER-L of 2 ppb, and Stations 2 and 3 exceeded the ER-M as well. The very large NRC number of 13,000 ppb indicates the contradictory nature of the evidence about the toxicity of this form.

The range in October 1991 for p.p'DDE was 3.0 to 67 ppb (Figure 25). All stations exceeded the ER-L for p.p'DDE of 2 ppb, and all except Stations 1, 8, 12 and 13 exceeded the ER-M as well. The NRC number of 28,000 indicates the difference in data base and opinion. Long and Morgan (1991) also calculated a total DDT ER-L of 3 ppb and of 350 ppb for the ER-M. The October 1991 range for total DDTs was from 3.0 ppb to 136 ppb, indicating that all stations equaled or exceeded the ER-L but none approached the ER-M.

Aroclors

The appearance of Aroclors 1254 and 1260 at high concentrations in the October 1989 survey and subsequent distribution throughout the marina was the subject of much concern because of the obvious introduction of these toxic substances into the marina where it had previously not been detected. The maximum Aroclor 1254 value was 330 ppb at Station 2 in October 1989, decreasing to 153 ppb, also at Station 2, in October 1990, and was below limits of detection in May 1991. Aroclor 1260 had a maximum of 200 ppb at Station 25 in October 1989, and a peak of 300 ppb at Station 11 in May 1991 (table IV.10). After possibly being introduced at more than one drainage source, the substances appeared to move around in the marina and then disappeared (were below the limits of detection) by October 1991.

Massive grading for development occurred along Lincoln Boulevard northeast of the marina, while smaller grading projects on Washington Street and along Ballona Lagoon took place at about the same time. Runoff could have carried sediments into Ballona Creek, Oxford Street basin and/or into storm drains in the marina. Sediments on the north side of Ballona Creek are known to have been contaminated by industrial activity during World War II and dumping also occurred in the area. Disturbance of contaminated sediments that might have been covered for years could cause contamination of runoff.

CONCLUSIONS: PESTICIDES AND CHLORINATED HYDROCARBONS

The remarkable introduction of chlorinated hydrocarbons in the form of Aroclors 1254 and 1260 sometime between October 1989 and October 1990 represents a very large environmental insult to the ecology of the marina, since it is toxic to organisms at about 50 ppb while levels were in some locations as much as six times that amount (Table IV.9). The equally striking disappearance (levels below the limits of detection) by October 1991 indicates the ability of the marina to be flushed of some constituents, since these chemicals do not biodegrade rapidly.

Of the pesticides, chlordane and the DDTs continue to be present in ecologically harmful levels. Chlordane is a continuing problem throughout the marina, with all stations showing concentrations about one or two orders of magnitude above the low effects range (ER-L) and exceeding the medium and apparent effects ranges (ER -M, AET respectively) defined by NOAA (Long and Morgan, 1991). In spite of the ban on Chlordane, it is either still being applied widely, leached from previously treated structures, or dumped into the marina.

DDTs exceed the ER-L range at most stations. The p.p'DDT levels exceed the ER-M and AET levels at all except Stations 1 and 13, and p.p'DDD exceeds the ER-L at most stations. The p.p'DDE levels exceed the ER-L at all stations and most exceed the ER-M range. The maxima have decreased in October 1991 from October 1990, but were lower in May 1991 after the spring rains than in either of the October periods. This indicates continuing input of DDTs from terrestrial drainage or from marina usage. The pesticide profile is thus not as encouraging as the PCB scenario.

V. FISH TISSUE ANALYSIS FOR PCBs, DDTs AND CHLORDANE

INTRODUCTION

Fish living in the Southern California Bight are exposed to a variety of contaminants at some locations, and the potential exists for them to accumulate pesticides and chlorinated hydrocarbons that are considered to be hazardous to human health at certain concentrations. Exposure varies since some species are widely ranging, while others are limited to small areas, some are water column fish while others are bottom feeders that are exposed more closely to contaminated sediments, and some ingest prey or browse on contaminated biota, accumulating substances through the food web. Some species seem not to accumulate contaminants, or are able to eliminate them metabolically.

There is often a wide range of variation in the body burden of accumulated contaminants among individuals of the same species that do bioaccumulate (e.g., Lee, 1984). Body burden also varies with the season. Fat soluble pesticides and chlorinated hydrocarbon contaminants are deposited in fats in the body tissue or stored in the liver, potentially damaging the liver; when fats are mobilized for supplying eggs with yolk, contaminants enter the eggs, potentially damaging eggs or larvae but depurating the adult fish of its body burden to some extent (Cross, 1986; Cross and Hose, 1988).

Since fish are usually gutted before consumption and liver and gonads not generally eaten, the public is protected from higher concentrations that occur in the organs. Birds that pursue the offal from fish cleaned by fishermen on the dock may receive a high dose of pesticides or PCBs, as might the family cat that dines on scraps.

The bight is known to have been contaminated with pesticides, such as Chlordane and DDTS, and polychlorinated biphenyls (PCBs) which were released into the ocean largely by industrial disposal through storm drains, sewage outfalls or ocean dumping (Chartrand et al., 1985), or in runoff via rivers and storm drains. Manufacture and/or use of these chemicals has been greatly restricted or banned, but some release continues, legally

1783

chemicals are very slow to degrade in the environment.

The California Environmental Protection Agency (CEPA) Office of Environmental Health Hazard Assessment (OEHHA) issued advisories in 1991 which suggest limiting consumption of eight species of fish caught at various locations between Pt. Dume and Newport Pier, as listed in Table V.1. OEHHA did not give the actual concentrations found in tissues nor the extent of variation in the 4,000 samples from 15 species taken from 24 locations.

Marina del Rey was not among the areas listed for restriction although the same species of fish listed by CEPA occur in the marina. Their conclusion is consistent with conclusions reached by USC Harbors Environmental Projects, based on specimens collected in January-February 1990, October-November 1990, May 1991 (Soule et al., 1991, 1992) and 2 November 1991, reported herein.

METHODS

Only one small survey of fish body burden could be conducted in the fall of 1991 due to budgetary constraints, but results offered good comparison to previous surveys. Fish were collected at the public dock in Fishermen's Village, purchased from anglers on 2 November 1991. Fish were iced in the field and returned to the USC Fish Harbor Laboratory where they were gutted. Samples of muscle tissue and combined samples of liver and gonad were wrapped separately for each fish specimen, labeled and frozen. Chemical analyses were performed by Associated Laboratories in Orange, California according to EPA approved methods. Nine fish of six species were analyzed for both body tissue and liver/gonad content, a total of 18 specimens.

In the initial survey in January 1990, the focus was on contamination of fish species by polychlorinated biphenyls (PCBs) that had been identified for the first time in the marina in the fall of 1989 (Soule et al., 1991), causing concern for both human health and also for the ecosystem. DDTs were added to the scope at that time because there was no information on body burden of the pesticide complex that has been so prominent in fish off

Table V.1. California Environmental Protection Agency recommended limitations of fish consumption published summer of 1991.

Site	Fish Species	Recommendations*
Newport Pier	Corbina	One meal every two weeks
Redondo Pier	Corbina	One meal every two weeks
Belmont Pier	Surfperch	One meal every two weeks
Pier J (Queen Mary)	Surfperch	One meal every two weeks
Malibu Pier	Queenfish	One meal a month
Short Bank	White croaker	One meal every two weeks
Malibu	White croaker	Do not consume
Point Dume	White croaker	Do not consume
Point Vicente	White croaker	Do not consume
Palos Verdes (Northwest)	White croaker	Do not consume
White's Point	White croaker	Do not consume
	Sculpin Rockfish Kelp bass	One meal every two weeks**
Los Angeles and Long Beach Harbors (esp. Cabrillo Pier)	White croaker	Do not consume
	Queenfish Black croaker Surfperch	One meal every two weeks
Los Angeles and Long Beach Breakwater (ocean side)	White croaker Queenfish Surfperch Black croaker	One meal a month
Horseshoe Kelp	Sculpin White croaker	One meal a month**

NOTE: in the following locations, no restrictions are recommended: Marina del Rey; Huntington Beach; Fourteen Mile Bank; Laguna Beach; Redondo Beach; Emma/Eva oil platforms; Catalina (Twin Harbors); Santa Monica Pier; Venice Beach; Venice Pier; Dana Point.

* This category represents maximum recommended frequency; one meal is about six ounces. ** Consumption recommendation is for all species combined.

Palos Verdes due to emissions from Montrose Chemical Co. through the Los Angeles County Sanitation system, and in pelagic fish elsewhere due to ocean dumping in the bight. Chlordane was added in the fall of 1990 (Soule et al., 1991) because there is increasing concern internationally about the effects of this long lasting pesticide complex (Mearns et al., 1991). Twelve species of fish were represented in 32 specimens of body tissue and of three liver/gonad samples in that survey.

Other surveys were made on 20 October and 3-4 November 1990, when 21 specimens of body tissue and 13 of liver/gonad from 10 species were collected for analysis, and on 25 May 1991, when 14 specimens each of body tissue and of liver/gonad from eight species were collected.

RESULTS AND DISCUSSION

The number of species and specimens available at the dock in November 1991 was very limited; only one specimen each of *Paralichthys californicus* (California halibut), *Phanerodon furcatus* (white surfperch), and *Xenistius californiensis* (salema) was found, and two each of *Seriphus politus* (queenfish), *Sphyraena argentea* (California barracuda) and *Atherinops californiensis*, jacksmelt, were collected. Results are presented in Table V.2. *Phanerodon* had not been obtained in previous pesticide-chlorinated hydrocarbon surveys and is a wide ranging species. *Xenistius* was found in the fall 1990 chemical survey, *Atherinopsis* was collected in all but the fall 1990 chemical survey, and the other species mentioned were collected in all chemical survey periods. For incidence of these species in diver surveys, and trawl, gill net, plankton net and beach seine in the marina see Table VIII.8, Chapter VIII in this volume.

The pesticides Aldrin, Alpha BHC, Lindane, Heptachlor, Heptachlor Epoxide, Beta BHC, Dieldrin, Endrin, Toxaphene, o.p'DDT and o.p'DDD were not detected, as has been true in previous surveys. Of the chlorinated hydrocarbons, no Aroclor 1016, 1221, 1232, 1242, 1248 or 1254 were detected (See Table V.2 footnote for limits of detection).

Chlordane (Synthetic polycyclic hydrocarbon)

Levels of Chlordane in *Atherinopsis* muscle were below limits of detection in the fall survey, whereas they had been high in liver and gonad in the spring 1991 survey, before their spawning season, apparently. The level in body tissue of *Paralichthys* was about the same as in previous samples but the level was lower in liver/gonad tissue than it was in the fall of 1990 or the spring of 1991 (Soule et al., 1992). In *Seriphus*, Chlordane levels in November 1991 were similar to some in October 1990 and May 1991, but levels in liver/gonad tissue were an order of magnitude lower than in one specimen in October 1990, perhaps indicative of prespawning condition. In *Sphyraena*, levels were much lower in fall 1991 than in the previous October survey, when one liver/gonad had 3,000 ppb, and the *Xenistius* specimen also had lower values.

In contrast, the single species of *Phanerodon furcatus* that has been taken in any of these surveys had very high levels in both muscle tissue (2,010 ppb) and liver/gonad (1,580 ppb). The species is not seen frequently in the marina, but has been present in the warm water year surveys (Table VIII.8).

Levels detected in marina fish seem to be an order of magnitude higher than in the local Regional Water Quality Control Board survey in 1985 of mussels and fish, but similar to levels found in NOAA surveys in 1984 and 1984 (Mearns et al., 1991), although the marina data base is small.

The mean Chlordane in marina fish muscle and liver/gonad combined was higher at 255 ppb (N=18) in the fall of 1991 than in May 1991, when it was 207.5 ppb (N=28) after the spring reproductive period. However, both were lower than the mean in the fall of 1990, when the mean was 618 ppb (N=34), and some liver/gonad tissue had very high levels. Whether this is an indication of accumulation for a later reproductive season or a genuine change is not known, but mean sediment levels for the two fall periods were almost identical (Tables IV.11 and 12, this volume). The mean level in body tissue decreased from 143.5 ppb in October 1990 to 54.3 ppb in May 1991 but increased to 249.7 ppb in

November 1991. In the same periods, the liver/gonad tissue had 1384.6 ppb, 360.7 ppb and 284.4 ppb respectively.

Table V.3 shows the mean levels of pesticides and chlorinated hydrocarbons in the four surveys. It must be recognized, however, that variation in species and in stage of reproduction make it difficult to identify trends.

NA = not analyzed ND = none detected (in ppb N = number of specimens)

PCBs (Polychlorinated biphenyls)

Of the PCBs, only Aroclor 1260 has been detected in the fish surveys. Body tissue levels in January 1990 (Soule et al., 1991) ranged from 15 ppb to 298 ppb, the latter occurring in *Paralichthys* (halibut), and in October 1990 ranged from below the limits of detection to a maximum of 230 ppb, in *Umbrina roncador* (yellow fin croaker), while it was below the limits of detection in body tissue in all 14 specimens in May 1991 (Soule et al., 1992). In liver/gonad samples the Aroclor 1260 levels were much higher than in tissues, up to a maximum of 4,270 ppb in January 1990 in *Synodus leucoceps* (California lizardfish). In October 1990, the range in liver/gonad tissue was from below limits of detection to 610 ppb, in *Seriphus* (queenfish) and 820 ppb in *Paralichthys*. Although there was no PCB detected in 16 of the total of 28 specimens (57%), including two liver/gonad tissues, other liver/gonad tissue ranged up to 1,010 ppb in *Myelobatis* (bat ray) and 6,790 ppb in one *Paralichthys*, apparently in prespawning condition.

In November 1991, both muscle and liver/gonad PCB levels were higher than in October 1990 in *Paralichthys* at 150 ppb and 690 ppb for the respective tissues, while in some other species liver/gonad levels were lower than in October 1990 or May 1991. However, in the fall of 1990 the body tissue levels in one *Seriphus* was 140 ppb but PCB was absent in the other, while one liver/gonad contained 140 ppb and was not detectable in the other, probably indicating depletion by reproduction. In May 1991, the *Seriphus* specimens had no detectable PCB in either tissue. In November 1991, two specimens of *Seriphus* had 180 and 220 ppb in body tissue but none in liver/gonad tissues. The maximum in November 1991 was 290 ppb in lever/gonad tissue of *Sphyraena* (barracuda).

The mean level of Aroclor 1260 in all tissues in January 1990 was 321.6 ppb, with the mean muscle tissue 150.8 ppb while the liver mean of three specimens was 1972.7 ppb. In the fall of 1990 the mean for all samples was 121.5 ppb, with a mean of 58.6 ppb in muscle and 223.1 ppb in liver/gonad. In the spring of 1991 the mean of all samples rose to 247.9 ppb, with none detected in muscle and 495.7 ppb in liver/gonad tissue, after which, in the fall of 1991, the mean of all tissues decreased to 90.7 ppb, but there was a mean of 94.4 ppb in muscle and 108.9 ppb in liver/gonad tissue, indicating a post spawning condition with storage in muscle tissue.

From the mid-1970s to the mid-1980s, data from the bight showed some extremes in fish tissue from 8.0 ppb in pelagic anchovy up to 14,815 ppb and in liver up to 162,072 ppb (Mearns et al., 1991). There are difficulties in comparing results due to differences in analytical techniques, especially in some of the earlier data, but it appears that there has been a large decrease in the PCBs in the bight.

The U.S. Food and Drug Administration limit for PCBs in edible tissue of 2.0 ppm

(2,000 ppb) far exceeds the mean of 90.7 ppb in 18 specimens (9 tissue, 9 liver/gonad), or 170 ppb in the six of nine fish body tissue samples in which PCB was detected. There is movement toward lowering the action level but marina fish, gutted and cleaned would still be judged safe even if an order of magnitude decrease to 0.2 ppm (200 ppb) were to be established by regulatory agencies.

<u>DDTs (Dichlorodiphenyltrichloroethane)</u>

In January 1990, one specimen of *Genyonemus lineatus* (white croaker) had no detectable body tissue DDT, DDD or DDE, one *Myliobatus californica* (bat ray) had no detectable DDT and one *Hyperprosopon argenteum* (walleye surfperch) had no DDE; all others of the 34 samples had all three forms. The maximum in body tissue was 1,665 ppb DDE in *Sphyraena argentea* (barracuda) and the maximum in liver/gonad was 6,806 ppb in the same *Synodus leucoceps* (lizardfish) that had the highest Aroclor 1260.

In the fall 1990 survey, no p.p'DDD or o.p'DDE were detected, and about half of the specimens had no detectable p.p'DDT, but 33 of 34 samples contained p.p'DDE. Of the seven specimens containing body tissue p.p'DDT, the mean concentration was 36 ppb, or if the total of 21 specimens are included, the mean is 12 ppb. Of the nine specimens containing liver/gonad p.p'DDT, the mean was 196.9 ppb, or 90.1 ppb for the total of 13 liver/gonad specimens. The mean body tissue level of p.p'DDE in fall 1990 was 179 ppb in the 20 of 21 fish sampled, or a mean of 170.6 ppb in the 21. All 13 liver/gonad tissues had p.p'DDE, with a mean of 2,788.7 ppb and a range from 16 ppb to 10,800 ppb (Table V.3).

In May 1991, following the spring rains, 11 of 28 specimens (39%) contained p.p'DDD, ranging where detected from 4.0 ppb in *Genyonemus* (white croaker) body tissue to 440 ppb in an *Atherinopsis* (jacksmelt) liver/gonad sample. The mean concentration in the seven samples having muscle p.p'DDD was 15.6 ppb, or the mean for all samples was 7.8 ppb. In liver/gonad tissue, the mean for the four contaminated samples was 213 ppb while it was 60.9 ppb for the 14 total samples.

The p.p'DDT concentrations in May 1991, found in 14 of 28 samples (50%), ranged from 4.0 ppb in *Genyonemus* (white croaker) body tissue to 430 ppb in *Paralichthys* (halibut) liver. The mean p.p'DDT concentration in the eight out of 14 muscle tissue specimens contaminated was 17 ppb, or for all 14 specimens, 9.7 ppb. In liver/gonad tissue the mean was 211.6 ppb in the six contaminated specimens, or 90.7 ppb in all 14 specimens.

The p.p'DDE in May 1991 occurred in all but five of 28 samples (82%), with concentrations, where detected, ranging from 27 ppb in *Paralichthys* (halibut) body tissue to 3,370 ppb in *Atractoscion* (white sea bass) liver/gonad; seven of the liver/gonad samples had concentrations above 1,000 ppb. The mean concentration in 10 contaminated muscle samples was 326.7 ppb, or 233.4 ppb in all 14 samples.

Not detected previously, the o.p'DDE found in May 1991 occurred in 18 of 28 samples (64%) in concentrations, where detected, that ranged from 4.0 ppb in *Paralichthys* (halibut) to 420 ppb in *Sphyraena* (barracuda). The mean in ten muscle tissue specimens contaminated was 40.6 ppb, or 29.0 ppb for all 14 specimens. Liver/gonad tissue had a mean of 347 ppb for seven contaminated specimens, or 173.6 ppb for all 14 specimens.

In November 1991, after the dry season, DDTs were more widespread but maximum concentrations were lower; p.p'DDT was found in 16 of 18 samples (88.9%), with concentrations where detected ranging from 5.0 ppb in jacksmelt body tissue to 210 ppb in *Seraphus* (queenfish) liver. The mean muscle tissue level among seven contaminated specimens out of nine total was 8.9 ppb, or 6.9 ppb for all nine specimens. All nine liver/gonad tissue samples were contaminated with a mean of 73.0 ppb.

The p.p'DDD also occurred in 16 of 18 specimens (88.9%), with concentrations ranging from 5.0 ppb in *Atherinops* (jacksmelt) both muscle tissue and liver/gonad to a maximum of 100 ppb in *Seriphus* liver/gonad. The mean in muscle tissue in seven contaminated specimens out of nine is 14.3 ppb, or 11.1 ppb in all nine specimens. In liver/gonad tissue, all nine specimens were contaminated, with a mean of 46.1 ppb.

Eighteen of 18 samples (100%) contained p.p'DDE, with concentrations ranging from 9.0 ppb in *Atherinops* liver/gonad tissue to 3,160 ppb in *Seriphus* liver/gonad tissue, with four of 18 samples containing more than 1,000 ppb. The mean muscle concentration 248.7 ppb while the mean of liver/gonad tissue was 1,202.1 ppb.

Not found in sediments, o.p'DDT first appeared in fish in the May 1991 survey. In October 1991, the o.p'DDE occurred in 17 of 18 specimens (94%), in concentrations ranging from 5.0 ppb in *Atherinops* body tissue to 340 ppb in *Seriphus* liver/gonad tissue. The mean for all 18 specimens was 70.2 ppb. For eight out of nine muscle specimens the mean was 27.8 ppb, or 24.7 ppb for all nine specimens, while the mean for liver/gonad tissue was 445.8 ppb where all nine were contaminated.

Mearns et al. (1991) summarized total DDTs (tDDTs) measured in white croaker, a bottom feeder, off Palos Verdes in the 1975-1977 period which had a mean tissue concentration of 39,200 ppb and a range of 5,230 ppb to 176,400 ppb; in 1980 the mean was 7,630 ppb with a range of 3,570 to 13,100 ppb. Fish collected offshore by commercial fishermen in 1979 contained from 40 to 480 ppb tDDTs, suggesting a general contamination with DDTs at relatively low levels; DDTs are apparently recycled in the environment rather than biodegraded completely.

Total DDTs in January/February 1990 were 322.0 ppb in 29 muscle tissue specimens and 3200.7 ppb in three liver/gonad specimens. In October/November 1990 the mean for muscle was 182.6 ppb in 21 muscle tissue specimens and 2,878.8 ppb in 13 liver/gonad specimens. In May 1991 in 14 muscle tissue specimens the mean tDDTs was 279.9 ppb and in 14 liver/gonad specimens the mean was 1750.2 ppb, with by far the largest amount being composed of p.p'DDE. In November 1991, tDDTs had a mean in muscle of 327.3 ppb in nine samples and 1,767.3 ppb in liver/gonad tissue. Total DDTs cannot be said to be declining, although it appears that p.p'DDT and p.p'DDD have declined while the incidence of DDEs has stayed about the same or increased.

CONCLUSIONS

There is a very large range of variation in pesticide concentrations between species, and between individuals of the same species, those with high fat (lipid) content in muscle contain much higher levels than those that have low lipid content. There are also seasonal differences in muscle content, depending on whether lipids are stored in the liver or being mobilized from muscle tissue to gonads for reproduction, which may result in a three to four orders of magnitude or more differences in some species between concentrations in muscle and in lever/gonad tissue. Generally, the difference is closer to one order or magnitude in marina specimens.

Aroclor 1260 seems to have a decreasing trend, although it was absent in 12 muscle tissue specimens in May 1991 but reappeared in the nine specimens sampled in November 1991.

Chlordane showed no clear trend, with increases in muscle tissue but decreases in liver/gonad tissue.

The levels of p.p'DDT and p.p'DDD appeared to be decreasing, while first appeared in May 1991 and has increased, o.p'DDE and p.p'DDE appears to fluctuate. This suggests that more of the metabolites are being recycled as compared to new DDT being assimilated. Total DDTs, however, cannot be said to be declining.

While the marina levels of pesticides in muscle are below FDA Action levels for human consumption, the levels in liver/gonad are undoubtedly harmful to fish physiology and reproduction. Also, when invertebrates, fish and birds feed on contaminated live or dead fish, they consume the organs as well as the muscle and thus accumulate much higher concentrations than would humans consuming cleaned and gutted fish. Thus it is important to the ecological system to control as much as is possible the continuing input of these harmful chemicals into the marina.

VI. BACTERIOLOGY

PUBLIC HEALTH

Public health standards for enteric bacterial contamination are important to a marina even though body contact with waters of the marina is not implicit in boating usage. However, the marina beach in Basin D is a body contact area, and boat owners and maintenance persons must also be protected from fecal bacterial exposure in marina waters. The Los Angeles County Depart :nt of Health Services is responsible for monitoring the beach area and for following u, n reported contamination from sewage line leakage, breaks or overflows.

Because water percolates into sewer lines during heavy rainfall periods, it is necessary at times for flow to be diverted into overflow facilities to protect the treatment plants from being overwhelmed. The City of Los Angeles Hyperion Plant Jackson Avenue facility is one such location that sometimes overflows into Ballona Creek during major storms, which could contaminate marina waters, although increased holding capacity built in recent years has ameliorated that emission.

Coliform bacteria occur everywhere naturally in soil and are washed down storm drains. Fecal coliforms are normal inhabitants of the intestinal tracts of warm blooded animals such as mammals, birds and some fish, and cold blooded vertebrates including other fish species. For many years coliforms were considered harmless indicators of fecal contamination which might include more serious pathogens such as those causing typhoid fever and dysentery. Now it is known that they can cause infections and diarrhea. Fecal coliforms are supposed to be more specific as evidence of human fecal wastes and the enterococcus bacteria were supposed to be more specific of recent human contamination because they die off faster on exposure to the air or receiving waters. These premises have not proven to be accurate, because fecal coliforms and enterococci have been also found in birds and other animals, but public health personnel feel that the suite of tests give a better picture of what may be occurring in the environment (R. Kebabjian, pers. comm.).

Birds are a major source of bacterial contamination on beaches, vessels and docks, with the feces containing very high counts of the enteric organisms. To control contamination, it was necessary to string monofilament or polypropylene lines between poles near marina beach to deter seagulls from roosting on the sands, particularly in the off season when few people were present (Soule and Oguri, 1989; Charness and Smith, 1990).

Fecal wastes can reach the marina from a number of sources including dogs, cats, horses and wild animals when wastes are washed into storm drains and down the channels, or when high tides sweep the breakwaters where people fishing have no sanitary facilities, or where visitors abandon disposable diapers. Some wastes may be illegally released from vessel heads or tanks may be bypassed or leak. Land which drains into Oxford Street basin receives street drainage, including rinsings from trash trucks, and hosts impromptu games and picnics where no sanitary facilities are available.

It is rainfall that produces the greatest rise in coliform and enterococcus counts in the marina, flushing storm drains and streets. It is essential that body contact with marina waters be avoided during storms and for several days afterward.

STANDARDS

Total Coliforms

Federal and County public health standards for total coliforms in recreations waters are that no single sample, when verified by a sample repeated in 45 hours, shall exceed 10,000 MPN (most probable number) per 100 ml. If daily monitoring were done, not more than 20 percent of the samples could exceed 1,000 MPN per 100 ml, but sampling is not normally done with this frequency unless there is a high contamination episode.

Fecal Coliforms

Standards for fecal coliforms provide that a minimum of five samples for any 30 day period shall not exceed the geometric mean of 200 per ml, or that not more than 10 percent of samples within a 60 day period may exceed 400 MPN per 100 ml. Since our monitoring is monthly, and the County Department of Health Services monitors irregularly, we have applied the 400 MPN per 100 ml as the standard for evaluating our data.

Enterococcus

Enterococcus bacteria are part of the *Streptococcus* species that occur in warm blooded animals, but were thought not to be present in farm animals such as cattle, horses and chickens, although they are not exclusive to humans. Later tests have shown their presence in fresh seagull feces, but they apparently die off rapidly. The enterococcus standard has been a geometric mean of 35 colonies (C) per 100 ml, or that no single sample shall exceed 100 C per ml. The State Water Resources Board Ocean Plan (1990) recommended a standard of a geometric mean of 24 C per ml for a 30 day period or 12 per ml for a six month period but this has not been implemented as a standard.

RESULTS AND DISCUSSION

Violations in the standards that were found in monthly monitoring are indicated in Table IV.1. With only two exceptions, violations within the marina occurred on days when it rained within a few days prior to the cruise or during it.

VOL 12 1907

R0051212

Since two stations that are monitored in Ballona Creek and two in Oxford Street flood control basin are not within the marina, it should be noted that most of the excessive counts were recorded there. At the same time, however, violations occurred at marina stations during the rainy periods in January, February, March and April. Oxford Street basin was in violation, either at Station 13 or 22, in all months. There were only two violations in the marina in the nine months surveyed which did not occur during rainy periods, one in November at Station 11 and one in December at Station 20. Whether these indicate vessel violations or strategic bird droppings is unknown. We have observed that a single gull dropping in water can visibly contaminate a cubic meter of water within seconds.

Complete monitoring data are presented in Tables VI.2 through VI.6, along with the minima, maxima and averages, and the number of samples included, with the standard deviation. Figures VI.1 through VI.9 illustrate the monthly profiles through the marina for the three parameters, along with lines indicating the standards applied.

CONCLUSIONS

The principal sources of contamination in the marina are associated with influx of material during rainy periods, and body contact with waters should be avoided during rains or for a few days afterward. There is little or no evidence that boat owners are violating regulations, although monitoring would have to be much more frequent and extensive to catch occasional violations. If consistent leakage or flushing occurred from a vessel, it would probably be evident; in the past a vessel suspected of such activity was noted because of consistently higher levels of coliforms, and ammonia and other nutrients at a station beside it.

Violations in the marina were much reduced from the 1990-1991 period (Soule et al., 1992). As has been emphasized previously, the Oxford Street flood control basin is almost always contaminated with high fecal coliform counts, as well as the trace and heavy metal contaminants discussed elsewhere in this report. The Los Angeles County Flood Control District has been informed of this contamination but has no plans for amelioration.

VII. BENTHIC FAUNA

INTRODUCTION

Benthic fauna, those organisms living in or on the bottom of the sea (benthos), are very important to the ecology of soft bottomed estuaries, harbors and marinas. The fauna of such areas are usually dominated by polychaetous annelid worms, molluscs and crustaceans, although in polluted areas or those disturbed by natural or manmade events, nematode round wor   polychaetes and oligochaete worms may dominate, at least temporarily. A change in grain size of sediments may also encourage a change in fauna.

Because some worms and crustaceans have short life spans, and consequently, short reproductive periods, they are able to recolonize very quickly an area that has been subjected to a disturbance such as heavy storm runoff. Many are able to tolerate a fairly wide range of salinity or temperature. Benthic organisms are good indicators of environmental stress since most are sedentary, sessile or attached, and thus are subjected to any environmental changes that occur. Some species had planktonic larvae which are moved about with tides and currents, offering potential for rapid recolonization of impacted areas. Dominant species are those that reproduce rapidly and year around.

PROCEDURES

Field sampling was conducted only once, on 17 October 1991. It is unfortunate that no May 1992 survey could be performed due to budgetary cutbacks, since the survey period included the heaviest rainy season in recent years and a strong El Niño event.

Field sampling was performed from the University of Southern California research vessel *Golden West* at 13 stations using a Campbell grab (modified Van Veen), which samples 0.1m^2 of bottom surface. Although a Reinecke box corer is a more accurate sampling device, it is not possible to operate the larger vessel needed to support it in the confines of some of the station locations.

Samples were washed through 1.0 and 0.5 mm screens at outer marina stations where debris and larger sand grains may be found, and through the 0.5 mm. screen at the inner marina stations where sediments are much finer. Animals retained on the screens are preserved in 10 percent buffered formalin in the field and transferred to 70 percent alcohol in the laboratory where they are rough sorted until identification and enumeration are performed by taxonomists. Numbers of individuals are multiplied by 10 to estimate the numbers per square meter of bottom sampled.

Numbers of species and total numbers of organisms are calculated, after which species are ranked according to the most numerous individuals at each station and for the entire marina. These lists can then be compared with those of previous surveys (Soule and Oguri, 1977, 1980, 1985, 1986, 1987, 1988, 1990; Soule, Oguri and Jones, 1991, 1992). The species diversity index (SDI) is calculated by two methods, the Shannon Wiener SDI and the Gleason's SDI; the Gleason SDI was used in the 1970s and the Shannon Wiener SDI was added in 1984. The Gleason SDI tends to be more influenced by large numbers of a given species than is the Shannon Wiener SDI.

RESULTS AND DISCUSSION

Complete benthic data for October 1991 are presented in Appendix D. There is a large data base for the fall season for annual comparisons, beginning with September 1977, and extending from October 1984 to October 1991.

Population Density

The mean number of individuals per m^2 in October 1991 for the 11 stations comprising the longest data base was 34,281, down slightly from 34,521 in October 1990 but well above the mean for eight autumn periods since 1984 of 18,613 individuals per m^2. The mean number in October 1991 for all stations, including Stations 12 and 25 which were added in 1989, was 50,872 per m^2, an exceedingly high number (Table VII.1). The mean for all stations including Stations 12 and 25 was 32,003 per m^2 for the three years the stations were sampled.

Unfortunately the high mean and total values represent an enormous increase in

Table VII.1. Numbers of benthic taxa or species/individuals per square meter in fall season.

nematode worms at Stations 12 and 2, with lesser amounts at Station 1. The total number of nematodes extrapolated for the marina in October 1990 was 167,570, comprising 49.93 percent of the total fauna. In May 1991, following heavy rains in March, the nematodes totaled only 27,960 in the marina, but in October 1991 the total had burgeoned to 478,610 or 72.37 percent of the total fauna but located at only three stations. There was a large decrease in total numbers of individuals at most other stations. This may have been ameliorated in the spring of 1992, as it was in 1991, by the heavy rains, but the stressed conditions of warm El Niño waters and contaminants suggest that recolonization by nematodes would have been repeated.

Whereas the only station that showed a decrease in population in October 1990 from the previous year was Station 6, large decreases occurred at a number of stations in October 1991: Station 1 had only 37 percent of the population of the previous autumn; Station 3 had 21 percent, Station 25, 54 percent; Station 5, 46 percent; Station 7, 41 percent; Station 9, 57 percent; Station 8 was seriously depleted with only 7 percent; and Station 10 had only 15 percent of the previous year's population. The changes in Station 8 are especially disconcerting since that area has been so important to the juvenile fishery resource in the past. The demise of the seagrass beds and the increase in contaminants at that location are causes for concern. Because of the nematodes, Station 12 had an eightfold increase in population and Station 2 had a greater than threefold increase.

Number of Species

The mean number of species per m^2, or of higher taxa where organisms cannot be identified to species level, was higher in October 1991 than in previous years with 41 species per m^2, due to a very large increases at Station 1, from 38 to 122, at Station 12, from 38 to 82, and at Station 2, from 54 to 76 species per m^2 (Table VII.1). Stations 12, 1, and 4 had shown increases in number of species in May 1991, (Soule et. al., 1991) as did inner marina stations, following the spring rains. The enormous increase in number of species at Stations 12, 1 and

2 in October 1991 also included appearances of species not previously seen in the marina, perhaps due to the warmer El Niño waters and to the deposition of new sediments during the previous spring rains.

Figures VII. 1, 2, and 3 illustrate the historical record of numbers of species; October 1991 had the highest recorded values for the marina at Stations 12 and 1. The previous high was 79 species at Station 3 in 1986. Station 3 often has had high numbers of species, but the number varies considerably from year to year.

The barrier to flushing in the Entrance Channel, which causes low circula in the inner marina and basins, may also account for the large decrease in numbers of species at Station 3 from 69 to 33. A large decrease there is not characteristic of that site; the prior low number recorded there was 25 species in September 1977, when the population was, however, more than double the 1991 figure. Whether drainage or illegal dumping activities on Ballona Lagoon caused decreases in both species and total population is not known. Construction in the area may have disturbed contaminated sediments.

Species Diversity

The range in species diversity as measured by the Shannon-Wiener Diversity Index (SWDI) was from 0.44 at Station 2 to 2.34 at Station 1, with a mean of 1.91 (Table VII.2). The theoretical SWDI in the marina should range from 2.4 to 4.3, but the maximum reached was 3.09 at Station 1 in October 1984, also a warm water post-El Niño year. The previous lows were 0.55 and 0.58 at Stations 12 and 2 respectively in October 1989.

The SWDI presented a mixed picture, with a large improvement in 1991 over 1990 at Stati . and increases at Stations 3, 4, 25, 7 and 9; minor increases occurred at Stations 8 and 10 but differences were too small to be important. Figures VII. 4, 5 and 6 illustrate the variation in SWI, with the 1990s generally demonstrating low values at Station 2, at the channel sandbar and wide variation at Stations 12 and 1. In the 1980s, Station 2 was much more consistent and there was wide variation at Station 1 (Station 12 was not being sampled at that time). The profile was most consistently high in 1978.

The weakness of using the diversity indices lies in the supposed improvement when total numbers at most stations are much reduced over the previous year but the numbers of species occurring are relatively stable, such as at Stations 8 and 10. This gives a higher index than is warranted by conditions.

The Gleason Diversity Index (GDI) showed the influence of the unprecedented high number of species at Station 1, reaching 11.77, and exceeding the previous October high of 7.03 at Station 3 in 1989. The low GDI in 1991 was 1.93 at Station 8, as compared to the lowest values of 1.46 at Station 9 in October 1987 and 1.52 at Station 8 in October 1989. Increases in both diversity indices occurred at Stations 4, 25 and 9, while decreases in both occurred at Stations 5 and 11 in October 1991. Thus the indices were not consistent at the other stations, but the means for all stations showed small increases in both indices in October 1991, due largely to conditions at Station 1, with its large increase in number of species and a relatively small population.

SPATIAL DISTRIBUTION AND DOMINANT SPECIES

As was the case in October 1990, the nematode round worms dominated the total numbers of individuals with even larger numbers, 479,110 per m^2 in October 1991 as compared to 190,570 per m^2 the previous year. Nematodes were limited in distribution at Stations 12, 1, and 2 in 1991, stations which were disturbed by the spring storms, with flushing at Stations 12 and 1 and deposition of new sediments at Station 2. Nematodes represented 49.9 percent of the total fauna in October 1990 whereas they formed only 12.3 percent in May 1991 soon after the flushing (Soule et al., 1991), but exploded to form 72.4 percent of the total fauna in October 1991 (Table VII.3).

The fact that the total for the entire marina was dominated by the nematodes at Station 2, with 43.5 percent of the total fauna, in turn emphasizes the reduced numbers at most other stations, which showed decreases of up to 93 percent, which occurred at Station 8.

The usually dominant polychaete species such as *Mediomastus*, *Pseudopolydora* *paucibranchiata* and *Prionospio heterobranchia* were again distributed throughout the entire marina but in much smaller numbers than usual forming only about 15 percent of the total (Table VII.3). Larger numbers of species which occurred in Ballona Creek at Station 12 included polychaetes, molluscs and crustaceans that often do not occur there. This suggests that the heavy rainfall, including waters released by the Los Angeles City Sanitation District and Los Angeles County storm drains during flood flow, flushed the channel, providing new sediments and nutrients that benefited the habitat. It also indicates that areas that at times are considered highly contaminated with metals and pesticides can support a diverse fauna a short time later, provided that flushing is good.

Flushing throughout most of the marina is inherently low, a condition which is exacerbated by failure of regulatory agencies to permit dredging of the channel entrance. This is probably responsible, at least in part, for the increase at all stations in the finest sediments the size of which are determined by screen mesh size. The finest is expressed as grain size of less than 200 mesh (<200). A decrease in sand (screen size 25) at all stations except Station 1 may represent deposition of fines during and after rains, which remain there due to the low flow rate during dry weather. This could impact the benthic fauna composition, and in turn perhaps affect the rest of the food chain organisms that feed on those species.

Station 12

Station 12 is located on the seaward side of the Ballona Creek footbridge that was formerly part of the coast highway before the marina entrance was constructed. Fauna at this station varies greatly, depending on the amount of rainfall, dry weather flow volume, overflows of primary treated sewage water, tide height and state and the accumulation of rubbish. Since there was unusually heavy rainfall in the basin in February and March 1992, the Ballona Creek Channel was flushed and supplied with new sediments, nutrients and contaminants from upstream with the finest sediments (<200) forming only 57 percent.

Station 12 had a moderate score for trace metals and non-metallic contaminants

Table VII.3. Dominant benthic species/taxa ranked by percent, 17 October 1991. Counts per m² are given by station and for the entire marina. Stations are listed by distance from the breakwater, with Station 12 in Ballona Creek and Station 1 off the mouth of Ballona Creek.

Tellina sp., juv.	500													500	0.08%

(Chapter IV), slightly higher than it was in October 1990 and May 1991, and about 35 percent lower than it was in October 1989. Total pesticides and chlorinated hydrocarbons dropped nearly 50 percent from May 1991, but still exceeded the October 1990 level slightly. In October 1989, the total was more than five times as high, with high Chlordane, DDTs, and Aroclor 1260.

Included in the unprecedented 82 species/taxa present at Station 12, was the usual component of common polychaete species plus a number of species represented by a few individuals of arthropods: gammerids, cummaceans, caprellids, and decapods. Also, a number of mollusc species, particularly pelecypods which seek enriched soft bottom habitats, occurred in small numbers and even included the gastropod *Bulla gouldiana* (the bubble shell) that used to be found in large numbers in outer Newport Bay and elsewhere along the coast in sandy bottoms. Table VII.4 indicates the ranking of species by number of occurrances in the marina, and shows the large number of species with only one or two occurrences is clear.

The dominant group was the nematodes, which formed 61.5% in October 1991 but were virtually gone in May 1991 (Soule et al, 1992). The pelecypod *Tagelus californianus* replaced *Protothaca staminea* in the top six, with the latter in tenth place and *Laevicardium substrianum* in eleventh in October 1991. Dominant species were as follows:

Species	Percent
Nematoda (unid.)	66.2
Mediomastus, sp.	17.5
Polydora paucibranchiata	3.8
Prionospio heterobranchia	2.4
Tagelus californianus	1.8
Armandia bioculata (=brevis)	1.4

Station 1

Station 1 is situated between the southern end of the breakwater and the south jetty of Ballona Creek. There, waters from the creek, the marina and Santa Monica Bay are mixed by tidal flow, drainage and wave action. Flushing is impeded by the sandbar deposition around the end of the jetty separating Ballona Creek from the marina entrance

Table VII.4. Benthic species ranked by number of station occurrences, 17 October 1991. Station order is based on distance of the station from the breakwater, with Station 12 located in Ballona Creek and Station 1 off the mouth of Ballona Creek. Not included are species with counts of less than 100 at one station.

channel. The finest sediments (<200) formed 62 percent of the sediments in October 1991 as compared with 31 percent in October 1990.

Station 1 had the lowest levels of trace metals-contaminants of all the stations in May 1991 after the rainy season, having been in the moderately contaminated category in October 1990. It remained the cleanest in October 1991 (Chapter IV). Levels of total pesticides/chlorinated hydrocarbons, rose from 58 ppb in October 1989 to 205 ppb in October 1990, to a peak of429 ppb in May 1991 and dropped back to 57 ppb in October 1991, due mostly to changes in Chlordane and DDTs levels. This also indicates a difference in the influx and movement of trace metal/contaminants and pesticides.

The large number of nematodes at Station 1 indicates a disturbed or stressed environment, such as would occur with the heavy freshwater rainfall runoff that impacted the habitat during the spring. The numbers of nematodes obscures the fact that an unprecedented 121 species occurred there, by far the largest number ever recorded for the marina. The previous high was 79 species at Station 3 in 1986. The large number of species found that rarely occur there indicates that the sediments were not inhibitory, which may be related to the reduction in pesticides.

Table VII.4 lists a large number of species having small numbers of individuals, that occurred at Station 1 and not elsewhere in the marina. Following are the dominant species:

Species	Percent
Nematoda (unid.)	39.7
Mediomastus, sp.	27.1
Ericthonis brasiliensis	4.8
Aoroides inermis	2.3
Prionospio lighi	2.1
Armandia bioculata (=brevis)	2.0

Station 2

Station 2 is located between the north and south jetties and the breakwater. It has for some years been degraded by the accumulation of sand, which has acted as a trap for fine, contaminant bearing sediments flushed from the marina or settled out from Ballona Creek waters carried on tidal exchanges. The grain size of surface sediments is now more than 90 percent fines (<200).

Trace metal and contaminant scores placed the station in the medium low range, improved over the October 1990 and May 1991 medium high levels, indicating that both wet and dry weather flushing had occurred. It ranked highest in total pesticide-chlorinated hydrocarbons, in October 1991 as it did in May 1991 and was third highest in October 1990. In spite of the disappearance of Aroclor 1254, it still ranked highest due to 436 ppb of Chlordane. However, total pesticides-chlorinated hydrocarbons decreased fr[illegible] 1121 ppb in October 1989, to 473 ppb in October 1990, rose to 569 in May 1991 and rem[illegible]ned at 541 ppb in October 1991. There is either differential flushing there or a continuing input, probably from Ballona Lagoon.

The population had deteriorated further in October 1991, with nematodes increasing to 92.9 percent from 71.2 percent of the population in October 1990 and 55.3 percent in May 1991. The total numbers, 278,610 nematodes and 5,870 oligochaetes out of a total of 310,060 individuals, gives a very low diversity, indicating a very poor ecological environment, probably impacted by the influx of freshwater runoff from Ballona Creek during the spring. The large number of species present there in very small numbers (Table VII.4) indicates good potential for recolonization if deposition of pesticides could be lessened.

The dominant species are listed as follows:

Species	Percent
Nematoda (unid.)	92.9
Oligochaeta (unid.)	1.9
Mediomastus, sp.	1.6
Oxyurostylus pacifica	0.8
Armandia bioculata (=brevis)	0.5
Pseudopolydora paucibranchiata	0.4

Station 3

Station 3 is located at the buoy marking the tide gate to Ballona Lagoon. The site is usually well flushed due to the tide gate but terrestrial and marine sediments disturbed in the

Lagoon area can impact the station. There was great change in the sediment characteristics, moving from 7.97 percent in October 1990 to 90.98 percent finest sediments (<200) in October 1991.

The trace metal and contaminant score rose from a low of 46 in October 1990 to 178 in May 1991 and dropped only slightly to 164 in October 1991. The pesticide-chlorinated hydrocarbon levels increased from 21 ppb in October 1990 to 401 ppb in May 1991 and 409 ppb in October 1991. This indicates a radical increase in the input of the major constituent, Chlordane, which may originate in soils or buildings surrounding Ballona Lagoon or the Venice Canals.

The number of species was less than half those of recent years, being more similar to 1977 numbers than to any others. The number of individuals fluctuates greatly at Station 3, but was less than 25 percent of that found in October 1990, similar to totals found in 1988 and 1985. The dominant species were typical of the open channels of the marina, as follows:

Species	Percent
Mediomastus, sp.	43.2
Prionospio heterobranchia	16.7
Euchone limnicola	6.7
Leitoscoloplos pugettensis	6.2
Mayerella banksia	4.2
Lumbrineris minima	3.7

Station 4

Station 4 is located off the riprap in front of the apartment houses seaward of the Coast Guard docks near the juncture of the entrance channel and the main channel. For several years it seems to have had a depression that trapped fine sediments and pollutants. The score for trace metals and contaminants increased but remained in the moderate level, along with an increase in the percentage of the finest grained sediments. Total pesticides and chlorinated hydrocarbons dropped from 206 ppb in October 1990 to 141 ppb in October 1991, chiefly due to the disappearance of Aroclor 1254.

The station improved in both numbers of species and individuals, the highest since

VOL 12

1 7937

the 1977 survey. The dominant species were as follows:

Species	Percent
Pseudopolydora paucibranchiata	36.1
Mediomastus, sp.	12.8
Euchone limnicola	11.7
Leitoscoloplos pugettensis	9.8
Mayerella banksia	5.7
Lumbrineris minima	4.1

Station 25

Added to the survey stations in 1989, Station 25 lies between the Bay Watch docks at the County Administration Building and the public fishing docks at Fisherman's Village. Drainage from the restaurant, Village and Administration parking lots enters the marina there, and vessel activity is high, although oil and grease levels in sediments are moderate. The sediment is 97.15 percent of the finest sediment (<200). The trace metal-contaminant score decreased slightly from the high range in October 1990 and May 1991 to the medium high range in October 1991. The pesticide-chlorinated hydrocarbon level dropped from 354 ppm in October 1989 to 327 ppm in October 1990, to 248 ppb on May 1991 and then to 173 ppm in October 1991, due largely to the disappearance of Aroclor 1260.

The number of species increased in October 1991, but the number of individuals decreased by about 46 percent from October 1990, although it was about the same as in May 1991. While the dominant species, listed below, show a better balanced diversity than most marina stations, even more important was the appearance in smaller numbers of several mollusc species such as *Protothaca staminea*, *Tivela stultorum*, and *Laevicardium substriatum* that have not been seen there previously (Table VII.4.).

Species	Percent
Mediomastus, sp.	29.0
Leitoscoloplos pugettensis	27.0
Prionospio heterobranchiata	8.3
Lumbrineris minima	6.2
Oligochaeta (unid.)	5.1
Aphelochaeta parvus (=*Tharyx*)	3.8

VOL 12

Station 5

Located in the center of the main channel off Burton Chace Park, Station 5 accumulates sediments and contaminants flushed from the basins during dry or low flow weather conditions but may be flushed by heavier rainfall. The finest grained sediment increased from 94 percent to 99.5 percent between October 1990 and October 1991. In May 1991, following heavy rains in March, contaminants and trace metal scores were increased over levels in October 1990, and in October 1991 increased again, but remained in the medium high category. Pesticide-chlorinated hydrocarbon levels changed from 324 ppb in October 1989 to 271 ppb in October 1990, and then dropped greatly to 218 ppb in May 1991 and 103 ppb in October 1991. The pesticide reduction was due mostly to a decrease in Chlordane and the disappearance of Aroclor 1254.

Small numbers of molluscs and crustaceans occurred at Station 5 (Table VII.4), but the following polychaete worm species dominated the fauna:

Species	Percent
Aphelochaeta parvus (=*Tharyx*)	34.4
Cirriformia spirabrancha	15.5
Mediomastus, sp.	29.0
Prionospio heterobranchia	8.9
Leitoscoloplos pugettensis	27.0
Lumbrineris minima	6.2

Station 6

Station 6 is located at the inner end of Basin B and has been among the cleaner stations in the marina. The percentage of the finest sediments increased from 50.44 percent in October 1990 to 79.69 in October 1991, after a decrease to 49.02 percent in May 1991. The contaminant-trace metal scores are usually in the medium low range with 73 in October 1990, increasing to 95 in May 1991 and moving up to the moderate level with 109 in October 1991, due to increases in IOD, COD, oil and grease, phosphate, organic nitrogen and sulfide. The pesticide-chlorinated hydrocarbon levels declined from 178 ppb in October 1990 to 35 ppb in May 1991 after the rainy season due to the disappearance of Aroclor 1254 by May; the total rose to 103 ppb in October 1991, due to a large increase in

1
7938

Chlordane during dry weather.

The number of species decreased by around 30 percent in 1990 and 1991 while the number of individuals has decreased from a peak of 12,940 in October 1988 to only 3,170 per m^2, close to a 75 percent decrease. This basin seems to be under stress from general pollution for unknown reasons, possibly decreased flushing. The species list is short (Table VII.4), but the dominant species are fairly typical of the low flushing inner basins, as is shown in the following list:

Species	Percent
Leitoscoloplos pugettensis	28.4
Pseudopolydora paucibranchiata	18.6
Prionospio heterobranchia	17.4
Mediomastus, sp.	9.2
Phoronida, unid.	7.3
Aphelochaeta parvus (=*Tharyx*)	5.1

Station 7

Station 7, located at the boat launch ramp at the inner end of Basin H, is subjected to dry and wet weather flow from storm drains and parking lots. In spite of the proximity of boatyards and the exposure to oil and grease from launchings, the contaminant-trace metal score is in the moderate range, although levels rose following the spring rains and then declined somewhat. The pesticide-chlorinated hydrocarbon total is usually in the medium low group. Levels decreased from 324 ppb in October 1989 to 150 ppb in October 1990, 141 ppb in May 1991 and to 92 ppb in October 1991. This was due primarily to the disappearance of Aroclors. The grain size increased from 67.56 percent finest sediments in (<200) October 1991 to 83.96 percent in May 1991 and increased slightly to 91.88 percent in October 1991.

The number of species ranged from 27 to 39 through 1986 but has ranged from 16 to 26 since, while the numbers of individuals has ranged from 18,870 to 4,590 since 1984, down from 32,740 in 1977. Dominant species are polychaetes, as follows:

VOL 12

Species	Percent
Aphelochaeta parvus (=*Tharyx*)	53.4
Lumbrineris minima	9.7
Leitoscoloplos pugettensis	9.3
Pseudopolydora paucibranchiata	9.0
Mediomastus, sp.	6.6
Prionospio heterobranchia	5.1

Station 8

Located off the only beach in the marina, Station 8 which was close to a sea grass (*Ruppia*) bed that had disappeared by October 1991, being replaced by filamentous enteromorpha algae and hydroids characteristic of eutrophic environments. The grass bed was an important habitat for larval and juvenile fish. The character of the bottom changed from being composed of sand and finer sediments down to 50 percent of the smallest grain size (<200), to 98.81 percent finest sediments. Whether this influx of fine sediments caused the change is unknown.

Contaminant-trace metal scores moved from moderate in October 1990 to medium high in May 1991 to high in October 1991, with increases in many parameters over the period. Total pesticide/chlorinated hydrocarbon levels moved from 86 ppb in October 1989 and October 1990, mostly of Aroclor 1254 and DDTs, to a high of 232 ppb in May 1991, due to increases in Chlordane, p.p'DDE and Aroclor 1260. The total dropped to 55 ppb in October 1991, with decreases in those parameters. However, damage may have been done to the sensitive sea grass beds by the influx of contaminant-trace metals and/or pesticides and chlorinated hydrocarbons, and/or by the influx of fine sediments.

The number of species has ranged from 9 in 1977 to 35 in 1986 while the previous range for numbers of individuals was from 1,990 per m^2 in 1988 to 14,950 in 1986, but the drop from 29 species and 12,780 individuals per m^2 in October 1990 to 14 species and 850 individual species in October 1991 is an extreme loss of food for the food chain, a 15 fold loss in population. The following are the dominant species:

1 7940

VOL 12

Species	Percent
Leitoscoloplos pugettensis	32.9
Pseudopolydora paucibranchiata	20.0
Prionspio heterobranchia	16.5
Lumbrineris erecta	8.2
Euchone limnicola	3.5
Cylichnella inculta	3.5

Station 9

Station 9 is located at the inner end of Basin F and receives runoff from storm drains and parking lots. A station that usually has a sediment size of 9[illegible] percent fines (<200) showed a decrease to 89.74 percent fines following the spring ra... in 1991 but increased during dry weather to 99.76 percent fines in October 1991.

Station 9 was ranked second highest in contaminant-trace metal scores in October 1990, May 1991 and October 1991. Total pesticide/chlorinated hydrocarbons increased from 306 ppb in October 1989, to 354 ppb in October 1990, decreasing to 167 ppb in May 1991 and to a low of 70 ppb in October 1991. This was due to large decreases in DDTs and the disappearance of Aroclor 1260.

The number of species increased by one but the number of individuals dropped 43 percent between October 1990 and October 1991. Numbers have fluctuated considerably at this station. The following polychaetes are the dominant species in October 1991:

Species	Percent
Pseudopolydora paucibranchiata	31.1
Cirriforma spirabrancha	16.7
Leitoscoloplos pugettensis	13.1
Lumbrineris minima	10.4
Chaetozone corona	8.6
Mediomastus, sp.	8.6

Station 10

Station 10 is located at the inner end of Basin E, subjected to the runoff and tidal flushing from the Oxford Street flood control basin which enters the marina via a tide gate. The percentage of the finest grain size (<200) at Station 10 was 94.79 in October 1990, was reduced to 75.33 percent by flushing from the spring rainstorms, and increased to

99.36 percent in October 1991. This indicates deposition during dry weather which may be related to progressively poorer flushing in the entire marina due to partial blockage at the entrance. Although the open part of the basin may flush, considerable accumulation of contaminated sediments occurs beneath the docks.

The trace metal-contaminant score at Station 10 continued to be the highest in the marina, ranking first or second in 14 of 20 parameters measured, indicative of the influx and deposition from the Oxford Street flood control basin. Total pesticides-chlorinated hydrocarbons rose from 419 ppb in October 1989 to 494 ppb in October 1990 and 487 ppb in May 1991, due to increases in Chlordane and Aroclors. This pattern was altered completely in October 1991, by a drop to 91 ppb due to movement of Chlordane out of the area and the disappearance of Aroclors.

The number of benthic species decreased from 28 to 15, about a 47 percent drop, and the number of individuals decreased from 7,390 per m^2, to 1,090 per m^2 an 85 percent decrease from October 1990 to October 1991. The population had been in good shape in May 1991 so the great decrease occurred during dry weather flow from Oxford Street basin. The following polychaete species were dominant in October 1991:

Species	Percent
Pseudopolydora paucibranchiata	27.5
Lumbrineris minima	19.3
Lumbrineris erecta	14.7
Prionospio heterobranchia	11.9
Leitoscoloplos pugettensis	8.3
Euchone limnicola	8.3

Station 11

Station 11 is located at the inner end of the main channel, which was open water before construction of new docks there about five years ago. The station scored in the high group in trace metals-contaminants in October 1989, October 1990, May 1991, and October 1991. Pesticide-chlorinated hydrocarbon totals have moved from 380 ppb to 443 and to 496 before dropping to 91 ppb in the same periods of time. Chlordane decreased and Aroclors disappeared, indicating the movement of these pollutants out of the area.

There has been modest improvement in the total numbers of species and individuals since the very low numbers in 1988 and 1989, but the fauna is still depauperate, ranking third above that of Stations 8 and 10 in low numbers. The following were dominant species at this station:

Species	Percent
Mediomastus, sp.	45.5
Pseudopolydora paucibranchiata	19.9
Cirriforma spirabrancha	12.8
Lumbrineris minima	7.1
Mysidopsis, sp.A	2.6
Leitoscoloplos pugettensis	1.9

CONCLUSIONS

The increase in numbers of species per m^2 at the entrance of Ballona Creek is encouraging, and indicates that conditions there were improved, whether by flushing during the heavy storms of March, or by upstream pollution control, or a combination of these and other, unknown factors. The increase in mean numbers of individuals per m^2 would be considered outstanding were it not due to enormous numbers of nematodes at Stations 12 and 2 that indicate a disturbed environment. During heavy runoff, many organisms are swept from surficial muds, and species capable of rapid recolonization will at first dominate; if newly deposited sediments contain toxicants, colonization and growth of many species will be inhibited. The mean number of individuals, including nematodes was a record high; without nematodes, it was slightly above the mean for the last six years.

The appearance of species not previously reported in Ballona Creek and at other stations, particularly of molluscs and crustaceans, may be associated with the reduction in DDTs and the disappearance of Aroclor 1254 and 1260, which were introduced into the marina sometime between October 1988 and October 1989. The continuing presence of Chlordane may be a very important inhibitory factor in the outer marina.

Reduction in flushing may an important factor in the inner marina basins, which already had limited circulation due to the marina configuration. The continued accretion of sand at the marina entrance could reduce water exchange sufficiently to inhibit the fauna, which would cause more settling of fine sediments carrying contaminants and retention of water or oil soluble pollutants. Fauna were decreased at Station 6, in Basin B, and were 50 percent below the lowest year of 1988 at Station 8 in Basin D, and were more than 50 percent below the previous low in 1989 at Station 10 in Basin E. The influx of pollutants into Basin D and the loss of the seagrass beds has seriously impacted this important habitat. Populations were low at Stations 5,7 and 9 but these have also fluctuated in past years.

VIII. FISH FAUNA

INTRODUCTION

Marina del Rey is an important habitat for fish eggs, larvae and young adults, serving as a shallow, warm water, high nutrient environment where turbidity offers some shelter from predators, and fulfilling the functions of wetlands (Stephens et al., 1991; Soule et al., 1991, 1992). It has been estimated that ninety percent of the natural wetlands in the Los Angeles a have been lost to development, making the marina of particular importance.

Fish surveys of the marina were first conducted by Harbors Environmental Projects, University of Southern California, in 1977-1979 when baseline studies were performed and techniques explored with funding assistance from the federal Sea Grant Program at USC. Five surveys were conducted in that period and four surveys were performed in 1980-81. After a hiatus, surveys were resumed in 1984, in cooperation with the *Vantuna* Research Group at Occidental College under the direction of Dr. John S. Stephens, Jr. and his staff. Semiannual surveys have been performed since then, with the exception of 1985, when only an annual October survey was conducted due to funding limitations.

More than 90 species, or higher taxa if not identifiable to species level, have been found in the marina during the survey periods. The mean number of species or higher taxa for the 16 surveys conducted under standardized techniques since 1984 is 39.25, about the same as the mean if the 1977-1981 surveys are included, indicating that the number of species in the marina in the spring and fall are relatively stable. Some fish eggs cannot be identified to species but others, previously not identified, have been placed in species more recently, altering the number of larval taxa slightly.

The mean for eight surveys conducted in October is 38.5 species, and for eight surveys conducted in May is 40, suggesting a slight seasonal variation, although such factors as turbidity can easily alter the total number of species on a given date. If monitoring were more frequent, such events would not affect the means as much.

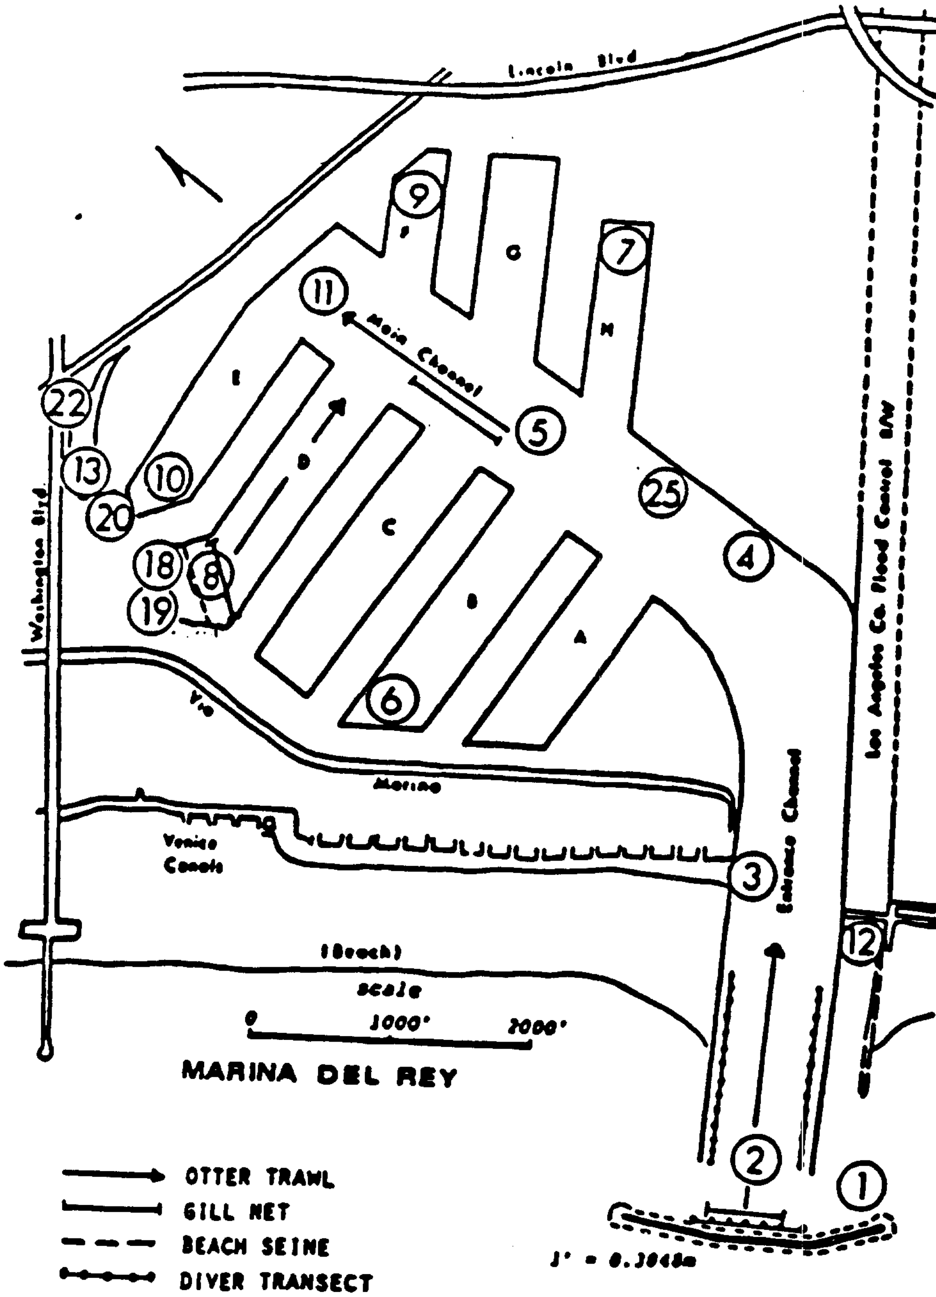

Figure VIII.1. Fish Sampling Stations for Marina del Rey.

PROCEDURES

Fish surveys were conducted on 17 and 18 October 1991, and on 21 and 22 May 1992 courtesy of Occidental College, at the stations indicated in Figure VIII.1. Techniques have been standardized since 1984, with otter trawls performed using a 15 ft semiballoon trawl towed for 10 minutes at three locations. A 100 ft multimesh gill net is deployed at three locations for 45 minutes each, and a 100 ft beach seine is deployed at an 8 ft depth about 30 yds from the beach in Basin D an[illegible]hed to the shore. Diver surveys are performed at the breakwater and along the jettie[illegible] of the entrance channel. Fish eggs and larvae (ichthyoplankton) are collected by towing a 333 μm mesh plankton net at 1 m depth for two minutes and on the bottom for three minutes. A diver assisted benthic sled is used to keep the net on the bottom in spite of variations in boat speed. Ichthyoplankton counts are standardized to counts per 100 m^3.

RESULTS AND DISCUSSION

October 1991

A total of 37 species was observed or captured by one or more techniques in October 1991: 18 from diver surveys; 8 from the beach seine; 3 from the gill net; 7 from the otter trawls and 11 from the ichthyoplankton.

Although the mean number of species/taxa is 38.5 for all October surveys, the mean numbers have been slightly below that since October 1988 (36.75), when unusually cold waters were present after a mild El Niño year (Table VIII.1). However, results of the diver surveys in October 1991 took place at a time of extreme tides, and the number of species sighted by divers was slightly lower than in October 1990.

The number of individuals captured in October 1991 was down about 22 percent from October 1990, due to a decrease in numbers of *Atherinops affinis* (topsmelt) usually caught by beach seine (Table VIII.2). However, otter trawl and gill net numbers were much higher.

In diver transects, the total number of fishes was 756 in October 1991, down about

74 percent from 2,953 counted in October 1990 (Soule et al., 1991). The number of ichthyoplankton was the highest seen in October surveys at 26,688 per m^3 (Table VIII.3), although it was less than half the record number of 59,359 per m^3 caught in May 1991. May numbers are usually higher than October numbers.

Table VIII. 4, at the end of this section, lists the totals of all species caught or observed with the various techniques in October 1991. Of particular interest was the record capture in the beach seine of 11 *Mustelus californicus*, the gray smoothhound shark, out of a school of about 25 adults in the swimming area. While these sharks, about one meter long, are harmless to humans, this would easily account for the low numbers of *Atherinops affinis* (topsmelt), a favorite forage fish, in the seine. Also, the disappearance of the sea grass bed near the beach might have affected the numbers of *Atherinops*. Diversity was good in the seine nevertheless.

Numbers of gill net species have been low since 1988, and the numbers of individuals has varied greatly. No fish were caught at gill net stations 2 and 5 in October, in the entrance channel and main channel respectively, where catches have been poor in recent years. Eleven species or taxa of ichthyoplankton were recorded (Table VIII.5).

Table VIII.6 lists the species that have been recorded in the marina since surveys began. Returning after an absence were *Atractoscion nobilis*, white sea bass, absent since 1987, and *Hyperprosopon argenteum*, walleye surfperch, absent since 1986; *Ilypnus gilberti*, cheekspot goby is sometimes present in May, but has not been observed in October since 1986. Species that are usually present but were not seen in October 1991, perhaps due to limited visibility, were *Heterostichus rostratus* giant kelp fish, *Paralabrax maculofasciatus*, spotted sand bass, and *Pleuronichthys ritteri*, spotted turbot.

May 1992

There were 39 species and higher taxa recorded in the May 1992 surveys: 20 in the diver survey, 9 by beach seine, 3 by gill net, 9 by otter trawl and 9 in the ichthyoplankton. The 3 gill net species caught in May 1992 equalled the number caught in October 1992 and were the highest since 1988 (Table VIII. 1).

The numbers of individuals were the lowest for any spring survey since 1984, primarily influenced by low catches of *Atherinops affinis*, topsmelt, and *Seriphus politus*, queenfish. Numbers of individuals were also low in May 1984 and May 1986 surveys (there was no May 1985 survey), possibly due to the impacts of the 1982-1983 warm El Niño waters which lingered in the Southern California Bight in 1984, followed by a radical cooling in October 1984. In March and April 1992 waters were warmer than normal due to an El Niño event, which may have affected thermal cues for the spring spawn.

While ichthyoplankton larval totals were high, second only to those in May 1991, egg totals were very low and no eggs were found in Basin D. That area is of great concern because of this and other indications that the habitat has deteriorated there, such as increases in pollutants and fine sediments and the demise of the sea grass bed. Because of the observed wide range of variation in numbers of species and individuals and the infrequency of surveys, it could be difficult to determine a downward trend in a timely fashion.

Both *Mugil cephalus*, striped mullet, which has been in the marina in almost all surveys, and *Strongylura exilis*, California needlefish, which has occurred frequently, returned to the species list after being absent in May 1991. A new record for marina surveys was the diver observed kelp surfperch, *Brachyistius frenatus*. *Mustelus californicus*, gray smoothhound shark, occurred for the first time in October 1991 and recurred in May 1992, perhaps due to the warm waters. An important reappearance was of the uncommon species *Albula vulpes*, the bonefish. In May, for the first time *Rhacochilus vacca*, pile surf perch, was not observed.

Ichthyoplankton and Numbers of Species

Since ichthyoplankton surveys were reinstituted in 1984, more larval taxa have been recognized as species, creating some redundancy with the species also enumerated as adults. The species list (Table VIII.6) has been revised and all published records rechecked against original data lists to reflect this. For example, the category Clinidae Type A theoretically includes larvae of several species of *Gibbonsia*, but *Gibbonsia elegans* is the only species of that genus observed in the marina. Gobiidae Type A/C includes larvae of *Ilypnus gilberti*, *Quietula y-cauda*, and *Clevelandia ios* in an early (preflexion) stage, all of which have the possibility of being found in the marina so this category must be maintained. Gobiidae may include any of eight or more local species, but Gobiidae Type D larvae are generally recognized as being *Lepidogobius lepidus*; that species was collected in the marina as an adult only once, in a beach seine in May 1986. Cottidae is used for sculpins which are too immature or damaged so that they cannot be identified, but may be one or more of four species that are found in the marina, *Scorpaenichthys marmoratus*, *Leptocottus armatus*, *Clinocottus analis*, and rarely, *Chitonotus pugetensis*. *Oligocottus/Clinocottus* A are also sculpin larvae. In early surveys Complex 2, consisting of larvae too young to be identified to species, was reported; this group may include one or more of four local species of croakers, *Atractoscion nobilis*, *Cheilotrema saturnum*, *Menticirrhus undulatus* and *Umbrina roncador*.

Long Term Occurrences

Now that 16 survey periods have been performed from May 1984 to May 1992 using the same techniques, it is of interest to list species that can be considered residents of the marina. While a mean of 40 species has been found in the marina, composition of the fish fauna varies seasonally and annually. Some 20 species can be considered to be year around residents or users of the marina. Of these, seven species and two larval taxa have been present in all surveys, five more species have been present in all but one survey, two species have been present in all but two surveys, and six species have been present in all but three surveys, as is listed below:

Present in all surveys :

Atherinops affinis	topsmelt
Embiotoca jacksoni	black surfperch
Girella nigrans	opaleye
Gobiidae A/C larvae	gobies
Hypsoblennius, spp. larvae	blennies
Micrometrus minimus	dwarf surfperch
Paralabrax clathratus	kelp bass
Paralabrax nebulifer	barred sand bass
Rachochilus vacca	pile surfperch

VOL 12 1992

Present in all but one survey:

Halichoeres semicinctus	rock wrasse
Mugil Cephalus	striped mullet
Paralichthys californicus	kelp bass
Rachochilus vacca	pile surfperch
Seriphus politus	queenfish

Present in all but two surveys:

Heterostichus rostratum	giant kelpfish
Hypsypops rubicundus	garibaldi

Present in all but three s[illegible]ys:

Cheilotrem[illegible] saturnum	black croaker
Chromis punctipinnis	blacksmith
Engraulis mordax	northern anchovy
Hypopsetta guttulata	diamond turbot
Oxyjulis californica	señorita
Paralabrax maculofasciatus	spotted sand bass

A few species exhibit some seasonality. For example, *Ilypnus gilberti*, cheekspot goby, was found in only three October surveys but was present in six May surveys while *Leptocottus armatus* was also found in three October surveys but occurred in seven May surveys. Others more often collected in May than October were *Menticirrhus undulatus*, California corbina, *Pleuronichthys verticalis*, hornyhead turbot, *Quietula y-cauda*, shadow goby, *Sardinops sagax caeruleus*, Pacific sardine, and *Urolophus halleri*, round ray. *Scorpaena guttata*, sculpin/spotted scorpionfish, and *Typhlogobius californiensis*, blind goby, were found only in May, while *Semicossyphus pulcher*, California sheephead, was seen twice, only in October. *Chromis punctipinnis* was present in all October surveys but missing in three May surveys.

CONCLUSIONS

The fish fauna of the marina as a whole has been stabilized around a mean number of 39 species, although there has been a wide range of variation seasonally and annually (Figure VIII.2).

There is a basic group of about twenty species and larval taxa that have always been present during all or most spring and fall surveys. Within the system, a number of other

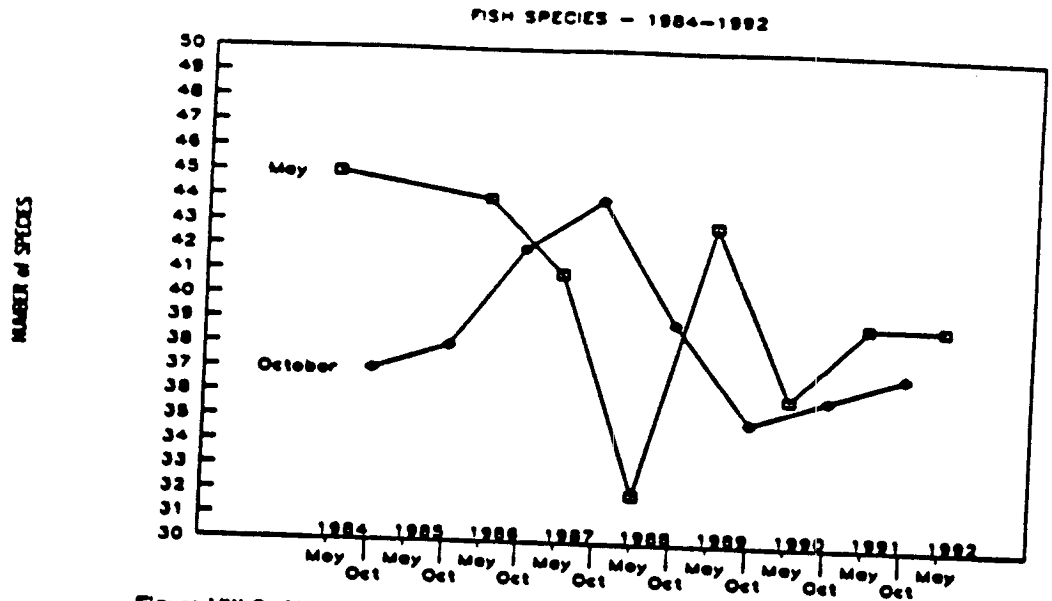

Figure VIII.2. Number of fish species/taxa by month and year.

species have appeared for several years and then disappeared, with no definitive pattern. Much of the variation is probably associated with the thermal fluctuations in warm winters associated with El Niño events. When the May 1984 survey was undertaken, a large warm water mass still lingered in the southern California Bight from the 1982-1983 El Niño, which dispersed in the fall of 1984. The influx of cooler water may have affected fall numbers of species until the faunal composition adjusted with more cool tolerant species. A smaller El Niño occurred in the winter of 1987, which may have affected the May 1988 survey and the subsequent October surveys. Although a strong El Niño event was in progress near the equator in January 1992, its effects on water temperature in the marina were not evident until above normal warming in March and April (Chapter II), after which it was cooler than in 1991. Such a shift in spring thermal patterns could alter spawning and recruitment patterns and might be at least partially responsible for low abundance. Because of the complexity of the thermal reproductive cues and the availability of food at the essential period, it is not possible to be

VOL 12

1954

certain which factors are driving the system when monitoring is not conducted at least monthly.

The impact of other factors such as pollutants is difficult to determine, due to the lack of records generally regarding small or large spills or influxes of contaminants through the storm drain system. It is of interest to note, however, that the only periods in which both the October and May surveys were low were in October 1989, May 1990 and October 1990. Coincidentally, this was the period in which the PCB spills/ releases were recorded, along with high Chlordane and DDTs (see Chapter IV).

Conditions at Station 8 in Basin D have deteriorated, with the loss of the sea grass bed, which provided shelter and foraging for larval and juvenile fish as well as forage fish schools. Sea grass has been replaced by filamentous algae and hydroids indicative of eutrophic environments. The finest fraction of sediment increased from 50 percent to over 98 percent in 1991, with a concomitant increase in trace metals and nonmetallic contaminants. Total pesticides and Aroclors increased, from 86 ppb in October 1989 to reach a high of 232 ppb in May 1991 and then decreased to a low of 55 ppb, in October 1991, but damage may well have been done to the delicate ecology of the basin by levels toxic to some plant and animal species. Sources of this influx of sediments, trace metals and other pollutants have not been identified, although they were probably associated with rainfall runoff. That area does not have large storm drain systems entering it and therefore should have been more protected from impact.

CRUISE: MDR 91-92   Date: 17 October 1991   Type: Benthic organisms, metals, pesticides

PERSONNEL: D. Soule, PI USC; M. Oguri USC; R. Bester USC; B. Jones USC; P. Hentschke USC; A. Zellars USC

VESSEL: *Golden West*

D. Reynoso
B. Wastell
T. Healy

ASSOCIATED LABORATORIES: Robert Webber

TIDE: High 0706 4.3 ft - Low 1230 2.6 ft

LEFT DOCK: 0830   WEATHER: Overcast

SAMPLING STATIONS:

SAMPLER: Campbell Grab, 1/2 & 1 ml Screens

STATION	TIME	PROCEDURE	COMMENTS
12	0837	Bottom sediment metals, pesticides. Benthic organisms	Took 12 grabs pooled samples Very sandy, would not sieve well.
1	0937		Strong sulfide odor. Pooled 6 grabs. Very sandy. Sun coming out
2	1016		Strong sulfide odor. Oily, plant debris plentiful. Sun fully out
3	0157		Not the usual amount sand. Sieved very well
4	1128		1st and 2nd grabs empty, 3rd grab successful
25	1143		1 Grab taken
5	1219		1 Grab taken
6	1252		1 Grab taken
8	0152		1 Grab taken
10	0143		1 Grab taken
11	0212		1 Grab taken
9	0237		1 Grab taken
7	0300		1 Grab taken
13	0320	West and Oxford Flood Control	Hand sampled from shore
22	0340	East and Oxford Flood Control, near Washington Blvd. culvert	Hand sampled from shore

PROJECT ORGANIZATION AND RESPONSIBILITIES

DR. JOHN R. FROINES, Department of Environmental Health, UCLA School of Public Health, Los Angeles, California 90024-1772, Telephone: 310-206-6141; and DR. IRWIN H. (MEL) SUFFET, Environmental Science and Engineering Program, Department of Environmental Health, UCLA School of Public Health, Los Angeles, California 90024-1772, Telephone: 310-206-8230 are the Co-Principal Investigators for this project. They and DR. ED RUTH, Institute of Geophysics and Planetary Science, UCLA School of Arts and Sciences, Los Angeles, California 90024-1567, Telephone: 310-825-5706, were directly responsible to the AMERICAN OCEANS CAMPAIGN for the quality and timely completion of this project TOXIC CHEMICAL RELEASE INTO THE SANTA MONICA BAY: A PILOT STUDY. They were also responsible for data interpretation and for preparation and submission to the AMERICAN OCEANS CAMPAIGN of reports. This study was in collaboration with Dr. Michael Stenstrom, Department of Civil Engineering, UCLA School of Engineering, Los Angeles, California 90024-1593, Telephone: 310-825-1408, who directed the field sampling program.

Drs. Froines and Suffet were assisted by five Task Leaders. MS. SIM-LIN LAU, and Mr KEN WONG of UCLA's, Department of Civil Engineering, Los Angeles, California 90024, Telephone: 310-825-7433, were the Field Task Leader and aid, respectively. MS. SIM-LIN LAU was responsible for coordination and logistics of the field sampling activities and sample tracking and control. She was also responsible for all laboratory activities related to water quality analysis of the aqueous samples. As Analysis Task Leader, MR. MARIO CAPANGPANGAN, UCLA, Department of Environmental Health Science, Telephone: 310-206-1242, oversaw all laboratory activities and data management. He reviewed and evaluated all analytical data generated during the project, and was responsible for the management, storage, retrieval, and manipulation of that data. MARIO was responsible for all laboratory activities related to the organic analysis of the suspened sediment samples. MS. LINDA SCHWEITZER, UCLA, Department of Environmental Health Science, Telephone: 310-206-1242, was responsible for all laboratory activities related to the organic analysis of the aqueous samples.

INTRODUCTION

The overall objective of this pilot study is to gather data on the identity and quantity of chemical constituents that are present in urban runoff storm drains during dry weather flow. These data are to amplify our limited understanding of the nature of the chemicals that are transported from the storm drains into the Santa Monica Bay. The results of this study will be combined with the review of the literature being conducted by EOA, Inc. to facilitate development of a plan which will define additional urban runoff sampling objectives, sampling procedures, and provide a basis to assess the potential health and ecological risks associated with urban runoff into the Santa Monica Bay.

US EPA National Water Quality Inventory 1990 report to Congress (EPA,1992) found that storm sewer runoff was responsible for 12-31 % of the impared rivers, lakes and estuaries in the US. Urban storm drains collect water from non-point sources and can pose a public health hazard [Leadership Needed to Reduce Nonpoint Source Pollution GAC DOC # RCED 91-10; Water 2000, 1991) to the final receiving water. All urban sources from street runoff to a home or an industrial lot can add a pollutant load to the receiving body of water, both during dry weather and wet weather flow (>10,000 gal per min). The hazard of chronic chemical exposure to human population as well as the ecology of receiving water from storm drains is still an open question.

The study results are divided into the following major sections:

1. Results of volatile organic analyses by EPA Method 524/624* equivalent method using a Capillary GC/MS final step. QA/QC evaluation of sampling and analysis are included in the Appendix section. A Method Detection Limit is defined for all targeted chemicals that were quantitatively analyzed. The MDL was modified to exclude any background blank problems. A group of tentitive identifications are reported also for a series of non-target volatile organic compounds that were present in some of the samples that were analyzed. Further work outside the scope of this project would be needed for a complete evaluation of the non-target compounds that would include their positive identification and quantification.

2. Results of a total base neutral organic analysis of a filtered aqueous phase and the associated suspended solids were completed by EPA Method 608/625*

equivalent method using a Capillary GC/MS final step. The suspended solids were extracted by a newly developed supercritical carbon dioxide isolation method. QA/QC evaluation of sampling and analysis are included in the Appendix section. A Method Detection Limit is defined for all targeted chemicals that were quantitatively analyzed. The MDL was modified to exclude any background blank problems. A group of tentitive identifications are reported also for a senes of non-target base neutral organic compounds that were present in some of the samples that were analyzed. Further work ouside the scope of this project would be needed for a complete evaluation of the non-target compounds that would include their positive identification and quantification.

DESCRIPTION OF SAMPLING SITES

Figure 1 shows a map of the monitoring sites and associated watershed for the study. A description of each sampling site follows.

Pico-Kenter Storm Channel at the bike path before the beach at Pico and Kenter Avenues in Santa Monica (See Figure 1). Figure 2, (Picture Set 1) shows the storm drain condition when the flow channel is open to the ocean. Figure 2 & 3, (Picture Sets 2 & 3) shows the sampling conditions of this study, which occurred during pumping of the dry weather flow to the Hyperion Wastewater Treatment Plant. Before May 30, 1992, the water in the Pico-Kenter Storm Channel flowed directly into the ocean. Large quantities of algal growth and trash were observed in the storm drain. After May 30, 1992, the storm drain was re-routed by a pumping station placed in the storm sewer line which directed the storm water at low flow conditions to the treatment plant at Hyperion. The maximum amount of water that could flow to Hyperion was set at 0.3 MGD.

After the pump system was installed, water was collected from a manhole just on the beach off the bike path next to the closed storm drain, Figures 3 & 4, (Picture Sets 2 & 3). The water was colored and smelled of decaying organic matter. Occasionally, Styrofoam "peanuts" were seen floating at the surface. During the sampling period, high water levels would overwhelm the pump system and some water was seen bypassing the diversion and once again moving through the storm water channel into the ocean. The pump system at Pico was set up to pump a maximum of 0.3 MGD to Hyperion. Any greater than this was bypassed to the ocean. The flow rate was not measured during sampling.

The 10 to 12 foot diameter Pico/Kenter storm drain at the Promenade under Pico Blvd. is the terminus to the ocean of the Kenter Caynon drain, Pico Blvd. drain and the Santa Monica Freeway or CA Department of Transportation drain. The dry weather flow is estimated to be 0.1 to 3 MGD. ("The Ecology of the Southern CA Bright," SCCWRP, 1973). At present, the dry weather flow is estimated to be 0.1 - 0.3 MGD (G. Green, Santa Monica, Personnal Communication, 1993).

Appendix I shows the background water data collected at Pico-Kenter. Figure 5 shows the conductivity; a measure of salinity and total background ion

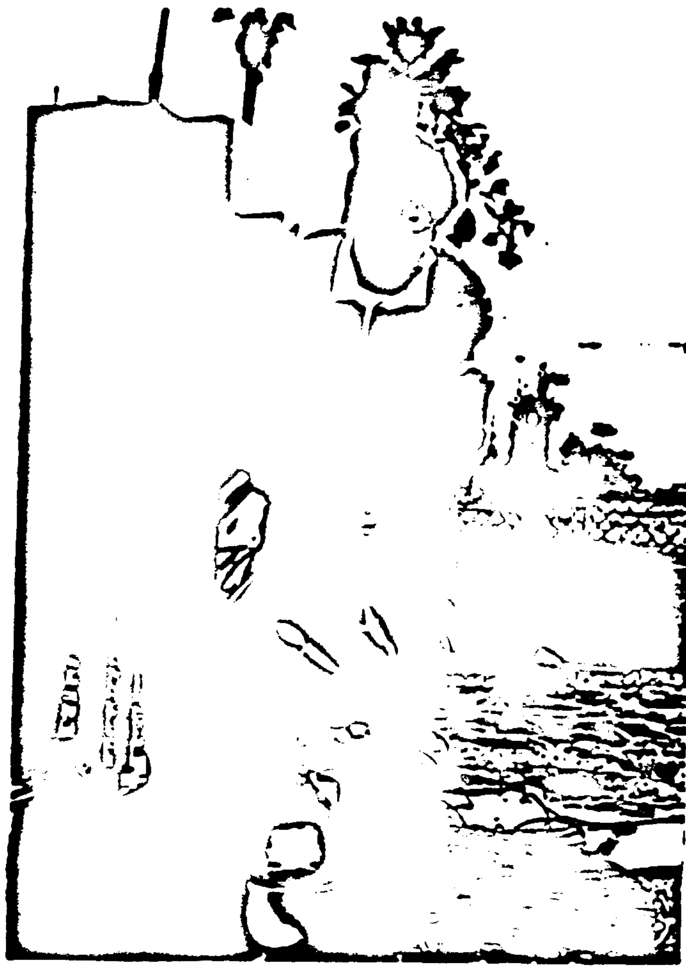
Figure 4. Picture Set 3 Of Sampling Location -- Pico-Kenter Sampling From Bypass Manhole

icture Set 3 - Pico-Kenter



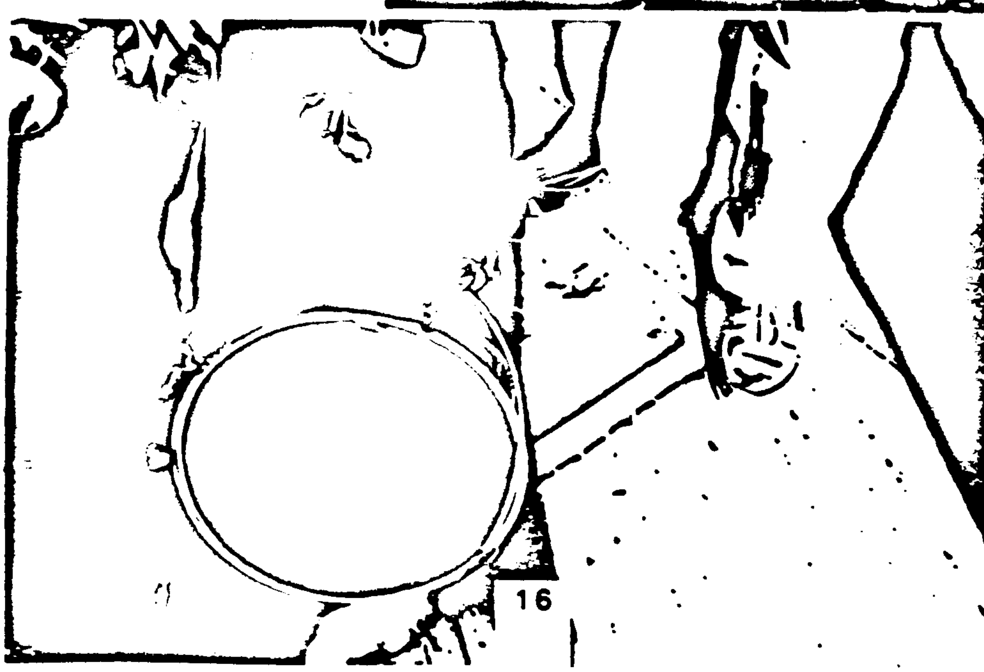


Figure 5

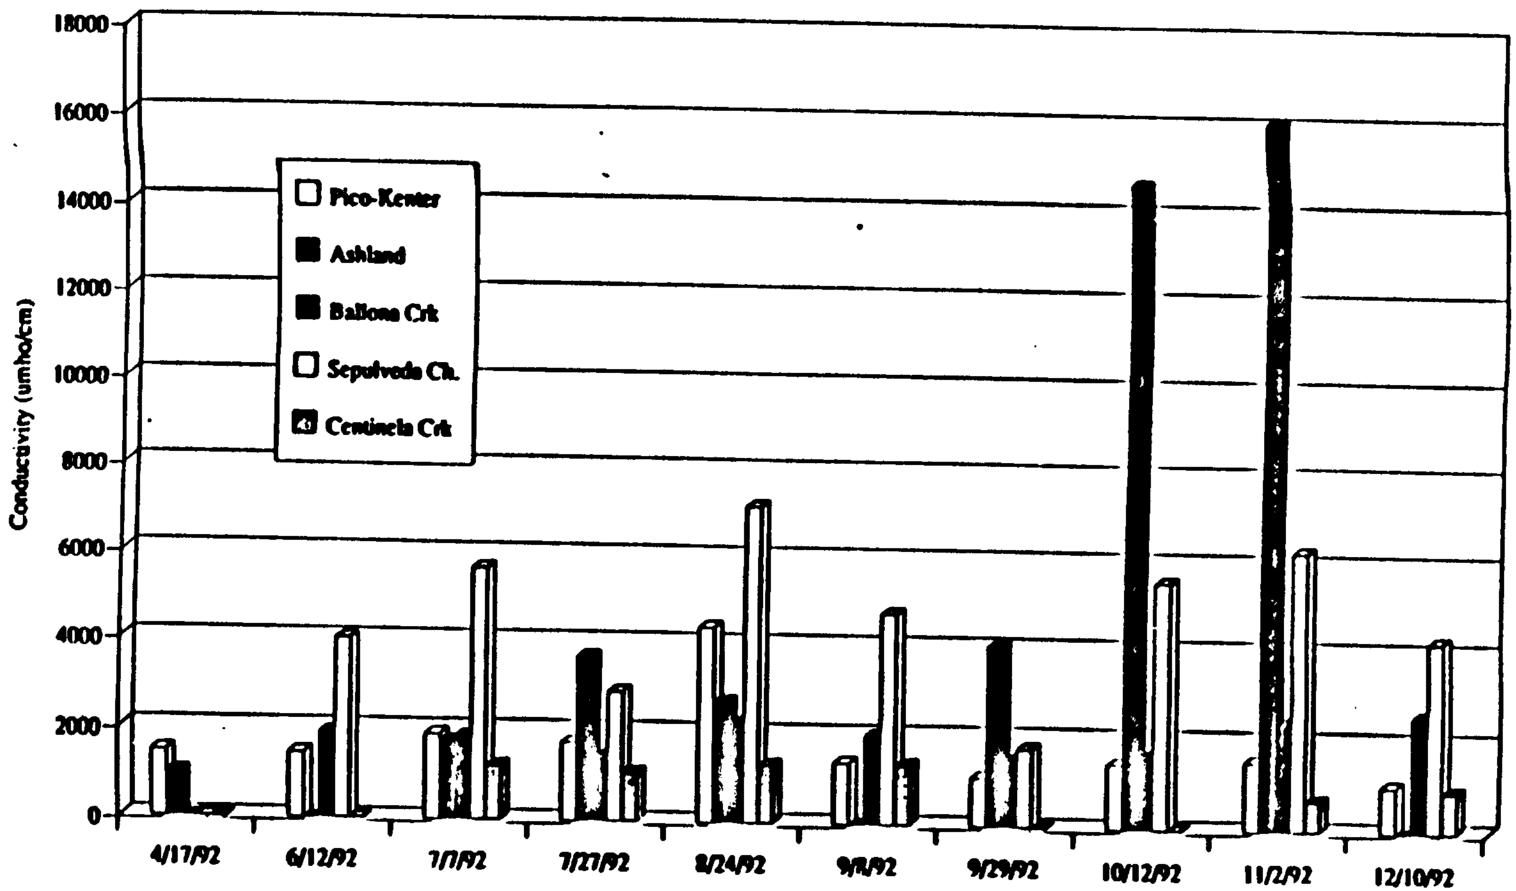
Conductivity Data of Storm Drains at Time of Sampling



concentration is relatively low at Pico-Kenter indicating a fresh water flow. Figure 6 shows the dissolved organic carbon analysis at Pico-Kenter during the time of sampling. The values for July through October were low at < 20 mg/l where as higher values of 70 to 90 mg/l were observed in November and December.

Ashland Avenue at a manhole at Ashland Ave and Ocean Boulevard. (See Figure 1 and Figures 7 & 8 (Picture Sets 4-5). This location is one block from the Santa Monica bike path on the sidewalk on Ocean Avenue in front of the parking lot entrance to the Santa Monica Shores apartment building (See Figure 1). Sometimes the levels in the manhole were too low to sample. Often there were a lot of leaves and other organic material present including mosquito larvae. Always a foul stench was detectable. Several times salt water intrusion was shown by the high conductivity levels. This site was the greatest problem area for collection of samples. Originally, we inspected the area where the Ashland Avenue Drain deposits onto the beach, as shown in Figure 8 (Picture Set 5). Continuous salt water intrusion made it impossible to sample there.

Appendix I shows the background water data collected at Ashland. Figure 9 shows the conductivity is lower at Ashland during April to September than October and November. The Ashland drain is under tidal control at the sampling location as observed in Figure 8, (Picture Set 5) and indicated in Figures 5 and 9. A comparison of Figures 5 and 9 show that a conductivity of 14,000 umhos/cm translates to about 3 % salinity whereas a conductivity of 2,100 umhos/cm corresponds to 1% salinity. Figures 5 and 9 shows the salinity at Ashland at the time of sampling was under a fresh water flow before October but partially under a tidal input during the October and November sampling dates . The tidal influence with concurrent increases of bromide ion in the water can change the distribution of THMs in these samples. Figure 9 shows a unique phenomenon of the Ashland Storm Drain at this sampling location. The dissolved oxygen concentration is low, <3.0 mg/l usually and very low on 8/24 and 7/27at <1.5 mg/l. This indicates that anoxic conditions can prevail from a stagnant water at this drain under low flow and the organic compounds present in the samples can also be of a reduced nature. Figure 6 shows the dissolved organic carbon analysis at Ashland during the time of sampling. The DOC values for the Ashland drain indicate that they are the highest of all the sampling locations except for one sampling occassion , 11/2/92. The TOC values range from 25 to 95, which

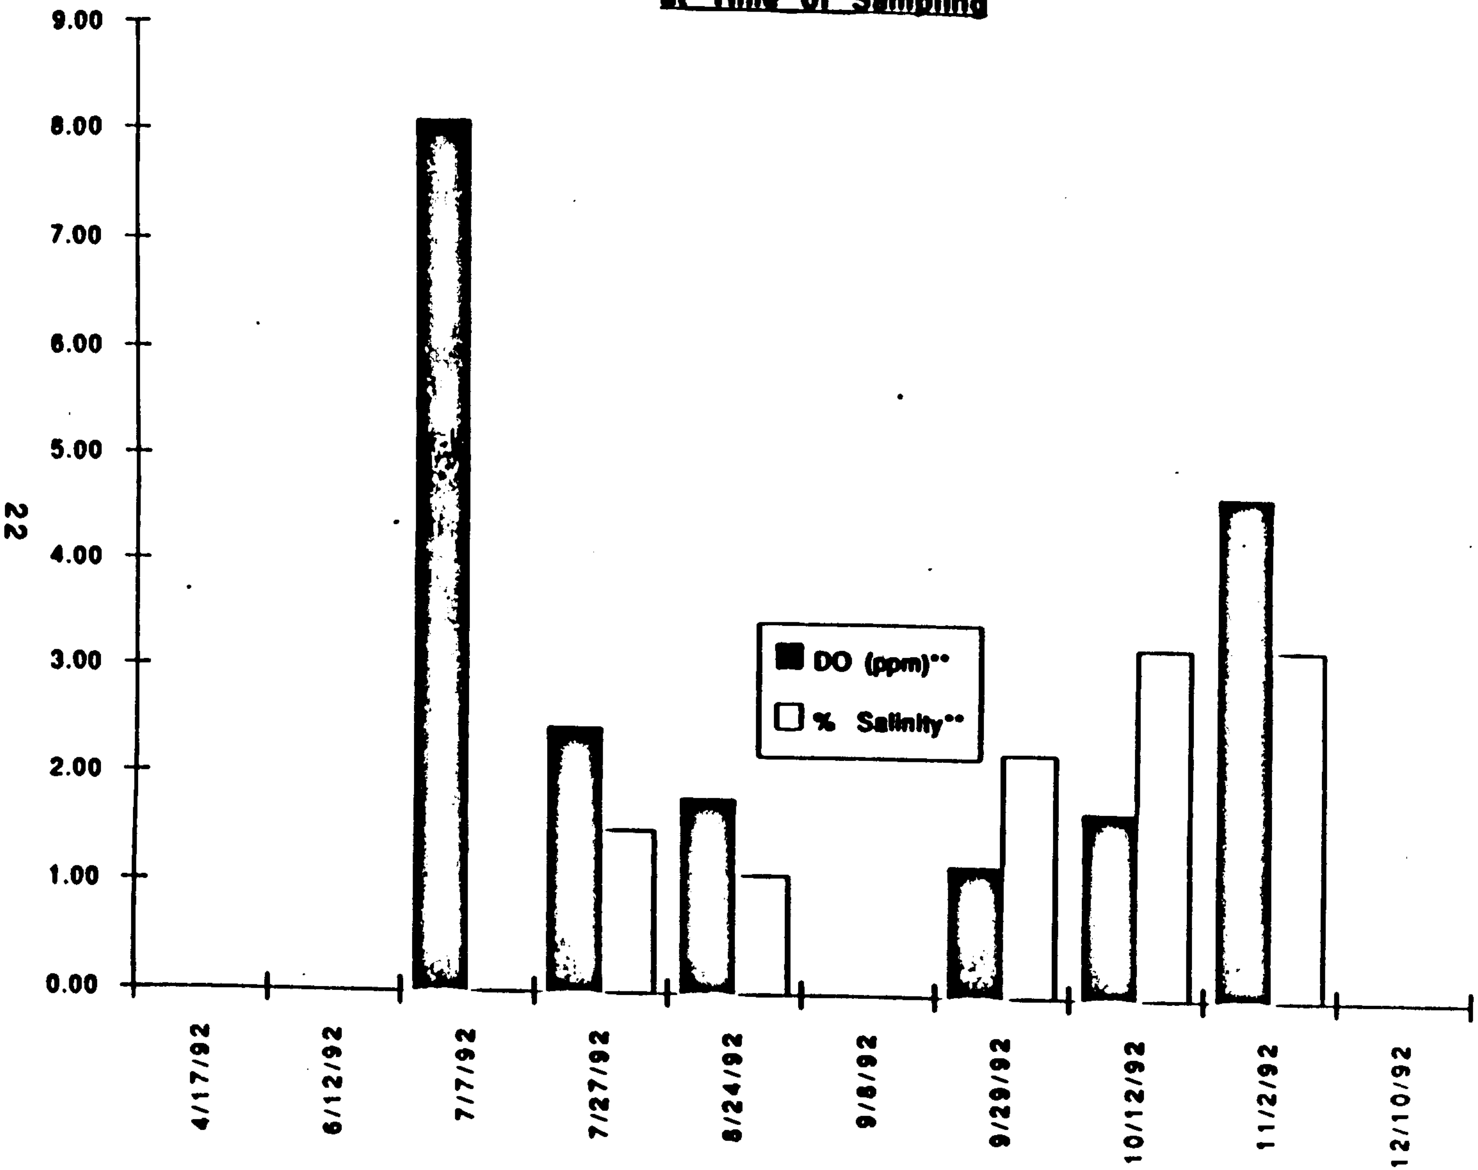
Ashland Avenue - Percent Salinity and Dissolved Concentration at Time of Sampling



are very high also indicate a stagnant water that is slowly accumulating chemicals.

Sepulveda Channel at the point just before the junction of Sepulveda Channel and Ballona Creek (See Figure 1 and Figure 10, Picture Set 6). The sampling location is behind the Mar Vista Gardens Apartments. Often the channel contained abandoned shopping carts, furniture, discarded toys and shoes, etc. Water levels were consistently low but always sufficient for sampling. Figure 11 shows the 35 foot cross-section of the Sepulveda Channel has a depth of 1.5 - 4 inches (average depth 2.5 inches) during low flow. Figure 12 shows the average flow rate varied between 0.56 - 2.14 ft^3/sec. at the Sepulveda Channel Site during the time of each sampling. Since the sampling location is difficult to reach, sampling equipment was lowered down by ropes to a person who was wading in the channel for samples collection.

Appendix I shows the background water data collected at Sepulveda. Figure 5 shows the conductivity is 4,00 to 6,000 umhos/cm at Sepulveda over the time of sampling. This indicates input of inorganic ions to this drain is not significant. The DOC values for the Sepulveda drain are low (< 10 mg/l) except for the November and December samples which are < 65 to 70 mg/l.

Ballona Creek at the point just below the junction of Sepulveda Channel and Ballona Creek (See Figure 1 and Figures 13 & 14, Picture Sets 7 & 8). Figure 11 shows that Ballona Creek cross-section is 35 feet wide with a depth of 1 -12 inches (average depth 5 inches). The typical low flow conditions are shown on Figure 12 (0.33 - 3.10 ft^3/sec.). Figure 13, (Picture Set 7) shows that during the early sampling dates, myriad styrofoam cups lined the channel as well as cigarette butts and other trash including occasional syringes. Later in the summer, altruistic environmentalists cleaned the trash periodically eliminating most of the visible urban contamination. This sampling area is easily accessible and unfortunately serves as a playground for children. A bike path also runs the length of the north side of the channel. Figure 14, (Picture Set 8) indicates where the settleable solids occur at this sampling site.

Appendix I shows the background water data collected at Ballona. Figure 5 shows the conductivity is low < 2,000 umhos/cm at Ballona over the time of

sampling. The DOC values for the Ballona drain indicate that they are <12 mg/l except for two samplings times in November and December. The DOC values are 30 to 95 mg/l indicating a buildup of organic material during the spring term.

Centinela Creek at the Inglewood Avenue Bridge. This drain sampling site is in the drain itself, inaccessible to the public. A ladder was used with ropes as safety precautions to lower down the person who samples. Figure 11 shows that this is a narrow 7 foot storm channel of 1.75 to 5.34 inch average depth under typical low flow conditions shown on Figure S5 (0.33 - 3.10 ft^3/sec.). Sampling equipment was lowered down by ropes for sample collection.

Appendix I shows the background water data collected at Centinela. Figure 5 shows the conductivity is low < 2,000 umhos/cm at Centinela. The DOC values for the Centinela drain indicate that they are <20 mg/l except for two samplings times in November and December. The DOC values are 65 to 70 mg/l indicating a buildup of organic material during the spring term.

Rainfall

Figure 15 presents the rainfall data that are applicable to the dates that the storm drains were sampled. Most of the rain for the year fell during March, one month before the first sample was taken. The sampling dates largely represent dry weather conditions. The "civil unrest" in Los Angeles occured April 29 to May 3 after the bulk of the rain. The significance of this is that the water from the fire fighting entered the storm drains and would have generated an unusual abundance of chemical pollutants which would appear in the samples. Therefore, the sampling was suspended until June 12 to assure that the drains had cleared the debris from the civil unrest. The sampling period between June 12 and October 12 was under dry weather flow. The November 2 sample was after a 0.5 inches of rain in late October and the sample on December 10 was after 2 inches of rain in early December.

EXPERIMENTAL

Field Sampling Techniques

Water samples were collected by holding a bucket pointed downstream in front and upstream from the person sampling. This bucket was used to "scoop" water and to fill a second bucket which would be transferred to a second person for bottling. The buckets of water would either be handed directly to another person or else lifted by rope to a person above the storm channel in the case of Sepulveda and Centinela. Picture set 6 shows the sampling method at Sepulveda.

Manholes were sampled by lowering buckets by rope down into the hole. The sampling bucket has a handle at the side of the base as well as the usual handle at the top. A rope at the base is used to tip the bucket at an angle so that the bucket can be filled and then the rope on the top handle is used to lift the bucket out of the manhole (sites Pico/Kenter and Ashland). Figure 7, (Picture set 4) shows the sampling method at Ashland.

Sample Storage

1. Water: Samples were stored at 4°C (usually less than two weeks) then filtered and extracted. A large walk-in refrigerator was used to store the water exclusively. Only water samples were kept in the refrigerator and no methylene chloride or other solvents were present in the refrigerator.

2. Suspended Sediments: After filtration, the filters containing the sediments were placed individually in glass jars with teflon-lined screw-cap lids. Analysis was completed after filtration by supercritical fluid extraction.

3. Purge and Trap Samples - Volatiles: Purge and Trap samples were either taken immediately to Dr. Ed Ruth's lab in the Institute of Geophysics and Planetary Science the day of sampling or the next day. When stored at our lab in the School of Public Health, they were stored in the same refrigerator as the water samples to be extracted.

VOL 12

1

8070

4. Liquid-Liquid Extracts and Suspended Solid Extracts: Samples were stored in 2 ml screw-cap vials, some with septa and others without septa but with a solid teflon-lined lid. Teflon tape was wrapped around the lids. Sample extracts were stored in a small laboratory refrigerator and then stored in a similar refrigerator at Dr. Ed Ruth's lab until analysis.

Field and Laboratory Sampling Parameters

Table 1 shows the field and laboratory sampling parameters. The sample volume, sample container and processing and storage information is presented on the table. Table 2 shows the laboratory analysis parameters.

Purgeable Volatile Organics Analysis

Volatile organics with low water solubility were analyzed by purge and trap capillary gas chromatography/mass spectrometry (GC/MS) following EPA 524/624° methodology. The method was modified slightly by including additional target analytes from the EPA Method 624 and hazardous substance lists as shown in Table 3 and utilizing capillary GC. While in the custody of the GC/MS facility, samples were stored refrigerated at 4°C in a room free of organic vapors adjoining the laboratory. Standards were stored in a separate freezer.

The following procedure was used to introduce the sample on the purge and trap device (Tekmar 4000). The plungers were removed from 5 ml and 25 ml syringes. The sample was removed from the refrigerator, the cap was removed, and 10-15 ml was poured into the 25 ml syringe. The syringe plunger was replaced, the syringe was inverted and the remaining air was displaced. A 25 mm 0.45 µm nylon acrodisc (Gelman) filter was fitted onto the syringe and the sample filtered into the 5 ml syringe, the syringe plunger was replaced, the syringe was inverted and the volume was adjusted to 5 ml. Five µl of fortification solution (one internal and two surrogate standards at 5 µg/ml each) was added to the sample through the luerlock opening. A second syringe was filled in an identical manner from the same sample bottle and reserved for reanalysis, if necessary. Initially, 25 ml aliquots of samples were used. However, because of severe foaming on one of the first four samples analyzed, 5 ml aliquots were used for all subsequent samples.

(b) California Ocean Plan, 1990. State of California, State Water Resources Control Board, Resolution No. 90-27, Adopted and Effective March 22, 1990. The lowest value is reported. All standards are 30 day average values.

(c) Sum of 1,2 and 1,3 dichlorobenzenes

The syringe was attached to the syringe valve on the purging device and the sample was injected into the sparger. The valve was closed and the sample was purged with helium at a rate of 40 ml/min for 11 minutes at ambient temperature. The trap (Supelco, Carbopack/Carbosieve) was then dry purged for 11 minutes at 4 ml/min to remove water. At the completion of the purge cycle, the apparatus was switched to the desorb mode. The cryogenic interface, located at the beginning of the capillary column, was cooled to -150°C and the trap was rapidly heated to 220°C while it was back-flushed with helium at 4 ml/min for 4 minutes. At the end of the 4 minute desorption cycle, the cryogenic trap was ballistically heated for 11 seconds, the temperature program of the gas chromatograph (Finnigan 9610) started and mass spectrometer (Finnigan 4000) data acquisition was begun.

Data were acquired (Superincos Data System, Finnigan) and stored over the mass range m/z 35-300 with a total scan cycle time of one second. Five or more spectra were measured during the elution of each GC peak. The gas chromatograph used a 30 meter narrow bore (0.32 mm) DB-624 (J&W Scientific) fused silica capillary column. The helium carrier gas flow rate was 40 cm/sec. The initial column temperature was 10°C and held for 5 minutes from the beginning of vaporization from the cryogenic trap, programmed at 6°C/min to 70°C, then heated to 200°C at 15°C/min and held at that temperature for 2 minutes. After desorbing the sample, the trap was reconditioned by returning it to the purge mode and heating it to 260°C for 10 minutes. The heater was turned off, the gas flow stopped, and the trap allowed to cool. The sparging vessel was rinsed two times with 25 ml volumes of reagent water (4 canister Milli-Q unit, Millpore Corp.) between each sample.

Compounds eluting from the gas chromatographic column were identified by comparing their measured mass spectra and retention times to reference spectra and retention times in a data base compiled by the user from the measurement of authentic standard compounds under the same conditions used for samples. Calibration standards were measured at six concentration levels (0.5, 2, 4, 6, 8 and 10 µg/l) and response factors calculated for each compound quantitation ion using linear regression analysis. The concentration of each identified compound was measured by relating the mass spectral response of the quantitation ion produced by that compound to the mass spectral response of the quantitation ion produced by a compound that was used as an internal standard. Calculation of the target analyte concentrations was made by the Autoquan Software package (Finnigan Corporation) using a linear fit of the three

VOL 12

1 8079

closest points in the multi-point response list for each analyte from the plot of area of unknown/area of standard versus amount of standard. For a compound to be quantitated, its spectra must match the library spectra by exceeding the fit threshold value of 900 out of 1000 and it must occur within the specified 10 second retention time window. Surrogate analytes, whose concentrations were known, were measured with the same internal standard calibration procedure.

Table 3 shows the Method detection limits (MDLs) were compound dependent and varied from 0.03-0.64 µg/l (ppb). The MDLs were determined based on the seventeenth edition of Standard Methods of Water and Waste Water (American Public Health Association, 1990). Analytes that were inefficiently purged from water could not be detected at low concentrations, but could be measured when present in sufficient amounts. Coeluting compounds with very similar mass spectra, typically structural isomers, were reported as a group. Trihalomethane concentrations were calculated individually.

Table 3 compares the MDLs with the US EPA Drinking Water Standards and the California Ocean Plan Standards for human health carcinogens and non-carcinogens as well as for marine aquatic life. The MDL values for the Drinking Water Standards are less than the California Ocean Plan Standards.

Analysis of Suspended Sediment and Filtered Water Extracts

Extractable organics were analyzed by capillary gas chromatography/mass spectrometry (GC/MS) following EPA 525/625* methodology as modified in USEPA Contract Laboratory Program (CLP) August 1991 Statement of Work. Organic compounds analyzed by this procedure are listed in Table 4. Table 4 shows the Method detection limits (MDLs) were compound dependent and varied. Analytes that were inefficiently extracted from water or suspended sediment could not be detected at low concentrations, but could be measured when present in sufficient amounts. Coeluting compounds with very similar mass spectra, typically structural isomers, were reported as a group.

Aliquots of 250 µl for filtered water extracts and 500 µl for suspended solids extracts were used for GC/MS analysis. All extracts were in methylene chloride and delivered in 1.5 ml glass vials. While in the custody of the GC/MS facility, sample

extracts were protected from light and stored in a refrigerator at 4°C away from potential contaminants in a room adjacent to the laboratory. Standards were stored in a separate refrigerator. Just prior to analysis the extract was allowed to warm to room temperature and the appropriate volume of internal standard mixture at 200 μg/ml added to the vial. Five μl was used in the 250 μl extract and 10 μl was used for the 500 μl extract to give a final concentration in the vial of 40 ng/μl. Using a 10 μl syringe, 1-1.2 μl of extract was injected splitless on the Finnigan 9610 gas chromatograph (GC) initiating the GC temperature program and the data acquisition on the Finnigan 4000 mass spectrometer (MS).

Data were acquired (Superincos Data System, Finnigan) and stored over the mass range m/z 35-500 with a total scan cycle time of one second. Five or more spectra were measured during the elution of each GC peak. The gas chromatograph used a 30 meter narrow bore (0.25 mm) DB-5MS (J&W Scientific) fused silica capillary column. The helium carrier gas flow rate was 40 cm/sec. The initial column temperature was 30°C and held for 4 minutes, programmed at 6°C/min to 300°C, and held at that temperature for 30 minutes.

Compounds eluting from the GC column were identified by comparing their measured mass spectra and retention times to reference spectra and retention times to reference spectra and retention times in a data base compiled by the user from the measurement of authentic standard compounds under the same conditions used for samples. Calibration standards were measured at five concentration levels (5, 10, 20, 50 and 80 ng/μl) and response factors calculated for each compound quantitation ion using linear regression analysis. The concentration of each identified compound was measured by relating the MS response of the quantitation ion produced by that compound to the MS response of the quantitation ion produced by a compound that was used as an internal standard. Calculation of the target analyte concentrations was made by the Autoquan Software package (Finnigan Corp.) using a linear fit of the three closest points in the multi-point response list for each analyte from the plot of area of unknown/area of standard versus amount of standard. For a compound to be quantitated, its spectra must match the library spectra by exceeding the fit threshold value of 900 out of 1000 and it must occur within the specified 10 second retention time window. Surrogate analytes, whose concentrations were known, were measured with the same internal standard calibration procedure.

1 8084

Table 4 compares the MDLs of water and suspended sediments with the US EPA Drinking Water Standards and the California Ocean Plan Standards for human health carcinogens and non-carcinogens as well as for marine aquatic life. The MDL values for water plus suspended sediments or total concentration of a chemical in the sample are about the same order of magnitude as the Drinking Water Standards and the California Ocean Plan Standards when 3-8 liters of water and the associated suspended sediments are extracted as were completed in the study. All quantitative calculations for the total concentration of chemical present in the water and suspended sediment phases were adjusted to a one liter water sample basis to enable a direct comparison to Drinking Water Standards and the California Ocean Plan Standards. All tables of results for base-neutal compounds are presented to directly compare the Drinking Water Standards and the California Ocean Plan Standards with the concentration of the chemical in a water sample of one liter with its associated suspended sediments.

Non-Target Compound Identification

Many of the compounds elucidated by GC/MS are not on either the volatile or semi-volatile target analyte list. These non-target analytes are tentatively identified using several techniques such as a) matching the unknown spectra to spectra in the 40,000 compound EPA/NIH Mass Spectral Data Base and b) interpretation of mass spectra by the mass spectroscopist and finally confirmation by coinjection of authentic compound standards. Determining chromatographic peaks on which identifications will be attempted can either be selected manually by the operator or be selected by using a modified Biller-Biemann type peak detection algorithm to search for compounds. The algorithm assumes that a compound is present whenever it finds the elution of more than three simultaneous masses which maximize within a single scan. Scans that are flagged as peaks are then searched against the EPA/NIH Mass Spectral Data Base and if the fit threshold is greather than 850 out of 1000, the spectra and tentative identification are presented to the spectroscopist for evaluation. All identifications are tentative until authentic compounds have been analyzed or coinjected under the same analytical conditions as the unknown.

Sample Preparation Techniques

Purge and Trap Analysis for Volatiles- Analytical Finish by EPA 524/624* Equivalent

Initially some 15 and 25 ml samples were analyzed, however, foaming occurred in these samples. Ashland samples had the heaviest foaming problem. These analyses and the remaining analyses were completed with 5 ml samples. The Method Detection Limit (MDL) is based upon 5 ml samples. All samples are filtered before analysis. See Table E3a for the MDL's that were determined for this study. All samples initially run at 15 to 25 ml were repeated at 5 ml. The percent recovery of surrogate standards are completed by comparison to the internal standard flourobenzene at 5 ug/l. Table 5 shows the percent recovery of surrogate standards.

Liquid-Liquid Extraction Method for Isolation of Base Neutral Compounds from Aqueous Phase Samples; Analytical Finish by EPA Method 608/625* Equivalent

A Corning Pyrex One-Step Continuous Extractor/concentrator (Fowler,1991) was used for continuous extraction of the base-neutral organic compounds in the water phase. In choosing glassware, a major consideration was that the apparatus has no susceptible breaking points such as glass-to-tubing connections which are a recipe for disaster. The Corning one-step apparatus was tested against others for practical utility.

1. Water:methylene chloride ratio (vol./vol.): (1L : 450 ml)
2. Water bath temp.: 95 ^{o}C.
3. Final volume of extract: extract to 5-10ml in extractor, then evaporate to 0.5 ml in concentrator tube with Kontes tube heater
4. Duration of extraction: 10 hours
5. Volume of sample for each extraction apparatus: 1 liter
6. Volume of sample needed for extraction to identify base-neutral compounds: 3-8 liters

The liquid-liquid extraction of water from the storm drains was done using a modied version of the Fowler method. To each extractor body, 450 ml of methylene chloride was poured in followed by one liter of water sample. It was

VOL 12

18087

R0051392

ascertained that as much as 450 ml of methylene chloride was needed to prevent crossover of water flowing from the extractor body to the side where the extracted sample is isolated since some solvent escapes from the system from evaporation in spite of the condensor.

To the water phase, 5 ul of base-neutral surrogate (1000 ppm) was added. After the two layers separated, the stopcock on the side-arm was opened and the methylene chloride allowed to move over to the side containing the concentrator tube. The concentrator tube was heated by water bath or heating block. (see below). During extraction, the methylene chloride extract refluxes gently with a condensation rate of 6 drops per minute. At this rate, the Snyder balls chatter gently leaving the sample in the concentrator tube and presumably only distilled methylene chloride reaches the condensor and collects back in the extractor body. The duration of extraction was ten hours. After this, the stopcock on the side-arm was closed and the sample in the concentrator tube concentrated to approximately 5 ml.

The 5 ml extracts from each site were combined and further concentrated in a Kontes tube heater to 0.5 ml. The sample was then dried (residual water remove) in a column of sodium sulfate; (0.5 gram of sodium sulfate previously dried in the oven was put into a Pasteur pipette with glass wool as plugs). The drying column was prewashed with three bed volumes of methylene chloride before eluting the sample. The column was then washed with three more bed volumes of methylene chloride. The extracts were evaporated with the Kontes tube heater with condensers attached to the concentrator tubes.

The samples were analyzed by GC. If the concentration of chemicals in the samples was low and the chromatogram only showed surrogates, more water was extracted and all the extracts combined and worked up again so that a sufficient sample volume was extracted for GC/MS and quantitative analysis.

A water bath was used as a heating source for all of the extractions except the 12-10-92 samples. The disadvantage of the water bath is that it has to be refilled every half hour or so in order to maintain the temperature. The temperature of the water bath is lowered slightly at this time. If the water level was allowed to drop more than a liter or more and large volumes of water were

VOL 12

1 8088

required to refill it, the lowered temperature could have altered the rate of extraction. This happened occasionally as it was impractical to always moniter the extraction continuously.

A water bath was not used as a heating source for the extractions 12-10-92 samples. Instead, a Supelco heating block system, which is made of aluminum and is designed to hold one concentrator tube each was used. Four blocks were placed on a hot plate and the heat conducted to the blocks. The temperature of the outside surface of the concentrator tube was 110 °C as measured with a thermometer through a slot in the block. The advantage of the heating block is that since there is no water bath to have to fill, it is more likely that the temperature will remain constant throughout the extraction. However, overheating can occur at low volumes of methylene chloride in the concentrator tube and bumping can occur.

The percent recovery of surrogate standards are completed by comparison to a standard solution of the surrogate standards. Table 6A shows the percent recovery of surrogate standards. The grand mean average of 105 water samples was 56.2%, which was within EPA guidelines of EPA Method for surrogate analysis (33 - >100%).

Supercritical Fluid Extraction of Filtered Suspended Sediments;
Analytical Finish by EPA Method 6081/625 Equivalent

The supercritical fluid extraction (SFE) of suspended sediments from storm drains was done by compacting the air-dried filter with sediment into a 10-ml sample cartridge. Recovery standard solution (200 ppm mixture of 1-chlorodecane and 1-chlorooctadecane in methanol) was then spiked into the sample in the cartridge at a ratio of 50 µl per 1.0 ml final volume of extract. In this case, the final volume of extract was planned to be 0.5 ml, so the recovery standard spiked was 25 µl. An ISCO SFX™ 2-10 Supercritical Fluid Extractor, (Lincoln Nebraska) was used in this study. The sediment was extracted under the following optimum conditions:

Pressure = 200 atm.	Temperature = 50 °C
Volume of CO_2 = 25 ml	Flow Rate = 1.2 to 1.4 ml/min

The extracts were collected in a 10-ml (initial volume) of methylene chloride contained in 30 ml round bottom culture tubes with screw caps (ISCO SFX™ 2-10

accessory). During extraction, the bubbling of CO_2 into the collection solvent caused much of it to evaporate to around 0.5 ml. After extraction, the final volume was adjusted to exactly 0.5 ml, followed by spiking of the internal standard mixture (1000 ppm mixture of 1-chlorotetradecane and 1-chlorohexadecane in methanol) at a ratio of 5 µl per 0.5 ml sample. The sample was prescreened by gas chromatography and then analyzed by GC/MS. Table 7 shows the percent recovery of surrogate standards in different samples calculated by GC analysis with a flame ionization detector by a standard curve procedure. The grand mean average of 20 suspended sediment samples was 87 % as shown in Table 6B.

Chlorinated Pesticides and PCB Analysis By EPA Method 608

Chlorinated Pesticides and PCB were isolated by the same method for suspended sediments and filtered water extracts as described above for EPA Method 525/625*. The methylene chloride extracts from the EPA Method 525/625* was solvent-exchanged with hexane. The hexane extracts were analyzed by EPA Method 608, with a Varian 3500 GC equipped with a Dual Electron Capture Detector (ECD). A detector temperature of 330°C was used with a splitless injector at 280°C. The programming temperature used was 1 min at 60°C, 15°C/min to 150°C, 2°C/min to 200°C, 5°C/min to 280°C hold 10 min. A 1 µl sample in hexane was injected into a single injector and then split using a 1 meter 0.32 mm fused silica retention gap and glass Y connector to two analytical columns. Column 1 was connected to channel A Electron Capture Detector J&W 30 meter DB-5 0.032 mm diameter and Column 2 was connected to channel B ECD J&W 30 meter DB-5 0.032 mm. diameter. A Varian Star Integrator/ Workstation Ver. A2 was used for data collection and processing. Quantitation from Channel A with confirmation from Channel B were used with an external calibration:

$$M_x = M_{STD} \times A_x / A_{STD}$$

M_x = amount compound in unknown run; A_x = area compound in unknown run
M_{STD} = amount compound in standard run; A_{STD} = area compound in standard run

Sample concentration was reported as ng/l of water sample. Table 8 shows the chlorinated pesticides and PCBs that were analyzed.

RESULTS

All compounds that are on the volatile organic chemical and base neutral analysis quantitative list, (Tables 3 and 4) were analyzed by GC/MS. Some compounds were analyzed by both methods, e.g. naphthalene. Volatile organic analysis data is for soluble compounds only, whereas base neutral data is for total concentration (soluble plus suspended sediment) to reflect the maximum load on the environment as sample dilution with the ocean will facilitated desorption from the sediments phase. The data obtained is compared to the drinking water standards e.g. THMs (Trihalomethanes = the sum of chloroform, dichlorobromomethane, chlorodibromomethane and bromoform), whose sum must be less that 100 ug/l in the final drinking water. The base neutral analyses are also compared to the California Ocean Plan's 30-day average discharge standards, which are based upon the criteria of human health - carcinogenic or noncarcinogens. The use of the concept of minimum initial dilution is used (the lowest average initial dilution within a single month of the year). We could assume that the storm drain discharge is from one discharger to the ocean. However, the initial dilution will vary with low (dry weather) flow vs higher (wet weather) flow. A set of possible dilution factors can be compared e.g. a minimum of 5 to 10 vs. 100, 1,000 or even 10,000-fold dilutions can be evaluated. No standard approach has been defined in the Ocean Plan, thus, it is up to interpretation of the flow data and mixing in the ocean. It should be remembered that the California Ocean Plan has no guidelines specifically for a storm drain.

Volatile Organic Chemicals

Tables 8 - 12 show the soluble, targeted volatile organic compounds (VOCs) that were quantified in storm drain samples from the 5 storm drains under dry weather flow from 6/12/92 to 12/10/92. Field and lab blank data (Appendix II) and MDLs were used to define the compounds that could be quantified. Tables 8 - 12 present the summary of the VOCs (b.p. <150 °C) that were quantified at the ug/l (ppb) level to two significant figures. The tables list the minimum detectable level for each compound as determined in our laboratory. (See Table 3). The only compounds that are quantified are those above the MDL. Appendix Tables IV.1a - 5a show the individual analyses by sample data in ng/l (ppt).

THMs - Trihalomethanes

(1) Note- Methylene chloride in the 9/8 AM sample (11.862 ug/l) is considered an artifact and is not included in the data. Thirteen samples were completed for methylene chloride.

Other compounds on the VOC quantifiable list (Table 3) were qualitatively identified by mass spectrometry in the samples, but are below the MDL and are not quantified. Appendix IV, Tables IV.1b - 5b shows the complete VOC analyses including date of analyses, the concentration of the compounds that were identified above their MDLs in ng/l and the identification of the compounds found below their MDLs presented as <MDL.

Table 13 compare the average tabulated VOC data for each site and overall grand average for all sites based upon occurrence >MDL. Tables 8 - 12 compare the VOC average data at each sites and the drinking water maximum contamination limits developed by the U.S. EPA (See Table 3). Only methylene chloride (a notorious laboratory artifact) was found in the storm drains of Pico/Kenter, Centinela and Ashland to exceed the MCL. Even assuming no dilution and a one-month average value represented by each sampling date, no California Ocean Plan standards are exceeded as these standards are much higher that the EPA drinking water standards for VOCs (See Table 3).

Table 14 shows the identification of non-targeted VOCs in some samples. Non-targeted VOCs were identified by the criteria that was presented in the experimental section. These compounds are not quantified and they are called "tentatively identified" compounds. Tentatively identified compounds are not compared with the GC retention time of the true compound or the mass spectrum of the true compounds obtained on the same GC/MS system as the targeted compounds. The term "tentative" means that further studies are needed to confirm their identification and to quantify them by use of references standards. Total ion current chromatograms from the mass spectrometric determination results are presented in Appendix V. Future evaluation of the non-targeted tentatively identified compounds falls into the category of future research.

Quality Assurance - VOC Laboratory Blanks, Field Blanks and Replicate Analysis

Appendix II., Table II.1 shows VOC samples suspected of methylene chloride contamination. Methylene chloride is a notorious laboratory artifact that can permeate into water samples stored in a refrigerator for purge and trap volatile organic compound analysis (Eichelberger and Budde, EPA Method 524.2, Revision 3, Section 4.3, 1989, Appendix Methods Section 1). Methylene chloride was the solvent used in

our studies for base neutral organic analysis and is present in the laboratory. The methylene chloride solvent extracts and water samples containing methylene chloride are stored in different refrigerators and processed as far away from each other in the laboratory as described in the Experimental Section. The methylene chloride contamination is so pervasive that "...... clothing previously exposed to methylene chloride during common liquid/liquid extraction procedures can contribute to sample contamination." In the present study, all initial VOC analyses from the 3 different sites on 6/12/92 were found to be contaminated by methylene chloride at levels of 129, 33, and 75 ppb. These analyses are noted as artifacts in our data evaluation. Quality control procedures were carefully monitored after this initial sampling period. Only on one other occasion 9/8/92 in 3 of the 5 AM samples can we say with assurance that contamination is suspected (See Appendix Table II. 1). The three 6/12/92 and three 9/8 AM samples are not included in the sample evaluations because of suspected artifact values.

Appendix Table II.2 shows that 5 compounds were present in the blanks above their MDL. The range of concentrations for the analysis of 5 laboratory and field blanks taken over the course of the study are shown to be within 0.1 ppb and within 0.03 ug/l of the MDLs. Only methylene chloride is as large as 0.07 ug/l of the MDL. Appendix Table III.2 shows that replicate analysis of two independent volatile organic analysis samples collected on 10/12/92 at Ballona Creek were in excellent agreement. All the targeted compounds that were identified and quantified are presented. Even compounds that were qualitatively identified and below their MDL are observed in both samples. The difference between quantitative values are within a 0.1 ppb even for the compounds identified by GC/MS below their MDLs; only bromomethane and chloroethane were identified in one sample and not in the other, however both were at extremely low concentrations, near their instrument detection limit at < 20% of their MDL.

Ballona Creek - Volatile Organic Compounds (VOCs)

Table 8 shows that 23 targeted VOCs were present above their MDLs in 17 samples collected over a 6 month dry weather flow period 6/12-12/10/92. Methylene chloride is a notorious laboratory contaminant and the analysis of the samples for 6/12 and 9/8 AM do not include data for methylene chloride (See Appendix Table II.1). Table 8 shows that the range of concentrations for each targeted quantifiable compounds for 9 days of sampling sometimes twice a day for 6 months were within an order of magnitude at the 0.1 to 1 ppb level including methylene chloride (after artifacts samples are removed from the data base). Only chloromethane, 2-butanone, methylene chloride and chloroform were quantified to be above 1 ppb in any of the 17 samples. The drinking water MCLs are shown on Table 8 indicate that no compound exceeded its standard. The compounds were greater than an order of magnitude less than the MCL for any sample except for methylene chloride. Even assuming no dilution and a one-month average value represented by each sampling date, the data are further below the proposed Ocean Plan Standards (California State Water Resources Control Board,1990a and b) as these standards are usually 5 times higher than drinking water standards.

The levels of VOCs present from targeted quantifiable compounds are from 2-6.5 ug/l in the 17 samples analyzed. Trihalomethanes (THMs) or haloforms - chloroform, dichlorobromomethane, dibromochloromethane and bromoform - are a significant portion of the VOCs as shown on Figure 16. (Please note that the "C" after the 12/10/92 sample in Figure 16 indicates a composite of a morning and afternoon sample.) Figure 16 shows that the total haloforms account for > 25 % of the VOCs present in 16 of the 17 samples. Five samples showed THMs to be > 50 % of the VOCs. Sources of THMs include any chlorinated water that contains natural organic matter measured as organic carbon in mg C/l. This includes drinking water sources and cooling waters that are chlorinated for disinfection purposes. It is estimated by NPDS permits that 10% of Ballona Creek water is from cooling tower runoff (Stenstrom, Private Communication, 1993).

Figure 17 shows that methylene chloride concentrations are < 2.2 ppb with 3 samples > 0.75 ppb. Total aromatic hydrocarbons from fuel emissions e.g. benzene and toluene were < 0.03 ug/l. Total ketones representing natural biota sources and oxygenated solvents are below 1 ug/l for 16 of 17 samples. The three oxygenated ketones, common names are 4-methyl-2-pentanone (methyl isobutyl ketone [MIBK]), 2-hexanone (methyl butyl ketone [MBK]) and 2-butanone (methyl ethyl ketone[MEK]) are industrial solvents and common products of ozonation of natural waters. Chlorinated solvents as represented by tetrachloroethene from sources as dry cleaning were also low (below 0.5 ug/l).

Figure 16

THMs and Total Volatiles (ng/l) - Ballona

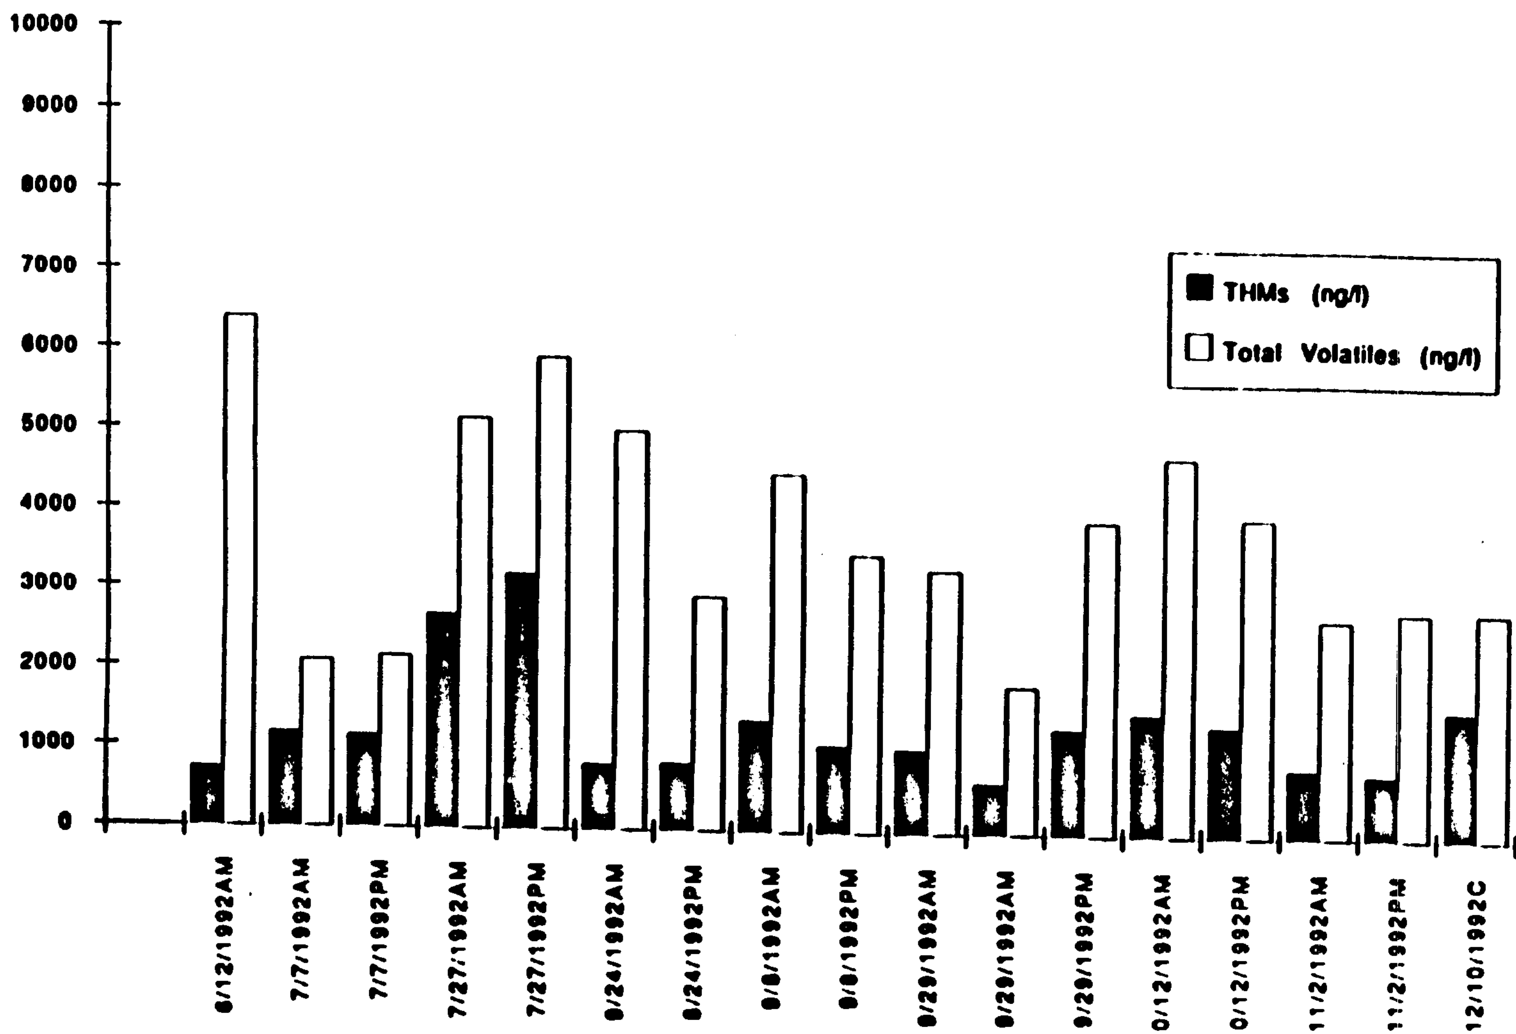

Figure 17

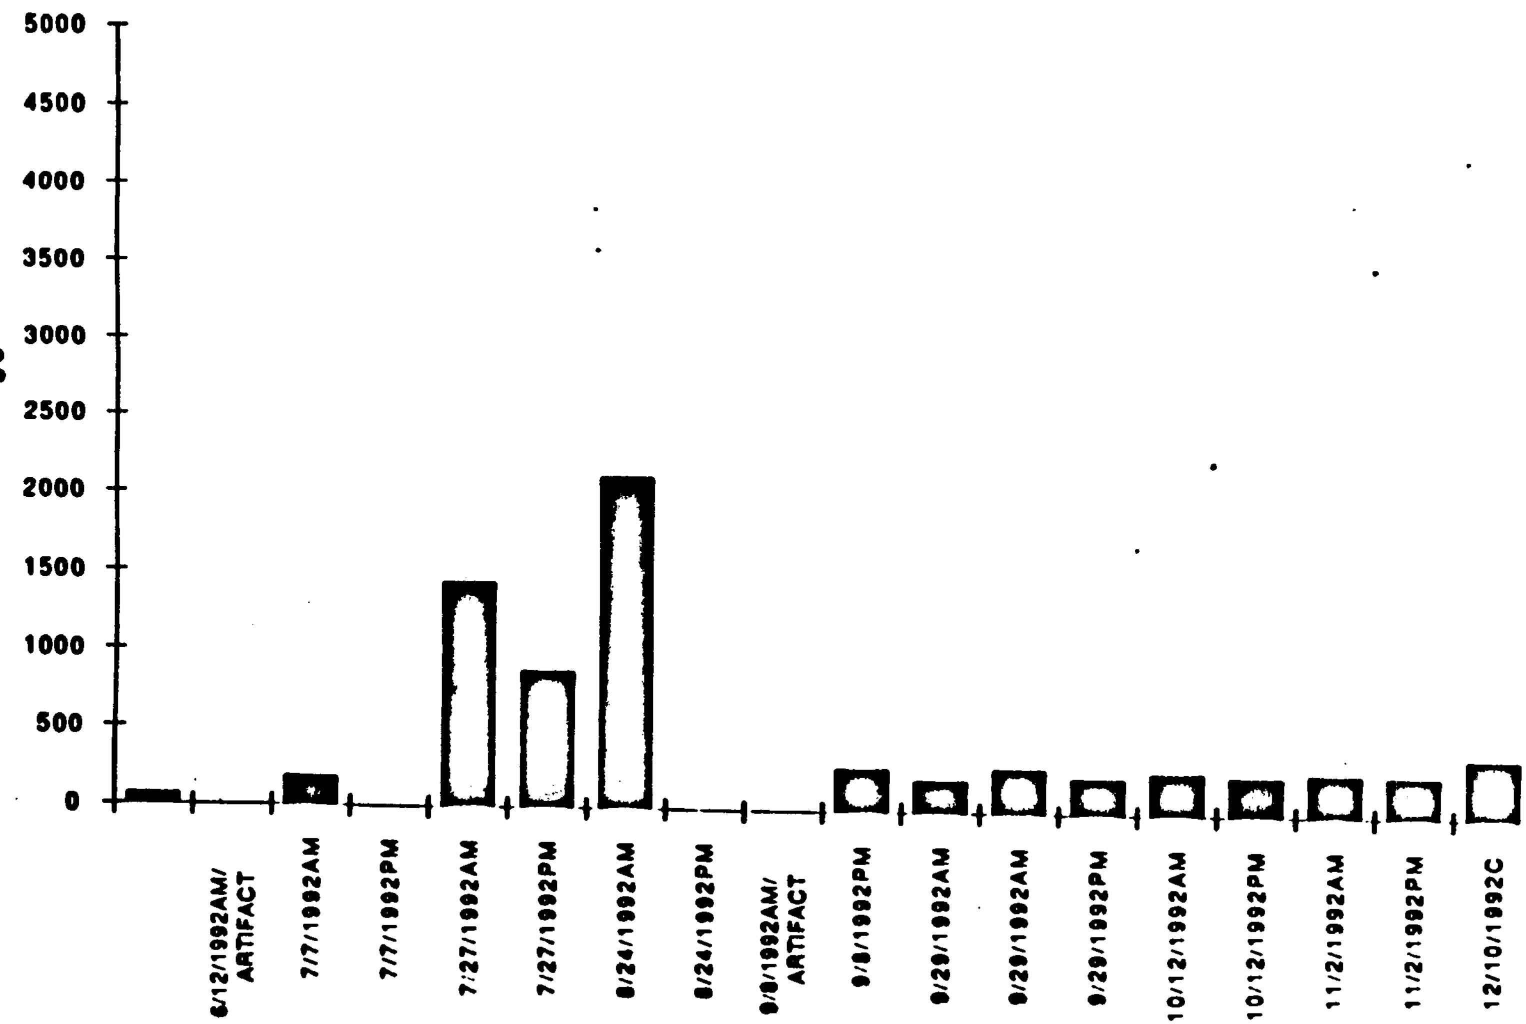
Methylene Chloride (ng/l) - Ballona



89

R0051412

VOL 1 2

The variability of the data for AM vs PM samples as well as for weekly and monthly samples are shown for total volatiles and THMs (Figure 16), methylene chloride (Figure 17) and for 2 low molecular weight volatiles (chloromethane and carbon disulfide) found in many of the samples in ng/l concentrations (Figure 18). The AM/PM variability for targeted quantifiable compounds was observed to be 1-2 ppb for total volatiles and the relative THMs/total volatiles concentration was consistent. THMs varied within a ppb for all AM/PM samples. Two samples were tested that were collected on 9/29 AM within 45 minutes of each other. The total volatiles varied as the other AM/PM samples within a ppb, (See Appendix, Table II.2). The weekly variability for targeted quantifiable compounds was observed to be 2-6 ppb for total volatiles. The THMs concentration varied within 3 ppb for 9 weeks of sampling over 6 months. Interestingly the largest variability was between two July samples of 2 ppb.

In contrast to the low ug/l levels of VOCs, Figure 6 shows that the dissolved organic carbon levels are greater than 1,000 times this level at 7-12 mg/l for the first six samples collected and near 10,000 times for the last two samples collected. Apparently, higher molecular weight chemicals are making up the bulk of the chemicals present. Probably, humic materials, algal metabolites and oily materials are associated with the DOC. A new study is needed to assess the type of DOC present.

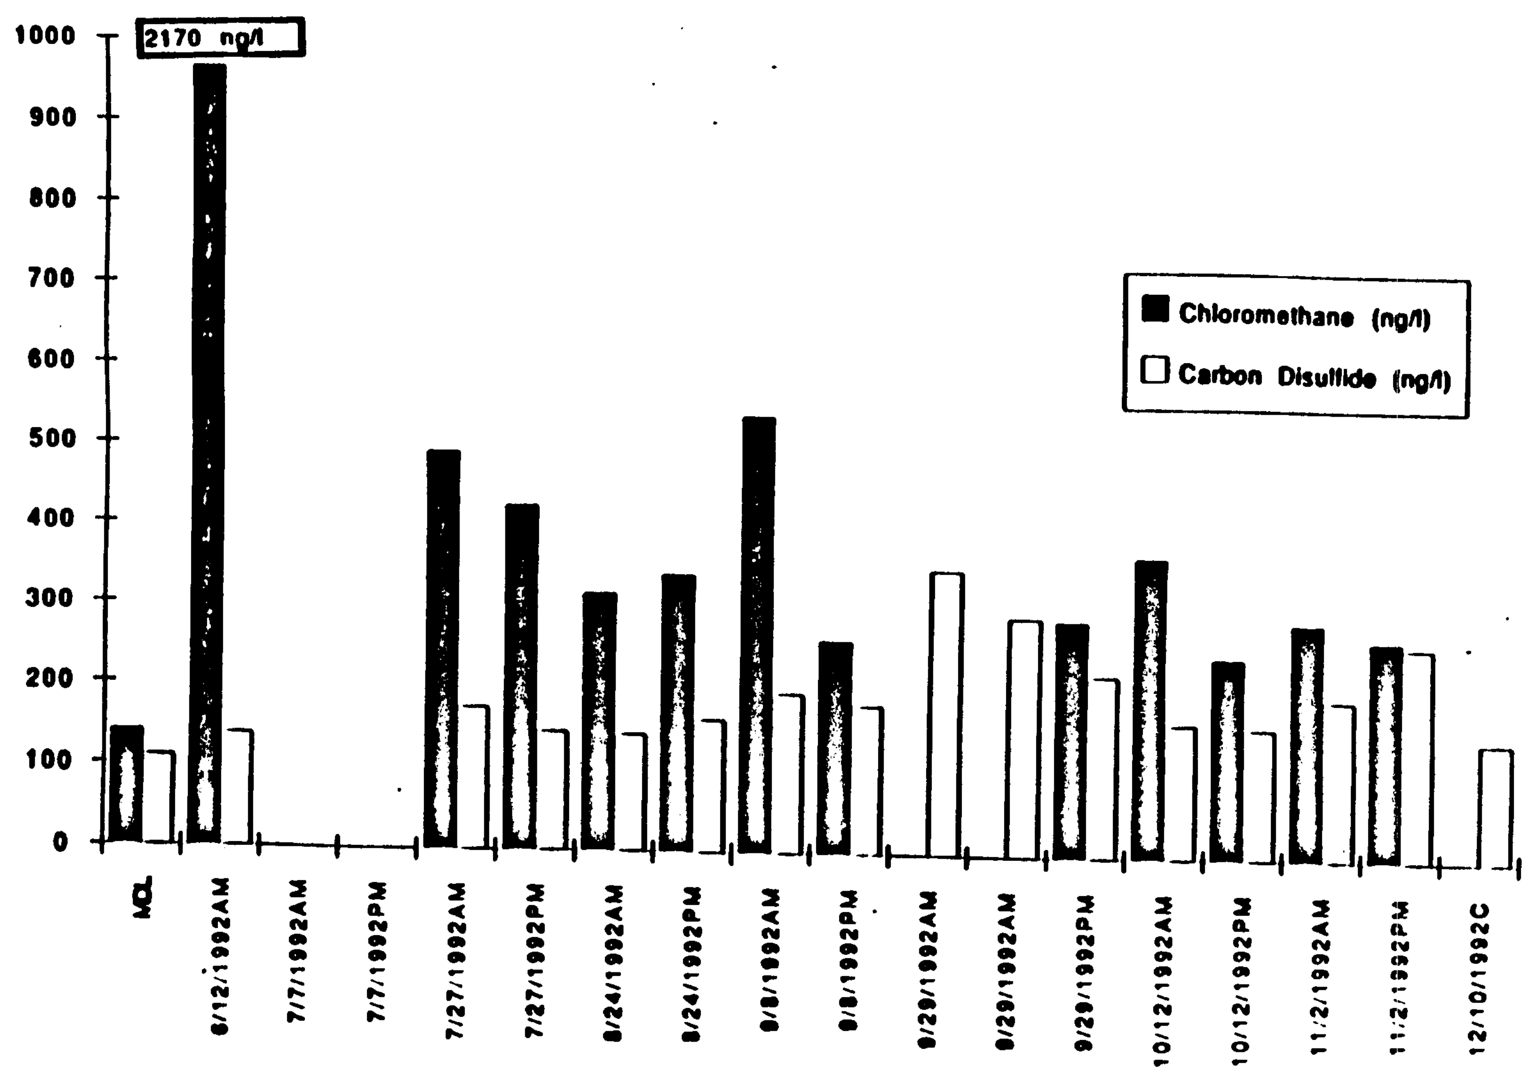
Figure 15 shows that the only significant rain that occurred during the sampling period was a half inch before the November 2 sample and almost 3 inches before the the December 10 sample. The DOC of these samples were ten times higher than the rest of the samples, yet, the total VOCs were lower than the rest of the samples. This indicates that the rain probably brought higher concentrations of humic materials and oily materials from the runoff of soil organic matter and petroleum products on the street into the storm drains while aeration and dilution decreased the VOCs concentrations.

Pico/Kenter Drain - Volatile Organic Compounds (VOCs)

Table 9 shows that 17 targeted VOCs were present above their MDLs in 15 samples collected over a 6 month dry weather flow period 6/12-12/10/92. Methylene chloride is a notorious laboratory contaminant and the analysis of the sample for 6/12 do not include data for methylene chloride (See Appendix, Table II.1). Table 9 shows that the range of concentrations for each targeted quantifiable compounds for 9 days

Figure 18

Chloromethane and Carbon Disulfide (ng/l) - Ballona



R0051414

VOL 12 1 8109

of sampling sometimes twice a day for 6 months was within an order of magnitude at the 0.1 to 1.5 ppb level except for methylene chloride (9/8 PM sample). Methylene chloride was the only compound that averaged above a ppb even after a sample considered an artifact was removed from the data base. Besides methylene chloride, only 2-butanone, 4-methyl-2-pentanone and bromoform were quantified to be above 1 ppb in any of the 15 samples. The drinking water MCLs are shown on Table 9 and indicate that only methylene chloride is within an order of magnitude of its proposed standard. The remaining compounds were over an order of magnitude less than the MCL for any sample. The data is further below the proposed Ocean Plan Standards (California State Water Resources Control Board, 1990a and b) as these standards are usually 5 X higher than drinking water standards even assuming no dilution and a one-month average value represented by each sampling date.

The levels of VOCs present from targeted quantifiable compounds are from 1 - 8 ug/l in the 17 samples analyzed. One sample - 9/8/92 PM shows that much higher levels of VOCs were present 14.27 ug/l due to a methylene chloride level of 12.81 ug/l. The trihalomethanes portion of the VOCs are shown on Figure 19. Figure 19 shows that the total haloforms account for <25% of the VOCs present in any sample except for the 7/7 AM sample (>50%). Lower relative THM/VOC levels are present at Pico/Kenter as compared to Ballona. Thus, a lower proportion of the sources of THMs, which include any chlorinated water, such as drinking water and cooling waters that are chlorinated for disinfection purposes are present.

Figure 20 shows that methylene chloride was predominant in this sample at 12.81 ug/l. There is no clear cut justification to eliminate this value from the data base except that it is possibly an artifact. In all the samples, the aromatic hydrocarbons from fuel emissions e.g. benzene and toluene were low (<0.6 ppb), as were the chlorinated solvents as represented by chloroethene (<1 ug/l). The targeted ketones representing natural biota sources and oxygenated solvents were also low (<2 ppb). Also, some non-targeted aldehydes were found at low levels in the Pico-Kenter samples (See Table 14 and Appendix IV.

The variability of the data for AM vs PM samples as well as weekly and monthly variability are shown for total volatiles and THMs (Figure 19), methylene chloride (Figure 20) and for 2 low molecular weight volatiles chloromethane and carbon disulfide found in many of the samples in ng/l concentrations (Figure 21). The AM/PM

Figure 19

THMs and Total Targeted Volatiles (ng/l) - Pico/Kenter

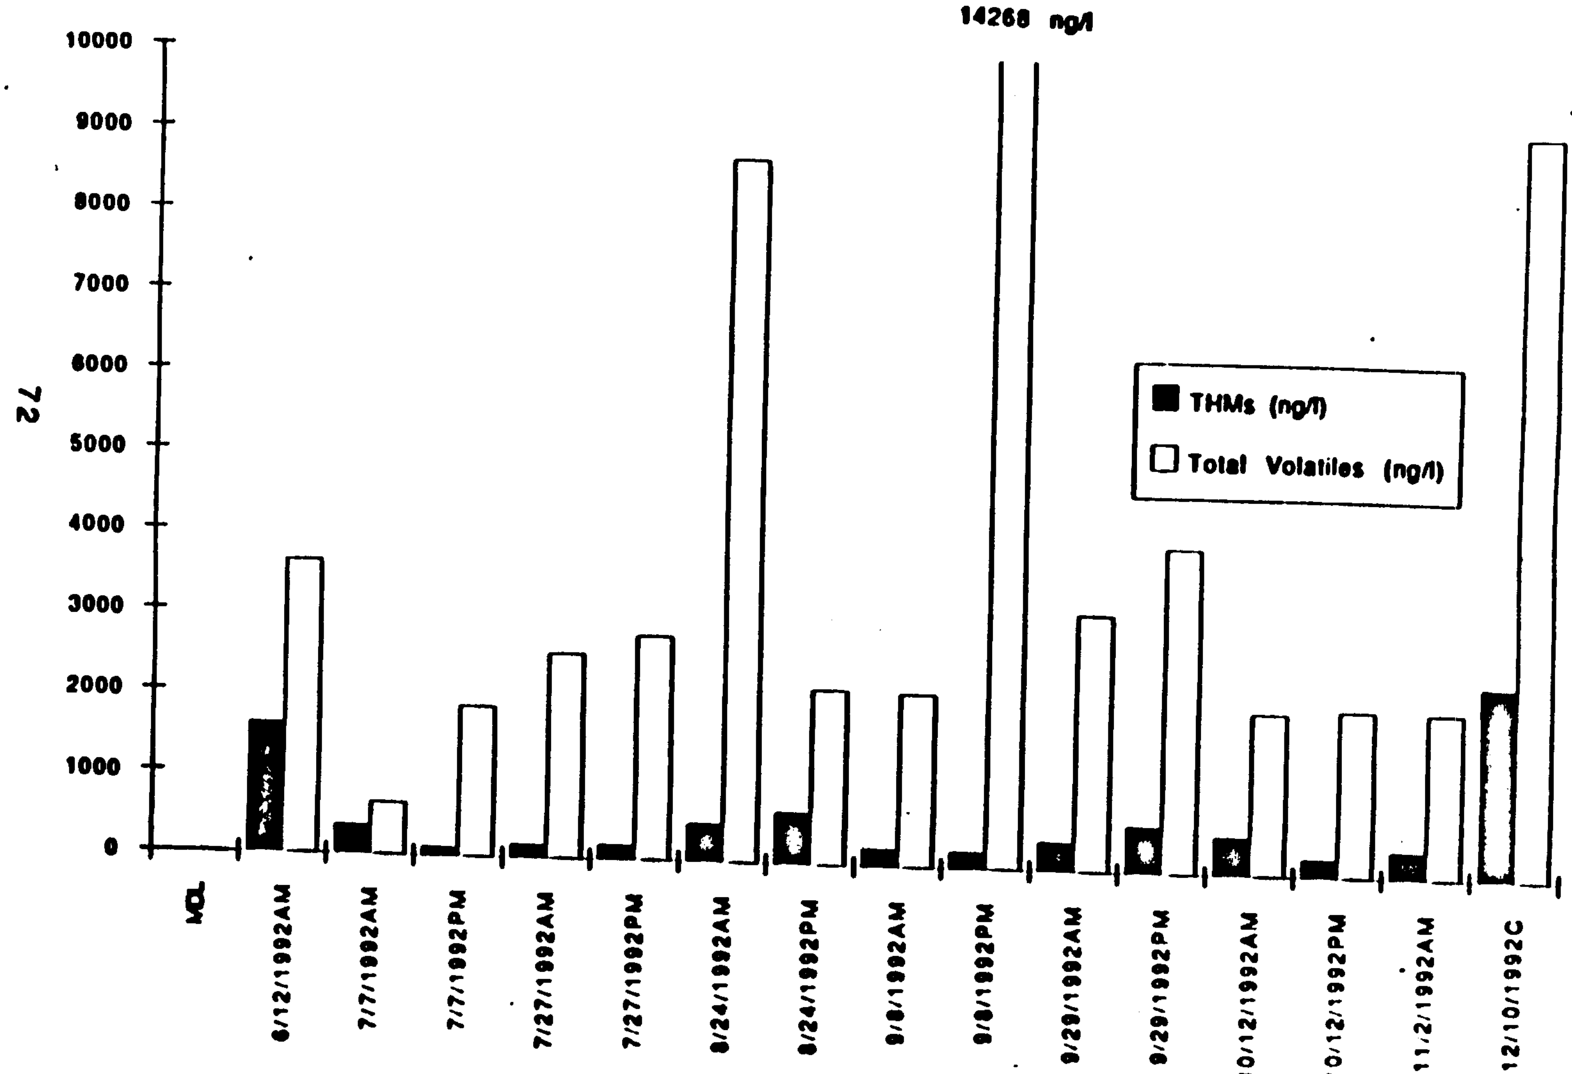


Figure 20

Methylene Chloride (ng/l) - Pico/Kenter

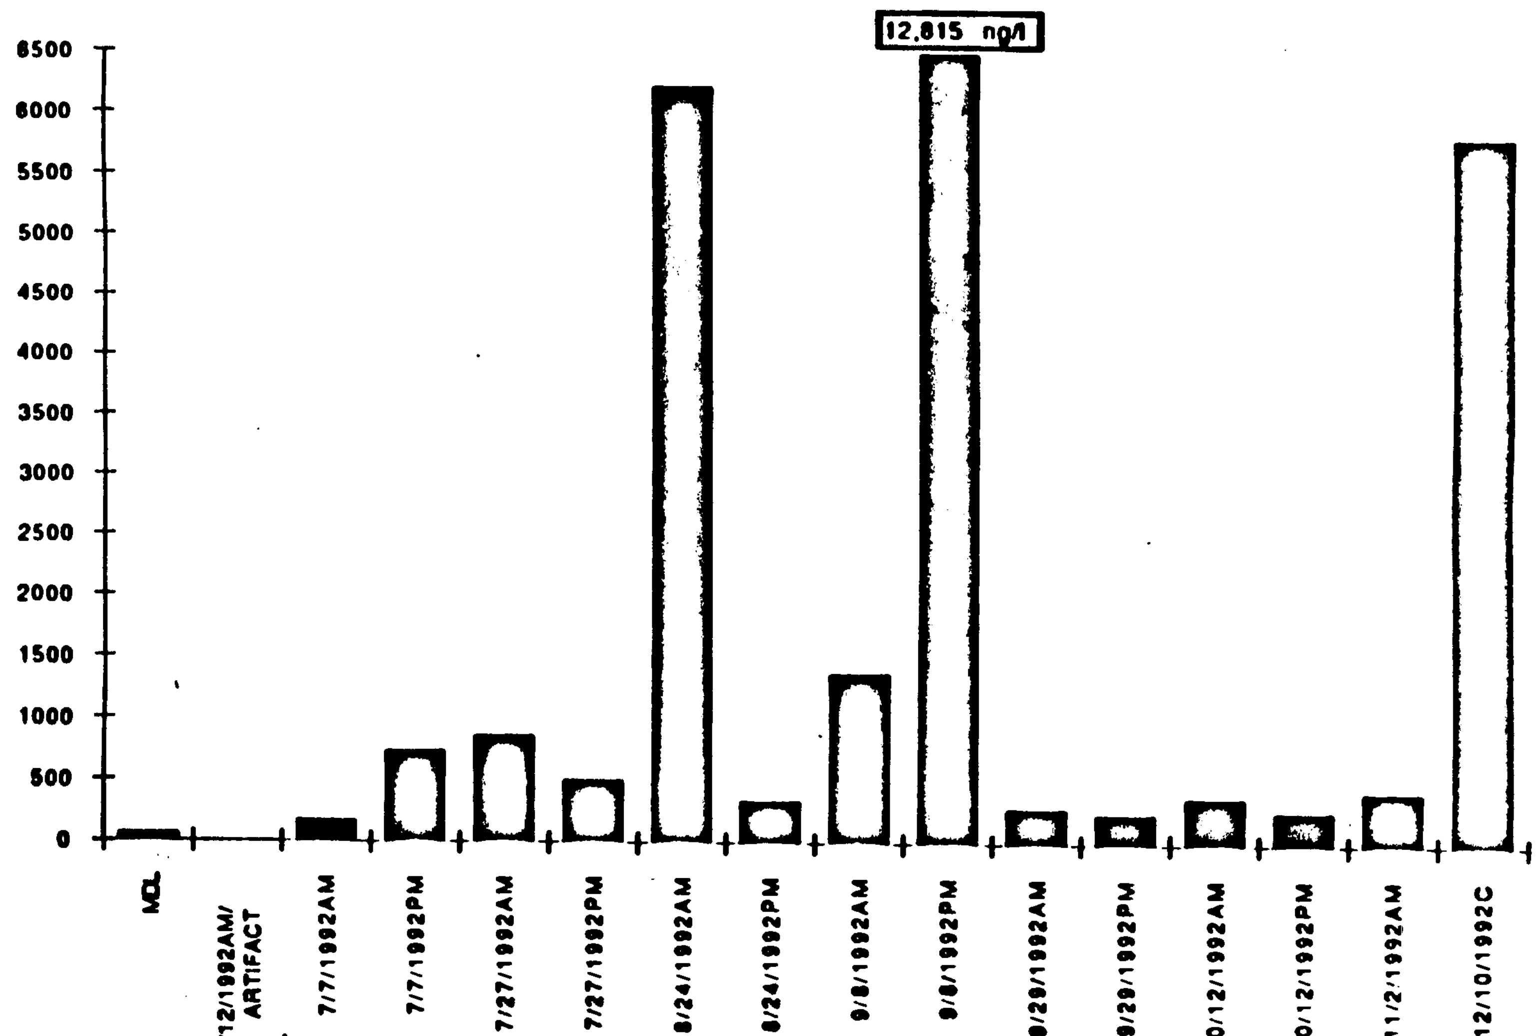

Figure 21

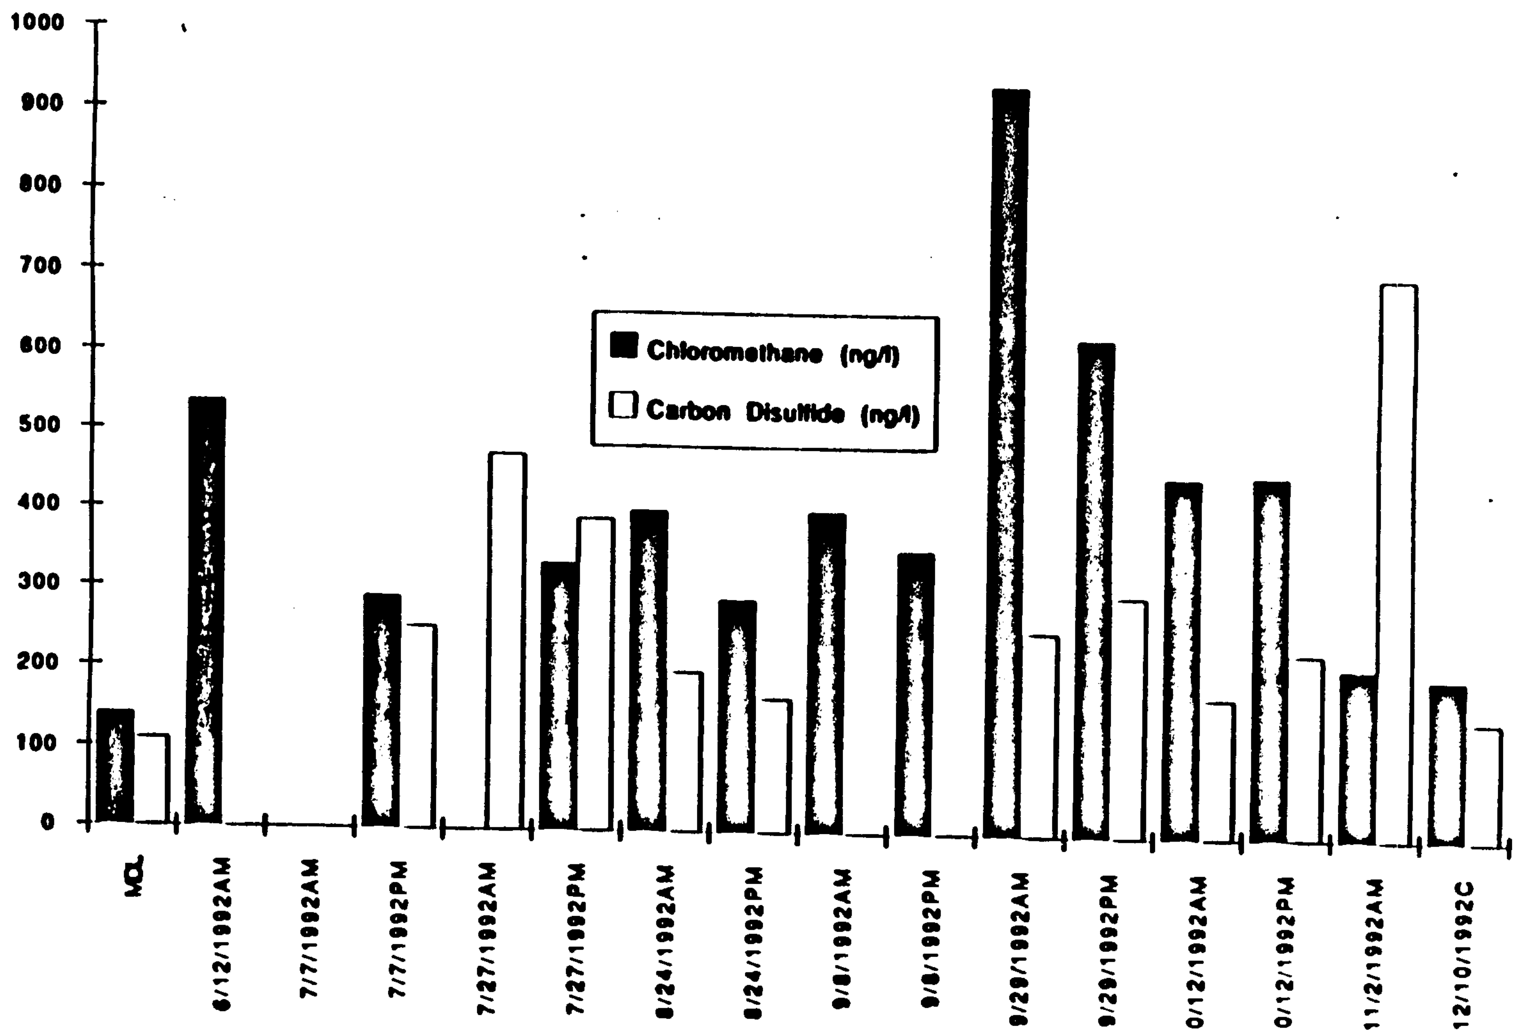
Chloromethane and Carbon Disulfide (ng/l) - Pico/Kenter



R0051418

VOL 12 1 8113

variability for targeted quantifiable compounds was observed to be 1-2 ppb for total volatiles except for the 8/24 and 9/8 with the high concentration of methylene chloride present in the PM sample. The relative THMs/total volatiles concentration was not consistent for these 2 days. The weekly variability for targeted quantifiable compounds was observed to be 0.5-9 ppb for total volatiles. The THMs concentration varied within 1 ppb for 8 weeks of sampling over 5 months. Only the December sample showed an increase to 3 ppb (See Appendix Table II.2).

In contrast to the low ug/l levels of VOCs, Figure 6 shows that the dissolved organic carbon levels are greater than 1,000 times this level at 11-18 mg/l for the first six samples collected and near 10,000 times for the last two samples collected. Apparently, as for Ballona, a higher molecular weight chemicals such a humic materials, algal metabolites and oily materials are associated with the DOC. A new study is needed to assess the type of DOC present.

Figure 15 shows that the only significant rain that occurred during the sampling period was a half inch before the November 2 sample and almost 3 inches before the the December 10 sample. The DOC of these samples were ten times higher than the rest of the samples, however, the total VOCs remained in the same concentration range as the other samples.

Sepulveda - Volatile Organic Compounds (VOCs)

Table 10 shows 21 targeted VOCs were present above their MDLs in 15 samples collected over a 6 month dry weather flow period 6/12-12/10/92. Two methylene chloride analysis were eliminated due to suspected artifacts - 6/12 and 9/8 AM (See Appendix Table II.1). Only methylene chloride, chloromethane, 2-butanone, and all 4 haloforms were quantified to be above 1 ppb in at least one of the 15 samples. The drinking water MCLs are shown on Table 10 and indicate that only, methylene chloride is within an order of magnitude of its proposed standard. The remaining compounds were over an order of magnitude less than the MCL for any sample. The data are further below the proposed Ocean Plan Standards (California State Water Resources Control Board, 1990a and b) as these standards are usually 5 times higher than drinking water standards even assuming no dilution and a one-month average value represented by each sampling date.

VOL 12 1 8/1/4

The range of concentrations for each targeted VOC compound for 9 days of sampling, sometimes twice a day for 6 months, varied between 1 and 9 ug/l in the 15 samples analyzed. This amount of targeted quantifiable VOCs is about the same as that at Pico/Kenter and Ballona samples. Figure 22 shows that the total haloforms account for > 30% of the total volatiles present in 8 of the 15 samples, including the four samples of 7/27/92 AM and PM, 9/8/92 AM and 12/10/92 which are over >50%. However, a much smaller number of the samples at Sepulveda are over 30% THMs than for samples from Ballona Creek (See Figure 16). This indicates that less drinking water or cooling water effluent on a relative basis enters the Sepulveda storm drain than Ballona except for the sample days noted.

Total aromatic hydrocarbons from fuel emissions e.g. benzene and toluene were below 0.5 ug/l, as were ketones (below 0.8 ug/l) representing natural biota sources and oxygenated solvents. The Sepulveda samples contained about the same magnitude of aromatic hydrocarbons as the Pico/Kenter storm drain, but this was still very low at <0.5 ppb. Total chlorinated solvents as represented by chloromethane were also low (< 1 ug/l).

The variability of the data for AM vs PM samples as well as for weekly and monthly samples are shown for total volatiles and THMs (Figure 22, methylene chloride (Figure 23) and for 2 low molecular weight volatiles (chloromethane and carbon disulfide) found in many of the samples in ng/l concentrations (Figure 24). (The true value for the 6/12/92 sample of chloromethane on Figure R9 is off-scale at 2,890 ng/l. The AM/PM variability for targeted quantifiable compounds was observed to be within 1 ppb for total volatiles except for the 7/7 samples containing 70% THMs and the 11/2 sample that contains 5 ug/l. The weekly variability for targeted quantifiable compounds was observed to be 1 - 8 ug/l for total volatiles. The THMs concentration varied within 8 ppb for 9 weeks of sampling over 6 months. Interestingly, the largest weekly variability were for the two July 27 samples. The last two samples had the lowest VOCs levels probably because of rainfall before each sampling that aerated and diluted the storm water.

In contrast to the low ug/l levels of VOCs, Figure 6 shows that the dissolved organic carbon levels are greater than 1,000 times this level at 10-18 mg/l for the first six samples (dry weather flow) collected and near 10,000 times for the last two samples collected after some rainfall. Apparently, higher molecular weight chemicals

such as, humic materials, algal metabolites and oily materials are making up the bulk of the chemicals present. A new study is needed to assess the type of DOC present.

Centinela - Volatile Organic Compounds (VOCs)

Table 11 shows 16 targeted VOCs were present above their MDLs in 11 samples collected over a 5 month dry weather flow period 7/7-12/10/92. Methylene chloride, a notorious laboratory contaminant and 4-methyl-2-pentanone averaged above a ppb. Also, 2-butanone, and the 4 haloforms were quantified to be above 1 ppb in some of the individual 11 samples. The concentration of 4-methyl-2-pentanone in the 9/8/92 PM sample was 45.79 ppb. This is the highest concentration of a non-chlorinated targeted compound that was found in any of the samples.

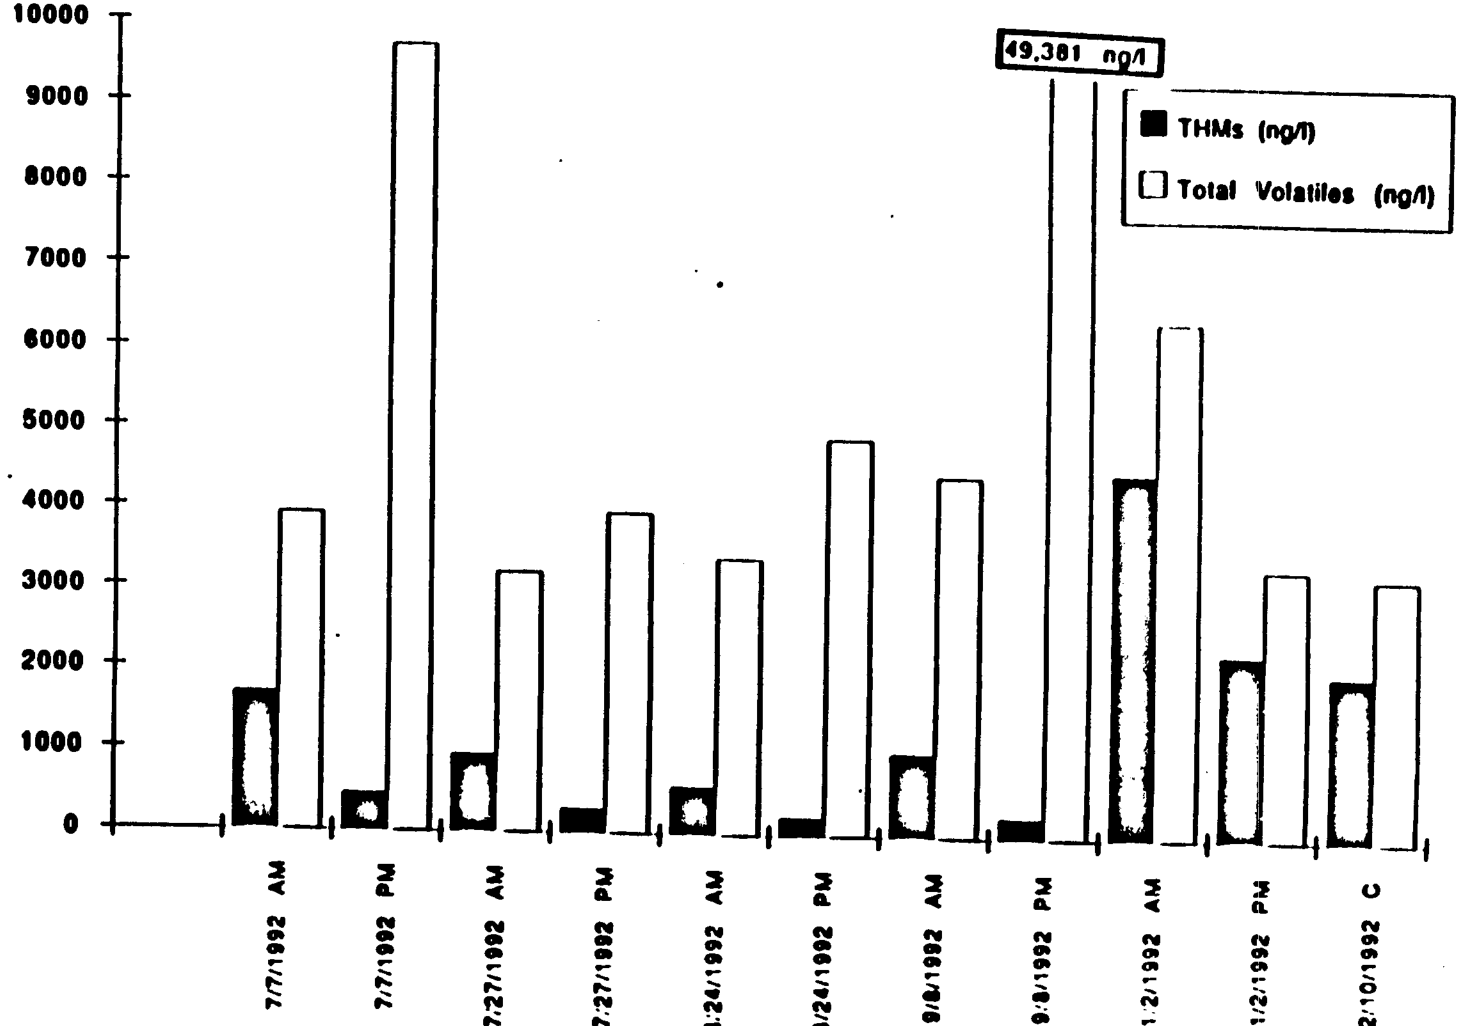
The drinking water MCLs are shown on Table 11 and indicate that the average value of the compound in these samples do not exceed their MCLs. One sample of methylene chloride does exceed its proposed standard in the 7/7 PM sample. The VOC compounds were over an order of magnitude less than the MCL for all the VOCs in each sample except for methylene chloride in the 7/7 PM sample. The data are also below the proposed Ocean Plan Standards (California State Water Resources Control Board, 1990a and b) as these standards are usually 5 times higher than drinking water standards even assuming no dilution and a one-month average value represented by each sampling date.

The levels of VOCs present from targeted quantifiable compounds are from 3 - 10 ug/l in 10 of the 11 samples analyzed in 6 days of sampling sometimes twice a day. Only in the sample with the 45.71ug/l, 4-methyl-2-pentanone is it higher (49.38ug/l). Figure 25 shows that the total haloforms account for > 50% of the targeted VOCs for 4 of the 11 samples. Sources of THMs include any chlorinated water that contains natural organic matter measured as organic carbon in mg C/l. This includes drinking water sources and cooling waters that are chlorinated for disinfection purposes. Haloform/Total VOC variability was the largest in these sets of storm drain samples as shown when comparing Figure 25 to Figures 16,19 and 22.

Figure 25 shows that the samples 7/7PM (high methylene chloride concentration) and 9/8/92 PM (high 4-methyl-2-pentanone concentration) have the highest levels of VOCs. Figure26 shows that methylene chloride was predominant in

Figure 25

THMs and Total Volatiles (ng/l) - Centinela



the 7/7 PM sample at the 8.2 ug/l level. Total aromatic hydrocarbons from fuel emissions like benzene and toluene were < 0.3 ug/l, less than Sepulveda and equivalent to the Pico/Kenter and Ballona samples. Ketones were below 1 ug/l for all the samples representing natural biota sources and oxygenated solvents except where the high level of 4-methyl-2-pentanone was present. Chlorinated solvents as represented by chloromethane were below 0.5 ug/l in all samples (Figure 27).

The variability of the data for AM vs PM samples as well as for weekly and monthly samples are shown for total volatiles and THMs (Figure 25), methylene chloride (Figure 26) and for 2 low molecular weight volatiles (chloromethane and carbon disulfide) found in many of the samples in ng/l concentrations (Figure 27). The AM/PM variability for total targeted quantifiable compounds was observed to be within a ppb for the 3 sample days that did not contain the high concentration of methylene chloride present (7/7) and 4-methyl-2-pentanone (11/2). THMs varied within 1-2 ppb for all AM/PM samples even when it was >50 % of the targeted VOCs (12/2). The weekly variability for THMs was observed to be 3 - 6 ppb. The weekly variability for methylene chloride was 0.5 - 5 ug/l.

Table 14 shows some non-targeted VOCs tentatively identified in a Centinela sample of 9/8/92. Figure 28 shows the unique GC/MS total ion current chromatogram of the sample with the high concentration of the ketone, 4-methyl-2-pentanone (common name = methyl, isobutyl ketone [MIBK]). Also, note that a tentatively identified GC/MS peak next to it is tentatively identified as 4-methyl-2-pentanol an oxidation product of the ketone. The internal standard (IS) in the sample is set at 5 ug/l. Thus, the pentanol is estimated to be at least 120 ug/l in this sample. The source of these compounds is not yet defined. MIBK is an industrial solvent. No drinking water or California ocean standards are available for these compounds.

In contrast to the low ug/l levels of VOCs, Figure 6 shows that the dissolved organic carbon levels are greater than 1,000 times. Apparently, higher molecular weight chemicals such as, humic materials, algal metabolites and oily materials are present. A new study is needed to assess the type of DOC present.

VOL 12

Ashland - Volatile Organic Compounds (VOCs)

The Ashland storm drain was the only drain that indicated high tidal influence as observed by measurements of salinity and conductivity, Figures 9 and 5, respectively and low oxygen content of the water, Figure 9. This effects the dilution of the sample, the types of trihalomethanes that are present in the sample and the chemicals effected by low oxygen content. The salt concentration in the samples also enables more efficient purge and trap analysis which would increase the concentration of volatiles found by analysis of those samples. Also, Ashland was the only drain which must fill sufficiently before it can flow to the ocean. The residence time in the storm drain and the associated oxygen content of the water present effected the type of chemical present in the storm drain as chemical and microbiological reactions can occur. Sampling could only be completed when sufficient sample was present. Sampling was not possible on 9/8 and 6/12/92. It was beyond the scope of this study to devote the manpower and time to clearly define the flow pattern, filling time, discharge time, anerobiosis or sea water tidal effect during this study, except by measurement of dissolved solids, conductivity and dissolved oxygen in the sample itself when it was taken in the field. A complete study of these factors as it relates to chemicals is suggested for further study. A continuous flow and chemical parameter monitoring station would be needed with sufficient control of the site to minimize vandalism at a highly visible location.

Table 12 shows 27 targeted VOCs were present above their MDLs in 14 samples collected over a 6 month dry weather flow period 6/12-12/10/92. This represents the most compounds identified in a storm drain site. Methylene chloride, a notorious laboratory contaminant, was 1 of 8 compounds that averaged above a ppb. Thirteen compounds in different samples were quantified to be above 1 ppb; methylene chloride, carbon disulfide, the 3 ketones, 7 aromatic hydrocarbons, dibromomethane, and the 4 haloforms. The drinking water MCLs are shown on Table 12 and indicate that only, methylene chloride exceeded its proposed standard. However, care for the potential artifact methylene chloride should be exercised before conclusions are drawn about methylene chloride. Further analysis of of this specific compound under rigorously controlled field and lab conditions are warranted in a special study to confirm these findings. Some of the remaining compounds were within an order of magnitude of the MCL for any sample. The Ashland drain represents the most contaminated drain, yet the drain with the lowest flow rate. The quantitative data are

VOL 12

1824

further below the proposed Ocean Plan Standards (California State Water Resources Control Board, 1990a and b) as these standards are usually 5 times higher than drinking water standards even assuming no dilution and a one-month average value represented by each sampling date.

Table 12 shows that the range of concentrations for each targeted quantifiable compounds for 8 days of sampling sometimes twice a day for 6 months was larger than for the other storm drains. The total volatiles varied from 3 to 11 ug/l for 7 sampling days of 8. The two 7/7/92 sample showed a much higher level (34 and 156 ug/l) of VOCs were present. Figure 29 shows that the total haloforms account for >50 % for 6 samples of the 14 samples with 877 and 19 ug/l of THMs in the two 7/7/92 samples. Figure 30 shows that methylene chloride was predominant in the sample of 7/7 AM. The concentrations present was 66 ug/l.

Total aromatic hydrocarbons from fuel emissions such as benzene and toluene were the highest in any storm drain at > 1 ug/l with a higher level in the 9/8 AM sample of 7 ppb (Figure 31) as were ketones which were 1 ug/l for 10 of 14 samples (See Figure 32) representing natural biota sources and oxygenated solvents. Chlorinated solvents from sources as dry cleaning were also the highest levels present in the storm drains.

The variability of the data for AM vs PM samples as well as for weekly and monthly samples are shown for total volatiles and THMs (Figure 29), methylene chloride (Figure 30) for total aromatic hydrocarbons (Figure 31), total ketones (Figure 32) and for 2 low molecular weight volatiles (chloromethane and carbon disulfide) found in many of the samples in ng/l concentrations (Figure 33). The AM/PM variability for targeted quantifiable compounds was observed to be 1-6 ppb for total volatiles (excluding sample 7/7), again the largest for any drain. The relative THMs/total volatiles concentration and THMs varied more between AM and PM samples than for any other drain especially for the samples of 7/7/92.

Figure 34 shows that the 7/7 AM sample contained >60% bromoform and the 11/2 PM sample contained >25% bromoform. It is hypothesized that this indicates that sea water reacted with haloforms and this may be the cause of more bromoform in this sample. The source of the sea water can be as small as a pool in the drain during low flow.

VOL 12

1 8-3-1

Ashland samples were selected for more complete analysis of non-targeted compounds to obtain an indication of what other compounds could be present. The complex total ion chromatograms in Appendix V and Table 14 show that some interesting 70 non-targeted compounds were tentatively identified by GC/MS in these samples. The primary type of compounds present were complex oily/petroleum hydrocarbon related alkanes and alkenes of straight chain, cyclic and aromatic nature. Also, sulfur compounds, dimethyl disulfide and 2-methyl furan were observed. Dimethyl disulfide is an anoxic product of biological decay. Naphthalenes, from potential street tar runoff and octyl and nonyl phenols possibly from detergent break-down were also observed. This suit of compounds indicates higher concentrated materials than the other drains due to the configuration and flow pattern of the drain.

Comparison of All Sample Sites - Volatile Organic Compounds

Table 13 compares the average tabulated VOC data for each site and overall grand average for all sites based upon occurrence >MDL. The drinking water MCLs are shown on Table 3 and indicate that only methylene chloride (dichloromethane) exceeds its MCL standard at Ashland Avenue. Resampling for the potential artifact methylene chloride should be completed before conclusions are drawn about it. The Ashland drain represents the most contaminated drain, yet it is the drain with the lowest flow rate. Some of VOCs present were within an order of magnitude of the EPA Drinking Water MCLs for a given sample. The quantitative data for each drain and the grand averages are below the proposed California Ocean Plan Standards (CA State Water Resources Control Board, 1990 a and b) even assuming no dilution and a one-month average value represented by each sampling date. This data indicates the targeted VOCs under dry weather flow are not a major problem. Primary interest is the further evaluation of nontarget compounds in other samples.

Base Neutral Organic Chemical Analysis

Tables 15 - 20 present the summary of the total concentrations of Base Neutral (BN) Organic Compounds (b.p. >100 °C) that were quantified at the ng/l level (ppt). Appendix VI (Table VI. 1-5) shows the complete data set for each sampling day at each site. The total concentration is the soluble chemicals plus the chemicals associated with the particulates that are present in the sample. Samples from the 5

sample. Samples from the 5 storm drains under dry weather flow from 6/12/92 to 12/10/92 were analyzed. Field and lab blank data (Appendix III) and MDLs (Table 21) were used to define the compounds that could be quantified.

The solid phase and the water phase were separated by filtration and analyzed for Base Neutral Organic Compounds as described in the experimental section. The data were then combined to present total concentration, which was necessary for quality control considerations. The total concentration values obtained in this study are presented as quality assured data. Adsorption of soluble compounds on the filters during the filtration process is suspected. Other research projects that are not part of the scope of this study are defining this analytical chemistry problem. The best data to present are the total concentration data since any compound adsorbed to the filter would be quantified as part of the suspended material.

Table 21 lists the minimum detectable level for each compound as determined in our laboratory. The only compounds that are quantified are those above the MDL. Other compounds on the Base Neutral Organic Compound quantifiable list (Table 4) were qualitatively identified by mass spectrometry in the samples, but are below the MDL and are not quantified. Appendix VI, Tables VI.1 - 5 shows the complete list of Base Neutral Organic Compounds analyzed including date of analysis, the concentration of the compounds that were identified above their MDLs in ng/l and the identification of the compounds found below their MDLs presented as <MDL.

Quality Assurance - Laboratory Blanks, and Field Blanks

Appendix III, Table III-1 shows the GC/MS System Blanks for the targeted Base Neutral Organic Compound including the rules used for quantitative calculations. Di-n-butyl phthalate was the only targeted compound identified above its MDL. Phthalates especially Di-n-butyl phthalate are laboratory artifacts from plasticizers present in many laboratory products. Appendix III, Table III-2 shows the targeted Base Neutral Organic Compounds found in the filters used to isolate the suspended solids in the samples. The maximum value observed in the total blank (system + suspended solid blank) was used as the most conservative (worst case) choice for a blank to compare to MDLs. Nine targeted Base Neutral

1 8146

Organic Compounds (Table 21) were found in the system and suspended solids blanks that were above their MDLs and the values of the blank are used instead of the MDLs to complete all quantitative analyses as was done for VOCs . These nine compounds are always presented as bold chemical names on all data tables to indicate that the blank value is used for comparison for quantitation and not the MDL. Five of the nine compounds are phthalate [diethyl, di-n-butyl, butylbenzyl, bis(2-ethylhexyl) and di-n-octyl] with the bis(2-ethylhexyl) phthalate the highest at 4.8 ug/l. Three low level concentrations of polynuclear aromatic hydrocarbons (PAHs) were also found in 1 of the 5 blanks studied. This could be caused by adsorption of the PAH compounds from the air when a filter is left open to the laboratory air for a time period. Quality control procedures were carefully monitored throughout the study.

Water blanks were studied as were water travel blanks as shown on Appendix Tables III-3 and 4. High concentration levels of the 5 common phthalates described above were found in these samples. No other targeted compounds were identified. The Milli-Q water system tubing made of Tygon was isolated as the source of the contamination. The tubing was changed and an all-glass activated carbon filter was installed to eliminate this problem.

Pico-Kenter - Base Neutral Organic Compounds

Table 15 shows that 38 targeted Base Neutral Organic Compounds were present above their MDLs in 11 samples collected over a 6 month dry weather flow period 6/12-12/10/92. The range of concentrations for each targeted quantifiable compound represents 9 days of sampling, sometimes twice a day for 6 months. Three phenols, benzoic acid, and 4 phthalates were quantified to be above 1 ppb in some of the 11 samples. The drinking water MCLs in Table 15 indicate that no compound exceeded the drinking water standard. Some samples with bis(2-ethylhexyl) phthalate exceed the proposed California Ocean Plan Standards if no dilution is included (California State Water Resources Control Board, 1990a and b). However, dilution is always considered in the California Ocean Plan. The relationship between the PAHs in these samples and the proposed California Ocean Plan Standards will be evaluated below. Other non-targeted base neutral compounds were identifed in selected base neutral samples (Table 22).

Centinela - Base Neutral Organic Compounds

Table 16 shows that 31 targeted Base Neutral Organic Compounds were present above their MDLs in 8 samples collected over a 6 month dry weather flow period 6/12-12/10/92. The range of concentrations for each targeted quantifiable compound represents 8 days of sampling for 6 months. Benzoic acid, and 3 phthalates were quantified to be above 1 ppb in some of the 8 samples. The drinking water MCLs in Table 16 indicate that bis(2-ethylhexyl) phthalate exceeded the drinking water standard. Bis(2-ethylhexyl) phthalate was found in the distilled water and suspended sediment blanks, Table 21, at 4.8 ug/l. Therefore, to assure that the levels are over drinking water standards, further verification is suggested. Bis(2-ethylhexyl) phthalate also exceeds the proposed California Ocean Plan Standards if no dilution is included (California State Water Resources Control Board, 1990a and b). However, dilution is always considered in the California Ocean Plan. The relationship between the PAHs in these samples and the proposed California Ocean Plan Standards will be evaluated below. Other non-targeted base neutral compounds were identifed in selected base neutral samples, (Table 22).

Sepulveda - Base Neutral Organic Compounds

Table 17 shows that 32 targeted Base Neutral Organic Compounds were present above their MDLs in 9 samples collected over a 6 month dry weather flow period 6/12-12/10/92. The range of concentrations for each targeted quantifiable compound represents 8 days of sampling for 6 months. Four phthalates were quantified to be above 1 ppb in some of the 9 samples. The drinking water MCLs in Table 17 indicate that bis(2-ethylhexyl) phthalate exceeded the drinking water standard and the proposed California Ocean Plan Standards if no dilution is included (California State Water Resources Control Board, 1990a and b). Bis(2-ethylhexyl) phthalate was found in the distilled water and suspended sediment blanks, Table 21, at 4.8 ug/l. Therefore, to assure that the levels are over drinking water standards, further verification is suggested as at Centinela. Bis(2-ethylhexyl) phthalate also exceeds the proposed California Ocean Plan Standards if no dilution is included. However, dilution is always considered in the California Ocean Plan. The relationship between the PAHs in these samples and the proposed California Ocean Plan Standards will be evaluated below. Other non-targeted base neutral compounds were identifed in selected base neutral samples, (Table 22).

Ballona - Base Neutral Organic Compounds

Table 18 shows that 36 targeted Base Neutral Organic Compounds were present above their MDLs in 10 samples collected over a 6 month dry weather flow period 6/12-12/10/92. The range of concentrations for each targeted quantifiable compound represents 8 days of sampling, sometimes twice a day for 6 months. Four phthalates were quantified to be above 1 ppb in some of the 9 samples with bis(2-ethylhexyl) phthalate exceeded the drinking water standard and the proposed California Ocean Plan Standards if no dilution is included (California State Water Resources Control Board, 1990a and b). Bis(2-ethylhexyl) phthalate was found in the distilled water and suspended sediment blanks, Table 21, at 4.8 ug/l. Therefore, to assure that the levels are over drinking water standards, further verification is suggested as at Centinela and Sepulveda. Bis(2-ethylhexyl) phthalate also exceeds the proposed California Ocean Plan Standards if no dilution is included. However, dilution is always considered in the California Ocean Plan. The relationship between the PAHs in these samples and the proposed California Ocean Plan Standards will be evaluated below. Other non-targeted base neutral compounds were identifed in selected base neutral samples, (Table 22).

Ashland Avenue - Base Neutral Organic Compounds

Table 19 shows that 41 targeted Base Neutral Organic Compounds were present above their MDLs in 8 samples collected over a 6 month dry weather flow period 6/12-12/10/92. The range of concentrations for each targeted quantifiable compound represents 8 days of sampling. Benzoic acid, 4-methylphenols, benzyl alcohol and 5 phthalates were quantified to be above 1 ppb in some of the 8 samples with bis(2-ethylhexyl) phthalate exceeded the drinking water standard and the proposed California Ocean Plan Standards if no dilution is included (California State Water Resources Control Board, 1990a and b) in all 8 samples. However, dilution is always considered in the California Ocean Plan. Bis(2-ethylhexyl) phthalate was found in the distilled water and suspended sediments blank, Table 21, at 4.8 ug/l. Therefore, to assure that the levels are over drinking water standards, further verification is suggested as at Centinela, Sepulveda and Ballona. Bis(2-ethylhexyl) phthalate also exceeds the proposed California Ocean Plan Standards if no dilution is included. However, dilution is always considered in the California Ocean Plan. The relationship between the PAHs in these samples and the proposed California Ocean Plan Standards will be evaluated below. The PAHs were the highest in this storm drain. Over 120 compounds were found at the Ashland Storm Drain as targeted (Table 19) and non-targeted Base Neutrals Compounds (Table 22).

VOL 12

Comparison of All Sampling Sites - Base Neutral Organic Compounds

Figures 35 - 38 compare the total targeted base neutral concentrations found at each site during each sampling period from July 7 to Dec 10, 1992. Figure 35 show that the total targetted base neutral concentration range from 2 ug/l to 174 ug/l with all but 2 of 36 samples between 2 ug/l to 42 ug/l and all but 5 of 36 samples between 2 ug/l and 21 ug/l. The primary type of base neutral found were phthalates, Figure 36. Phthalates make up the most significant part of the base neutral varying from 50 to 97 % of the base neutrals found in any sample. Figure 37 shows the total PAHs are from 0.017 - 26 ug/l. The total PAHs are < 1.6 ug/l except for 1 sample of 26 ug/l as Sepulveda on August 24, 1992. Figure 38 shows the total phenols are the lowest fraction of the total base neutrals with only one sample higher than 10 ug/l.

1 8152

In Figure 39, pyrene is highlighted as an exemplary PAH to help describe how the PAHs vary in concentration from sample to sample. The August 24 samples from all locations show the highest concentrations of pyrene (0.12 - 7.56 ug/l). Figure 15 shows that a dry weather flow condition was prevalent in this sampling period. Samples from Ashland contain the highest level of pyrene concentration with 2 samples above 0.1 ug/l on July 27 during dry weather flow and on December 10 after about 3 inches of rain a week before. The complete PAH data presented in Appendix VI show the variation of the other PAHs with sampling data.

Figure 40 shows the concentrations of the phthalate, butyl benzyl phthalate that was not present as a phthalate in any blanks. The Aug. 24 sample also

California Ocean Plan Standards
(California State Water Resources Control Board, 1990a and b)

Tables 15-20 compares the tabulated Base Neutral Organic Chemical data and the drinking water maximum contamination limits developed by the U.S. EPA and the proposed California Ocean Plan Standards (California State Water Resources Control Board, 1990a and b). Tables 15-20 shows that the total concentrations of each chemical quantified does not exceed any of the EPA drinking water standards except for bis(2-ethylhexyl) phthalate at all but Pico-Kenter. Bis(2-ethylhexyl) phthalate was found in the suspended sediment and distilled water blanks, Table 21, at 4.8 ug/l. Therefore, to assure that the levels are over drinking water standards, further verification is suggested. This is a similar problem to the ubiquitious VOC- methylene chloride problem which also needs further verification.

Tables 15-20 indicate that most samples analyzed for Base Neutral Organic Compounds exceed the proposed 30-day average California Ocean Plan Standards especially for total PAHs without consideration of dilution. The proposed California Ocean Plan Standard for PAHs is a total PAH concentration of 8.8 ng/l. The sum of the PAHs includes all PAHs analyzed plus 2 additional PAHs that were not analyzed in the present study.

The following facts must be considered when evaluating the data in this report versus the California Ocean Plan. The CA Ocean Plan includes an <u>initial dilution clause</u> (pp. 18-19 of CA Ocean Plan), which implies it is for point sources of municipal and industrial origin and not from storm water runoff which this work has considered a non-point pollution source. "The process which results in the rapid and irreversible turbulent mixing of wastewater with ocean water around the point discharge" is the initial dilution and this factor is applied to the standard. Permits are developed around models which define the dilution at the outfall. The State Water Resources Control Board, Division of Water Quality, Ocean Plan Unit, completed a California Ocean Plan Triennial Review 1991-4, (Doc 92-5WQ, October 22, 1992). On page 37 the "staff concluded that the Ocean Plan

VOL 12

1 8 / 5 9

should be amended to clarify its applicability to stormwater discharges. A schedule of compliance for dischargers similar to the schedule in the Inland Surface Waters and the Enclosed Bays and Estuary Plans should be considered." It is for this reason that the quantitative data presented in this report cannot be directly evaluated for dilution and impact on health via the California Ocean Plan. It is our opinion that the California Ocean Plan can be considered a state opinion of what chemicals are important to evaluate, but, not as having a direct quantitative relationship to the compounds that are present.

VOL 12

Non-Target Base Neutral Organic Compounds

Table 22 shows the identification of non-targeted Base Neutral Organic Chemicals in selected samples. Non-targeted Base Neutrals were identified by the criteria that were presented in the experimental section. These compounds are not quantified and they are called "tentatively identified" compounds. Tentatively identified compounds are not compared with the GC retention time of the true compound or the mass spectrum of the true compounds obtained on the same GC/MS system as the targeted compounds. The term "tentative" means that further studies are needed to confirm their identification and to quantify them by use of references standards. Total ion current chromatograms from the mass spectrometric determination results are presented in Appendix VII. Future evaluation of the non-targeted tentatively identified compounds falls into the category of future research. Selected n-alkanes and fatty acid methyl esters (FAMES), tris(2-butoxyethyl) phosphate, diazinon, dimethoate (organophospahate pesticides), and chlorinated pesticides and polychlorinated biphenyls (PCBs) have been confirmed by comparison to authentic standards.

1 8/60

Organophosphate Pesticides Analysis

Table 23 shows diazinon and dimethoate, 2 organophosphate pesticides, were found in 6 of the base neutral samples that were analyzed. These two compounds are part of the nontarget base neutral compounds that need further investigation. They have not been included in Table 22 as they were found in different samples. Further evaluation of the source of these compounds is needed.

Chlorinated Pesticides and PCBs Identification

Table 24 shows chlorinated pesticides and PCB analyses that were determined in the 9/8/92 samples from the five drains. The data from each drain indicates the presence of chlorinated pesticides and PCBs to be greater than their MDLs of 0.5 ng/l. Tables 25 and 26 show blank analyses by GC/MS and GC-Electron Capture Detection (ECD) with two GC columns, respectively. The blank analyses for unexposed filters that are directly analyzed by supercritical fluid extraction show that chlorinated pesticides and PCBs are present at 1 - 2 ng/l. On the other hand, the blank analyses for filters that were analyzed by supercritical fluid extraction after exposure in the hood for one day show an order of magnitude increase of chlorinated pesticides and PCB contamination. The levels of chlorinated pesticides and PCBs are present in these blanks at 1 - 20 ng/l. The source of the blank contamination in the room and hood space at the ng/l level is unknown. The pesticide dieldrin was found in concentrations above background at two sites, Pico Kenter and Centinela. Alpha-chlordane was eight times the background at Ashland. The storm drain with consistent PCB concentrations greater than the blank level was Ashland. Assuming a minimum background level of 1 ng/L, the concentrations at Ashland were as high as 88 times greater than the blank levels. PCBs were also identified at Centinela with the concentrations ranging from one to 17 times the background. 2,4,4'-trichlorobiphenyl, 3,3',4,4'-tetrachlorobiphenyl, 2,2',3,4,4',5-hexachlorobiphenyl and 2,2',3,4,4',5,5'-heptachlorobiphenyl were positively identified in the samples, and there was no quantifiable contamination in the blank. These compounds were found at several of the sites. Two decachlorobiphenyls were also identified, but at one site each only. The source of the 1-20 ng/l contamination of the blanks is currently being investigated.

Hydrocarbon Characterization In Urban Runoff

Dry weather and storm water runoff from urban areas such as the Los Angeles Basin contain hydrocarbons from diverse origins such as street and river runoff, atmospheric fallout, terrestrial dust, etc. Yet, several of the principal sources for hydrocarbon input can be distinguished, since fossil fuels have a hydrocarbon signature different from those of biogenic sources. For example, aromatic hydrocarbons show distinct characteristics in combustion and petroleum-based sources. Combustion PAHs are dominated by parent compounds, whereas the methylated homologs dominate in petroleum (Youngblood and Blumer, 1975).

Fossil fuel and petroleum hydrocarbons, complex mixtures of organic compounds, also contain unique compounds often referred to as biomarkers. These compounds are very stable structurally-specific molecules that usually can be related to precursor compounds in a specific type of source material As the source material is converted to fossil fuel, the precursor molecules are chemically altered to form biomarkers. Two common types of biomarkers, often used to provide information on source and maturity of crude oils and the existence of which indicates the presence of fossil fuel or petroleum hydrocarbons, are steranes and triterpanes (Philip, 1985). Steranes are tetracyclic aliphatic hydrocarbons derived primarily from C27 to C29 sterols. Triterpanes are pentacyclic aliphatic hydrocarbons derived from cell wall precursors in certain plants and microorganisms. One of the most ubiquitous groups of pentacyclic triterpane biomarkers are those based on the hopane structure.

Sterane and hopane biomarkers can be detected at very low concentrations by using GC/MS to monitor the molecular ion decomposition fragments m/z 217 and m/z 191 respectively. The distributions obtained can be used to confirm the presence of fossil fuel and petroleum hydrocarbons and in some cases, e.g., large spills, their source.

The biomarker fingerprints for an Ashland 07-27-92 filter extract are shown in Figures 41 and 42. The associated compounds are listed in Table 27. These data indicate the presence of petroleum hydrocarbons in the Ashland sample. The abundance of both C27 and C29 steranes indicates both a marine and terrestrial source material while the presence of 17a(H), 18a(H),21B(H)-28,30-bisnorhopane suggests hydrocarbon contribution from California crude (Siefert et al., 1978). Both the lack of unsaturated biomarkers (sterenes and triterpenes) and the presence of rearranged steranes (diasteranes) and 20S and 20R epimers of extended hopanes is consistent with mature petroleum. Little biodegradation has taken place as evidenced by the lack of 25-norhopane homologs and the lack of removal of the 5a(H), 14a(H), 17a(H) 20R isomers from the C27-C29 steranes. The unusually high abundance of extended tricyclic diterpanes may indicate again a terrestrial contribution to the oil or source rock but may also indicate a source of hydrocarbons to the Ashland runoff from resins of higher plants (Table 27). Further evaluation of the sample for petroleum hydrocarbon odors is needed.

In summary, Tables 15-20 compare the data that are greater than the minimal detectable limit versus EPA Drinking Water Standards and the California Ocean Plan Standards placing the quantitative data in perspective. Most samples analyzed for Base Neutral Organic Compounds (See Tables 15-20) exceed the proposed California Ocean Plan Standards for PAHs of 8 ng/l. A few samples exceed the EPA Drinking Water Standards for methylene chloride and the California Ocean Plan for Bis(2-ethylhexyl) phthalate; however both of these are notorious laboratory contaminants. The data presented show that the phthalates data are sufficiently quality assured as the concentrations are an order of magnitude greater than any of the blank values. However, the methylene chloride data need further confirmation with discrete sampling for it alone under meticulously controlled conditions. The CA Ocean Plan was not designed for evaluation of non-point source storm water runoff as discussed on page 121 of this report. Therefore, the CA Ocean Plan Standards can only be used to guide which compounds are considered to be important for future evaluations. The Ocean Plan should be amended to clarify its applicability to storm water discharge.

DISCUSSION

There are 64 storm drains that terminate in the Santa Monica Bay. During the winter rainy season, the storm drains provide access to the Bay for large quantities of rain water. During the dry season, water from urban runoff, construction, illegal dumping, and other sources results in a continuous influx of chemical contaminants to the Santa Monica Bay. Unlike many other coastal areas around the United States such as the San Francisco Bay area, the Chesapeake Bay, and New York-New Jersey area, there is no major source of river water into the Bay. The effluent from storm drains then represents a major contributor of potentially contaminated water to the Santa Monica Bay.

This pilot study is the most comprehensive investigation to date of chemical releases from storm drains into the Santa Monica Bay. This is also one of the first studies to consider the relationship between chemicals in the water and those bound to sediment. The findings in this study should form the basis for follow-up studies to further characterize the chemical releases, address their impact on the ecology of the Bay, identify the sources of the contamination, further characterize flow patterns into the Bay, quantitatively assess health risk, and establish monitoring protocols and limits for chemical releases into the Santa Monica Bay.

This investigation must be viewed as a pilot study since resource limitations prevented us from determining the potential sources of the contamination, examining a larger number of storm drains, investigating the concentration of metals, and evaluating a wider range of toxicants. Additional studies are required to address a number of unanswered questions. These will be discussed below.

The overall objective of this study was to gather data on the identity and quantity of potential toxic constituents that are present in urban runoff storm drains. These data are to amplify our limited understanding of the nature of chemicals that are transported from storm drains into Santa Monica Bay. The storm drains studied were "Pico/Kenter", "Ballona", "Sepulveda", "Ashland" and "Centinela". The analyses were completed over a six month "dry weather" flow period June 12 to December 10, 1992. Before the November 2 and December 10 sampling days, 0.5 and 3 inches rain fell, respectively. The complete data base is tabulated in Appendices IV and VI for volatile organic chemicals and base neutral organic chemicals, respectively.

A minimum of 50 trace organic compounds was identified in each storm drain with over 120 compounds found at the Ashland Storm Drain. Included in this evaluation are 16 - 27 targeted Volatile Organic Chemicals (VOCs), 31 - 41 targeted Base Neutral Organic Compounds (semi-volatiles), over 65 non-targeted VOCs and over 50 semi-volatiles. The individual concentrations ranged from ng/L to ug/L in the storm drain samples. Compounds with toxicologic significance were the phthalates, polycyclic aromatic hydrocarbons (PAHs), chlorinated hydrocarbons, phenols, and other carcinogenic organic compounds. Some of these compounds were found in small quantities. See discussion below.

Special quantitative analyses were conducted for two organophosphate pesticides, diazinon and dimethoate, as well as chlorinated pesticides, and PCBs. Diazinon and dimethoate were found in some of the base neutral sample extracts. The chlorinated pesticides, alpha-chlordane and dieldrin and a number of PCBs were identified in the storm drain samples. The greatest concentrations were found at Ashland, but there was evidence for PCBs at other sites as well. Further work is required to quantify the PCBs found in storm drain effluent with particular attention to elimination of laboratory blank contamination.

These results raise an important issue: what is the source of these compounds? Perhaps the organophosphates pesticides are from readily available home garden products, but there is no obvious point source that can be readily identified that would account for the PCB releases, alpha-chlordane and dieldrin. Presumably the PCBs identified in this study, and the dioxins and chlorinated naphthalenes identified by Fisher et al. (1993) are products of combustion from chlorine and carbon containing compounds. PCBs can derive from settling of PCB-associated aerosols from the ambient air environment into the open storm drains. Evaluation of ambient air concentrations should be conducted to determine the potential for airborne PCBs to enter storm drains. Studies to further characterize these compounds and their origins should be a high priority for state and local officials as some of these compounds have the potential to bioaccumulate and are both toxic and/or carcinogenic. Thus, such studies would represent the most important contributor to any risk assessment carried out on the compounds identified in this study.

In contrast to the ng/l to ug/l levels of Base Neutrals and VOCs, the dissolved organic carbon (DOC) levels are greater than 1,000 times this level (mg/l) for the first six samples collected and near 10 times more for the last two samples collected. Apparently, higher molecular weight chemicals are making up the bulk of the chemicals present. Probably, humic materials, algal metabolites, and oily materials are associated with the DOC. A new study is needed to assess the type of DOC present and its interaction with the trace organic chemicals present. There is no evidence on the toxicity of these currently uncharacterized organic compounds although concerns have been raised about the toxicity of products of chlorination from the humic materials.

A recent study by the City of Santa Monica focused on an evaluation of the use of ozone to reduce or mitigate the flow of chemical constituents into the Santa

Monica Bay via the Pico-Kenter storm drain (Ozone Disinfection and Treatment of Urban Storm Drain Dry-Weather Flows, Santa Monica Bay Restoration Project, June 1992). In addition there are two unpublished reports in the grey literature that have investigated chemical contamination of storm drain effluent. The first report by Young and Bodeen, EPA Report #600/X-91/030, April 1991, summarized data from a number of studies conducted between 1970 and 1985. DDT, dieldrin, and PCBs were observed in storm drain effluent from Ballona Creek. A second study by Schafer and Gossett, June 1988, entitled "Storm Runoff in Los Angeles and Ventura County" conducted for the California Regional Water Quality Control Board (LA region-SCCWRP C292) also identified DDT, PCBs, PAHs, and alkanes in storm drain effluent from Ballona Creek. It appears that little attention has been given to the findings from these studies. More recently, Fisher et al., (1993 as per Stentstrom, personal communication) in a paper being prepared for publication, have reported the presence of dioxins, furans, and polychlorinated naphthalenes in storm drain effluent entering the Santa Monica Bay.

This latter study has direct relevance to the results reported here insofar as the more complex chlorinated products, e.g., dioxins, are generally associated with PCBs. Further investigation of the concentration of both dioxins and PCBs is necessary to determine if both classes of compounds can be detected and quantified in the same storm drain effluent. Secondly, a study of this nature may also provide a basis to use one species of chlorinated hydrocarbon as a surrogate to estimate the concentration of other chlorinated compounds for purposes of exposure and risk assessment.

Volatile Organic Compounds

In this study, 33 volatile organic compounds were found in the effluent from the 5 storm drains. Five compounds, bromoform, chloroform, dibromochloromethane, dichloromethane(methylene chloride), and 4-methyl-2-pentanone had overall averages in the part per billion range (Table 13), whereas the concentration of the remaining compounds was in the part per trillion range. The largest number of compounds and the greatest concentrations were found at Ashland Avenue where 29 compounds were found. The concentrations of the trihalomethanes, bromoform, chloroform, and dibromochloromethane, and of methylene chloride, were 10.6, 4.1, 4.9, and 6.3 ppb at this site. The site with the fewest identified volatiles was Pico-

Kenter where 17 compounds were identified, of which only methylene chloride was greater than one ppb. There was significant variability between sites in terms of the concentrations of volatiles identified. For example, the concentrations of bromoform ranged from 10.6 ppb at Ashland to 0.2 ppb at Ballona.

These data are consistent with earlier work conducted by UCLA under contract to the City of Santa Monica where samples were collected from the Pico-Kenter storm drain. During a 1986 monitoring study conducted by Los Angeles County Public Works, the concentration of methylene chloride ranged from 0.3 to 1.6 ppb, while the 1989-90 City of Santa Monica study found a range of 0.03 to 18 ppb with an average of 1.4 ppb. This latest study found the concentration range to be 0.2 to 12.8 ppb with an average of 2.2 ppb. There are similar results for the other volatiles collected in the City of Santa Monica study and this study.

The compounds bromodichloromethane, bromoform, chloroform, 1,2-dichloroethane (ethylene dichloride), methylene chloride, trichloroethene (trichloroethylene-TCE), and tetrachloroethene (tetrachloroethylene or perchloroethylene-PCE), all of which were identified in effluent, are considered probable human carcinogens by EPA, and dibromochloromethane is considered a possible carcinogen. Benzene is recognized as a human carcinogen by EPA. The identified compounds, benzene, bromochloromethane, bromodichlorometh- ane, bromoform, chloroform, 1,1-dichloroethane, 1,2-dichloroethane, methylene chloride, trichloroethylene and perchloroethylene are classified as chemicals known to cause cancer under the State of California's Proposition 65 (The Safe Drinking Water and Toxic Enforcement Act of 1986). Carbon disulfide, chloroform, and toluene are listed under Proposition 65 as reproductive toxicants. Styrene oxide, a metabolite of styrene, is listed as a carcinogen under Proposition 65.

The trihalomethanes (bromodichloromethane, bromoform, chloroform) and the solvent, methylene chloride were found at all 5 sites. The trihalomethane concentrations identified in the study are well below those generally found in chlorinated drinking water. For example, the range of bromoform in U.S. surface waters ranges from 133 to 27,000 ng/L, and the level of chloroform ranges from 267 to 198,000 ng/L. The EPA National Organics Reconnaissance study (Preliminary Assessment of Suspected Carcinogens in Drinking Water, Report to Congress, U.S. Environmental Protection Agency, 1975) found the median levels of bromoform and chloroform in finished water to be 5,000 and 21,000 ng/L respectively. These values can be compared to the levels of bromoform (1,350 ng/L) and chloroform (1,150 ng/L) found in this study. The risk of cancer from ingestion of 2 liters of water/day containing 1,000 ng/L of bromoform has been estimated to be 5.6×10^{-8} and the corresponding risk for chloroform would be 4.3×10^{-8} (Froines et. al., 1991; "Evaluation of the Potential Health Risks Presented by Chemical Agents Associated with the San Diego Total Resource Recovery Program - Final Report", Prepared by the University of California, Los Angeles for the Western Consortium for Public Health, June 1991). The cancer risk from dermal contact with storm drain effluent containing trihalomethanes would be well below these values.

The VOCs identified in this study are toxic compounds, but they are not likely to exert their systemic or acute toxicity at the levels found in this study. Whether they would have adverse health effects in combination with other contaminants is not known. For example, it is not known whether trace quantities of organic solvents will facilitate absorption of larger organic molecules through dermal contact.

The data indicate that a number of volatile organic compounds recognized as being potential human carcinogens or reproductive toxicants were identified as being present in the effluent from the five storm drains. All the identified toxicants are capable of absorption through dermal contact as well as via inhalation or ingestion. The actual concentrations of the volatile organic compounds are relatively low as might be anticipated by the fact that these compounds are volatile and likely to evaporate from the storm drain effluent. In general these data and those derived from earlier studies demonstrate that small amounts of volatile organic compounds, some with well recognized toxicity/carcinogenicity, are routinely found in storm drain effluent.

The actual risk associated with any one compound would be low, for example, relative to drinking water standards. However, a quantitative risk assessment would evaluate risk as the sum of the individual risks, and the contribution of the volatile organic compounds would then be evaluated in terms of their contribution to the overall risk to the most highly exposed individual. It is beyond the scope of this project to conduct such a risk assessment, but it is likely that the risk from the volatile organic compounds would remain low relative to that derived from the phthalates, PAHs, PCBs, and chlorinated pesticides (see below).

If a State monitoring program were to be established for storm drains, the trihalomethanes, PCE, TCE, methylene chloride, benzene, and the dichloroethanes should be included as compounds of interest.

Base Neutral Compounds

The chemical compounds identified as "base neutral compounds" are organic compounds of higher molecular weight than the volatile organic compounds and as a result they generally have a lower vapor pressure and are significantly less volatile. They are often described as "semi-volatile compounds". The base neutral analysis includes compounds such as polycyclic aromatic hydrocarbons (PAHs), phthalates, phenols, some chlorinated aromatic compounds, and other miscellaneous compounds. These compounds are particularly important insofar as there is considerable evidence for their toxicity, and we anticipated finding significant quantities of a number of the chemical compounds.

Phthalates

Six phthalates were identified as being present in the storm drain effluent from all five sites. The most important compound identified and characterized was bis(2-ethylhexyl)phthalate. This compound was found in the greatest quantity of all the phthalates. Bis(2-ethylhexyl)phthalate (DEHP) is classified as a probable human carcinogen by U.S. EPA, the National Toxicology Program, and the International Agency for Research on Cancer (IARC). It has produced cancers in both rats and mice as a result of oral administration of DEHP. It is classified as a carcinogen and reproductive toxicant under Proposition 65 in California. It is considered a chemical teratogen and may damage the testes. Repeated exposure may result in neurological consequences. It has acute toxicity and produces irritation of the eyes, nose, and throat. Exposure to DEHP can occur through inhalation, ingestion, or dermal contact. The maximum contaminant level (MCL) established for DEHP in drinking water by EPA is 4 ppb. The California Ocean Water Plan limit is 3.5 ppb.

The average concentration found for DEHP in this study was 6.6 ppb. The greatest concentration, 14.8 ppb was found at Ashland and the lowest concentration identified was at Sepulveda with a value of 4.3 ppb. In our view, these concentrations of the suspected carcinogen require additional follow-up. Based on the concentration of DEHP and the other phthalates, phthalates should be considered candidates if a monitoring program is established.

This compound would not be expected to bioaccumulate although the data are far from complete in this respect. There is potential for dermal contact and absorption which is likely to be the source of greatest exposure.

The toxicity of the remaining phthalates has not been well characterized with the exception of butyl benzyl phthalate. EPA is considering establishing a drinking water standard for this compound. EPA considers it a possible human carcinogen on the basis of a chronic animal bioassay conducted by the National Toxicology Program where there was evidence for mononuclear cell leukemia in female rats.

The largest average concentration of butyl benzyl phthalate was found at Ashland, 1.5 ppb, and the lowest, 0.7 ppb, was at Centinela Avenue. The overall average concentration was 1.1 ppb.

The other phthalates have not been characterized with respect to their carcinogenicity or reproductive toxicity. No other chronic toxicity has been described. The phthalates appear to be genotoxic in some assays. For example, dimethyl phthalate and diethyl phthalate were found to be weak direct-acting mutagens in forward and reverse assays. Dimethylphthalate was active in the mouse lymphoma forward mutation assay in the presence of metabolic activation. Therefore, additional research must be conducted to evaluate their potential as human carcinogens. Their presence in storm drain effluent is a matter of concern even through the experimental data is regrettably limited.

Phthalates are widely used in industrial applications and are particularly widespread contaminants as a result of their use as plasticizers. They are likely to be found wherever there are plastics found, and generally are considered ubiquitous contaminants. The phthalates are often found as laboratory contaminants and any identification and quantification of these compounds always has a degree of uncertainty associated with their analysis. Further studies would be valuable to further confirm the concentrations of these substances in storm drain effluent.

VOL 12

1 8/7/8

Further attention to these compounds should be given in the development of any monitoring protocol.

Polycyclic Aromatic Hydrocarbons

PAHs represent one of the most important groups of chemical compounds found in this study. There were 17 PAHs identified in the storm drain effluent: acenaphthene, anthracene, benz(a)anthracene, benzo(b)fluoranthene, benzo(k)fluoranthene, benzo(g,h,i)perylene, benzo(a)pyrene, chrysene, dibenzo(a,h)anthracene, dibenzofuran, fluoranthene, fluorene, indeno(1,2,3,4-c,d)pyrene, 2-methylnaphthalene, naphthalene, phenanthrene, and pyrene (Table 20). The average concentrations ranged from 8 ng/L for dibenzofuran to 513 ng/L for chrysene. The concentration of benzo(a)pyrene was 400 ug/L.

The greatest concentration of PAHs was found at Sepulveda where the benzo(a)pyrene, chrysene and pyrene concentrations were 1,803 ng/L, 2,016, and 956 ng/L respectively. These values may be compared to the California Ocean Plan guidelines which seeks to limit PAH concentrations to 8.8 ng/L. These comparisons are made for illustrative purposes only. The comparisons are made without considering dilution of effluent in ocean water, and we hesitate to make any quantitative comparison between the standards and our findings.

The concentrations of PAHs identified in this study are lower than those found in the 1989-90 investigation of Pico-Kenter storm drain by the City of Santa Monica. There is no obvious explanation for the differences. The laboratory conducting the analyses for both studies was the same - UCLA.

Seven of these compounds, benz(a)anthracene, benzo(b)fluoranthene, benzo(k)fluoranthene, benzo(a)pyrene, chrysene, dibenzo(a,h)anthracene, and indeno(1,2,3,4-c,d)pyrene are considered possible human carcinogens by EPA. All seven are classified as compounds known to cause cancer under California's Proposition 65, and an eighth compound, fluoranthene, is also so named. Five of the seven compounds were identified at all five storm drain sites. Two compounds, dibenzo(a,h)anthracene and indeno(1,2,3,4-c,d)pyrene were found at two and three sites, respectively. The primary health risk that would be associated with PAHs in water would probably derive from dermal contact. The carcinogenicity of this class of compounds was originally recognized as a result of studies which focused on dermal contact.

The information on the toxicity/carcinogenicity of the other PAHs is more equivocal than for the 7 identified above, but there is evidence that these and other PAHs not sampled in this study are carcinogenic. Of those not sampled for in the study, nitro-PAHs are found in important quantities in ambient air in southern California, and they are considered more carcinogenic than PAHs. For example, 6-nitrochrysene, a product of nitration of chrysene in the atmosphere, is considered an order of magnitude more potent than benzo(a)pyrene. We were not able to sample for these substituted PAHs nor other more polar PAHs. The dibenzopyrenes were also not sampled for in this study, and they are considered by the State of California to be approximately ten times more potent carcinogens than benzo(a)pyrene. Thus, it is possible that unsampled PAHs may be present in storm drain effluent. Further studies to enlarge the scope of the PAH characterization are necessary and important.

The PAHs found in this study are partitioned between water and sediment in the water. The PAHs are usually associated with the sediment phases. The amount that would be available for dermal absorption to a swimmer/surfer/wader is not well understood. There are very few studies that have characterized on a quantitative basis the desorption of contaminants from suspended sediments into ocean water when a contaminated sediment comes in contact with uncontaminated ocean water. Further studies are necessary to determine the kinetics of the desorption or release of PAHs from sediment in storm drain effluent to ocean water.

The following studies should be conducted to improve our understanding of the processes influencing the transport and fate of sparingly soluble organic pollutants such as PAHs in flowing surface waters and estuarine systems.

1. Further studies to characterize the nature of the suspended solids (SS) and dissolved organic matter (DOM) in each storm drain.
2. Improved definition of the equilibrium state of the storm drain systems.
3. Studies to determine the kinetics of sorption and desorption using the SS/DOM characteristic of each venue and characterization of the dry weather and rainfall runoff.

There are a wide range of sources of PAHs to the storm drains and it was not surprising to find them in significant concentrations. PAHs do not derive from a point source. They represent products of an urban society which emphasizes the use of petroleum based transport. They are often products of incomplete combustion and are ubiquitous in the environment. They may emanate from exhaust, tires, used motor oil, or other transport-related processes as well as from industrial sources which create products of incomplete combustion. PAHs represent important toxic air contaminants and are particle associated. This study examined a relatively small number of PAHs. In general, PAHs are widely recognized as being carcinogenic and the finding of meaningful quantities in storm drain effluent is a matter for further consideration. They have been found in other studies of storm drain effluent in the U.S. and abroad.

The primary issue with PAHs is not whether they are going to be found, but the degree of contamination, the necessity of monitoring for their presence, and ultimately the control of their releases to the Bay. In a society with an emphasis on petroleum based products, the control of releases to the Bay may prove difficult, but it requires attention since there are potential health and environmental consequences from the contamination by PAHs. The scope of any monitoring program will of necessity follow additional characterization of the number and quantities of PAHs not sampled for in this study. It would be useful to determine if a surrogate PAH could be established that would enable estimation of a wide range of PAHs based on the assessment of a few.

Other Carcinogens Identified

Azobenzene, 1,4-dichlorobenzene, N-nitrosodiphenylamine, and N-nitrosodi-n-propylamine were identified in some storm drains. These compounds are considered to be carcinogens under Proposition 65 by the State of California. They are not regulated by U.S. EPA in the context of drinking water. With the exception of 1,4-dichlorobenzene, EPA classifies these compounds as probable human carcinogens. Azobenzene and 1,4-dichlorobenzene were identified at all 5 sites. The concentrations of these compounds were generally low, and their contribution to the overall risk associated with storm drain effluent would probably be insignificant in

VOL 12

1/8/81

relation to the PAHs, phthalates, and chlorinated organic compounds such as the chlorinated pesticides, PCBs and dioxins.

Phenols

Seven phenols were identified as being present in storm drain effluent in this study. Phenol and 2-nitrophenol were found at all five sites, 4-methyl phenol at 3 sites, and 4-chloro-3-methyl phenol, 2-methyl phenol, 4-nitrophenol, and 2,4-dimethyl phenol were found at one site. 2-Methyl phenol is classified as a possible human carcinogen by EPA. All these phenols are known to possess acute toxicity. Acute toxicity would not be anticipated at the levels found in the study, but acute toxicity could be anticipated when phenols are combined with the myriad of other chemicals identified in the study depending on the degree of dilution by ocean water. There is less evidence of their capacity to produce chronic toxicity although the data are somewhat limited. There is evidence from animal studies of reproductive toxicity associated with exposure to phenols, and phenol is classified as a reproductive toxicant under Proposition 65. This class of compounds would be important in any monitoring program that was established as a result of this and other studies.

Pesticides and Polychlorinated Biphenyls

The evaluation of pesticides and polychlorinated biphenyls was not a central feature of this investigation. However, selected samples were analyzed for pesticide and PCB content. The organophosphate pesticide diazinon was identified in water from Centinela, Ashland, and Pico-Kenter, while dimethoate was found at Ballona (Table 23). These are commonly used pesticides, and it is not surprising that they were identified.

We recommend that monitoring for pesticides be considered in the future, although until further studies are conducted to further characterize pesticide releases, we would not recommend routine monitoring. We have no direct knowledge of the persistence of these pesticides in aqueous media such as the Santa Monica Bay.

The finding of alpha-chlordane, dieldrin and PCBs, the latter especially in the Ashland drain, represents an important finding in this study (Table 24). These substances are of particular significance because of their potential toxicity, persistence, and potential for bioaccumulation in the environment. This contracted study did not include the evaluation of the storm drain effluent for PCBs and chlorinated pesticides, but we chose to investigate them, albeit in a preliminary manner, to expand the scope of the investigation. Earlier studies of Ballona had identified PCBs in effluent from that storm drain. The source of the PCBs is not apparent, but it seems likely they are products of combustion of compounds containing chlorine and carbon or derive from the PCB-associated aerosols from the ambient air environment. Our findings clearly indicate the need for follow-up studies to further characterize the releases of these compounds to the Santa Monica Bay.

PCBs are considered to be probable carcinogens by EPA and IARC. They are classified as 2A ("probable carcinogen") by IARC on the basis of limited human evidence and sufficient animal evidence. PCBs are listed as chemicals known to cause cancer and reproductive toxicity under Proposition 65. In addition to PCBs the analysis identified the chlorinated pesticides, chlordane and dieldrin. Chlordane is considered possible carcinogens by IARC. Chlordane and dieldrin are listed as carcinogens under Proposition 65 in California.

Some PCBs were identified in all the storm drains although the vast majority was found at Ashland. The concentrations of the PCBs identified in the study may be compared to the California Ocean Plan for purposes of discussion. The California Ocean Plan limit for PCBs is 0.019 ng/L. Many of the PCBs identified in this study exceed that value by a factor greater than a thousand. For example, the total PCBs found in the Ashland drain was 451 ng/L (Table 24). Assuming a background of approximately 125 ng/L, the concentration of identified PCBs is approximately 325 ng/L which is 17,000 times the California Ocean Plan limit. These values must be interpreted very carefully because the actual quantification of the PCBs is incomplete especially given the background laboratory contamination identified in the study, and the appropriate level of dilution to be assumed in going from the storm drain to ocean water is not obvious. We conclude that PCBs were identified in the storm drain effluent and the concentrations in at least one storm drain was a matter requiring followup. PCBs are found in aerosols in the ambient air, and the contribution of airborne PCBs to the bay and storm drains requires further followup studies.

A quantitative risk assessment would combine the health risk from the chlorinated pesticides, PCBs, PAHs, volatile organic compounds, phthalates, and other identified carcinogens and toxicants in order to develop a total risk characterization and to determine the relative risks from each constituent. This represents a major undertaking that does not lie within the scope of this project but is an essential element of any future research. A quantitative risk assessment methodology should be developed to investigate the risk to swimmers/surfers, waders as well as addressing the consequences of the bioaccumulation of toxicants in fish and other sea life. The latter exposure, bioaccumulation in sea life, may represent the most important route of exposure for PCBs whereas the PAH exposure via dermal contact may be most important for that class of compounds. Toxicity studies that examine the impact of the release of toxicants on sea life and the ecology of the Bay are clearly desirable.

Non-target Chemicals

The focus of this study was on the identification and characterization of volatile organic compounds and semi-volatile organic compounds. During the course of the study a large number of these substances was identified and quantified in the effluents from the five storm drains. In addition to the compounds that were originally examined using the EPA analytical methodology, a large number of non-target chemicals was also identified. These are listed in Table 22 and 25. Characterization of the toxicity of these compounds is almost non-existent. Thus, we do not know whether the parent compounds or their breakdown products constitute a health risk to humans or may have adverse consequences to marine life or the environment at their concentrations in storm drain effluents. Some of the compounds are toxic, but whether the concentrations of these agents is significant remains to be determined. However, this preliminary work demonstrates that the original focus on specific substances may have been too limited, and that further studies in the future to identify and characterize these non-target substances may be a reasonable priority as California moves forward to develop a monitoring plan and control program for its storm drains.

VOL 12 1/8/84

CONCLUSIONS

This pilot study has identified and quantified the existence of a large number of organic compounds in five storm drains. The study has demonstrated that the problem of chemical contamination is not limited to any single storm drain and suggests the need to investigate other storm drain effluent to the Santa Monica Bay.

The study also demonstrated that many of the compounds identified are widely recognized as being probable or possible carcinogens, reproductive toxicants, or having other chronic and acute toxicities. In some cases, for example, volatile organic compounds, the concentrations of the most toxic of the compounds, namely the trihalomethanes, benzene, methylene chloride, perchloroethylene, and trichloroethylene were very low, and reflected the high volatility of the compounds combined with the high surface area for evaporation. In other cases the concentrations of the toxicants appeared to be more substantial. The concentrations of certain phthalates, PAHs, chlorinated pesticides and PCBs appear to be a matter of concern.

We did not attempt to conduct a quantitative risk assessment, because there were too many uncertainties in the available data to justify actual calculations of risk. For example, we were aware that PAHs are associated with sediment in the storm drain effluent. Whether those PAHs are desorbed from the sediment when the storm drain reaches the Bay is a question that will require additional investigation. It is likely that the PAHs will remain adsorbed to sediment even while some partition to the ocean water and become available for dermal contact with a human or other sea life. A series of studies are required to determine the desorption of contaminants from the suspended sediment. Second, we did not have an estimate of the dilution that would occur in going from the storm drain to the Bay. Finally, the permeability characteristics of some of the toxicants are incompletely understood. The development of methodology to conduct a quantitative risk assessment should be a priority in any follow-up studies. These studies could make use of EPA guidelines on the estimation of dermal uptake, and it is possible to develop a number of different exposure scenarios that would result in a range of risk estimates. Subsequent analysis would also need to include an estimation of the uncertainty in the range of risk values.

In addition to the limitations described above the data are not available to describe the mass flux under dry and wet weather flows and to use these findings as a model. We have only studied dry weather flows, and wet weather flows are necessary to broaden the scope of the data available to characterize the releases to the environment. We lack information on flow rates, currents, dilution and dilution speed into the Santa Monica Bay. Some of these issues have been pointed out by Eisenberg, Olivieri, & Associates (EOA) in their initial document to American Oceans, and these remarks and the others raised by EOA deserve further attention.

Throughout this discussion section we have made numerous recommendations for additional studies, and we have attempted to identify those compounds which would form the basis for an ongoing monitoring program. These recommendations should now be combined with those developed by EOA in their preliminary report to develop a more comprehensive strategy for addressing the flow of chemical contaminants into the Santa Monica Bay. Previous studies in the grey literature have also identified similar compounds to those described here, although those reports seem to have been given little attention. It is important that the results of all the studies be combined and both a long term and short term strategy be developed to address the consequences of storm drain runoff into the Santa Monica Bay.

In this study we have emphasized those compounds for which there is ample evidence for chronic toxicity associated with long term exposure to the toxicants in question. We have not addressed the issue of acute toxicity associated with these same and other toxicants. There have been numerous reports of acute toxicity associated with contact with water in the Bay and whether these illustrations of acute toxicity are derived from bacterial contamination or chemical toxicity or both is unclear.

It is not apparent whether the concentrations of chemical contaminants identified in storm drain effluent in this and other studies meet or exceed water quality objectives developed by the State of California or local jurisdictions. With the exception of the California Ocean Plan guidelines, there appear to be no defined objectives which we could use for comparison purposes. If these values exist we could then determine if the concentrations are greater than the water quality objectives, how much are they exceeded, and how frequently they are being exceeded. The approaches used by these various agencies in the setting of water quality objectives and how are they evaluated, enforced, or reviewed is a matter of importance from the standpoint of public policy. The EOA report discusses these and other issues in greater detail, but the fundamental question is how government agencies are addressing the monitoring and control of the flow of toxic chemicals into the Santa Monica Bay and what additional studies are relevant to provide an improved data base for policy decisions concerning the need to protect the public health and the environment.

Finally, the ultimate issue is how are we going to protect the Santa Monica Bay from chemical contamination? These are not easily answered questions, but it is clear that we need greater attention to identifying the scope and magnitude of the potential problems, conducting important scientific studies to better and more thoroughly characterize the issues before us, and to develop the means to monitor and control the effluent into the Bay. As stated at the outset of this discussion, the storm drains that empty into the Santa Monica Bay are an important source of chemical contaminants that may have adverse effects on humans who use the Bay for recreation, food, and other purposes as well as having negative consequences for marine life and the overall natural environment. The Santa Monica Bay is a natural resource of untold beauty and benefit to the citizens of Southern California, and we believe that continued effort is necessary to maintain this environment from the consequences of chemical pollution. The preservation of this natural resource should have the highest priority for our officials and scientists. This study reported here represents only a first step in an effort to develop a series of investigations that will enable State and local officials to take proactive steps in terms of monitoring and control to limit chemical releases tc the Bay.

RULES FOR QUANTITATIVE CALCULATIONS -

1) ASSUME 100% EXTRACTION OF 1 L Of WATER INTO 0.5 ML SOLVENT FOR ALL BLANKS.

THIS IS NANOGRAMS TOTAL FOR MDL.

2) IF BLANKS ARE >MDL, THEN DETERMINE THE AVERAGE BLANK VALUE AND RANGE OF BLANK VALUES.

REPORT SAMPLE VALUE IF SAMPLE VALUE IS >MAXIMUM BLANK VALUE. THIS IS THE CONSERVATIVE APPROACH.

3) IF THE SAMPLE VALUE IS >MDL, THE VALUE ALSO MUST BE >MAXIMUM BLANK VALUE TO BE REPORTED.

4) IF THE SAMPLE VALUE IS <MDL AND THERE IS NONE FOUND IN A BLANK, IT IS REPORTED AS <MDL.

5) IF THE SAMPLE VALUE IS <MAXIMUM BLANK VALUE, IT IS REPORTED AS <MDL AS IT MAY BE IN THE SAMPLE.

* Average of 4 system blank samples and 5 suspended sediment sample blanks.

RULES FOR QUANTITATIVE CALCULATIONS -

1) ASSUME 100% EXTRACTION OF 1 L OF WATER OR 1 GRAM OF SUSPENDED SEDIMENT(SS) INTO 0.5 ML SOLVENT FOR ALL BLANKS
THIS IS NANOGRAMS TOTAL FOR MDL. THE WEIGHT OF SS PRESENT WERE 0.003 TO 0.0 GRAMS.
2) IF BLANKS ARE >MDL, THEN DETERMINE THE AVERAGE BLANK VALUE AND RANGE OF BLANK VALUES
REPORT SAMPLE VALUE IF SAMPLE VALUE IS >MAXIMUM BLANK VALUE. THIS IS THE CONSERVATIVE APPROACH.
3) IF THE SAMPLE VALUE IS >MDL, THE VALUE ALSO MUST BE >MAXIMUM BLANK VALUE TO BE REPORTED.
4) IF THE SAMPLE VALUE IS <MDL AND THERE IS NONE FOUND IN A BLANK, IT IS REPORTED AS <MDL.
5) IF THE SAMPLE VALUE IS <MAXIMUM BLANK VALUE, IT IS REPORTED AS <MDL AS IT MAY BE IN THE SAMPLE

Table III. 3

WATER BLANKS - BASE NEUTRAL ANALYSIS

SAMPLE NUMBER	MDL	F8237	F8221	AVG.	RANGE
		Field Blank	H20,Tv1 Blank		
DATE		DATE ??	12/10/93		
Volume of Solvent Extract		0.5	0.5		
Volume of Water		4	4		
CHEMICAL NAME	ng/L	ng/L	ng/L	ng/L	ng/L
Diethyl Phthalate	60	165	122	143	122-165
Di-n-Butyl Phthalate	60	1958	1772	1865	1772-1958
Butylbenzyl Phthalate	300	1082	2775	1928	1082-2775
Bis(2-Ethylhexyl) Phthalate	48	5110	4496	4803	4496-5110
Di-n-Octyl Phthalate	64	114		114	-

1) FIELD BLANK - LABORATORY MILLI-Q WATER IS POURED INTO A SAMPLING BUCKET IN THE FIELD AND TREATED AS A REAL SAMPLE.

2) WATER BLANK - LABORATORY MILLI-Q WATER IS TAKEN TO THE FIELD AND RETURNED TO THE LAB. THE SEALED WATER BOTTLE IS THEN RETURNED TO THE LAB FOR ANALYSIS.

3) THESE SAMPLES WERE NOT FILTERED BEFORE EXTRACTION AND REPRESENT THE COMPOUNDS FOUND IN THE LABORATORY DISTILLED WATER.

TABLE III-4

Preface

The Santa Monica Bay is an extraordinary natural resource. It is home to unique wetland, sand dune and open ocean ecosystems that support a rich diversity of wildlife and serve as migration stopovers for marine mammals and birds. The Bay's beaches are invaluable recreational resources and important sources of revenue for the region. Yet, the Bay is at risk. It has been stressed by the daily activities of a region where nearly nine million people live within an hour's drive of its shores. Here, as elsewhere in the United States, a burgeoning human population brings with it increasing pollution and causes impacts which threaten the health of coastal waters.

The Santa Monica Monica Bay Restoration Project (SMBRP) was formed in 1988 under the National Estuary Program in response to the crucial problems of the Bay. The SMBRP was charged with the responsibility of assessing the Bay's problems, developing solutions and putting them into action. Under a five year development process outlined in the Clean Water Act, a plan of action was structured with the involvement of talented and dedicated individuals representing a diverse group of stakeholders organized into SMBRP's Management Committee, Technical Advisory Committee and Public Advisory Committee. The Santa Monica Bay Restoration Plan is the product of this partnership of government, environmentalists, scientists, industry and the general public.

This Public Summary brings together the scientific characterization of the Bay described in the SMBRP's "State of the Bay 1993" report and other technical investigations, along with the Project's recommendations for action that comprise the Bay Restoration Plan. With over 200 actions, the Plan addresses the need for pollution prevention, public health protection, habitat restoration and comprehensive resource management. Implementing the Bay Restoration Plan will fulfill the goal of a Santa Monica Bay that is protected and restored as a valued resource for people, and as a healthy environment for the fish, plants and wildlife that live in its waters and along its shores.

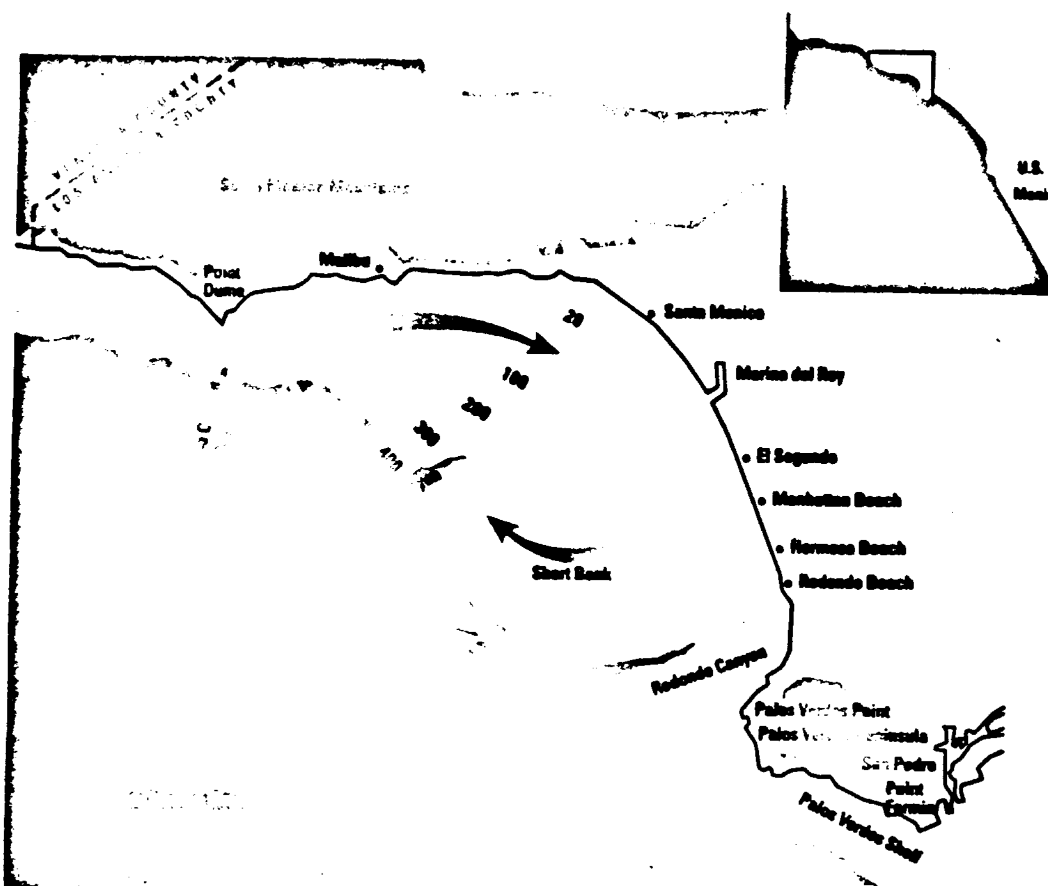
Where Land Meets Sea

In Southern California, as everywhere on earth, life begins with water. The history of our region is the history of water: water's action upon the land as it moves from clouds to highlands to the sea; water's nurturing of life from microscopic to human to gray whales and sequoias; and the actions of humans to obtain water and to control its course.

In the beginning, to paraphrase the sacred stories of many cultures, the earth was covered by water. This was about 5 billion years ago. Over the next few billion years, land rose from the waters, and took its time gliding, sliding and colliding until it assumed its present configuration.

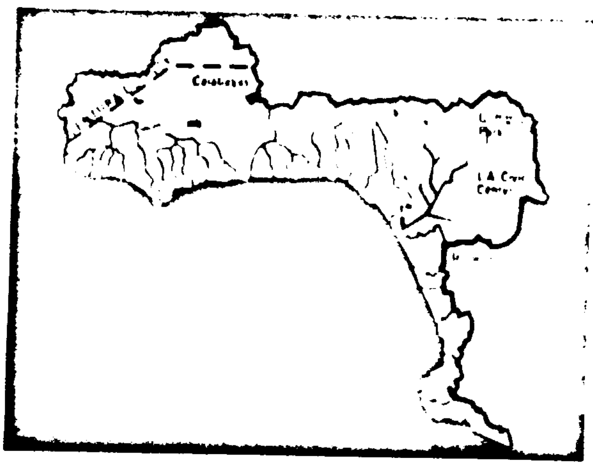
Today's Santa Monica Bay is a relatively small feature in a larger geographic region – the offshore, submerged lands from Point Conception, California to

Santa Monica Bay and the Southern California Bight (inset).



Cape Colnett, Baja California and 100 miles seaward to the Patton Escarpment (ridge). This larger region is known as the Southern California Bight[1], the seaward boundary of which is the California Current.

Southern California's mountainous land form is largely the result of the slow grind of the Pacific tectonic plate against the North American tectonic plate, with the San Andreas fault marking the point of friction between the two. Sediments[2] eroding from four surrounding ranges (the Santa Monica, San Gabriel, San Bernardino and Santa Ana Mountains) over the last two million years have filled the habitable portion of the Los Angeles Coastal Plain to its present elevation, near sea level.



The 414-square-mile Santa Monica Bay Watershed.

Santa Monica Bay is the submerged portion of the Los Angeles basin. It has a gently sloping (about 0.5) continental shelf which extends seaward to the shelf break about 265 feet underwater, then drops more steeply to the floor of the Santa Monica Basin, at about 2,630 feet. The shelf ranges in width from a few hundred yards to about 12 miles. It is broadest off El Segundo, narrowest off Redondo Beach, and is transected by three submarine canyons: Dume Submarine Canyon off Point Dume; Santa Monica Submarine Canyon seven miles offshore of Ballona Creek; and Redondo Submarine Canyon, a few hundred yards off King Harbor.

The Bay floor is of two types, hard-bottom and soft bottom, with different kinds of plant and marine life considered native to each type. Sea bottom is formed by the movement and strength of currents, although the proximity of the sediment source can be important. Coarse sand and gravel are found under swiftly moving water; fine silt and clay settle to the bottom in quiet water. In most parts of Santa Monica Bay the sea floor consists primarily of fine to moderately coarse sediments, though some areas have "hard" bottoms of bedrock, gravel, and phosphorite.

The Watershed

The area that drains naturally into the Bay—the Bay watershed[3]—follows the crest of the Santa Monica Mountains on the north from the Ventura-Los Angeles County line to Griffith Park. From there it extends south and west across the Los Angeles plain to include the area east of Ballona Creek and north of the Baldwin Hills. South of Ballona Creek the natural drainage is a narrow coastal strip between Playa del Rey and Palos Verdes.

Less than 300 years ago, much of what is now the City of Los Angeles was a vast rolling plain of grassland scattered with oak trees. In low-lying areas

[1] bight: a. A bend or curve, esp. in a shoreline. b. A wide bay formed by such a bend or curve.

[2] sediment: Material that settles to the bottom or is suspended in water.

[3] watershed: The region draining into a river, river system, or body of water.

VOL 12

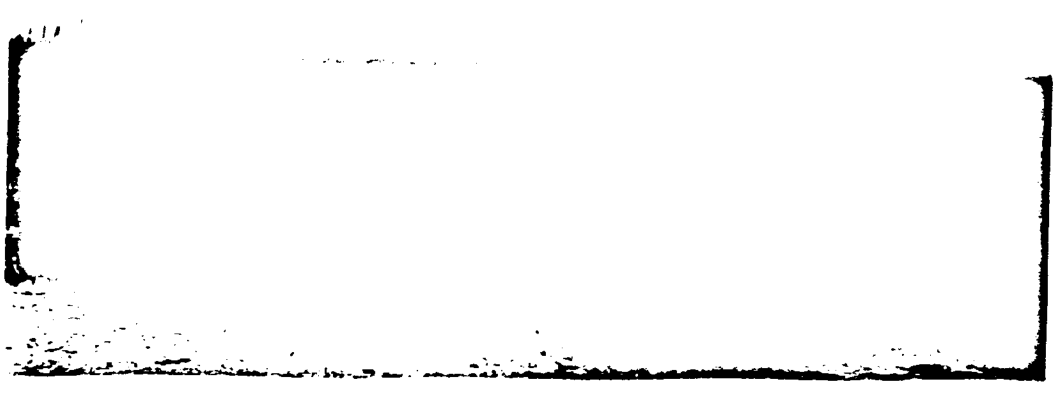
between hills and bluffs, a major river (now called the Los Angeles) and dozens of lesser streams meandered through broad valleys to the sea. They carried so much fresh water to the sea that when the explorer Juan Cabrillo first anchored in San Pedro Bay in 1542, he could haul fresh water, which floats on heavier seawater, aboard ship with a bucket.

Sprinkled across the plain to the coast were eight different kinds of wetlands, vital ecosystems that provided flood control, groundwater recharge, sediment retention and wildlife habitat. There were riverside forests of sycamore, cottonwood and alder, interspersed with marshes, ponds and lakes, and impenetrable thickets of willow, wild grape, and brambles. The highest points of land were the peaks of the Baldwin and Palos Verdes hills. Chaparral vegetation covered the north-facing slopes of these peaks, while oak savannah blanketed the drier south-facing slopes. In even drier spots, edible yucca grew, and wild sage.

The coastal areas we've given names like Malibu and Santa Monica and El Segundo were a mixture of sand dunes, sagebrush, scrub, fresh and saltwater marshes, and lagoons. These areas teemed with life, from the microscopic to resident and migratory birds, to dozens of kinds of mussels, to fish such as tuna, trout, halibut, ling-cod and sardine. Thousands of porpoises, sea lions, sea otters and seals dwelt in colonies along the coast and on the offshore islands.

In Southern California, rainfall varies with elevation; the coastal plain can receive as few as 12 inches a year, on average, while the nearby San Gabriels

Duck hunting in the coastal marshes south of Santa Monica, circa 1903.

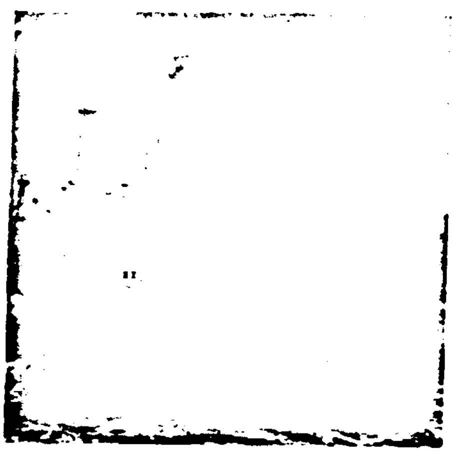


1 8263

can receive as much as 40. In the winter, much of the coastal plain was a vast lake, stretching from the silt-rich highland of present-day Culver City west to the ocean; and freshwater springs bubbled year-round in modern Beverly Hills.

During heavy rains, torrents from the mountains would flood the area, and the swollen Los Angeles River would change its course, sometimes emptying into Santa Monica Bay at Ballona Creek, sometimes emptying into San Pedro Bay, always depositing rich, dark soil across the plain.

Venice-Del Rey oil field, circa 1930.



The land absorbed more water in those days, before humans laid a concrete skin over it; and it supported a wider variety of plants and animals, both year-round and seasonal. The region's larger animals included deer, antelope, coyote, mountain lion, and bear.

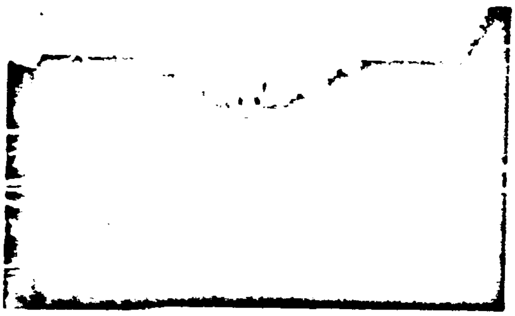
It was this ability to support life that made the coastal plain so desirable, and more exploitable than the rugged northern portion of the watershed, where the mountains drop precipitously to the sea. The plain's suitability for agriculture and grazing led to the first of many waves of human activity that has transformed the southern portion of the watershed into one of the world's most populous urban areas.

The Urban Era

The first of these modern-day human waves were Spanish settlers who occupied the land of the native Chumash and Gabrieleno peoples and carved the plain into ranchos for cattle and for crops like grapes, corn, beans, barley and wheat. To support these farms, they dammed the rivers and streams that fed the *cienegas*, or swamps. Many low-lying flood plains were diked and free-flowing watercourses channelized with crudely dug ditches. Not only did the course of the waters change, and the wetlands disappear, but a process was begun that would change the nature of the coastal beaches, by thwarting the sediment flows that replenish beach sands.

After the plain was sectioned for ranchos, it was bisected again and again by wagon roads. Later, railroads were built to carry the crops and the cattle east and to bring more settlers west. To complement the railroad, the Anglo settlers, who had wrested political control from the Spanish, envisioned a major port, first at Ballona, then at Wilmington; thus many more acres of coastal wetlands disappeared in the service of commerce.

In 1892, oil was discovered. It seemed, for a time, that every back yard had a derrick. More wetlands were drained and filled to support infrastructure for the booming industry, an industry that didn't peak until the 1920's. Constant spills further polluted and destroyed the freshwater wetlands. Echo Lake, near downtown Los Angeles, caught fire and burned for three days after one oil spill. The coastal regions near the salt water marshes like Ballona and Del Rey Lagoons were particularly rich, and derricks sprung up there in numbers to rival (and choke off) the sea grasses.



Gondoliers along Aldebaran Canal, now Market Street, 1908.

The coast also became desirable real estate, as a network of electric trolley cars was developed to bring people to newly-subdivided Playa del Rey, Santa Monica, and Venice. The construction of the latter community, begun in 1905, consumed 160 acres of marsh as cigarette magnate Abbott Kinney sought to realize his dream of reproducing the ancient Italian city of canals on the Southern California coast. It was an era when anything seemed possible, and profitable.

By 1915, the new residents of the coastal plain had enough of the flooding that plagued them during wet years. They formed the Los Angeles County Flood Control District to begin transforming the first crude rancho ditches into a system of storm drains, concrete ditches, covered culverts, and corrugated pipes that today stretches over 5,000 miles and carries millions of gallons of water each day (billions on rainy days) directly to the ocean.

What builders and planners of the growing flood control system may not have taken into account was how these channels would also speed the flow of man-made pollutants to the sea. Los Angeles was in a hurry in those days, not only to stop the devastation caused by floods, but to capitalize on the nation's growing fascination with sunny California by building an urban infrastructure that would accommodate massive immigration.

The "taming" of the Los Angeles River and its tributaries was finally accomplished after World War II, and most of our wetlands were history. Today only five percent remains of what existed 300 years ago.

The Values of the Bay

Healthy Bay, Healthy City

As humans tamed the land and the rivers and the streams, first on the coastal plain, then gradually across the more rugged parts of the watershed, the impact of "civilization" was immediately visible. But each new wave of immigrants also saw the region through new eyes; they did not know what life forms their predecessors had displaced. As the immigrants lived their dreams, their actions had an equal, but less visible impact on the Bay waters. That impact will be discussed at length in later chapters; first, it's important to place the value of the Bay in context, and to define what we mean by the *values* of the Bay.

Consider a tide pool. While nine million humans live within an hour's drive of the Bay, more than nine million living things, visible and invisible, can be found in a single mile-long stretch of rocky shoreline. The rocky shore at low tide is possibly the most prolific life zone in the world—a roiling Gold Rush-era fantasy of interspecies homesteaders, claim jumpers and tide pool poachers.

VOL 12

18265

[illegible] DIVERSITY

Science professor Edward O Wilson writes of the importance of diversity in his book, The Diversity of Life[c]. He begins by asking, "What difference does it make if some species are extinguished, even if half the species on Earth disappear?" He then answers

"Let me count the ways. New sources of scientific information will be lost. Vast potential biological wealth will be destroyed. Still undeveloped medicines, crops, pharmaceuticals, timber, fibers, pulp, soil-restoring vegetation, petroleum substitutes, and other products and amenities will never come to light. It is fashionable in some quarters to wave aside the small and obscure, the bugs and weeds....

The life-sustaining matrix is built of green plants with legions of microorganisms and mostly small, obscure animals—in other words, weeds and bugs. Such organisms support the world with efficiency because their diversity allows them to divide labor and swarm over every meter of the earth's surface. Field studies show that as biodiversity is reduced, so is the quality of the services provided by ecosystems; the descent can be unpredictably abrupt. As extinction spreads, some of the lost forms prove to be keystone species, whose disappearance brings down other species and triggers a ripple effect among the demographics of the survivors. The loss of a keystone species is like a drill accidentally striking a power line. It causes lights to go out all over."

Not only is every square inch of tide pool used by some plant or animal, but the competition for attachment sites is so keen that residents set up housekeeping on top of each other.

So what? If we've never seen a tide pool, never watched a saddleback or bottlenosed dolphin arc through the waters off Topanga Beach, never swum in the water, or eaten a California halibut, or worked in the tourist industry; of what possible value is the Bay to us?

A healthy Santa Monica Bay helps sustain life in Los Angeles County. It is a building block upon which many other values important to the people of Los Angeles—industry, tourism, recreation, aesthetics—depend. At a time when Southern California must cope with a plague of critical social and economic challenges, the health of Santa Monica Bay is far from a luxury. Its waters are where much of life in this region begins.

Oxygen: A Source of Life

Bay waters are a major source of oxygen, without which there is no human life. Because the world's seas produce more than 40 percent of the world's oxygen, the Pacific Ocean is like a giant rainforest off our coast, creating oxygen in incredible quantity as a byproduct of photosynthesis[a].

The ocean water that circulates through the Bay every three to four days contains, within about the first 150 feet, microscopic plants called phytoplankton[b] upon which the rest of life, from the smallest fish to the largest humans, depends for food and oxygen. The phytoplankton use sunlight, which penetrates to a depth of approximately 150 feet when the water is clear, to create food and oxygen by photosynthesis. All living things create some "waste" products, and the waste product of plants is the oxygen necessary to animal life. If the ocean's phytoplankton die, humans will eventually follow.

Habitat and Species Diversity

The Bay also provides habitat, a home to such a diversity of species—at least 5000 at last count—that some are not yet catalogued, classified or named.

Why is diversity important? It's another building block supporting human life.

The diverse ecosystems in the Santa Monica Bay watershed include the land habitats previously mentioned, from semi-wilderness areas in the Santa Monica Mountains that still shelter coyote and wild rabbits, to wetlands which support

[a] photosynthesis: the production of organic substances, chiefly sugars, from carbon dioxide and water occurring in green plant cells supplied with enough light to allow chlorophyll to aid in the transformation of the radiant energy to a chemical form.

[b] phytoplankton: Minute plant life that lives in water. Similar minute animal life is called zooplankton. Zooplankton feed on phytoplankton and, in many cases, on each other.

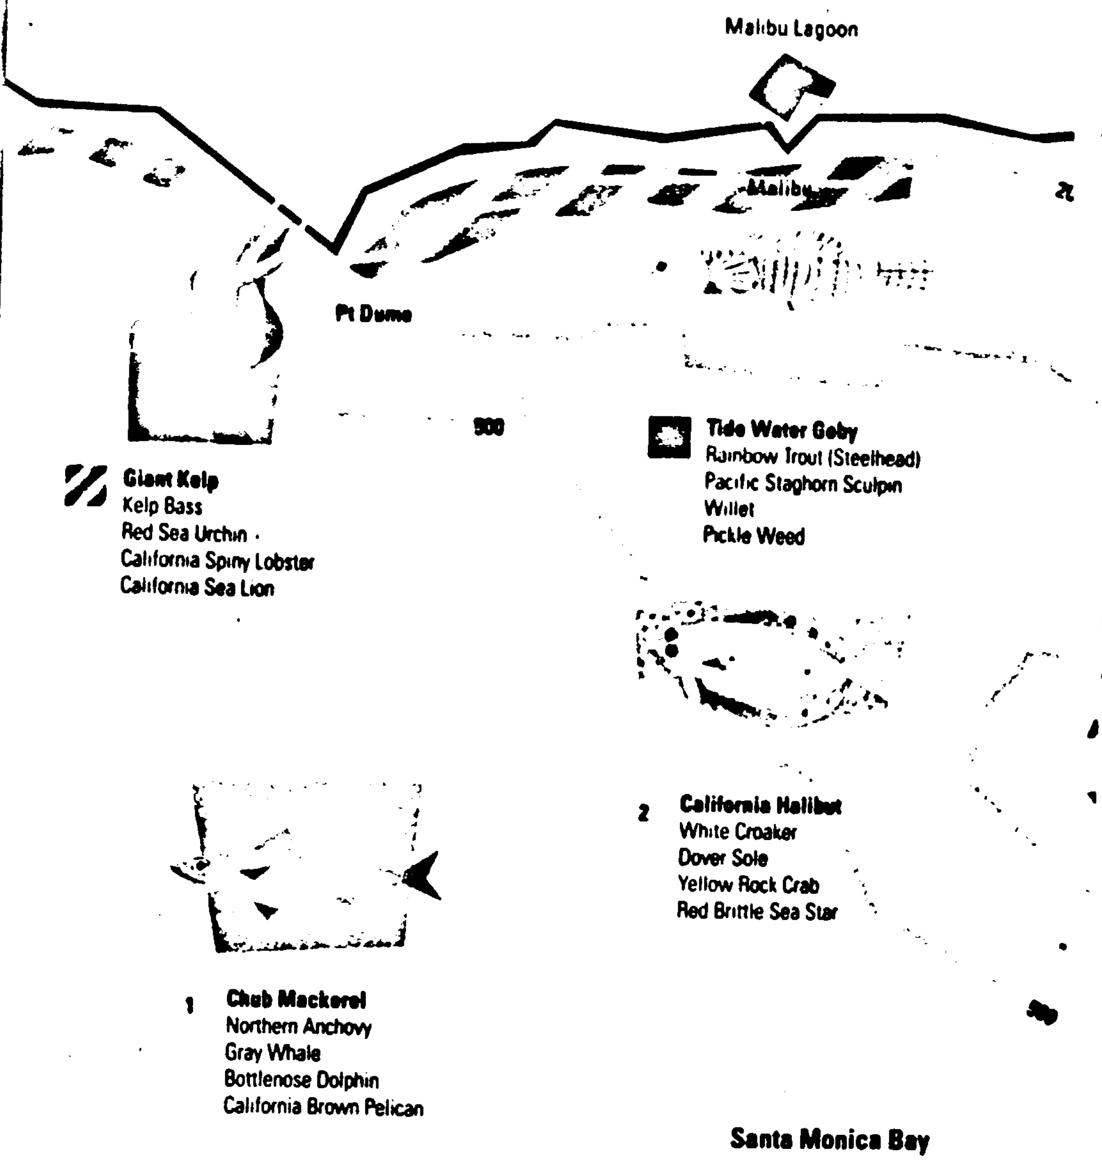
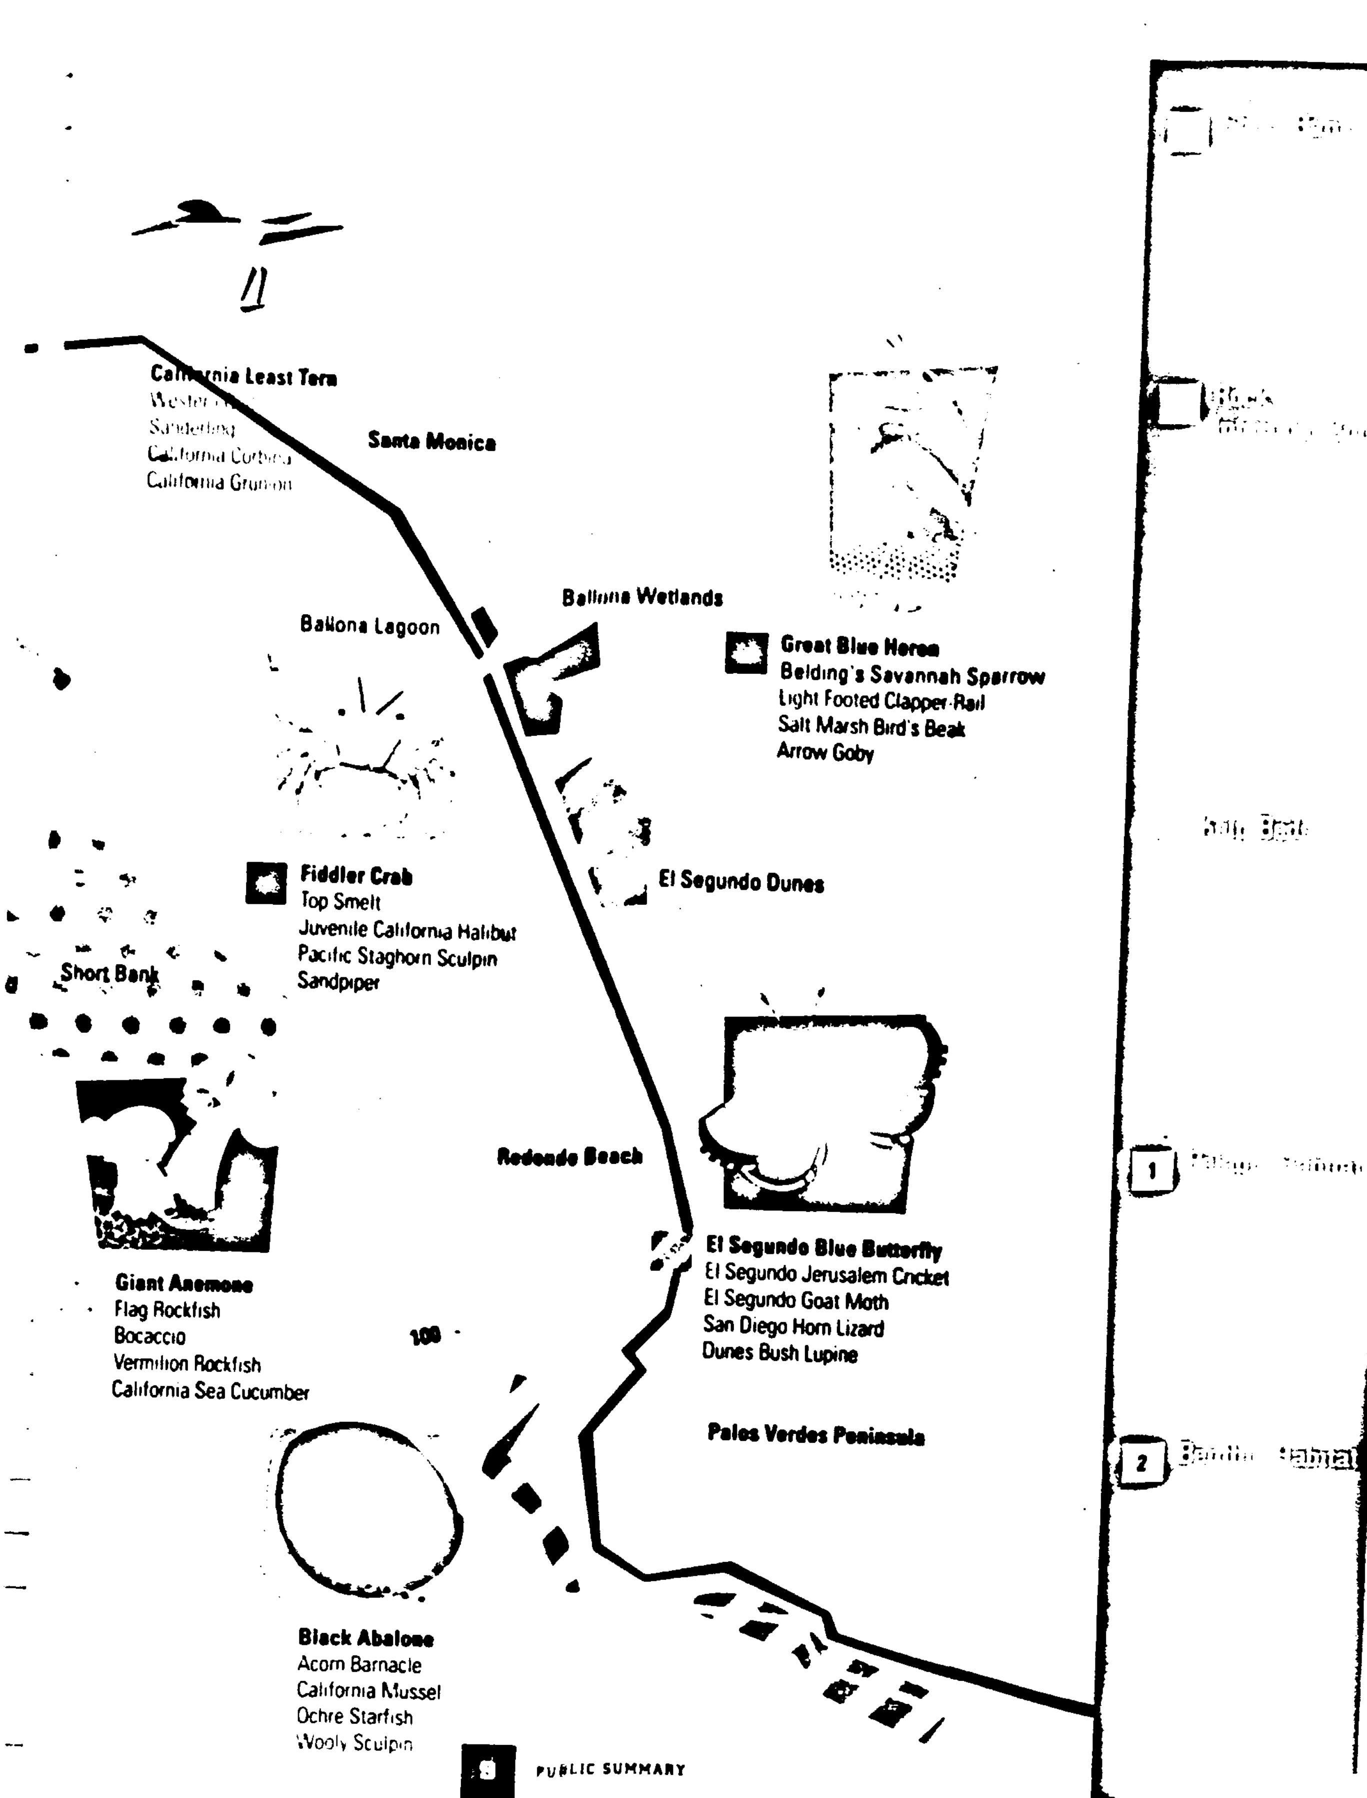
Santa Monica Bay Habitats

VOL 12

18267



More than 5,000 species of plants, fish, birds and other wildlife call Santa Monica Bay and its environs "home." Each bay habitat is unique and can boast a variety of species, including those listed above.



California Least Tern
California Corbina
California Grunion
Santa Monica
Ballona Wetlands
Ballona Lagoon
Great Blue Heron
Belding's Savannah Sparrow
Light Footed Clapper Rail
Salt Marsh Bird's Beak
Arrow Goby
Fiddler Crab
Top Smelt
Juvenile California Halibut
Pacific Staghorn Sculpin
Sandpiper
El Segundo Dunes
Short Bank
Redondo Beach
El Segundo Blue Butterfly
El Segundo Jerusalem Cricket
El Segundo Goat Moth
San Diego Horn Lizard
Dunes Bush Lupine
Giant Anemone
Flag Rockfish
Bocaccio
Vermilion Rockfish
California Sea Cucumber
100
Palos Verdes Peninsula
Black Abalone
Acorn Barnacle
California Mussel
Ochre Starfish
Wooly Sculpin

2

VOL 12

18268

resident and migrant birds, dozens of varieties of worms and snails and other "small, obscure animals" who, through their lives, process and cleanse the water.

The *pelagic*, or open-ocean habitat is the primary home to fish such as the Pacific sardine, northern anchovy, Pacific mackerel, and Pacific bonito; as well as marine mammals such as seals and sea lions. The pelagic habitat is also home to the eggs and larvae of many invertebrates. Phytoplankton are the dominant plant life there.

The dominant *benthic* (sea-floor) habitat in Santa Monica Bay is soft-bottom. Few attached plants live in this habitat but invertebrates are abundant and diverse. Denizens include crabs and shrimp, snails, worms and echinoderms (sea urchins, starfish, and sea cucumbers).

Santa Monica Bay is home to a number of rare, threatened or endangered species. They include:

California brown pelican
California least tern
Belding's savannah sparrow
California gnatcatcher
El Segundo blue butterfly
Lyon's pentachaeta
Santa Monica Mountains dudleya
Conejo buckwheat
Santa Susanna tarweed
Valley oak

Hard-bottom areas includes kelp beds in Santa Monica Bay west of Malibu and around the Palos Verdes Peninsula. Giant kelp attaches itself to the hard bottom and grows in luxurious forests toward the sunlight above.

Intertidal zones, including mud flats, tide pools, sandy beaches, and wave-swept rocks, provide important habitat and breeding grounds for a variety of plants and animals such as marine algae, some fishes, and invertebrates such as snails, worms, mussels, crabs, clams. These organisms are an important link in the aquatic food web to larger marine animals (fishes, lobsters, and octopi) and some terrestrial animals, especially birds.

Both the beaches and other intertidal zones of Santa Monica Bay are important nesting and feeding grounds for migratory waterfowl and shorebirds. Egrets, herons, gulls, terns, sanderlings, marbled godwits, willets, kildeer, plovers, grebes, mallards and many other birds depend upon these areas for food, rest, and/or breeding grounds. For example, the federally-listed, endangered California least tern comes to Venice Beach and the Marina del Rey area each April to nest and rear its young in the sand, leaving in September to winter in Central and South America.

Wetlands and *mudflats* of Santa Monica Bay support a variety of marine and terrestrial life. Wetlands are especially important as nursery grounds for species such as California halibut. *Riparian* habitats, alongside watercourses across the watershed, provide food, cover and water for many diverse species as well.

Santa Monica Bay habitats are home to a number of rare, threatened or endangered species. Birds include California brown pelican (marine), California least tern and western snowy plover (beach nesting species), Belding's savannah sparrow (wetlands), and the American peregrine falcon and California gnatcatcher (watershed habitats). Butterflies include the El Segundo blue,

SANTA MONICA BAY: A VITAL ECONOMIC RESOURCE

The Bay is a Major Tourist Destination

Number of tourists who visited Santa Monica Bay beaches in 1990. 3 8 million people

Rank of tourism as a Regional Industry : Second largest, behind business and management services

Number of tourist industry jobs: 437,000 full and part-time

Contribution of tourism jobs to the region's payroll: $4 25 billion annually

Tourist dollars contributed directly to the region (1991): $7.1 billion

The Bay is One of the Region's Primary Recreational Resources

Number of public beaches along the Bay: 22

Length of shoreline: 50 miles

Annual attendance at Bay beaches: 45 to 60 million

Average number of visitors per summer weekend: 620,000

Busiest beach in the County: Santa Monica Beach

Length of coastal bike path: 22 miles

World's largest man-made small craft marina: Marina Del Rey; 6,000 slips

Number of sport fishing trips made in Southern California (1989): 5.5 million

Expenditures on saltwater fishing in Southern California (1989): $536 million

Value of cargo going through L.A./Long Beach ports (1990): $1 trillion

Palos Verdes blue, and wandering skipper. Plants include Santa Monica Mountains dudleya, Lyon's pentachaeta, Conejo buckwheat, and Santa Susanna tarweed. Valley oaks receive special attention in the Santa Monica Mountains because most individuals are very old and this is the southernmost extent of their range.

The Bay's Other Benefits

The Bay's values are also defined according to the economic benefits of its water-dependent activities, such as tourism, boating, fishing, shell fishing, and recreation; shipping; and its contribution to the cultural and the aesthetic qualities of Los Angeles County.

TOURISM

Tourism is the Los Angeles region's second largest industry, with 392,000 full and part-time jobs. It contributes $3.6 billion annually to the region's payroll.

In 1991, 25.3 million people visited Los Angeles County, contributing $7.2 billion in direct expenditures. Many of these visitors flock to the region's primary recreation resource, Santa Monica Bay. In the City of Santa Monica alone, 85 percent of the tourists (more than 2.1 million people) visit the beach.

Tourist facilities and activities are abundant around Santa Monica Bay. Hotels, motels, weekly rental apartments, restaurants, shops, and conference facilities all cater to local and out-of-town visitors. In addition, Los Angeles International Airport funnels a large percentage of its 48 million annual passengers into the Santa Monica Bay area for at least a portion of their stay.

RECREATION

Recreational features and activities can be either natural or developed, commercially or non-commercially operated. Undeveloped natural recreation areas are scarce along the predominantly urban coastline; pristine wildlife conditions no longer exist. Yet significant natural resources remain. For example, the Ballona Wetlands Complex (between Marina del Rey and Playa del Rey at the mouth of Ballona Creek) is a surviving wetland area that contributes not only to species diversity but also provides open space and aesthetic enjoyment in an otherwise urban area.

Some relatively undisturbed marsh and riparian habitat is also found in the Malibu Creek drainage, where local residents hope to restore the steelhead run,

VOL 12

18270

and the Santa Monica Mountains offer a wide range of natural habitats, especially inland and west of the Malibu coast.

Activities at the 22 public beaches along the 50-mile shoreline include sunbathing, swimming, boating, and surfing, as well as skin- and SCUBA-diving. Over 45 million people visit Santa Monica Bay beaches each year.

Other developed natural recreation facilities include the 22-mile-long beach bike path, which extends from Santa Monica to Redondo Beach, and several bluff-top parks overlooking the Bay.

Commercial recreation opportunities range from bicycle and roller skate rentals, to "fun zone" arcades, restaurants, bars, and art galleries. Some areas have evolved into recreation attractions of their own: Main Street and Santa Monica Pier in Santa Monica; the Venice Boardwalk; Malibu Pier; Fisherman's Village in Marina del Rey; and King Harbor in Redondo Beach.

Over 45 million people visit Santa Monica Bay beaches each year.

SPORT FISHING

Fishing is one of the most fundamental human uses of the Bay and includes commercial passenger fishing vessels (party boats), pier fishing, private boat fishing, scientific collecting, and limited commercial fishing.

While sport fishing is allowed throughout the Bay, commercial fishing has been prohibited in the Bay (east of a line between Malibu Point and Palos Verdes Point) to protect local fish populations, which could be depleted by a combination of both commercial and sport fishing.[1] Commercial fishing activity in the rest of the Bay centers around gill-netting for California halibut west of Malibu and south of Palos Verdes Point. Commercial catches from Santa Monica Bay are negligible.

Although statistics are not available for Santa Monica Bay alone, 5.5 million sport fishing trips were made in Southern California in 1989. In 1991-1992 the Bay's sport fishery was dominated by chub mackerel, barred sand bass, and kelp bass. California spiny lobster is an important invertebrate also frequently caught.

The sport fishery catch has some economic value as food, but fees paid to charter operators and other onshore expenditures have a much greater impact on the local economy. Expenditures on saltwater fishing in Southern California totaled $536.3 million in 1989, 16 percent on licenses and gear, 23 percent on boat related expenses, and 61 percent on trip-related expenses. Los Angeles County residents accounted for 37 percent of that total. About 465,000 of the 6.1 million households in Southern California coastal counties included at least one member who went sport fishing in 1989.

Recreational fishing facilities in the Bay area include piers at Malibu, Santa Monica, Venice, Manhattan Beach, Hermosa Beach, and Redondo Beach and a

[1] However, commercial bait boats are allowed, under experimental gear permits, to fish for live bait throughout the bay.

fishing barge off Redondo Beach. There are small craft harbors at Marina del Rey and at King Harbor in Redondo Beach. Fourteen artificial reefs designed to enhance marine life and improve sport fishing opportunities have been installed offshore (at Malibu, Paradise Cove, Santa Monica, Marina del Rey, Manhattan Beach, Hermosa Beach, and Redondo Beach) since 1958 and nine of these remain. Commercial passenger fishing vessels (party boats) depart from Marina del Rey, Redondo Beach and Malibu.

SHIPPING

The Bay is also used for shipping petroleum to and from the Chevron refinery in El Segundo. While the Ports of Los Angeles and Long Beach are located in San Pedro Bay, ships heading into and out of those ports use shipping lanes directly adjacent to the Bay. The two ports constitute the fastest growing major cargo center in the world. The value of import-export cargo going through the ports increased from $61.8 billion in 1986 to $1 trillion in 1990.

> **Essayist Wendell Berry speaks of those junctures of soul and territory that take place at edges like the coastline when he writes "This is the phenomenon of edge or margin that we know to be one of the powerful attractions of a diversified landscape, both to wildlife and to humans. The human eye itself seems drawn to such margins, hungering for the difference made in the countryside by a hedgy fencerow, a stream, or a grove of trees. And we know that these margins are biologically rich, the meeting of two kinds of habitat."**

AESTHETIC AND SPIRITUAL RESOURCE

The Santa Monica Bay shore offers great physical beauty: broad beaches, boardwalks, and piers; vistas of Palos Verdes Peninsula, Malibu, and Santa Catalina Island; and a variety of public and private facilities and spaces.

These aesthetic resources make an intangible but important contribution to the local economy. They tend to boost tourism and recreation and provide spectacular locations for television and motion picture filming, two staples of the regional economy.

Finally, the Bay is a spiritual resource. The inner connection to the natural world has moved at least as many humans over the years as have the efforts of governments to mandate change. The natural environment speaks to something deep in all of us. The Bay's ability to touch that deep place is one of its greatest gifts.

THE URBAN

ENCOUNTER: HUMAN

IMPACTS ON THE BAY

1 8274

R0051579

[illegible] Impacts on the Bay

Scientific Characterization — The Basis for Action

Chapter One of this summary described the most significant physical as well as social features of the Santa Monica Bay. Chapters Two and Three will characterize the environmental condition of the Bay in order to give a better understanding of the basis for the actions recommended in the Santa Monica Bay Restoration Plan (BRP).

Those recommendations, summarized in Chapter Four, are based in part on a comprehensive scientific characterization of the Bay conducted by the Santa Monica Bay Restoration Project (SMBRP). The "State of the Bay 1993" report examined the various sources of pollutants that enter the Santa Monica Bay, the fate of those contaminants once they enter the Bay, and the impact of pollution on the health of marine life, as well as on the health of humans who use the Bay as a source of food or recreation.

Like many scientific inquiries, the SMBRP's characterization studies could not answer all questions conclusively. But much is now known that was not known before the SMBRP was formed, and the accumulated information serves as a reliable guide for those public agencies that intend to fulfill the public's c[illegible] policies that protect the Bay and its resources.

[illegible] specifically on the sources and causes of pollution, beginning with the region's explosive population growth and the building of the region's infrastructure to accommodate this growth. It also presents a general framework for setting priorities for action against specific types and sources of pollution. Chapter Three focuses on the Bay itself, and the way in which human activities have changed the Bay's natural processes to put marine life as well as human users at risk. We also take a look at the progress and gains in Bay health that have occurred in recent years.

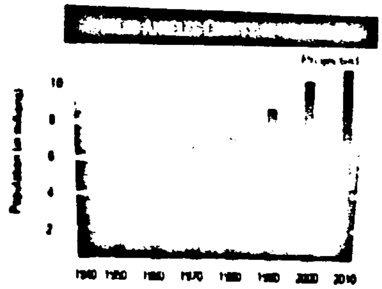
Human Impacts: Population and Land Use

"The Spanish explorers were attracted to Los Angeles and San Diego by their natural harbors," author Peter Steinhart wrote in 1991. "But the abundance of food in the sea off our coasts was what allowed them to stay. The richness of the marine environment enabled the cities of Southern California to take root and grow."

And grow. And grow. The population shift to California since 1880 is one of the largest in history, with at least five distinct waves of migration adding up to a population of 30 million people who now call the Golden State home. Nine million people live within an hour's drive of Santa Monica Bay, and those numbers threaten the rich marine environment that drew settlers in the first place.

Many of the problems facing the Bay's habitats and natural resources can be traced to the proximity of the large human population and its impact on the physical, chemical and biological characteristics of the Bay.

In short, what happens "upstream" affects the ecosystem "downstream." Intensified land uses bring intensified pressures, including contaminated urban runoff; increased domestic and industrial waste disposal; conversion of open space to residential, commercial, and transportation system development; stream alteration; introduction of non-native plant and animal species; and increasing use of natural habitats for recreation.



More than 11 million people will be living in Los Angeles County by the year 2010.

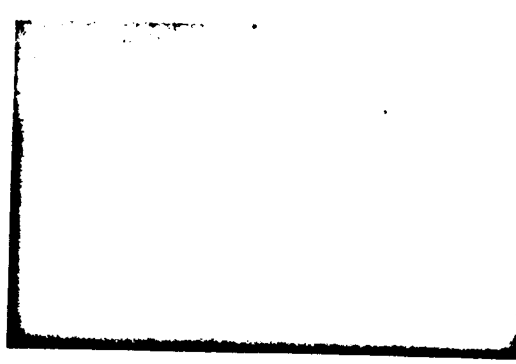
The population of Los Angeles County has increased over 300 percent since 1940, and is predicted to grow another 30 percent by the year 2010. This growth has dramatically affected land use as homes, buildings and roads have been built upon what was once open land. Population increases into the next century, projected to come less from immigration than from the descendants of those already living here, will require a substantial increase in infrastructure to support them.

Watershed Development

Los Angeles, the second largest city in the United States, is one of the world's most sprawling and built-out metropolitan areas. If we are generous with our definition of "watershed," the impact of Los Angeles' build-out can be felt as far away as the Feather, Sacramento and Colorado Rivers and the slopes of the Eastern Sierras, whence we draw most of our water supply.

As the second largest city in the United States, Los Angeles is one of the world's most sprawling and built-out metropolitan areas.

But even limiting our definition of watershed to the 414 square miles that drain into the Bay, it is obvious that build-out has indelibly altered the landscape. Natural rivers and creeks have been confined in concrete channels, wetlands have been drained and filled, and the flood plains and hillsides have been covered by asphalt streets, parking lots and buildings.

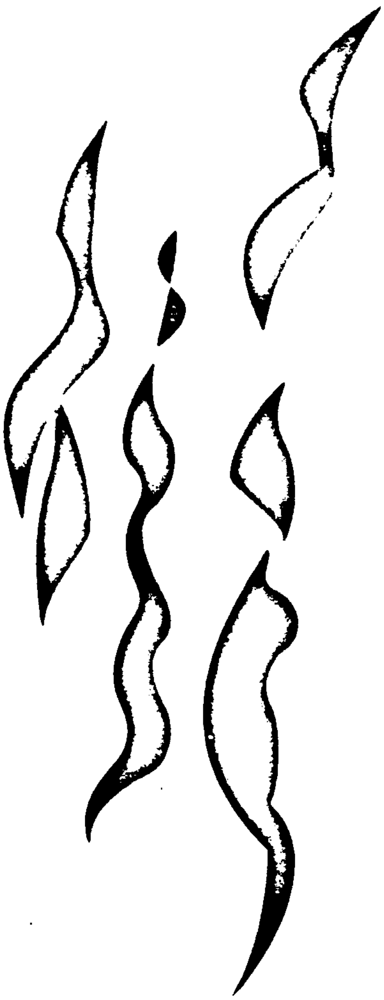


Our growth has resulted in the loss of natural functions that are critical to the health of the ecosystem—open areas for groundwater recharge; buffers or undisturbed areas that can trap and assimilate contaminants; vegetation that moderates stream temperatures and provides cover and food supplies for fish and wildlife populations. While these incremental changes, viewed separately, may seem insignificant, their cumulative impact over time and throughout the watershed may be quite substantial.

VOL 12

18276

R0051581



Impacts of Growth—Pollution

Population growth and land development have had serious consequences for Santa Monica Bay. As the numbers of humans living and working in the watershed grew, so did the waste products—pollutants[1]—generated. The problem of pollution increased until deliberate policies were enacted that slowed or reversed that trend while continuing to accommodate growth.

Pollutants enter the Bay through numerous pathways, including flood control channels, streams, sewage treatment plant outfalls, and aerial fallout. Most often, they are carried by water. As water cycles through the watershed, it brings with it a wide mix of contaminants—sediment and nutrients from open land and building sites; oils, grease and litter from roads and parking lots; fertilizers and pesticides from yards and parks; heavy metals from industrial sites; human waste and household chemicals from homes and businesses.

Understanding the effect that pollutants have on the environment is complicated because pollutants are influenced by many interactive factors. The manner in which contaminants are introduced into the environment, their chemical and physical properties, and the types of processes that operate on them all control their dispersal, accumulation and ultimate fate in the environment.

A polluted Santa Monica Bay is not acceptable to the people of Southern California. Neglecting our duty to be stewards of the Bay's ecological health will bring both economic and environmental damage to the region. It is important, however, to come to an understanding not only of what key factors led to pollution of the Bay, but also to establish a framework by which the most damaging pollutants and pollution sources will be addressed first, and in a manner that most effectively preserves the myriad values of the Bay.

Pollutants of Concern

Hundreds of known pollutants exist in the urban environment and may enter the Bay on a regular or irregular basis. Since it is neither feasible nor necessary to control all types and sources of pollutants, the SMBRP has focused on those that pose the greatest problems. SMBRP's analysis suggests that 19 pollutants are of most immediate concern in Santa Monica Bay. These **Pollutants of Concern**—which include toxic organic compounds, heavy metals, pathogens, nutrients and sediments, trash and debris, and others—were identified based on the following factors:

- Current loadings or historic deposits of those contaminants currently affect the Bay's beneficial uses (e.g. recreational use, wildlife habitat, etc.);
- Elevated levels of the contaminant are found in Bay sediments; and/or have the potential to bioaccumulate[2];
- There are detectable inputs of the contaminants at a level that is potentially toxic to marine life and/or humans.

1 Substances are classified as pollutants when they are present in the environment in such quantities or concentrations that they become harmful to human health, marine life or the ecosystem. While the California Water Code distinguishes between "pollutant" (substances that affect any beneficial use) and "contaminant" (substances that affect public health), these terms are used interchangeably in this document.

2 Bioaccumulation: The accumulation of a substance (usually a contaminant) in the tissues of an organism. This usually occurs with substances that organisms cannot easily break down, which are often transferred intact to organisms at higher levels of the food chain.

VOL 12

18278

Toxic Organic Compounds	
DDT	Was a widely used pesticide prior to ban in 1972. An animal and potential human carcinogen; persistent in environment, biomagnifies. Major source to Bay was Montrose Chemical Co. via Los Angeles County sewage treatment system until 1970. Although mostly buried, levels in ocean sediments remain high in certain locations and certain fishes.
PCBs (polychlorinated biphenyls)	Wide range of industrial applications prior to 1970s (transformers, capacitors, etc.). Among the most persistent and toxic of organic compounds; biomagnifies. Accumulated in sediments and caused contamination of seafood.
PAHs (polycyclic aromatic hydrocarbons)	Found in crude oil, fuel oil, crankcase oil; released during combustion. Many are potent carcinogens or mutagens.
Chlordane	Environmentally persistent insecticide used extensively in termite control. Potentially toxic to sensitive marine species. Still found in sediments although banned in 1987.
TBT (tri-butyl tin)	Widely used as an antifouling agent in vessel paints until restricted in 1987. Very toxic and bioaccumulates in all organisms.
Heavy Metals Cadmium / Chromium Copper / Lead/Nickel Silver / Zinc	Heavy metals are utilized in a large variety of industrial applications. Often associated with fuel combustion, vehicle tire and brake wear and decay of products such as batteries, paints and plastics. Potentially toxic in high concentrations and can accumulate in the tissues of plants and animals. Present in wastewater and surface runoff and have accumulated in sediments in many areas.
Pathogenic Bacteria and Viruses	Disease-causing organisms that may pose potential health risks to swimmers and waders. Sources include leaking sewer lines, illegal sewer connections or dumping, malfunctioning septic tanks, outdoor campers. Carried to beaches via stormdrain runoff.
Nutrients and Sediments	Nutrient sources include fertilizers, runoff from livestock areas, detergents, etc. Sediments result from erosion, land grading activities. Excessive nutrients can cause eutrophication (algae growth); sediments can smother tidepools and artificial reefs, resulting in sedimentation of coastal lagoons. Can be a problem in some areas with limited circulation.
Trash and Debris	Caused by littering, dumping of trash into storm drains, at beaches, into marine environment. Impairs aesthetic value of Bay, some (like plastics) can injure or kill marine life.
Oil and Grease	Sources include waste oil dumping, natural oil seeps, oil spills and food waste. Some components of oil and grease (e.g. PAHs) are known to be toxic.
Biological and Chemical Oxygen Demand	Sources include organic material from human and animal waste. Can deplete oxygen content of receiving waters.
Chlorine	Used in sewage disinfection, swimming pools. Harmful to most marine organisms. Also forms toxic chlorinated organic compounds.

The consequences of these pollutants can be seen around the Bay. Historic discharges of DDT and PCBs have accumulated in Bay sediments and caused contamination of certain seafood species. Popular swimming beaches are posted with warnings due to high pathogen levels found near storm drain outlets. Copper, lead, tri butyl tin and chlordane have been found in sediments and biota in marina areas. These are but a few examples of pollutant impacts on Santa Monica Bay. Finding solutions to these problems requires that we understand where these pollutants come from (their sources), how they reach the Bay (the pathways) and how they impact Bay resources.

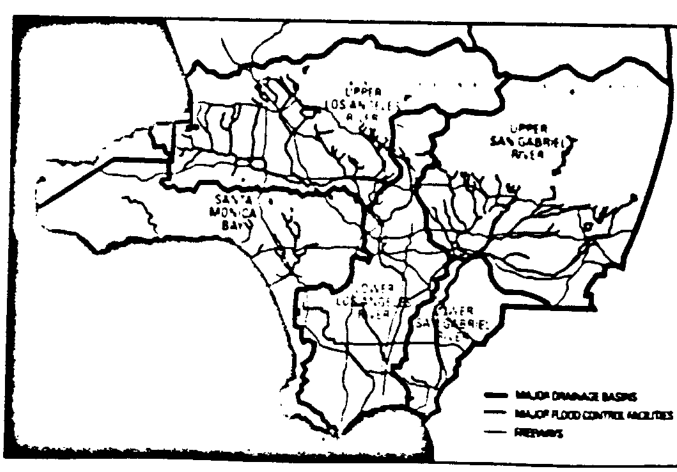
Following the Pollution Trail: Pollutant Sources and Pathways

Contaminants entering the Bay may originate on land, in the air, or at sea outside of the Bay itself. Although the sources of pollution are numerous and disparate, they are ultimately the product of all the people who live, work and play in this region. Everyday human activities—the way we manage our households, care for our cars, manufacture and consume products—directly influence the amounts and types of pollutants that enter the Bay, and do varying degrees of environmental damage.

The effects of these activities are transmitted to the Bay via numerous pathways—runoff to creeks and storm drains, municipal wastewater treatment and industrial discharges, boating and shipping activities, aerial fallout, dredging, ocean dumping and advection.

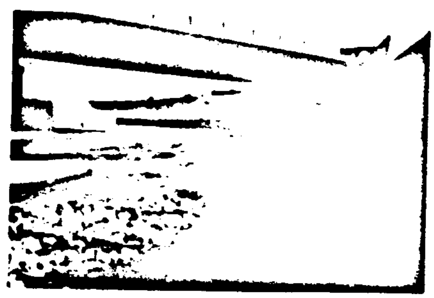
The Santa Monica Bay Restoration Project's attempt to develop and set forth effective policies to safeguard the environmental values of the Bay has required the Project to look closely at how pollutants get from here to there, with "here" representing the source of each potentially harmful pollutant, and "there" representing the impacts on a key Bay resource. The trails lead in one direction—downstream—but to many different policy conclusions.

The Los Angeles County storm drain system includes over 5000 miles of open channels and underground storm drains that carry floodwaters and urban runoff to the ocean.



Storm Water Urban Runoff Pollution

Urban and storm water runoff—carried to the Bay through the region's massive storm drain system—is a serious concern, in both dry and rainy seasons. These waters, which flow over rooftops, parking lots, freeways, construction sites, industrial facilities and other impervious surfaces, collect and carry an assortment of pollutants through open channels and underground storm drains directly to the ocean without treatment[3]. The 5,000 mile storm drain network, built to move flood waters quickly to the ocean, is completely separate from the sewer system, which conveys wastewater from households and businesses to wastewater treatment facilities.



Storm water and urban runoff contribute about one-fourth of the total pollutant load to the ocean.

Storm water runoff is controlled primarily through the use of source control programs known as Best Management Practices (BMPs). This approach is embodied in the municipal storm water National Pollutant Discharge Elimination System (NPDES) permit issued to Los Angeles County (as principal permittee) and the 89 cities and other governmental entities (as co-permittees) by the Los Angeles Regional Water Quality Control Board in 1990. General storm water discharge permits for industrial facilities and construction sites were issued by the State Water Resources Control Board in the summer of 1992. The municipal permit provides a new regulatory framework considered practical, cost-effective and adapted to the distinct structure of the region's storm water drainage system—its large size, proximity of cities and the overlapping jurisdiction over drainage facilities.

URBAN RUNOFF FLOWS

Urban runoff is a daily problem. Ten to 25 million gallons of water flow through storm drains into Santa Monica Bay every day, even in dry weather. Ten *billion* gallons can flow through the system on a rainy day, which amounts to more than one-third of the daily flow of such major U.S. rivers as the Arkansas, the Susquehanna or the Willamette—rivers that flow in states where rain is a year-round phenomenon. Each year an average of 30 billion gallons of storm water and urban runoff are discharged through more than 200 outlets—some as large as a 370 feet-wide concrete channel, some so small that they are hard to detect—into Santa Monica Bay.

Storm water pollutant runoff volumes and pollutant concentrations are often comparable to effluent flows from municipal wastewater treatment facilities. As the quality of sewage discharges has improved, the relative contribution of storm water and urban runoff to the total pollutant load to the Bay has increased. Currently, is it estimated that one-fourth of the total pollutant inputs to the Bay are attributable to pollutants carried by storm water and urban runoff. A 1990 SMBRP study concluded that significant quantities of many pollutants

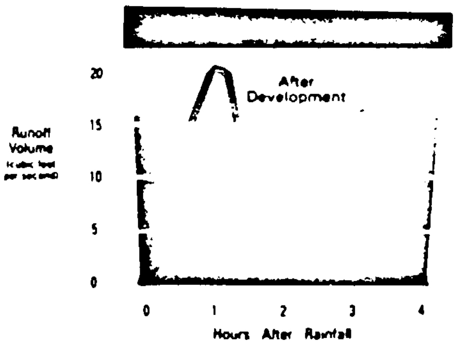
3 with the exception of the dry-weather diversion of runoff from the Pico-Kenter storm drain

of concern were discharged annually through the storm drain system to the Bay, and that the concentrations of some of these pollutants were among the highest in the nation.

Storm water/urban runoff is known or suspected to be responsible for water quality impairment in nearshore areas close to the mouths of storm drains, and in some lagoons and marinas. The SMBRP storm water toxicity study performed by the University of California at Los Angeles (UCLA) and the Southern California Coastal Waters Research Project (SCCWRP) found that urban runoff in several storm drains during dry weather was toxic to marine organisms even at diluted levels. Other studies found high levels of bacterial indicators at mouths of storm drains, and evidence that human fecal waste was contaminating storm drain waters at least some of the time.

Modifications of the natural landscape through traditional urban development patterns can profoundly change runoff characteristics. Altering naturally vegetated lands to impervious surfaces such as roadways, roofs, and parking lots results not only in increased pollutant runoff but also in higher flow velocities.

While it is generally recognized that increased pollutant loads have impacts on the integrity of stream, wetland and nearshore environments, the physical action of higher stream flow velocities alone also contribute to habitat degradation.



RUNOFF SOURCES AND LOADS

Urban and storm water runoff is made up of infinitely variable types of matter—the by-products of human activity in the watershed.

Land use is one of the major variables in runoff pollution, and has therefore been the focus of most urban runoff source studies performed in the nation to date. The type of land use strongly influences the type and concentration of pollutants found in urban runoff. Runoff quantities and velocities increase when roads, buildings or pavement ("impervious surfaces") cover land that once absorbed and filtered rainfall. The more impervious area, the greater the runoff. For example, there is more runoff from industrial areas where 90 percent of the surfaces are impervious compared to single-family residential areas where an average of 55 percent of the surfaces are impervious.

Pollutant loads originate from human activities that occur within each type of land use. As the adjoining table shows, the origins of the pollutants from each land use are as varied as the diversity of the region's economy and population. Metal-plating and auto repair shops, construction worksites, lawns overtreated with fertilizers and pesticides, "do-it-yourselfers" who dump motor oil, paints or solvents into the street, drivers and pedestrians who toss cups, plastic bags, "disposable" diapers, cigarette butts and other trash on the ground—these are just a few of the sources of PAHs, heavy metals, suspended solids, phosphates, oil and grease, pathogens and debris which constitute what we call "urban runoff." A land use analysis simply relates each of these activities to the areas within the watershed where they occur most commonly.

[illegible]ANTS[illegible]AND USE

Pollutant of Concern	Industrial/ commercial	Transportation	Residential	Construction	Public	Other
PAHs	Oil leaks, spills	Fuel and oil combustion, spills	Motor oil dumping	Fuel and oil combustion, leaks		Natural oil seeps; brush fires
Chlordane	Stored product discharge		Stored product discharge			
Cadmium	Metal plating	Fuel combustion; tire wear	Batteries; paint	Paint		Water supply
Copper	Metal plating, antifouling paints, manufacturing	Fuel leaks, combustion, auto part wear	Insecticides, fungicides		Insecticides, fungicides	Water supply
Lead	Lead metal, chemicals; paint	Leaded fuel combustion, coolant leaks	Paint; batteries	Paint		Water supply
Nickel	Metal plating, industrial applications	Fuel combustion, auto part wear				
Zinc	Galvanizing; pigments	Fuel, oil and coolant leaks; tire wear	Paint	Paint		Water supply
Pathogens			Septic tank or sewer leaks, illegal connections, pets		Sewer leaks, dumping or illegal connections, human waste	Wildlife
Total Suspended Solids	Dust and dirt	Pavement wear	Erosion	Erosion from land grading	Soil runoff	Natural erosion
Nutrients	Detergents, facility cleaning	Fertilizers	Fertilizers, detergents		Fertilizers, livestock manure	Natural erosion
Debris	Trash dumping	Litter	Yard waste, litter	Trash dumping	Litter	Natural vegetation
Oil and Grease	Waste oil dumping, oil leaks	Oil leaks, spills	Waste oil dumping	Oil leaks	Oil leaks	Natural oil seep

An SMBRP study, "Assessment of Urban Runoff Pollution," resulted in the development of the first maps of the 28 Santa Monica Bay sub-watersheds and the land uses associated with them, and calculated pollutant loadings from storm water/urban runoff to Santa Monica Bay.

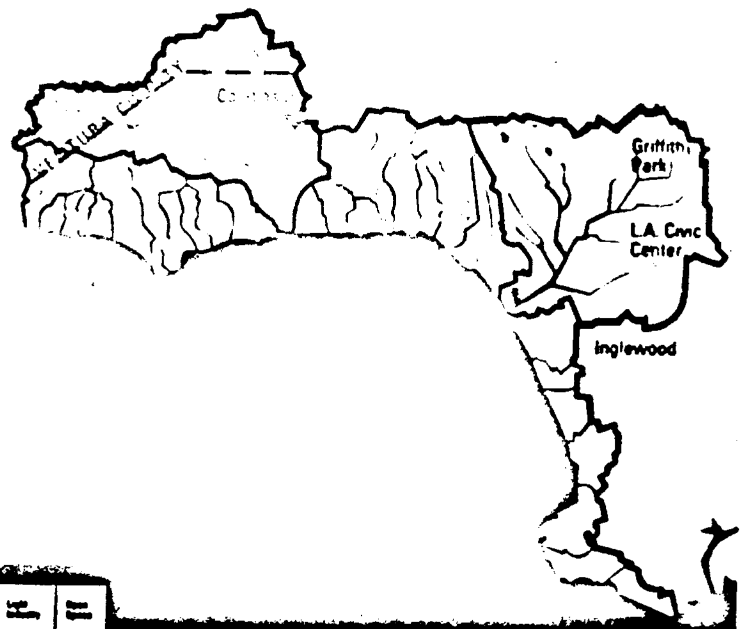
Overall, it was found that residential and open land uses together comprise 90 percent of the total Santa Monica Bay watershed area, and contribute 82 percent of the total runoff and the largest pollutant loads to the Bay. Sub-watersheds in the undeveloped northern section of the Bay have the lowest concentrations of pollutants; the urbanized South Bay and West Los Angeles drainages have the highest loads and concentrations of pollutants. On a land use basis, single-family residential areas contributed the largest loads of heavy metals and nutrients, open areas[4] supplied the largest load of total suspended solids (TSS), and the largest quantities of oil and grease were associated with multi-family and commercial areas.

However, a better picture of urban runoff characteristics is illustrated by comparing the Bay's two major sub-watersheds—**Ballona Creek and Malibu Creek**. The present drainage of Ballona Creek is located in the heavily urbanized coastal plain of the Santa Monica Bay watershed; the more "rural"

4 It is important to note however that runoff from open areas with natural vegetative cover is not necessarily at levels that are harmful to the environment.

VOL 12

The Santa Monica Bay watershed is comprised of 28 sub-watersheds, the largest of which are Ballona and Malibu Creeks. Land uses in the watershed are 33 percent residential, 10 percent commercial industrial and 57 percent open-undeveloped.



[illegible]	[illegible]	[illegible]	[illegible]	[illegible]	[illegible]	[illegible]

[illegible]	x	x	x	x		x	x	x
[illegible]								

By determining land uses and associated pollutant loads, pollution reduction programs can be designed to focus on the most problematic sources within the watershed.

Malibu Creek drainage encompasses parklands in the Santa Monica Mountains as well as the rapidly urbanizing cities of the Ventura Freeway corridor. Although these areas are similar in size, the focus of pollutant reduction efforts will vary due to the differences in land use mix and the resulting differences in the loadings of Pollutants of Concern in each area.

Actions taken in the **Ballona Creek** sub-watershed, with its large population and developed economy, will need to focus on abating litter and debris, pathogens, heavy metals (especially lead), PAHs, oil and grease and other pollutants associated with its heavily urbanized setting. In **Malibu Creek**, dominated by open lands (some of which are being developed) efforts must focus on pollutants associated with land grading and construction, malfunctioning septic systems, agriculture, and improperly disposed human wastes. Sediment, nutrients and pathogens are the primary pollutants of concern in this area.

Municipal and Industrial Discharges

Outfalls for municipal wastewater discharges, power plant cooling water discharges and industrial waste effluent are generally referred to as "point sources." There are seven major point source facilities in the Santa Monica Bay watershed: three municipal waste treatment plants, three coastal generating stations, and one oil refinery. In addition, over 160 smaller commercial

1 8283

R0051588

VOL 12

and industrial facilities discharge non-process wastewaters to storm drain channels that flow to the Bay.

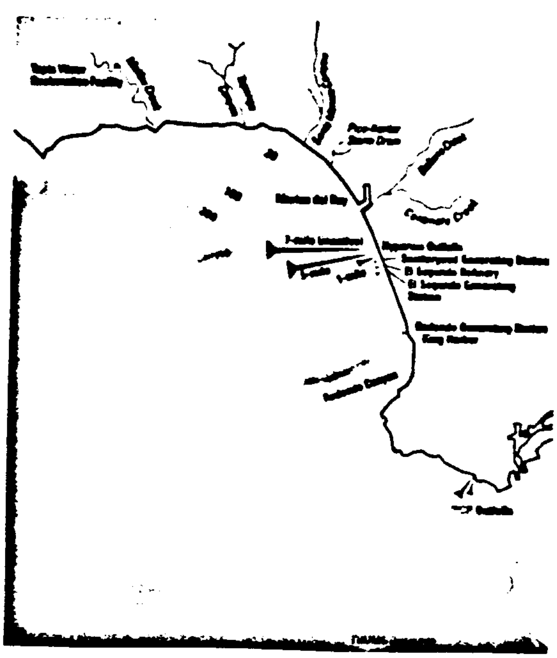
Each major point source facility has a variety of responsibilities for managing wastewater discharges. All must meet requirements set forth in their National Pollutant Discharge Elimination System (NPDES) permits, monitor their discharges for compliance with their permits, and submit monthly reports to the Los Angeles Regional Water Quality Control Board (LARWQCB) and the U.S. Environmental Protection Agency (EPA).

MUNICIPAL FACILITIES

Municipal wastewater facilities receive sewered wastes from domestic, commercial, and industrial sources. Residential wastewater (sewage) contains a variety of household cleaners and detergents; oil, grease, and solvents; food wastes; and enteric (intestinal) bacteria from human fecal waste. It is estimated that each person in the region generates approximately 100 gallons of wastewater per day. Commercial and industrial wastes include oils and grease, metals, and a variety of synthetic organic substances.

Municipal wastes are collected by an extensive network of main and feeder sewers which drain into central treatment plants where they undergo various levels of treatment (see sidebar). In the Los Angeles area, about 85 percent of the flow to treatment plants is domestic sewage and about 15 percent is industrial.

Major point sources and drainage channels in the Santa Monica Bay area.



A primary by-product of the treatment process is sewage sludge (also referred to as biosolids). Sludge production increases significantly as plants upgrade to secondary treatment. Sludge can be a valuable resource (as it is often rich in nutrients) or a hazardous product if it contains high levels of contaminants such as metals and pathogens. Pollution prevention and source control programs that minimize contaminants in wastewater therefore increase opportunities to effectively use this resource.

The region's municipal treatment plants provide service to over seven million people in portions of Los Angeles and Ventura counties. The City of Los Angeles' Hyperion Treatment Plant (Hyperion) and the County Sanitation Districts' Joint Water Pollution Control Plant (JWPCP) discharge treated wastewaters directly into Santa Monica Bay. The Las Virgenes Municipal Water District's Tapia Water Reclamation Facility periodically discharges tertiary treated wastewaters into Malibu Creek.

18284

Each day, about 645 million gallons of treated municipal wastewater are discharged to Santa Monica Bay from Hyperion and the JWPCP. During exceptionally heavy rains, this volume increases due to infiltration of storm water runoff.

Hyperion Treatment Plant

Los Angeles' first ocean outfall was completed in 1894 and discharged raw (untreated) sewage across the beach near Playa del Rey. Today, the Hyperion Treatment Plant discharges a non-chlorinated mixture of primary and secondary effluent through an outfall located five miles offshore at a depth of 190 feet. Pursuant to a Consent Decree, the Hyperion Plant is undergoing a $1.1 billion upgrade to full secondary treatment levels, scheduled to be in place by 1998.

SEWAGE TREATMENT

1 Sewage treatment occurs in several stages. Preliminary sewage treatment consists of screening, pulverization, and grit removal. **Primary treatment** usually consists of clarification with or without chemical treatment, in most cases by settling solids and skimming. At the end of this stage substantially all floating and settled solids have been removed and half of the metals and conventional pollutants are eliminated.

2

The City of Los Angeles' wastewater collection and treatment system serves over three million residents in a 480 square mile area. The Hyperion Plant is the largest of the City's four major wastewater treatment facilities and provides solids treatment for sludge discharged from two upstream facilities located in the San Fernando Valley. In 1991, Hyperion discharged 315 million gallons per day (mgd) of treated wastewater into the Bay, of which nearly 58 percent underwent secondary treatment and sludge digestion.

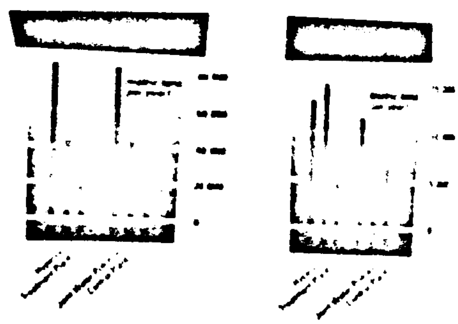
Before its termination in 1987, digested sewage sludge was discharged through a seven-mile outfall at the head of the Santa Monica Submarine Canyon. Presently, about 1100 wet tons per day of biosolids are being used for city composting, land applications, chemical solidification and in Hyperion's energy recovery system.

The flows and levels of contaminants discharged by Hyperion have fluctuated over the years. Annual flow increased from about 340 mgd in 1974 to about 410 mgd in 1983. Between 1988 and 1992, average flow was 339 mgd, a reduction attributed to water conservation measures and increased capacity at an upstream water reclamation plant.

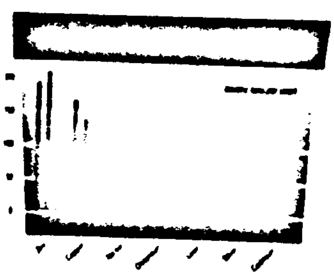
Mass emissions of most constituents have decreased in recent years due to better source control, improved chemical treatment and an increase in secondary treatment from 100 mgd in 1986 to 200 mgd in 1991. Between 1981 and 1991, emissions of total suspended solids were reduced by 83 percent. Annual emissions of oil and grease declined over two-thirds, and various heavy metals were reduced by 74-97 percent from 1981 levels. In 1992, Hyperion reached secondary treatment levels for all constituents except biological oxygen demand (BOD).

VOL 12

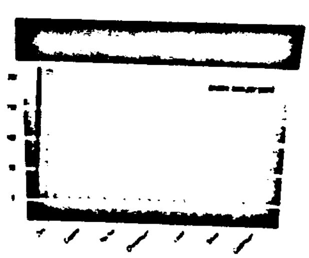
1 8285



Annual mass emissions of total suspended solids and oil and grease from Santa Monica Bay wastewater treatment facilities.



Estimated mass emissions of various heavy metals from the Hyperion Treatment Plant in 1981, 1986, and 1991.



Estimated mass emissions of various heavy metals from the Joint Water Pollution Control Plant in 1981, 1986, and 1991.

Joint Water Pollution Control Plant

Until the 1920s, most of the communities in Los Angeles County not serviced by Hyperion used cesspools and septic tanks. In the late 1920s, the County Sanitation Districts of Los Angeles County (CSDLAC) were formed and Whites Point on the Palos Verdes Peninsula was selected as an ocean outfall site, in part because it was far from the popular beaches of Santa Monica Bay.

The CSDLAC Joint Outfall System presently treats the wastewaters of more than four million people and 10,000 businesses and industries in a service area of approximately 583 square miles. Approximately 30 percent of the sewage in the Joint Outfall System is treated to tertiary standards in water reclamation plants and 70 percent is treated at the JWPCP in Carson. The JWPCP is the largest of the Districts' wastewater treatment facilities and processes solids from five upstream water reclamation plants.

In 1991, the JWPCP discharged an average of 330 million gallons of wastewater per day, 58 percent of which was subject to secondary treatment. (This flow is about 12 percent less than the average daily discharge of 356 million gallons during 1974 to 1987.) The combined flow is chlorinated and discharged through outfalls located approximately two miles off shore at a depth of 200 feet. The JWPCP residuals are sold as soil amendment or land spread or are disposed of in a landfill.

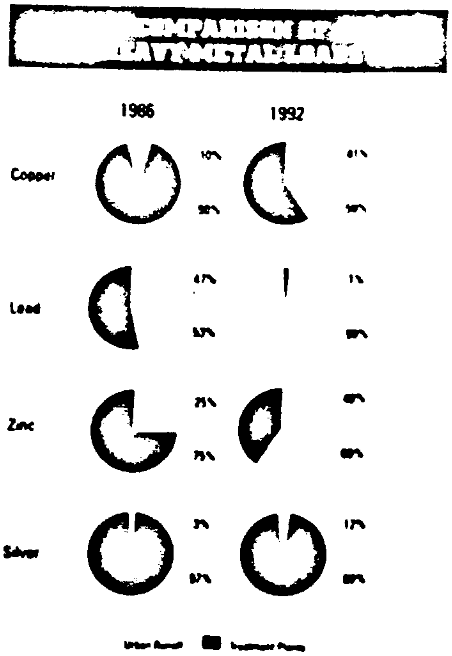
Like the Hyperion Plant, the quality of the JWPCP effluent has also improved. Since 1981, annual mass emissions of total suspended solids have declined by 62 percent and oil and grease by 48 percent. Significant reductions (ranging from 77 to 94 percent) in emissions of heavy metals have also occurred.

Until 1972, the JWPCP outfall discharged extremely high levels of DDT, a result of the disposal of DDT process waste into the sewerage system. Following the termination of these inputs and the subsequent ban on its manufacture and use, DDT emissions have declined precipitously. A comparable pattern is seen with emissions of PCBs, which have dropped to non-detectable levels since 1987.

Fifteen years after applying for a waiver from full secondary treatment, LACSD agreed in a lawsuit settlement to build

VOL 12

18286



Urban runoff contributes an increasingly greater proportion of the pollutants discharged to the Bay

As significant reductions in emission of heavy metals have occurred at sewage treatment plants, urban runoff correspondingly represents a larger percentage of heavy metal loadings to the Bay.

In 1986, loadings of the heavy metals copper, lead, zinc, and silver from sewage treatment plants in Santa Monica Bay were 160, 72, 290, and 25 metric tons respectively. By 1992, they had been reduced to 26, 4.7, 65, and 6 metric tons, respectively. Rough estimates of annual loadings for the same heavy metals carried to the Bay in urban runoff are a constant 18 metric tons of copper, 65 of lead, 96 of zinc, and 0.8 of silver. These charts show the relative contribution of pollutants from each source.

While the database is still insufficient to evaluate trends in urban runoff loading rates, the above estimates are illustrative of the need to shift greater attention to the myriad of diffuse pollutant sources that contribute to urban runoff.

a $400 million advanced treatment system. A full secondary treatment system is to be operational at the JWPCP by July 2002.

Tapia Water Reclamation Facility

The Tapia Water Reclamation Facility (Tapia) was constructed in 1965 as a joint venture agreement between the Las Virgenes Municipal Water District and the Triunfo County Sanitation District. The joint venture now also runs Rancho Las Virgenes, which grows feed crops for animals using dewatered sludge as fertilizer. Tapia serves a population of 80,000 from three cities, the western portion of Los Angeles County and a small portion of Ventura County.

The Tapia plant currently provides tertiary treatment of wastewater. Tertiary treated wastewater is reclaimed and used for irrigation, dust control and fire suppression. Sludge is currently digested and either pumped to land injection farms or dewatered and hauled to landfills.

Tapia has 10 mgd of treatment capacity, although flows have averaged about 2.5 mgd. The facility does not discharge on a daily basis, particularly in summer, since it can reuse much of the reclaimed water it produces. Annual mass emissions of total suspended solids, BOD, and certain metals have generally been low. Because flows in Malibu Creek are subject to human contact, Tapia's discharged wastewater must be completely pathogen-free.

An expansion of Tapia and Rancho Las Virgenes begun in 1991 will allow for the handling of 16.1 mgd of wastewater and dewatered sludge by 1994. Additional sludge from expansion will be composted for use in landscaping.

INDUSTRIAL DISCHARGES TO SEWERS AND STORM DRAINS

More than 160 commercial and industrial facilities discharge into storm drain channels in the Santa Monica Bay watershed, and over 16,000 discharge into municipal sewer systems that flow to the Bay.

Industries that discharge into the storm drain system must provide on-site treatment and are subject to NPDES permit limitations; only non-process wastewaters can be discharged. Industrial stormwater discharges to storm drain systems are also subject to NPDES permit limitations.

Facilities that rely on municipal systems are generally controlled under pretreatment or industrial waste discharge permits issued by the publicly-owned treatment works (POTWs) in accordance with federal, state and local source control regulations. Pretreatment processes remove toxic and conventional pollutants before they are discharged into sewage systems. Recent improvements in POTW effluent and sludge quality can largely be attributed to pretreatment and pollution prevention programs.

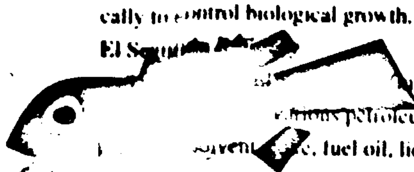
INDUSTRIAL DISCHARGES TO THE BAY

Four major industrial facilities discharge treated wastewaters directly into the Bay. They include three electric power generating stations (the City of Los Angeles Department of Water and Power's Scattergood Plant, and Southern California Edison's El Segundo and Redondo Plants) and Chevron's El Segundo Refinery.

Power Stations

The power generating stations use seawater from Santa Monica Bay to cool steam condensers. Cool seawater is pumped into the station, circulated through noncontact heat exchangers, and discharged at temperatures above the intake temperature. In addition to elevated temperatures, the once-through cooling water may include treated wastewater which is determined to be non hazardous as defined by state and federal regulations. Chlorine is also injected periodically to control biological growth.

El Segundo Refinery



...ery has been in operation since 1911 and ... petroleum products including gasoline, jet fuel, ... solvent..., fuel oil, liquefied petroleum gases and propylene polymer.

Since the early 1970s, Chevron has discharged secondary treated wastewater through an outfall 500 feet offshore of the beach at Grand Avenue. The refinery discharges six to seven mgd of treated water during dry weather and up to 20 mgd during wet conditions. In February 1993, Chevron announced that it would extend the outfall pipe to a distance of two-thirds of a mile, effectively removing the last point source discharge from the nearshore environment.

Nonpoint Sources

MARINE DEBRIS AND BEACH LITTER

Marine debris is more than just a litter problem; it kills marine wildlife, damages the Bay's aesthetic qualities and is expensive for coastal communities to clean up. Over 4000 tons of trash are collected from beaches annually, at a cost of $3.6 million to Santa Monica Bay communities in fiscal year 1988-89 alone. While much of it is left by the millions of beachgoers who visit the Bay annually, much is carried there through storm drains.

Debris includes plant remains such as trees, kelp, and grass clippings as well as the shells, bones, and carcasses of animals. It also includes aesthetic nuisances such as paper, plastic, and wood, as well as fishing line and nets. More dangerous items include glass and metal objects which pose physical hazards on the beaches and on the bottom of the Bay, and some plastic items

VOL 12

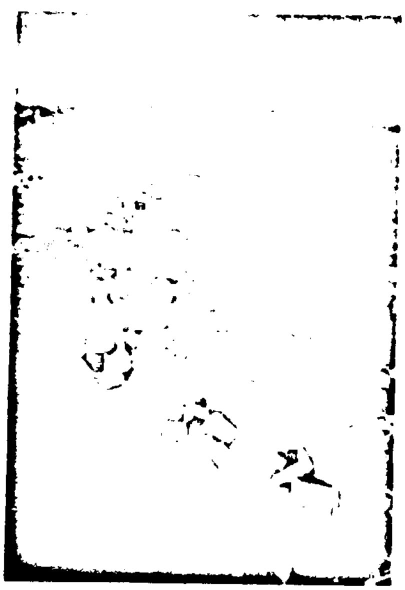
1 8288

which can harm or kill marine life if they are eaten or if animals become entangled in them.

MARINAS AND BOATING

Most of the Bay's small craft traffic is concentrated in Marina del Rey and King Harbor, which together have approximately 7,500 berths and hundreds more dry-docks. Marinas act as collecting basins for a variety of substances, such as raw and chemically treated sewage, fish wastes, antifouling paint additives, oil and grease, wash water, urban runoff and trash.

The contaminants of most concern from boats include antifouling bottom paints which can contain copper and trace amounts of mercury, arsenic and PCBs. In addition, paint primers may contain zinc, chromium and lead, and most recently, tri-butyl tin (TBT). Although TBT can no longer be used on most recreational boats, TBT from earlier applications may slough off or be scraped off boats and is found in harbors and marina sediments.



Beach debris, much of it carried there by storm drains, costs local communities millions of dollars to clean up.

AERIAL FALLOUT

Automobiles are the largest single generator of smog in California, contributing about 60 percent of the total. Each car produces its own weight in hydrocarbons each year. California motor vehicles also emit more than 10,000 pounds of carbon monoxide each day. Given that some seven million motor vehicles are registered in Los Angeles County alone, aerial fallout is a potentially significant contributor of contaminants to the Bay.

Relatively few studies have been conducted to assess the types and amounts of contaminants which enter the ocean via aerial fallout but some recent studies indicate that it may be an important source of lead, nickel, zinc and some PAHs[5].

OIL AND HAZARDOUS MATERIALS SPILLS

Crude oil and refined petroleum products can enter the marine environment through tanker accidents, fueling, tank cleaning, bilge pumping, improper disposal or on-land spills into storm drains. Other hazardous substances may also be spilled as a result of transportation, industrial accidents or illegal disposal practices.

Spills of oil and other hazardous materials occur every year in the Bay and its watershed, each with the potential for serious impacts on the water quality and marine resources. Spills can kill marine organisms outright through smothering, hypothermia or acute toxicity. The animals and populations that survive may display symptoms of stress or chronic poisoning, such as increased mortality rates or reproductive failures.

5 PAHs: Polycyclic (or polynuclear) aromatic hydrocarbons

Two natural seeps, one about 2.3 miles off Redondo Beach, the other about 4.5 miles off Manhattan Beach, also release oil into the Bay. Daily flow from these is estimated at 2 to 18 barrels (84 to 756 gallons), but may be several times this amount during and after local earthquakes.

DREDGING AND DISPOSAL

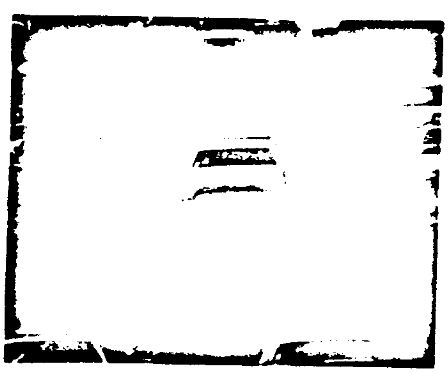
Dredged materials from built-up sediments around harbor entrances may be discarded into the ocean off Southern California in large quantities, if these sediments meet Ocean Dumping Act requirements. Dredged material can also be used for beach replenishment, landfill in harbors for new construction, or disposed of in sanitary landfill sites.

Two areas of historical sediment buildup and dredging activity are the Marina del Rey entrance channel and Redondo Beach King Harbor. Dumping of dredged materials can reintroduce buried contaminants into the ocean at the dumpsite. These can then be carried by currents into the Bay.

There is currently one permitted ocean dump site nearby the Bay. Known as LA-2, this site receives dredge materials from maintenance and construction activities at Los Angeles and Long Beach harbors that must be tested for toxicity. If found to be toxic, the dredge spoils cannot be disposed of at this site.

With over seven million vehicles registered in Los Angeles County alone, aerial fallout is a potentially significant source of contaminants to the Bay.

Prior to 1972, there was also dumping of DDT from the Montrose Chemical Company at a site (known as LA-1) in the San Pedro Channel 10 miles north-west of Catalina Island in 2500 feet of water. Some DDT and other industrial wastes may also have been illegally dumped before reaching the LA-1 site.



ADVECTION

Advection refers to the movement of substances from one area to another via ocean currents. While Bay current patterns are complex and require further study, we do know that oil slicks and contaminants in the surface layer of ocean water can float into the Bay on wind-generated currents and waves, and that tar from the Santa Monica Channel is carried into the Bay. Contaminants from the Los Angeles-Long Beach Harbor may enter the Bay from the south in a subsurface current that flows north along the Palos Verdes Shelf.

Conclusions

In our examination of the human impacts on the Bay, what we have found gives us both cause for concern and cause for hope. While the major pollutants of concern, DDT and PCBs, are no longer discharged into the Bay, they still remain at the top of the list of concerns because they decay so slowly. On the positive side, public and governmental pressure has succeeded in greatly reducing contaminants that enter Santa Monica Bay from local sewage treatment plants, power generating stations and heavy industry. With

VOL 12

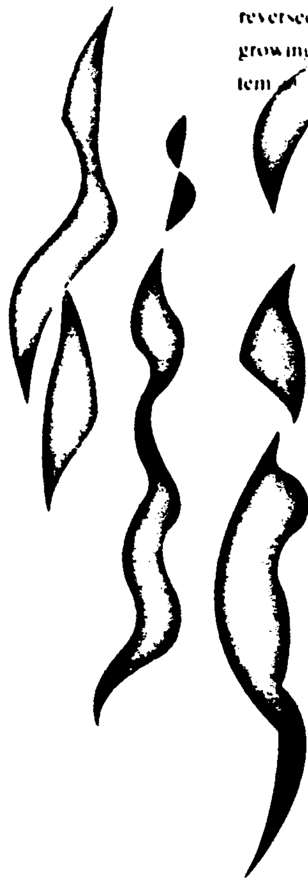
18290

VOL 12

1 8291

better control of these traditional "point sources," pollution reduction efforts are now focusing on urban and storm water runoff.

For all the human use and overuse, the Bay's health is improving, as we will learn in the next chapter. However, the gains that have been made could be reversed without vigilant efforts to offset the environmental effects of our growing human population. Our watershed is a complex, interrelated ecosystem and wherever you live, work or play, you are an integral part of it.



THE HEALTH

OF

SANTA MONICA BAY

3

VOL 12

1

8292

Survey after survey has shown that people throughout the Los Angeles region place a high value on protecting the marine life that depends on Santa Monica Bay. Moreover, millions of people consider swimming, surfing and fishing in Santa Monica Bay as rewarding experiences that they want to be able to enjoy without fearing for their health.

People throughout this region place a high value on protecting the marine life of Santa Monica Bay.

In this chapter, we conclude the summary of the scientific characterization of the Bay. Whereas Chapter Two described growth and urbanization of the region, the origins of pollutants and the pathways of transmission to the Bay, Chapter Three tells the rest of the story—what happens to pollutants once they enter the Bay, the effects of human activities on water quality and habitats, and how marine life and human health are affected.

Chapter Three's examination of the Bay's health moves from a general description of pollutant distribution to a more specific examination of threatened resources and values. Combined with Chapter Two, this portion of the summary sets the stage for the Bay Restoration Plan (BRP), which is presented in abridged form in Chapter Four.

Distribution of Contaminants

Contaminants are supplied to Santa Monica Bay from a variety of sources, as described in Chapter Two. Having entered the Bay, numerous physical, chemical and biological processes can act upon them and affect their distribution and impact on the environment. Contaminants move into three physical reservoirs in the marine environment: the sea-surface microlayer, the water column and sediments. The tissues of living organisms—marine plants and animals, and humans—constitute a potential fourth reservoir.

THE SEA-SURFACE MICROLAYER

The sea-surface microlayer is a critical habitat—only two-thousandths of an inch thick. It is a nursery for both eggs and larval stages of fish and other pelagic organisms. Accumulation of metals and organic compounds in the microlayer can be toxic or cause biological abnormalities in these life forms.

Pollutants that do not dissolve in water and are buoyant—such as petroleum hydrocarbons—tend to accumulate in the sea-surface microlayer, forming the surface slicks seen most frequently in calm waters near shore and in harbors. Contaminants like PAHs (hydrocarbons) have been observed in the microlayer at concentrations 100 to 10,000 times greater than in other parts of the water column.

Atmospheric pollutants also contaminate the sea-surface microlayer. However, aerial fallout is difficult to quantify and relatively few studies have been conducted to assess the kinds and amounts of pollutants which enter the Bay from this source.

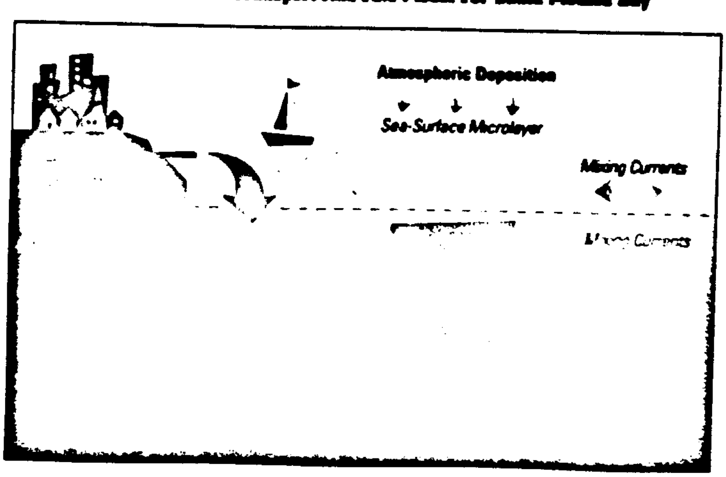
THE WATER COLUMN

Visualize a pillar of water reaching up from the Bay bottom to the surface, like a core sample of the Bay at a single moment in time. While the nature of this imaginary pillar changes constantly, this cross-section of a body of water is what scientists call the water column. Contaminants in the water column can include heat, turbidity, nutrients and pathogens. (Most trace metals and many toxic organics are bound to particles and eventually sink rather than remain in the water column.)

There is no single measure by which to assess the quality of the Bay's waters; it can be polluted in terms of some substances and be otherwise perfectly normal. There are, however, state and federal standards for water quality (e.g. the California Ocean Plan and Federal Marine Water Quality Criteria) that are designed to protect the marine environment. In general, water quality in Santa Monica Bay meets these standards. However, in certain areas, such as lagoons and marinas where water circulation and exchange are low, and areas near storm drain outlets, standards may not be met on a consistent basis.

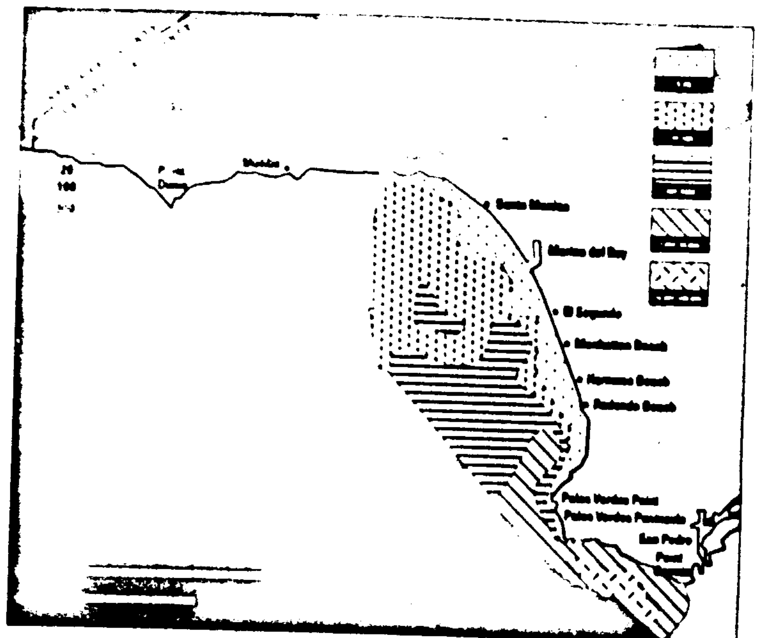
The majority of water in the Santa Monica Bay is healthy, partly because it is an open embayment with major currents that regularly change the water every three to four days, and also because of significant reductions in pollutant loadings from sewage treatment facilities. The major threat to Bay water quality today is pollution from urban runoff.

Generalized Contaminant Transport And Fate Model For Santa Monica Bay



Numerous physical, chemical and biological processes can act upon contaminants and affect their fate in the environment.

While areas with high levels of contaminants such as DDT still remain, the top layer of sediment over most of the Bay is actually cleaner than it was in the 1980's.



Concentrations of DDT in surface sediments of Santa Monica Bay, 1988.

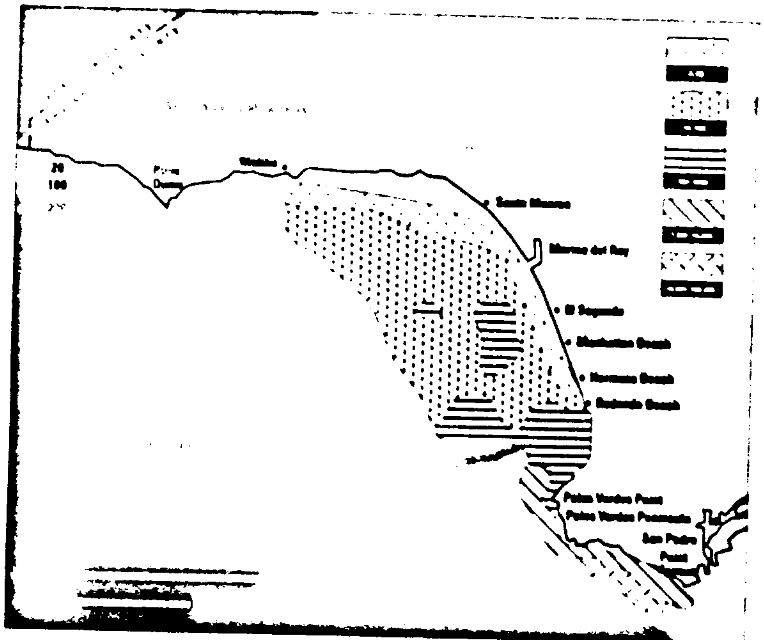
SEDIMENTS

Remember the childhood riddle, "Where does a fish keep his money?" The answer: "A riverbank."

A simple play on words, but in a sense, sediments are a bank, where contaminants and pollutants are deposited to be dispersed, buried and resuspended over time through the action of waves, currents, dredging or bottom-feeding organisms. Because many contaminants are bound to particles, contamination is far more concentrated and more readily measured in sediments than in the water column.

Organic compounds such as DDT, PCBs, PAHs, chlordane and TBTs (see Pollutants of Concern table, Chapter Two), are found in sediments at various locations in the Bay. These contaminants are a major concern because they are present in concentrations that are harmful to marine organisms. DDT, PCBs and chlordane are of particular concern because they biomagnify, meaning that they increase in concentration at higher levels of the food chain. That's why dolphins and sea lions can have DDT concentrations in their tissues up to 80 times higher than we find in sediments.

DDT in white croaker is an example of the overall problem of contaminated sediments. DDT is a cancer-causing chemical that was discharged in large quantities off the Palos Verdes Shelf during the 1950s and '60s. Although banned in 1972, deposits of DDT and its derivatives, DDD and DDE, remain in



Total DDT concentrations in surface sediments of Santa Monica Bay and Palos Verdes Shelf, 1989. (Map contours contain areas of measurement).

Bay sediments where they very slowly degrade or disperse.

White croaker (a commonly caught sportfish) are bottom-feeders; they eat small sediment-dwelling organisms that have ingested DDT and thereby accumulate the chemical in their tissues. Hence the posted warnings against eating white croaker caught in Santa Monica Bay.

Also found in Bay sediments are a set of heavy metals: cadmium, copper, chromium, nickel, silver, zinc and lead. The major sources of sediment contamination have been wastewater treatment facilities; thus the accumulations are highest near treatment plant outfalls off Palos Verdes and Playa del Rey. Fortunately, successful source control programs have decreased discharges of most heavy metals (with the exception of silver) and resulted in declining levels of contaminants in sediments.

While areas with high levels of contaminants such as DDT, PCBs and lead still remain, the top layer of sediment over most of the Bay is actually cleaner than it was in the 1980s. Wastewater pretreatment programs, improved treatment technology, and efforts to educate the public and businesses about preventing pollution have all contributed to this improvement.

Habitat Impacts

Human activities—agriculture, urbanization, commercial and industrial development—have significantly degraded and altered the Bay's habitats since the era of Spanish missions and ranchos. Pollution of the marine environment, as well as natural variability and phenomena such as the climate and water temperature changes wrought by El Niño events, have also contributed to changes in the Bay's plant and animal communities.

THE PELAGIC HABITAT

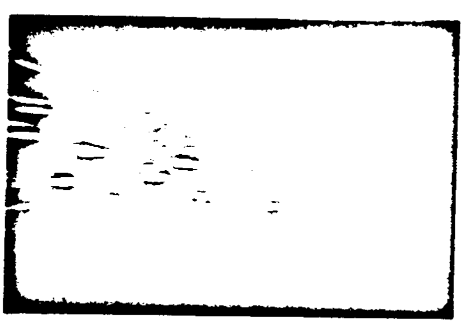
The open water (*pelagic*) habitat of Santa Monica Bay sustains an abundance of life. It is affected by nutrients, sunlight, currents, fresh water, sediments, temperature fluctuations and weather. Due in part to these ever-changing factors, the Bay's 306 square miles of pelagic habitat supports a great variety of organisms. The smallest include bacteria, phytoplankton and zooplankton. The largest are whales, dolphins, sharks and large fishes. In the middle of the pelagic food web are anchovies, sardines, mackerels and squid. As with all food chains, the smaller organisms tend to be food for the larger, and variation or loss of any part of the chain affects all parts.

The Bay's pelagic habitat varies on a fairly regular, seasonal basis. Two factors which probably most affect the abundance of pelagic animals are temperature and phytoplankton production.

THE BENTHIC HABITAT

Another name for the bottom of the Bay is the *benthic* habitat. Scientists have been measuring the effects of pollution on the plants and animals of the benthic habitat, particularly near the sewage outfalls from Hyperion and the JWPCP, since the early 1950s. Benthic organisms are considered good indicators of environmental health because they are not as mobile as fish and they live in the sediments where contaminant concentrations are generally the highest.

Most of the Santa Monica Bay sea floor consists of soft sediments, which are a mixture of sand, silt and clay. This subtidal, soft-bottom habitat supports a diverse number of organisms, including more than 100 species of bottom-dwelling (*demersal*) fish. Major members of the fish community in the Bay's shallow soft-bottom regions include white croaker, queenfish, surfperches, California halibut and barred sandbass.



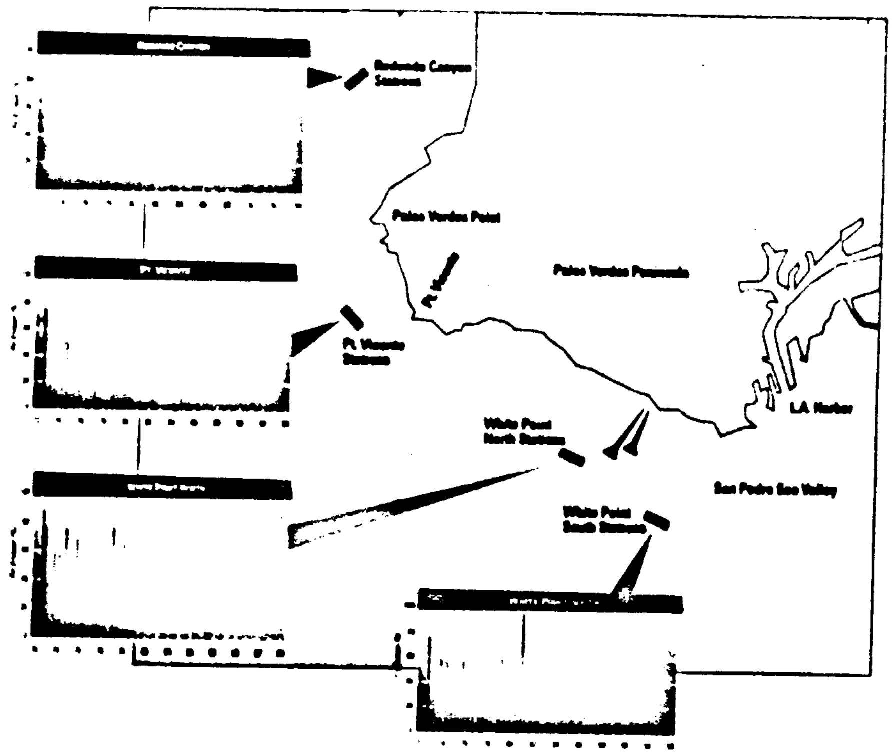
The pelagic habitat of the Bay sustains an abundance of life.

Through the 1970s, the Bay's benthic habitat appeared more changed and degraded the closer one measured to the sewage outfall discharge areas. This meant that these areas of Bay bottom supported far fewer numbers and types of species of plants and animals; in short, the environment was unhealthy and lacked diversity.

Today, the ocean floor areas affected directly by wastewater outfalls have become significantly smaller. Although the effects of the wastewater on surrounding fish and invertebrate communities are still noticeable, environmental monitoring programs show that marine life communities near outfalls are beginning to resemble those in more pristine areas.

Tumors, fin erosion and other diseases—at one time common—are now only rarely observed in demersal fish such as Dover sole. Sensitive species are returning to areas from which they were long absent. Even the severely

The incidence of fish diseases such as fin erosion has declined significantly over the past two decades.



degraded environment around the now-closed Hyperion seven-mile sludge pipe is slowly recovering, as evidenced by declining contaminant concentrations in sediments and increased species diversity.

The benthic environment can also be impacted by trash and debris that sink to the bottom of the Bay. One particular section of the Bay floor, to the north of Hyperion's seven-mile outfall, has a reef of old beer and soda cans at a depth of about 175 feet, refuse dumped for decades by fishermen and pleasure boaters.

KELP BEDS

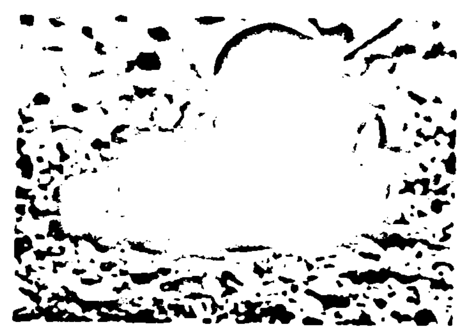
Over the years, kelp bed canopies have varied considerably in size and extent. The reasons for fluctuations in both the size of kelp bed canopies and the health of the plants have been studied and debated for decades. Over-harvesting, waste discharge, storms, oil spills, turbidity and warm water are all thought to have contributed to the loss of kelp beds. To date, no single cause has been identified and the luxuriant regrowth of kelp in areas from which it had disappeared has reassured many that declines are reversible.

However, it does seem that nutrient availability is a major influence on the health and survival of kelp. This is also true of large, destructive storms, the impact of which was clear in 1983 and 1988 when storms decimated the kelp canopy.

VOL 12 1 8299

BEACHES AND ROCKY INTERTIDAL HABITATS

Prior to development, the coast between Santa Monica and the Palos Verdes Peninsula consisted primarily of sand dunes and sandy beaches which shifted due to the action of air and water currents. The process of urban development over the years has changed the way beaches are created, both because jetties and other man-made structures interfere with the coastal distribution pattern, and because the sediments which help replenish beach sands are now held back by dams or diverted into flood control channels and deposited elsewhere on the coast.



Certain species are of particular concern specifically because of the loss or degradation of Southern California beach habitat. These include the endangered California least tern, El Segundo blue butterfly and Western snowy plover.

Projects underway to protect the California least tern include providing protected nesting habitat near suitable foraging areas. Venice Beach has one of the most successful breeding sites in California. The SMBRP has worked with other local agencies to establish a second colony near Playa del Rey.

The El Segundo dunes, habitat for the El Segundo blue butterfly, are a remnant of a once vast coastal ecosystem. Over 900 species of plants and animals have recently been recorded on these dunes, at least 11 of which exist only within its boundaries. Restoration of this unique habitat has begun and plans are underway to establish a Dune Habitat Preserve.

Oil spills are also a potential threat to beach and intertidal habitats, especially to such species as the California grunion, which lays its eggs on sandy beaches.

The recovery of the endangered California least tern population depends on the availability of protected nesting habitat.

With intense and increasing human use of the beaches and waters of Santa Monica Bay, both trash and the need for beach clean-up have increased. Finally, beaches and rocky intertidal habitats are vulnerable to the contaminants often contained in urban runoff. Filter-feeding intertidal organisms have a particularly high potential for bioaccumulating toxic organic compounds. The susceptibility of intertidal communities can be inferred from the high concentrations of trace metals such as lead and chromium found in the tissues of California mussels near Marina del Rey.

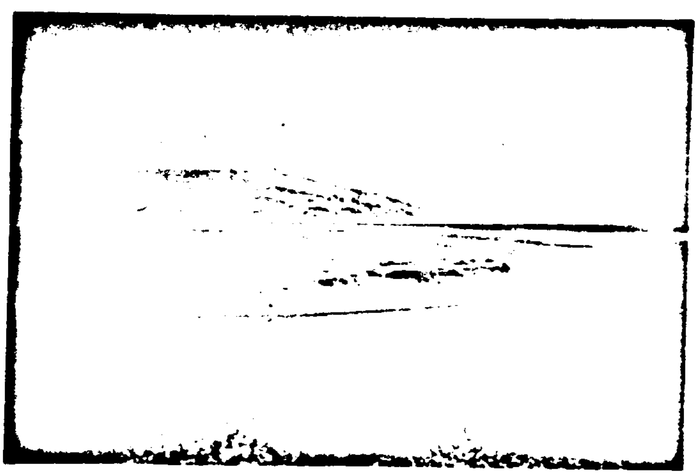
WETLANDS

Wetlands in Southern California include freshwater, saltwater and brackish-water marshes, swamps and mud flats. Marine wetlands develop where streams enter the ocean across a low, flat coast and are modified by differences in salinity and by the tidal cycle. Wetlands help mitigate flooding, filter and recharge groundwater, and provide feeding and breeding habitat for fish and waterfowl.

There are ten brackish wetlands along the edge of Santa Monica Bay, the largest of which are the Ballona Wetlands Complex (Ballona Wetlands, Ballona Lagoon, Del Rey Lagoon) and Malibu Lagoon.

At one time, the Ballona Complex was 2,100 acres of coastal estuary and wetlands. With the development of Marina del Rey, the Venice canals, and other residential and commercial properties; the draining of wetlands for agricultural use and to control insects; and the channelization of Ballona Creek; the Ballona Complex has been reduced to approximately 430 acres. The 260-acre Ballona Wetland is the largest remaining wetland within this complex. The site is a mixture of habitats dominated by coastal salt marsh. The 16-acre Ballona Lagoon is an artificially confined tidal channel that connects the Venice canals to the Pacific Ocean.

Malibu Lagoon is the most significant coastal lagoon in the Santa Monica Bay area, providing habitat for fish and resident and migratory birds.



The 40-acre Malibu Lagoon, at the mouth of Malibu Creek, is also a remnant of a larger system.

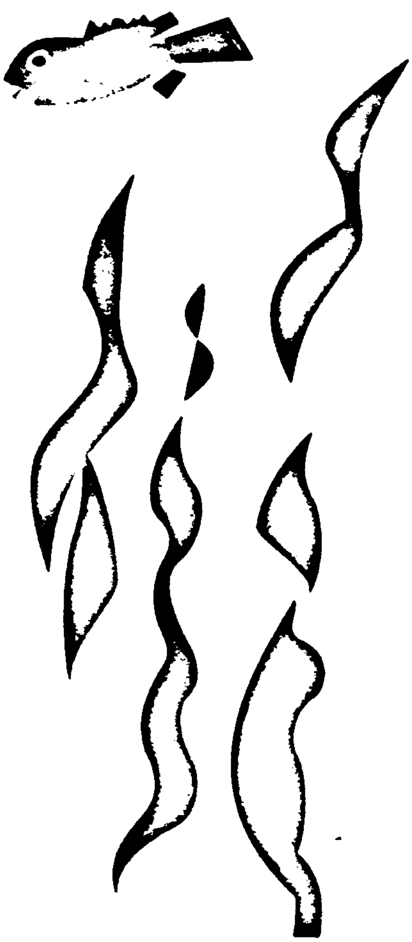
Most local wetlands support less biological diversity and are less productive because of their degraded condition. Restricted water flow, which results in poor water quality (high levels of nutrients and/or contaminants), is the main concern at most sites. Additional adverse impacts include the lack of shallow water habitat, disruption of upstream flow, introduction of non-native plants and animals, debris and bacteria from urban runoff, and recreational over-use.

The wetlands of Santa Monica Bay support a variety of marine and terrestrial life; however, many of the species characteristic of pristine salt marshes of Southern California are lacking. Vegetation is often sparse and includes or is dominated by introduced species which often compete with native species. The salt-marsh bird's beak (a federally- and state-listed endangered plant) is no longer found in the area. Belding's savannah sparrow (a state-listed endangered species) is a year-round resident of salt marshes, foraging and nesting in pickleweed, a dominant plant of the upper marsh. The population of this sparrow was low but stable until 1990, when it began to decline, in part because of predation by introduced red foxes. Attempts to remove the foxes have met with limited success.

Other "listed" birds which have not been seen for some time (due to the absence of cordgrass) are the light-footed clapper rail and the black rail. The black-necked stilt, another species of concern, has not nested recently in the local wetlands.

Animal communities in the sediments, lagoons and channels of local wetlands are also less diverse than in the past; some of the most abundant invertebrates found now are indicators of stressed conditions. Populations of some fish species, such as steelhead trout, have decreased to precariously low numbers. The tidewater goby was recently reintroduced to its original habitat at Malibu Lagoon, although its survival is far from guaranteed.

Although several plans have been developed to preserve and restore Santa Monica Bay wetlands, attempts have often been hampered by the complex issues associated with wetlands restoration. The SMBRP has mapped and inventoried the Bay's remaining wetlands and has targeted key areas for restoration, enhancement, and protection. Habitat restoration plans are an important feature of the BRP, and are described in Chapter Four of this summary.



Potential Human Health Impacts

Throughout millenia, humans have used nearby bodies of water for food and recreation. The loss of the ability to enjoy fishing, swimming or surfing in Santa Monica Bay because of potential human health risks would deprive many people of this important natural and economic resource. Yet surveys indicate that in the minds of many residents as well as potential tourists, Santa Monica Bay has been essentially closed due to pollution. While the perception of danger is often exaggerated, it is based on real problems that must be resolved through effective action.

Seafood Consumption

Synthetic organic contaminants such as PCBs and DDT (and its derivatives DDD and DDE) present the greatest risk to individuals who consume seafood from Santa Monica Bay. Over the past 25 years, several species (especially filter-feeding invertebrates and demersal fishes) from contaminated areas have exhibited very high levels of PCBs and DDTs. After the discharge of these chemicals was stopped in the early 1970s, contaminant levels in fish tissues declined steeply. However, since about 1982, no additional decreases have been observed.

Because of the presence of these chemicals in fish from the Palos Verdes Shelf and northern Santa Monica Bay, the state Office of Environmental Health Hazard Assessment (OEHHA) conducted a comprehensive seafood contamina-

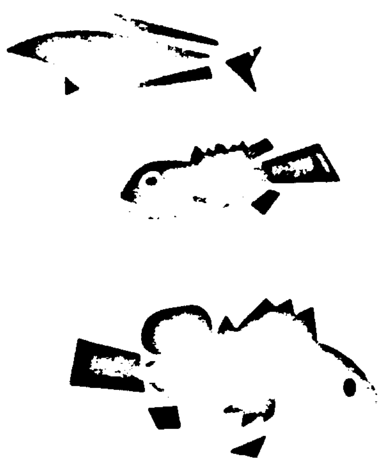
18302

tion study and risk assessment in 1991. OEHHA measured levels of several contaminants (including PCBs and DDTs) in fishes from the Bay and assessed the potential health hazards of consuming various fish species.

The OEHHA report was supplemented by a SMBRP study of local seafood contamination released in 1992. This survey examined the extent of contamination in yellow rock crab and white croaker at several Bay locations.



White croaker is generally considered to be the most contaminated fish in the Bay, especially those from areas such as the Palos Verdes Shelf. Other species found to be relatively contaminated at certain locations are California corbina, queenfish, surfperches and California scorpionfish. Contaminant concentrations in Pacific bonito, chub mackerel, Pacific sanddab, Pacific barracuda, opaleye, halfmoon and California halibut are generally very low. Site- and species-specific consumption recommendations for the most frequently caught and consumed fishes in the Santa Monica Bay area are shown on the previous page.

In general, metal levels in edible tissue of fishes and invertebrates from near the JWPCP and HTP outfalls in the last ten years have not been substantially higher than at reference (clean) sites elsewhere in Southern California. Although sediments near the outfalls often contain high metal concentrations, there does not appear to be an appreciable health risk from metals contamination because metals do not bioaccumulate or biomagnify in fish.

An SMBRP-funded study will describe seafood consumption rates and patterns of Santa Monica Bay anglers by ethnic group, fishing site and fish species. This information will ultimately be used to calculate the potential health risks specific to consumption of Santa Monica Bay seafood and to develop warnings and educational materials that are targeted to particular user groups.

Swimming

Reports from the public, environmental organizations, political leaders, the news media and others indicate that swimmers increasingly complain about ear, eye, wound and intestinal infections, skin rashes and other illnesses that allegedly occur as a result of contact with Bay waters.

Generally, these reports are anecdotal from the perspective of public health officials, inasmuch as they are generally made second-hand, or long after the incidents took place—i.e. circumstances which do not allow a researcher to form even the most preliminary conclusions. Therefore, no clear evidence that swimmers are in fact experiencing increased rates of such illnesses due to Bay pollution is available. At the same time, there is no basis for discounting the anecdotal evidence either.

One thing is clear: the reports of illness from swimming in the Bay have contributed to the public's alienation from this most accessible recreational resource. Beach closures due to sewage spills and warnings of contaminated storm drain runoff have heightened this concern. Indeed, the Bay has developed a reputation for severe pollution—an undeservedly extreme characterization of the Bay's pollution problems—largely because of the continuing perception that swimming in the Bay is hazardous. An SMBRP survey of 500 Los Angeles County adults showed that 41 percent of the public does not visit the Bay because of their concern about water pollution, with many claiming, "I might get sick if I swim in the water."

In investigating sources of pollutants that could be responsible for possible adverse health effects, SMBRP researchers have found evidence that points to pathogens (enteric viruses and possibly pathogenic bacteria) that may be carried by urban runoff through storm drains into the Bay. In studies completed between 1989 and 1991, enteric viruses were found in the effluent at three widely-dispersed locations during dry-weather periods: Pico-Kenter and Herondo storm drains and Malibu Lagoon. These outlets collect flow from scattered locations and varied land uses around the watershed.

Warning signs near flowing storm drain outlets are part of an effort to alert beachgoers of potential pathogen contamination in urban runoff.

This was a disturbing and curious finding, inasmuch as enteric viruses are associated with human excrement. Why would pathogens be present in the storm drain system, given that it is completely separate from the sewer system? Possible sources include illegal sewer connections to the storm drain, leaking sewer lines, malfunctioning septic tanks, inadequate waste disposal by recreational vehicles, campers or transients. Research thus far has yet to yield a final answer.

Although high indicator bacteria counts have been found in nearshore waters surrounding storm drain outlets, no scientific studies have been undertaken to investigate the possible links between incidence of illness and swimming in urban runoff-contaminated waters. Additional sources of human pathogens in nearshore areas include sewage overflows into storm drains (especially during heavy rains), small boat waste discharges and bathers themselves.

Several approaches to address pathogen contamination have been implemented or are being investigated. One obvious and needed approach is to prevent pathogens and pathogen-contaminated runoff from entering the storm drain system.

Alternatively, pathogens in runoff can be diverted away from nearshore areas, as is the case at the Pico-Kenter storm drain, where the cities of Los Angeles and Santa Monica reached an agreement and in 1992 began to treat the drain's dry-weather flow at the Hyperion Treatment Plant.

A third, ongoing approach is to minimize public exposure to pathogens with warnings and advisories. SMBRP has been instrumental in placing updated warning signs near storm drain outlets and advising beachgoers 1) not to swim within 100 yards of flowing storm drains; and 2) not to swim in the Bay during and for up to three days after a storm.

As long as swimmers follow these warnings, the Bay's waters should be considered safe to swim in, and not a health risk as far as pathogens are concerned. Potential health risks associated with exposure to chemical contaminants are generally difficult to establish and are considered by public health officials to be relatively low. Obviously, this risk would be greater if a hazardous substance spill occurred.

Where Do We Go From Here?

In the first three chapters of this public summary, we've examined the history of the Santa Monica Bay watershed, the impacts of pollution on it, and what we know about its present health. Given what we know, how can we learn more about what we don't know, rectify the mistakes we've made, and rehabilitate and restore this fragile but resilient ecosystem?

The first three chapters of this summary have illustrated that what we do to the web of life affects us all. In view of this truth, what specific actions can we take to protect Santa Monica Bay and its environs? How can we more effectively promote pollution prevention? How can we ensure Bay seafood is safe to eat, and that it is safe to swim in Bay waters? In short, how can we be sure that the health of this valuable and treasured ecosystem is adequately protected? These questions are addressed in the remaining pages of this summary.

[1]Enteric: intestinal

[2]Indicator: a species of plant, animal, or bacterium whose presence is associated with or indicative of, a particular environmental condition

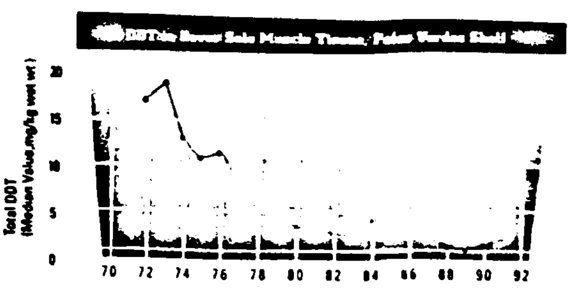
W IS THE BAY DOING?

It is difficult to analyze the effect that human activities have on the condition of the Bay because of the presence of numerous and complex variables. The following indicators nonetheless provide quick "snapshots" of Bay health. They relate back to the basic concerns of how safe it is to swim in and eat seafood from the Bay, and about the health of Bay marine life.

In Chapter 2, we saw that Pollutant Loads to the Bay from sewage treatment facilities continue their decade-long decline. As a result, urban runoff contributes an increasingly greater proportion of pollutants discharged to the Bay.

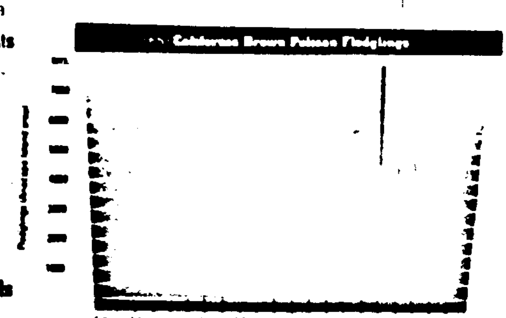
Species Diversity and Benthic Organism Health have improved. Areas of the ocean floor showing species diversity and healthy "normal" creatures have increased. Page 39 shows how incidences of fish diseases such as fin erosion and tumors are now only rarely observed and sensitive species are returning to areas where they were previously absent.

Contamination of Bay Sediments can be assessed by examining concentrations of toxic compounds in fish tissue. Dover sole is one type of fish that is used to measure sediment contamination because it feeds at the bottom of the Bay and remains in a localized area. Although DDT concentrations in Dover sole tissue has declined since the 1970's, it has not changed significantly over the last decade, especially on the Palos Verdes Shelf where DDT remains in ocean floor sediments. Once clean-up decisions about the DDT contamination are finalized, we can expect to see improvements in this indicator as well.



Population Trends of Endangered Bird Species are also measures of Bay health.

The California brown pelican nearly became extinct due to almost complete reproductive failure caused by extreme eggshell thinning induced by the pesticide DDT. This pollutant magnified in the food web and was ingested by pelicans through the fish that they consumed. Reproductive success of the pelican has increased substantially since the termination of DDT disposal into coastal waters.



The California least tern visits Southern California in mid-April to breed. California beaches once teemed with these little birds but human encroachment on their favorite nesting sites had reduced the population of these terns to an estimated 600 nesting pairs statewide by 1975. The establishment of protected nesting sites, such as the one at Venice Beach, has helped the birds bounce back to nearly 1,800 nesting pairs between the San Francisco Bay and the Mexican border.

Bacterial Contamination in the Surf Zone indicates where swimming in the Bay may be more or less problematic. It is not a perfect guide because the bacterial indicators—coliform and enterococcus—could indicate the presence of animal waste or plant decay, as well as human fecal waste, which is of greater concern. Nonetheless, the chart on page 46 focuses on bacterial indicator measurements during dry weather—traditionally the time of greatest use of the Bay by swimmers. It shows that the standards for these indicators are exceeded on numerous occasions at certain storm drains and piers around the Bay during the summer season.

ACTIONS

FOR BAY

RESTORATION

VOL 12

Actions for Bay Restoration

The Public Summary has thus far explored Santa Monica Bay's physical and biological features and the effects of human activity on the Bay ecosystem. This chapter provides an overview of the Restoration Project's recommended actions to restore, protect and improve the Bay.

This summary follows the structure of the Bay Restoration Plan. The condensed chapter format states the **Problem** to be solved; describes the **Actions**; and highlights the **Priorities** in easy-to-read, bullet form. For reasons of space, we do not list every individual action item, implementor and timeframe. Instead, we provide a narrative that focuses on the intent and scope of the recommended actions. The full, comprehensive set of recommendations is available in the companion Bay Restoration Plan, available on request.

PLAN CONTENTS

The Santa Monica Bay Restoration Project

In 1988, the U.S. Environmental Protection Agency and the State of California recognized Santa Monica Bay as a natural resource that must be protected and preserved. As a result, the Santa Monica Bay Restoration Project was nominated and accepted into the National Estuary Program (NEP). As an NEP, the Santa Monica Bay Restoration Project (SMBRP) is charged with assessing the Bay's problems and with producing a Bay Restoration Plan (BRP) to serve as a blueprint for the Bay's recovery.

Summary of the Bay Restoration Plan

PREVENTING POLLUTION AT THE SOURCE

Pollutants clearly pose the most significant problem to the Bay, its users and its inhabitants. The first section of the Plan addresses the problem of Bay pollution by delineating management strategies and programs that apply to pollutants that are of concern in Santa Monica Bay, as well as the major sources and pathways by which they enter the Bay.

Reducing pollutant loadings to the Bay in a manner that prevents degradation to the marine ecosystem, protects beaches and minimizes risks to human health is a key goal of the Plan. Integrated and comprehensive management and control of various pollutant sources is another.

The Plan recognizes that it is neither feasible nor necessary to control all types and sources of pollutant inputs and therefore focuses on those that present the greatest problems to the

1
8
3
0
9

Bay. This Plan's approach to comprehensive pollution management therefore identifies 19 "pollutants of concern" as the priorities for action during the five-year Plan implementation period. This approach emphasizes prevention at the source, targets pollutant reduction measures on an area-specific basis, addresses historic contamination separately from new contaminant sources, and calls for a revised regulatory approach utilizing the concept of mass emissions. Each of these strategies applies to specific, but often overlapping, sets of pollutants. Pollutant sources are also targeted in accordance with their impacts on the marine environment and on human health.

Integral to "preventing pollution at the source" are effective public education and involvement programs, as well as a comprehensive monitoring program that assesses the environmental condition of Santa Monica Bay and the effects of human activities on it.

Integrated Pollution Management

Problem: Historically, water quality management addressed pollution problems that were most visible and most readily fixed. Pollution reduction measures therefore focused primarily on end-of-the-pipe solutions to discharges from individual municipal and industrial point sources of pollution. Although this approach has successfully dealt with significant pollution problems, a new management framework is necessary to integrate control of point and nonpoint pollutant sources such as storm water discharges, urban runoff and atmospheric deposition.

Actions: Integrated pollution management is a two-pronged approach that provides a framework to more cohesively and efficiently address water quality issues. The Plan calls for **watershed-based coordination** of permitting and other water quality regulatory functions. Some of the expected outcomes include concurrent development and renewal of discharge permits by watershed, standardized monitoring requirements and more cost-effective implementation of control measures.

Integrated pollution management provides a framework to more cohesively and efficiently address water quality issues.

The second integral component of improved water quality management is implementation of a **"mass emissions" approach.** This approach, which would apply to 12 pollutants of concern, would complement the existing concentration-based regulatory system by establishing non-punitive performance goals to measure progress made toward protection of the Bay's beneficial uses.

Priorities:

- Coordinate all components of the NPDES program with other regulatory functions on a watershed or sub-watershed basis.
- Revise current NPDES permits to incorporate new pollutant management approaches and develop new enforcement mechanisms if necessary.
- Develop and implement a mass emissions approach. Also establish initial mass loading discharge performance goals for pollutants of concern that

VOL 12

1 8310

accumulate in the marine environment and for which there are reasonable mass loadings estimates and feasible control measures.

Pollution Prevention and Source Reduction

Problem: Pollutants originate from many diffuse but potentially significant sources in the Santa Monica Bay watershed. People, cars, boats and businesses send pollutants to the Bay through indirect channels such as sewer and storm drain systems, as well as through direct discharges such as industrial outfalls. Toxic pesticides and chemicals, metals, waste oils, plastics and debris are among the many types of pollutants released into the environment from these sources.

Managing and controlling pollutants that come from many small, diverse sources is a difficult task. With a projected population of about 12 million people in Los Angeles County by the year 2010, it can be expected that the generation of pollutants will increase unless we continue our efforts to reduce and prevent these discharges.

Actions: The Plan is based on the simple principle that it is more effective to reduce or eliminate pollutants at their source, **before** they are created. Pollution prevention, unlike control methods which capture waste only **after** it is created, requires re-thinking how polluting substances and products are used in the home and in the workplace. Fortunately, practices such as reducing toxics use on land and conserving water also help improve conditions in the Bay. Programs that reduce pollutant loads to sewage treatment plants, reduce household hazardous wastes, educate the public about the impacts of marine debris and litter on the ocean ecosystem, reduce air pollution and encourage the development of innovative approaches to pollution prevention are all part of a comprehensive strategy to prevent and reduce pollutant discharges into the environment.

Priorities:

- Coordinate and expand public education programs that focus on reducing generation of household toxics.
- Expand programs for recycling and collection of household hazardous wastes.
- Encourage creation of markets for use of recycled hazardous materials.
- Continue support of annual Coastal Cleanup Day and Adopt-a-Beach activities.
- Implement measures that prevent discharges of pollutants into marina waters.

PRINCIPLES

Over the last five years, seven principles served as the foundation on which the Bay Restoration Plan was built

Environmental Stewardship: Our generation has inherited the responsibility to act as stewards of the Earth's natural resources

Consensus Planning: The Plan was developed collaboratively with the Bay's many stakeholders, using the best available scientific and technical information.

Enhanced Regulatory Enforcement: It is essential to first improve implementation of existing laws and regulations before creating new ones.

Fiscal Responsibility: The Plan recognizes the fiscal limits of public agencies and the importance of balancing investments in Bay restoration with the need for economic development, public safety, and other social and environmental goals.

Respect For Diversity: The diversity of life in the Bay and its watershed richly contributes to the region's environment, economy and quality of life.

Community Involvement: The Plan incorporates the views and interests not only of the Management Conference but also of the communities that its members represent.

Watershed Perspective: The Santa Monica Bay watershed is viewed as a single hydrological entity and the political jurisdictions within it recognize that the Bay unites them.

Nearly 50,000 households around the Los Angeles basin participated in hazardous waste roundup days in 1993.

- Ensure that sufficient pumpout facilities are available, maintained and used at moorage facilities in marinas.

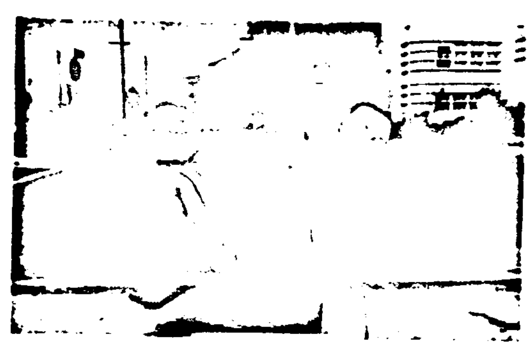
Storm Water/Urban Runoff

Problem: Storm water/urban runoff is the most significant source of "nonpoint" pollution to Santa Monica Bay. Twelve of the Bay's 19 pollutants of concern are found in urban runoff including pathogens, toxic metals, nutrients and trash. Pollutants found in storm drain runoff originate from a vast array of activities in the watershed and discharge into nearshore areas of the Bay mostly without treatment, degrading the Bay's recreational, biological and aesthetic values.

Efforts to manage storm water/urban runoff are carried out under municipal, industrial and construction National Pollutant Discharge Elimination System (NPDES) permits. In 1990, the municipal NPDES permit was issued to Los Angeles County, its 89 cities and other governmental entities and directed them to select and develop Best Management Practices (BMPs) to prevent pollutant discharges. The term of the current permit will expire in 1995.

Actions: Many innovative approaches to address the distinct issues associated with management of storm water/urban runoff pollution are presented in Chapter 3 of the Plan. It is proposed that the current NPDES permit framework be strengthened by improving coordination of the program and by implementing management measures on a watershed basis. A major challenge of the storm water permit is to ensure the implementation of the most effective BMPs. Examples of BMPs include land use ordinances that control construction site erosion, and public education campaigns. The Plan establishes a selection hierarchy, recommending that economical, non-structural measures with watershed-wide benefits be implemented first.

Programs such as storm drain stenciling involve the public in reducing urban runoff pollution.



Priorities:

- Revise and incorporate new program elements into the storm water NPDES permits.

R0051617

ACCOMPLISHMENTS

The SMBRP has undertaken many significant projects and programs that support and further the goals of Bay restoration and protection. They include:

- Initiation of Los Angeles County's first municipal stormwater permit.
- Restoration of the Zuma Creek wetland.
- A 14-point program of "early actions" to jump-start the Bay restoration process.
- A mini-grants program which provides funding to schools, inner-city youth, environmental groups, and municipalities to involve the public in Bay resource protection and pollution prevention efforts.
- An innovative research project that found human enteric viruses in several storm drain outlets to the Bay. Design of the first epidemiological study to assess human heath risk of swimming in contaminated runoff on the West Coast.
- A seafood contamination study and analysis of local sportfish consumption patterns which will lead to better information about potential health risks of consuming of Bay seafood.
- Creation of a nation-wide campaign for school-age children (utilizing the Teenage Mutant Ninja Turtles) to raise awareness about urban runoff and storm drain pollution.
- A demonstration project on ozone treatment of dry weather storm drain flows.
- Marine debris educational displays and recycling stations on Bay beaches. Tripled volunteer participation in Coastal Cleanup Day.
- A public opinion survey that gauged attitudes about the Bay and the public's willingness to participate in its restoration.
- Creation of the non-profit Santa Monica Bay Restoration Foundation.

- Increase staffing for regulatory oversight of the storm water NPDES program and for local agency coordination and compliance activities.
- Develop mechanisms to address small discharges of contaminated runoff.
- Investigate technically achievable and cost-effective strategies to ensure better compliance with existing storm water regulations and achieve water quality improvements in areas impaired by storm water discharges.
- Review environmental impact documents to ensure that impacts of storm water discharges are addressed and mitigated.
- Reduce impacts of transportation activities on storm water/urban runoff pollutant loads.
- Develop and implement a five-year urban runoff education strategy.
- Implement "tested" Best Management Practices (Menu "A" BMPs) by 1996.
- Adopt and enforce land use ordinances that reduce runoff from commercial and industrial facilities and at construction sites.
- Conduct pilot projects to assess the effectiveness and applicability of additional (Menu "B" and "C") BMPs.
- Conduct research on dry-weather, wet-weather and sediment toxicity of urban runoff, and recommend necessary changes to monitoring programs.

Municipal and Industrial Discharges

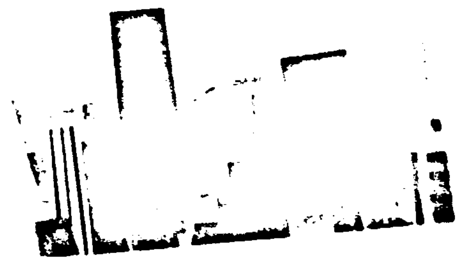
Problem: Los Angeles County's nine million residents utilize the Bay for a wide variety of purposes, including the discharge of treated domestic, commercial and industrial wastes. Currently about 645 million gallons of treated municipal wastewater are discharged to the Bay by the region's two major sewage treatment systems.

Although municipal wastewaters have been a significant source of contaminants to the Bay, extensive and continuing improvements in treatment processes along with stringent industrial waste controls have reduced contaminant levels to a fraction of former levels. Effects of wastewater outfalls on surrounding fish and invertebrate communities are still noticeable, however, environmental monitoring programs show that these marine life communities are beginning to resemble those in more pristine areas. Nonetheless, future population

VOL 12 1 8313

and economic growth could offset these gains unless a continuing, comprehensive pollutant reduction strategy is implemented.

Actions: The Plan calls for a variety of actions to reduce pollutant discharges and improve management and control of pollution from municipal and industrial sources. Completing upgrades to full secondary treatment of all direct municipal wastewater discharges to Santa Monica Bay is a primary element of this program. The Plan also outlines the necessity of beneficially using both the resultant reclaimed water and biosolids from wastewater treatment. Reclaimed (tertiary treated) water, which is currently generated at many upstream treatment plants, is a reliable, drought-proof water source that can help meet the region's vast needs for landscape and agricultural irrigation, industrial cooling water supply, and most importantly, groundwater recharge. Concurrently, water reuse can significantly reduce wasteloads discharged to the ocean.



Recommendations for improved management of point source discharges include ensuring adequate staffing and resources for NPDES permit enforcement activities; revamping of permit processing and record keeping procedures; implementing the comprehensive monitoring and data management program; and enhancing industrial pretreatment programs.

A priority of the Plan is to ensure that the Hyperion and JWPCP wastewater treatment facilities attain full secondary treatment levels.

Priorities:

- Complete construction of full secondary facilities at the Hyperion Treatment Plant and remedy storm-related sewage overflow problems by 1998.
- Install full secondary treatment facilities at the County Sanitation Districts' Joint Water Pollution Control Plant by 2002.
- Continue to develop markets and opportunities for use of reclaimed water.
- Explore alternative mechanisms/strategies to ensure adequate staff and resources, legal support for NPDES and pretreatment permit activities.

Oil and Hazardous Materials Spills

Problem: Hazardous materials spills, including oil, can cause massive ecological damage in a very short time. Moreover, the cumulative effect of numerous minor spills can also adversely impact the Bay's ecosystem.

Actions: Using a four-part strategy, the Plan addresses both land spills (which make their way to the Bay via the storm drain system), and marine spills. The focus is on spill prevention, effective response, restoration of resources to their pre-spill condition and public education. The Plan calls for reducing the spillable inventory of hazardous materials in the watershed, speedy mobilization through improved inter-agency coordination, establishment of animal rehabilitation centers, compilation of a natural resources data base, and spill response training for fishermen and other volunteers.

Priority:

- Sign a Memorandum of Understanding (MOU) that authorizes cross-jurisdictional entry into storm drains to investigate spill incidents.

Contaminated Sediments

Problem: Hazardous amounts of toxic PCBs and DDT were dumped and/or discharged into the Bay between the 1940s and mid-1970s. Subsequent federal bans on these and other toxic substances have resulted in their overall decline, however, they persist in Bay sediments, where they are a source of contaminants to the marine ecosystem.

DDT and PCB toxic hot spots on the Palos Verdes Shelf are the subject of a federal lawsuit concerning damages to the Bay's natural resources.

Actions: In order to protect human health and the environment, specific "hot spots" caused by historic and present contaminant sources must be targeted for cleanup. The toxic hot spots of DDTs and PCBs around the JWPCP outfalls on the Palos Verdes Shelf and Slope are the subject of a pending lawsuit filed by the National Oceanic and Atmospheric Administration (NOAA). A natural resource damage assessment is currently underway and settlements will be used to remediate the damages to those resources.

Long-term protection of the Bay's sediments requires the development of sediment quality criteria based on research on the relationships between toxic discharges, sediment contamination and effects on the Bay's ecosystem.

PROTECTING THE PUBLIC FROM POTENTIAL HEALTH RISK

The question of potential health risk associated with eating Bay seafood and swimming in the Bay has been a major public concern. Such concern stems from reports that certain local sportfish are contaminated and accounts of swimmers experiencing illnesses due to contact with Bay waters. Chapter Three of this summary provides a detailed look at these public health issues, describing the current state of knowledge based on recent scientific studies.

The overriding goal is to protect and inform the public about potential health risks associated with fishing and swimming in the Bay. Identifying and eliminating the pollutant sources that impact these activities is the first step to achieving public health protection. However, reducing risks also means

VOL 12

1835

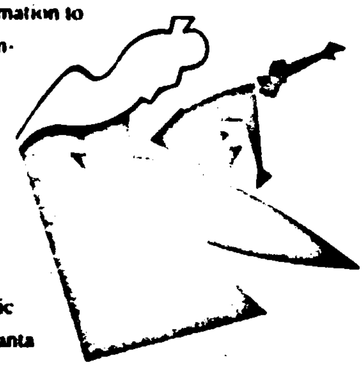
providing the public with information about the extent of potential health hazards, so that all potential consumers and users are well-informed enough to make choices.

SMBRP research efforts will lead to definitive health risk guidelines for Santa Monica Bay anglers.

Seafood Consumption

Problem: Eating contaminated seafood is the primary means by which humans are exposed to toxic substances in the marine environment. While recent studies have shown that health risks are limited to certain seafood species at certain locations, the public perception remains that all seafood in the Bay is contaminated.

Actions: Linking seafood consumption with possible adverse health effects requires a scientific evaluation known as "risk assessment." Risk assessments attempt to evaluate how chemical dosages are correlated with physical responses. The SMBRP is currently evaluating information about fish contaminant levels and consumption patterns in the Bay, which will lead to definitive health risk guidelines for Santa Monica Bay anglers. Long-term needs are for periodic updates of seafood risks, integration of seafood contamination information into the regional monitoring program, and development of a program to more effectively communicate information to the public about the benefits and risks of consuming Bay seafood.



Priority:

- Update and effectively disseminate seafood health risk information to Santa Monica Bay anglers on a regular basis.

Swimming in Bay Waters

Problem: It is clear that pathogens, or microscopic agents that cause illness, periodically enter the Santa Monica Bay surf zone. However, determining the sources of contamination, preventing pathogens from entering into swimming areas, and accurately assessing and informing the public about potential health risks associated with contaminated runoff remain a challenge.

Actions: Finding and removing pathogens where they originate is the primary means for reducing potential health risks to Santa Monica Bay swimmers. The Plan therefore calls for the development of a practical tool to identify these sources. Alternatively, under certain conditions, it is possible to divert or treat dry-weather flows, as is now being done with the flow from the Pico-Kenter storm drain.

An epidemiology study is regarded as the ultimate step necessary to answer the question, "How safe is it to swim in the Bay?"

An assessment of health risks (otherwise known as an epidemiology study) is regarded as the ultimate step necessary to answer the question, "How safe is it to swim in the Bay?" With this study, we will finally know if a risk exists and whether that risk differs accord-

VOL 12

18316

ing to where you swim. Together with a yet-to-be-developed bacterial indicator system, the "epi" study will also provide the basis for revising public health standards and water quality objectives.

As long as prevention and treatment measures do not sufficiently remove pathogen inputs, swimmers need to be properly warned about where and when pollution occurs.

Priorities:

- Develop a methodology for and conduct a sanitary survey to identify sources of human pathogen contamination.
- Conduct inspections and correct problems such as malfunctioning septic tanks, illegal connections to storm drains, and sewer line leaks.
- Divert and treat urban runoff where appropriate.
- Conduct an epidemiology study to assess health risk of recreational exposure to storm drain runoff in Santa Monica Bay.
- Accurately communicate health risk information to the public to minimize exposure to pathogens and to encourage use of safe swimming areas.

RESTORING, PROTECTING AND MANAGING BAY HABITATS AND RESOURCES

Restoration of degraded habitats, rebuilding of key species, and increased enforcement of marine resource protection laws are crucial for a healthy Santa Monica Bay.

Santa Monica Bay and its watershed are comprised of unique yet interdependent habitats that support an abundance and diversity of life. The Bay's aquatic ecosystem is made up of the marine ecosystem, wetlands, beaches and intertidal zones. The marine ecosystem is a collective term for three of the Bay's aquatic habitats—pelagic (open ocean), subtidal soft-bottom (seafloor sediments), and subtidal hard-bottom (seafloor reefs or outcrops). The transition areas between land and sea are the beaches, intertidal zones and coastal wetlands. Freshwater wetlands and riparian corridors are key elements of the freshwater ecosystem.

Despite the relative abundance of both aquatic and terrestrial life in and around the Bay, habitats in the Bay's watershed have been significantly degraded, altered and lost since the time that California was settled by Spanish missionaries. The marine ecosystem has been impacted by pollution, with declines of certain species and accumulation of persistent toxins in fish, birds and marine mammals. The goals for habitat restoration, protection and management respond to the need for a healthy and diverse ecosystem, while also recognizing the need for wise human use of these resources.

In order to ensure long-term protection of Bay resources, comprehensive habitat management strategies are needed. Reducing pollutant inputs into the ecosystem, restoring and increasing the quantity and quality of habitats, reversing declines in native species, increasing enforcement of natural resource regulations and promoting public stewardship of the Bay's environment are all vital to successful habitat protection and restoration.

Marine Ecosystem

Problem: Throughout the years, both natural and human-induced actions have resulted in degradation and, in some cases, elimination of particular habitats within the Bay's ecosystem. Loss of natural shoreline habitat and wetlands have reduced nursery areas for fish. Poaching and overharvesting have impacted species populations. Deep-water discharges of treatment plant effluents adversely affected large areas of the seafloor community through the 1970s. Biomagnification of toxins such as DDT and PCBs severely impaired the reproductive success of California brown pelicans. Natural events such as storms, elevated water temperatures associated with El Niños, and landslides also alter the marine environment.

Nevertheless, improvements are seen in certain Bay marine habitats, as evidenced by the now-lush kelp forests and rocky intertidal plant and animal communities off Palos Verdes, and by the ongoing recovery of fish and invertebrate communities near wastewater outfalls.

Actions: At this point, emphasis must be placed on the restoration of many of the degraded habitats around the Bay, as well as the enhancement of impacted species. Declining populations of key species need to be rebuilt, greater protection must be provided for unique and sensitive habitats, and increased enforcement of marine resource protection laws and regulations is necessary. Increasing the public's awareness of the importance of the Bay's marine resources and the impact that human actions can have on them is a crucial link to a restored and healthy marine ecosystem.

Priorities:

- Identify cost-effective methods to rebuild declining populations of key species such as abalone, Pismo clam, California spiny lobster, California halibut and white seabass.
- Characterize and map Santa Monica Bay's unique and sensitive habitats and other natural resources of special significance to ensure better long-term protection.
- Increase the number of Wildlife Protection Officers along Santa Monica Bay to enhance enforcement and education activities.
- Encourage citizen monitoring and reporting of wildlife violations.

The Plan focuses on restoring the ecological diversity and productivity of existing wetlands to increase both their function and value.

Wetlands

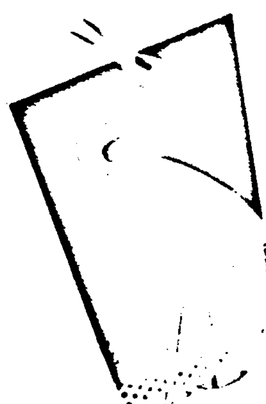
Problem: Wetlands are one of the most productive ecosystems in nature, providing essential habitat for a vast number of diverse species of plants and animals. The major impact to Santa Monica Bay wetlands has been the direct loss of habitat through draining, dredging, filling, diking and channelization to

VOL 12 1 83/8

R0051623

make way for farms, port/harbor facilities, housing and commercial development. It is estimated that more than 95% of the historic wetlands acreage of the Santa Monica Bay watershed has been destroyed.

What remains today are a few small coastal wetlands and lagoons, and some riparian (streamside) freshwater wetlands in the canyon areas of the northern part of the watershed. The coastal wetlands and lagoons are located in and near urban areas and are thus subject to intense human activity (intrusion, trash and invasive non-native plant species), while riparian wetlands are threatened by nonpoint source pollution and development pressures. Many species of animals and plants, some of which are listed as threatened and endangered, depend upon these habitats, making restoration and protection of these wetlands vital to a healthier Bay ecosystem.



Actions: Enhancement of wetland habitat in the Santa Monica Bay watershed focuses on restoring the ecological diversity and productivity of existing wetlands to increase both their function and value. Innovative actions to acquire and create wetland acreage, establishment of local land use ordinances to protect wetlands, and development of special area management plans are all called for in the Plan. A local/regional focus that complements state and federal wetland protection actions should result in comprehensive wetland management.

Priorities:

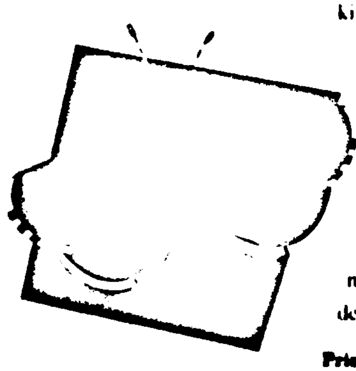
- Restore Ballona Wetlands. Determine the type and amount of habitat value to be attained through restoration and determine mitigation requirements based on the proposed development. Reach agreement on the "best" overall restoration design to achieve these habitat values. Develop a funding package to restore and maintain the wetlands and provide for long-term management and monitoring.
- Restore Ballona Lagoon to enhance its tidal flow and increase its habitat value.
- Restore Malibu Lagoon to enhance its habitat values and to ensure safe recreational use of the adjacent beach and ocean waters.
- Develop a special area management plan (SAMP) to protect and restore wetlands and riparian areas of the Santa Monica Bay watershed.

Beaches and Intertidal Zones

Problem: Beaches and intertidal zones are unique coastal habitats and home to hundreds of species of birds, fish, mammals and other wildlife. Development and urbanization of the Los Angeles basin has destroyed much of the original coastal habitat which once consisted of narrow beaches, rocky shore, sand dunes and wetlands rich in biological diversity and abundance.

Intertidal zones are also affected by storm drain discharges of debris and sediment, as well as beach litter and marine debris. Trash and other objects can

VOL 12



kill marine wildlife, degrade the aesthetic values of the Bay, and pose serious health and safety problems for Bay users.

Actions: The Plan calls for enhancing the protection of beach and intertidal habitats for threatened and endangered species and other species of concern. Protection entails providing safe habitat areas for species such as the California least tern, and increasing the enforcement of existing regulations concerning harvesting of marine life/tidepool organisms. Improved beach litter cleanup methods and public education and involvement to reduce trash and debris are also necessary to protect intertidal habitats.

Priority:

- Augment ongoing efforts to restore the El Segundo Dunes and create a Dunes Habitat Preserve.

WATERSHED PLANNING

Water quality, resource protection and human health issues related to swimming and fishing in the Bay need to be managed in an integrated fashion in order to achieve watershed-wide planning and management goals. The first three sections of the Plan describe actions that apply to and are coordinated within the entire Santa Monica Bay watershed. This section focuses on the need for integrated planning at the watershed and sub-watershed levels, and is followed by a practical example—the Malibu Creek Watershed Pilot Plan. This new planning strategy furthers the goal of enhanced Bay protection.

18320

Planning and Management for Sub-Watersheds

Comprehensive watershed planning cuts across political boundaries and is based on the cooperative effort of many stakeholders.

Problem: Many people are unaware that activities occurring inland, or "upstream," have an impact on coastal areas "downstream." Until recently, land use planning was treated separately from managing the quality of receiving waters. As a result, water quality and environmental resources have deteriorated, particularly in rapidly urbanizing areas. Environmental resource protection has also been hindered by the fact that human activities have not generally been organized and managed around hydrologic or watershed boundaries, resulting in fragmented mandates and management priorities which have made it difficult to effectively solve problems. These problems call for a comprehensive watershed planning approach that cuts across political boundaries and is based on the cooperative effort of many stakeholders.

Actions: Successful watershed-wide management planning is affected by actions that occur in each of the Bay's sub-watersheds. Planning at the sub-watershed level acknowledges the distinctions among sub-watersheds and can more accurately reflect the particular needs of each area. Development of sub-watershed management plans should occur in areas where there is current or potential impairment of beneficial uses in receiving waters, where there is a prevalence of biologically sensitive habitats, and where there is high likelihood of intensified land use.

Priority:

- Explore the feasibility of creating Joint Powers Authorities, Watershed Commissions, special districts, or other cooperative entities to effectively implement watershed-based environmental management.

Malibu Creek Pilot Plan

Problem: The Malibu Creek sub-watershed, which incorporates the relatively rural Santa Monica Mountains and the cities in the Ventura Freeway corridor and on the coast, has more than doubled its population in the last 20 years. It has consequently changed from low-intensity land uses that contributed few, if any, human-generated contaminants, to urban developments that significantly increase the pollutant load to the Bay. At the terminus of Malibu Creek, Malibu Lagoon receives the natural and artificial runoff from the entire sub-watershed. The Malibu Creek sub-watershed's environmental quality is impaired by three major causes: pollutant inputs, modifications of natural stream flows and loss of sensitive habitats.

Actions: Significant local interest in finding solutions to problems made the Malibu Creek sub-watershed particularly suitable as a test case for developing and implementing a specific management plan. With funding from the SMBRP, a facilitated mediation process was employed to identify the basic environmental and management concerns of the various stakeholders in the watershed, and to come to agreement on how to resolve existing or perceived problems and how to prevent further environmental degradation.

A watershed-based approach must be taken to protect the sensitive Bay environment since it can be affected by building activities taking place miles inland.

The actions and concepts described in the Malibu Creek Pilot Plan have been partially derived from this fact-finding and consensus-building process, although specific agreements about implementation priorities and specific language on certain actions have yet to be worked out. Early actions should be undertaken to reduce pollutant impacts in the lower sub-watershed and lagoon and to protect key species while long-term options are being evaluated. Both short- and long-term plans must include a program for restoring and protecting the native biodiversity, and creation of specific BMPs to reduce sediment and other pollutant loads from hillside developments.

VOL 12

18321

Once the success of the Pilot Plan has been determined, applicable elements of the Plan should be utilized to develop management plans for the Bay's other priority sub-watersheds.

Priorities:

- Conduct a source survey to identify and eliminate major sources of human pathogens into Malibu Lagoon and the adjacent surfzone.
- Agree on a near-term means of regulating water levels in the lagoon and improving the breaching/management protocol.
- Investigate the relationships between groundwater movement into the creek and lagoon and the role of septic tanks in contributing pollutants to the creek, lagoon and surfzone.
- Develop a plan to minimize and mitigate water quality and quantify impacts on the lagoon that result from surface discharge of groundwater pollution abatement programs.
- Pursue increased capacity for seasonal storage of reclaimed water and other effluent disposal options to reduce unseasonable flows to Malibu Creek and restore a more natural hydrologic regime.
- Develop site-specific BMPs for hillside developments.
- Create buffer zones adjacent to sensitive habitats and evaluate the adequacy of current standards.
- Enhance and restore the lower portions of Malibu Creek.
- Develop and implement a lagoon restoration plan.

CROSS-CUTTING ISSUES

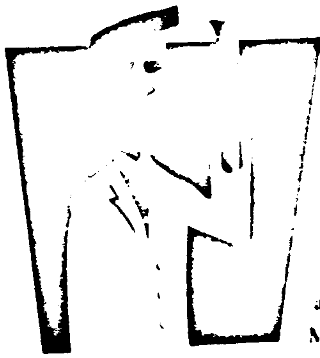
Monitoring, research, and public outreach are essential components in all chapters of the Plan. This section combines the recommendations contained in each chapter and describes the framework to coordinate and implement them.

Public Education and Involvement

The PIE Program reaches out to the Bay's many communities and encourages innovative public education regarding Bay issues.

Problem: Increased public awareness and education are integral to the successful restoration and protection of the Santa Monica Bay environment. Public education programs identified in the Plan center around several themes: increasing awareness about how our actions can have a direct impact on the Bay; enhancing public appreciation for the Bay's many environmental and economic values; communicating potential health risks, and gaining public support for and involvement in Bay restoration efforts.

Actions: With a wealth and diversity of programs that are currently reaching out to the public, it appears that the most effective—and most *cost-effective*—way to conduct public outreach concerning Santa Monica Bay is to unite existing efforts under one umbrella. Coordination through a Bay Information and Education Council would bring non-profit environmental groups, government agencies, and private sector organizations together to share programs and ensure that efforts are not needlessly duplicated. Encouraging and supporting innovative public outreach activities through the Public Involvement and Education (PIE) mini-grants program of the Santa Monica Bay Restoration Foundation is also recommended.



Priority:

- Implement the PIE mini-grants program.

Comprehensive Monitoring Program

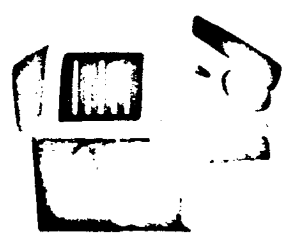
Problem: Environmental monitoring is one of the primary methods of collecting information in order to evaluate trends over time. Although about $2 million is expended each year for monitoring activities in Santa Monica Bay, this investment has not resulted in answers to the public's concerns about human health risks and the health of the Bay.

The Comprehensive Monitoring Framework provides a blue print for restructuring current monitoring activities to provide answers to the public's concerns about human health risks and the health of Santa Monica Bay.

Action: Over the past several years, a framework for the Comprehensive Monitoring Program has been developed. This framework provides a blueprint for how the current monitoring system could be restructured to provide more meaningful information, and how data generated by individual monitoring programs should be linked into a comprehensive whole. A pilot program, focused on entities that conduct ambient compliance monitoring, will test some of the redesigned and standardized components of the whole program. Natural resource and public health components will be phased in at later stages of program development. An effective system for information management and exchange is also being developed.

Priorities:

- Involve all appropriate entities in a "retooled" Santa Monica Bay monitoring program.
- Design a "user-friendly" Santa Monica Bay data management system with a centralized index but with a decentralized database system.
- Actively maintain the index and documentation, and coordinate the efforts of the various sources and users.



Research Needs

Problem: The SMBRP has undertaken a number of technical studies that have greatly enhanced our level of knowledge about Bay conditions and about potential health risks associated with swimming or consuming seafood. These research efforts have also formed the basis of many Plan actions. However, several important information gaps remain. Further research is still necessary to address issues such as sediment quality objectives, impacts of nonpoint pollutant sources on beneficial uses, sanitary surveys, swimming-related health risks and improvement of bacterial indicator systems.

Action: The Monitoring and Research Implementation Committee will oversee and coordinate priority research efforts identified in the Plan.

VOL 12

1834

MAKING THE PLAN WORK

The success of the Bay Restoration Plan (BRP) is largely dependent upon the establishment of an effective oversight and management strategy for assuring its implementation. Without such a strategy, the BRP is destined to be just another "plan on the shelf." An oversight committee structure to assure effective management and a finance strategy to implement the Plan's priority actions are therefore proposed.

Oversight and Management of Plan Implementation

Ensuring that a plan is implemented is a challenging undertaking. The Bay Watershed Council will facilitate coordination of action implementation, promote financing for Plan actions, and ensure that the Plan is consistently implemented. The Council will also continue the public/private and federal/state/local partnership that has been forged through the SMBRP, and will promote accountability for Plan implementation.

The Bay Watershed Council will continue the partnership that has been forged through the SMBRP and will promote accountability for Plan implementation.

Priorities:

- Carry out activities to assure Plan implementation: pursue financing strategies, monitor Plan progress, prepare State of the Bay reports, convene and staff meetings of the Bay Watershed Council and staff the Santa Monica Bay Restoration Foundation.
- Carry out the public education and involvement and comprehensive Bay monitoring programs; coordinate research activities; coordinate wetlands restoration and watershed planning efforts under the guidance of the Watershed Implementation Committees.

Finance Summary

More than 200 actions are presented in the Bay Restoration Plan, totaling approximately $131 million. Seventy-four of them have been designated as "priority actions." These 74 priorities are the focus of the Plan's financing strategy. Thirty-three have funding which is considered "within existing resources," meaning that they (a) have already been funded from within existing budgets; (b) have funds that have been earmarked for their implementation; (c) can be accomplished by shifting of internal resources, or (d) can be financed by the funding of another priority action. The remaining 41 priority actions carry a total price tag of $64.7 million, and must be financed from other sources.

The strategy for funding these actions focuses on three potential sources: state and federal grant and loan programs, existing and proposed bond measures, and private sector fundraising through the Santa Monica Bay Restoration Foundation. Experienced members of the region's financial community will also be brought together on a Blue Ribbon Finance Committee to provide guidance on additional innovative funding opportunities.

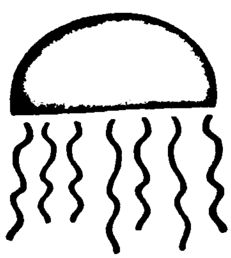
The preceding sections give an indication of the breadth of the actions needed to restore Santa Monica Bay. Within the Plan itself, important additional information is provided regarding implementors, timeframe for action and cost. The larger questions to be addressed now are: Who will oversee the implementation of the plan, and who will pay for it?

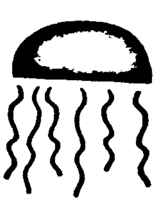
The short answer to this question is: YOU. Members of the public whose demands for a healthier Bay brought the Santa Monica Bay Restoration Project (SMBRP) into existence must take responsibility for supporting the Plan, and for supporting mechanisms to fund it.

Some things you can do now to help implement the Plan and to do your share to improve Santa Monica Bay are:

- Call your elected officials to ask for their support of the Plan.
- Vote for bond measures which provide funding for Bay cleanup and restoration.
- Encourage your neighborhood schools to add curriculum about Bay ecology and restoration.
- Read and implement the "Nine Simple Things to Do for the Bay" fact sheet, available from the SMBRP.
- Request a copy of the Plan by telephoning or writing us at the address on the back cover.

Conclusion





In this Public Summary we have surveyed much about Santa Monica Bay: its many natural resources, its biological and human values, the impacts of human activities on its health, and in this chapter, a plan for its protection and restoration. We have found that the Bay is out of balance, primarily because of the steep rise in population which began a century ago, and the concomitant introduction of human products that pollute the Bay. A heavy toll was taken on the Bay's ecosystem—wetlands destroyed, fisheries decimated, beaches closed by sewage spills and storm water contamination.

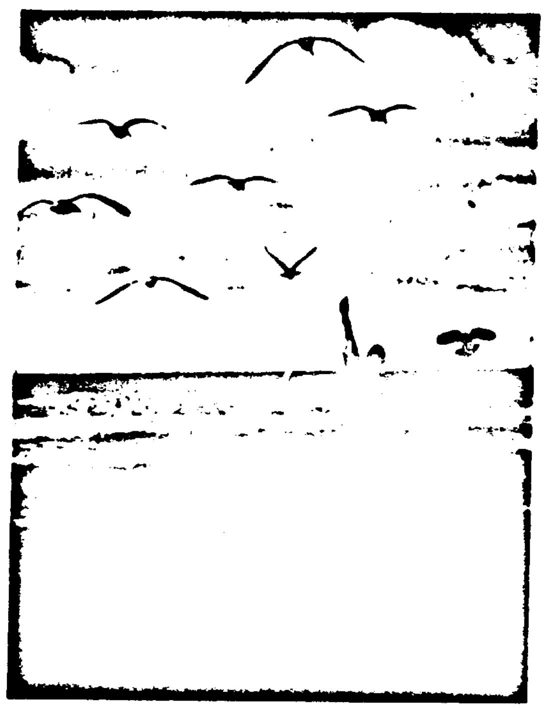
The power of humans to destroy an ecosystem is awesome, but it is matched by the power of humans to protect and restore it. We see that the Bay is making a comeback, and the balance is being restored—slowly but surely. While the Bay will never again be pristine, and progress could easily be

VOL 12 1 8325

VOL 12

reversed, the actions of humans to mitigate pollution and other harmful effects of our growth are having a decisive effect. Remaining wetlands are being protected and revived. Sewage plants are discharging cleaner effluent, and programs are in place to reduce runoff pollution.

While tremendous progress has been made, a great deal still remains to be done to safeguard this precious resource—to right the balance. We now have the tool to carry out these tasks comprehensively, and with your support of the Bay Restoration Plan, we may begin our work.



The Bay is making a comeback, and the balance is being restored —slowly but surely.

I. INTRODUCTION

As required by National Pollutant Discharge Elimination System (NPDES) Permit No. CA0061654, a proposed Stormwater/Urban Runoff Monitoring Program for the Santa Monica Bay Drainage Basin was submitted to the Regional Water Quality Control Board, Los Angeles Region (RWCQB), for approval on March 26, 1992. On January 11, 1993, as part of the RWQCB's overall review of our second-year compliance, tentative approval of the monitoring program was received by the RWQCB pending revision of the program to incorporate specific recommendations made by the RWQCB.

On June 17, 1993, a revised review of second-year compliance was received from the RWQCB. This revision was to incorporate comments submitted to the RWQCB by the various Co-Permittees on the RWQCB's original second-year compliance review. In its June 17, 1993 letter, the RWQCB staff proposed the following revisions to the monitoring program:

	Tasks	Completion Date	Report of Compliance to Regional Board
a.	Develop methodology to make refined estimates of pollutants discharged to Santa Monica Bay	July 1, 1993	July 15, 1993
b.	Make a first estimate of pollutant loads to Santa Monica Bay on the basis of monitoring	July 1, 1994	July 15. 1994
c.	Complete a basic QA/QC plan for the Storm Water Monitoring Program	July 1, 1993	July 15, 1993
d.	Develop and implement a pilot project to establish monitoring of long-term trends in stormwater quality	July 1, 1993	Jan. 15, 1994
e.	Develop monitoring for identification of sources of pollutants	July 1, 1993	Jan. 15, 1994
f.	Develop and implement a monitoring program to evaluate the effectiveness of BMPs	Jan. 1, 1994	Jan. 15, 1994
g.	Develop and implement a monitoring program to identify locations of illegal practices and elimination sources of pollutants	Jan. 1, 1994	Jan. 15, 1994
h.	Develop and implement a program to evaluate stormwater impacts on selected receiving waters	July 1, 1994	July 15, 1994

The revised monitoring program described herein addresses tasks "a" through "e". Tasks "f" through "h" will be developed as future amendments to the program. It should be noted, however, that a number of concerns were presented to the RWQCB staff regarding Tasks "f" through "h" as part of our comments on their second-year compliance review. Resolution of our concerns will be needed prior to completion of these tasks.

The monitoring program described herein includes the establishment of nine monitoring sites for both mass emissions and individual land-use monitoring. Storm samples will be collected for five storms per year. Dry-weather samples will be collected bimonthly. Samples will be tested for a wide range of constituents including Bacteria; General Minerals; Biochemical Oxygen Demand; Total Organic Carbon and total Petroleum Hydrocarbons; Volatile Organic Compounds and Suspended Solids; Volatile Suspended Solids; and Semi-volatile Organic Compounds.

Automated refrigerated water samplers will be used for the collection of flow-composite samples. These samplers will be located on the ground surface in secure enclosures allowing easy access for retrieval of samples. The samplers have large (10 gallon) water collection capacity, and, thus, can be programmed in advance to cover a wide range of storm sizes without requiring one or more bottle change outs during a storm event.

Data collected by the program will be utilized by water quality modelling to estimate pollutant loads to receiving waters. Also, questions concerning what types of pollutants emanate from various land uses will be addressed. Lastly, data collected over the years under this program can be used in an attempt to assess any long-term trends in water quality.

VOL 12

1 8335

II. PROPOSED MONITORING SITES

<u>SITE SELECTION CRITERIA</u>

A. Monitoring Site Selection Overview

In order to characterize the quality of runoff from the Santa Monica Bay Drainage Basin, a combination of single land-use sites and large watersheds representing multiple land uses ("mass emissions" sites) have been selected.

For the Santa Monica Bay Drainage Basin nine monitoring sites have been proposed. Four of the nine sites will be mass emissions stations. Five will be land-use specific stations. The remaining site will function as both a mass emissions and land-use specific monitoring station. Additional land-use specific monitoring stations will be proposed as part of the monitoring program to be developed for Phase III of the NPDES Permit. As stated in our third-year report, dated July 1, 1993, we estimated submittal of the proposed monitoring program for Phase II to the RWQCB by February 28, 1994.

The proposed monitoring sites represent an effort to select the most suitable locations based on our established criteria for sampling. Where feasible, we have incorporated into the program those storm drains which have water quality issues which are of concern to the community.

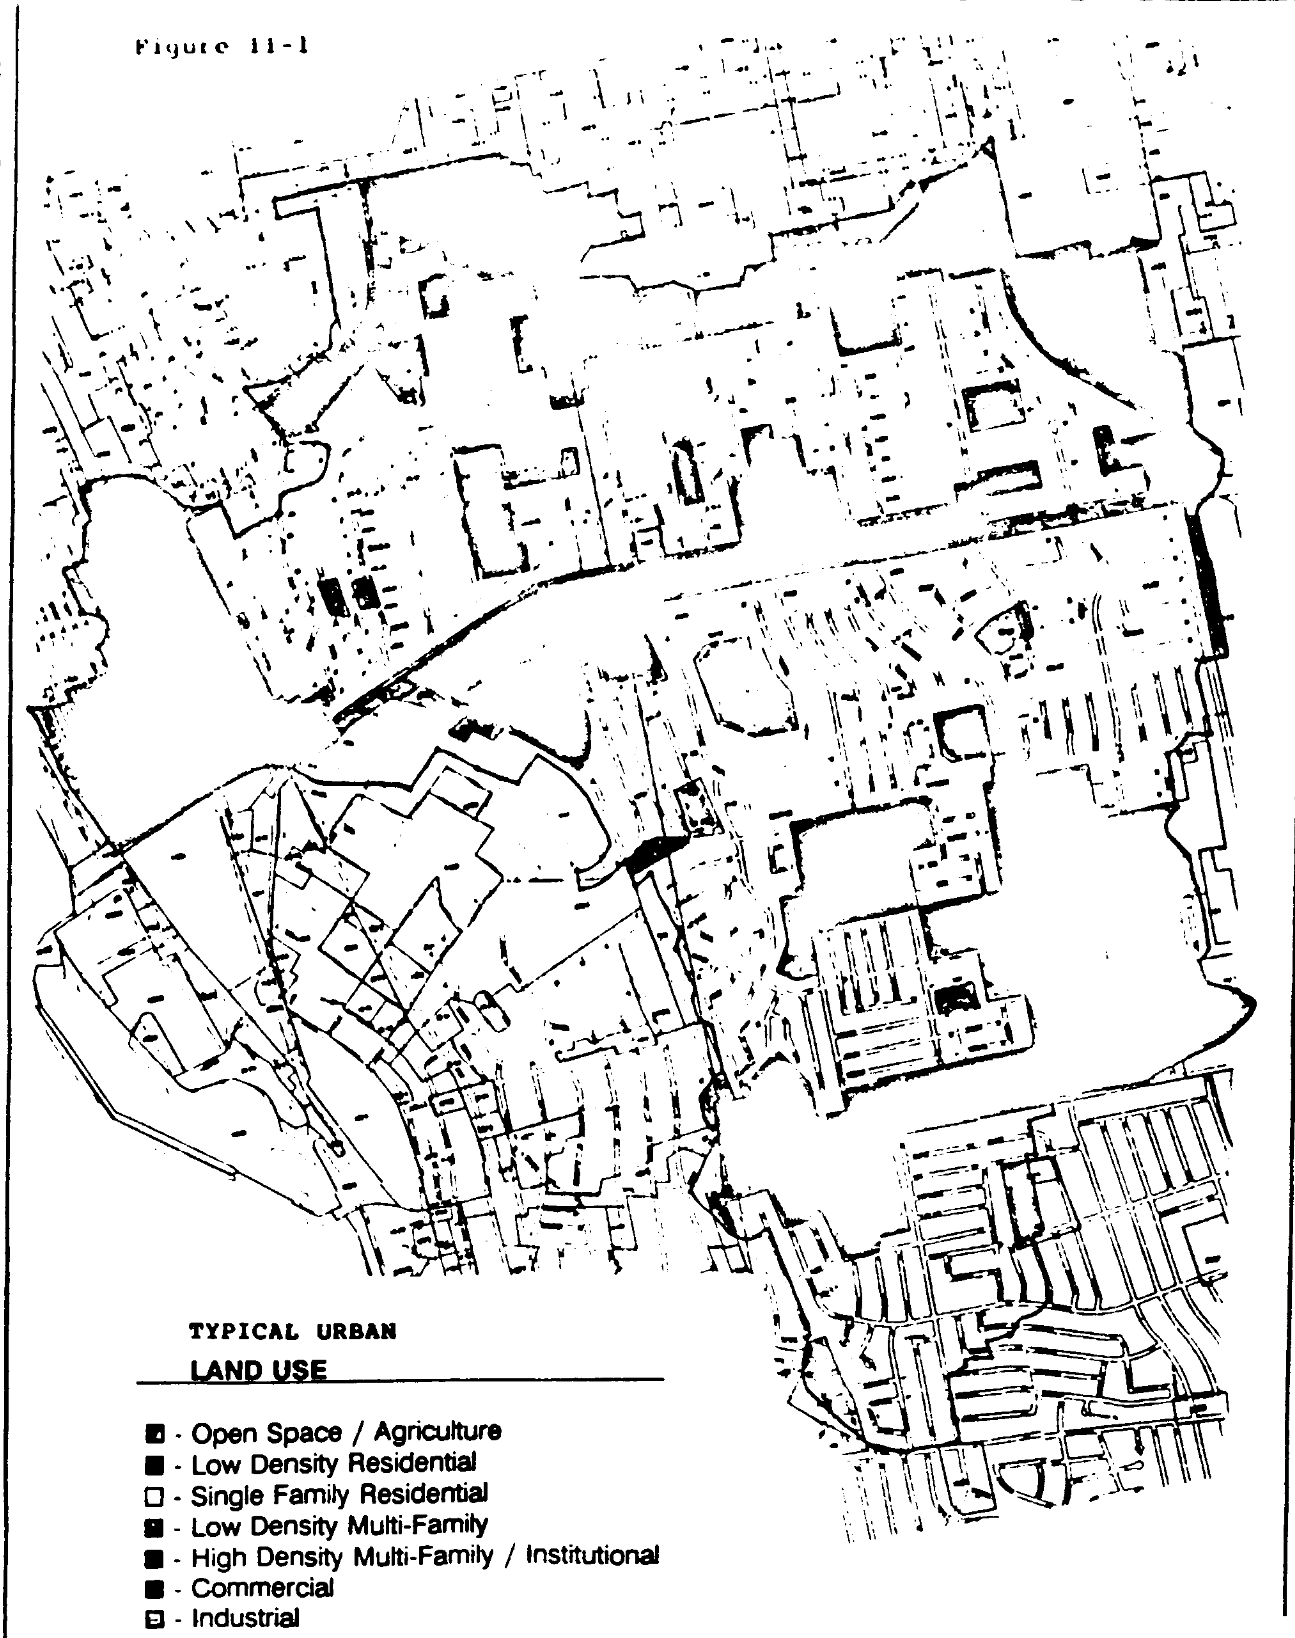
B. Specific Criteria for Mass Emissions Monitoring Sites

Mass emissions monitoring sites shall be located at the outlet (or the furthest downstream position practicable) of watersheds contributing the largest relative inputs to the Santa Monica Bay. These watersheds will typically have a complex multiple land-use composition. See Figure II-1.

C. Specific Criteria for Land-Use Specific Monitoring Sites

Land use-specific monitoring sites shall be located in watersheds where the upstream tributary area is comprised predominantly of one land use. It is important that the contributing watershed be at least 50 acres in size, in order to produce effective runoff characteristics.

Figure II-1



VOL 12

1 8336

R0051641

D. Criteria for both Mass Emissions and Land-Use Specific Sites

In selecting a specific storm drain for inclusion as either a mass emissions or land-use specific site, the following technical and operational requirements were addressed:

- What type of sampling equipment is to be used, and what limitations exist?
- What are the hydraulics of the underground storm drain, open channel/natural watercourse? What is the Design Q?
- Is there past flow data available for the given stream?
- What past hydrology studies have been performed in the watershed?. What is the hydrologic Q?
- If the storm drain is underground, is it currently under designed? Could it experience surcharge conditions?
- Within the watershed, what is the corresponding land use? Is land use uniform and homogenous throughout the upper tributary area? If yes, this is a possible land-use site.
- Has previous sampling in the potential watershed been conducted in the past? Where? When? Why?
- Are tidal or backwater influences a concern?
- Is the location selected the only outfall point for the upstream watershed, or are there multiple outfall points?
- Is the storm drain structurally sound at present? Will installation of sampling equipment compromise the stability of the storm drain?
- Will the monitoring equipment impede flow or reduce flood protection?
- For natural watercourses, is there an existing improved section where a rating curve can be easily established?
- What is the practicable design distance from the storm drain invert (low flow) to the location where the sampler shall be placed?
- Can electric power be provided, in a cost- effective manner, to the site?

VOL 12

1 8337

- Will additional right-of-way be required?
- Will the sampler installation interfere with projects planned or in progress in the general vicinity?
- If located in a residential neighborhood, will the location of the automated sampler and its operation result in any objections from the local residents?

VOL 12

1 8338

PROPOSED MASS EMISSIONS AND LAND-USE SPECIFIC MONITORING SITES

A. The following locations have been proposed as Mass Emissions sites:

1. Ballona Creek at Los Angeles County Department of Public Works Stream Gauge No. F38C-R in the City of Los Angeles.

   The Ballona Creek station will be located at the existing stream gauge station between Sawtelle Boulevard and Sepulveda Boulevard. This facility currently measures stream flow and precipitation. At this location, the upstream tributary watershed of Ballona Creek is 88.7 square miles. The entire Ballona Creek watershed at its outlet to the ocean is 127.1 square miles, but because of tidal influences the sampling site must be located upstream. Therefore, the actual sampled watershed is less.

   The land-use breakdown is as follows:

Open Space/Agriculture	19%
Low Density Residential	1%
Single Family Residential	25%
Low Density Multi-Family	5%
High Density Multi-Family/Institutional	32%
Commercial	14%
Industrial	4%

   The overall impervious factor for this watershed is 53%.

   Ballona Creek, at the gaging station, is an improved (concrete lined) trapezoidal channel. The vertical lift from the invert of the channel to the sampler location is approximately 30 feet. The horizontal distance is approximately 100 feet. Due to the elevation difference, an auxiliary pump will be required. See Figure III-3 for the proposed sampler installation.

   This proposal replaces the existing County Department of Public Works Surface Water Quality Monitoring Station at the Sawtelle Boulevard bridge.

2. Malibu Creek at County Stream Gauge No. F130-R in Unincorporated County of Los Angeles.

   The Malibu Creek monitoring station will be located at the existing stream gauge station, off of Malibu Canyon Road, south of Piuma Road. The existing facility provides flow measurement only. Because of

VOL 12 18339

tidal influences and the lack of any downstream improved section, the sampling site must be located here. Constructing an improved section at a location downstream would be costly, and would yield little difference in results. At this location, the tributary watershed to Malibu Creek is 104.9 square miles. The entire Malibu Creek watershed at its outlet to the ocean is 109.9 square miles. Therefore the actual sampled watershed is less.

The land-use breakdown is as follows:

Open Space/Agriculture	54%
Low Density Residential	29%
Single Family Residential	7%
Low Density Multi-Family	4%
High Density Multi-Family/Institutional	1%
Commercial	4%
Industrial	1%

The overall impervious factor for this watershed is 13%.

There are at least seven agencies, presently, that are monitoring the quality of surface water, sediment, groundwater and/or the overall health of the ecosystem (bioassessment and biomonitoring) within the Malibu Creek watershed. This proposed sampling location will replace the existing County Department of Public Works Surface Water Quality Sampling Station at Cross Creek Road.

3. **County of Los Angeles Kenter Canyon Storm Drain in the City of Santa Monica.**

Kenter Canyon Storm Drain is an underground brick arch drain. It outlets at the west end of Pico Boulevard. The outlet structure is commonly referred to as the Pico-Kenter storm drain. This outlet is the combination of three storm drains: Kenter Canyon, Caltrans 10 Freeway Storm Drain, and County Bond Issue Project No. 249, Pico Boulevard Drain, Line B. Only flows from the Kenter Canyon Storm Drain will be sampled.

The location where sampling will be conducted is upstream of the outlet structure. The tributary watershed area for Kenter Canyon Storm Drain is 6.4 square miles (the tributary area of the Caltrans drain and Pico Boulevard Drain is 0.8 square miles).

VOL 12 18340

The land-use breakdown is as follows:

Open Space/Agriculture	5%
Low Density Residential	39%
Single Family Residential	22%
Low Density Multi-Family	8%
High Density Multi-Family/Institutional	10%
Commercial	12%
Industrial	4%

The overall impervious value for this watershed is 39%.

The Pico-Kenter Drain has been a focal point for Santa Monica Bay with regards to the quality of dry-weather flows. The City of Santa Monica is currently pumping dry-weather flows to a City of Los Angeles sanitary sewer line, existing below The Promenade.

The County Department of Public Works presently samples the Pico-Kenter outlet structure. This proposed sampling location replaces the existing County Department of Public Works Surface Water Quality Monitoring Station at the Pico-Kenter outlet structure.

4. **County of Los Angeles Bond Issue Project No. 1105, Line A, in the Cities of Hermosa and Redondo Beach.**

Project No. 1105, Line A is an underground box/pipe in Herondo Street from Hermosa Avenue/Harbor Drive to Pacific Coast Highway. The proposed sampling location is near the intersection of Herondo Street and Valley Drive. At this location, the tributary watershed area is 4.23 square miles.

The land-use break down is as follows:

Open Space/Agriculture	2%
Low Density Residential	0%
Single Family Residential	63%
Low Density Multi-Family	16%
High Density Multi-Family/Institutional	4%
Commercial	10%
Industrial	5%

The overall impervious value for this watershed is 50%.

It is proposed that the sampling station be placed in the center median of Herondo Street. This is due to the lack of adequate sidewalk clearance. Tidal influences, depth to storm drain invert, and surcharge effects are the major factors impacting the selection of this site.

B. The following locations have been chosen as Land-Use Specific sites:

1. Trancas Canyon at Private Drain No. 658 in the City of Malibu.

   The Trancas Canyon watershed is proposed for the monitoring of open space. The upstream watershed of Private Drain (PD) No. 658 is virtually undeveloped, with the only significant development being the Malibu Country Club in the upper reach. The Santa Monica Mountains National Recreation Area is the largest land holder in the watershed.

   The proposed monitoring site is to be located at the upstream end of PD No. 658, adjacent to the northerly end of Paseo Canyon Drive. PD No. 658 is a reinforced concrete trapezoidal channel. Immediately upstream exists a small debris basin which will provide protection for the sampler. The residential area surrounding PD No. 658 is privately maintained. Installation of the monitoring station will be dependent on our ability to satisfy the requirements of the local homeowners association. The tributary watershed area is 7.45 square miles.

   The land-use breakdown is as follows:

Open Space/Agriculture	97%
Low Density Residential	3%
Single Family Residential	0%
Low Density Multi-Family	0%
High Density Multi-Family/Institutional	0%
Commercial	0%
Industrial	0%

   The overall impervious value for this watershed is 1%.

   It is anticipated that because of the size, impervious value, soil types, and vegetation within the watershed, little to no dry-weather flows will exist. This has been previously observed.

2. County Bond Issue Project No. 5401, Line A in the City of Manhattan Beach.

   Project No. 5401 is proposed for the monitoring of a single family residential area.

At the proposed monitoring location, Project No. 5401 is an underground box drain. This storm drain discharges to a pond in Polliwog Park. During a storm, the pond serves as a detention basin for flood control. After reaching a certain elevation, stormwater in the pond is pumped over a hill, under Manhattan Beach Boulevard, to the west to Project No. 552. One potential location for placement of the sampler appears to be in the park, however, because stormwater may back up into the drain, an alternative location for sampling is at Redondo Avenue and 11th Street. The tributary watershed area is approximately 200 acres.

The land-use breakdown is as follows:

Open Space/Agriculture	0%
Low Density Residential	0%
Single Family Residential	98%
Low Density Multi-Family	0%
High Density Multi-Family/Institutional	0%
Commercial	2%
Industrial	0%

The overall impervious value for this watershed is 42%.

Homes and lots are generally similar in type and size throughout the tributary drainage area, providing an ideal homogenous land use.

3. City of Los Angeles Storm Drain No. D-2361 located in downtown Los Angeles.

The City's Storm Drain No. D-2361 is proposed for the monitoring of a commercial/industrial land use.

The proposed monitoring site is near the intersection of 21st Street and Grand Avenue. Storm Drain No. D-2361 is a 48" diameter pipe. The tributary watershed area is about 150 acres.

The land-use breakdown is as follows:

Open Space/Agriculture	0%
Low Density Residential	0%
Single Family Residential	0%
Low Density Multi-Family	0%
High Density Multi-Family/Institutional	0%
Commercial	49%
Industrial	51%

The overall impervious value for this watershed is 91%.

It is believed with all certainty that this storm drain will experience, at some time, surcharge conditions. The storm drain is more than 50 years old and is undersized. Based on our research, however, this would be the only location available in the Santa Monica Bay Drainage Basin for the monitoring of a sizeable industrial area.

4. **City of Santa Monica Pier Storm Drain adjacent to the Santa Monica Mall.**

The City's Pier Storm Drain is proposed to be a monitoring site for commercial land use.

The monitoring site will be located at the intersection of Second Street and Colorado Avenue. The section of drain under consideration is from Ocean Avenue to 2nd Street in Colorado Avenue. This reach of drain empties into a manhole shaft of a deeper storm drain which subsequently discharges below the Santa Monica Pier. The tributary watershed area is approximately 50 acres.

The land-use breakdown is as follows:

Open Space/Agriculture	0%
Low Density Residential	0%
Single Family Residential	0%
Low Density Multi-Family	0%
High Density Multi-Family/Institutional	4%
Commercial	96%
Industrial	0%

The overall impervious value for this watershed is 92%.

This watershed is dominated by the Santa Monica Mall. The remaining land-use elements are commercial office buildings, small shops, restaurants and high density apartments/hotels.

5. **County Bond Issue Project No. 558, Line A in the City of Palos Verdes Estates.**

The monitoring location proposed for Project 558 will not only be utilized as a mass emissions station, but also function as a single family residential land-use site.

The monitoring site for this storm drain will be in the vicinity of the intersection of Paseo Lunado and Palos Verdes Drive West. The tributary watershed area is approximately 1.7 square miles.

The land-use breakdown is as follows:

Open Space/Agriculture	14%
Low Density Residential	0%
Single Family Residential	81%
Low Density Multifamily	3%
High Density Multifamily/Institutional	0%
Commercial	2%
Industrial	0%

The overall impervious value for the watershed is 40%.

It is anticipated that because of the size, impervious value, soil types, and vegetation within the watershed, little to no dry-weather flows will exist. This has been previously observed.

Monitoring Site Installation

The monitoring sites have been prioritized for installation as follows:

Ballona Creek
Malibu Creek
Trancas Canyon (Private Drain 658)
Kenter Canyon
Herondo Drain (Bond Issue Project 1105)
Bond Issue Project 558
Bond Issue Project 5401
City of Santa Monica Storm Drain
City of Los Angeles Storm Drain

Priority has been given to the open channel sites, which are the easiest to install plus serve as the mass emissions stations. The remaining sites involve the underground drains. We are targeting to have as many sites as possible operational by the onset of the rainy season, with the remainder to follow as soon as possible during the rainy season.

VOL 12

1 8345

III. MONITORING EQUIPMENT

WATER QUALITY SAMPLERS

Refrigerated Water Quality Samplers

Stormwater sampling for this NPDES permit must include a technique for collecting flow composite samples for storms as well as time composite samples for dry-weather applications. The utilization of automatic refrigerated water quality samplers (Figure III-1) represent the best available technology at present to meet the goals of the Permit.

The water quality samplers to be utilized at each of the nine monitoring sites must be AC powered to carry the load needed to provide refrigeration. All samples will be stored at 4°C.

Each sampler will incorporate a peristaltic pump for sample collection. Due to the inability of the peristaltic pump to effectively pump flows beyond a vertical lift of between 15-20 feet, an explosion proof auxiliary pump will be required. Most of our sites have vertical lifts in excess of 15 feet. Auxiliary pumps will be needed. This factor will complicate the installation of our sampling equipment at many locations, especially in the underground drains.

Each sampler will be securely stored in a steel box, similar to a traffic signal controller enclosure. Samplers will be located on the sidewalk or secured right-of-way for closed conduits or along the banks of open channels and natural watercourses.

FLOW MONITORING

Flow monitoring equipment is a fundamental aspect of water quality sampling. Because the Monitoring Program proposal includes flow composite sampling during storms and dry weather, flow monitoring equipment must be utilized with the sampler. There are various makes and models of flow meters. Some of the various flow meters available utilize pressure transducers, ultrasonic sensors, bubblers, stilling wells, etc.

The above-mentioned flow measuring devices are designed for open-channel flow conditions. The water elevation in a storm drain is measured by the equipment and then, from either a rating table previously established, or from an equation such as Manning's equation, the flow rate is determined. The County's Department of Public Works uses rating tables which are generated from analysis of storm drain cross sections and upstream/downstream flow characteristics. The rating tables are modified if it is demonstrated in the field that the stream velocity measurements indicate a non-uniform

VOL 12 1 8346

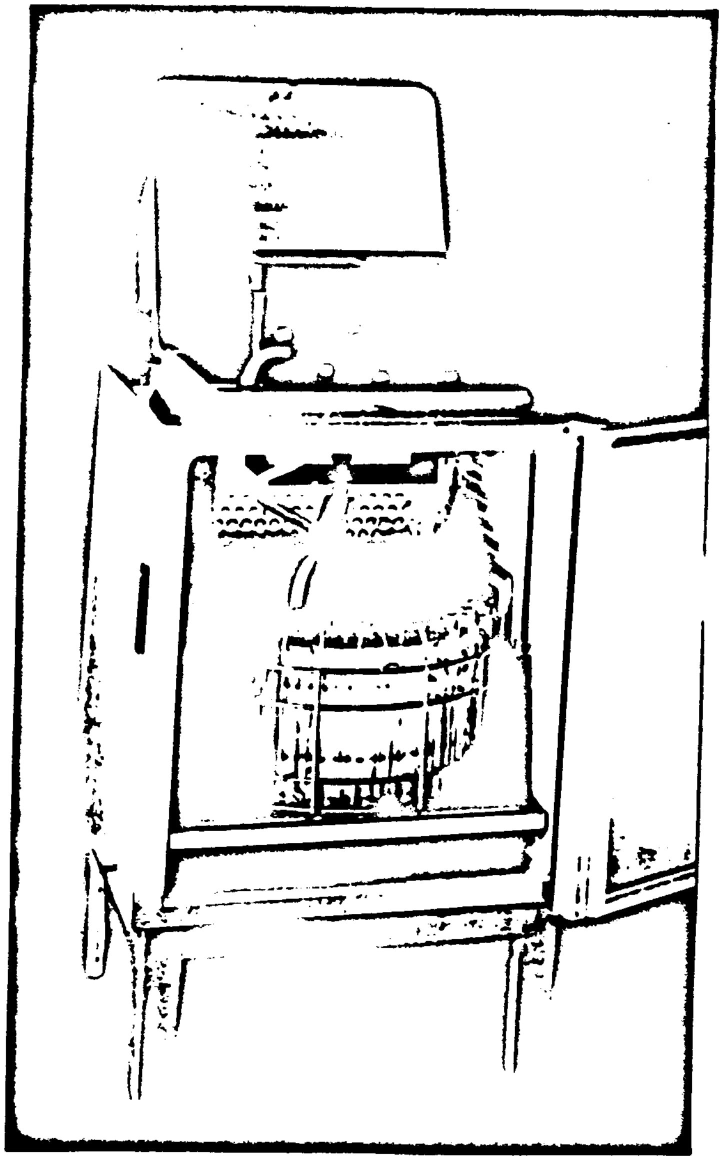


Figure III-1

Refrigerated Water Quality Sampler

relationship with the calculated table values. Past efforts in stormwater flow measurement indicates that all of the proposed stations will require time and multiple storm events to gather necessary data needed for calibration of the measurement devices.

The type of flow measurement device selected for use is the pressure transducer. The maximum depth of flow for the proposed nine sites approaches 22 feet. With the pressure transducer fixed at the bottom of the drain, a depth range from dry condition to 22 feet will have to be measured. The flow meter incorporating the pressure transducer will be compatible with the sampler.

Closed conduits, however, present an additional problem. Many closed conduits surcharge during storm conditions, usually caused by the conduit being undersized for its tributary watershed. The frequency of surcharging is dependent on the degree to which the storm drain is undersized. When surcharge conditions are reached, the drain now functions under pressure flow. The flow measurement devices discussed above are only accurate under open channel flow conditions. The measurement of flow under pressure would require the use of velocity meters. These are very costly devices that would need to be located directly in the flow stream. Therefore, efforts were made to select storm drains that do not surcharge, or do so infrequently to an extent that flow measurements are not significantly compromised.

RAIN GAUGE

For every monitoring station, a minimum of one automatic (intensity measuring) rain gauge will be placed within the upper tributary watershed. Los Angeles County Department of Public Works operates various automatic rain gauges throughout the Santa Monica Drainage Basin. Existing gauges in close proximity to the proposed monitored watersheds will be utilized in calculating stormwater runoff and shall be essential to developing runoff characteristics of these watersheds.

Large watersheds such as Malibu and Ballona Creeks will require multiple rain gauges to accurately characterize the rainfall. The number and location of these additional rain gauges is currently being researched.

EQUIPMENT INSTALLATION

The approach taken for the installation of sampling equipment is important to those who will maintain it. Access, ease of operation, safety, protection from the elements, etc., are typical design considerations. Each stations design must take into account at least these basic elements.

Figures III-2, III-3, and III-4 are generic drawings which show typical installations of sampling equipment in storm drains utilized in the Monitoring Program.

Selected site conditions will dictate the approach taken with regards to installation of the monitoring equipment.

The automated samplers intake hose and the flow meter pressure transducer cable must be protected from trash and debris, vandalism, and the physical forces of the flow velocity during storm events. It must also be installed to allow routine inspection and maintenance. In some instances, the intake hose and pressure transducer cable will be placed in a separate conduit casing (or in a small channel with a bolted cover) in a cored notch, a few inches below the channel's finished surface. In other locations, the intake line and pressure transducer cable will be placed in a separate protective conduit casing, bolted in the storm drain pipe or box conduit.

The strainer and pressure transducer will likewise be located within a protective enclosure to shield them from trash and debris and to minimize vandalism.

An auxiliary peristaltic pump will be needed at many sites due to the hydraulic lift requirements. This will complicate installation and maintenance. An auxiliary pump will be placed in a waterproof enclosure for most applications. The waterproof enclosure will be above the low-flow, dry-weather level to ensure that it will not be continuously submerged.

IV. MONITORING EQUIPMENT PROGRAMMING

1. Storm Weather Sampling

The automated sampler will need to be properly programmed in order to collect a representative flow-composite sample.

To program the sampler, the following information is needed: target storm size, flow rate to trigger sampling, estimate of runoff volumes, total sample volume required, number of sample intervals desired, sample volume to be collected at each interval, and flow rate to end sampling.

2. Storm Size to be Sampled

The "Surface Drainage Water Quality Monitoring Program" report, prepared by Woodward-Clyde Consultants for the Santa Monica Bay Restoration Project, analyzed local rainfall data to determine the appropriate storm size to be targeted for monitoring. Based on their analysis, targeted storm events should be between 6 and 25 hours in duration and average rainfall of about 0.4 to 1.7 inches.

3. Minimum Sample Volume to be Collected

The minimum volume of stormwater needed to perform the necessary analyses is shown below, (for composite flow-weighted samples only):

Constituent	Quantity
Semivolatile Organic Compounds	1 L
Pesticides and PCBs	1 L
Herbicides	1 L
Soluble Metals	500 mls
Other Constituents	4,325 mls
	7,825 mls ≈ 8 liters or approximately 2 gallons

The refrigerated automated sampler has a total capacity of 10 gallons. Subtracting the two gallons required for analysis, the sampler will have an eight-gallon reserve capacity. Therefore, the sampler will be programmed to collect two gallons of stormwater from a 0.4" storm. With the eight-gallon excess capacity, the sampler would theoretically have adequate capacity to handle storms up to two inches in size (0.4" x 5 = 2.0"). This will significantly reduce the need to change bottles during a storm event.

VOL 12

4. <u>Estimate of Runoff Volume</u>

To program the sampler, the estimated runoff volume from a minimum precipitation of a 0.4-inch storm event over the entire area of a watershed must be calculated. The procedure used to estimate the runoff volume of the above storm is taken from the Los Angeles County Department of Public Works Hydrology Manual, which is generally accepted by agencies within Los Angeles County for the performance of hydrology studies.

The procedure to be used is briefly described below.

a) Calculate the Overall Runoff Coefficient for the Watershed:

$$C_D = 0.9\ IMP + Cu\ (1 - IMP)$$

where:

IMP = Proportion impervious for the land use comprising the watershed.

C_u = Undeveloped area runoff coefficient (based on soil type and rainfall intensity).

C_D = Developed area runoff coefficient.

For watersheds with multiple land-use types, the overall C_D for the watershed is the weighted average of the C_D for each land-use type:

$$C_D = \frac{\Sigma_1^n\ C_{Dx}\ A_x}{\Sigma_1^n\ A_x}$$

b) Calculate the rainfall volume for the watershed:

The rainfall volume is calculated by multiplying the storm size, in inches, by the area of the watershed.

c) Calculate the runoff volume for the watershed:

The resultant runoff volume is determined from the following formula:

Runoff Volume = Rainfall Volume x (C_D)

(A detailed example of the above procedure can be found in Appendix 1).

1 8354

5. Determination of Sampling Parameters

As discussed previously, eight liters of stormwater runoff will need to be collected by composite sampling. A minimum of 20 aliquots will be collected from each storm to obtain the eight-liter composite sample. Therefore, the volume of sample to be collected at each aliquot is:

8 liters/20 aliquots = 400 mls

The 20 aliquots will be spaced at equal runoff volume intervals throughout the storm. Therefore, the size of the runoff volume interval (Δ runoff volume) for a specific watershed would be determined as follows:

$$\Delta \text{ runoff volume} = \frac{\text{total runoff volume}}{20}$$

where:

total runoff volume = total estimated runoff volume for targeted storm.

The flow rate at which storm sampling would be initiated at each station would be dependent on whether the site has any consistent dry weather or base flow.

For stations that do not have any dry-weather flow, sampling would be initiated upon detection of flow. For those having dry-weather flow, sample collection would begin after detecting a flow rate above the maximum-observed, yearly dry-weather flow level. Sampling would halt when the flow returns to 120 percent of pre-storm base flow. As the monitoring program progresses, more specific operational criteria for the samplers at each station can be developed based on site-specific flow information.

6. Dry-Weather Sampling

Dry-weather flow samples will be collected at all sites exhibiting significant dry-weather flow. For those sites with continuous dry-weather flow, a 24-hour composite sample will be collected. For those with intermittent flow, a sample will be collected as flow is available.

VOL 12

1 8355

V. MONITORING CONSTITUENTS

1. List of Constituents

The selection of the monitoring constituents was based on an evaluation of the EPA final stormwater regulations and the existing monitoring program of the LACDPW. Initially, the constituents monitored during dry weather and under storm conditions will be the same. As water quality data is gathered over time and analyzed, revisions to the list of constituents monitored for both dry weather and under storm conditions may be made as deemed appropriate.

2. Constituents and Sample Collection Methods

The sample collection methods proposed for use are a combination of grab sampling and composite sampling. The details of each method will be elaborated in Part VI: Sampling Procedures. The definition of each type of sample is:

Grab Sample - a discrete, individual sample taken within a short period of time, usually less than 15 minutes.

Composite Sample - a mixed or combined sample that is formed by combining a series of individual and discrete samples (aliquots) of specific volume, collected at specific volume intervals.

The time required to complete the cycle of compositing a sample covers a wide range, from a few hours to over to over 24 hours.

However, certain constituents have very short holding times and specific collection or preservation needs. The existence of and concentration of these constituents cannot be tested by composite samples and must be analyzed from grab samples.

All constituents listed in Table V-1 will be tested by composite sampling. Those listed in Table V-2 must be collected manually by grab samples.

Grab samples are preferred for certain water quality tests because field measurements such as pH and temperature should be instantaneous measurements of stormwater; bacteria have a short holding time; oil and grease tends to adhere on the surfaces that it contacts; volatile organic compounds (VOCs) have a tendency to volatilize when in contact with air; and, cyanide is very reactive and unstable.

3. Chemical Analysis Methods

The chemical analysis methods for each constituent is listed in Tables V-1 and V-2. Also listed are the associated detection limits, sample volumes, preservation needs, and holding times required of each analysis method.

Weather forecasting and estimation of storm size is an inexact science. Therefore, rainstorms may occur where the total sample volume collected via composite sampling is insufficient to perform all the desired analyses. Table V-3 presents a prioritized list of the water quality tests to be performed on the composite sample. For those storms where an insufficient total sample volume has been collected, the tests to be performed will be in accordance with the priority listed on Table V-3.

TABLE V-1

CONSTITUENTS TO BE TESTED FROM FLOW-COMPOSITE SAMPLES

LIST OF CONSTITUENTS	EPA METHOD	DETECTION LIMIT	SAMPLE VOLUME	HOLDING TIME	PRESERVATION
<u>Semivolatile Organic Compounds</u>					
Acid					
Benzoic acid	8250		1 Liter	Samples must be extracted within 7 days and extract must be completely analyzed within 40 days. See footnote[7]	Cool, 4°C [illegible] of $Na_2S_2O_3$ See footnote[8]

VOL 12

FOOTNOTES (Tables V-1 and V-2)

[1] Should be added to empty sample container to be used for collection of sample _if_ residual chlorine is present in the sample.

[2] Samples must be extracted within seven days and extract must be completely analyzed within 40 days.

[3] Use NaOH or H_2SO_4, as needed, to adjust the pH. Volume of acid of base must be noted.

[4] If aldrin is one of the pesticides to be tested and the sample is known to have residual chlorine present, then this preservative should in the empty sample container to be used for the collection of the sample.

[5] Maximum holding time is 24 hours when sulfide is present. Optionally, sample may be tested with lead acetate paper before pH adjustment, to determine if sulfide is present. If sulfide is present, it can be removed with the addition of cadmium nitrate powder until a negative spot is obtained. The sample then should be filtered and NaOH added to adjust the pH to >12.

[6] Should only be used in the presence of residual chlorine.

[7] This is an arbitrary holding time selected. None is given in EPA method 418.1 - the approved method to use for TPH testing.

[8] According to 40 CFR 136.3 Table II Notes, Note (2): "For composite chemical samples, each aliquot should be preserved at the time of collection. When use of an automated sampler makes it impossible to preserve each aliquot, then chemical samples may be preserved by maintaining at 4°C until compositing and sample splitting is completed."

1 8365

1 8366

VI. SAMPLING PROCEDURES

This Stormwater/Urban Runoff Monitoring Program is divided into two sub-programs, namely: the dry-weather flow monitoring sub-program, and the storm flow monitoring sub-program. For each of these sub programs, two types of samples will be collected at each monitoring location: Grab samples and composite samples. The constituents to be analyzed for either a grab or composite sample are discussed in Section V, and the automated sampling equipment to be used is described in Section III.

1. Storm Sampling

a. <u>Pre-storm Preparation</u>

In preparing and mobilizing personnel and equipment for a given sampling event, LACDPW will utilize the weather forecasts from the National Weather Service and also from Pacific Weather Analysis, as well as other Department resources such as the LACDPW Alert System. The Alert System is a system of rain and stream flow gauges within the LACDPW flood control system which predicts/measures runoff amounts at key locations and transmits the data via telemetry to LACDPW headquarters. Important deciding factors in mobilizing for a storm sampling event include the probability of rainfall, its expected amount, and its intensity. When a representative storm is expected, sampling personnel will prepare for collection of grab samples as well as verify that the automated samplers are activated for composite flow sampling.

b. <u>Grab Samples</u>

All attempts will be made to collect grab samples during the beginning of the storm on the rising limb of the hydrograph. Such timing is expected to provide concentrations reflecting the higher levels of contaminants which are expected to be observed in the first part of a storm event as compared to those observed during the remainder of the event.

Grab samples will normally be collected using manual sampling equipment such as bucket with rope, dipper, funnel, etc. For manual grab sampling, please refer to Appendix 2 - "Surface Water Sampling Instruction Manual". Grab sample bottles, however, would have to be filled using manual operation of the automated samplers if sample points are inaccessible, such as the closed conduit sampling stations.

c. <u>Flow-Composite Samples</u>

Flow-composite storm samples will be obtained using an automated sampler to collect samples at flow paced intervals. Samples collected at each station will be combined in the laboratory to create a single flow-weighted sample from each station for analysis.

During a storm event, the sampler is programmed to activate automatically when the water level in the channel or storm drain exceeds the maximum diurnal water surface elevation. A sample will be collected each time a set volume of water has passed the monitoring point. The sample will be distributed into glass containers within the refrigerated sampler. The containers will need to accumulate a minimum of eight liters of runoff during each storm, so as to ensure a sufficient sample volume available to perform the necessary laboratory analyses. The automated sampler will deactivate when the water level in the channel or storm drain falls to about 120 percent of the observed maximum diurnal water surface elevation. For detailed discussion on the automated sampler programming, please see Section IV.

Upon conclusion of the storm event, samples will be retrieved from the automated samplers. Samples will be retrieved within the maximum allowable holding times required of the various test methods.

At the same time samples are collected, rainfall and runoff data collected by the sampler will be downloaded for transfer to the office.

2. **Dry-Weather Sampling**

The frequency of dry-weather sampling is once every other month. This frequency was established based on the assumption that the majority of the flow during dry weather comes from discharges that are presently covered by an NPDES permit. The deviation in test results from time to time would therefore be expected to be minor.

As water quality data is gathered under this program, it may be necessary to increase the frequency of monitoring of some constituents, and likewise may be necessary to decrease or eliminate the monitoring frequency of other constituents, shown not to be of a concern.

a. <u>Grab Samples</u>

Grab samples will normally be collected using manual sampling equipment such as bucket with rope, dipper, funnel, etc. For manual grab sampling, please refer to Appendix 2 - "Surface Water Sampling Instruction Manual". Grab sample bottles, however, would have to be filled using automated samplers if sample points are inaccessible, such as closed conduit sampling stations. Specific grab samples will be collected each time composite samples are retrieved.

b. Flow-Composite Samples

During dry weather, an eight-liter composite sample will be collected over a 24-hour period.

Samples will be retrieved and delivered to the laboratory within the maximum allowable holding times of all the various test methods.

3. **Sample Transfer and Chain of Custody**

The LACDPW contracts for laboratory services with the Los Angeles County Agricultural Commission Laboratory, located at 11012B Garfield Avenue, South Gate, CA 90280.

LACDPW maintains a sampling protocol involving appropriate procedures for manually collecting surface water samples and transferring custody of samples. This sampling protocol is detailed in the attached Surface Water Sampling Instruction Manual (Appendix 2). In addition LACDPW maintains frequent contact with our contract laboratory as to the proper containers and handling of samples in order to effect appropriate analyses of the constituents of interest. A chain of custody record shown in the Instruction Manual will be completed to allow step-by-step accounting of the sampling path from origin to analysis. Important information on the custody form includes:

- Name of Person(s) collecting the sample
- Sample Laboratory ID numbers
- Date and Time of Sample Collections
- Names and signatures of all persons handling the samples in the field and in the laboratory.

4. **Personnel Training**

LACDPW's Surface Water Sampling Instruction Manual (Appendix 2) deals with procedures and equipment used in surface water sampling for both manual and automated sampling, grab samples and composite samples, chain-of-custody, and safety of the field personnel. A copy of this manual is issued to all field personnel.

Prior to sampling, all water quality field personnel are provided training that includes familiarization with all the sampling areas, procedures for proper labeling, handling and storage of sample bottles, getting samples from each monitoring site to the laboratory, handling chain-of-custody, performing manual sampling, and operating automatic sampling equipment.

5. **Health and Safety**

General health and safety issues and concerns when performing water quality monitoring is also addressed in the LACDPW Health & Safety Program for all its employees. The program requires each employee to complete a safety matrix, which details hazards, that could be encountered in performing his/her duties. Safety Directives covering instructions on how to deal with said hazards are issued each employee. Example of hazards on a field sampler's safety matrix include: hazardous weather conditions, working in confined spaces, hazards associated with chemicals, snakes, poison ivy, traffic, falling, drowning, etc.

It is also LACDPW policy to require field sampling personnel to undergo a minimum of 40 hours of Hazardous Materials Awareness training, and subsequent required review courses. This training includes instructions on how to evaluate potentially hazardous situations and safety concerns.

VOL 12 1 8371

VII. QUALITY ASSURANCE/QUALITY CONTROL PLAN

Field Quality Assurance/Quality Control

1. Overview

Properly performed monitoring station set up, water sample collection, transport, and laboratory analysis are vital to the collection of accurate data. Quality Assurance / Quality Control is an essential component of the Monitoring Program.

It is important to note that this Quality Assurance/Quality Control Plan is for the fixed sites described in the Monitoring Plan, Section II, and not for the planned Illegal/Illicit Discharge Investigation Program which will have its own QA/QC plan.

This QA/QC Plan describes the procedures for bottle labeling, chain-of-custody tracking, field setup, the sampler equipment check and setup, sample collection, the use of field blanks to assess field contamination, the use of field duplicate samples, and transportation to the lab. The QA/QC Plan shall be in place and enforced at all times.

An important part of this QA/QC Plan is the continued learning process of all field personnel. Field personnel must be adequately trained from the onset and must continue to have new information about stormwater sampling techniques shared with them. During the early stages of implementation, field personnel will evaluate the field activities and the possible effects on the QA/QC Plan. Enhancement of the Plan, if needed, will be implemented and an updated QA/QC Plan submitted to the Regional Water Quality Control Board for their use.

2. Bottle Preparation

Bottles will be grouped in sets. For each monitoring station, a minimum of three sets will exist in order to guarantee a consistent rotation of bottles. All bottle labels will be generic in appearance and will look similar to the example on the following page.

BOTTLE NUMBER: ____ of ____	DATE:
STATION NAME:	TIME:
☐ GRAB ☐ COMPOSITE OTHER: ____________	PRESERVATIVES:
LABORATORY ANALYSIS REQUESTED:	COLLECTED BY:
	RECEIVED BY:

Figure VII-1

Bottles shall be cleaned at the laboratory. After the bottles are returned, they will be labeled and stored away as a set package. Each station will have the same number, size and types of bottles existing for each rotation. Clean bottles utilized for composite sampling will be replaced in the sampler at the time of each bottle collection, assuring a pre-setup sampling routine. All bottles not in use will be stored in plastic ice chests used for transporting bottles. The size of composite sample bottles has been limited to a maximum of 2½ gallons each, to ensure ease of handling.

3. **Chain-of-Custody Procedure**

Chain-of-custody procedures and forms provide legal evidence that a sample has not been tampered with. This is achieved by establishing a written record tracing possession of the sample from collection through its final analysis. Primarily we are interested in field chain-of-custody procedures. The contract laboratory's own QA/QC includes chain-of-custody procedures which are in agreement with the field procedures. (See attached Laboratory QA/QC plan.) The chain-of-custody forms will remain at all times with the corresponding samples. Chain-of-custody forms shall be filled out and signed by field staff before actual physical possession of water samples has been turned over either to other staff or to the laboratory. A sample chain-of-custody form is presented as Figure VII-2.

4. **Field Setup Procedures**

All field sampling locations are fixed sites, with the sampler placed on public road rights of way or flood control rights of way. One field staff can conduct the sampler setup and sample collection at each monitoring station. After each sample collection, field staff will prepare the sampler to collect samples either in storm mode or in dry-weather mode. The staff member will also inspect visible hoses and cables to ensure proper working conditions in accordance with manufacturing specifications. Inspection of the strainer, pressure transducer and auxiliary pump can only occur during daylight hours in non-storm conditions.

During a storm event, grab samples will be collected during the initial portion of the storm (on the rising limb of the hydrograph) and subsequently taken directly to the lab. The automated sampler will be checked at the time grab samples are collected to ensure proper working conditions at the site (to see if flow composite samples are being collected). Dry-weather collection techniques will be similar with a 24-hour composite sample and subsequent grab samples being collected.

After a sampling event, all bottles will be collected and samples packed with ice and foam insulation inside individually marked ice chest(s). Field personnel will transport these samples to the Department of Public Works headquarters. Chain-of-custody forms will be completed by field staff before relinquishing them to other staff personnel for transportation of the samples to the laboratory. Under no circumstance will samples be removed from the ice chest during transportation from the field to the laboratory. All samples transported to the laboratory will meet the holding time criteria described in Section V.

5. **Travel Blanks and Field Duplicates**

Potential field contamination will be assessed through analysis of travel blanks and duplicate composite samples. The use of field travel blanks for each monitoring station during every sampling event, represents an attempt to quantify post sampling contamination. The Monitoring Program will also include the use of field duplicates to assess the accuracy of lab results. The collection of a field duplicate will occur for each sampling event. The duplicate will be for one sampling station, unknown to the laboratory. At the present time, this methodology for assessing post sampling contamination and the accuracy of laboratory testing procedures will provide adequate data to measure the accuracy of the results provided to us from the laboratory.

LABORATORY QUALITY ASSURANCE/QUALITY CONTROL

The Los Angeles County Department of Public Works has contracted with the Office of the County Agricultural Commissioner/Weights and Measures Environmental Toxicology Laboratory for all laboratory analysis. A part of this Quality Assurance/Quality Control Plan for the Monitoring Program includes the QA/QC for the Laboratory which is enclosed as two documents (see Appendices 3 and 4). The Laboratory QA/QC Plan is a part of the Monitoring Program.

VOL 12

1 8375

VOL 12

VIII. DATA STORAGE AND REPORTING

The following categories of data are being collected as part of the monitoring program:

- Rainfall
- Runoff
- Water Quality Test Data
- Quality Assurance/Quality Control Data

All of the data will be stored in electronic format to allow for ease of retrieval interpretation, and graphic presentation.

Rainfall and runoff data will be collected from each monitoring station after each storm event and stored in a central file. The data will be arranged by monitoring station to show the total rainfall amount and total runoff volume, plus a hydrograph for each sampled storm event.

Water quality data for each monitoring station will be stored in a PC database. The data will also be entered into the EPA's STORET database. QA/QC data will be stored in a PC database.

For each sampled storm event, a report will be prepared summarizing the rainfall, runoff, and water quality data. At the end of each storm season (July 1 to June 30), a yearly monitoring report will be prepared summarizing the data collected.

1 8376

R0051681

IX. PROGRAM MANAGEMENT

Implementation and overall coordination of the Monitoring Program activities, including evaluation of the contract laboratory services will be the responsibility of the Program Manager. The Program Manager will assign field sampling personnel from a pool of technical staff (10 currently available) trained in sampling procedures and methods.

The Program Manager is responsible for evaluation of weather forecasts as provided by our storm forecasting service, and will decide on which storms warrant mobilization for the sampling activities. The Program Manager will assign one of the Field Engineers as an Event Coordinator, who will coordinate the sampling event with the designated field personnel.

For storm sampling, the stations have been divided into three groups as shown below. The stations have been apportioned based on anticipated difficulty of sampling as well as travel to and from each station.

GROUP	MONITORING STATIONS
1	Trancas Canyon Station
	Malibu Creek Station
2	Ballona Creek Station
	Kenter Drain Station
	City of Santa Monica Storm Drain Station
3	Herondo Drain Storm Drain Station
	Palos Verdes Station
	Manhattan Beach Station
	Downtown L.A. Storm Drain Station

One individual will also be assigned to perform field sampling for each group. Each individual will be responsible for all the sampling activities needed at each site within each group.

VOL 12

1 8377

For dry-weather sampling, the stations have been grouped as follows:

GROUP	MONITORING STATIONS
1	Ballona Creek Station
	Trancas Canyon Station
	Malibu Creek Station
	Kenter Drain Station
	City of Santa Monica Storm Drain Station
2	Herondo Drain Station
	Palos Verdes Station
	Manhattan Beach Station
	Downtown L.A. Storm Drain Station

Each staff member assigned a Group of stations will be responsible for: Field equipment maintenance and operation; proper collection and handling of samples; and field QA/QC and field sampling protocol.

The Program Manager will be responsible for on-going review, and evaluation of the overall QA/QC program related to sampling and laboratory procedures.

8379

X. ESTIMATION OF POLLUTANT LOADINGS

One of the objectives of the monitoring program is to assess the annual pollutant loadings to Santa Monica Bay. Knowing the types and quantities of pollutants discharged into the Bay are important in assessing the impacts of stormwater on the Bay.

Model Selection

The model to be utilized to calculate basin-wide mass pollutant loadings is the Simple Method as described in the EPA's "Guidance Manual for the Preparation of Part 2 of the NPDES Permit Applications for Discharges from Municipal Separate Storm Sewer Systems." Due to the size of the Santa Monica Bay Drainage Basin (411 square miles), this method will provide a good estimate of pollutant loadings, without requiring the extensive amount of detailed hydrologic and hydraulic data needed by more sophisticated models. Once pollutant loads have been estimated basin wide, an initial assessment can be made as to their potential impacts on the Bay. Subsequently, more detailed, dynamic modelling of select, representative watersheds in the Bay can be performed to more accurately track and assess pollutant impacts.

Calculation Procedure

Calculation of annual pollutant loadings will be performed as follows:

1. Calculate annual pollutant loads for each drainage area.

   Utilizing the formula below, calculate annual pollutant loads for each drainage area:

   Equation 1: $$L_i = \frac{(P)(CF)(Rv_i)}{12}(C_i)(A_i)(2.72)$$

   where:

   - L_i = Annual pollutant load (lb/drainage area/yr)
   - P = Annual precipitation (in/yr)
   - CF = Correction factor that adjusts for storms where no runoff occurs
   - Rv_i = Weighted-average runoff coefficient for the drainage area
   - C_i = Event mean concentration of pollutant (mg/L)
   - A_i = Drainage area (acres)

   The numbers 12 and 2.72 are conversion factors that account for unit conversions.

Each of the parameters in Equation 1 is defined below:

- Annual pollutant load is the total amount of a specific pollutant discharged in pounds per time period (in this case, per year) for the particular drainage area being modeled.

- Annual precipitation is the total inches of rainfall occurring in a single year. Estimates of the annual rainfall are calculated utilizing the historical rainfall data compiled for Los Angeles County by the Los Angeles County Flood Control District and, subsequently, the LACDPW.

- Correction factor is an adjustment factor for the number of storm events that do not actually produce any runoff (i.e., the percentage of storm events that have a total accumulation greater than a specific threshold value). This value will be calculated based on a review of historic rainfall data for Los Angeles County.

- Weighted-average runoff coefficient is a relative measure of the percentage of rainfall that becomes surface runoff. Runoff coefficients will be calculated utilizing the procedure described in Section IV.

- Event mean concentration of pollutant is the event mean concentration value for the specific pollutant determined from an analysis of the flow-weighted composite samples obtained by the monitoring program.

- Drainage area is the size of the area being modeled.

2. Use the per-drainage area annual pollutant loads to calculate per-watershed annual pollutant loads.

   The following equation will be used to calculate per-watershed annual pollutant loads.

   Equation 2 $L_w = \Sigma L_i$

   where:

   L_w = Annual pollutant load for a particular watershed

   ΣL_i = Summation of individual annual pollutant loadings from all drainage areas within a specific watershed

3. Use the per-watershed annual pollutant loadings to calculate basin-wide annual pollutant loads.

   The following equation will be used to calculate basin-wide annual pollutant loads.

VOL 12

1 8380

R0051685

Equation 3 $L_a = \Sigma L_w$

where:

L_a = Annual pollutant load for entire basin

ΣL_w = Summation of individual annual pollutant loadings from all watersheds within the basin

The above procedure can also be utilized to estimate seasonal pollutant loads and per storm event pollutant loads as needed.

Constituents to be Modeled

Annual pollutant loadings will be calculated for the following constituents:

BOD_5
COD
TSS
Dissolved Solids
Total Nitrogen
Total ammonia plus organic nitrogen
Total Phosphorus
Dissolved Phosphorus
Cadmium
Copper
Lead
Zinc

Development of Annual Pollutant Loadings

We are targeting installation of our monitoring stations for operation during the 1993-94 storm season. Upon completion of the storm season by the end of April 1994, and assuming sufficient storms have occurred for sampling, event mean concentrations will be calculated. We estimate that the pollutant loads for the Bay will be developed by August 1, 1994.

XI. LONG-TERM TRENDS IN STORMWATER/URBAN RUNOFF QUALITY

As discussed in Section II, nine fixed-station monitoring sites are proposed for the Santa Monica Bay Drainage Basin. The locations of these sites have been chosen to be representative of the various watersheds and land uses within the Basin.

In addition to providing data necessary for calculation of the event mean concentrations, long-term data from these sites can be evaluated for any trends. The objective of this evaluation is to determine if there are any statistically significant differences in pollutant concentrations and loadings which could be related to the implementation of Best Management Practices (BMPs) as opposed to random variability in hydrologic factors such as the frequency, intensity, and duration of storm events.

Complicating this evaluation is the fact that there is no, location specific, baseline data available prior to the implementation of BMPs. Monitoring at the nine stations will be commencing concurrently with implementation of various BMPs. Therefore, dependent on the number of storms available, at least five or more years of data will be needed before reasonable statistical analysis of trends could be performed due to the large degree of natural variability. Therefore, we recommend that any statistical analysis of trends be performed after the conclusion of the fifth year of monitoring.

XII. SOURCES OF STORMWATER POLLUTANTS

It is suspected that different land uses contribute certain types and amounts of pollutants to the storm drain system. Therefore, monitoring sites will be located to characterize runoff from individual land uses. As discussed in Section II, the following stations are being proposed for individual land-use monitoring.

STATION	LAND USE
Private Drain No. 658 (Trancas Canyon)	Open Space
Project No. 5401, Line A (Manhattan Beach)	Single Family
City of Los Angeles Storm Drain No. D-2361 (Downtown Los Angeles)	Commercial/Industrial
City of Santa Monica Pier Storm Drain	Commercial
Project No. 558, Line A (Palos Verdes Estates)	Single Family

Evaluating the quality of runoff from highway surfaces is also important. We are working with Caltrans to locate a section of freeway where runoff from the road surface would be isolated from surrounding land uses and is collected by a storm drain that meets the physical requirements for location of a sampling station. Establishment of this site is estimated to occur around Fall of 1994 prior to the 1994-95 rainy season.

Up to five storm samples per year will be collected from each site. Dry-weather flow samples will be collected bimonthly. Both storm and dry-weather samples will be tested for all constituents listed in Section V.

As discussed in Section XI, upon conclusion of the 1993-94 rainy season, event mean concentrations will be calculated for sampled constituents and mass pollutant loads determined for the specific constituents described in the aforementioned section. This will provide an initial assessment of the type and quantity of constituents present in the runoff from these specific land uses.

VOL 12 1 8383

APPENDIX 1

STEP-BY-STEP PROCEDURE

FOR

RUNOFF ESTIMATION

VOL 12

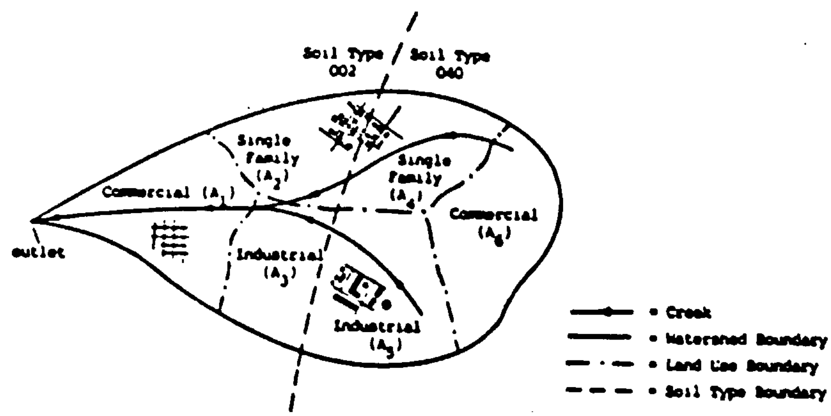
1

8384

EXAMPLE

1. Calculate the Runoff Coefficient for a Study Area

   Typical Example: The Study Area shown is comprised of two soil types and three land-use types.



Upon examining the Study Area, there are six unique soil types - land-use type combination areas. The areas are numbered 1 through 6. The data for these areas is summarized below:

Area Number	Soil Type	Land Use	Imp.	Area (Square Miles)
1	002	COM	.95	6
2	002	SF	.42	2
3	002	IND	.90	3
4	040	SF	.42	3
5	040	IND	.90	2
6	040	COM	.95	3

In general, the runoff coefficient is first calculated for each individual area. A weighted average calculation is performed to arrive at the overall runoff coefficient for the Study Area.

The detailed procedures is described below:

a) First the Undeveloped Runoff Coefficient (C_u) is determined for each area from the runoff coefficient curve for the soil type for the area. This is done by first choosing the rainfall intensity (in/hr). With this rainfall intensity value go to the runoff coefficient curve and select C_u.

VOL 12 1 8385

b) The developed Runoff Coefficient (C_D) is then calculated for each area based on the following formula:

$$C_D = .9IMP + C_U\ (1-IMP)$$

The IMP is the imperviousness value assigned to the land use within each area.

c) After calculating C_D for each individual area, a weighted average calculation is performed to come up with the average C_D for the entire Study Area.

Now we will calculate C_D for the Study Area:

Select rainfall intensity

The rainfall intensity to be used will be 1.5 in/hr. If the rainfall intensity is not known or no specific value is to be used, then C_U automatically goes to the minimum or default value of 0.1 which is the same for all soil types. The calculation process should be established to use the default value unless a user specified rainfall intensity is provided.

Determine C_U

The Study Area is comprised of two soil types. C_U for these soil types is:

Soil type	C_U
002	.79
040	.75

Calculate C_D

Calculate C_D for each area:

Area No.	C_U	Imp.	C_D
1	.79	.95	.89[1)]
2	.79	.42	.83
3	.79	.90	.79
4	.75	.42	.81
5	.75	.90	.89
6	.75	.95	.89

1) C_D for Area 1 = .9(.95) + .79(1-.95) = 0.89

Therefore, C_D for the Study Area is:

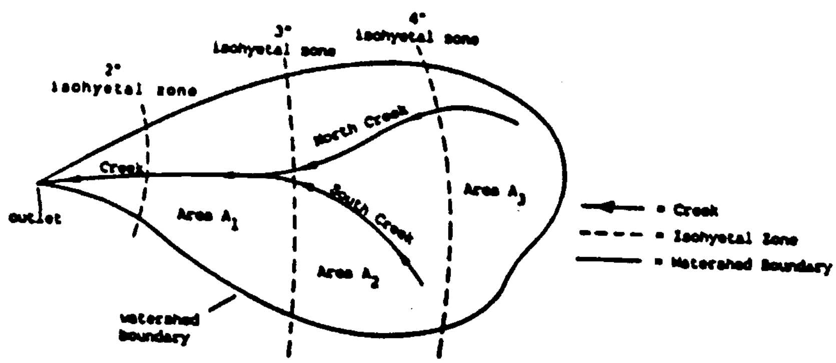
$$C_D \text{ Study Area} = \frac{C_{D1}\text{ Area}_1 + C_{D2}\text{ Area}_2 + C_{D3}\text{ Area}_3 \ldots}{(\text{Area}_1, + \text{Area}_2 + \text{Area}_3 \ldots)}$$

$$= \frac{.89(6) + .83(2) + .79(3) + .81(3) + .89(2) + .89(3)}{(6+2+3+3+2+3)}$$

$$= .86$$

2. **Calculate Rainfall Volume Over the Study Area**

The Study Area is shown below and encompasses the indicated isohyetal zones.



The total area of the Study Area is 10 mi^2. The portion of the Study Area encompassed by each isohyetal zone is listed below:

Zone	Area(mi^2)
2"	3
3"	7
4"	9

The total rainfall volume deposited on the study area is:

$$\text{rainfall volume} = [2(3) + 3(7) + 4(9)]\ (640\ \tfrac{acres}{mile^2})\ (1/12)$$

$$= 3360 \text{ Acre}\cdot\text{feet}$$

$$\text{or } \frac{3360\ \ 12\ (\frac{inches}{foot})}{19(mi^2)\ (640\ \frac{acre}{mile^2})} = 3.3\text{" depth over the entire study area}$$

VOL 12

1 8387

3. **Calculate the Runoff Volume for a Study Area**

For the Study Area used in this example, the runoff coefficient (C_D)=0.86.

runoff volume = Rainfall Volume (C_D)

= 3360 Acre•feet (0.86)

= 2890 Acre•feet

SURFACE WATER SAMPLING INSTRUCTION MANUAL

PUBLIC WORKS

LOS ANGELES COUNTY

"Public Service That Works"

LOS ANGELES COUNTY
DEPARTMENT OF PUBLIC WORKS

WASTE MANAGEMENT DIVISION

VOL 12

1839/

I. INTRODUCTION

This manual covers collection of surface water samples for the Department's Stormwater/Urban Runoff Monitoring Program, and compliments the sampling procedures contained in the Work Plan for the Stormwater/Urban Runoff Monitoring Program (Work Plan).

Two sampling techniques, Manual Sampling (sampling by hand) and Automated Sampling (sample collection by use of powered devices such as the Automated sampler) are used in the monitoring program. Both manual sampling and automated sampling techniques are discussed in this sampling manual, with reference to the above-mentioned Work Plan.

Samples collected for both dry weather and storm flow monitoring programs are typed either "Grab" or "Composite". Grab sample is an individual discreet sample collected for characterizing water quality at a particular time. Grab samples normally would be collected using manual sampling techniques, unless sampling collection can only be achieved using automatic samplers, such as at manhole stations that are very deep and not accessible using manual grab sampling equipment. Composite samples are series of individual samples collected at paced intervals and combined to create a single weighted composite. Composite samples would normally be obtained, using automated sampling techniques.

The following instructions will help you collect samples and transport water samples safely and correctly. Safety is of the utmost importance, but if a sample is not collected or transported correctly, the subsequent lab analysis results will be compromised or invalidated.

It should be noted that these instructions are merely a guide to meet the specific needs of the Department. They are not intended to be a comprehensive guide to water quality sampling. Numerous textbooks, handbooks, and manuals are available for those interested in more detailed information on sampling methodology.

II. COLLECTION OF SAMPLES

Water samples will be collected in bottles supplied by the contract laboratory. All sample bottles, except bacteria bottles have been acid-washed and thoroughly rinsed with distilled water to eliminate contamination. Bacteria bottles contain a dechlorinating chemical. DO NOT RINSE THE SAMPLE BOTTLES BEFORE FILLING.

However, the bucket, dipper and funnel should be rinsed at each new sampling location. Use the water at each new site to rinse off any contaminates left in the bucket from prior sites.

DO NOT USE SOAP OR ANY OTHER DETERGENTS TO CLEAN SAMPLING EQUIPMENT.

A. Manually Collecting Grab Samples

A Manual grab is collected by inserting a container (bucket, dipper, etc.) under the surface of the water body to be sampled and/or dipping a container down current of a discharge with the container opening facing upstream. The following manual sampling procedures should be followed, in accordance with the source of the sample as well as requirements for certain analyses:

1. Nonflowing - Reservoirs, Lakes, and Ponds

   The sampling technique will depend on the location and purpose of the investigation. The following general rules should be observed:

   a. Select a location away from areas where water may tend to be stagnant.

   b. Take samples at a location that is definable in plan and depth so that subsequent samples can be taken from the same location. This is important where a study is to be made regarding water quality changes with time.

2. Flowing Water

   a. When sampling with a bucket and line from above the streamflow, first attach the line to the bridge railing or some other firmly fixed object. Lower the bucket gently into the center of the channel. Make sure the bucket is submerged to avoid the collection of floating debris.

VOL 12

18392

R0051697

b. When sampling for oil and grease, sample should be collected at the air/water interface to insure collection of representative samples.

c. Avoid hitting the bottom of the channel so that deposited sediments are not collected.

d. When using the bucket and line adjacent to the low-flow channel, gently swing the bucket into the center of the flow to collect the sample.

e. After raising the bucket, take the temperature of the sample immediately for at least 30 seconds.

f. Pour off any floating debris and decant the water from the bucket into the sample bottles.

3. Bacteriological Samples

Bacteriological samples should be taken under sterile conditions, observing the following precautions (also refer to Section C 2. Sample Bottles):

a. Do not rinse the bottle. The bacteria bottle contains a dechlorinating chemical which must mix with the sample.

b. Do not fill the bottle completely; leave about 1/2 inch to allow mixing of the contents.

c. When sampling, prevent contaminating the lip and cover of the sampling bottle by avoiding contact with anything but the sample or the source of the sample.

B. Collecting Grab Samples By Automated Sampler

Collection of grab samples can also be accomplished by using the automated samplers. This is accomplished by temporarily bypassing the automated sampling program and utilizing the pumping unit of the automated sampler to fill the grab sample bottles. This sampling technique may be used if sample points for grab samples are inaccessible, such as at sampling stations that are very deep below the ground surface and cannot be accessed using manual grab sampling equipment. However, once the grab samples are collected, the automated sampling system must be restored to its ready mode for performing its programmed functions.

VOL 12

18393

C. Flow Composite Samples

Flow weighted composite samples are collected using the automated samplers, programmed to collect samples for Storm Sampling (at flow paced intervals), and for Dry Weather Sampling (at fixed time intervals). For both storm sampling and dry-weather sampling, sample bottles must be retrieved within the maximum holding times required of the various test methods. Sample bottles are to be placed in coolers with frozen blue ice for transport to the laboratory for compositing and analysis.

VOL 12

1 8394

C. Flow Composite Samples

Flow weighted composite samples are collected using the automated samplers, programmed to collect samples for Storm Sampling (at flow paced intervals), and for Dry Weather Sampling (at fixed time intervals). For both storm sampling and dry-weather sampling, sample bottles must be retrieved within the maximum holding times required of the various test methods. Sample bottles are to be placed in coolers with frozen blue ice for transport to the laboratory for compositing and analysis.

VOL 12

118395

III. SAMPLING EQUIPMENT

You will be provided with the sampling equipment necessary for your assignment. The equipment may consist of the following items:

- Bucket and rope
- Sample bottles
- Thermometer
- Personal equipment: (if applicable)
  - Hard hat and vest
  - Flashlight
  - Thomas Guide and location sketch
  - Rubber Gloves

A. Bucket and Rope

All surface samples collected manually by the Water Quality Management/Storm Water Section are of the type known as "grab samples". Under this procedure a sample may be collected in a bucket at a randomly selected time, over a period of time not to exceed 15 minutes.

B. Sample Bottles

You will be provided with the appropriate sample bottles and containers by the contract laboratory. Sample containers are easy to contaminate, therefore, AVOID TOUCHING the mouth of the bottle or the inner surface of the cap. Except when otherwise stated all containers should be filled to within 1" of the top NEVER TO OVERFLOWING. Identify the sample and provide necessary information requested on the container label using a waterproof ink pen. Place all glass containers into plastic protective bubble pack bags, and/or pack the containers in the cooler with shock absorbing materials to minimize the possibility of breakage. Add frozen blue ice, and deliver to the contract laboratory.

2. **SPECIFIC INSTRUCTIONS**

a. General Mineral (Gen Min):

Fill unpreserved container to within 1" of the top. It is not necessary to rinse out the container with the sample. Tighten the cap to prevent leakage.

b. Microbiology (Micro):

Fill unpreserved 1 Liter plastic container to within 1" of the top. It is not necessary to rinse out the container with the sample. Tighten the cap to prevent leakage. Place container in cooler with "Blue Ice" to minimize the effect of high temperatures on deaths of microbes. The maximum holding time for bacteria samples is six hours from the time of collection. Therefore, the samples must immediately be transported to the laboratory. Also, refer to preceding Section B 3. Bacteriological Samples.

c. Total Petroleum Hydrocarbon (TPH or TPH, Cr+6):

Fill unpreserved container to within 1" of the top. It is not necessary to rinse out the container with the sample. Tighten the cap to prevent leakage. This container is glass and, if possible, should be placed into a bubble bag for transportation to prevent breakage.

d. Metals:

Fill preserved container to within 1" of the top. DO NOT RINSE OUT OR OVERFILL. Contains Nitric Acid as a preservative. Tighten cap to prevent leakage.

e. Oil and Grease (O & G) :

Fill preserved container to within 1" of the top. DO NOT RINSE OUT OR OVERFILL. Contains Sulfuric Acid as a preservative. Tighten cap to prevent leakage. This container is glass and, if possible, should be placed into a bubble bag for transportation to prevent breakage.

f. Pesticide-PCB's (Pest-PCB):

Fill unpreserved container to within 3" of the top. It is not necessary to rinse out the container with the sample. Tighten the cap to prevent leakage. This container is glass and, if possible, should be placed into a bubble bag for transportation to prevent breakage.

g. Total Organic Carbon (TOC):

Fill unpreserved container to within 1" of the top. It is not necessary to rinse out the container with the sample. Tighten the cap to prevent leakage. This container is glass and, if possible, should be placed into a bubble bag for transportation to prevent breakage.

h. Biological Oxygen Demand (BOD):

Fill unpreserved container to within 1" of the top. It is not necessary to rinse out the container with the sample. Tighten the cap to prevent leakage.

i. Volatile Organics (EPA 601/602):

Slowly fill the two 40ml vials to overflowing, being careful not to aerate the sample. Carefully place the cap onto the vial and tighten to prevent leakage. Make sure that the teflon surface of the septum (hard white side) is facing the sample, the soft silicon side of the septum should be visible from the top of the cap. Invert the vials to confirm proper sample collection (bubbles should not be observed). If bubbles are present, open the vials, add more sample, reseal the vials, and recheck for air bubbles. Place the glass vials into the plastic protective bubble bag and, if possible, store in a cooler with "Blue Ice".

j. Base-Neutral-Acid Extractables (BNA):

Fill unpreserved container to within 3" of the top. It is not necessary to rinse out the container with the sample. Tighten the cap to prevent leakage. This container is glass and, if possible, should be placed into a bubble bag for transportation to prevent breakage.

VOL 12

1 8399

k. Herbicides (Herb):

Fill unpreserved container to within 3" of the top. It is not necessary to rinse out the container with the sample. Tighten the cap to prevent leakage. This container is glass and, if possible, should be placed into a bubble bag for transportation to prevent breakage.

3. SPECIAL SAMPLES

a. Organic Nitrogen (TKN):

Fill preserved 250 ml plastic container to within 1" of the top. DO NOT RINSE OUT OR OVERFILL. Contains Sulfuric Acid as a preservative. Tighten cap to prevent leakage.

b. Radioactivity (Gross alpha & beta):

Fill preserved 1 Liter plastic container to within 1" of the top. DO NOT RINSE OUT OR OVERFILL. Contains Nitric Acid as a preservative. Tighten cap to prevent leakage.

c. Asbestos:

Fill unpreserved 1 Liter plastic container to within 1" of the top. It is not necessary to rinse out the container with the sample. Tighten the cap to prevent leakage.

d. Chlorinated Organic Substances (COS):

Use same sampling procedure as for EPA 601/602. The EPA reference manual is available in the Water Quality Section.

e. Nitrite-N (1 ppb DL):

Fill unpreserved 125 ml plastic container to within 1" of the top. It is not necessary to rinse out the container with the sample. Tighten the cap to prevent leakage.

C. Thermometer

Water temperatures are always taken during sampling, and you will be provided with a thermometer for this purpose.

D. Dissolved Oxygen Meter

If your assignment requires the measurement of dissolved oxygen, you will be provided with a DO meter and instructions on its use. Calibration of the meter is essential prior to each use. Instructions to operate the DO meter will be provided prior to usage.

E. <u>Personal Equipment</u>

Before leaving on a sampling assignment, make sure that you have all of the personal equipment necessary to carry out your assignment. This would include your hard hat and vest, gloves,flashlight if necessary, Thomas Guide, etc, and location sketches showing the various surface sampling stations and access points.

VOL 12 1 8401

IV. SAFETY

Safety Reminders:

1. Safety is more important than the samples. Never place yourself in a dangerous or unsafe sampling situation.

2. Always park your vehicle where it is safe. Pull into an access road or park your vehicle on a street where parking is permitted and walk to the site. NEVER PARK ON A BRIDGE.

3. Wear your hard hat and a high-visibility vest when you leave your vehicle.

4. Wear waterproof boots with high-traction soles when walking or standing on wet surfaces. Slippery surfaces should be avoided.

5. Never stand or walk in moving water.

6. Never get too close to a low-flow channel. Use your bucket and line to obtain a surface sample.

7. **Never enter an enclosed drain, tunnel, or a confined space.**

8. If waters are flowing outside the low-flow channel, lower the bucket and line from a bridge.

9. When sampling from a bridge, always tie one end of your rope to the railing or some other firmly fixed object. Do not lean excessively over the guard rail.

10. Be alert for hazardous situations. Your personal safety is your first responsibility. Common sense safety precautions must be exercised if you come upon an unusual material, discharge, smell, dumping, etc. Take note of your observations. Your notes may be used in follow-up investigations and/or supporting future analytical findings. Sample must not be taken if common sense judgement indicate that your safety is jeopardized.

11. Wear gloves when handling samples and wash your hands with soap and water when finished.

12. Wash all equipment, boots, gloves, bucket, etc., when finished.

13. When ascending or descending unstable or slippery slopes and embankments, avoid holding breakable bottles, and pointed or sharp objects with bare hands.

14. Each employee has Physical Class Limitations established under the Occupational Health Manual of Policies and Procedures of the Department. Exerting physical efforts or lifting weights over your physical class limit must be avoided to prevent physical injury. Ice chests with full sample bottles may exceed the weight-class requirements; in such cases, the ice chest must be transported by a minimum of two persons.

VOL 12

1 8402

V. LABELING AND FIELD OBSERVATIONS

Each sample bottle will normally be pre-labeled by the Water Quality Unit. It is important, however, that each sample be identified as to the source, date, and time of acquisition. If a sample is taken from a large body of water, for example, the location should be described in such a way as to enable the same sample point to be relocated in the future if it becomes necessary.

VOL 12

1

8403

VI. DELIVERY OF SAMPLES

Samples should be delivered to the contract laboratory as soon as possible to prevent alteration of the sample between time of sampling and time of analysis. In order to avoid the need to preserve the samples overnight, samples should be delivered to the contract laboratory no late than 5:00 p.m., unless prior arrangement with the contract laboratory is made.

VOL 12

18404

VII. CHAIN OF CUSTODY

The Chain-of-Custody Record form shown must be completed for each delivery of samples to the contract laboratory. When sampling for potential court case litigation, consult the laboratory for the appropriate testing procedures, splitting and sealing of samples, and chain of custody.

QA OBJECTIVES

1. Establish the laboratory's ability to qualitatively and quantitatively analyzed various types of environmental samples for pollutants by:

   - identifying the qualifications and responsibilities of laboratory personnel;

   - enumerating the existing laboratory instrumentation and equipment together with the procedures for their sevice and maintenance to assure proper operation:

   - providing sources of analytical methods accepted by regulatory agencies for use in the laboratory.

2. Provide guidelines pertaining to sampling protocols, chain-of-custody, and storage of samples to maitain sample integrity prior to analyses.

3. Define the laboratory's calibration procedures and frequency of calibration.

4. Identify all the necessary steps to validate the laboratory's results.

5. Define all the necessary quality control checks that must be followed prior to the analysis and/or in the course of analyzing samples.

6. Identify all laboratory records and information needed to document the quality of analyses performed in the laboratory.

COUNTY OF LOS ANGELES
Office of Agricultural Commissioner/Weights and Measures
ENVIRONMENTAL TOXICOLOGY LABORATORY

<u>Organizational Chart</u>

- Agricultural Commissioner
  - Chief Deputy
    - Deputy Director
      - Secretary I
      - Laboratory Chief
        - Intermediate Typist Clerk
        - Senior Toxicologist
          - Toxicologist (4)
            - H/P Technologist
              - Lab. Support Supervisor I
        - Senior Industrial Hygiene Chemist
          - Industrial Hygiene Chemist
            - Tox. Technologist
              - Laboratory Assistant

1. Organization

A. Minimum Personnel Qualification and Background

1. Deputy Director Graduation from an accredited college with specialization in chemistry, biochemistry, biology, or agricultural chemistry, and three years experience in analytical chemistry, biochemistry, pharmacology, or toxicology laboratory. An advanced degree in chemistry or biochemistry will be accepted for the required experience on the basis of one year for Master's degree and two years for a Ph.D.

2. Chief-A Bachelor of Science degree and at least three years experience in chemistry, biochemistry, pharmacology, biology, or toxicology, one year of which must have involved the chemical analysis of environmental samples. An advanced degree in chemistry or biochemistry will be accepted for the required experience on the basis of one year for a Master's degree and two years for a Ph.D.

3. Senior Toxicologist-Graduation from an accredited college with specialization in chemistry or biochemistry, and two years experience in analytical chemistry, biochemistry, pharmacology, or toxicology. An advanced degree in chemistry or biochemistry will be accepted for the required experience on the basis of one year for a Master's degree and two years for a Ph.D.

4. Senior Industrial Hygiene Chemist-Master of science degree with a major in general or physical chemistry and five years experience as a professional chemist conducting basic analytical research in chemistry, or four years experience as as Industrial Hygienu Chemist.

5. Toxicologist-Graduation from an accredited college with specialization in chemistry or biochemistry, and one year experience in analytical chemistry, biochemistry, pharmacology, or toxicology. Completion of one year graduate work in an accredited college with specialization in chemistry or biochemistry will be accepted for the required experience.

6. Industrial Hygiene Chemist-Bachelor of science degree with major in chemistry a biochemistry, and either (1) a Master's degree in chemistry, biochemistry, or a related field of environmental chemistry and two years experience as a professional chemist doing increasingly complex analytical procedures, or (2) four years experience as a professional chemist doing increasingly complex analytical procedures.

7. Herbicide Pesticide Technologist-Graduation from an accredited college with specialization in chemistry, biochemistry, toxicology, biological & natural sciences and six months experience performing chemical analyses or completion of sixty semester units of which 16 must have been in chemistry and two years experience performing toxicological analyses.

VOL 12

1845

8. Toxicological Technologist-same as Herbicide/Pesticide Technologist.

9. Senior Laboratory Assistant-Six months experience at the laboratory assistant level.

10. Laboratory Assistant-Six months experience in laboratory work in a public health, medical, chemical, or biological laboratory, or completion of a course in laboratory science such as general chemistry or bacteriology.

B. Personnel Responsibilities

1. Deputy Director

-Directs, plans, assigns, reviews and evaluates work performed by laboratory personnel.

-Provides consultation in environmental toxicology to DHS, Agriculture Comm. and other agencies.

-Testifies as an expert witness for Los Angeles County on the analysis and interpretation of findings.

-Supervises the analysis and interpretation of laboratory data and correlates this with biochemical and metabolic effects.

-Publish scientific papers and reports. Make presentations concerning H/P contamination in our community. Attends and participates in conventions, meetings and conferences of professional organizations concerning H/P.

2. Chief

-Assists in the planning, assignment, supervision, and review of the work of laboratory personnel.

-Provides technical direction to laboratory personnel in performing a variety of chemical analyses of water, soil, plant, animal and other environmental samples utilizing various techniques such as spectrophotometry, chromatography, gravimetric, and volumetric analyses.

-Establishes and sets up special test procedures for detecting pesticides and other chemicals for which the laboratory has minimal or no experience, including all required and necessary quality control steps in such procedures.

VOL 12

1 8 4 1 6

-Establishes minimum quality control guidelines for all methods and tests performed in the laboratory.

-Develops laboratory statistics and reports on analytical procedures in assisting laboratory personnel in making the more difficult or unusual determinations, to identify priorities, and to establish work flow measures.

-Conducts training of laboratory personnel.

-May testify as an expert witness for the Chief Environmental Toxicologist.

3. Senior Toxicologist

-Provides technical guidance to laboratory personnel and performs chemical analyses to determine the presence and quantity of pesticides and other chemicals of interest in samples submitted to the laboratory for study utilizing wet and instrumental methods.

-Develops procedures for and conducts non-routine analysis on samples involving new and uncommon pesticides where standard methods are not established.

-Routinely monitors at regular intervals the accuracy and precision of laboratory results by checking quality control data obtained by laboratory personnel as part of their daily workload.

-Ensures that all quality control guidelines of the laboratory are met and recorded in specific quality control record books.

-Prepares daily work assignments of lower level laboratory personnel.

-Engages in continuing research and experimentation to develop and improve analytical procedures.

-Writes reports on analyses outlining methods used and results.

-Assists the Supervising Toxicologist in performing an analysis of unknown substances.

-Contacts pathologists, law enforcement officers, pharmacists and others to obtain information on cases as necessary.

VOL 12

1

8417

VOL 12

4. Senior Industrial Hygiene Chemist

-Prepares work schedules, assigns and rotates Industrial Hygiene Chemists to various jobs, evaluates work performance and recommends resolutions to employee relations problems.

-Tests or directs the testing of new equipment, prepares written evaluations, and makes recommendations for its acquisition; prepares written instructions on the application and oper tion of new equipment for the procedure manual.

-Supervises a program of quality control to ensure the accuracy of test reports.

-Orients new employees to the overall operations of the section and trains or supervises their training.

-Serves as the consultant to Public Health Programs staff on problems relating to toxic and potentially dangerous chemicals.

-Analyzes samples that require the highest level of technical skill, experience and knowledge.

-Instructs environmental health personnel in the proper procedures for collecting field samples.

-Calibrates all laboratory equipment for the section.

5. Toxicologist

-Performs chemical analyses of water, soil, plant, animal, and other samples utilizing standard laboratory techniques such as spectrophotometry, chromatography and gravimetric and volumetric analysis.

-Follows accepted procedures and required quality control measures for conducting routine analyses such as determinations for pesticides and other organic/inorganic compounds.

-Writes reports on analyses outlining methods used and results.

-Contacts inspectors, law enforcement officers, and others to obtain information on cases as necessary.

-Assists the Senior Toxicologist in performing analysis of unknown substances.

1 8 4 1 8

-Prepares standard chemical solutions and reagents to specific requirements.

6. Industrial Hygiene Chemist

-Collects field samples and conducts surveys regarding industrial hygiene, sanitation, and exposure of workers to health hazards.

-Conducts laboratory and field analyses of abrasives, solvents, and other materials used in industrial plants and makes specialized measurements of air samples to identify and measure contaminants.

-Maintains and operates a chemical laboratory, anticipating needs for ordering chemicals and equipment.

-Develops new and special methods, procedures and equipment to be used for chemical and physical determinations in laboratory and field studies.

-Conducts research on problems of toxicology and other chemical problems as necessary for industry, County and other governmental agencies.

-Maintains laboratory records and prepares reports on results of studies and projects.

-Interprets data and confers with engineers, various divisions of the Health Department, and industrial managers to solve chemical problems concerning industrial health and hazards to workers.

-Operates a variety of laboratory and field testing equipment.

7. Herbicide/Pesticide Technologist

-Performs chemical procedures requiring the use of analytical apparatus to confirm existence of herbicides and pesticides in plant, soil, water, and animal tissue specimens.

-Utilizes techniques such as gas chromatography in chemical analyses of various specimens to determine the quantity of herbicides and pesticides present.

-Follows quality control guidelines on all chemical procedures and analyses performed.

VOL 12

-Conducts preliminary research contributing to the development of new methods and procedures for the purpose of enhancing the quality of test analysis.

-Prepares standard chemical solutions and reagents to specific requirements.

-Performs routine maintenance on laboratory equipment and apparatus including cleaning and calibration.

-Prepares written reports delineating technical procedures exercised during analysis and test findings.

-Interprets gas chromatography graphs to determine specimen findings and submits interpretations to a Senior Toxicologist for review.

8. Toxicological Technologist

-Performs chemical analysis of environmental and biological samples using established procedures to determine the presence or absence of pesticides.

-Utilizes known instrumentation techniques such as gas and high pressure liquid chromatographs to determine the quality and quantity of pesticides present.

-Follows quality control guidelines on all chemical procedures and analyses performed.

-Prepares reference standards, chemical solutions, and reagents to specific requirements.

-Performs routine maintenance on laboratory equipment and apparatus including cleaning and calibration.

-Interprets charts and reading generated by various laboratory instruments used and submits interpretations to a toxicologist or senior toxicologist for review.

-Maintains register of all samples which includes detailed information on the methods used and findings.

-Assist in the development of new methods and procedures to improve the quality and reliability of test results.

-Follows experimental procedures under the guidance of a senior toxicologist to test for new pesticides.

18420

VOL 12

9. Senior Laboratory Assistant

- Trains laboratory assistants in the specific procedures established by the laboratory for the preparation of samples for analysis by toxicological technologists and toxicologists, the preparation of reagents, and the performance of other such laboratory tasks.

- Observes the performance of other laboratory assistants of their assigned tasks both in training and on-the-job situations, and makes corrections necessary to assure maintenance to established quality and quantity standards.

- Prepares samples for laboratory testing by adding reagents, solvents, and/or standards using prescribed techniques and instruments appropriate to the type of sample.

- Processes samples for subsequent analysis by higher level personnel by performing duties such as extractions and filtrations.

- Operates laboratory equipment pre-calibrated by qualified personnel to perform assigned tasks such as platform shakers, rotovaporators, and pH meters.

- Prepares specific quantities of reagents and solutions of compounds including acids and bases, following written procedures, by mixing components to standard ratios using such laboratory apparatus as weighing balances and volumetric glasswares; lifts and moves containers holding several gallons or other substantial quantities of constituent parts or compounds produced.

- Performs routine maintenance on miscellaneous devices such as water baths, rotovaporators, and platform balances.

- Cleans and treats glassware used in laboratory testing following steps and procedures prescribed by higher level personnel.

- Stores apparatus, glassware, and other supplies in designated areas when not is use.

- Stores reagents and chemicals in designated areas as required by safety rules and regulations.

1 8421

10. Laboratory Assistant

- Receives samples such as water, soil, plant, etc. together with standard laboratory request form providing information such as sample I.D. and tests to be performed; verifies sample I.D. and assigned laboratory I.D. number by matching information on request form and sample container.

- Assigns laboratory identification to all samples received and writes this I.D. number on request forms and corresponding sample containers.

- Logs in sample information such as sample I.D., laboratory I.D. number, and tests to be performed in laboratory record book.

- Stores all samples received in appropriate storage locations and submit corresponding laboratory request forms to senior toxicologist.

- Prepares samples for analyses by chopping, weighing, and/or measuring where appropriate.

- Performs preliminary work on samples such as adding solvents and reagents, setting-up necessary glassware, and loading on platform shakers.

- Operates automatic laboratory equipment pre-calibrated by qualified personnel such as a pH meter to perform specific test.

- Transcribes laboratory test results from laboratory worksheets into permanent record book.

- Cleans & treats glassware used in laboratory testing following steps & procedures prescribed by higher level personnel.

- Cleans and stores apparatus, glassware and other supplies in designated areas when not in use.

- Stores reagents and chemicals in designated areas as required by safety rules and regulations.

VOL 12

II. Sampling Procedures

A. Hazardous Waste

1. Organochlorine pesticides, Polychlorinated Biphenyls, and Organophosphorous Pesticides.

   Wide mouth borosilate or soda glass container of 16 oz. size should be used. The container must have tight, screw-type lid with teflon liner. Sample bottle must not be prewashed with the sample before collection. Composite sample should be collected in refrigerated glass container.

   The sample must be iced or refrigerated from the time of collection until extraction. Preservatives should not be used in the field unless more than 24 hour will be elapse before delivery to laboratory. If the sample will not be extracted within 48 hours of collection, the sample should be adjusted to pH range of 6.0 to 8.0 with sodium hydroxide or sulfuric acid. Note the volume of acid or base added to the sample.

   All samples must be extracted within 7 days and completely analyzed within 30 days of collection for organochlorine, pesticide and polychlorinated biphenyls, and analyzed within 14 days of collection for organophosphorous pesticides.

2. Phenols

   Wide mouth borosilate or soda glass container must be used, and the container must not be prewashed with sample before collection. Composite samples should be collected in refrigerated glass container.

   The sample must be iced or refrigerated from the time of collection until extraction. If free chlorine is present in the sample, add 35 mg. of sodium thiosulfate per ppm free chlorine per liter/kg. Adjust the sample pH to approximately 2, as measured by pH paper with sulfuric acid solution or 10 N sodium hydroxide. record the weight of sodium thiosulfate and volume of sulfuric acid or sodium hydroxide used.

   All samples must be extracted within 7 days and completely analyzed within 30 days of collection.

VOL 12

1 8423

VOL 12

3. Halogenated Volatile Organics, Non-Halogenated Volatile Organics, and Acrolein, Acrylonitrile, Acetonitrile.

Samples must be collected in glass containers of at least 25 ml. size. Fill the sample container in such a manner that no air bubbles pass through the sample as the container is being filled. Seal the bottle so that no air bubbles are entrapped in it. Solid and semisolid samples are to be taken in the same way.

The samples must be iced or refrigerated from the time of collection until extraction. If the sample may contain free or combined chlorine, add 10 mg. sodium thiosulfate per. 40 ml./gm. for up to 5 ppm. chlorine. Fill the container with sample just to overflowing, seal the container, and shake vigorously for 1 minute.

All the samples must be analyzed within 14 days of collection.

4. Base, neutral, acid extractables.

All samples must be collected in glass container with teflon-lined screw caps. The samples must be iced or refrigerated at 4°c from time of collection until extraction. All samples must be extracted within 14 days of collection and completely analyzed within 40 days of extraction.

5. Phthalate Esters, Nitroaromatics, Cyclic Ketones, Poly nuclear Aromatic Hydrocarbons and Chlorinated Hydrocarbons.

All samples must be collected in refrigerated glass containers and the containers must not be prewashed with sample before collection. The sample must be iced or refrigerated from time of collection until extraction. Chemical preservative should not be used unless more than 24 hour will elapse before delivery to the laboratory. If the samples will not be extracted within 48 hours of being collected, the sample should be adjusted to a pH range of 6.0-8.0 with sodium hydroxide or sulfuric acid. Record the amount of acid or base used.

All samples must be extracted within 7 days and completely analyzed within 30 days of collection.

1
8424

6. Toxic Metals

All sample containers must be prewashed with detergents, acids and deionized water. Plastic and glass containers are acceptable. Aqueous samples must be acidified to pH less than 2 with nitric acid. Non-aqueous sample shall be refrigerated. The maximum holding time of sample for mercury is 38 days in glass container and 13 days in plastic container.

7. Non-metallic

a. Cyanide

Oxydizing agents decompose most cyanides. To test the presence of oxidizing agents, test a drop of liquid sample with potassium iodidestarch test paper: a blue color indicates the need for treatment. Add ascorbic acid a few crystals at a time until a drop of sample produce no color on the test paper. Then add an additional 0.6 gm. of ascorbic acid for each liter of liquid sample.

Samples must be preserved with 2 ml. of 10 N. sodium hydroxide per liter of sample at time of collection (pH is greater than or equal to 12).

Samples should be refrigerated at 4°c and analyzed as soon as possible.

Sample could be stored in glass or plastic container.

b. Fluoride

Sample should be collected in glass or plastic container.
Maximum holding time is 28 days.

c. Sulfide

Sample should be collected in glass or plastic container. Aqueous samples must be preserved with zinc acetate or the analysis must be started immediately.

8. Physical property testing

All samples should be collected in glass container with teflon liner and stored at 4°c.

VOL 12 1 8425

B. Drinking Water

1. Organochlorine Pesticides and Nitrogen - and Phosphorus-Containing Pesticides

Use 1-L borosilicate glass bottle with TEF-fluorocarbon lined screw cap, add 10 mL. of mercuric chloride as preservative to the bottle for a concentration of 10 mg/L.

When sampling tap water, allow the system to flush for about 10 minutes to stabilize temperature. Adjust the water flow to approx. 500 ml./min. befor collecting the sample. Note that the bottle must not be pre-rinsed with the sample. If a well is to be sample, collect the water in a wide-mouth beaker then transfer to the sample bottle with preservative. Seal the bottle then shake vigorously for 1 minute.

Store the sample at 4°c. Extract within 7 days of collection and analyze within 40 days of extraction.

2. Volatile Organic Compounds

Use 40 ml. vials with screw caps equipped with PTFE-faced silicone septum. These vials maybe ordered from Pierce or equivalent pre-cleaned and ready to use. Carry a field blank filled with reagent water to the sampling site with empty vials.

Fill sample bottles to overflowing. No air bubbles should pass through the samples as the bottle is filled, or be trapped in the bottle when the bottle is sealed.

When sampling tap water, allow the system to flush for about 10 minutes to reach stable temperature. Adjust water flow to about 500 ml./min. them collect the sample. If a well is to be sampled, collect the water in a wide-mouth beaker then transfer to the sample vial.

Collect all samples in duplicate.

Adjust pH of sample to < 2 by the addition of 2 drops of 50% HCl. Seal the sample bottle with the PTFE-face down and shake vigorously for 1 minute. Immediately store sample at 4°c after collection. Analyze samples within 14 days of collection.

3. Carbamate Pesticides

Use 100-ml. or larger capacity glass or plastic bottle equipped with screw cap. Carry a field blank filled with TypeII water to the sampling site with the empty sample bottle. Add 7 mg/100 ml. of sodium thiosulfate to the empty bottles and field blanks as preservative.

Do not pre-rinse container with sample before sampling.

When sampling tap water, allow the system to flush for about 10 minutes to obtain stable temperature. Adjust the flow to approx. 500 ml./min. then collect water in a wide-mouth beaker the carefully transfer the sample to the bottle. Fill the bottle within 2 cm. of the top.

In the laboratory, samples to be analyzed for oxamyl, 3-hydroxycarbofuran, and carbaryl must be further preserved immediately at the laboratory by adjusting pH to 3. This maybe done with the addition of 50% HCL.

Store samples at 4°c and extract within 7 days of collection and complete the analysis within 40 days of extraction.

4. **Trace Metals**

Use 125-ml. polyethylene bottles with screw caplid. Prior to use, wash bottle with detergent and tap water; rinse with 1:1 nitric acid, tap water, 1:1 hydrochloric acid, tap water, and finally de-ionized water in that order.

For determination of dissolved or suspended metals, no preservative need be added at the time of collection. For determination of total metals, both dissolved and suspended, acidfy sample to pH 2 or less with the addition of 1:1 redistilled HNO_3 at the time of collection. For determination of total recoverable metal acidify sample at the time of collection with 0.625 ml. of conc. HNO_3 for 125 ml. of sample. Analyze sample within 30 days of collection.

C. Sample Labeling and Identification

Immediately after collection, the sample must be sealed, labeled, and the sample analysis request form filled out for each sample.

VOL 12

1842?

1. Sample Labels

Sample labels are used for the specific identification of samples. Gummed paper labels affixed to the containers are adequate, but it should not be affixed to the sample lids. The labels should be filled out at time of collection and should include the following information:

Field Number
Name of Collector
Date and Time
Place of Collection

2. Sample Seals

Sample seals are used to detect unauthorized tampering of samples ater collection, upto the time of analysis. The seals must be affixed to the sample container in a way that it has to be broken in order to open the sample container.

Seals must be affixed to the container by the collector.

3. Sample Analysis Request Form

Sample analysis request form accompanies the sample when it is delivered to the laboratory. The field portion of this form should be completed by the collector. The laboratory section is for completion by the laboratory analyst. The sample request form should include at the minimum:

Name of Collector
Date and Time of Collection
Location of Sampling Site
Field Number
Type of Sample
Analysis Requested
Date Received by the Laboratory
Laboratory Number
Results of Analysis
Date of Analytical Report
Name of Analyst
Remarks on Sample

VOL 12

1 8428

III. Sample Custody

When a sample arrives, it should be logged in immediately. The laboratory receiving personnel should look at the sample to verify:

- -Is the proper container used?
- -Is the container properly filled?
- -Is the quantity sufficient?
- -Is the sample seal intact?
- -Is the sample request form filled properly?

If the answer to any of the above question is no, the laboratory supervisor must be notified immediately. Also, the receiving personnel must verify if the sample had been appropriately preserved. If not, if must be preserved according to instructions in Table 1. This Table is posted for reference in the receiving area.

All samples received must be logged in a logbook and a unique laboratory number must be noted on the sample container, sample analysis request form, and log-book. In addition, the logbook must include information of laboratory sample number, sample identification information, type and condition of sample, and analysis requested. The recipient of the sample should sign the chain of custody form (see below).

Chain of Custody

Chain of Custody is a documentation of the sample history form collection to data reporting. A sample is considered under a person's custody if (1) it is in a person's physical possession, (2) in view of the person after he has taken possission, (3) secured by that person so that no one can tamper with the sample, or (4) secured by that person in an area which is restricted to authorized personnel.

The chain of custody form records the history of sample possession from collection, to analysis, and finally, to sample disposal. The form is printed on the same sheet as the sample request form. It must accompany the sample upon delivery to the laboratory. Information on the chain of custody form should include at least the following:

Name of the person in possession of sample
Affiliation of the person in possession
Date in possession

Once the sample has been logged in and the laboratory assume responsibility for it, the sample must be stored in a secure location. Whether the location should be refrigerated or not depends on the type

VOL 12

1 8429

of sample or analysis requested. Refer to Table 1 for storage conditions. Typically, all samples for organic analyses must be stored in the refrigerator/freezer. Samples for trace metal analysis maybe stored at room temperature except those requiring Chromium VI analysis. The latter must be refrigerated.

Refrigerator/Freezer used for sample storage must be different from those used for storing standards. In addition, samples for volatile analysis must be stored separately form non-volatiles. On each refrigerator/freezer, a chart is posted outside to record daily temperature readings, date, and name of person monitoring the temperature.

After properly receiving and securing the sample, worksheets are written up providing information on sample laboratory number, type, analysis requested, received date, and maximum holding time. Table 1 posted in the receiving area also contain information on holding times as a guide in preparing the work sheets.

A copy of this section on sample custody is posted in the receiving area to serve as a guide for the receiving personnel.

B. Drinking Water

Analysis Requested	Storage & Preservation	Maximum Holding Time
Volatile Organic Chemicals	4°C, Acidify to pH 2 with 1+1 HCl (1 drop/20 mL sample)	14 days
Base/Neutral and Acid Extractables, Non-purgeable Organic Chemicals	4°C, Protected from light, For chlorinated waters add Sodium Thiosulfate, 80 mg/L of sample	Extract within 7 days; complete analysis with: 40 days of extraction
Ethylene Dibromide (EDB) Dibromochloropropane (DBCP)	4°C, No chemical Preservative	28 days
Organohalide Pesticides and Aroclors	4°C, Sodium Thiosulfate, 3 mg crystals/	Extract within 7 days; complete analysis with: 40 days of extraction
Nitrogen or phosphorus Containing Pesticides	4°C, *Mercuric Chloride to 10 mg/L	14 days
Chlorinated Pesticides	4°C, *Mercuric Chloride to 10 mg/L	Extract within 7 days; complete analysis with: 40 days of extraction
Chlorinated Herbicides	4°C, No chemical preservative	Extract within 7 days; complete analysis with: 40 days of extraction
N-Methyl Carbamoyloximes	4°C**, Sodium Thiosulfate, 7 mg/100 mL; Acidity to pH3 with HCl (1+1) (Samples for Aldicarb and Endothall must be frozen)	Extract within 7 days; complete analysis with: 40 days of extraction
Bentazon	4°C, No chemical preservative	Extract within 7 days; complete analysis with: 40 days of extraction

*Use caution in handing this toxic chemical. Dispose of contaminated sample in appropriate manner.

IV. Calibration Procedures and Frequency of Calibration

A. Standards and References

1. Sources of Standards

99% of our standards come from the following sources:

Quality Assurance Branch
EMSL - Cincinnati
U.S. Environmental Protection Agency
Cincinnati, Ohio 45268

U.S. Environmental Protection Agency
Pesticides & Industrial Chemical Repository
(MD-8)
Research Triangle Park, NC 27711

Supelco, Inc.
Supelco Park
Belleforte, PA 16823-0048

Aldrich Chemicals
P.O. Box 2060
Milwaukee, Wisconsin 53201

National Bureau of Standards
Gaithersburg, Maryland 20899

All standards are obtained from reliable sources who can certify the purity of the materials.

Upon receipt, all neat standards are entered into an inventory book which includes the date received, who received it, source or supplier, lot number, conc./purity, expiration date, date opened, and who opened the bottle. The bottle itself containing the neat standard is labelled with the date received and initialled, expiration date, and date opened and initialled.

2. Preparation of Standards

Standards are prepared as outlined in the laboratory's specific Standard Operating Procedures (SOP) Manual. All information pertinent in the preparation of the standard are entered in the laboratory's Standard Preparation Book. Which include the following:

VOL 12 118433

VOL 12

1 8434

3.						
4.						
5.						
6.						
7.						
8.						

Standard solution bottles are also labelled individually with the concentration, solvent used, date prepared, expiration date and initials of the preparer.

3. Storage of Standards

All degradable and volatile organic compounds are stored in a freezer at below 0°C. This is true for any concentration: neat or solution.

Trace metal standards, except chromium VI, are stored at room temperature. Chromium VI is refrigerated.

4. External Reference Standards

Whenever possible, check standards are ordered from the EPA or NIST. These are used to verify the accuracy of the working standards. If unavailable from EPA or NIST, standards from another supplier or different lot number from the same supplier are used as check standards.

B. Calibration Procedures and Frequency

Specific calibration procedures are included in the analytical method and in the operator manual of that instrument. Each analytical instrument is calibrated at least daily when in use. The analyst is responsible for calibration. All the calibration data are kept in specific QC books.

There are calibration guidelines in the use of gas chromatographs, HPLC's, and atomic absorption spectrophotometers. These guidelines are applicable regardless of the instruments' make and model.

GC and HPLC Calibration Guidelines

1. Calibration Curve

Initially before use, a 5-point calibration curve must be established for each analyte of interest in order to determine the linearity of the concentration range of interest in the GC system to be used. A calibration curve is established by plotting the system response, as in peak height or peak area, versus the concentration of the standard applied to the system. The concentration of the standards used must correspond to the expected range of concentration in real samples, or must define the working range of the detector used. One standard concentration that must be included should be near but above the method detection limit (check individual method references for tabulated list of MDLs). An alternative to establishing a calibration curve is

VOL 12

1 8435

the definition of calibration factors (CFs) for the analyte of of interest at each standard concentrations.

$$CF = \frac{\text{Total Peak Area/Height}}{\text{Mass Injected (ng)}}$$

For each analyte, five CFs would be obtained. Calculate the percent relative standard deviation of the CFs. If the %RSD is less than 20%, it can be assumed that the line defined by the CFs is linear through the origin and that the CF can be used instead of a calibration curve for calculation of the concentration of the analyte in real samples.

2. Calibration Standard

On a daily basis, a calibration standard must be injected and analyzed in the GC system to be used in the analysis. The response of the standards must fall within ±15% of the established calibration curve or factor (see appropriate QC Record Book for current values). If outside the ±15% limit, the cause of change must be determined and corrected, if possible. If the problem is one that is inherent in the system and cannot be corrected, then a new 5-point calibration curve must be established (see Pre-Analysis QC Requirements) before any real sample can be analyzed. Monitor the response of the calibration standard every 10 samples. The ±15% limit must be met with every injection of the standard. Record daily calibration parameter in Form 2.

3. Retention Time (RT) Windows

Prior to any new analyte testing and each time a new GC column is installed, retention time windows must be defined initially for each analyte and its corresponding surrogate and matrix spike standards there after. To determine the RT windows, make a minimum of three injections of all single analyte standard mixture and multiresponse analyte like chlordane over a 71-hour period. Calculate the standard deviation of the absolute RTs of each analyte with every injection. For multiresponse analyte, choose a major peak from the group of peaks and calculate the standard deviation of its absolute RTs from every injection. The RT windows are defined as the ±3S, where S is the standard deviation, of the absolute retention time for each analyte. Record all Rts and windows in Form 2. From the injection of the calibration standard of the analyte of interest, determine the retention time and make certain it falls within the established windows.

AA spectrophotometer Calibration Guidelines

Calibration Curve

- must be prepared each day with a minimum of a reagent blank and three standards at different levels of concentrations. Determine the absorbances of each blank and standards. Plot the absorbances versus the concentrations. This plot establishes the linear curve for the day of the atomic absorption spectrophotometer used. Follow themanufacturer's instructions in preparing the calibration curve for the particular instrument used. Verify the curve every ten samples by analyzing a blank and a mid-level standard. The results of the verification should be within +20% of the original curve. If not a new curve must be generated. Use form 3 to record calibration data.

VOL 12

V. Analytical Procedures

A. Methods Used

All the analytical procedures used are from published sources from the following list:

1. Test Methods for Evaluating Solid Waste, SW-846, 3rd Edition, Office of Solid Waste and Emergency Response, U.S. Environmental Protection Agency, Washington, D.C. November, 1986.
2. Methods for Chemical Analysis of Water and Wastewater, EPA-600/4-79-020, 1984 U.S. Environmental Protection Agency.
3. Standard Methods for the Examination of Water and Wastewater, 15th and 16th Edition, APHA-AWWA-WPCF, Washington, D.C. (1980-1085).
4. The Determination of Inorganic Anions in Water by Ion Chromatograph - Method 300.0, EPA-600/4-84-017, March 1984, U.S. Environmental Protection Agency.
5. EPA Drinking Water Methods, 500 Series.

If applicable; certain methods are written in out line form for routine use in the laboratory. They are included in the laboratory's Standard Operating Procedure (SOP) Manual. For any analyst using methods for the first time, it is recommended that references noted on the upper right hand corner of the outlined form be thoroughly studied prior to the use of the outline.

B. Detection Limit

Method Detection Limit (MDL)

Method detection limit is the lowest concentration level detectable in the laboratory instrument. It corresponds to an analyte signal-to-noise ratio of two with the analyte being introduced to the instrument in clean solution, i.e., reagent water or reagent grade organic solvent. Typically, the laboratory has the same MDL as those listed under specific analytical methods such as the EPA 500 series. The laboratory verifies that the listed MDLs are indeed applicable by directly injecting or introducing standards at the MDL level to the instrument and obtaining a signal-to-noise ratio of at least two from the injection.

1841

Practical Quantitation Limit (PQL)

Practical quantitation limit (PQL) is the lowest quantifiable level that can be reliably achieved during a routine laboratory analysis of an analyte in a given matrix. This value is typically higher than the MDLs because it is matrix dependent. In determining PQLs, the laboratory follows the method given in the publication EPA-600/4-82-057, Appendix A.

C. Record of Analysis

For each analytical batch, all pertinent data related to the analysis including method used, sample weight or volume, dilutions, standard concentrations, description of instruments used and name of analypt are entered into a permanent log-book (Hazardous Waste) or worksheets (drinking water) which are filed as permanent records of the laboratory.

D. The laboratory maintains Standard Operating Procedures (SOP) Manual for both hazardous waste and drinking water analyses. These manuals contain the different analytical methods used in the laboratory in outline form. This is a cookbook-type outline generated from published methods which includes, whenever applicable, the following:

1. Scope and Applications
2. Detection limits (instrument and method)
3. Precision and Bias
4. Working range
5. Summary of Method
6. Sample collection, preservation, and holding times
7. Comments
    A. Interferences
    B. Helpful hints
8. Safety issues (specific to the method)
9. Apparatus
10. Reagents and standards
11. Procedure (detailed step-by-step)
    A. Sample preparation
    B. Calibration
    C. Analysis
12. QA/QC requirements
    A. QC samples
    B. Acceptance criteria (precision and accuracy)
    C. Correction action required
13. Calculations
14. Reporting

    C. Significant figures and reporting values below detection limit
15. References
    A. Method source
    B. Deviations from source method and rationale

VOL 12

18442

VOL 12

VI. Data Reduction, Validation and Reporting

A. Data Reduction

Equations and calculation procedures are included in the laboratory's SOPs. All the calculations must be attached to the copy of laboratory report for filing. Corrections for the blanks maybe made where appropriate. Calculations by the instrument/integrator is acceptable.

B. Data Validation

All results generated by the laboratory must be validated through the simultaneous analyses of required quality control (QC) samples/standards with the unknown sample. These include:

1. Instrument calibration with three concentration levels of standard and continuing single standard calibration every ten sample of an analytical batch.
2. Analysis of a method blank every batch of 20 samples for hazardous waste (every batch of 10 samples for drinking water) or type of matrix, which ever is more frequent.
3. Analysis of matrix spiked samples in duplicate at least once for every batch of 20 samples for hazardous waste (every batch of 10 samples for drinking water) or type of matrix which ever is more frequent.
4. Once during the analysis, an external reference standard should be used to check the concentration of the calibration standard.

After completing the analyses of an analytical batch, results of the above QCs must be recorded and plotted in the appropriate quality control chart (see form 4). Precision and accuracy control charts are maintained to determine if the QC results of an analysis are within established control limits. Control limits are initially set after the analysis of ten matrix spike and duplicate samples.

Thereafter, they are periodically set to reflect current performance.

It is the responsibility of the analyst to determine that all appropriate quality control operations have been performed and that all QC results fall within established limits. If any of the required QC is out of control the analyst must initiate corrective actions.

1843

R0051748

C. Data Reporting

Analytical results are ready to be reported as soon as it is verified that all quality control data fall within the laboratory's established limits. All data generated, both for the actual sample and the quality control sample must be entered in the appropriate worksheet, log-book and QC books. All information related to the sample analysis such as weight, volume, and QC results must be recorded. All results reported to the submitting agency would be presented with the appropriate number of significant figures, proper units such as ppm, method used, and practical quantitation limits. Worksheets, instrument out puts (e.g. chromatogram), analytical results, sample request for and report of analysis form are put together in a file and submitted to the laboratory supervisor for review. The supervisor signifies his/her approval by signing the report of analysis form to be sent to the submitting agency.

VII. Internal Quality Control Procedures

In order to document the laboratory's ability to test for the analyte of interest, certain quality control procedures are followed. These procedures are divided into two: (1) pre-analysis QC requirements and (2) daily or on-going QC requirements.

1. Pre-Analysis QC Requirements - QC Check Samples

   The laboratory's ability to generate results with acceptable accuracy and precision using a published method must first be verified before the analysis of actual samples. This is done through the analysis of four QC check samples prepared according to Sec. 8.6.2, Method 8000, SW-846. Briefly, QC check samples are prepared by spiking four aliquots of reagent water with known amounts of the analytes in the method to be used. The average recovery ($\bar{R}$) of the analytes in ug/L and the standard deviation (s) in ug/L of the recoveries are calculated and compared with those listed under the QC Acceptance Criteria Table found at the end of each published method. If the $\bar{R}$ and s values calculated fall within the limits defined in the table, then the system performance is acceptable and analysis of actual samples can begin. If any individual analyte's $\bar{R}$ or s fall outside the limit, then the system performance in unacceptable for that analyte. QC check samples must then be analyzed just for the analyte that failed. If re-analysis produced results within limits, then the system performance is acceptable. Repeated failure signifies a general problem with the measurement system. If this occurs, the source of the problem must be located and corrected - then QC check samples must again be ran for all the analytes.

2. Daily QC Requirements

   On a daily basis or each time a sample or batch of samples is analyzed, certain quality control samples must be ran: method blanks, duplicates, and matrix spike/matrix spike duplicates. From these quality control samples, control charts may then be generated which would allow for the establishment of accuracy and precision limits for the laboratory.

   Method Blank

   The analytical result of the method blank (or reagent blank) must be free of any analyte contamination. If contaminated, the source of contamination must be determined and corrected. After correction, the batch must then be re-analyzed if the sample quantity permits; or

VOL 12

if not, results of the analysis maybe released with appropriate warnings on the nature of the contamination.

Hazardous waste - blanks must be ran once every analytical batch of 20 samples or less or each type of matrix whichever is more frequent. Since it is impossible to obtain a universal matrix blank for non-aqueous/ solid samples, only reagent water is used.

Drinking water - blanks must be ran once every analytical batch of ten or less. Reagent grade water is used as blank.

Duplicate Samples

Duplicate samples are prepared by dividing a sample in two and analyzing them separately. Duplicate samples serve the purpose of monitoring the precision of measurement system. The results of the duplicate analyses must be within 20% of each other. If not an error has occured and it must be determined and corrected. The batch must then be re-analyzed. If the duplicate samples are negative for the analytes tested, then the matrix spike (see below) must be ran in duplicate to measure the precision. Duplicates must be ran once for every batch of 20 hazardous waste samples or less or each matrix type whichever is more frequent. Drinking water analysis requires duplicates to be ran every 10 samples.

Matrix Spike/Matrix Spike Duplicates (MS/MSD)

A predetermined amount of the analyte standard is added to a sample matrix to prepare the matrix spike sample. If the unknown samples to be analyzed are expected to be negative, then the sample matrix for spiking is first split into duplicates prior to the addition of the standard. Both matrix spike and matrix spike duplicate are analyzed simultaneously with the unknown samples. Recoveries of the analyte from the spike samples measure the accuracy of the method and the percent difference between the matrix spike and matrix spike duplicate assesses the precision of the analysis. The level of standard for spiking must be at the regulatory level or the method quantification limit. Samples with analyte concentration greater than 0.1% do not require the analysis of matrix spikes. Matrix spike and matrix spike duplicates must be ran for 5 % of the total analytical batch or each matrix type of hazardous waste. Drinking water requires the analysis of MS/MSD for 10% of the analytical batch. The accuracy and precision obtained from the MS/MSD must fall within the established lower and upper control limits of the laboratory. Continuing spike recoveries are recorded in form 4.

1847

3. Other QC Requirements

Periodically, samples are re-analyzed by another analyst. This is especially true in situations wherein a seemingly valid result is obtained but does not agree with the history of the sample.

Good Laboratory Practices

Good laboratory practices are followed to assure continued production of reliable results. These include not only topics previously discussed, i.e., sample custody, calibration, analytical procedures, data handling, and internal quality control procedures, but also glassware cleaning, verification that the sample containers, reagents and laboratory water are free of contamination, local and state safety codes are followed, fume hoods are routinely monitored, and hazardous waste are disposed of properly.

1. Glassware cleaning - glassware used for metal analysis should be acid washed. Refer to the published analytical methods for detailed procedures. Glassware used for organic analysis should be washed with solvent used in the analytical procedure. If trace amount of the organic contamination is found, it maybe necessary to clean the glassware in a muffle furnace.

2. Only reagent grade chemicals are used.

3. Type II deionized water is used in the analytical method and for method blanks.

4. Sample containers must be verified to be free of contamination. To accomplish this, a container from every lot received is rinsed with water or methanol, whichever is applicable, and analyzed.

5. Air flow in the fume hoods are monitored periodically by qualified personnel. The maximum operating height of the fume hood door is marked accordingly.

6. Safety procedures are adhered to. The laboratory has a safety manual that is distributed to all personnel. It covers topics on emergency procedures as in cases of fire or chemical spills, laboratory safety procedures with regards to handling different types of chemicals and executing certain laboratory tasks, and state-required hazardous material communication procedures.

7. Local and state safety codes are incorporated in the laboratory safety manual. As with all other safety procedures in the manual, they must be adhered to.

VOL 12

1

8448

VIII. Performance and Sytem Audits

The laboratory undergoes periodic performance and system audits through external and internal proficiency samples.

External Proficiency Samples

Currently, the laboratory has three sources of external proficiency samples. They are the California Dept. of Food and Agriculture, California Dept. of Health Services, and the Environmental Protection Agency.

CDFA Proficiency Samples

On a quarterly basis, the CDFA sends a minimum of four proficiency samples to the laboratory. Fifty percent of these are plant tissues and the other 50% are environmental samples such as water, soil, and swabs. The samples are spiked with pesticides from the organochlorine, organophosphorus, and/or carbamate group. Results of the proficiency sample analyses are sent back to CDFA for evaluation and they in turn mailback to the laboratory statistical analysis of results as compared with theoretical valves and other laboratories' results.

CDHS

Periodically, the laboratory had received performance evaluation samples from the CDHS. The samples received were for both hazardous waste and drinking water analysis. The samples were spiked with some of the analytes the laboratory was accredited for. As with the CDFA proficiency samples, after submitting the P.E. sample results to CDHS, the laboratory receives a statistical analysis of the results reflecting the comparison of results with the CDHS's accept/reject criterion.

EPA

On January 1990, the laboratory enrolled with the EPA to participate with the latter's Performance Evaluation Sample Program in water pollution. As a result, the laboratory anticipates receiving and analyzing P.E. sample for waste water periodically in the future.

Internal Proficiency Sample

Effective January 1990, the laboratory, on a quarterly basis, prepares and analyzes internal proficiency samples. A minimum of three samples are involved representing any of the environmental samples such as water, soil, plant, and wipe. The proficiency samples are spiked with some of the analytes typically ran in the laboratory. Reports are prepared from the results of the proficiency samples and compiled in the appropriate QC record book.

VOL 12

1849

IX. Preventive Maintenance

All minor maintenance and repair needed are accomplished by laboratory personnel. For major breakdowns, sufficient funds are budgeted annually to enable the laboratory to obtain service calls from qualified manufacturer's service engineers. The laboratory maintains a log book on any repair or maintenance of instruments.

All microbalance and platform balance are calibrated annually by qualified service engineers. On a weekly basis, the calibration of the balances are verified with standard weights.

All other service and maintenance needed by our laboratory for instruments and equipments are referred to their corresponding manufacturers. Based on yearly service expenses of the past years, sufficient amount budgeted annually to cover any future costs.

With the exception of Tracor Instruments which is located in Texas, all other manufacturers of our instruments could provide service within 48 hours after notification. Tracor has no local service representative so they take approximately one week before they send a serviceman.

The laboratory maintains a log book on instrument maintenance and repair for all major equipment used in the laboratory. It contains records on when an instrument is maintained and/or serviced, who provided the service, and what actions were taken.

X. Assessment of Accuracy and Precision

Accuracy

Accuracy means the nearness of a result or the average of a set of result to the true value. Accuracy is represented by the percent recovery (R) if an analyte from a given matrix using a specific method. The percent recovery may be calculated as:

$$R = \frac{A-B}{T} \times 100\%$$

where: A is the calculated concentration of the analyte in the spiked matrix after analysis

B is the background concentration of the analyte in the matrix blank, if any.

T is the known value of the analyte spiked in the matrix blank.

To set the accuracy control limits of an analyte in a given matrix using a specific method, calculate the average of R values ($\bar{R}$) and their standard deviation (S_r). The accuracy control limit as recommended by the EPA is then defined as:

$$RLCL = \bar{R} - 2S_r$$

$$RUCL = \bar{R} + 2S_r$$

where: RLCL is the accuracy lower control limit
RUCL is the accuracy upper control limit.

Precision

Precision is the measurement of agreement of a set of replicate results among themselves without the assumption of any prior information as to the true value. Precision is measured using replicate or duplicate sample analysis. Precision as relative percent difference (RPD) is calculated as:

$$RPD = \frac{X_1 - X_2}{X} \times 100\%$$

where: X_1 and X_2 are results of duplicate analyses

X is the average of X_1 and X_2

As recommended by EPA, the laboratory's precision limit is ±20%.

VOL 12

Control Charts

Precision and accuracy control charts are maintained for at least 10% of the analytes (min. 3 and max. 10) for a given method using form 4. Control limits are initially set after 10 data points. Thereafter, limits are periodically set to reflect current performance.

1

8452

XI. Corrective Action

Corrective action is initiated in out-of-control situations. A situation is considered out-of-control if any of the laboratory's internal quality control samples (see section VII) are outside established limits, i.e.:

1. Method blanks are coming out positive for the analyte of interest signifying that the analytical system is contaminated.

2. Results of duplicate samples are outside the 20% limit.

3. Spike recoveries fall outside the established laboratory's accuracy control limits.

For any of the above conditions, the senior personnel assigned to the unit will be notified immediately. It is his/her responsibility to decide which of the following corrective actions must be taken:

1. The analyst provides additional information or recalculations.

2. Instrument calibration and operation are checked. Calibration standards are checked and new ones are prepared if necessary. Instrument malfunctions are corrected.

3. New reagents are used if needed.

4. The analyst repeats the analysis of spiked samples using the same method.

5. A different analyst repeats the analysis of spiked samples using the same method.

6. The analyst repeats the analysis of spiked samples using a modified or new method.

No laboratory result will be sent until the problem is solved. All out-of-control situations and the corrective actions taken are documented by the senior personnel and submitted to the laboratory supervisor and/or chief for review.

VOL 12 1 8453

XII. Quality Assurance Report

On a monthly basis, senior personnel assigned to different units submit quality assurance reports for review by laboratory supervisor/chief. The reports contain a summary of the unit's QA activities during the period. The report includes the following information:

1. Date of analysis
2. Number of samples in the batch
3. Analytical batch number
4. Type of matrix
5. Analyte tested
6. Number of method blanks and results.
7. Number of matrix spikes and results
8. Number of dupilcates and results
9. Detection limits
10. Name of analyst

In additon a copy of reports on out-of-control situations and corrective actions taken during the period are attached. The laboratory supervisor and/or chief reviews the QA report, signifies approval by signing them, and the reports are filed accordingly.

NOTE: This is a supplemental manual to be used in conjunction with the Laboratory's previous Quality Assurance Manual.

VOL 12 18461

TABLE OF CONTENTS

QA OBJECTIVES

1. Establish the laboratory's ability to perform qualitative and quantitative microbiology testing of drinking water and wastewater by:

   - identifying the qualifications and responsibilities of laboratory personnel (in previous QA Manual);
   - enumerating the existing laboratory instrumentation and equipment used in microbiology testing together with the procedures for their service and maintenance to assure proper operation;
   - providing sources of analytical methods accepted by regulatory agencies for use in the laboratory.

2. Provide guidelines pertaining to sampling protocols, chain-of custody, and storage of samples to maintain sample integrity prior to analyses.

3. Define the laboratory's calibration procedures and frequency of calibration.

4. Identify all the necessary steps to validate the laboratory's results.

5. Define all the necessary quality control checks that must be followed prior to the analysis and/or in the course of analyzing samples.

6. Identify all laboratory records and information needed to document the quality of analyses performed in the laboratory.

VOL 12

1 8462

SAMPLING PROCEDURES

Containers

Approved container for bacteriological sampling are presterilized Nasco Whirl-Pak bag or 4 oz. sterilized Nalgene or glass bottles. All samples containers must contain two drops of 10% sodium thiosulfate. One sample bottle from each batch of bottles prepared must be checked for sterility by adding several sterile tubes of single strenght lauryl tryptose and incubating for 48 hours and checking for growth.

Collection

Samples must be representative of the potable water distribution system. Water taps used for sampling are free of aerators, strainers, hose attachments, mixing type faucets, and purification devices. Maintain a steady water flow for at least 2 minutes to clear the service line before sampling. Collect at least a 100 mL sample volume, allow at least ½ inch air space to facilitate mixing of sample by shaking. Do not rinse sample container!

Holding/travel time between sampling and analysis is not to exceed 30 hours for potable water samples. If laboratory is required by State regulation to analyze samples after 30 hours and up to 48 hours, the laboratory is to indicate that the data may be invalid because of excessive delay before sample processing. No samples received after 48 hours are to be analyzed. Sample collectors who deliver samples directly to the laboratory should ice samples immediately after sample collection. All samples received in the laboratory are to be analyzed on the day of receipt.

Waste and surface water sample holding time is not to exceed 6 hours.

Labeling and Identification

Immediately after collection, the sample bottle must be labeled and the sample analysis request and report form filled out for each sample.

1. Sample Labels

   Samples labels are used for the specific identification of samples collected. Gummed paper labels affixed to the containers are adequate, but it should not be affixed to the sample lids. The labels should be filled

VOL 12 1 8463

out at the time of collection and should include the following information:

Sampling Site
Name of Collector
Date and Time of Collection

2. <u>Sample Analysis Request and Report Form</u>

The sample analysis request and report form (exhibit 1) accompanies the sample when it is delivered to the laboratory. The collector should complete the field portion of this form by providing information on sample site location, sample type, purpose of the sample, date and time of collection, free chlorine residual, collector's initial, and any remains.

Upon receipt of the sample the laboratory will log-in the sample and at the minimum, the following information will be stored and maintained:

Date of Collection, Receipt, and Analysis
Time of Collection, Receipt, and Analysis
Receiving personnel initial
Client and/or System name
Sample Site location and/or description
Purpose of the sample
Assigned individual laboratory identify number
Name of the Analyst
Analysis Requested
Results of Analysis
Remarks on the sample (if any)

EQUIPMENT TEMPERATURE AND USE RECORD

Incubator Temperature

The total coliform incubator are maintained at 35± 0.5°c and have a thermometer graduated in at least 0.5°c increments. A daily log of the temperatures read to 0.1°c are kept together with the date the entry was made and the initial of the person making the entry (see exhibit 2).

Water Bath Temperature (For Fecal Coliform)

Similarly, the fecal coliform water bath are maintained at 44.5± 0.2°c and have a thermometer graduated in at least 0.2°c increments. A log of the temperatures when the water bath is in use read to 0.1°c are kept together with the date the entry is made and the initials of the person making the entry (see exhibit 3).

Sterilizing Oven Temperature

A thermometer immersed in a sand bath is kept inside the sterilizing over to monitor the temperature. Records of all items being sterilized, total sterilization time, and temperature are kept (see exhibit 4).

Autoclave

An autoclave/Sterilization log is maintained. The log includes the date, time in, time out, total elapsed time, sterilization time, items sterilized, sterility controls, maximum temperature reached, and any maintenance performed (see exhibit 5).

Certified Thermometer

All thermometers used in laboratory are crosschecked against a certified thermometer annually. Records of calibrations and corrections are maintained (see exhibit 6).

LABORATORY WATER QUALITY MONITORING

Bottled water is purchased from an outside source with an accompanying certificate of suitability. This is the water used to prepare the media. The parameters in the certificate include:

PARAMETER	LIMITS	FREQUENCY
Conductivity	>0.5 megohms resistance or <2 micromhos/cm at 25°c	Monthly
Pb, Cd, Cr, Cu, Ni, and Zn	Not greater than 0.05 mg/L per contaminant. Collectively, no greater than 0.1mg/L	Annually
Total Chlorine Residual	Nondetectable	Monthly
Heterotrophic	<500/mL	Monthly
Quality of Reagent	Ratio 0.8 - 3.0	Annually

Copies of the certificates of suitability are kept and maintained on file.

1 8472

MEDIA PREPARATION

The attached exhibit 7 is completed for each batch of media prepared. The information included in the form are:

- Data of preparation
- Preparer's initial
- Media prepared
- Weight of dehydrated media taken
- pH of autoclaved media
- Test of media with positive/negative cultures
- Sterility check

All completed media preparation forms are kept in a binder for easy reference.

ANALYTICAL PROCEDURES

Methods

The methods followed by the laboratory taken from Standard Methods for the Examination of Water and Wastewater, 16th edition, 1985 are:

Total Coliform by Multi-Tube Fermentation (MPN)	Method 908A
Fecal Coliform by MPN	Method 908C
Total Coliform by Membrane Filter (MF)	Method 909A
Fecal Coliform by MF	Method 909C

The outline forms of the above methods are attached as Appendix A of this supplemental manual.

Quality Control

1. For each bottle of media positive, negative, and sterile checks will be performed and a log of the check results will be maintained (see exhibit 8).

2. Positive and sterile checks will be performed for every batch of prepared media and a log of the check results will be maintained (see exhibit 9).

3. Positive and negative controls are ran with each analytical batch for EC test.

4. For each analytical batch tested by membrane filtration technique, a sterile control is ran at the beginning and end of the sample run, and a positive control is ran after the last sample.

5. For each lot of membrane filters, sterile and positive checks are ran.

6. The Completed Test must be done every three months or every positive confirmed potable water sample, which ever applies. A log of all positive potable confirmed sample is maintained.

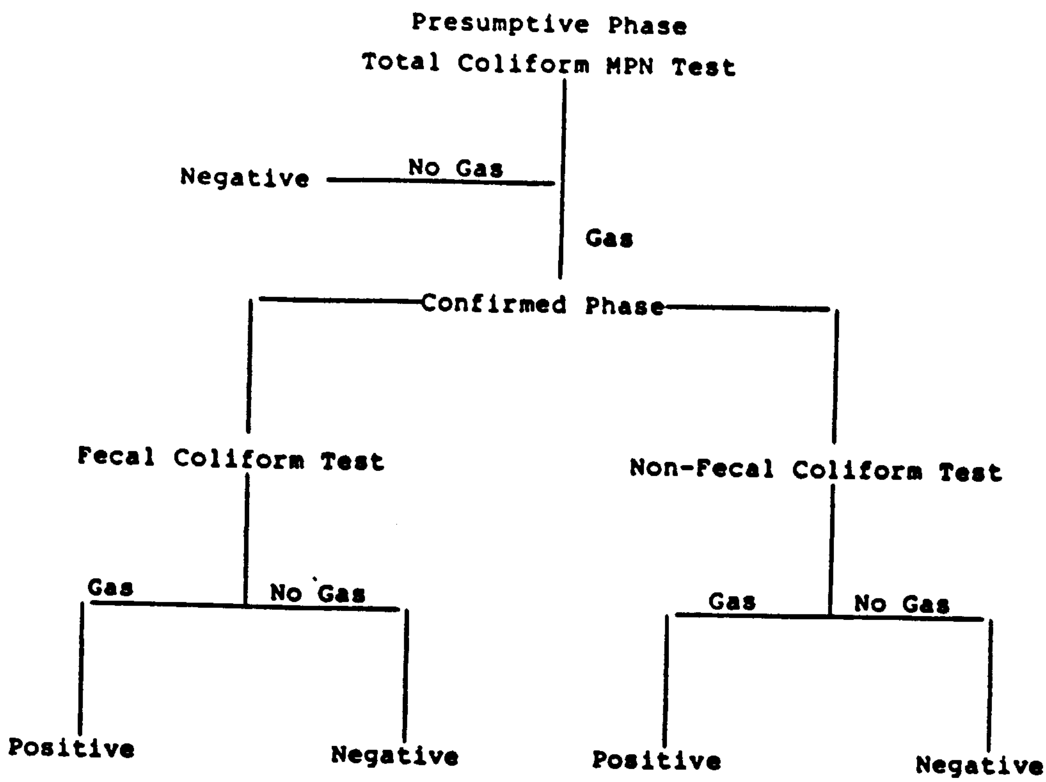
APPENDIX A: Methodology Outline

SUMMARY
OF
MULTIPLE-TUBE FERMENTATION TECHNIQUE
FOR THE COLIFORM GROUP



Effective Date: May 1991
Reference: Standard Method 908A

Total Coliform Multiple Tube Test

Reagents: Presumptive phase fermentation tubes with lauryl tryptose broth.

Quality Control:

Perform duplicate analyses on 10% of samples or at least one sample per test run.

Procedure:

1. Pipet ten 10 ml portions of the sample in a series of presumptive phase fermentation tubes; mix thoroughly.
2. Incubate fermentation tubes at 35± 0.5°c.
3. After 24± 2h, shake the tubes and examine for gas formation then take the following steps:

Gas Formation	Step To Proceed
Yes	Positive Test - continue to test for fecal and non-fecal coliforms.
No	Continue to step 4 below.

4. Continue incubating up to 48± 3h then again reexamine for gas formation.

Gas Formation	Steps To Proceed
Yes	Positive Test - continue to test for fecal and non-fecal coliform.
No	Negative Test - procedure completed

NOTE: For drinking and recreational water samples with heavy growth but no gas formation, continue on to test for non-fecal coliforms.

Calculation: See Calculation: Estimation of Bacterial Density

Effective Date: May 1991
Reference: Standard Method 908

VOL 12

Fecal Coliform Test

<u>Reagent</u>: EC Medium Tubes

<u>Quality Control</u>:

Run one each positive and negative controls for each analytical batch.

<u>Procedure</u>:

1. Gently shake or rotate presumptive tube.
2. With a sterile 3 mm metal loop, transfer one loopful of culture to EC medium tubes.
3. Incubate tubes in a water bath at 44.5± 0.2°c for 24± 2hr. Be certain to Place all EC tubes in the water bath within 30 minutes after the transfer of the culture.
4. Periodically check the EC medium tube during the incubation period for any gas formation.

Gas Formation	Steps To Proceed
Yes	Positive - fecal coliforms present
No	Coliforms present are of non-fecal origin and next step will depend on the result of the non-fecal coliform test.

<u>Calculation</u>: See Calculation: Estimation of Bacterial Density

1

8482

Effective Date: May 1991
Reference: Standard Method 908A

VOL 12

1
8483

Non-Fecal Coliform Test

Reagent: Brilliant Green Lactose Bile Broth (BGB) fermentation tube.

Procedure:

1. Gently shake or rotate primary fermentation tube showing gas.
2. With a sterile metal loop 3 mm in diameter, transfer one loopful of culture to a BGB fermentation tube.
3. Incubate BGB tube for 48± 3 hr. at 35± 0.5°c.
4. Periodically check BGB tubes during the incubation period for any gas formation.

Gas Formation	Steps To Proceed
Yes	Positive Confirmed Test - proceed to completed test for 10% of positive samples or at least one positive source water every quarter.
No	Negative Confirmed Test - procedure completed.

Calculation: See Calculation: Estimation of Bacterial Density

Effective Date: May 1991
Reference: Standard Method 9221D, 16th ed.

VOL 12

Calculation: Estimation of Bacterial Density

This method is used to calculate the Most Probable Number (MPN) of coliform/100 ml of sample.

No. of Tubes Giving Positive Reaction Out of 10 of 10 ml Each	MPN Index/100 ml	95% Confidence Limits (Approximate) Lower	Upper
0	<1.1	0	3.0
1	1.1	0.03	5.9
2	2.2	0.26	8.1
3	3.6	0.69	10.6
4	5.1	1.3	13.4
5	6.9	2.1	16.8
6	9.2	3.1	21.1
7	12.0	4.3	27.1
8	16.1	5.9	36.8
9	23.0	8.1	59.5
10	>23.0	13.5	Infinite

No. of Tubes Giving Positive Reaction Out of 5 of 10 ml each	MPN Index/100 ml	95% Confidence Limits Lower	Upper
0	2.2	0	6.0
1	2.2	0.1	12.6
2	5.1	0.5	19.2
3	9.2	1.6	29.4
4	16.0	3.3	52.9
5	16.0	8.0	Infinite

1 8484

For volumes other 5ml or 10ml, use the following equation to solve for the MPN value:

$$\text{MPN value (from table)} \times \frac{10}{\text{Largest vol. tested}} = \text{MPN/100ml}$$

Note: MPN value is taken from table 9221:V of the Standard Methods.

VOL 12 1 8485

Total Coliform Membrane Filter Procedure

Reagents: LES Endo Agar in petri dishes

Quality Control:

Run a sterile control at the beginning and end of the analytical batch and a positive control after the last sample.

Procedure:

1. Assemble filtration apparatus according to manufacturer's instruction.
2. Filter 100 ml sample under partial vacuum.
3. Rinse filtration apparatus with filter still in place with three 20 ml partions of sterile dilution water.
4. Remove membrane filter with a sterile forcep and place it on LES Endo Agar-filled petri dishes with a rolling motion to prevent entrapment of air.
5. Incubate dish for 22 to 24 hr. at 35± 0.5°c.
6. Count colonies that have pink to dark-red color with a metallic green-gold surface sheen using low-powered dissecting microscope.
7. Confirm all sheen colonies counted or a minimum of five colonies from drinking water samples by transferring growth from each colony to parallel tubes of lauryl tryptose broth and brilliant green lactose bile (BGB) broth.
8. Incubate both tubes at 35± 0.5°c for 48 hr.
9. Formation of gas in the BGB tubes confirms the colony as coliform. If only the lauryl tryptose broth showed any gas production, then transfer to a second BGB tubes. This second BGB tube must produce gas at 35± 0.5°c with 48 hr. to verify the colony as coliform.

Calculation:

$$\frac{\text{(Total) Coliform Colonies}}{\text{100 ml}} = \frac{\text{Coliform Colonies Counted X100}}{\text{ml sample filtered}}$$

95% Confidence Limits Using 100 ml Sample.

Number of Coliform Colonies Counted	95% Confidence Limits Lower	Upper
1	0.025	3.0
2	0.35	4.7
3	0.81	6.3
4	1.4	7.7
5	1.6	11.7
10	4.8	18.4

For counts, c, greater than 20 organism, the above limits maybe calculated by:

Upper Limit= $c + [2(2 + \sqrt{c})]$
Lower Limit= $c - [2(1 + \sqrt{c})]$

Effective Date: May 1991
Reference: Standard Method 909C

Fecal Coliform Membrane Filter Procedure

Reagents: M-FC Broth

Quality Control:

Run a Sterile control at the beginning and end of the analytical batch and a positive control after the last sample.

Procedure:

1. Preparation of culture dish: Place a sterile absorbent pad in each culture dish and pipet approximately 2 ml M-FC broth to saturate the pad. carefully remove any excess liquid from culture dish.

2. Assemble filtration apparatus according to manufacturer's instruction.

3. filter 100 ml sample under partial vacuum.

4. Rinse filtration apparatus with filter still in place with three 20 ml partions of sterile dilution water.

5. Remove membrane filter with sterile forcep and place it on prepared culture dish in a rolling motion to prevent entrapment of air.

6. Seal petri dishes, submerge in water bath, and incubate for 24± 2h at 44.5± 0.2°c. Anchor dishes below water surface to maintain critical temperature requirements. Make certain that the petri dishes are in the water bath within 30 minutes after filtration.

7. Count colonies in various shades of blue using low powered microscope. These are colonies produced by fecal coliform bacteria.

Calculation:

$$\text{(Total) Coliform Colonies/100 ml} = \frac{\text{Coliform Colonies Counted X100}}{\text{ml sample filtered}}$$

95% Confidence Limits: The same as for Total Coliform Membrane Filter Technique.

Effective Date: September 1991
Reference: Standard Method
14th Edition
Method 910A

VOL 12

Presumptive Test for Fecal Streptococcus Group

(Multiple-Tube Technique)

Reagents: Presumptive Phase Tubes with Azide Dextrose Broth

Quality Control:

1. Perform duplicate analyses on 10% of samples or at least one sample per test run.
2. Run Sterility Check and Positive Control with each batch of samples.

Procedure:

1. Pipet ten 10ml sample in a series of presumptive phase tubes: mix thoroughly.
2. Incubate tubes at 35 deg C ± 0.5 deg C.
3. After 24±2 hours, shake and examine tubes for turbidity then take the following steps:

Turbid	Step to Proceed
yes	Positive Test - continue to test fecal and non-fecal streptococcus.
no	Continue to step 4 below.

4. Continue incubating up to 48±3 hours then again re-examine for turbidity.

Turbid	Step to Proceed
yes	Positive Test - continue to test for fecal and non-fecal streptococcus.
no	Negative - procedure completed.

VOL 12

Confirmed Test for Fecal Streptococcus

Reagent: Petri dishes with Enterococcesel (BBL trade name)

Quality Control:

Run one each of positive and sterile controls with each batch.

Procedure:

1. Gently shake or rotate presumptive tube.
2. With a sterile 3mm metal loop, streak a portion of the growth from each positive presumptive tube (with azide dextrose broth) on a petri dish containing enteroccocosel agar.
3. Incubate the dish inverted at 35±0.5 deg C for 24±2 hours.
4. Brownish-black colonies with brown halos confirm the presence of fecal streptococcus.

Calculation: See Calculation: Estimation of Bacterial Density

1 8489

Effective Date: September 1991
Reference: Standard Methods 14th edition Method 910A

Confirmed Test for the Enterococcus Group

Reagent: Brain Heart Infusion Broth tubes containing 6.5% Sodium Chloride.

Procedures:

1. Transfer brownish-black colonies with brown halos to a tube of brain heart infusion broth containing 6.5% NaCl.

2. Incubate at 45 deg C for 24 hours.

3. Periodically check the tubes during incubation for growth.

4. Growth in 6.5% NaCl broth indicates that the colony belongs to the enterococcus group.

Calculation: See Calculation: Estimation of Bacterial Density

Effective Date: September 1991
Reference: Standard Methods
14th edition
Method 910B

VOL 12

Membrane Filter Procedure for Fecal Streptococcus

Reagents: KF Streptococcus Agar

Quality Control:

Run a sterile control at the beginning and end of the analytical batch and a positive control after the last sample.

Procedure:

1. Assemble filtration apparatus according to manufacturer's instructions.
2. Filter 100ml of sample under partial vacuum.
3. Remove membrane filter with a sterile forcep and place it on directly to KF Streptococcus agar medium in petri dish with a rolling motion to prevent entrapment of air.
4. Invert culture plates and incubate at 35±0.5 deg C for 48 hours.
5. Count colonies that have dark red to pink color using a low power binocular, wide field dissecting microscope.

Calculation:

$$\frac{\text{Total Colonies}}{\text{100ml}} = \frac{\text{Colonies Counted X 100}}{\text{ml sample filtered}}$$

For 95% Confidence Limits using 100ml sample, check Standard Method 909A.6.

I. INTRODUCTION

As required by National Pollutant Discharge Elimination System (NPDES) Permit No. CA0061654, a proposed Stormwater/Urban Runoff Monitoring Program for Phase II and III of the Permit, the Upper Los Angeles River (II), Upper San Gabriel River (III), Lower Los Angeles River (IV), Lower San Gabriel River (V), and Santa Clara River Drainage Basins is hereby submitted to the Regional Water Quality Control Board, Los Angeles Region (RWCQB), for approval. Comments and concerns made by the RWQCB in its December 21, 1993 letter to the Los Angeles County Department of Public Works (LACDPW) related to our proposed Santa Monica Bay Stormwater/Urban Runoff Monitoring Program, have been incorporated into this report.

The monitoring program described herein includes the establishment of fifteen monitoring sites for both mass emissions and individual land use monitoring. Five mass emissions sampling sites are identified in this report. One other mass emission sampling site will be located in the Santa Clarita Valley Basin (Santa Clara River Watershed), and will be identified later this year in a supplemental report to the RWQCB. Eight land use specific sites will likewise be identified in the supplemental report to be submitted later this year to the RWQCB.

Storm samples will be collected for five storms per year. Dry-weather samples will be collected bimonthly. Samples will be tested for a wide range of constituents including Bacteria; General Minerals; Biochemical Oxygen Demand; Total Organic Carbon and total Petroleum Hydrocarbons; Volatile Organic Compounds and Suspended Solids; Volatile Suspended Solids; and Semi-volatile Organic Compounds.

Automated refrigerated water samplers will be utilized in the collection of flow-composite samples. These samplers will be located on the ground surface in secure enclosures allowing easy access for retrieval of samples. The samplers have large (10 gallon) water collection capacity, and, thus, can be programmed in advance to cover a wide range of storm sizes without requiring one or more bottle change outs during a storm event.

Data collected by the program will be used for water quality modelling to estimate pollutant loads to receiving waters. Also, questions concerning what types of pollutants emanate from various land uses will be addressed. Lastly, data collected over the years under this program can be used in an attempt to assess any long-term trends in water quality.

The proposed monitoring sites re ... ations based on our established criteria fo ... incorporated into the program those storm drains which have water quality issues which are of concern to the community.

2. Specific Criteria for Mass Emissions Monitoring Sites

Mass emissions monitoring sites have been proposed along drainage systems covering the largest tributary watershed area feasible within each drainage basin. These watersheds will typically have a complex multiple land use composition.

In selecting a specific storm drain for inclusion as either a mass emissions or land use specific site, the following technical and operational requirements were addressed:

- What type of sampling equipment is to be used, and what limitations exist?
- What are the hydraulics of the underground storm drain, open channel/natural watercourse? What is the Design Q?
- Is there past flow data available for the given stream?
- What past hydrology studies have been performed in the watershed?. What is the hydrologic Q?
- If the storm drain is underground, is it currently under designed? Could it experience surcharge conditions?
- Within the watershed, what is the corresponding land use? Is land use uniform and homogenous throughout the upper tributary area? If yes, this is a possible land use site.
- Has previous sampling in the potential watershed been conducted in the past? Where? When? Why?

VOL 12

II. PROPOSED MONITORING SITES

A. SITE SELECTION CRITERIA

1. Monitoring Site Selection Overview

In order to characterize the quality of runoff from the Phase II and III areas, a combination of large watersheds representing multiple land uses ("mass emissions" sites) and single land use sites are to be selected.

For these Drainage Basins fifteen monitoring sites are proposed. Six of the fifteen sites will be mass emissions stations (one to be submitted at a later date). Nine proposed sites will be land use specific stations (to be submitted at a later date) where smaller homogenous land use watersheds will be sampled.

The proposed monitoring sites represent an effort to select the most suitable locations based on our established criteria for sampling. Where feasible, we have incorporated into the program those storm drains which have water quality issues which are of concern to the community.

2. Specific Criteria for Mass Emissions Monitoring Sites

Mass emissions monitoring sites have been proposed along drainage systems covering the largest tributary watershed area feasible within each drainage basin. These watersheds will typically have a complex multiple land use composition.

In selecting a specific storm drain for inclusion as either a mass emissions or land use specific site, the following technical and operational requirements were addressed:

- What type of sampling equipment is to be used, and what limitations exist?
- What are the hydraulics of the underground storm drain, open channel/natural watercourse? What is the Design Q?
- Is there past flow data available for the given stream?
- What past hydrology studies have been performed in the watershed?. What is the hydrologic Q?
- If the storm drain is underground, is it currently under designed? Could it experience surcharge conditions?
- Within the watershed, what is the corresponding land use? Is land use uniform and homogenous throughout the upper tributary area? If yes, this is a possible land use site.
- Has previous sampling in the potential watershed been conducted in the past? Where? When? Why?

1 8497

- Are tidal or backwater influences a concern?
- Is the location selected the only outfall point for the upstream watershed, or are there multiple outfall points?
- Is the storm drain structurally sound at present? Will installation of sampling equipment compromise the stability of the storm drain?
- Will the monitoring equipment impede flow or reduce flood protection?
- For natural watercourses, is there an existing improved section where a rating curve can be easily established?
- What is the practicable linear distance from the storm drain invert (low flow) to the location where the sampler shall be placed?
- Can electric power be provided, in a cost-effective manner, to the site?
- Will additional right-of-way be required?
- Will the sampler installation interfere with projects planned or in progress in the general vicinity?
- If located in a residential neighborhood, will the location of the automated sampler and its operation result in any objections from the local residents?

B. Monitoring Site Installation

The monitoring sites have been prioritized for installation as follows:

Los Angeles River @ Wardlow Road
Rio Hondo Channel @ Beverly Boulevard
San Gabriel River @ San Gabriel River Parkway
Coyote Creek @ Spring Street
Los Angeles River @ Tujunga Avenue

We propose to have these sites operational by the onset of the 1995-96 rainy season.

C. PROPOSED MASS EMISSIONS MONITORING SITES

1. **LOS ANGELES RIVER downstream of Wardlow Road at Los Angeles County Department of Public Works Stream Gage No. F319-R in the City of Long Beach.**

The Los Angeles River monitoring station will be located at the existing stream gage station between Willow Street and Wardlow Road. This facility currently measures stream flow and precipitation. At this location, the total upstream tributary drainage area for Los Angeles River is 815 square miles. This river is the largest watershed outletting to the Pacific Ocean in Los Angeles County. Tidal influences dictate the position for the sampling site.

Los Angeles River, at the gaging station, is an improved (concrete lined) trapezoidal channel. The vertical lift from the invert of the low-flow channel to a sampler location above the western levee is approximately 23 feet. Since the vertical lift exceeds 15 feet, an auxiliary pump will be needed to perform automated sampling. The linear distance from the top of the river levee to the low-flow channel exceeds 200 feet. The linear distance posses some concern. Pump wear and tear for reverse and forward pump cycles for this linear distance would be excessive. Since it is typical to find dry weather flows uniformly across the channel at this location (the low-flow channel can no longer carry the volume of flow found in the river), it maybe feasible to locate the strainer along the invert near the side of the river as the preferred design. Another option for placement of the automated sampler involves lowering the sampling equipment adjacent to the toe of the levee slope, and jacking the necessary conduits through the levee. This design may eliminate the need for an auxiliary pump if the strainer is positioned near the side of the river, however, it cannot compromise the levee by allowing storm water to migrate through the conduits.

The Los Angeles River sampling location below the Wardlow Road bridge (Old TG PG 70B-6/ New TG PG 795C-1) has been an active stream gaging station since 1931.

Flows in the River are partially regulated by the following: Sepulveda, Pacoima, Big Tujunga, Hansen, Devil's Gate, Lopez Debris Dam, as well as Whittier Narrows, Santa Anita, Sawpit, Eaton, Sierra Madre, and Santa Fe Dams; Project No. 85 Diversion; as well several spreading grounds, and debris basins. This will require an immense coordination effort in gathering, collecting and interpreting water quality data collected from this station. Because these dams and spreading grounds serve as flood control and water conservation facilities, small storms may not produce significant runoff from particular areas within the watershed, and therefore not contribute to the flow which is measured at the Wardlow Road gaging station. Large storms which produce significant runoff maybe detained, only to be released at a time when it is believed that potential flooding hazard conditions have subsided. There are numerous other scenarios which may occur, all impacting our water quality monitoring efforts at this site.

The overwhelming majority of the flows found in the River during dry weather periods are the result of NPDES permitted point discharges regulated by the California Regional Water Quality Control Board.

Various land uses exist within the River's tributary watershed area. Residential areas of various sizes and densities include single family, duplexes, condominiums / townhomes, and apartments. Commercial strips of many uses, malls, office buildings, etc., can be found within the watershed. Industrial developments of all types and sizes are identified within the tributary watershed. Undeveloped or open space properties are typically found in the foothill areas, but are not limited specifically to these areas. A percentage breakdown for these land uses will be included in the supplemental Monitoring Program Report to be submitted later this year.

This proposal will replace the existing County Department of Public Works surface water grab sampling site at Wardlow Road.

CROSS-SECTION

LOS ANGELES RIVER AT WARDLOW ROAD

VOL 12

2. **COYOTE CREEK below Spring Street at Los Angeles County Department of Public Works Stream Gage No. F354-R in the City of Long Beach.**

The Coyote Creek station will be located at the existing stream gage station below Spring Street. This facility currently measures stream flow and precipitation. At this location the upstream tributary area is 185 square miles (extending into Orange County). The confluence with San Gabriel River dictates the position for the sampling site.

Coyote Creek, at the gaging station, is an improved (concrete lined) trapezoidal channel. The vertical lift from the invert of the low-flow channel to a sampler location above the western levee is approximately 20 feet. Since the vertical lift exceeds 15 feet, an auxiliary pump will be needed to perform automated sampling. The linear distance to the low-flow channel is nearly 60 feet, and does not appear to be a problem. The strainer and pressure transducer can be mounted in the low-flow channel. Another option being explored for placement of the automated sampling equipment involves lowering the equipment along the backside of the levee towards the toe of the levee slope, and jacking the necessary conduits through the levee. This design may eliminate the need for an auxiliary pump, however, it cannot compromise the levee by allowing storm water to migrate through the conduits during a storm.

The Coyote Creek sampling location below the Spring Street (Old TG PG 76F-1 / New TG PG 796H-2) has been an active stream gaging station since 1963.

Flows in the River are partially regulated by the following: Fullerton, Brea, and Carbon Canyon Dams. This factor will require coordination with Orange County in gathering, collecting and interpreting water quality data collected from this station. Because these dams, as well as other facilities serve as flood control structures, small storms may not produce significant runoff from particular areas within the watershed, and therefore not contribute to the flow which is measured at the Spring Street gaging station. Large storms which produce significant runoff maybe detained, only to be released at a time when it is believed that potential flooding hazard conditions have subsided. There are numerous other scenarios which may occur, all impacting our water quality monitoring efforts at this site.

The overwhelming majority of the flows found in the Creek during dry weather periods are the result of NPDES permitted point discharges regulated by the California Regional Water Quality Control Board.

Various land uses exist within the Creek's tributary watershed area. Residential areas of various sizes and densities include single family, duplexes, condominiums / townhomes, and apartments. Commercial strips of many uses, malls, office buildings, etc., can be found within the watershed. Industrial developments of all types and sizes are identified within the tributary watershed. Undeveloped or open space properties are typically found in the foothill areas, but are not limited specifically to these areas. A percentage breakdown for these land uses will be included in the supplemental Monitoring Program Report to be submitted later this year.

This proposed sampling location will replace the existing LACDPW surface water quality grab sampling stations at Orangethorpe Boulevard and at Willow Street.

3. **LOS ANGELES RIVER at Tujunga Avenue at Los Angeles County Department of Public Works Stream Gage No. F300-R in the City of Los Angeles.**

This Los Angeles River station will be located at the existing stream gage station above Tujunga Avenue. This facility currently measures stream flow. At this location the upstream tributary area is 401 square miles (almost half of the entire Los Angeles River watershed area).

Los Angeles River, at the gaging station, is an improved (concrete lined) open box channel. The vertical lift from the invert of the low-flow channel to a sampler location above the northerly wall of the channel is approximately 19 feet. Since the vertical lift exceeds 15 feet, an auxiliary pump will be needed to perform automated sampling. The linear distance to the low-flow channel is nearly 90 feet, and does not appear to pose a problem. The strainer and pressure transducer can be mounted in the low-flow channel. The auxiliary pump would have to be mounted in a vault in the channels northern wall between 10 and 15 feet above the invert.

The Los Angeles River proposed sampling location above the Tujunga Avenue bridge (Old TG PG 23D-4 / New TG PG 562J-6), and downstream of the Tujunga Wash outfall has been an active stream gaging station since 1950.

Flows in the River are partially regulated by the following: Sepulveda, Pacoima, Big Tujunga, Hansen, Lopez Debris Dams; also Project No. 85 Diversion; as well as several spreading grounds and debris basins. This will require an immense coordination effort in gathering, collecting and interpreting water quality data collected from this station. Because these dams and spreading grounds serve as flood control and water conservation facilities, small storms may not produce significant runoff from particular areas within the watershed, and therefore not contribute to the flow which is measured at the Tujunga Avenue gaging station. Large storms which produce significant runoff maybe detained, only to be released at a time when it is believed that potential flooding hazard conditions have subsided. There are numerous other scenarios which may occur, all impacting our water quality monitoring efforts at this site.

The overwhelming majority of the flows found in the River during dry weather periods are the result of NPDES permitted point discharges regulated by the California Regional Water Quality Control Board.

Various land uses exist within the River's tributary watershed area. Residential areas of various sizes and densities include single family, duplexes, condominiums / townhomes, and apartments. Commercial strips of many uses, malls, office buildings, etc., can be found within the watershed. Industrial developments of all types and sizes are identified within the tributary watershed. Undeveloped or open space properties are typically found in the foothill areas, but are not limited specifically to these areas. A percentage breakdown for these land uses will be included in the supplemental Monitoring Program Report to be submitted later this year.

This proposal will replace the existing LACDPW surface water quality grab sampling station at Tujunga Avenue.

4. RIO HONDO CHANNEL - Above Beverly Boulevard, and downstream of Whittier Narrows Dam, at U.S.G.S. - U.S. Army Corps of Engineers Stream Gage No. 11102300 or E327-R.

Rio Hondo Channel station will be located at the existing stream gage station above Beverly Boulevard. This facility currently measures stream flow. At this location the upstream tributary area is 124 square miles (excluding the area above Santa Fe Dam).

Rio Hondo Channel, at the gaging station, is an improved (concrete lined) trapezoidal channel. The vertical lift from the invert of the low-flow channel to a sampler location above the western levee is approximately 19 feet. Since the vertical lift exceeds 15 feet, an auxiliary pump will be needed to perform automated sampling. The linear distance to the channel's invert (there is no low-flow channel) is nearly 50 feet and does not appear to be a problem. The strainer and pressure transducer can be mounted in the invert of channel. Another option for placement of the automated sampler involves lowering the equipment along the backside of the levee towards the toe of the levee slope, and jacking the necessary conduits through the levee. This design may eliminate the need for an auxiliary pump, however, it cannot compromise the levee by allowing storm water to migrate through the conduits. The U.S.G.S. indicates that discharges below 100 cfs are poor for stream gaging.

The Rio Hondo Channel sampling location above the Beverly Boulevard bridge (Old TG PG 54F-1 / New TG PG 676F-1) has been an active stream gaging station since 1965 and is operated by the U.S.G.S. and the U.S. Army Corps of Engineers.

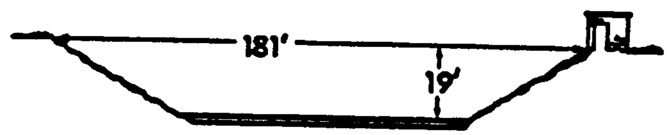
Flows in the Channel are partially regulated by the following: Sierra Madre, Santa Anita, Sawpit, Eaton, Santa Fe and Whittier Narrows Dams; as well as several spreading grounds and debris basins. This factor will require an immense coordination effort in gathering, collecting and interpreting water quality data collected from this station. Because these dams, as well as other facilities serve as flood control structures, small storms may not produce significant runoff from particular areas within the watershed, and therefore not contribute to the flow which is measured at the Beverly Boulevard gaging station. Large storms which produce significant runoff maybe detained, only to be released at a time when it is believed that potential flooding hazard conditions have subsided. There are numerous other scenarios which may occur, all impacting our water quality monitoring efforts at this site.

The overwhelming majority of the flows found in the Channel during dry weather periods are the result of NPDES permitted point discharges regulated by the of California Regional Water Quality Control Board.

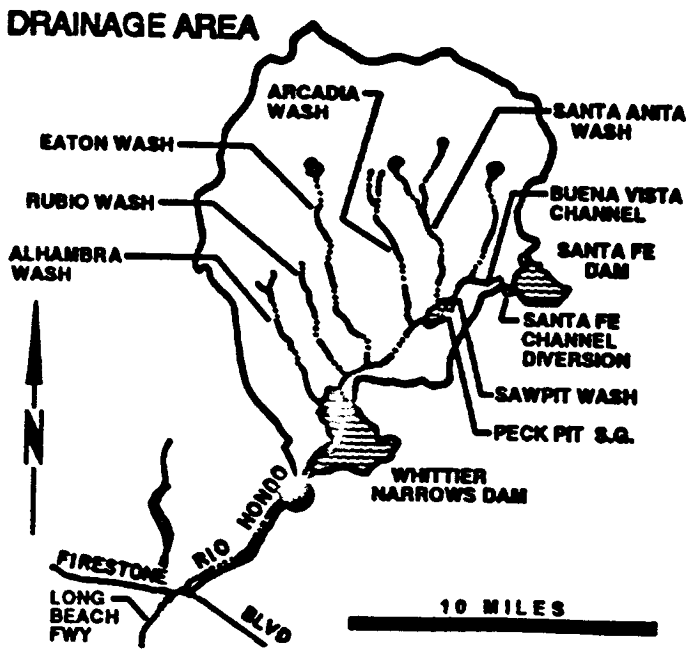
Various land uses exist within the Channel's tributary watershed area. Residential areas of various sizes and densities include single family, duplexes, condominiums / townhomes, and apartments. Commercial strips of many uses, malls, office buildings, etc., can be found within the watershed. Industrial developments of all types and sizes are identified within the tributary watershed. Undeveloped or open space properties are typically found in the foothill areas, but are not limited specifically to these areas. A percentage breakdown for these land uses will be included in the supplemental Monitoring Program Report to be submitted later this year.

This proposal will replace the existing LACDPW surface water quality grab sampling station at Stewart & Gray.

CROSS-SECTION



DRAINAGE AREA



RIO HONDO CHANNEL ABOVE BEVERLY BOULEVARD

5. **SAN GABRIEL RIVER - Downstream of San Gabriel River Parkway, downstream of Whittier Narrows Dam at Los Angeles County Department of Public Works Stream Gage No. F263C-R.**

The San Gabriel River monitoring station will be located at the existing stream gage station, below San Gabriel River Parkway. This facility currently measures stream flow. At this location the upstream tributary area is 460 square miles.

San Gabriel River, at the gaging station, is a grouted rock-concrete stabilizer along the western levee, and a natural section on the eastern side. Flow measurement and water sampling will occur in the grouted rock area along the western levee of the river. The vertical lift from the invert of the concrete stabilizer to a sampler location above the western levee is approximately 15 feet. Since the vertical lift to the sampler would be in excess of 15 feet, an auxiliary pump to perform automated sampling may be warranted. The linear distance to the concrete stabilizer is nearly 70 feet. The linear distance to the concrete stabilizer does not appear to be a problem. The strainer and pressure transducer will be mounted in the concrete stabilizer.

The San Gabriel River sampling location below the San Gabriel River Parkway bridge (Old TG PG 55C-1 / New TG PG 676J-2) has been an active stream gaging station since 1968.

Flows in the River are partially regulated by the following: Whittier Narrows, Big Dalton, San Dimas, Puddingstone Diversion, Puddingstone, Live Oak, Thompson Creek, Santa Fe, Morris, San Gabriel, and Cogswell Dams; as well several spreading grounds; and debris basins. This will require an immense coordination effort in gathering, collecting and interpreting water quality data collected from this station. Because these dams and spreading grounds serve as flood control and water conservation facilities, small storms may not produce significant runoff from particular areas within the watershed, and therefore not contribute to the flow which is measured at the San Gabriel River Parkway gaging station. Large storms which produce significant runoff maybe detained, only to be released at a time when it is believed that potential flooding hazard conditions have subsided. There are numerous other scenarios which may occur, all impacting our water quality monitoring efforts at this site.

The overwhelming majority of the flows found in the River during dry weather periods are the result of NPDES permitted point discharges regulated by the California Regional Water Quality Control Board.

Various land uses exist within the River's tributary watershed area. Residential areas of various sizes and densities include single family, duplexes, condominiums / townhomes, and apartments. Commercial strips of many uses, malls, office buildings, etc., can be found within the watershed. Industrial developments of all types and sizes are identified within the tributary watershed. Undeveloped or open space properties are typically found in the foothill areas, but are not limited specifically to these areas. A percentage breakdown for these land uses will be included in the supplemental Monitoring Program Report to be submitted later this year.

III. MONITORING EQUIPMENT

A. WATER QUALITY SAMPLERS

Refrigerated Water Quality Samplers

Stormwater sampling for this NPDES permit must include a technique for collecting flow composite samples for storms as well as time composite samples for dry weather applications. The utilization of automatic refrigerated water quality samplers (Figure III-1) represent the best available technology at present to meet the goals of the Permit.

The water quality samplers to be utilized at each of the monitoring sites will be AC powered to carry the load needed to provide refrigeration. All samples will be stored at 4°C.

Each sampler will incorporate a peristaltic pump for sample collection. Due to the inability of the peristaltic pump to effectively pump beyond a vertical lift of 15 feet, a water tight auxiliary pump will be required at all stations. The reason for the the auxiliary pump to be water tight is that it may become submerged for periods of time during a storm. For underground drains the auxiliary pump needs also to be rated explosion proof. The explosion proof rating is required for the auxiliary pump because gases in a confined space, such as an underground storm drain, may excite the pumps motor causing an explosion. Most of our sites have vertical lifts in excess of 15 feet, requiring auxiliary pumps.

Each sampler will be securely stored in a steel box, similar to a traffic signal controller enclosure. Samplers will be located on the sidewalk or secured right-of-way for closed conduits or along the banks of open channels and natural watercourses.

B. FLOW MONITORING

Flow monitoring equipment is a fundamental aspect of water quality sampling. Because the Monitoring Program proposal includes flow composite sampling during storms, flow monitoring equipment must be utilized with the sampler. There are various makes and models of flow meters. Some of the various flow meters available utilize pressure transducers, ultrasonic sensors, bubblers, stilling wells utilizing a float, etc.

The above mentioned flow measuring devices are designed for open-channel flow conditions. The water elevation in a storm drain is measured by the flow monitoring equipment and then, from either a rating table previously established at the site, or from an equation such as Manning's a flow rate is determined. The County's Department of Public Works uses rating tables which are generated from analysis of storm drain cross sections and upstream/downstream flow characteristics. The rating tables are modified if it is demonstrated in the field that the stream velocity measurements indicate a non-uniform relationship with the calculated table values. Past efforts in stormwater flow measurement indicates that all of the proposed stations will require time and multiple storm events to gather necessary data needed for calibration of the measurement devices.

The type of flow measurement device selected for use is a pressure transducer. The maximum depth of flow for the proposed five sites approaches 23 feet. With the pressure transducer fixed at the bottom of the drain, a depth range from dry condition to 23 feet will have to be measured. The flow meter incorporating the pressure transducer must be compatible with the sampler.

Closed conduits, however, present an additional problem (none of the proposed five sampling sites identified in this report are within enclosed drains). Many closed conduits surcharge during storm conditions, usually caused by the conduit being undersized for its tributary watershed. The frequency of surcharging is dependent on the degree to which the storm drain is undersized. When surcharge conditions are reached, the drain now functions under pressure flow. The flow measurement devices discussed above are only operable under open channel flow conditions. The measurement of flow under pressure would require the use of velocity meters. These are very costly devices that would need to be located directly in the flow stream. Therefore, efforts were made to select storm drains that do not surcharge, or do so infrequently to an extent that flow measurements are not significantly compromised.

C. RAIN GAGE

For every monitoring station, a minimum of one automatic (intensity measuring) rain gage will be placed within the upper tributary watershed. Los Angeles County Department of Public Works operates various automatic rain gages throughout the County. Existing gages in close proximity to the proposed monitored watersheds will be utilized in calculating stormwater runoff and shall be essential to developing runoff characteristics of these watersheds.

Large watersheds such as those identified in this Report will require multiple rain gages to accurately characterize the rainfall. The number and location of these additional rain gages is currently being researched.

D. EQUIPMENT INSTALLATION

The approach taken for the installation of sampling equipment is important to those who will maintain it. Access, ease of operation, safety, protection from the elements, etc., are typical design considerations. Each station's design must take into account at least these basic elements.

Figures III-2, III-3, and III-4 show typical installations of sampling equipment in storm drains utilized in the Monitoring Program.

Selected site conditions will dictate the approach taken with regards to installation of the monitoring equipment.

The automated sampler intake hose and the flow meter pressure transducer cable must be protected from trash and debris, vandalism, and the physical forces of the flow velocity during storm events. It must also be installed to allow routine inspection and maintenance. Therefore, the intake hose and pressure transducer cable will be placed in separate conduits below the invert surface, a few inches below the channel's finished surface.

The strainer and pressure transducer will likewise be located within a protective enclosure to shield them from trash and debris and to minimize vandalism.

As stated before an auxiliary peristaltic pump will be needed at many sites due to the hydraulic lift requirements. This will complicate installation, maintenance and operations. The auxiliary pump will be placed above the low-flow, dry weather level to ensure that it will not be continuously submerged. A seperate conduit will be utilized to run power to the auxiliary pump.

IV. MONITORING EQUIPMENT PROGRAMMING

A. Storm Weather Sampling

The automated sampler will need to be properly programmed in order to collect a representative flow-composite sample.

To program the sampler, the following information is needed: target storm size, flow rate to trigger sampling, estimate of runoff volumes, total sample volume required, number of sample intervals desired, sample volume to be collected at each interval, and flow rate to end sampling.

B. Storm Size to be Sampled

The "Surface Drainage Water Quality Monitoring Program" report, prepared by Woodward-Clyde Consultants for the Santa Monica Bay Restoration Project, analyzed local rainfall data to determine the appropriate storm size to be targeted for monitoring. Based on their analysis, targeted storm events should be between 6 and 25 hours in duration and average rainfall of about 0.4 to 1.7 inches.

C. Minimum Sample Volume to be Collected

The minimum volume of stormwater needed to perform the necessary analyses is shown below, (for composite flow-weighted samples only):

Constituent	Quantity
Semivolatile Organic Compounds	1 L
Pesticides and PCBs	1 L
Herbicides	1 L
Soluble Metals	500 ml
Other Constituents	4,325 ml
	7,825 ml = 8 Liters or approx. 2 Gallons

The refrigerated automated sampler has a total capacity of 10 gallons. Subtracting the two gallons required for analysis, the sampler will have an eight gallon reserve capacity. Therefore, the sampler will be programmed to collect two gallons of stormwater from a 0.4" storm. With the eight gallon excess capacity, the sampler would theoretically have adequate capacity to handle storms up to two inches in size (0.4" x 5 = 2.0"). This will significantly reduce the need to change bottles during a storm event.

D. <u>Estimate of Runoff Volume</u>

To program the sampler, the estimated runoff volume from a minimum precipitation of a 0.4-inch storm event over the entire area of a watershed must be calculated. The procedure used to estimate the runoff volume of the above storm is taken from the Los Angeles County Department of Public Works Hydrology Manual, which is generally accepted by agencies within Los Angeles County for the performance of hydrology studies.

The procedure to be used is briefly described below.

a) Calculate the Overall Runoff Coefficient for the Watershed:

$$C_D = 0.9\ IMP + Cu\ (1 - IMP)$$

where:

IMP = Proportion impervious for the land use comprising the watershed.

C_u = Undeveloped area runoff coefficient (based on soil type and rainfall intensity).

C_D = Developed area runoff coefficient.

For watersheds with multiple land use types, the overall C_D for the watershed is the weighted average of the C_D for each land use type:

$$C_D = \frac{\Sigma_{1-n}\ C_{Dx}\ A_x}{\Sigma_{1-n}\ A_x}$$

b) Calculate the rainfall volume for the watershed:

The rainfall volume is calculated by multiplying the storm size, in inches, by the area of the watershed.

c) Calculate the runoff volume for the watershed:

The resultant runoff volume is determined from the following formula:

$$\textit{Runoff Volume} = \textit{Rainfall Volume} \times (C_D)$$

(A detailed example of the above procedure can be found in Appendix 1).

E. Determination of Sampling Parameters

As discussed previously, eight liters of stormwater runoff will need to be collected by composite sampling. A minimum of 20 aliquots will be collected from each storm to obtain the eight liter composite sample. Therefore, the volume of sample to be collected at each aliquot is:

$$\textit{8 liters/20 aliquots} = \textit{400 ml}$$

The 20 aliquots will be spaced at equal runoff volume intervals throughout the storm. Therefore, the size of the runoff volume interval (Δ runoff volume) for a specific watershed would be determined as follows:

$$\Delta \textit{ runoff volume} = \textit{total runoff volume} / 20$$

where:

total runoff volume = total estimated runoff volume for targeted storm.

The flow rate at which storm sampling would be initiated at each station would be dependent on whether the site has any consistent dry weather or base flow.

For stations that do not have any dry weather flow, sampling would be initiated upon detection of flow. For those having dry weather flow, sample collection would begin after detecting a flow rate above the maximum-observed, yearly dry weather flow level. Sampling would halt when the flow returns to 120 percent of pre-storm base flow. As the monitoring program progresses, more specific operational criteria for the samplers at each station can be developed based on site specific flow information.

F. Dry Weather Sampling

Dry weather flow samples will be collected at all sites exhibiting adequate dry weather flow. For those sites with continuous dry weather flow, a 24-hour composite sample will be collected. For those with intermittent flow, a sample will be collected as flow is available.

VOL 12

1 8518

V. MONITORING CONSTITUENTS

A. List of Constituents

The selection of the monitoring constituents was based on an evaluation of the EPA final stormwater regulations and the existing monitoring program of the LACDPW. Initially, the constituents monitored during dry weather and under storm conditions will be the same. As water quality data is gathered over time and analyzed, revisions to the list of constituents monitored for both dry weather and under storm conditions may be made as deemed appropriate.

B. Constituents and Sample Collection Methods

The sample collection methods proposed for use are a combination of grab sampling and composite sampling. The details of each method will be elaborated in Part VI: Sampling Procedures. The definitions of sample types are:

- **Grab Sample** - a discrete, individual sample taken within a short period of time, usually less than 15 minutes.
- **Composite Sample** - a mixed or combined sample formed by combining a series of individual and discrete samples (aliquots) of specific volume, collected at specific volume intervals.

The time required to complete the cycle of compositing a sample covers a wide range, from a few hours to over to over 24 hours.

However, certain constituents have very short holding times and specific collection or preservation needs. The existence of and concentration of these constituents cannot be tested by composite samples and must be analyzed from grab samples.

All constituents listed in Table V-1 will be tested by composite sampling. Those listed in Table V-2 must be collected manually by grab samples.

Grab samples are preferred for certain water quality tests because field measurements such as pH and temperature should be instantaneous measurements of stormwater; bacteria have a short holding time; oil and grease tends to adhere on the surfaces that it contacts; volatile organic compounds (VOCs) have a tendency to volatilize when in contact with air; and cyanide is very reactive and unstable.

C. Chemical Analysis Methods

The chemical analysis methods for each constituent is listed in Tables V-1 and V-2. Also listed are the associated detection limits, sample volumes, preservation needs, and holding times required of each analysis method.

Weather forecasting and estimation of storm size is an inexact science. Therefore, rainstorms may occur where the total sample volume collected via composite sampling is insufficient to perform all the desired analyses.

Table V-3 presents a prioritized list of the water quality tests to be performed on the composite sample. For those storms where an insufficient total sample volume has been collected, the tests to be performed will be in accordance with the priority listed on Table V-3.

TABLE V - 1

CONSTITUENTS TO BE TESTED (FLOW COMPOSITE SAMPLES)

LIST OF CONSTITUENTS	EPA METHOD	DETECTION LIMIT	SAMPLE VOLUME	HOLDING TIME	PRESERVATIVE
<u>Semivolatile Organic Compounds</u>		(ug/l)			
Acids	8250				
Benzoic Acid	8250	≤5			
Benzyl Alcohol	8250	≤5

* Standard Methods for the Examination of Water and Wastewater, 1989, 17th Edition, published jointly by APHA, AWWA, and WPCF.

FOOTNOTES (Tables V-1 and V-2)

1. Should be added to empty sample container to be used for collection of sample if residual chlorine is present in the sample.

2. Samples must be extracted within seven days and extract must be completely analyzed within 40 days.

3. Use NaOH or H_2SO_4, as needed, to adjust the pH. Volume of acid of base must be noted.

4. If Aldrin is one of the pesticides to be tested and the sample is known to have residual chlorine present, then this preservative should in the empty sample container to be used for the collection of the sample.

5. Maximum holding time is 24 hours when sulfide is present. Optionally, sample may be tested with lead acetate paper before pH adjustment, to determine if sulfide is present. If sulfide is present, it can be removed with the addition of Cadmium nitrate powder until a negative spot is obtained. The sample then should be filtered and NaOH added to adjust the pH to > 12.

6. Should only be used in the presence of residual chlorine.

7. This is an arbitrary selected holding time. None is given in EPA method 418.1 - the approved method to use for TPH testing.

8. According to 40 CFR 136.3 Table II Notes, Note (2): "For composite chemical samples, each aliquot should be preserved at the time of collection. When use of an automated sampler makes it impossible to preserve each aliquot, then chemical samples may be preserved by maintaining at 4°C until compositing and sample splitting is completed."

VI. SAMPLING PROCEDURES

This Stormwater/Urban Runoff Monitoring Program is divided into two sub-programs, namely: the dry weather flow monitoring sub-program, and the storm weather flow monitoring sub-program. For each of these sub-programs, two types of samples will be collected at each monitoring location: Grab samples and composite samples. The constituents to be analyzed for either a grab or composite sample are discussed in Section V, and the automated sampling equipment to be used is described in Section III.

A. Storm Sampling

1. Pre-storm Preparation

In preparing and mobilizing personnel and equipment for a given sampling event, LACDPW will utilize the weather forecasts from the National Weather Service and from Pacific Weather Analysis, along with other Department resources such as the LACDPW Alert System. The Alert System is a system of rain and stream flow gages within the LACDPW flood control system which predicts/measures runoff amounts at key locations and transmits the data via telemetry to LACDPW headquarters. Important deciding factors in mobilizing for a storm sampling event include the probability of rainfall, its expected amount, and its intensity. When a representative storm is expected, sampling personnel will prepare for collection of grab samples and verify that the automated samplers are activated for composite flow sampling.

2. Grab Samples

All attempts will be made to collect grab samples during the beginning of the storm on the rising limb of the hydrograph. Such timing is expected to provide concentrations reflecting the higher levels of contaminants which are expected to be observed in the first part of a storm event as compared to those observed during the remainder of the event.

Grab samples will normally be collected using manual sampling equipment such as bucket with rope, dipper, funnel, etc. For manual grab sampling, please refer to Appendix 2 - "Surface Water Sampling Instruction Manual". Grab sample bottles, however, would have to be filled using manual operation of the automated samplers if sample points are inaccessible, such as the closed conduit sampling stations.

3. Flow-Composite Samples

Flow-composite storm samples will be obtained using an automated sampler to collect samples at flow paced intervals. Samples collected at each station will be combined in the laboratory to create a single flow-weighted sample from each station for analysis.

During a storm event, the sampler is programmed to activate automatically when the water level in the channel or storm drain exceeds the maximum annual dry weather flow rate. A sample will be collected each time a set volume of water has passed the monitoring point. The sample will be distributed into glass containers within the refrigerated sampler. The containers will need to accumulate a minimum of eight liters of runoff during each storm, so as to ensure a sufficient sample volume available to perform the necessary laboratory analyses. The automated sampler will deactivate when the water level in the channel or storm drain falls to about 120 percent of the observed maximum annual dry weather flow rate. For detailed discussion on the automated sampler programming, please see Section IV.

Upon conclusion of the storm event, samples will be retrieved from the automated samplers. Samples will be retrieved within the maximum allowable holding times required of the various test methods. At the same time samples are collected, rainfall and runoff data will be logged and stored for transfer to the office.

B. <u>Dry Weather Sampling</u>

The frequency of dry weather sampling is once every other month. This frequency was established based on the assumption that the majority of the flow during dry weather is from discharges that are presently covered by permits issued by the RWQCB. The deviation in test results from time to time would therefore be expected to be minor.

As water quality data is gathered under this program, it may be necessary to increase the frequency of monitoring of some constituents, and likewise may be necessary to decrease or eliminate the monitoring frequency of other constituents, shown not to be of a concern.

1. **Grab Samples**

Grab samples will normally be collected using manual sampling equipment such as bucket with rope, dipper, funnel, etc. For manual grab sampling, please refer to Appendix 2 - "Surface Water Sampling Instruction Manual". Grab sample bottles, however, would have to be filled using automated samplers if sample points are inaccessible, such as closed conduit sampling stations. Specific grab samples will be collected each time composite samples are retrieved.

2. **Flow-Composite Samples**

During dry weather, an eight liter composite sample will be collected over a 24-hour period.

Samples will be retrieved and delivered to the laboratory within the maximum allowable holding times of all the various test methods.

C. <u>Sample Transfer and Chain of Custody</u>

The LACDPW contracts for laboratory services with the Los Angeles County Agricultural Commission Laboratory, located at 11012B Garfield Avenue, South Gate, CA 90280.

LACDPW maintains a sampling protocol involving appropriate procedures for manually collecting surface water samples and transferring custody of samples. This sampling protocol is detailed in the attached Surface Water Sampling Instruction Manual (Appendix 2). In addition LACDPW maintains frequent contact with our contract laboratory as to the proper containers and handling of samples in order to effect appropriate analyses of the constituents of interest. A chain of custody record will be completed for each sample collected to allow step-by-step accounting of the sampling path from origin to analysis. Important information on the custody form includes:

VOL 12

1 8530

- Name of Person(s) collecting the sample
- Sample Laboratory ID numbers
- Date and Time of Sample Collections
- Names and signatures of all persons handling the samples in the field and in the laboratory.

D. Personnel Training

LACDPW's Surface Water Sampling Instruction Manual (Appendix 2) deals with procedures and equipment used in surface water sampling for both manual and automated sampling, grab samples and composite samples, chain-of-custody, and safety of the field personnel. A copy of this manual is issued to all field personnel.

Prior to sampling, all water quality field personnel are provided training that includes familiarization with all the sampling areas, procedures for proper labeling, handling and storage of sample bottles, getting samples from each monitoring site to the laboratory, handling chain-of-custody, performing manual sampling, and operating automatic sampling equipment.

E. Health and Safety

General health and safety issues and concerns when performing water quality monitoring is also addressed in the LACDPW Health & Safety Program for all its employees. The program requires each employee to complete a safety matrix, which details hazards, that could be encountered in performing his/her duties. Safety Directives covering instructions on how to deal with said hazards are issued each employee. Example of hazards on a field sampler's safety matrix include: hazardous weather conditions, working in confined spaces, hazards associated with chemicals, snakes, poison ivy, traffic, falling, drowning, etc.

It is also LACDPW policy to require field sampling personnel to undergo a minimum of 40 hours of Hazardous Materials Awareness training, and subsequent required review courses. This training includes instructions on how to evaluate potentially hazardous situations and safety concerns.

VOL 12 18531

VII. FIELD QUALITY ASSURANCE/QUALITY CONTROL PLAN

A. Overview

Properly performed monitoring station set up, water sample collection, transport, and laboratory analysis are vital to the collection of accurate data. Quality Assurance / Quality Control is an essential component of the Monitoring Program.

It is important to note that this Quality Assurance/Quality Control Plan is for the fixed sites described in the Monitoring Plan, Section II, and not for the planned Illegal/Illicit Discharge Investigation Program which will have its own QA/QC plan.

This QA/QC Plan describes the procedures for bottle labeling, chain-of-custody tracking, field setup, the sampler equipment check and setup, sample collection, the use of field blanks to assess field contamination, the use of field duplicate samples, and transportation to the lab. The QA/QC Plan shall be in place and enforced at all times.

An important part of this QA/QC Plan is the continued learning process of all field personnel. Field personnel must be adequately trained from the onset and must continue to have new information about stormwater sampling techniques shared with them. During the early stages of implementation, field personnel will evaluate the field activities and the possible effects on the QA/QC Plan. Enhancement of the Plan, if needed, will be implemented and an updated QA/QC Plan submitted to the Regional Water Quality Control Board for their use.

B. Bottle Preparation

Bottles will be grouped in sets. For each monitoring station, a minimum of three sets will exist in order to guarantee a consistent rotation of bottles. All bottle labels will be generic in appearance and will look similar to the following example:

BOTTLE NUMBER: ____ of ____	DATE:
STATION NAME:	TIME:
☐ GRAB OTHER: ☐ COMPOSITE ____________	PRESERVATIVES:
LABORATORY ANALYSIS REQUESTED:	TEMPERATURE:
	COLLECTED BY:

Figure VII-1

Bottles shall be cleaned at the laboratory. After the bottles are returned, they will be labeled and stored away as a set package. Each station will have the same number, size and types of bottles existing for each rotation, unless special grab samples are requested. Clean bottles utilized for composite sampling will be replaced in the sampler at the time of each bottle collection, assuring a pre-setup sampling routine. All bottles not in use will be stored in plastic ice chests used for transporting bottles. The size of composite sample bottles has been limited to a maximum of 2½ gallons each, to ensure ease of handling.

C. <u>Chain-of-Custody Procedure</u>

Chain-of-custody procedures and forms provide legal evidence that a sample has not been tampered with. This is achieved by establishing a written record tracing possession of the sample from collection through its final analysis. Primarily we are interested in field chain-of-custody procedures. The contract laboratory's own QA/QC includes chain-of-custody procedures which are in agreement with the field procedures. (See attached Laboratory QA/QC plan.) The chain-of-custody forms will remain at all times with the corresponding samples. Chain-of-custody forms shall be filled out and signed by field staff before actual physical possession of water samples are turned over either to other staff or to the laboratory. A sample chain-of-custody form is presented as Figure VII-2.

D. Field Setup Procedures

All field sampling locations are fixed sites, with the sampler placed on public road rights of way or flood control rights of way. One field staff member can conduct the sampler setup, but two staff members are necessary for sample collection at each monitoring station. After each sample collection, field staff will prepare the sampler to collect samples either in storm mode or in dry weather mode. Staff members will also inspect visible hoses and cables to ensure proper working conditions in accordance with site design. Inspection of the strainer, pressure transducer and auxiliary pump can only occur during daylight hours in non-storm conditions.

During a storm event, grab samples will be collected during the initial portion of the storm (on the rising limb of the hydrograph) and subsequently taken directly to the lab. The automated sampler will be checked at the time grab samples are collected to ensure proper working conditions at the site (to see if flow composite samples are being collected). Dry weather collection techniques will be similar with a 24-hour composite sample and subsequent grab samples being collected.

After a sampling event, all bottles will be collected and samples packed with ice and foam insulation inside individually marked ice chest(s). Field personnel will transport these samples to the Department of Public Works headquarters. Chain-of-custody forms will be completed by field staff before relinquishing them to other staff personnel for transportation of the samples to the laboratory. Under no circumstance will samples be removed from the ice chest during transportation from the field to the laboratory. All samples transported to the laboratory will meet the holding time criteria described in Section V.

E. Travel Blanks and Field Duplicates

Potential field contamination will be assessed through analysis of travel blanks and duplicate composite samples. The use of field travel blanks for each monitoring station during every sampling event, represents an attempt to quantify post sampling contamination. The Monitoring Program will also include the use of field duplicates to assess the accuracy of lab results. The collection of a field duplicate will occur for each sampling event. The duplicate will be for one sampling station, unknown to the laboratory. At the present time, this methodology for assessing post sampling contamination and the accuracy of laboratory testing procedures will provide adequate data to measure the accuracy of the results provided to us from the laboratory.

LABORATORY QUALITY ASSURANCE/QUALITY CONTROL

The Los Angeles County Department of Public Works has contracted with the Office of the County Agricultural Commissioner/Weights and Measures Environmental Toxicology Laboratory for all laboratory analysis. A part of this Quality Assurance/Quality Control Plan for the Monitoring Program includes the QA/QC for the Laboratory which is enclosed as two documents (see Appendices 3 and 4). The Laboratory QA/QC Plan is a part of the Monitoring Program.

VOL 12 1 8535

VOL 12

VIII. DATA STORAGE AND REPORTING

The following categories of data are being collected as part of the monitoring program:

- Rainfall
- Runoff
- Water Quality Test Data
- Quality Assurance/Quality Control Information

All of the data will be stored in electronic format to allow for ease of retrieval interpretation, and graphic presentation.

Rainfall and runoff data will be collected from each monitoring station after each storm event and stored in a central file. The data will be arranged by monitoring station to show the total rainfall amount and total runoff volume, plus a hydrograph for each sampled storm event.

Water quality data for each monitoring station will be stored in a PC database. QA/QC information will be stored in a PC database.

For each sampled storm event, a report will be prepared summarizing the rainfall, runoff, and water quality data. At the end of each storm season (July 1 to June 30), a yearly monitoring report will be prepared summarizing the data collected.

1 8536

IX. PROGRAM MANAGEMENT

Implementation and overall coordination of the Monitoring Program activities, including evaluation of the contract laboratory services will be the responsibility of the Program Manager. The Program Manager will assign field sampling personnel from a pool of technical staff (14 currently available) trained in sampling procedures and methods.

The Program Manager is responsible for evaluation of weather forecasts as provided by our storm forecasting service, and will decide on which storms warrant mobilization for the sampling activities. The Program Manager will assign one of the Field Engineers as an Event Coordinator, who will coordinate the sampling event with the designated field personnel.

For storm weather and dry weather sampling, the stations have been divided into two groups as shown below. The stations have been apportioned based on anticipated difficulty of sampling as well as travel to and from each station.

GROUP	MONITORING STATIONS
1	Los Angeles River @ Tujunga Avenue
	Los Angeles River @ Wardlow Road
2	San Gabriel River @ San Gabriel River Parkway
	Rio Hondo Channel @ Beverly Boulevard
	Coyote Creek @ Spring Street

Two individuals will be assigned to perform field sampling for each group. Each sampling crew will be responsible for all the sampling activities needed at each site within each group. Each staff member assigned to a Group of stations will be responsible for: Field equipment maintenance and operation; proper collection and handling of samples; and field QA/QC and field sampling protocol.

The Program Manager will be responsible for on-going review, and evaluation of the overall QA/QC program related to sampling and laboratory procedures.

X. ESTIMATION OF POLLUTANT LOADINGS

One of the objectives of the monitoring program is to assess the annual pollutant loadings from large watersheds within these Drainage Basins. Knowing the types and quantities of pollutants discharged from these watersheds are important in assessing the impacts of stormwater on receiving waters.

A. Model Selection

The model to be utilized to calculate basin-wide mass pollutant loadings is the Simple Method as described in the EPA's "Guidance Manual for the Preparation of Part 2 of the NPDES Permit Applications for Discharges from Municipal Separate Storm Sewer Systems." Due to the size of these Drainage Basins, this method will provide a good estimate of pollutant loadings, without requiring the extensive amount of detailed hydrologic and hydraulic data needed by more sophisticated models. Once pollutant loads have been estimated basin wide, an initial assessment can be made as to their potential impacts on receiving waters. Subsequently, more detailed, dynamic modelling of select, representative watersheds in these Drainage Basins can be performed to more accurately track and assess pollutant impacts.

B. Calculation Procedure

Calculation of annual pollutant loadings will be performed as follows:

1. **Calculate annual pollutant loads for each drainage area.**

Utilizing the formula below, calculate annual pollutant loads for each drainage area:

Equation 1:

$$L_i = \frac{(P)\ (CF)\ (Rv_i)}{12}\ (C_i)\ (A_i)\ (2.72)$$

where:

L_i = Annual pollutant load (lb/drainage area/yr)
P = Annual precipitation (in/yr)
CF = Correction factor that adjusts for storms where no runoff occurs
Rv_i = Weighted-average runoff coefficient for the drainage area
C_i = Event mean concentration of pollutant (mg/L)
A_i = Drainage area (acres)

The numbers 12 and 2.72 are conversion factors that account for unit conversions.

Each of the parameters in Equation 1 is defined below:

- **Annual pollutant load** is the total amount of a specific pollutant discharged in pounds per time period (in this case, per year) for the particular drainage area being modeled.
- **Annual precipitation** is the total inches of rainfall occurring in a single year. Estimates of the annual rainfall are calculated utilizing the historical rainfall data

compiled for Los Angeles County by the Los Angeles County Flood Control District and, subsequently, the LACDPW.

- **Correction factor** is an adjustment factor for the number of storm events that do not actually produce any runoff (i.e., the percentage of storm events that have a total accumulation greater than a specific threshold value). This value will be calculated based on a review of historic rainfall data for Los Angeles County.

- **Weighted-average runoff coefficient** is a relative measure of the percentage of rainfall that becomes surface runoff. Runoff coefficients will be calculated utilizing the procedure described in Section IV.

- **Event mean concentration of pollutant** is the event mean concentration value for the specific pollutant determined from an analysis of the flow-weighted composite samples obtained by the monitoring program.

- **Drainage area** is the size of the area being modeled.

2. Use the per-drainage area annual pollutant loads to calculate per-watershed annual pollutant loads.

The following equation will be used to calculate per-watershed annual pollutant loads.

Equation 2:

$$L_w = \Sigma L_i$$

where:

L_w = Annual pollutant load for a particular watershed

ΣL_i = Summation of individual annual pollutant loadings from all drainage areas within a specific watershed

3. Use the per-watershed annual pollutant loadings to calculate basin-wide annual pollutant loads.

The following equation will be used to calculate basin-wide annual pollutant loads.

Equation 3:

$$L_B = \Sigma L_w$$

where:

L_n = Annual pollutant load for entire basin

ΣL_w = Summation of individual annual pollutant loadings from all watersheds within the basin

The above procedure can also be utilized to estimate seasonal pollutant loads and per storm event pollutant loads as needed.

VOL 12

Constituents to be Modeled

Annual pollutant loadings will be calculated for the following constituents:

BOD_5	Total Phosphorus
COD	Dissolved Phosphorus
TSS	Cadmium
Dissolved Solids	Copper
Total Nitrogen	Lead
Total ammonia plus organic nitrogen	Zinc

Development of Annual Pollutant Loadings

We are targeting installation of our monitoring stations to commence May 1995. Upon completion of the storm season, April 1996, and assuming sufficient storms have occurred for sampling and that sampling equipment can be calibrated, event mean concentrations will be calculated. We estimate that the pollutant loads could be developed by August 1, 1996.

18540

VOL 12

XI. LONG-TERM TRENDS IN STORMWATER/URBAN RUNOFF QUALITY

As discussed in Section II, a total of fifteen fixed-station monitoring sites are proposed for the Upper and Lower Los Angeles River, Upper and Lower San Gabriel River, and the Santa Clarita Valley (Santa Clara River) Drainage Basins. The locations of five of these sites have been chosen to be representative of the various watersheds within the Basin. The locations to be selected and included in a supplemental submittal, one mass emissions sampling site in the Santa Clarita Valley Basin and nine land use specific sites, will meet the same criteria as established in this Monitoring Program Report.

In addition to providing data necessary for calculation of the event mean concentrations, long-term data from these sites can be evaluated for trends. The objective of this evaluation is to determine if there are any statistically significant differences in pollutant concentrations and loadings which could be related to the implementation of Best Management Practices (BMPs) as opposed to random variability in hydrologic factors such as the frequency, intensity, and duration of storm events.

Complicating this evaluation is the fact that there is no, location specific, baseline data available prior to the implementation of BMPs. Monitoring at these selected sites will commence concurrently with implementation of various BMPs. Therefore, dependent on the number of storms available, at least five or more years of data will be needed before reasonable statistical analysis of trends could be performed due to the large degree of natural variability. Therefore, we recommend that any statistical analysis of trends be performed after the conclusion of the fifth year of monitoring.

8542

APPENDIX 1

STEP-BY-STEP PROCEDURE

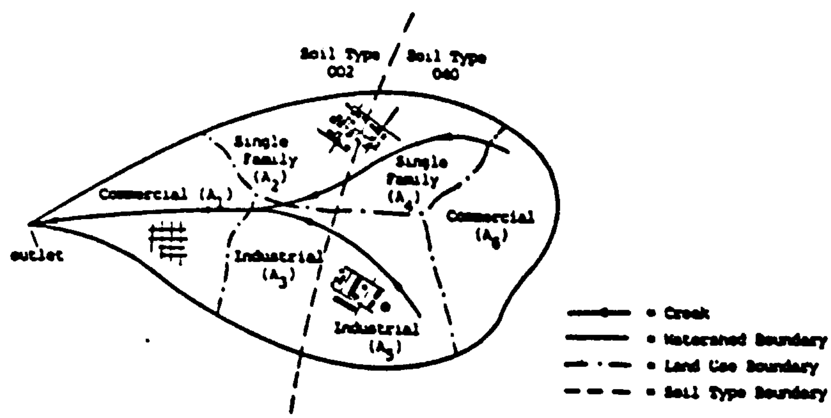
FOR

RUNOFF ESTIMATION

EXAMPLE

1. **Calculate the Runoff Coefficient for a Study Area**

Typical Example: The Study Area shown is comprised of two soil types and three land-use types.



Upon examining the Study Area, there are six unique soil types - land-use type combination areas. The areas are numbered 1 through 6. The data for these areas is summarized below:

Area Number	Soil Type	Land Use	Imp.	Area (Square Miles)
1	002	COM	.95	6
2	002	SF	.42	2
3	002	IND	.90	3
4	040	SF	.42	3
5	040	IND	.90	2
6	040	COM	.95	3

In general, the runoff coefficient is first calculated for each individual area. A weighted average calculation is performed to arrive at the overall runoff coefficient for the Study Area.

The detailed procedures is described below:

a) First the Undeveloped Runoff Coefficient (C_U) is determined for each area from the runoff coefficient curve for the soil type for the area. This is done by first choosing the rainfall intensity (in/hr). With this rainfall intensity value go to the runoff coefficient curve and select C_U.

b) The developed Runoff Coefficient (C_D) is then calculated for each area based on the following formula:

$$C_D = .9IMP + C_U (1\text{-}IMP)$$

The IMP is the imperviousness value assigned to the land use within each area.

c) After calculating C_D for each individual area, a weighted average calculation is performed to come up with the average C_D for the entire Study Area.

Now we will calculate C_D for the Study Area:

Select rainfall intensity

The rainfall intensity to be used will be 1.5 in/hr. If the rainfall intensity is not known or no specific value is to be used, then C_U automatically goes to the minimum or default value of 0.1 which is the same for all soil types. The calculation process should be established to use the default value unless a user specified rainfall intensity is provided.

Determine C_U

The Study Area is comprised of two soil types. C_U for these soil types is:

Soil type	C_U
002	.79
040	.75

Calculate C_D

Calculate C_D for each area:

Area No.	C_U	Imp.	C_D
1	.79	.95	.89[1)]
2	.79	.42	.83
3	.79	.90	.79
4	.75	.42	.81
5	.75	.90	.89
6	.75	.95	.89

1) C_D for Area 1 = .9(.95) + .79(1-.95) = 0.89

Therefore, C_D for the Study Area is:

$$C_D \text{ Study Area} = \frac{C_{D1}\,\text{Area}_1 + C_{D2}\,\text{Area}_2 + C_{D3}\,\text{Area}_3 \ldots}{(\text{Area}_1, + \text{Area}_2 + \text{Area}_3 \ldots)}$$

$$= \frac{.89(6) + .83(2) + .79(3) + .81(3) + .89(2) + .89(3)}{(6+2+3+3+2+3)}$$

$$= 0.86$$

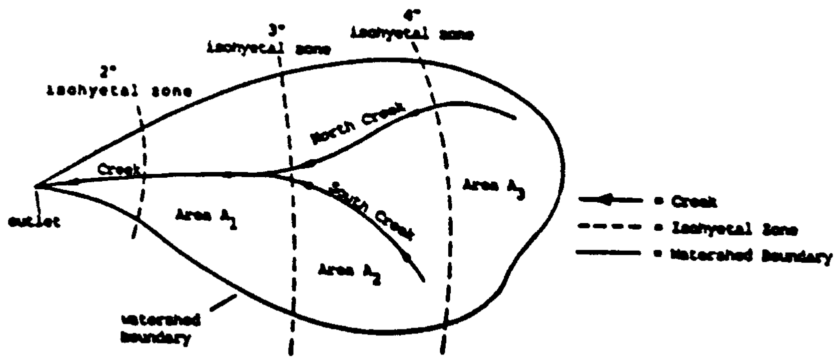
VOL 12

18544

R0051849

2. **Calculate Rainfall Volume Over the Study Area**

The Study Area is shown below and encompasses the indicated isohyetal zones.



The total area of the Study Area is 10 mi². The portion of the Study Area encompassed by each isohyetal zone is listed below:

Zone	Area(mi²)
2"	3
3"	7
4"	9

The total rainfall volume deposited on the study area is:

rainfall volume = $[2(3) + 3(7) + 4(9)]\ (640\ \frac{acres}{mile})\ (1/12)$

= 3360 Acre•feet

or $\frac{3360\ 12\ (\frac{inches}{foot})}{19(mi^2)\ (640\ \frac{acres}{mile})}$ = 3.3" depth over the entire study area

VOL 12

1 8545

3. **Calculate the Runoff Volume for a Study Area**

For the Study Area used in this example, the runoff coefficient (C_D) = 0.86.

runoff volume = Rainfall Volume (C_D)

= 3360 Acre-feet (0.86)

= 2890 Acre-feet

NOTE: Drainage Basins II, III, IV, and V have many flood control facilities such as dams which may detain flood waters and/or reduce runoff projected for a watershed.

VOL 12

1 8547

APPENDIX 2

SURFACE WATER SAMPLING

INSTRUCTION MANUAL

I. INTRODUCTION

This manual covers collection of surface water samples for the Department's Stormwater/Urban Runoff Monitoring Program, and compliments the sampling procedures contained in the Work Plan for the Stormwater/Urban Runoff Monitoring Program (Work Plan).

Two sampling techniques, Manual Sampling (sampling by hand) and Automated Sampling (sample collection by use of powered devices such as the Automated sampler) are used in the monitoring program. Both manual sampling and automated sampling techniques are discussed in this sampling manual, with reference to the above-mentioned Work Plan.

Samples collected for both dry weather and storm flow monitoring programs are typed either "Grab" or "Composite". Grab sample is an individual discreet sample collected for characterizing water quality at a particular time. Grab samples normally would be collected using manual sampling techniques, unless sampling collection can only be achieved using automatic samplers, such as at manhole stations that are very deep and not accessible using manual grab sampling equipment. Composite samples are series of individual samples collected at paced intervals and combined to create a single weighted composite. Composite samples would normally be obtained, using automated sampling techniques.

The following instructions will help you collect samples and transport water samples safely and correctly. Safety is of the utmost importance, but if a sample is not collected or transported correctly, the subsequent lab analysis results will be compromised or invalidated.

It should be noted that these instructions are merely a guide to meet the specific needs of the Department. They are not intended to be a comprehensive guide to water quality sampling. Numerous textbooks, handbooks, and manuals are available for those interested in more detailed information on sampling methodology.

II. COLLECTION OF SAMPLES

Water samples will be collected in bottles supplied by the contract laboratory. All sample bottles, except bacteria bottles have been acid-washed and thoroughly rinsed with distilled water to eliminate contamination. Bacteria bottles contain a dechlorinating chemical. DO NOT RINSE THE SAMPLE BOTTLES BEFORE FILLING.

However, the bucket, dipper and funnel should be rinsed at each new sampling location. Use the water at each new site to rinse off any contaminates left in the bucket from prior sites.

DO NOT USE SOAP OR ANY OTHER DETERGENTS TO CLEAN SAMPLING EQUIPMENT.

A. Manually Collecting Grab Samples

A Manual grab is collected by inserting a container (bucket, dipper, etc.) under the surface of the water body to be sampled and/or dipping a container down current of a discharge with the container opening facing upstream. The following manual sampling procedures should be followed, in accordance with the source of the sample as well as requirements for certain analyses:

1. Nonflowing - Reservoirs, Lakes, and Ponds

The sampling technique will depend on the location and purpose of the investigation. The following general rules should be observed:

a. Select a location away from areas where water may tend to be stagnant.

b. Take samples at a location that is definable in plan and depth so that subsequent samples can be taken from the same location. This is important where a study is to be made regarding water quality changes with time.

2. Flowing Water

a. When sampling with a bucket and line from above the streamflow, first attach the line to the bridge railing or some other firmly fixed object. Lower the bucket gently into the center of the channel. Make sure the bucket is submerged to avoid the collection of floating debris.

VOL 12 1859

b. When sampling for oil and grease, sample should be collected at the air/water interface to insure collection of representative samples.

c. Avoid hitting the bottom of the channel so that deposited sediments are not collected.

d. When using the bucket and line adjacent to the low-flow channel, gently swing the bucket into the center of the flow to collect the sample.

e. After raising the bucket, take the temperature of the sample immediately for at least 30 seconds.

f. Pour off any floating debris and decant the water from the bucket into the sample bottles.

3. <u>Bacteriological Samples</u>

Bacteriological samples should be taken under sterile conditions, observing the following precautions (also refer to Section C 2. Sample Bottles):

a. Do not rinse the bottle. The bacteria bottle contains a dechlorinating chemical which must mix with the sample.

b. Do not fill the bottle completely; leave about 1/2 inch to allow mixing of the contents.

c. When sampling, prevent contaminating the lip and cover of the sampling bottle by avoiding contact with anything but the sample or the source of the sample.

B. <u>Collecting Grab Samples By Automated Sampler</u>

Collection of grab samples can also be accomplished by using the automated samplers. This is accomplished by temporarily bypassing the automated sampling program and utilizing the pumping unit of the automated sampler to fill the grab sample bottles. This sampling technique may be used if sample points for grab samples are inaccessible, such as at sampling stations that are very deep below the ground surface and cannot be accessed using manual grab sampling equipment. However, once the grab samples are collected, the automated sampling system must be restored to its ready mode for performing its programmed functions.

VOL 12

18550

C. Flow Composite Samples

Flow weighted composite samples are collected using the automated samplers, programmed to collect samples for Storm Sampling (at flow paced intervals), and for Dry Weather Sampling (at fixed time intervals). For both storm sampling and dry-weather sampling, sample bottles must be retrieved within the maximum holding times required of the various test methods. Sample bottles are to be placed in coolers with frozen blue ice for transport to the laboratory for compositing and analysis.

VOL 12

18551

III. SAMPLING EQUIPMENT

You will be provided with the sampling equipment necessary for your assignment. The equipment may consist of the following items:

- Bucket and rope
- Sample bottles
- Thermometer
- Personal equipment: (if applicable)
  - Hard hat and vest
  - Flashlight
  - Thomas Guide and location sketch
  - Rubber Gloves

A. Bucket and Rope

All surface samples collected manually by the Water Quality Management/Storm Water Section are of the type known as "grab samples". Under this procedure a sample may be collected in a bucket at a randomly selected time, over a period of time not to exceed 15 minutes.

B. Sample Bottles

You will be provided with the appropriate sample bottles and containers by the contract laboratory. Sample containers are easy to contaminate, therefore, AVOID TOUCHING the mouth of the bottle or the inner surface of the cap. Except when otherwise stated all containers should be filled to within 1" of the top NEVER TO OVERFLOWING. Identify the sample and provide any necessary information requested on the pre-printed computer generated container label by using a waterproof ink pen. Place all glass containers into plastic protective bubble pack bags, and/or pack the containers in the cooler with shock absorbing materials to minimize the possibility of breakage. Add frozen blue ice, and deliver to the contract laboratory.

2. SPECIFIC INSTRUCTIONS

a. General Mineral (Gen Min):

Fill unpreserved container to within 1" of the top. It is not necessary to rinse out the container with the sample. Tighten the cap to prevent leakage.

b. Microbiology (Micro):

Fill unpreserved 1 Liter plastic container to within 1" of the top. It is not necessary to rinse out the container with the sample. Tighten the cap to prevent leakage. Place container in cooler with "Blue Ice" to minimize the effect of high temperatures on deaths of microbes. The maximum holding time for bacteria samples is six hours from the time of collection. Therefore, the samples must immediately be transported to the laboratory. Also, refer to preceding Section B 3. Bacteriological Samples.

c. Total Petroleum Hydrocarbon (TPH or TPH, Cr+6):

Fill unpreserved container to within 1" of the top. It is not necessary to rinse out the container with the sample. Tighten the cap to prevent leakage. This container is glass and, if possible, should be placed into a bubble bag for transportation to prevent breakage.

d. Metals:

Fill preserved container to within 1" of the top. DO NOT RINSE OUT OR OVERFILL. Contains Nitric Acid as a preservative. Tighten cap to prevent leakage.

e. Oil and Grease (O & G):

Fill preserved container to within 1" of the top. DO NOT RINSE OUT OR OVERFILL. Contains Sulfuric Acid as a preservative. Tighten cap to prevent leakage. This container is glass and, if possible, should be placed into a bubble bag for transportation to prevent breakage.

f. Pesticide-PCB's (Pest-PCB):

Fill unpreserved container to within 3" of the top. It is not necessary to rinse out the container with the sample. Tighten the cap to prevent leakage. This container is glass and, if possible, should be placed into a bubble bag for transportation to prevent breakage.

g. Total Organic Carbon (TOC):

Fill unpreserved container to within 1" of the top. It is not necessary to rinse out the container with the sample. Tighten the cap to prevent leakage. This container is glass and, if possible, should be placed into a bubble bag for transportation to prevent breakage.

VOL 12 1 8555

h. Biological Oxygen Demand (BOD):

Fill unpreserved container to within 1" of the top. It is not necessary to rinse out the container with the sample. Tighten the cap to prevent leakage.

i. Volatile Organics (EPA 601/602):

Slowly fill the two 40 ml vials to overflowing, being careful not to aerate the sample. Carefully place the cap onto the vial and tighten to prevent leakage. Make sure that the teflon surface of the septum (hard white side) is facing the sample, the soft silicon side of the septum should be visible from the top of the cap. Invert the vials to confirm proper sample collection (bubbles should not be observed). If bubbles are present, open the vials, add more sample, reseal the vials, and recheck for air bubbles. Place the glass vials into the plastic protective bubble bag and, if possible, store in a cooler with "Blue Ice".

j. Base-Neutral-Acid Extractables (BNA):

Fill unpreserved container to within 3" of the top. It is not necessary to rinse out the container with the sample. Tighten the cap to prevent leakage. This container is glass and, if possible, should be placed into a bubble bag for transportation to prevent breakage.

k. Herbicides (Herb):

Fill unpreserved container to within 3" of the top. It is not necessary to rinse out the container with the sample. Tighten the cap to prevent leakage. This container is glass and, if possible, should be placed into a bubble bag for transportation to prevent breakage.

3. SPECIAL SAMPLES

a. Organic Nitrogen (TKN):

Fill preserved 250 ml plastic container to within 1" of the top. DO NOT RINSE OUT OR OVERFILL. Contains Sulfuric Acid as a preservative. Tighten cap to prevent leakage.

b. Radioactivity (Gross alpha & beta):

Fill preserved 1 Liter plastic container to within 1" of the top. DO NOT RINSE OUT OR OVERFILL. Contains Nitric Acid as a preservative. Tighten cap to prevent leakage.

c. Asbestos:

Fill unpreserved 1 Liter plastic container to within 1" of the top. It is not necessary to rinse out the container with the sample. Tighten the cap to prevent leakage.

d. Chlorinated Organic Substances (COS):

Use same sampling procedure as for EPA 601/602. The EPA reference manual is available in the Water Quality Section.

e. Nitrite-N (1 ppb DL):

Fill unpreserved 125 ml plastic container to within 1" of the top. It is not necessary to rinse out the container with the sample. Tighten the cap to prevent leakage.

VOL 12

18557

C. Thermometer

A thermometer is provided because water temperatures are required for each sampling site location.

D. Dissolved Oxygen Meter

If your assignment requires the measurement of dissolved oxygen, a DO meter will be provided with the necessary instructions on its use. Calibration of the meter is essential prior to each use. Instruction classes on the DO meter's operation will be provided prior to usage.

E. Personal Equipment

Before leaving on a sampling assignment, make sure that all personal equipment necessary to carry out the assignment packed and stored in the vehicle. This would include a hard hat and vest, gloves, flashlight if necessary, Thomas Guide, etc., thermometer, and location sketches showing the various surface sampling stations and access points.

VOL 12 18558

IV. SAFETY

Safety Reminders:

1. Safety is more important than the samples. Never place oneself in a dangerous or unsafe sampling situation.

2. Always park vehicles where it is safe. Pull into an access road or park the vehicle on a street where parking is permitted and walk to the site. NEVER PARK ON A BRIDGE.

3. Wear a hard hat and a high-visibility vest when leaving the vehicle.

4. Wear waterproof boots with high-traction soles when walking or standing on wet surfaces. Slippery surfaces should be avoided.

5. Never stand or walk in moving water.

6. Never get too close to a low-flow channel. Use a bucket and line to obtain a surface sample.

7. **Never enter an enclosed drain, tunnel, or a confined space.**

8. If waters are flowing outside the low-flow channel, lower the bucket and line from a bridge.

9. When sampling from a bridge, always tie one end of a rope to the railing or some other firmly fixed object. Do not lean excessively over the guard rail.

10. Be alert for hazardous situations. Personal safety is an employee's first responsibility. Common sense safety precautions must be exercised if one comes upon an unusual material, discharge, smell, dumping, etc. Take notes on all observations. Notes may be used in follow-up investigations and/or supporting future analytical findings. A sample must not be taken if common sense judgment indicates that ones safety is jeopardized.

11. Wear gloves when handling samples and wash hands with soap and water when finished.

12. Wash all equipment, boots, gloves, bucket, etc., when finished.

13. When ascending or descending unstable or slippery slopes and embankments, avoid holding breakable bottles, and pointed or sharp objects with bare hands.

14. Each employee has Physical Class Limitations established under the Occupational Health Manual of Policies and Procedures of the Department. Exerting physical efforts or lifting weights exceeding ones physical class limit must be avoided to prevent physical injury. Ice chests with full sample bottles and ice may exceed the weight-class requirements; in such cases, the ice chest must be transported by a minimum of two persons.

V. LABELING AND FIELD OBSERVATIONS

Each sample bottle will normally be pre-labeled by the Water Quality Unit. It is important, however, that each sample be identified as to the source, date, and time of acquisition. If a sample is taken from a large body of water, for example, the location should be described in such a way as to enable the same sample point to be relocated in the future if and when it becomes necessary.

VOL 12

1 8560

VI. DELIVERY OF SAMPLES

Samples should be delivered to the contract laboratory as soon as possible to prevent alteration of the sample between time of sampling and time of analysis. In order to avoid the need to preserve the samples overnight, samples should be delivered to the contract laboratory no later than 5:00 p.m., unless prior arrangement with the contract laboratory has been made.

VOL 12

1 8561

VII. CHAIN OF CUSTODY

The Chain-of-Custody Record form shown must be completed for each delivery of samples to the contract laboratory. When sampling for potential court case litigation, consult the laboratory for the appropriate testing procedures, splitting and sealing of samples, and chain of custody.

VOL 12

QA OBJECTIVES

1. Establish the laboratory's ability to qualitatively and quantitatively analyzed various types of environmental samples for pollutants by:

   - identifying the qualifications and responsibilities of laboratory personnel;

   - enumerating the existing laboratory instrumentation and equipment together with the procedures for their sevice and maintenance to assure proper operation;

   - providing sources of analytical methods accepted by regulatory agencies for use in the laboratory.

2. Provide guidelines pertaining to sampling protocols, chain-of-custody, and storage of samples to maitain sample integrity prior to analyses.

3. Define the laboratory's calibration procedures and frequency of calibration.

4. Identify all the necessary steps to validate the laboratory's results.

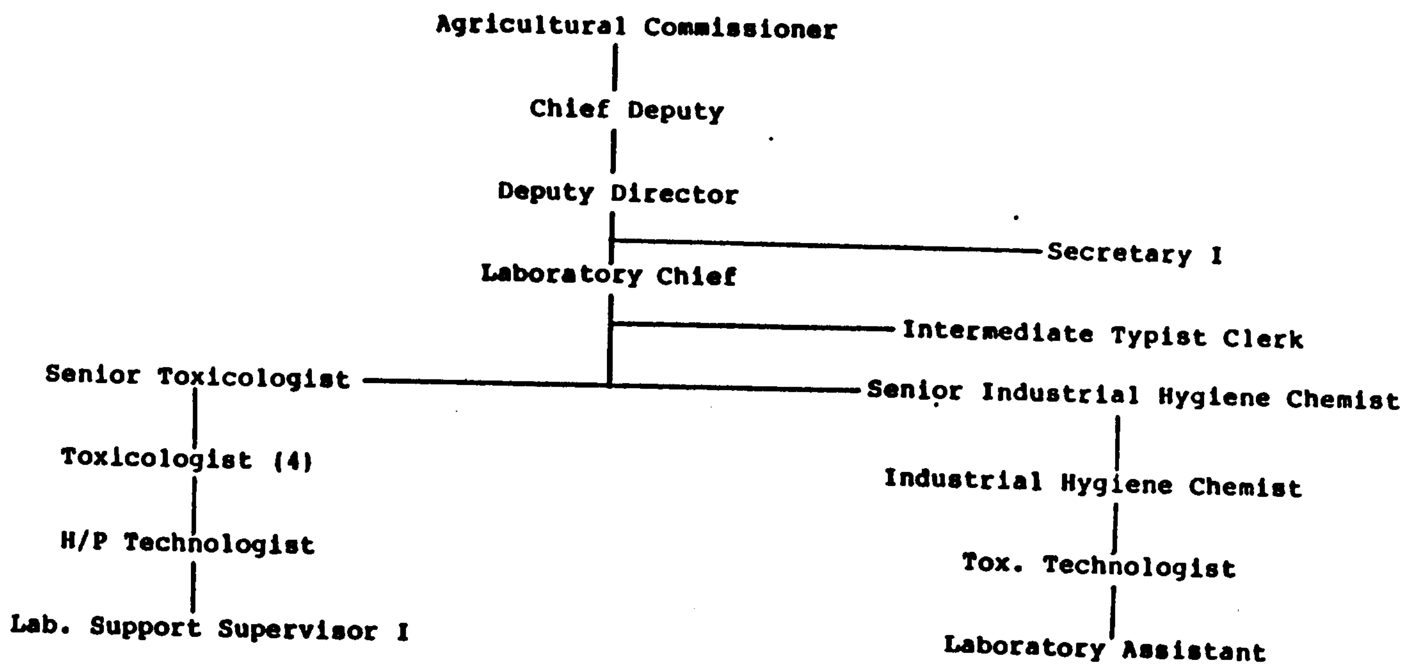
5. Define all the necessary quality control checks that must be followed prior to the analysis and/or in the course of analyzing samples.

6. Identify all laboratory records and information needed to document the quality of analyses performed in the laboratory.

1 8567

COUNTY OF LOS ANGELES
Office of Agricultural Commissioner/Weights and Measures
ENVIRONMENTAL TOXICOLOGY LABORATORY

Organizational Chart



1. Organization

A. Minimum Personnel Qualification and Background

1. Deputy Director Graduation from an accredited college with specialization in chemistry, biochemistry, biology, or agricultural chemistry, and three years experience in analytical chemistry, biochemistry, pharmacology, or toxicology laboratory. An advanced degree in chemistry or biochemistry will be accepted for the required experience on the basis of one year for Master's degree and two years for a Ph.D.

2. Chief-A Bachelor of Science degree and at least three years experience in chemistry, biochemistry, pharmacology, biology, or toxicology, one year of which must have involved the chemical analysis of environmental samples. An advanced degree in chemistry or biochemistry will be accepted for the required experience on the basis of one year for a Master's degree and two years for a Ph.D.

3. Senior Toxicologist-Graduation from an accredited college with specialization in chemistry or biochemistry, and two years experience in analytical chemistry, biochemistry, pharmacology, or toxicology. An advanced degree in chemistry or biochemistry will be accepted for the required experience on the basis of one year for a Master's degree and two years for a Ph.D.

4. Senior Industrial Hygiene Chemist-Master of science degree with a major in general or physical chemistry and five years experience as a professional chemist conducting basic analytical research in chemistry, or four years experience as as Industrial Hygiene Chemist.

5. Toxicologist-Graduation from an accredited college with specialization in chemistry or biochemistry, and one year experience in analytical chemistry, biochemistry, pharmacology, or toxicology. Completion of one year graduate work in an accredited college with specialization in chemistry or biochemistry will be accepted for the required experience.

6. Industrial Hygiene Chemist-Bachelor of science degree with major in chemistry a biochemistry, and either (1) a Master's degree in chemistry, biochemistry, or a related field of environmental chemistry and two years experience as a professional chemist doing increasingly complex analytical procedures, or (2) four years experience as a professional chemist doing increasingly complex analytical procedures.

7. Herbicide Pesticide Technologist-Graduation from an accredited college with specialization in chemistry, biochemistry, toxicology, biological & natural sciences and six months experience performing chemical analyses or completion of sixty semester units of which 16 must have been in chemistry and two years experience performing toxicological analyses.

VOL 12 1 8559

8. Toxicological Technologist-same as Herbicide/Pesticide Technologist.

9. Senior Laboratory Assistant-Six months experience at the laboratory assistant level.

10. Laboratory Assistant-Six months experience in laboratory work in a public health, medical, chemical, or biological laboratory, or completion of a course in laboratory science such as general chemistry or bacteriology.

B. Personnel Responsibilities

1. Deputy Director

-Directs, plans, assigns, reviews and evaluates work performed by laboratory personnel.

-Provides consultation in environmental toxicology to DHS, Agriculture Comm. and other agencies.

-Testifies as an expert witness for Los Angeles County on the analysis and interpretation of findings.

-Supervises the analysis and interpretation of laboratory data and correlates this with biochemical and metabolic effects.

-Publish scientific papers and reports. Make presentations concerning H/P contamination in our community. Attends and participates in conventions, meetings and conferences of professional organizations concerning H/P.

2. Chief

-Assists in the planning, assignment, supervision, and review of the work of laboratory personnel.

-Provides technical direction to laboratory personnel in performing a variety of chemical analyses of water, soil, plant, animal and other environmental samples utilizing various techniques such as spectrophotometry, chromatography, gravimetric, and volumetric analyses.

-Establishes and sets up special test procedures for detecting pesticides and other chemicals for which the laboratory has minimal or no experience, including all required and necessary quality control steps in such procedures.

VOL 12

1 8570

-Establishes minimum quality control guidelines for all methods and tests performed in the laboratory.

-Develops laboratory statistics and reports on analytical procedures in assisting laboratory personnel in making the more difficult or unusual determinations, to identify priorities, and to establish work flow measures.

-Conducts training of laboratory personnel.

-May testify as an expert witness for the Chief Environmental Toxicologist.

3. Senior Toxicologist

-Provides technical guidance to laboratory personnel and performs chemical analyses to determine the presence and quantity of pesticides and other chemicals of interest in samples submitted to the laboratory for study utilizing wet and instrumental methods.

-Develops procedures for and conducts non-routine analysis on samples involving new and uncommon pesticides where standard methods are not established.

-Routinely monitors at regular intervals the accuracy and precision of laboratory results by checking quality control data obtained by laboratory personnel as part of their daily workload.

-Ensures that all quality control guidelines of the laboratory are met and recorded in specific quality control record books.

-Prepares daily work assignments of lower level laboratory personnel.

-Engages in continuing research and experimentation to develop and improve analytical procedures.

-Writes reports on analyses outlining methods used and results.

-Assists the Supervising Toxicologist in performing an analysis of unknown substances.

-Contacts pathologists, law enforcement officers, pharmacists and others to obtain information on cases as necessary.

VOL 12

1 8571

4. Senior Industrial Hygiene Chemist

-Prepares work schedules, assigns and rotates Industrial Hygiene Chemists to various jobs, evaluates work performance and recommends resolutions to employee relations problems.

-Tests or directs the testing of new equipment, prepares written evaluations, and makes recommendations for its acquisition; prepares written instructions on the application and oper tion of new equipment for the procedure manual.

-Supervises a program of quality control to ensure the accuracy of test reports.

-Orients new employees to the overall operations of the section and trains or supervises their training.

-Serves as the consultant to Public Health Programs staff on problems relating to toxic and potentially dangerous chemicals.

-Analyzes samples that require the highest level of technical skill, experience and knowledge.

-Instructs environmental health personnel in the proper procedures for collecting field samples.

-Calibrates all laboratory equipment for the section.

5. Toxicologist

-Performs chemical analyses of water, soil, plant, animal, and other samples utilizing standard laboratory techniques such as spectrophotometry, chromatography and gravimetric and volumetric analysis.

-Follows accepted procedures and required quality control measures for conducting routine analyses such as determinations for pesticides and other organic/inorganic compounds.

-Writes reports on analyses outlining methods used and results.

-Contacts inspectors, law enforcement officers, and others to obtain information on cases as necessary.

-Assists the Senior Toxicologist in performing analysis of unknown substances.

VOL 12

1852

-Prepares standard chemical solutions and reagents to specific requirements.

6. Industrial Hygiene Chemist

- -Collects field samples and conducts surveys regarding industrial hygiene, sanitation, and exposure of workers to health hazards.
- -Conducts laboratory and field analyses of abrasives, solvents, and other materials used in industrial plants and makes specialized measurements of air samples to identify and measure contaminants.
- -Maintains and operates a chemical laboratory, anticipating needs for ordering chemicals and equipment.
- -Develops new and special methods, procedures and equipment to be used for chemical and physical determinations in laboratory and field studies.
- -Conducts research on problems of toxicology and other chemical problems as necessary for industry, County and other governmental agencies.
- -Maintains laboratory records and prepares reports on results of studies and projects.
- -Interprets data and confers with engineers, various divisions of the Health Department, and industrial managers to solve chemical problems concerning industrial health and hazards to workers.
- -Operates a variety of laboratory and field testing equipment.

7. Herbicide/Pesticide Technologist

- -Performs chemical procedures requiring the use of analytical apparatus to confirm existence of herbicides and pesticides in plant, soil, water, and animal tissue specimens.
- -Utilizes techniques such as gas chromatography in chemical analyses of various specimens to determine the quantity of herbicides and pesticides present.
- -Follows quality control guidelines on all chemical procedures and analyses performed.

VOL 12

18573

-Conducts preliminary research contributing to the development of new methods and procedures for the purpose of enhancing the quality of test analysis.

-Prepares standard chemical solutions and reagents to specific requirements.

-Performs routine maintenance on laboratory equipment and apparatus including cleaning and calibration.

-Prepares written reports delineating technical procedures exercised during analysis and test findings.

-Interprets gas chromatography graphs to determine specimen findings and submits interpretations to a Senior Toxicologist for review.

8. Toxicological Technologist

-Performs chemical analysis of environmental and biological samples using established procedures to determine the presence or absence of pesticides.

-Utilizes known istrumentation techniques such as gas and high pressure liquid chromatographs to determine the quality and quantity of pesticides present.

-Follows quality control guidelines on all chemical procedures and analyses performed.

-Prepares reference standards, chemical solutions, and reagents to specific requirements.

-Performs routine maintenance on laboratory equipment and apparatus including cleaning and calibration.

-Interprets charts and reading generated by various laboratory instruments used and submits interpretations to a toxicologist or senior toxicologist for review.

-Maintains register of all samples which includes detailed information on the methods used and findings.

-Assist in the development of new methods and procedures to improve the quality and reliability of test results.

-Follows experimental procedures under the guidance of a senior toxicologist to test for new pesticides.

9. Senior Laboratory Assistant

- Trains laboratory assistants in the specific procedures established by the laboratory for the preparation of samples for analysis by toxicological technologists and toxicologists, the preparation of reagents, and the performance of other such laboratory tasks.

- Observes the performance of other laboratory assistants of their assigned tasks both in training and on-the-job situations, and makes corrections necessary to assure maintenance to established quality and quantity standards.

- Prepares samples for laboratory testing by adding reagents, solvents, and/or standards using prescribed techniques and instruments appropriate to the type of sample.

- Processes samples for subsequent analysis by higher level personnel by performing duties such as extractions and filtrations.

- Operates laboratory equipment pre-calibrated by qualified personnel to perform assigned tasks such as platform shakers, rotovaporators, and pH meters.

- Prepares specific quantities of reagents and solutions of compounds including acids and bases, following written procedures, by mixing components to standard ratios using such laboratory apparatus as weighing balances and volumetric glasswares; lifts and moves containers holding several gallons or other substantial quantities of constituent parts or compounds produced.

- Performs routine maintenance on miscellaneous devices such as water baths, rotovaporators, and platform balances.

- Cleans and treats glassware used in laboratory testing following steps and procedures prescribed by higher level personnel.

- Stores apparatus, glassware, and other supplies in designated areas when not in use.

- Stores reagents and chemicals in designated areas as required by safety rules and regulations.

VOL 12

18575

10. Laboratory Assistant

- Receives samples such as water, soil, plant, etc. together with standard laboratory request form providing information such as sample I.D. and tests to be performed; verifies sample I.D. and assigned laboratory I.D. number by matching information on request form and sample container.

- Assigns laboratory identification to all samples received and writes this I.D. number on request forms and corresponding sample containers.

- Logs in sample information such as sample I.D., laboratory I.D. number, and tests to be performed in laboratory record book.

- Stores all samples received in appropriate storage locations and submit corresponding laboratory request forms to senior toxicologist.

- Prepares samples for analyses by chopping, weighing, and/or measuring where appropriate.

- Performs preliminary work on samples such as adding solvents and reagents, setting-up necessary glassware, and loading on platform shakers.

- Operates automatic laboratory equipment pre-calibrated by qualified personnel such as a pH meter to perform specific test.

- Transcribes laboratory test results from laboratory worksheets into permanent record book.

- Cleans & treats glassware used in laboratory testing following steps & procedures prescribed by higher level personnel.

- Cleans and stores apparatus, glassware and other supplies in designated areas when not in use.

- Stores reagents and chemicals in designated areas as required by safety rules and regulations.

VOL 12

18576

VOL 12

II. Sampling Procedures

A. Hazardous Waste

1. Organochlorine pesticides, Polychlorinated Biphenyls, and Organophosphorous Pesticides.

   Wide mouth borosilate or soda glass container of 16 oz. size should be used. The container must have tight, screw-type lid with teflon liner. Sample bottle must not be prewashed with the sample before collection. Composite sample should be collected in refrigerated glass container.

   The sample must be iced or refrigerated from the time of collection until extraction. Preservatives should not be used in the field unless more than 24 hour will be elapse before delivery to laboratory. If the sample will not be extracted within 48 hours of collection, the sample should be adjusted to pH range of 6.0 to 8.0 with sodium hydroxide or sulfuric acid. Note the volume of acid or base added to the sample.

   All samples must be extracted within 7 days and completely analyzed within 30 days of collection for organochlorine, pesticide and polychlorinated biphenyls, and analyzed within 14 days of collection for organophosphorous pesticides.

2. Phenols

   Wide mouth borosilate or soda glass container must be used, and the container must not be prewashed with sample before collection. Composite samples should be collected in refrigerated glass container.

   The sample must be iced or refrigerated from the time of collection until extraction. If free chlorine is present in the sample, add 35 mg. of sodium thiosulfate per ppm free chlorine per liter/kg. Adjust the sample pH to approximately 2, as measured by pH paper with sulfuric acid solution or 10 N sodium hydroxide. record the weight of sodium thiosulfate and volume of sulfuric acid or sodium hydroxide used.

   All samples must be extracted within 7 days and completely analyzed within 30 days of collection.

1 8577

3. Halogenated Volatile Organics, Non-Halogenated Volatile Organics, and Acrolein, Acrylonitrile, Acetonitrile.

Samples must be collected in glass containers of at least 25 ml. size. Fill the sample container in such a manner that no air bubbles pass through the sample as the container is being filled. Seal the bottle so that no air bubbles are entrapped in it. Solid and semisolid samples are to be taken in the same way.

The samples must be iced or refrigerated from the time of collection until extraction. If the sample may contain free or combined chlorine, add 10 mg. sodium thiosulfate per. 40 ml./gm. for up to 5 ppm. chlorine. Fill the container with sample just to overflowing, seal the container, and shake vigorously for 1 minute.

All the samples must be analyzed within 14 days of collection.

4. Base, neutral, acid extractables.

All samples must be collected in glass container with teflon-lined screw caps. The samples must be iced or refrigerated at 4°c from time of collection until extraction. All samples must be extracted within 14 days of collection and completely analyzed within 40 days of extraction.

5. Phthalate Esters, Nitroaromatics, Cyclic Ketones, Poly nuclear Aromatic Hydrocarbons and Chlorinated Hydrocarbons.

All samples must be collected in refrigerated glass containers and the containers must not be prewashed with sample before collection. The sample must be iced or refrigerated from time of collection until extraction. Chemical preservative should not be used unless more than 24 hour will elapse before delivery to the laboratory. If the samples will not be extracted within 48 hours of being collected, the sample should be adjusted to a pH range of 6.0-8.0 with sodium hydroxide or sulfuric acid. Record the amount of acid or base used.

All samples must be extracted within 7 days and completely analyzed within 30 days of collection.

VOL 12

1 8578

6. Toxic Metals

All sample containers must be prewashed with detergents, acids and deionized water. Plastic and glass containers are acceptable. Aqueous samples must be acidified to pH less than 2 with nitric acid. Non-aqueous sample shall be refrigerated. The maximum holding time of sample for mercury is 38 days in glass container and 13 days in plastic container.

7. Non-metallic

a. Cyanide

Oxyidizing agents decompose most cyanides. To test the presence of oxidizing agents, test a drop of liquid sample with potassium iodidestarch test paper: a blue color indicates the need for treatment. Add ascorbic acid a few crystals at a time until a drop of sample produce no color on the test paper. Then add an additional 0.6 gm. of ascorbic acid for each liter of liquid sample.

Samples must be preserved with 2 ml. of 10 N. sodium hydroxide per liter of sample at time of collection (pH is greater than or equal to 12).

Samples should be refrigerated at 4°c and analyzed as soon as possible.

Sample could be stored in glass or plastic container.

b. Fluoride

Sample should be collected in glass or plastic container.
Maximum holding time is 28 days.

c. Sulfide

Sample should be collected in glass or plastic container. Aqueous samples must be preserved with zinc acetate or the analysis must be started immediately.

8. Physical property testing

All samples should be collected in glass container with teflon liner and stored at 4°c.

VOL 12

1 8579

R0051884

B. Drinking Water

1. Organochlorine Pesticides and Nitrogen - and Phosphorus-Containing Pesticides

   Use 1-L borosilicate glass bottle with TEF-fluorocarbon lined screw cap, add 10 mL. of mercuric chloride as preservative to the bottle for a concentration of 10 mg/L.

   When sampling tap water, allow the system to flush for about 10 minutes to stabilize temperature. Adjust the water flow to approx. 500 ml./min. befor collecting the sample. Note that the bottle must not be pre-rinsed with the sample. If a well is to be sample, collect the water in a wide-mouth beaker then transfer to the sample bottle with preservative. Seal the bottle then shake vigorously for 1 minute.

   Store the sample at 4°c. Extract within 7 days of collection and analyze within 40 days of extraction.

2. Volatile Organic Compounds

   Use 40 ml. vials with screw caps equipped with PTFE-faced silicone septum. These vials maybe ordered from Pierce or equivalent pre-cleaned and ready to use. Carry a field blank filled with reagent water to the sampling site with empty vials.

   Fill sample bottles to overflowing. No air bubbles should pass through the samples as the bottle is filled, or be trapped in the bottle when the bottle is sealed.

   When sampling tap water, allow the system to flush for about 10 minutes to reach stable temperature. Adjust water flow to about 500 ml./min. them collect the sample. If a well is to be sampled, collect the water in a wide-mouth beaker then transfer to the sample vial.

   Collect all samples in duplicate.

   Adjust pH of sample to <2 by the addition of 2 drops of 50% HCl. Seal the sample bottle with the PTFE-face down and shake vigorously for 1 minute. Immediately store sample at 4°c after collection. Analyze samples within 14 days of collection.

3. Carbamate Pesticides

Use 100-ml. or larger capacity glass or plastic bottle equipped with screw cap. Carry a field blank filled with TypeII water to the sampling site with the empty sample bottle. Add 7 mg/100 ml. of sodium thiosulfate to the empty bottles and field blanks as preservative.

Do not pre-rinse container with sample before sampling.

When sampling tap water, allow the system to flush for about 10 minutes to obtain stable temperature. Adjust the flow to approx. 500 ml./min. then collect water in a wide-mouth beaker the carefully transfer the sample to the bottle. Fill the bottle within 2 cm. of the top.

In the laboratory, samples to be analyzed for oxamyl, 3-hydroxycarbofuran, and carbaryl must be further preserved immediately at the laboratory by adjusting pH to 3. This maybe done with the addition of 50% HCL.

Store samples at 4°c and extract within 7 days of collection and complete the analysis within 40 days of extraction.

4. **Trace Metals**

Use 125-ml. polyethylene bottles with screw caplid. Prior to use, wash bottle with detergent and tap water; rinse with 1:1 nitric acid, tap water, 1:1 hydrochloric acid, tap water, and finally de-ionized water in that order.

For determination of dissolved or suspended metals, no preservative need be added at the time of collection. For determination of total metals, both dissolved and suspended, acidify sample to pH 2 or less with the addition of 1:1 redistilled HNO_3 at the time of collection. For determination of total recoverable metal acidify sample at the time of collection with 0.625 ml. of conc. $HN O_3$ for 125 ml. of sample. Analyze sample within 30 days of collection.

C. Sample Labeling and Identification

Immediately after collection, the sample must be sealed, labeled, and the sample analysis request form filled out for each sample.

VOL 12 1858 1

1. Sample Labels

Sample labels are used for the specific identification of samples. Gummed paper labels affixed to the containers are adequate, but it should not be affixed to the sample lids. The labels should be filled out at time of collection and should include the following information:

Field Number
Name of Collector
Date and Time
Place of Collection

2. Sample Seals

Sample seals are used to detect unauthorized tampering of samples ater collection, upto the time of analysis. The seals must be affixed to the sample container in a way that it has to be broken in order to open the sample container.

Seals must be affixed to the container by the collector.

3. Sample Analysis Request Form

Sample analysis request form accompanies the sample when it is delivered to the laboratory. The field portion of this form should be completed by the collector. The laboratory section is for completion by the laboratory analyst. The sample request form should include at the minimum:

Name of Collector
Date and Time of Collection
Location of Sampling Site
Field Number
Type of Sample
Analysis Requested
Date Received by the Laboratory
Laboratory Number
Results of Analysis
Date of Analytical Report
Name of Analyst
Remarks on Sample

VOL 12

1 8582

III. Sample Custody

When a sample arrives, it should be logged in immediately. The laboratory receiving personnel should look at the sample to verify:

- -Is the proper container used?
- -Is the container properly filled?
- -Is the quantity sufficient?
- -Is the sample seal intact?
- -Is the sample request form filled properly?

If the answer to any of the above question is no, the laboratory supervisor must be notified immediately. Also, the receiving personnel must verify if the sample had been appropriately preserved. If not, if must be preserved according to instructions in Table 1. This Table is posted for reference in the receiving area.

All samples received must be logged in a logbook and a unique laboratory number must be noted on the sample container, sample analysis request form, and log-book. In addition, the logbook must include information of laboratory sample number, sample identification information, type and condition of sample, and analysis requested. The recipient of the sample should sign the chain of custody form (see below).

Chain of Custody

Chain of Custody is a documentation of the sample history form collection to data reporting. A sample is considered under a person's custody if (1) it is in a person's physical possession, (2) in view of the person after he has taken possission, (3) secured by that person so that no one can tamper with the sample, or (4) secured by that person in an area which is restricted to authorized personnel.

The chain of custody form records the history of sample possession from collection, to analysis, and finally, to sample disposal. The form is printed on the same sheet as the sample request form. It must accompany the sample upon delivery to the laboratory. Information on the chain of custody form should include at least the following:

Name of the person in possession of sample
Affiliation of the person in possession
Date in possession

Once the sample has been logged in and the laboratory assume responsibility for it, the sample must be stored in a secure location. Whether the location should be refrigerated or not depends on the type

VOL 12

1 8583

of sample or analysis requested. Refer to Table 1 for storage conditions. Typically, all samples for organic analyses must be stored in the refrigerator/freezer. Samples for trace metal analysis maybe stored at room temperature except those requiring Chromium VI analysis. The latter must be refrigerated.

Refrigerator/Freezer used for sample storage must be different from those used for storing standards. In addition, samples for volatile analysis must be stored separately form non-volatiles. On each refrigerator/freezer, a chart is posted outside to record daily temperature readings, date, and name of person monitoring the temperature.

After properly receiving and securing the sample, worksheets are written up providing information on sample laboratory number, type, analysis requested, received date, and maximum holding time. Table 1 posted in the receiving area also contain information on holding times as a guide in preparing the work sheets.

A copy of this section on sample custody is posted in the receiving area to serve as a guide for the receiving personnel.

Table 1

A. Hazardous Waste

Analysis Requested	Storage & Preservation	Maximum Holding Time
Inorganic Tests:		
Cyanide, total & amenable to chlorination	P, G Cool, 4°C, NaOH to pH 12, 0.6g ascorbic acid	14 days
Fluoride	P None required	28 days
Hydrogen ion (pH)	P, G None required	analyze immed.
Metals:		
Chromium VI	P, G 4°C	24 hours
Mercury	P, G HNO_3 to pH 2	28 days
Metals except chromium VI and mercury	P, G HNO_3 to pH 2	6 months
Phenols	G only Filter immediately, Cool, 4°C cool, 4 C, H_2SO_4 to ph 2	28 days
Sulfide	P, G Cool, 4°C, zinc acetate plus sodium hydroxide to pH 9	7 days
Organic Tests:		
Purgeable Halocarbons	G, Teflon-lined septum Cool, 4°C 0.008% $Na_2S_2O_3$	14 days
Purgeable aromatic hydrocarbons	G, Teflon-lined septum Cool, 4°C 0.008% $Na_2S_2O_3$, HCI to pH2	14 days
Acrolein and acrylonitrile	G, Teflon-lined septum Cool, 4°C 0.008% $Na_2S_2O_3$, adjust ph to 4-5	14 days
Phenols	G, Teflon-lined cap Cool, 4°C, 0.008% $Na_2S_2O_3$	7 days until extraction 40 days after extractio
Phthalate esters	G, Teflon-lined cap Cool, 4°C	7 days until extraction 40 days after extractic
PCBs acrylonitrile	G, Teflon-lined cap Cool, 4°C	40 days after extractic
Nitroaromatics and isophorone	G, Teflon-lined cap Cool, 4°C, 0.008% $Na_2S_2O_3$ store in dark	40 days after extractic
Polynuclear aromatic hydrocarbons	G, Teflon-lined cap Cool, 4°C 0.008% $Na_2S_2O_3$ store in dark	40 days after extractic
Chlorinated hydrocarbons	G, Teflon-lined cap Cool, 4°C	40 days after extractic

B. Drinking Water

Analysis Requested	Storage & Preservation	Maximum Holding Time
Volatile Organic Chemicals	4°C, Acidify to pH 2 with 1+1 HCl (1 drop/20 ml. sample)	14 days
Base/Neutral and Acid Extractables, Non-purgeable Organic Chemicals	4°C, Protected from light, For chlorinated waters add Sodium Thiosulfate, 80 mg/l. of sample	Extract within 7 days; complete analysis within 40 days of extraction
Ethylene Dibromide (EDB) Dibromochloropropane (DBCP)	4°C, No chemical Preservative	28 days
Organohalide Pesticides and Aroclors	4°C, Sodium Thiosulfate, 3 mg crystals/	Extract within 7 days; complete analysis within 40 days of extraction
Nitrogen or phosphorus Containing Pesticides	4°C, *Mercuric Chloride to 10 mg/l.	14 days
Chlorinated Pesticides	4°C, *Mercuric Chloride to 10 mg/l.	Extract within 7 days; complete analysis within 40 days of extraction
Chlorinated Herbicides	4°C, No chemical preservative	Extract within 7 days; complete analysis within 40 days of extraction
N-Methyl Carbamoyloximes	4°C**, Sodium Thiosulfate, 7 mg/100 ml.; Acidity to pH3 with HCl (1+1) (Samples for Aldicarb and Endothall must be frozen)	Extract within 7 days; complete analysis within 40 days of extraction
Bentazon	4°C, No chemical preservative	Extract within 7 days; complete analysis within 40 days of extraction

*Use caution in handing this toxic chemical. Dispose of contaminated sample in appropriate manner.

VOL 12 1 8586

IV. Calibration Procedures and Frequency of Calibration

A. Standards and References

1. Sources of Standards

99% of our standards come from the following sources:

Quality Assurance Branch
EMSL - Cincinnati
U.S. Environmental Protection Agency
Cincinnati, Ohio 45268

U.S. Environmental Protection Agency
Pesticides & Industrial Chemical Repository
(MD-8)
Research Triangle Park, NC 27711

Supelco, Inc.
Supelco Park
Belleforte, PA 16823-0048

Aldrich Chemicals
P.O. Box 2060
Milwaukee, Wisconsin 53201

National Bureau of Standards
Gaithersburg, Maryland 20899

All standards are obtained from reliable sources who can certify the purity of the materials.

Upon receipt, all neat standards are entered into an inventory book which includes the date received, who received it, source or supplier, lot number, conc./purity, expiration date, date opened, and who opened the bottle. The bottle itself containing the neat standard is labelled with the date received and initialled, expiration date, and date opened and initialled.

2. Preparation of Standards

Standards are prepared as outlined in the laboratory's specific Standard Operating Procedures (SOP) Manual. All information pertinent in the preparation of the standard are entered in the laboratory's Standard Preparation Book. Which include the following:

VOL 12

18587

R0051892

VOL 12

5.						
6.						
7.						
8.						

Standard solution bottles are also labelled individually with the concentration, solvent used, date prepared, expiration date and initials of the preparer.

3. Storage of Standards

All degradable and volatile organic compounds are stored in a freezer at below 0°C. This is true for any concentration: neat or solution.

Trace metal standards, except chromium VI, are stored at room temperature. Chromium VI is refrigerated.

4. External Reference Standards

Whenever possible, check standards are ordered from the EPA or NIST. These are used to verify the accuracy of the working standards. If unavailable from EPA or NIST, standards from another supplier or different lot number from the same supplier are used as check standards.

B. Calibration Procedures and Frequency

Specific calibration procedures are included in the analytical method and in the operator manual of that instrument. Each analytical instrument is calibrated at least daily when in use. The analyst is responsible for calibration. All the calibration data are kept in specific QC books.

There are calibration guidelines in the use of gas chromatographs, HPLC's, and atomic absorption spectrophotometers. These guidelines are applicable regardless of the instruments' make and model.

GC and HPLC Calibration Guidelines

1. Calibration Curve

Initially before use, a 5-point calibration curve must be established for each analyte of interest in order to determine the linearity of the concentration range of interest in the GC system to be used. A calibration curve is established by plotting the system response, as in peak height or peak area, versus the concentration of the standard applied to the system. The concentration of the standards used must correspond to the expected range of concentration in real samples, or must define the working range of the detector used. One standard concentration that must be included should be near but above the method detection limit (check individual method references for tabulated list of MDLs). An alternative to establishing a calibration curve is the definition of calibration factors (CFs) for the analyte of of interest at each standard concentrations.

$$CF = \frac{\text{Total Peak Area/Height}}{\text{Mass Injected (ng)}}$$

For each analyte, five CFs would be obtained. Calculate the percent relative standard deviation of the CFs. If the %RSD is less than 20%, it can be assumed that the line defined by the CFs is linear through the origin and that the CF can be used instead of a calibration curve for calculation of the concentration of the analyte in real samples.

2. Calibration Standard

On a daily basis, a calibration standard must be injected and analyzed in the GC system to be used in the analysis. The response of the standards must fall within ±15% of the established calibration curve or factor (see appropriate QC Record Book for current values). If outside the ±15% limit, the cause of change must be determined and corrected, if possible. If the problem is one that is inherent in the system and cannot be corrected, then a new 5-point calibration curve must be established (see Pre-Analysis QC Requirements) before any real sample can be analyzed. Monitor the response of the calibration standard every 10 samples. The ±15% limit must be met with every injection of the standard. Record daily calibration parameter in Form 2.

3. Retention Time (RT) Windows

Prior to any new analyte testing and each time a new GC column is installed, retention time windows must be defined initially for each analyte and its corresponding surrogate and matrix spike standards there after. To determine the RT windows, make a minimum of three injections of all single analyte standard mixture and multiresponse analyte like chlordane over a 71-hour period. Calculate the standard deviation of the absolute RTs of each analyte with every injection. For multiresponse analyte, choose a major peak from the group of peaks and calculate the standard deviation of its absolute RTs from every injection. The RT windows are defined as the ±3S, where S is the standard deviation, of the absolute retention time for each analyte. Record all Rts and windows in Form 2. From the injection of the calibration standard of the analyte of interest, determine the retention time and make certain it falls within the established windows.

AA spectrophotometer Calibration Guidelines

Calibration Curve

- must be prepared each day with a minimum of a reagent blank and three standards at different levels of concentrations. Determine the absorbances of each blank and standards. Plot the absorbances versus the concentrations. This plot establishes the linear curve for the day of the atomic absorption spectrophotometer used. Follow themanufacturer's instructions in preparing the calibration curve for the particular instrument used. Verify the curve every ten samples by analyzing a blank and a mid-level standard. The results of the verification should be within +20% of the original curve. If not a new curve must be generated. Use form 3 to record calibration data.

VOL 12

V. Analytical Procedures

A. Methods Used

All the analytical procedures used are from published sources from the following list:

1. Test Methods for Evaluating Solid Waste, SW-846, 3rd Edition, Office of Solid Waste and Emergency Response, U.S. Environmental Protection Agency, Washington, D.C. November, 1986.

2. Methods for Chemical Analysis of Water and Wastewater, EPA-600/4-79-020, 1984 U.S. Environmental Protection Agency.

3. Standard Methods for the Examination of Water and Wastewater, 15th and 16th Edition, APHA-AWWA-WPCF, Washington, D.C. (1980-1085).

4. The Determination of Inorganic Anions in Water by Ion Chromatograph - Method 300.0, EPA-600/4-84-017, March 1984, U.S. Environmental Protection Agency.

5. EPA Drinking Water Methods, 500 Series.

If applicable; certain methods are written in out line form for routine use in the laboratory. They are included in the laboratory's Standard Operating Procedure (SOP) Manual. For any analyst using methods for the first time, it is recommended that references noted on the upper right hand corner of the outlined form be thoroughly studied prior to the use of the outline.

1
8
5
9
5

B. Detection Limit

Method Detection Limit (MDL)

Method detection limit is the lowest concentration level detectable in the laboratory instrument. It corresponds to an analyte signal-to-noise ratio of two with the analyte being introduced to the instrument in clean solution, i.e., reagent water or reagent grade organic solvent. Typically, the laboratory has the same MDL as those listed under specific analytical methods such as the EPA 500 series. The laboratory verifies that the listed MDLs are indeed applicable by directly injecting or introducing standards at the MDL level to the instrument and obtaining a signal-to-noise ratio of at least two from the injection.

Practical Quantitation Limit (PQL)

Practical quantitation limit (PQL) is the lowest quantifiable level that can be reliably achieved during a routine laboratory analysis of an analyte in a given matrix. This value is typically higher than the MDLs because it is matrix dependent. In determining PQLs, the laboratory follows the method given in the publication EPA-600/4-82-057, Appendix A.

C. Record of Analysis

For each analytical batch, all pertinent data related to the analysis including method used, sample weight or volume, dilutions, standard concentrations, description of instruments used and name of analypt are entered into a permanent log-book (Hazardous Waste) or worksheets (drinking water) which are filed as permanent records of the laboratory.

D. The laboratory maintains Standard Operating Procedures (SOP) Manual for both hazardous waste and drinking water analyses. These manuals contain the different analytical methods used in the laboratory in outline form. This is a cookbook-type outline generated from published methods which includes, whenever applicable, the following:

1. Scope and Applications
2. Detection limits (instrument and method)
3. Precision and Bias
4. Working range
5. Summary of Method
6. Sample collection, preservation, and holding times
7. Comments
   A. Interferences
   B. Helpful hints
8. Safety issues (specific to the method)
9. Apparatus
10. Reagents and standards
11. Procedure (detailed step-by-step)
    A. Sample preparation
    B. Calibration
    C. Analysis
12. QA/QC requirements
    A. QC samples

    B. Reporting limits
    C. Significant figures and reporting values below detection limit
15. References
    A. Method source
    B. Deviations from source method and rationale

VCL 12 1 8596

VOL 12

VI. Data Reduction, Validation and Reporting

A. Data Reduction

Equations and calculation procedures are included in the laboratory's SOPs. All the calculations must be attached to the copy of laboratory report for filing. Corrections for the blanks maybe made where appropriate. Calculations by the instrument/integrator is acceptable.

B. Data Validation

All results generated by the laboratory must be validated through the simultaneous analyses of required quality control (QC) samples/standards with the unknown sample. These include:

1. Instrument calibration with three concentration levels of standard and continuing single standard calibration every ten sample of an analytical batch.

2. Analysis of a method blank every batch of 20 samples for hazardous waste (every batch of 10 samples for drinking water) or type of matrix, which ever is more frequent.

3. Analysis of matrix spiked samples in duplicate at least once for every batch of 20 samples for hazardous waste (every batch of 10 samples for drinking water) or type of matrix which ever is more frequent.

4. Once during the analysis, an external reference standard should be used to check the concentration of the calibration standard.

After completing the analyses of an analytical batch, results of the above QCs must be recorded and plotted in the appropriate quality control chart (see form 4). Precision and accuracy control charts are maintained to determine if the QC results of an analysis are within established control limits. Control limits are initially set after the analysis of ten matrix spike and duplicate samples.

Thereafter, they are periodically set to reflect current performance.

It is the responsibility of the analyst to determine that all appropriate quality control operations have been performed and that all QC results fall within established limits. If any of the required QC is out of control the analyst must initiate corrective actions.

18597

C. Data Reporting

Analytical results are ready to be reported as soon as it is verified that all quality control data fall within the laboratory's established limits. All data generated, both for the actual sample and the quality control sample must be entered in the appropriate worksheet, log-book and QC books. All information related to the sample analysis such as weight, volume, and QC results must be recorded. All results reported to the submitting agency would be presented with the appropriate number of significant figures, proper units such as ppm, method used, and practical quantitation limits. Worksheets, instrument out puts (e.g. chromatogram), analytical results, sample request for and report of analysis form are put together in a file and submitted to the laboratory supervisor for review. The supervisor signifies his/her approval by signing the report of analysis form to be sent to the submitting agency.

VII. Internal Quality Control Procedures

In order to document the laboratory's ability to test for the analyte of interest, certain quality control procedures are followed. These procedures are divided into two: (1) pre-analysis QC requirements and (2) daily or on-going QC requirements.

1. **Pre-Analysis QC Requirements - QC Check Samples**

   The laboratory's ability to generate results with acceptable accuracy and precision using a published method must first be verified before the analysis of actual samples. This is done through the analysis of four QC check samples prepared according to Sec. 8.6.2, Method 8000, SW-846. Briefly, QC check samples are prepared by spiking four aliquots of reagent water with known amounts of the analytes in the method to be used. The average recovery ($\bar{R}$) of the analytes in ug/L and the standard deviation (s) in ug/L of the recoveries are calculated and compared with those listed under the QC Acceptance Criteria Table found at the end of each published method. If the $\bar{R}$ and s values calculated fall within the limits defined in the table, then the system performance is acceptable and analysis of actual samples can begin. If any individual analyte's $\bar{R}$ or s fall outside the limit, then the system performance in unacceptable for that analyte. QC check samples must then be analyzed just for the analyte that failed. If re-analysis produced results within limits, then the system performance is acceptable. Repeated failure signifies a general problem with the measurement system. If this occurs, the source of the problem must be located and corrected - then QC check samples must again be ran for <u>all</u> the analytes.

2. **Daily QC Requirements**

   On a daily basis or each time a sample or batch of samples is analyzed, certain quality control samples must be ran: method blanks, duplicates, and matrix spike/matrix spike duplicates. From these quality control samples, control charts may then be generated which would allow for the establishment of accuracy and precision limits for the laboratory.

   Method Blank

   The analytical result of the method blank (or reagent blank) must be free of any analyte contamination. If contaminated, the source of contamination must be determined and corrected. After correction, the batch must then be re-analyzed if the sample quantity permits; or

VOL 12 1 8500

if not, results of the analysis maybe released with appropriate warnings on the nature of the contamination.

Hazardous waste - blanks must be ran once every analytical batch of 20 samples or less or each type of matrix whichever is more frequent. Since it is impossible to obtain a universal matrix blank for non-aqueous/solid samples, only reagent water is used.

Drinking water - blanks must be ran once every analytical batch of ten or less. Reagent grade water is used as blank.

Duplicate Samples

Duplicate samples are prepared by dividing a sample in two and analyzing them separately. Duplicate samples serve the purpose of monitoring the precision of measurement system. The results of the duplicate analyses must be within 20% of each other. If not an error has occured and it must be determined and corrected. The batch must then be re-analyzed. If the duplicate samples are negative for the analytes tested, then the matrix spike (see below) must be ran in duplicate to measure the precision. Duplicates must be ran once for every batch of 20 hazardous waste samples or less or each matrix type whichever is more frequent. Drinking water analysis requires duplicates to be ran every 10 samples.

Matrix Spike/Matrix Spike Duplicates (MS/MSD)

A predetermined amount of the analyte standard is added to a sample matrix to prepare the matrix spike sample. If the unknown samples to be analyzed are expected to be negative, then the sample matrix for spiking is first split into duplicates prior to the addition of the standard. Both matrix spike and matrix spike duplicate are analyzed simultaneously with the unknown samples. Recoveries of the analyte from the spike samples measure the accuracy of the method and the percent difference between the matrix spike and matrix spike duplicate assesses the precision of the analysis. The level of standard for spiking must be at the regulatory level or the method quantification limit. Samples with analyte concentration greater than 0.1% do not require the analysis of matrix spikes. Matrix spike and matrix spike duplicates must be ran for 5 % of the total analytical batch or each matrix type of hazardous waste. Drinking water requires the analysis of MS/MSD for 10% of the analytical batch. The accuracy and precision obtained from the MS/MSD must fall within the established lower and upper control limits of the laboratory. Continuing spike recoveries are recorded in form 4.

VOL 12

1 8601

3. Other QC Requirements

Periodically, samples are re-analyzed by another analyst. This is especially true in situations wherein a seemingly valid result is obtained but does not agree with the history of the sample.

Good Laboratory Practices

Good laboratory practices are followed to assure continued production of reliable results. These include not only topics previously discussed, i.e., sample custody, calibration, analytical procedures, data handling, and internal quality control procedures, but also glassware cleaning, verification that the sample containers, reagents and laboratory water are free of contamination, local and state safety codes are followed, fume hoods are routinely monitored, and hazardous waste are disposed of properly.

1. Glassware cleaning - glassware used for metal analysis should be acid washed. Refer to the published analytical methods for detailed procedures. Glassware used for organic analysis should be washed with solvent used in the analytical procedure. If trace amount of the organic contamination is found, it maybe necessary to clean the glassware in a muffle furnace.

2. Only reagent grade chemicals are used.

3. Type II deionized water is used in the analytical method and for method blanks.

4. Sample containers must be verified to be free of contamination. To accomplish this, a container from every lot received is rinsed with water or methanol, whichever is applicable, and analyzed.

5. Air flow in the fume hoods are monitored periodically by qualified personnel. The maximum operating height of the fume hood door is marked accordingly.

6. Safety procedures are adhered to. The laboratory has a safety manual that is distributed to all personnel. It covers topics on emergency procedures as in cases of fire or chemical spills, laboratory safety procedures with regards to handling different types of chemicals and executing certain laboratory tasks, and state-required hazardous material communication procedures.

7. Local and state safety codes are incorporated in the laboratory safety manual. As with all other safety procedures in the manual, they must be adhered to.

VOL 12

1 8602

VOL 12

VIII. Performance and Sytem Audits

The laboratory undergoes periodic performance and system audits through external and internal proficiency samples.

External Proficiency Samples

Currently, the laboratory has three sources of external proficiency samples. They are the California Dept. of Food and Agriculture, California Dept. of Health Services, and the Environmental Protection Agency.

CDFA Proficiency Samples

On a quarterly basis, the CDFA sends a minimum of four proficiency samples to the laboratory. Fifty percent of these are plant tissues and the other 50% are environmental samples such as water, soil, and swabs. The samples are spiked with pesticides from the organochlorine, organophosphorus, and/or carbamate group. Results of the proficiency sample analyses are sent back to CDFA for evaluation and they in turn mailback to the laboratory statistical analysis of results as compared with theoretical valves and other laboratories' results.

CDHS

Periodically, the laboratory had received performance evaluation samples from the CDHS. The samples received were for both hazardous waste and drinking water analysis. The samples were spiked with some of the analytes the laboratory was accredited for. As with the CDFA proficiency samples, after submitting the P.E. sample results to CDHS, the laboratory receives a statistical analysis of the results reflecting the comparison of results with the CDHS's accept/reject criterion.

EPA

On January 1990, the laboratory enrolled with the EPA to participate with the latter's Performance Evaluation Sample Program in water pollution. As a result, the laboratory anticipates receiving and analyzing P.E. sample for waste water periodically in the future.

Internal Proficiency Sample

Effective January 1990, the laboratory, on a quarterly basis, prepares and analyzes internal proficiency samples. A minimum of three samples are involved representing any of the environmental samples such as water, soil, plant, and wipe. The proficiency samples are spiked with some of the analytes typically ran in the laboratory. Reports are prepared from the results of the proficiency samples and compiled in the appropriate QC record book.

1

8503

IX. Preventive Maintenance

All minor maintenance and repair needed are accomplished by laboratory personnel. For major breakdowns, sufficient funds are budgeted annually to enable the laboratory to obtain service calls from qualified manufacturer's service engineers. The laboratory maintains a log book on any repair or maintenance of instruments.

All microbalance and platform balance are calibrated annually by qualified service engineers. On a weekly basis, the calibration of the balances are verified with standard weights.

All other service and maintenance needed by our laboratory for instruments and equipments are referred to their corresponding manufacturers. Based on yearly service expenses of the past years, sufficient amount budgeted annually to cover any future costs.

With the exception of Tracor Instruments which is located in Texas, all other manufacturers of our instruments could provide service within 48 hours after notification. Tracor has no local service representative so they take approximately one week before they send a serviceman.

The laboratory maintains a log book on instrument maintenance and repair for all major equipment used in the laboratory. It contains records on when an instrument is maintained and/or serviced, who provided the service, and what actions were taken.

VOL 12

1 8604

X. Assessment of Accuracy and Precision

Accuracy

Accuracy means the nearness of a result or the average of a set of result to the true value. Accuracy is represented by the percent recovery (R) if an analyte from a given matrix using a specific method. The percent recovery may be calculated as:

$$R = \frac{A-B}{T} \times 100\%$$

where: A is the calculated concentration of the analyte in the spiked matrix after analysis

B is the background concentration of the analyte in the matrix blank, if any.

T is the known value of the analyte spiked in the matrix blank.

To set the accuracy control limits of an analyte in a given matrix using a specific method, calculate the average of R values ($\bar{R}$) and their standard deviation (S_r). The accuracy control limit as recommended by the EPA is then defined as:

$$RLCL = \bar{R} - 2S_r$$

$$RUCL = \bar{R} + 2S_r$$

where: RLCL is the accuracy lower control limit
RUCL is the accuracy upper control limit.

Precision

Precision is the measurement of agreement of a set of replicate results among themselves without the assumption of any prior information as to the true value. Precision is measured using replicate or duplicate sample analysis. Precision as relative percent difference (RPD) is calculated as:

$$RPD = \frac{X_1 - X_2}{X} \times 100\%$$

where: X_1 and X_2 are results of duplicate analyses

X is the average of X_1 and X_2

As recommended by EPA, the laboratory's precision limit is ±20%.

VOL 12 1 8605

R0051910

Control Charts

Precision and accuracy control charts are maintained for at least 10% of the analytes (min. 3 and max. 10) for a given method using form 4. Control limits are initially set after 10 data points. Thereafter, limits are periodically set to reflect current performance.

VOL 12 1 8606

XI. Corrective Action

Corrective action is initiated in out-of-control situations. A situation is considered out-of-control if any of the laboratory's internal quality control samples (see section VII) are outside established limits, i.e.:

1. Method blanks are coming out positive for the analyte of interest signifying that the analytical system is contaminated.

2. Results of duplicate samples are outside the 20% limit.

3. Spike recoveries fall outside the established laboratory's accuracy control limits.

For any of the above conditions, the senior personnel assigned to the unit will be notified immediately. It is his/her responsibility to decide which of the following corrective actions must be taken:

1. The analyst provides additional information or recalculations.

2. Instrument calibration and operation are checked. Calibration standards are checked and new ones are prepared if necessary. Instrument malfunctions are corrected.

3. New reagents are used if needed.

4. The analyst repeats the analysis of spiked samples using the same method.

5. A different analyst repeats the analysis of spiked samples using the same method.

6. The analyst repeats the analysis of spiked samples using a modified or new method.

No laboratory result will be sent until the problem is solved. All out-of-control situations and the corrective actions taken are documented by the senior personnel and submitted to the laboratory supervisor and/or chief for review.

VOL 12

18607

VOL 12

1 8608

XII. Quality Assurance Report

On a monthly basis, senior personnel assigned to different units submit quality assurance reports for review by laboratory supervisor/chief. The reports contain a summary of the unit's QA activities during the period. The report includes the following information:

1. Date of analysis
2. Number of samples in the batch
3. Analytical batch number
4. Type of matrix
5. Analyte tested
6. Number of method blanks and results.
7. Number of matrix spikes and results
8. Number of duplicates and results
9. Detection limits
10. Name of analyst

In additon a copy of reports on out-of-control situations and corrective actions taken during the period are attached. The laboratory supervisor and/or chief reviews the QA report, signifies approval by signing them, and the reports are filed accordingly.

TABLE OF CONTENTS

VOL 12

1 8 6 1 3

QA OBJECTIVES

1. Establish the laboratory's ability to perform qualitative and quantitative microbiology testing of drinking water and wastewater by:

   - identifying the qualifications and responsibilities of laboratory personnel (in previous QA Manual);
   - enumerating the existing laboratory instrumentation and equipment used in microbiology testing together with the procedures for their service and maintenance to assure proper operation;
   - providing sources of analytical methods accepted by regulatory agencies for use in the laboratory.

2. Provide guidelines pertaining to sampling protocols, chain-of custody, and storage of samples to maintain sample integrity prior to analyses.

3. Define the laboratory's calibration procedures and frequency of calibration.

4. Identify all the necessary steps to validate the laboratory's results.

5. Define all the necessary quality control checks that must be followed prior to the analysis and/or in the course of analyzing samples.

6. Identify all laboratory records and information needed to document the quality of analyses performed in the laboratory.

VOL 12

SAMPLING PROCEDURES

Containers

Approved container for bacteriological sampling are presterilized Nasco Whirl-Pak bag or 4 oz. sterilized Nalgene or glass bottles. All samples containers must contain two drops of 10% sodium thiosulfate. One sample bottle from each batch of bottles prepared must be checked for sterility by adding several sterile tubes of single strenght lauryl tryptose and incubating for 48 hours and checking for growth.

Collection

Samples must be representative of the potable water distribution system. Water taps used for sampling are free of aerators, strainers, hose attachments, mixing type faucets, and purification devices. Maintain a steady water flow for at least 2 minutes to clear the service line before sampling. Collect at least a 100 mL sample volume, allow at least ½ inch air space to facilitate mixing of sample by shaking. Do not rinse sample container!

Holding/travel time between sampling and analysis is not to exceed 30 hours for potable water samples. If laboratory is required by State regulation to analyze samples after 30 hours and up to 48 hours, the laboratory is to indicate that the data may be invalid because of excessive delay before sample processing. No samples received after 48 hours are to be analyzed. Sample collectors who deliver samples directly to the laboratory should ice samples immediately after sample collection. All samples received in the laboratory are to be analyzed on the day of receipt.

Waste and surface water sample holding time is not to exceed 6 hours.

Labeling and Identification

Immediately after collection, the sample bottle must be labeled and the sample analysis request and report form filled out for each sample.

1. Sample Labels

   Samples labels are used for the specific identification of samples collected. Gummed paper labels affixed to the containers are adequate, but it should not be affixed to the sample lids. The labels should be filled

VOL 12 1/86/15

out at the time of collection and should include the following information:

Sampling Site
Name of Collector
Date and Time of Collection

2. <u>Sample Analysis Request and Report Form</u>

The sample analysis request and report form (exhibit 1) accompanies the sample when it is delivered to the laboratory. The collector should complete the field portion of this form by providing information on sample site location, sample type, purpose of the sample, date and time of collection, free chlorine residual, collector's initial, and any remains.

Upon receipt of the sample the laboratory will log-in the sample and at the minimum, the following information will be stored and maintained:

Date of Collection, Receipt, and Analysis
Time of Collection, Receipt, and Analysis
Receiving personnel initial
Client and/or System name
Sample Site location and/or description
Purpose of the sample
Assigned individual laboratory identify number
Name of the Analyst
Analysis Requested
Results of Analysis
Remarks on the sample (if any)

EQUIPMENT TEMPERATURE AND USE RECORD

Incubator Temperature

The total coliform incubator are maintained at 35± 0.5°c and have a thermometer graduated in at least 0.5°c increments. A daily log of the temperatures read to 0.1°c are kept together with the date the entry was made and the initial of the person making the entry (see exhibit 2).

Water Bath Temperature (For Fecal Coliform)

Similarly, the fecal coliform water bath are maintained at 44.5± 0.2°c and have a thermometer graduated in at least 0.2°c increments. A log of the temperatures when the water bath is in use read to 0.1°c are kept together with the date the entry is made and the initials of the person making the entry (see exhibit 3).

Sterilizing Oven Temperature

A thermometer immersed in a sand bath is kept inside the sterilizing over to monitor the temperature. Records of all items being sterilized, total sterilization time, and temperature are kept (see exhibit 4).

Autoclave

An autoclave/Sterilization log is maintained. The log includes the date, time in, time out, total elapsed time, sterilization time, items sterilized, sterility controls, maximum temperature reached, and any maintenance performed (see exhibit 5).

Certified Thermometer

All thermometers used in laboratory are crosschecked against a certified thermometer annually. Records of calibrations and corrections are maintained (see exhibit 6).

LABORATORY WATER QUALITY MONITORING

Bottled water is purchased from an outside source with an accompanying certificate of suitability. This is the water used to prepare the media. The parameters in the certificate include:

PARAMETER	LIMITS	FREQUENCY
Conductivity	>0.5 megohms resistance or <2 micromhos/cm at 25°c	Monthly
Pb, Cd, Cr, Cu, Ni, and Zn	Not greater than 0.05 mg/L per contaminant. Collectively, no greater than 0.1mg/L	Annually
Total Chlorine Residual	Nondetectable	Monthly
Heterotrophic	<500/mL	Monthly
Quality of Reagent	Ratio 0.8 - 3.0	Annually

Copies of the certificates of suitability are kept and maintained on file.

VOL 12

MEDIA PREPARATION

The attached exhibit 7 is completed for each batch of media prepared. The information included in the form are:

Data of preparation
Preparer's initial
Media prepared
Weight of dehydrated media taken
pH of autoclaved media
Test of media with positive/negative cultures
Sterility check

All completed media preparation forms are kept in a binder for easy reference.

ANALYTICAL PROCEDURES

Methods

The methods followed by the laboratory taken from Standard Methods for the Examination of Water and Wastewater, 16th edition, 1985 are:

Total Coliform by Multi-Tube Fermentation (MPN)	Method 908A
Fecal Coliform by MPN	Method 908C
Total Coliform by Membrane Filter (MF)	Method 909A
Fecal Coliform by MF	Method 909C

The outline forms of the above methods are attached as Appendix A of this supplemental manual.

Quality Control

1. For each bottle of media positive, negative, and sterile checks will be performed and a log of the check results will be maintained (see exhibit 8).

2. Positive and sterile checks will be performed for every batch of prepared media and a log of the check results will be maintained (see exhibit 9).

3. Positive and negative controls are ran with each analytical batch for EC test.

4. For each analytical batch tested by membrane filtration technique, a sterile control is ran at the beginning and end of the sample run, and a positive control is ran after the last sample.

5. For each lot of membrane filters, sterile and positive checks are ran.

6. The Completed Test must be done every three months or every positive confirmed potable water sample, which ever applies. A log of all positive potable confirmed sample is maintained.

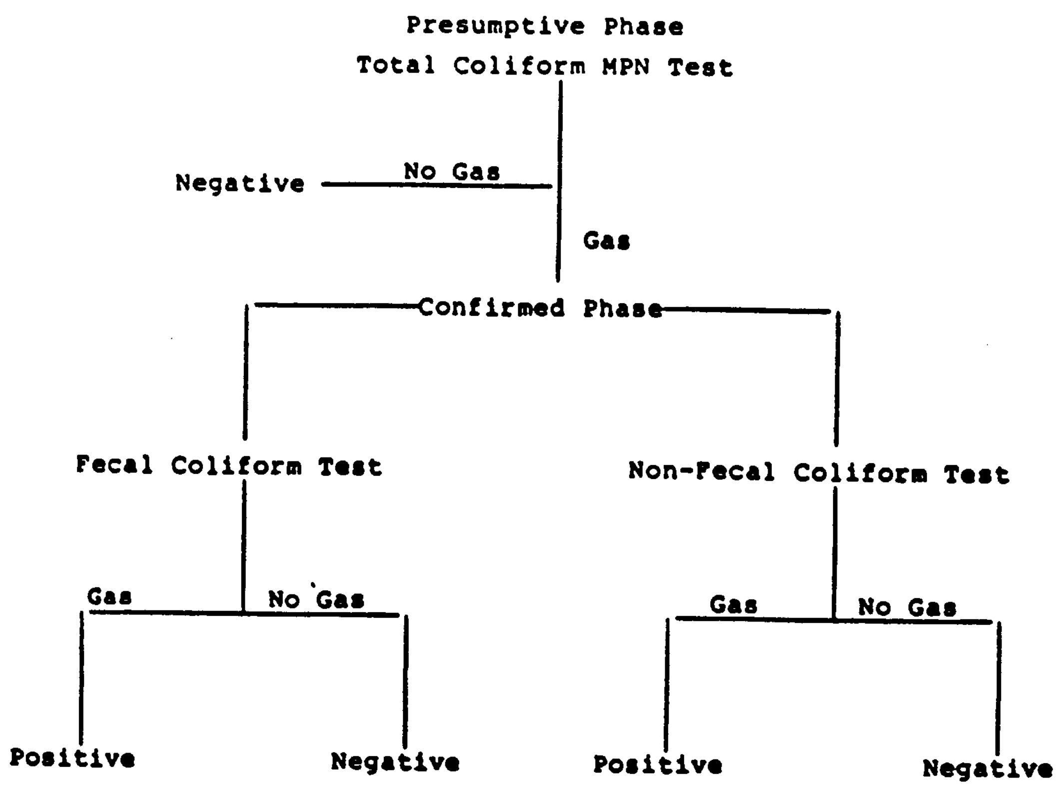
APPENDIX A: Methodology Outline

SUMMARY
OF
MULTIPLE-TUBE FERMENTATION TECHNIQUE
FOR THE COLIFORM GROUP



Effective Date: May 1991
Reference: Standard Method 908A

VOL 12

Total Coliform Multiple Tube Test

Reagents: Presumptive phase fermentation tubes with lauryl tryptose broth.

Quality Control:

Perform duplicate analyses on 10% of samples or at least one sample per test run.

Procedure:

1. Pipet ten 10 ml portions of the sample in a series of presumptive phase fermentation tubes; mix thoroughly.
2. Incubate fermentation tubes at 35± 0.5°c.
3. After 24± 2h, shake the tubes and examine for gas formation then take the following steps:

Gas Formation	Step To Proceed
Yes	Positive Test - continue to test for fecal and non-fecal coliforms.
No	Continue to step 4 below.

4. Continue incubating up to 48± 3h then again reexamine for gas formation.

Gas Formation	Steps To Proceed
Yes	Positive Test - continue to test for fecal and non-fecal coliform.
No	Negative Test - procedure completed

NOTE: For drinking and recreational water samples with heavy growth but no gas formation, continue on to test for non-fecal coliforms.

Calculation: See Calculation: Estimation of Bacterial Density

1

8633

Effective Date: May 1991
Reference: Standard Method 908

VOL 12

Fecal Coliform Test

Reagent: EC Medium Tubes

Quality Control:

Run one each positive and negative controls for each analytical batch.

Procedure:

1. Gently shake or rotate presumptive tube.
2. With a sterile 3 mm metal loop, transfer one loopful of culture to EC medium tubes.
3. Incubate tubes in a water bath at 44.5± 0.2°c for 24± 2hr. Be certain to Place all EC tubes in the water bath within 30 minutes after the transfer of the culture.
4. Periodically check the EC medium tube during the incubation period for any gas formation.

Gas Formation	Steps To Proceed
Yes	Positive - fecal coliforms present
No	Coliforms present are of non-fecal origin and next step will depend on the result of the non-fecal coliform test.

Calculation: See Calculation: Estimation of Bacterial Density

18634

Effective Date: May 1991
Reference: Standard Method 908A

Non-Fecal Coliform Test

Reagent: Brilliant Green Lactose Bile Broth (BGB) fermentation tube.

Procedure:

1. Gently shake or rotate primary fermentation tube showing gas.
2. With a sterile metal loop 3 mm in diameter, transfer one loopful of culture to a BGB fermentation tube.
3. Incubate BGB tube for 48± 3 hr. at 35± 0.5°c.
4. Periodically check BGB tubes during the incubation period for any gas formation.

Gas Formation	Steps To Proceed
Yes	Positive Confirmed Test - proceed to completed test for 10% of positive samples or at least one positive source water every quarter.
No	Negative Confirmed Test - procedure completed.

Calculation: See Calculation: Estimation of Bacterial Density

VOL 12

1 8635

R0051940

Effective Date: May 1991
Reference: Standard Method 9221D, 16th ed.

Calculation: Estimation of Bacterial Density

This method is used to calculate the Most Probable Number (MPN) of coliform/100 ml of sample.

No. of Tubes Giving Positive Reaction Out of 10 of 10 ml Each	MPN Index/ 100 ml	95% Confidence Limits (Approximate) Lower	Upper
0	<1.1	0	3.0
1	1.1	0.03	5.9
2	2.2	0.26	8.1
3	3.6	0.69	10.6
4	5.1	1.3	13.4
5	6.9	2.1	16.8
6	9.2	3.1	21.1
7	12.0	4.3	27.1
8	16.1	5.9	36.8
9	23.0	8.1	59.5
10	>23.0	13.5	Infinite

No. of Tubes Giving Positive Reaction Out of 5 of 10 ml each	MPN Index/ 100 ml	95% Confidence Limits Lower	Upper
0	2.2	0	6.0
1	2.2	0.1	12.6
2	5.1	0.5	19.2
3	9.2	1.6	29.4
4	16.0	3.3	52.9
5	16.0	8.0	Infinite

For volumes other 5ml or 10ml, use the following equation to solve for the MPN value:

$$\text{MPN value (from table)} \times \frac{10}{\text{Largest vol. tested}} = \text{MPN/100ml}$$

Note: MPN value is taken from table 9221:V of the Standard Methods.

Total Coliform Membrane Filter Procedure

Reagents: LES Endo Agar in petri dishes

Quality Control:

Run a sterile control at the beginning and end of the analytical batch and a positive control after the last sample.

Procedure:

1. Assemble filtration apparatus according to manufacturer's instruction.
2. Filter 100 ml sample under partial vacuum.
3. Rinse filtration apparatus with filter still in place with three 20 ml partions of sterile dilution water.
4. Remove membrane filter with a sterile forcep and place it on LES Endo Agar-filled petri dishes with a rolling motion to prevent entrapment of air.
5. Incubate dish for 22 to 24 hr. at 35± 0.5°c.
6. Count colonies that have pink to dark-red color with a metallic green-gold surface sheen using low-powered dissecting microscope.
7. Confirm all sheen colonies counted or a minimum of five colonies from drinking water samples by transferring growth from each colony to parallel tubes of lauryl tryptose broth and brilliant green lactose bile (BGB) broth.
8. Incubate both tubes at 35± 0.5°c for 48 hr.
9. Formation of gas in the BGB tubes confirms the colony as coliform. If only the lauryl tryptose broth showed any gas production, then transfer to a second BGB tubes. This second BGB tube must produce gas at 35± 0.5°c with 48 hr. to verify the colony as coliform.

Calculation:

$$\frac{\text{(Total) Coliform Colonies}}{\text{100 ml}} = \frac{\text{Coliform Colonies Counted X100}}{\text{ml sample filtered}}$$

95% Confidence Limits Using 100 ml Sample.

Number of Coliform Colonies Counted	95% Confidence Limits Lower	Upper
1	0.025	3.0
2	0.35	4.7
3	0.81	6.3
4	1.4	7.7
5	1.6	11.7
10	4.8	18.4

For counts, c, greater than 20 organism, the above limits maybe calculated by:

Upper Limit= $c + [2(2 + \sqrt{c})]$
Lower Limit= $c - [2(1 + \sqrt{c})]$

VOL 12

1
8638

Effective Date: May 1991
Reference: Standard Method 909C

Fecal Coliform Membrane Filter Procedure

Reagents: M-FC Broth

Quality Control:

Run a Sterile control at the beginning and end of the analytical batch and a positive control after the last sample.

Procedure:

1. Preparation of culture dish: Place a sterile absorbent pad in each culture dish and pipet approximately 2 ml M-FC broth to saturate the pad. carefully remove any excess liquid from culture dish.

2. Assemble filtration apparatus according to manufacturer's instruction.

3. filter 100 ml sample under partial vacuum.

4. Rinse filtration apparatus with filter still in place with three 20 ml partions of sterile dilution water.

5. Remove membrane filter with sterile forcep and place it on prepared culture dish in a rolling motion to prevent entrapment of air.

6. Seal petri dishes, submerge in water bath, and incubate for 24± 2h at 44.5± 0.2°c. Anchor dishes below water surface to maintain critical temperature requirements. Make certain that the petri dishes are in the water bath within 30 minutes after filtration.

7. Count colonies in various shades of blue using low powered microscope. These are colonies produced by fecal coliform bacteria.

Calculation:

$$\text{(Total) Coliform Colonies/100 ml} = \frac{\text{Coliform Colonies Counted X100}}{\text{ml sample filtered}}$$

95% Confidence Limits: The same as for Total Coliform Membrane Filter Technique.

<u>Presumptive Test for Fecal Streptococcus Group</u>

(Multiple-Tube Technique)

<u>Reagents</u>: Presumptive Phase Tubes with Azide Dextrose Broth

<u>Quality Control</u>:

1. Perform duplicate analyses on 10% of samples or at least one sample per test run.
2. Run Sterility Check and Positive Control with each batch of samples.

<u>Procedure</u>:

1. Pipet ten 10ml sample in a series of presumptive phase tubes: mix thoroughly.
2. Incubate tubes at 35 deg C ± 0.5 deg C.
3. After 24±2 hours, shake and examine tubes for turbidity then take the following steps:

Turbid	Step to Proceed
yes	Positive Test - continue to test fecal and non-fecal streptococcus.
no	Continue to step 4 below.

4. Continue incubating up to 48±3 hours then again re-examine for turbidity.

Turbid	Step to Proceed
yes	Positive Test - continue to test for fecal and non-fecal streptococcus.
no	Negative - procedure completed.

VOL 12

Membrane Filter Procedure for Fecal Streptococcus

Reagents: KF Streptococcus Agar

Quality Control:

Run a sterile control at the beginning and end of the analytical batch and a positive control after the last sample.

Procedure:

1. Assemble filtration apparatus according to manufacturer's instructions.

2. Filter 100ml of sample under partial vacuum.

3. Remove membrane filter with a sterile forcep and place it on directly to KF Streptococcus agar medium in petri dish with a rolling motion to prevent entrapment of air.

4. Invert culture plates and incubate at 35±0.5 deg C for 48 hours.

5. Count colonies that have dark red to pink color using a low power binocular, wide field dissecting microscope.

Calculation:

$$\frac{\text{Total Colonies}}{\text{100ml}} = \frac{\text{Colonies Counted X 100}}{\text{ml sample filtered}}$$

Waterbodies, Wetlands and their Beneficial Uses in the Los Angeles Region (4)

VOL 12

Volume 1. Waterbodies and their Beneficial Uses

A Report Presented to
L.A. Regional Water Quality Control Board

1 8645

Prem K Saint, Ted L. Hanes, William J. Lloyd
California State University, Fullerton

July, 1993

VOL 12 | 1 | 8646

EXECUTIVE SUMMARY

As a part of the Basin Plan update all the waterbodies, under the jurisdiction of the Regional Water Quality Control Board, Los Angeles Region, were evaluated for beneficial use designation. The investigation combined record search, field investigations and geographic information systems to recommend additions to the list of waterbodies and to designate appropriate beneficial uses. The study period, between summer 1991 and spring 1993, covered the last two years of a six-year drought and a winter of above normal precipitation and runoff in southern California.

The national Geographical Named Index System (GNIS) was utilized to compare their lists with the current waterbody inventory in the Basin Plans to produce a list of waterbodies to be added. We recommend an addition of 126 rivers, 44 lakes and reservoirs, 45 groundwater basins, 9 coastal features and 108 wetlands to the revised basin plan.

Wetlands are a new category of waterbodies as well as beneficial uses for the Los Angeles Region. Using the information in the National Wetland Inventory maps, the California Department of Fish and Game Natural Diversity Database we surveyed over 350 field sites for ecological and hydrological characteristics. We recommend the designation of WETLAND beneficial use for 15 estuarine and coastal wetlands, 14 lacustrine wetlands and 79 riparian wetlands.

During the last hundred years, as result of agricultural and urban development, the coastal plains of the Los Angeles Basin have experienced a loss of 90 % of the coastal marshes and 95-97 % of the riparian wetlands. The remaining wetlands provide habitat for rare and endangered species and sanctuaries for recreation for a dense urban population.

We recommend the expansion of the BIOL (Areas of Special Biological Significance), WILD (Wildlife Habitat) and GWR (Groundwater Recharge) designations as these apply to a highly urban Region such as Los Angeles. The uniqueness of the several remnant wilderness habitats in the waterbodies, especially with Rare and Endangered Species of animals and plants, would further protect water quality in these areas from pressures of urbanization.

We have identified and listed all the major groundwater basins and designated appropriate beneficial uses after consultations with managers of the water basins. We also acknowledge that the groundwater basins are recharged through influent streams and lakes in areas of bedrock in the surrounding hills and mountains. In order to protect the quality of our groundwater resources, which provide up to 70-80% of thr region's water supplies, we recommend that all those waterbodies in the recharge zones be designated as GWR.

Waterbodies, Wetlands and Beneficial Uses
of the Los Angeles Region

LIST OF TABLES

Acknowledgement

This project has been funded wholly or in part by the United States Environmental Protection Agency using Federal 201(G)(I)(B) grant funds under Assistance Agreement No. C9009532-90-2 to the State Water Resources Control Board and by Agreement No. 0-169-254-0 in the amount of $129,178 to conduct a Waterbody Identification and Update of Beneficial Use Designation study. The contents of this document do not necessarily reflect the views and policies of the U.S. Environmental Protection Agency and the State Water Resources Control Board, nor does mention of trade names or commercial products constitute endorsement or recommendation for use.

VOL 12 1 8 6 5 1

1. UPDATING THE WATER QUALITY BASIN PLAN

1.1. INTRODUCTION

Federal and State laws establish the requirements for adequate planning, implementation, management and enforcement for control of water quality. Two Federal laws that specifically address the water quality management are the Water Pollution Control Act of 1972, and the Clean Water Act of 1977. The state law that governs water quality in California is the Porter-Cologne Water Quality Act of 1969.

The Federal and State water quality planning requirements call for the development, and periodic update of, Water Quality Control Basin Plans. The Basin Plans for the Los Angeles Regional Water Quality Control Board were last updated in 1978.

According to the section 13050 of the California Water Code, a Basin Plan for an area consists of three components:

1. Establishment of Beneficial Uses that are to be protected,
2. Water Quality Objectives that protect those uses, and
3. Implementation Plan that achieves those objectives.

This project report deals with the first part of the process and evaluates the existing beneficial uses in the 1978 Basin Plans and recommends beneficial uses for additional waterbodies of the region.

1.2. SCOPE AND OBJECTIVES:

The study covers the Los Angeles Hydrologic Basin Planning Area, Region 4, of the State Water Resources Control Board. The region is roughly coterminous with Los Angeles and Ventura Counties (Fig 1.1). The objectives of the study are to evaluate all the waterbodies and their beneficial uses in the region and recommend additional waterbodies, designate and update beneficial uses.

The various tasks performed to achieve these objectives are as follows:

1. Comparison of Waterbody Inventories in the Basin Plans with the U.S. Geological Survey Geographical Named Index System (GNIS) and other available inventories, to produce a list of additional surface waterbodies to be added. The surface waterbodies consist of rivers, lakes, bays, harbors, estuaries and wetlands. The groundwater basins were classified according to the State Water Resources Bulletin No. 118.

2. Identification and Field Survey of Wetlands, as identified in the National Wetland Inventory Maps and in reports

of other agencies.

3. Selection of Waterbodies and recommendations for Wetlands, to be added to the 1993 Basin Plan.

4. Determination of lengths and areal extent of all existing and recommended waterbodies.

5. Determination of Beneficial Use Designations (Existing, Potential, Intermittent) for each of the newly added waterbody or segment, using field surveys and agency surveys.

6. Re-evaluation of Existing Beneficial Uses in the 1978 Basin Plans, using field surveys and agency surveys.

7. Preliminary Assessment of the portions of the Los Angeles and San Gabriel Rivers, to characterize the vegetation and other biota related to occurrence of fish in these reaches.

2. ORGANIZATION AND METHODS

The fieldwork, data analysis and mapping of the waterbodies was carried out from July, 1991 to March, 1993. An interdisciplinary team from the Departments of Biological Sciences, Geography and Geological Sciences at California State University, Fullerton, performed most of the tasks. The supervision of the various tasks was as follows:

Biology tasks by Dr. Ted Hanes,

Geographic Information System and Cartography tasks by Dr. Bill Lloyd,

Groundwater basin mapping and assessment tasks by Dr. John Foster, who also acted as the Co-Principal Investigator, and

Surface Water Hydrology and Water Quality tasks by Dr. Prem Saint, who also acted as the Principal Investigator.

Beneficial Use Designation and Update was a cooperative effort between members of the various teams.

Several graduate and undergraduate students were involved in doing field surveys, data assessment and cartographic work; the listing on the inside front cover identifies all those who participated in this project.

2.0. METHODOLOGY

Apart from literature review and data collection from agency surveys, most new information for decision making came from field surveys and Geographic Information System (GIS) Analysis.

VOL 12

1 8654

2.1. GIS Methodology

Creation of GIS Layers

Study Area:

The boundaries of the GIS study area was constructed by combining the boundaries of the various hydrologic subdivisions that comprise Region 4 of the Water Quality Control Board. The boundaries of the individual Hydrologic Units, Hydrologic Areas and Hydrologic Subareas were digitized from mylar reproductions of U.S.G.S. 7.5 minute U.S.G.S. quadrangle maps provided by the W.Q.C.B. Basin boundaries and basin identifiers were clearly marked on the mylar maps for all areas except the Channel Islands. Island boundaries were digitized from U.S.G.S. 1:100000 scale topographic maps and assigned identifiers based on existing reports from the W.Q.C.B. All basins with identifiers beginning with the number "4" were included in a DRBASIN layer. These individual basins were then collapsed into a SUBREGIONS layer containing 10 groups of closely related basins, and a STUDY AREA layer containing all of the Region 4 basins.

Basin boundaries and all other geographic information in the GIS data base were projected into Universal Transverse Mercator (UTM) Zone 11 coordinates where necessary.

Streams:

STREAMS layers for each of the individual basins were created by clipping out all of the stream features for each basin from the U.S.G.S. 1:100000 digital line graphs. Stream segments were numbered in upstream order for each separate drainage contained within a basin. A computer program was developed which permitted naming of the streams through reference to data contained in the U.S.G.S. Geographic Names digital file. Names were cross-checked by referring to the 7.5 minute U.S.G.S. topographic quadrangle maps. Any named stream appearing on the 7.5 minute quad which was not included in the 1:100000 digital line graph data was added to the STREAMS layer by digitizing from the 7.5 minute quads.

In many cases, the precise channel followed by a tributary when it reaches a main stream cannot be determined and have not been mapped by the U.S.G.S. Where the gap between tributary and main stream was less than approximately 500 meters, the tributary was extended to the nearest point on the main stream. In rare instances where the gap was substantially larger than 500 meters, the tributary was retained as a separate, unconnected drainage.

Information from the digital line graph data and from the 7.5 minute quads was used to classify each stream as either permanent or intermittent.

VOL 12

1 8655

Lakes:

A LAKES layer for each of the basins was created by digitizing all lake and reservoir features for each basin from the U.S.G.S. 7.5 minute topographic quadrangle maps. Lake and reservoir features from the U.S.G.S. 1:100000 digital line graphs were added to the data base in cases where the date of the DLG data was later than that of the 7.5 minute quad. Lakes and ponds with areas less than 1 acre were omitted from the LAKES coverage. All features for each basin were assigned a unique number and all named features were also assigned their name based on the U.S.G.S. Geographic Names file and the U.S.G.S. 7.5 minute topographic maps.

Information from the digital line graph data and from the 7.5 minute quads was used to classify each feature as either permanent or intermittent, manmade or natural.

Coastal Features:

Coastal features were selected from a list of all named coastal features contained in the U.S.G.S. Geographic Names file. The locations of shoreline features were digitized into a COASTAL layer from 7.5 minute U.S.G.S. topographic quadrangle maps.

Features were classified as either estuaries, oceans\bays or harbors.

Wetlands:

Riparian wetlands were digitized from U.S. Fish and Wildlife Service 7.5 minute quadrangle maps into a RIPARIAN layer. Coastal wetlands were outlined on 7.5 minute U.S.G.S. topographic quadrangle maps and digitized into an AREA WETLAND layer in the GIS data set. Inland lacustrine wetlands were copied into the AREA WETLAND layer from the LAKES layer.

Water Quality Monitoring Stations:

The locations of water quality sampling and monitoring stations were derived from latitude and longitude information contained in a list of all stations within the study area. The latitude and longitude values were projected into UTM Zone 11 coordinates in a SAMSTN layer.

Field Sites:

The locations of field photograph sites were digitized directly into an FSITES layer from site locations indicated on U.S.G.S. 7.5 minute topographic quadrangle maps.

VOL 12

Identification of Included and Proposed Features

All streams and lakes were classified as either "included" or "missing" based on whether or not they were identified by name in the existing Beneficial Use plan of the Regional Water Quality Control Board. Some streams which were indirectly included in the existing plan by virtue of the tributary rule were given the designation "tributary." The classification was accomplished by developing a computer program which compared the names of all features in each basin with a list of features that has been assigned beneficial uses in the existing plan. Reports were then created listing all streams and tributaries in upstream order by basin. Separate reports were prepared for all lakes. These reports, containing the feature name, included/missing designation, and a permanent/intermittent designation, were then used in the identification of candidate features for inclusion in the revised Beneficial Use plans.

A small number of the "missing" streams and lakes were changed to "proposed" when a decision was made to include them in the new Beneficial Use plans. All "included" and "proposed" streams and lakes were then merged into a single BENEFICIAL USE GIS data base spanning all of Region 4.

"Included" and "proposed" coastal features were identified directly from the master list of all coastal features. These features were then merged into the BENEFICIAL USE data base.

"Included" and "proposed" wetland features were also merged into the BENEFICIAL USE data base.

Finally, the SAMPSTN and FSITES layers were merged into the BENEFICIAL USE data base.

18556

Attaching Beneficial Uses

Each "included" or "proposed" stream, lake, coastal features and wetland was assigned a unique GIS identifier. A data base file was then created which contained the identifier, the feature name, feature type and basin identifier. This data base file was then expanded to include existing and proposed beneficial use designations. After completion of the beneficial use tables, the data can then be joined back into the GIS using the unique GIS identifier as a linking field.

2.2. FIELD SURVEYS

During the summer of 1991, field survey forms were designed (Appendix A.1.), and several field ecologists were trained by Dr. Hanes to carry out field surveys. As part of the survey, field stations were photographed and data collected on hydrological and ecological characteristics of the site. USGS 7.5 minute topographic maps were used in the field to record field sites. All field forms and photographs are presented as Appendix 1 (bound separately).

Hydrological observations included the presence of water, depth, width and flow characteristics. Approximate discharge was measured using float method, and in some cases, current meter method. Channel characteristics, including degree of erosion were also recorded. Occasionally water quality was measured for field temperature and electrical conductivity.

Ecological observations included floral and faunal information. For vegetation surveys sites were reconnoitered by driving or hiking a large enough area to become familiar with the communities present. Stands best representing each community were chosen and sampled by quadrant- or belt-transect method, for estimating species composition by percent cover. Techniques described in the *Federal Manual for Identifying and Delineating Jurisdictional Wetlands, 1989,* was used in the determination of the presence of hydrophytes.

Animal observations consisted of bird sightings (especially obligate wetland habitat birds, like Belted Kingfisher and Osprey), and noting the presence of fish and amphibians.

After summer 1993, more intensive surveys of beneficial uses were carried out using form type Appendix A2. Over 350 sites were surveyed as part of the field investigations.

2.3. AGENCY AND INTEREST GROUP SURVEYS

A list of 50 agencies and interest groups was compiled in cooperation with the Regional Water Quality Control Board staff. Three surveys were conducted using the survey forms, included in Appendix B.1.

(i) Existing Beneficial Use Survey for existing waterbodies,
(ii) Proposed Beneficial Use Survey for Coastal Waters,
(iii) Proposed Beneficial Use Survey for Groundwater Basins.

There were 27 responses and the summary of responses is included in Appendix B.2.There were follow-up telephone calls for clarification of comments, as indicated in the summary of responses. The comments were incorporated in planning future field surveys for beneficial use investigations. Copies of the agency survey responses are included in Appendix 2, bound separately.

3. HYDROLOGIC AREAS AND SUB-AREAS OF THE LOS ANGELES REGION SUB-REGIONS OF THE REGION 4

For the purposes of this investigation, the Region 4, Los Angeles Region, was subdivided into ten subregions (Fig 1.0). The subregions are:

A. Pitas Point Ventura

B. Sespe Creek

C. Piru Creek

D. Upper Santa Clara River

E. Oxnard Plain- Santa Paula- Calleuguas- Conejo

F. San Fernando Valley

G. Raymond- San Gabriel- Spadra- Anaheim

H. Coastal Plain

I. Malibu

J. Channel Islands

Each sub-region is divided into a number of Hydrological Units(HUs), Hydrological Areas (Has) and Hydrological SubAreas (HSAs). The boundaries of these divisions for each sub-region are shown in Fig 1.1- 1.10. The criteria for the division into the sub-regions included uniformity of hydrological and landuse and water use conditions as well as convenience of sizes for map reproduction purposes. Many of the subregions are similar to those identified and described in the 1978 Basin Plans (LARWQCB, 1978).

3.1. EXISTING AND PROPOSED WATERBODIES

Fig 1.1- 1.10 also identify the streams, lakes and reservoirs that were listed in the 1978 Basin Plan and those that are proposed for addition to the 1993 Basin Plan. The additional waterbodies, listed as proposed, were agreed upon between the Regional Board staff and California State University, Fullerton investigation team. The criteria used for proposed waterbodies were:

(a) perennial flows,
(b) size of the tributary,
(c) areas of special biological significance,
(d) areas with wilderness and wetland habitats,
(e) areas with reported rare and endangered species,
(f) waterbodies with stream gaging and water quality monitoring stations,
(g) waterbodies with significant landuse or wateruse.

Table 1.0 lists all the named surface waterbodies of the Region 4, by Hydrologic Units, and indicates whether a given waterbody is included in the 1978 Plan, or is proposed for the 1993 Plan. The table also indicates the type of waterbody, according to the following scheme:

stream, includes rivers and streams, without significant riparian wetlands.

riparian stream, includes rivers and streams, with riparian wetlands (riverine and palustrine), proposed for inclusion in the wetland category.

lake, includes lakes and reservoirs, without significant lacustrine wetlands.

inland wetland, includes mostly lakes, reservoirs and swamps, with lacustrine and palustrine wetlands, proposed for inclusion in the wetland category.

beach/bay, estuary, include coastal features, without significant coastal wetlands. These also include tidal prisms of the 1978 Plan.

coastal wetland, includes estuarine and palustrine wetlands, proposed for inclusion in the coastal wetland category.

islands, includes waterbodies of the Channel Islands, with no significant streams, lakes and reservoirs.

biolsig refers to areas of special biological significance, as approved by the Regional Water Quality Control Board.

3.2. WATERBODY DIMENSIONS AND FLOW CHARACTERISTICS

Table 2.1. lists all the named rivers and streams, included or proposed, and with measures of stream length and channelized streams, in miles. Channelized streams include portions with concrete sides and/or bottoms.
The table also lists streams that are intermittent (I), or permanent (perm), identified by interpretation of USGS 7.5 minute maps, and several verified through field inspections. The table also identifies streams with significant riparian wetlands, proposed for inclusion in the wetland category.

Table 2.2 lists all the lakes and reservoirs, included or proposed, with areal extent, in acres. It also lists lakes and reservoirs that are intermittent or permanent, as identified by map interpretation and several verified through field inspections. The table also identifies lacustrine wetlands, proposed for inclusion the wetland category.

Other tables include: Table 2.3 Groundwater Basins
Table 2.4 Wetlands

The computer aided measures of lengths and areas were checked for accuracy, using manual instruments like planimeter and stadiometer. The calculations were found to be within the domain of reasonable accuracy.

Included means that the waterbody was included in the 1978 Basin Plan of the Los Angeles Water Quality Control Board.

@ The length includes the total length of the river. Wetland conditions exist in portions of the rivers.

VOL 12

3.3. COASTAL FEATURES

The coastal features, shown in Fig. 2.1- 2.5, and listed in Table 2.5. include beaches, bays, harbors, estuaries, and coastal wetlands of the mainland and islands of the Channel Islands.

The names of these features are obtained from:
- 1978 Basin Plan
- USGS Maps
- L.A. Department of Beaches and Harbors maps.

Also shown on the maps are features called 'nearshore zones', 'other nearshore zones', and Areas of Special Biological Significance (ASBS).

The 'nearshore zone', as defined in the 1978 Basin Plan (LARWQCB, 1978), is " bounded by the shoreline and a line 1,000 feet from the shoreline or the 30-foot depth contour, whichever is further from the shoreline." The 'other nearshore zone' would be the nearshore area other than the coastal features named on the maps.

An estuary is a semi-enclosed coastal feature, with a free connection with the open sea, and within which seawater is mixed with freshwater, derived from land. Estuarine conditions exist at the mouths of the Ventura River(Fig 2.1), the Santa Clara River and the Calleuguas Creek (Fig 2.2), Zuma Creek and Malibu Creek (Fig 2.3), Ballona Creek, Dominguez Channel, Los Angeles River and San Gabriel River (Fig 2.4). The 'tidal prism' feature, listed in the 1978 Basin Plan, is the salt water wedge along the bottom of the river mouth, due to density differential, and is a part of the estuary. We recommend that the 'tidal prism' be correctly referred to as the 'estuary', and that an estuarine (EST) beneficial use be assigned accordingly.

The Areas of Special Biological Significance (ASBS), shown on the coastal feature maps, were selected by the Regional Water Quality Control Board. These ASBS contain "biological communities of such extraordinary, even though unquantifiable, value that no acceptable risk of change in their environment as a result of man's activities can be entertained." (SWRCB, 1972) The waterbodies contained in the ASBS would qualify for BIOL as a beneficial use.

The Coastal Wetlands, listed in Table 2.4a include estuarine and palustrine (and not marine) wetlands and are described, in detail in the Volume 2 of the report subtitled: Wetlands and their Beneficial Uses.

3.4. GEOLOGY AND GROUNDWATER RESOURCES

Geology plays an important role in defining the physiography, surface water and groundwater hydrology and water quality in the region. There may also be some correlation between the occurrence of various riparian vegetation wetland habitats (Fig 6.0-6.9) and physiography and geology. The general geology of the Region 4 is depicted in Fig 3.0-3.9 and the associated groundwater basins are shown in Fig 4.0-4.9.

The pre-Cretaceous Pelona Schist and igneous and metamorphic rocks form the basement complex, are exposed in the San Gabriel Mountains, Sierra Pelona, Liebre and Alamo Mountains. These mountains are the source areas and upper reaches of San Gabriel River, Santa Clara River and Piru Creek. Surface water and groundwater associated with these rocks has low total dissolved solids and are largely calcium-bicarbonate type waters. Groundwater occurs and moves through fractures, and becomes part of deep percolation, with recharge from precipitation and stream infiltration. Most of the streams in these areas would qualify for groundwater recharge (GWR) as their beneficial use.

Cretaceous and Tertiary sediments consist largely of marine shales, siltstones, sandstones and conglomerates, exposed in the Puente Hills, Palos Verdes Hills, Santa Monica Mountains, Simi Valley, Topa Topa and Sulphur Mountains and in the upper reaches of the Ventura River and Sespe Creek. The waters are largely calcium-sulphate and calcium-bicarbonate types. The Tertiary volcanics, exposed in the Santa Monica and Conejo Mountains, are sources of local groundwater in these regions.

Most of the usable groundwater occurs in the Quaternary non-marine and alluvial sediments, which occur in the alluvial filled valleys and coastal basins. The groundwater basins, shown in Fig 4.0-4.9, are named after California Department of Water Resources (DWR) Bulletin 118. The bedrock, with dark shading, surrounding the groundwater basins, with light shading, has been labeled as 'Non-water bearing' in most DWR bulletins. This is a reflection of the 1950s thinking when resource hydrogeology was of major concern. Major solid waste disposal landfills (Puente Hills, BKK, Stringfellow Quarry, and others) were sited on the bedrock and some have become sources of groundwater pollution through fracture flow in connection with the alluvial filled valleys and basins. We recommend the use of the term 'mostly bedrock' in preference to 'non-water bearing' in the groundwater maps.

In the Ventura and Santa Clara River valleys,(Fig 4.0-4.4), groundwater basins form a string of alluvial filled basins, where groundwater movement is largely from the upper basin to the lower basin. The basins of the Ventura River (Fig 4.1) are: Upper Ojai, Ojai, Upper Ventura and Lower Ventura. In the Santa Clara River, from upstream to downstream, these include Acton Valley, Bouquet, Placerita and Castaic Canyons (Fig 4.4), Piru, Filmore and Santa

VOL 12

18733

Paula, Mound Basin and Oxnard Plain (Fig 4.5). In the Colleguas-Conejo valleys, the tributary groundwater basins to the Oxnard Plain are Simi, Las Posas and Pleasant Valleys. In the upper valleys the aquifer thickness is shallow, (100-300 ft.), with mostly unconfined aquifers. There are several reaches of rising groundwater in the Santa Clara River, giving rise to a corridor of continuous riparian vegetation (Fig 6.0).

In the coastal Oxnard Plain groundwater basin, site of agricultural, industrial and urban development, there are multiple aquifers and most of the groundwater is under confined conditions. Groundwater formations within the basin, from top to bottom, are the semi-perched zone, the Oxnard, Mugu, Hueneme, Fox Canyon and Grimes Canyon aquifers. This is one of the few areas in Region 4 where hydrogeologic information is available to allocate distinct beneficial uses to each aquifer.

The major groundwater basins, in the eastern part of the Los Angeles county, belong to two inland valleys, San Fernando Valley and San Gabriel Valley, and a coastal plain, with Central, West Coast and Santa Monica Basins (Fig 4.0).

The San Fernando subregion, consists of Upper Los Angeles River Area(ULARA), with four distinct groundwater basins: the Sylmar, Verdugo, Eagle Rock and San Fernando Valley (Fig 4.6). The Sylmar and Verdugo are tributary groundwater basins to the San Fernando Valley. Groundwater occurs under unconfined conditions in the alluvium and confined conditions in the bedrock. San Fernando Valley is a major groundwater basin, supplying water for municipal (MUN), industrial(IND), processing(PRO) and agricultural (AGR) uses, and recharged through a number of artificial recharge basins, located in the Tujunga and Pocoima Washes. Groundwater flow is largely from west to east, towards pumping well fields in the Crystal Springs area, near Griffith Park. South of the well field, groundwater flows towards the Los Angeles narrows, an area of rising groundwater resulting from shallow bedrock. The area supports riparian wetland vegetation in the unlined channel of the Los Angeles River.

The Main San Gabriel Basin (Fig 4.7), with its tributary Raymond, Chino, Spadra and Puente Basins, is a major groundwater producer for municipal, industrial, processing and agricultural uses. Groundwater movement is towards pumping well fields, and south towards Whittier Narrows, an area of rising groundwater, due to shallow bedrock. The area supports riparian and lacustrine wetland vegetation.

The Coastal Plain subregion has four groundwater basins: Central, West Coast, Santa Monica and Hollywood Basins (Fig 4.8). The Central Basin, separated from the West Coast Basin by Newport-Inglewood Fault, is recharged by percolating waters from the San Gabriel River, the Rio Hondo and the Los Angeles River in the Montebello and Los Angeles Forebay areas. Beyond the forebays, the groundwater is under confined conditions and flows towards pumping well fields and towards the West Coast Basin. As in the Central Basin, groundwater occurs in a number of deep aquifers. Rising groundwater from shallow aquifers were responsible for extensive historical coastal and inland wetlands. Ballona Estuary and Wetlands are fed by groundwater flows from Santa Monica Groundwater Basin.

Groundwater in the Malibu subregion (Fig 4.9) occurs in the thin alluvial fill valleys of the coastal streams, in the volcanics and in fractures of the Topanga and Modelo bedrock formations. Groundwater resources are limited. They are recharged from precipitation and urban runoff, and flow south, along the stream gradient, towards the ocean.

3.5. STREAM CHANNELIZATION

As a result of urbanization of the region, flood control measures resulted in the construction of several dams and concrete channels. Figures 5.0-5.9 depict the location of the channelized and natural stretches of the streams. Channelized streams include river sections, with or without concrete linining. The information for these maps was obtained from Los Angeles County and Ventura County Flood Control District offices, U.S. Geological Survey maps, and verified through field surveys,

The stretches of maximum channelization are in Oxnard Plain (Fig 5.5), San Fernando Valley (Fig 5.6), San Gabriel Valley (Fig 5.7) and the Coastal Plain (Fig 5.8).

The beneficial use effects of channelization are:

(a) Loss of groundwater recharge capabilities, as in the foothills in San Gabriel and San Fernando Valleys,

(b) Loss of Riparian Wetlands, as in the middle reaches of San Gabriel and Los Angeles Rivers,

(c) Loss of Recreation (REC-1 and REC-2) facilities in fenced off, concrete-lined channels, with precipitous side slopes.

4.0 OTHER MAPS RELATED TO BENEFICIAL USE DETERMINATION

4.1. RARE FIND MAPS

Figures 6.0-6.9 are depiction of riparian and other wetland vegetation and sitings of rare and endangered species of animals, as contained in the Rare Find database. The Rare Find computer database is a part of the California Department of Fish and Game Natural Diversity Database. It contains 1:100,000 basemaps, with computer printouts, containing information on endangered, threatened and rare plants and animals, and vegetation communities considered to be of special concern. The database is updated on an annual basis; the one used for this study covered the period of

VOL 12

18735

June 1991 to June, 1992.

The species represented on the map are: birds, insects, fish, reptiles, mammals and plants. The vegetation communities of concern represented are varieties of marsh, scrub, forest and woodland. Some of these communities are described in detail in the wetland volume the report. Since the Rare Find database is limited to the sitings reported by various investigators, inaccessible areas, like the Condor Sanctuary, the Piru and Sespe Creek Basins have major data gaps. Similar gaps may exist in the Santa Monica Mountains and the San Gabriel Mountains.

The Rare Find database was used to allocate RARE, WILD and BIO beneficial uses to waterbodies, covered by these maps. These could also be used to demarcate stretches of streams that may contain riparian wetlands.

4.2. WETLAND MAPS

As described in the wetland section of this report, a number of waterbodies are recommended for allocation of wetland (WET) beneficial use. Three types of wetlands depicted on these maps are: Riparian Wetlands, Lacustrine Wetlands and Coastal Wetlands. Figures 7.0-7.9 show the location of recommended wetlands. Since the coastal and lacustrine wetlands have a limited areal extent, their location is accurate on these maps. For riparian wetlands, the maps show the whole stream or tributary containing significant wetland stretches. The approximate location of the stretches can be determined by comparing the information on Rare Find maps (Figure 6.0-6.9). Table 2.4 gives a list of recommended wetlands and their acreage or mileage.

4.3. WATER QUALITY SAMPLING STATIONS

Water Quality Sampling is performed on a regular basis by the LA Regional Water Quality Control Board. This is a part of the water quality assessment program, under the California Clean Water Strategy and the Federal Clean Water Act.

Figure 9.0 shows the location of Water Quality Sampling Stations in Region 4.

4.4. WATER QUALITY ASSESSMENT MAPS

Figures 10.0 to 10.9 show the water quality assessment designation for various waterbodies in Region 4. The classifications are defined as follows:

Good: Water supports and enhances the designated water use,

Intermediate: Water generally supports beneficial use, with occasional degradation in water quality,

Impaired: Waterbodies cannot reasonably be expected to attain or maintain applicable water quality standards.

CHAPTER 5: BENEFICIAL USES

Beneficial uses, simply put, are the many ways water can be used by the people and/or by the wildlife. In the Statewide Policy of Water Quality (1967), the State Water Resources Control Board defined beneficial uses of water as "that use of water that is in general productive of public benefit and which promotes peace, health, safety and welfare of the people of the State." Section 13020 et seq of the California Water Code identified uses of water as follows:

" 'Beneficial uses' of waters of the state may be protected against quality degradation include, but are not necessarily limited to, municipal, agricultural and industrial supply; power generation; recreation; aesthetic enjoyment; navigation; and preservation and enhancement of fish, wildlife and other aquatic resources or preserves."

Section 303 of the Clean Water Act (PL 92-500, as amended) defines water quality standards as consisting of both the uses of the waters involved and the water quality criteria which are applied to protect those uses. Under the Porter Cologne Water Quality Control Act (California Water Code, Division 7), these concepts are separately considered as beneficial uses and water quality objectives.

For the Basin Planning effort, the State Board adopted, in 1972, a uniform list of description of beneficial uses to be applied to all waters. The complete list and definitions are contained in Table 4.0. To the original 21 beneficial uses three more were subsequently added and include Aquaculture (AQUA), Wetland Habitat (WET) and Estuarine (EST). For the purposes of this report the 24 beneficial uses are considered for allocation to the various waterbodies in the region.

1895

5.1. DECISION CRITERIA FOR BENEFICIAL USE DESIGNATION

The various elements in the decision process for the designation of beneficial uses is summarized in Figure 8.

Literature review consists of a survey of publications, regulations, consulting and research reports.

Regional Water Quality Control Board Basin Plans include those from the Los Angeles Basin as well as the Santa Ana Region(for comparison).

The Los Angeles Regional Water Quality Control Board 1975 Water Quality Control Plans 4A (Santa Clara Basin) and 4B (Los Angeles Basin) contain beneficial use tables 4, 5 and 6. According to our guidelines, beneficial use could only be added or upgraded (not removed), except in extremely rare instances where it can be documented that a gross error was made in assigning these uses in 1975. Beneficial uses could not be de-designated because of water quality impairment.

The Management Memorandum No. 20 (MM-20) lists four steps in the planning strategy for water quality management. These are:

1. Establishment of beneficial uses
2. Establishment of water quality objectives
3. Classification of waterbody segments for water quality and effluent limitation allocation
4. Development of alternative water quality management plans.

The MM-20 also includes tables for evaluating quality of water required for the following beneficial use categories:

Municipal (MUN)
Water contact recreation (REC-1)
Non contact recreation (REC-2)
Fresh water habitats (WARM, COLD, SPWN, MIGR, WILD)
Saltwater habitats (COMM, MAR, SAL, SHELL, SPWN, MIGR)
Agriculture (AGR), including irrigation and livestock

The Natural Diversity Database of the California Department of Fish and Game, covering the period of June 1991 to June 1992 was used to allocate RARE, WILD and BIO and WET categories of beneficial uses.

Landuse maps, including the maps of concrete and channelized river reaches (Figs 5.0- 5.9) were used to evaluate the compatibility of the various beneficial use designations to landuses.

Los Angeles Regional Water Quality Control Board Resolution No 89-03 was used to determine the MUN designation of all the waterbodies. According to this resolution all waterbodies not listed in the 1978 basin plan beneficial use tables 4, 5 and 6, were given a MUN designation. The State Water Resources Control Board Resolution No 88-63, which is the basis for the LA Regional resolution, further states that:

" All surface and ground waters of the State are considered to be suitable, or potentially suitable, for municipal and domestic water supply and should be so designated by Regional Boards". The exceptions are waters with total dissolved solids of more than 3000 mg/l, or untreatable contaminated waters or groundwaters which are not capable of producing 'an average, sustained yield of 200 gallons per day'.

Field surveys were conducted to document the existing conditions of habitats, erosion, diversions and usage of the existing and proposed waterbodies in the basin. The methodology is described in section 2.2 and the field survey forms are included in Appendix 2.

Public Agencies and Interest Group Surveys were conducted to seek the comments to our proposed designations of beneficial uses. The methodology is described in section 2.3 and the summary of comments is included in Appendix 3. The footnotes in the beneficial use tables (Table 4.1, 4.2) include the lists of agencies and interest groups whose comments were incorporated in our beneficial use recommendations.

5.2. BENEFICIAL USE RECOMMENDATIONS

Our recommended beneficial uses are presented as follows:

Table 4.1. Groundwater Resources

Table 4.2. Surface Water Resources

The groundwater resources include the groundwaters contained in designated groundwater basins (Fig 4.0-4.9) and 'other' groundwaters contained in the fractures and pore spaces of basin tributary valleys and bedrock. The occurrence and distribution of groundwater resources is described in section 4.7.

The surface water resources include rivers, lakes and reservoirs, coastal features and wetlands.The occurrence and distribution of the surface waters are described in sections 4.3 (rivers), 4.4 (lakes and reservoirs), 4.5 (coastal features), and 4.6 (wetlands).

5.2.1. Groundwater Resources (Table 4.1)

We recommend that the groundwater beneficial uses be designated according to the various basins as contained in Table 4.1. In the case of Oxnard and Pleasant Valley HSA's where enough information is available, beneficial use designation for the individual aquifers be included. This is consistent with the existing 1975 Basin Plans. An attempt was made to explore the feasibility of this scheme for the well defined aquifers in the West Coast Basin (HSA 405.12), and Central Basin (HSA 405.15). The multiple aquifer source of water in many wells in these basins makes the beneficial use designation by aquifers, quite impractical.

We recommend that 'all other groundwater' designation apply to all waters not included in the basins, to protect the groundwaters in the bedrock and tributary creeks. There are small supply wells in these areas which also form the recharge zones for the major basins.

5.2.2. Surface Water Resources (Table 4.2 and footnotes)

We recommend that the Municipal(MUN) designation be added to all the waterbodies that qualify for such designation, according to State Water Resources Control Board Resolution 88-63 and LA-RWQCB Resolution 89-03. The waterbodies are identified in Table 4.2.

We recommend that Groundwater Recharge (GWR) designation be added to all the rivers, lakes and reservoirs, located in the recharge zones of the various basins. In these areas, listed in Table 4.2, recharge occurs naturally through infiltration of precipitation, stream and lake waters through fractures and other pores.

VOL 12 1 8797

We recommend that the designation BIOL be expanded to include waterbodies other than those legally declared as Areas of Special Biological Significance (ASBS). Several waterbodies with rare and endangered species and those with wetlands, as identified in table 4.2, have unique ecological features to make them biologically significant. Some individual field observations and agency survey responses give further details.

We recommend that all the waterbodies included in the California Department of Fish and Game Rarefind and Natural Diversity Database, as shown in Table 4.2, be designated under RARE beneficial use category. The footnotes of the table 4.2. give details of the individual animal and plant listings.

We recommend that all the river mouths and tidal prisms, displaying estuarine conditions, and so identified in Table 4.2, be designated as EST.

We recommend that all the rivers, lakes and estuaries, displaying wetland hydrology, soil and vegetation conditions, and so identified in Table 4.2. be designated as WET category.

5.3. Comments on individual waterbodies and hydrological areas

The extensive footnotes for table 4.2. identify the sources of agency comments and the identity of the animals, rare plants and vegetation communities of interest, contained in the Rarefind Database. The following are excerpts from field observations, literature review and agency responses.

The Pitas Point HU consists of mountainous terrain, with many small canyons, with intermittent streams. Javon Creek, however, has several sections of perennial flow. According to the response from the Friends of Ventura River, this water provides existing wildlife habitats supporting regionally restricted plants, riparian wetland plants and spawning grounds for native Rainbow trout. The lower reaches provide habitat for cold water species such as native Rainbow trout and warm water species such as Threespined stickleback.

Lower Ventura River HA

The Ventura River Estuary, apart from providing wetland habitat, is an existing spawning habitat for cold water species of fish such as Prickly sculpin; habitat for federally classified or candidate rare and endangered species such as Tidewater Goby, Least Tern and Brown Pelican. **Lower Ventura River** provides existing and the **Canada Larga** provides intermittent migration and spawning habitat for native warm and cold water species including Steelhead, Threespined Stickleback and Prickly sculpin.

The Nearshore Zone provides existing spawning habitat for a variety of marine fish; the cobble tidepools provide habitat for shellfish, including Chione and Littleneck clams which are extensively harvested by sportfishers.

VOL 12

1 8799

Upper Ventura River HA
The mainstem of the Ventura River is an interrupted stream, with perennial flow below the confluence with San Antonio Creek, due to rising groundwater and discharge effluent from Ojai Valley Sanitation District. In the upper reaches, water from Ventura River is diverted to Lake Casitas.
Murietta Canyon, East Fork and West Fork Coyote Creek, Matilija Creek, West Fork Santa Ana Creek are existing spawning habitat for Steelhead rainbow trout. **Lake Casitas and Matilija Reservoirs**, operated by Casitas Municipal Water District (CMWD) control the flows of their tributary streams and have existing municipal, recreational and fisheries beneficial uses.
Horn Canyon, in the Ojai Valley, was found to be flowing in the upper mountainous reaches, after five years of drought. It is a source of municipal and irrigation water supply for the local Thatcher School, and hiking trails along the creek attest to its use for recreational and fisheries use. **Reeves Creek**, a tributary to the San Antonio Creek, provides migratory and spawning habitat for Steelhead rainbow trout.
Santa Clara-Calleguas HU
The Santa Clara River is the largest unurbanized river system, with extensive riparian habitat, in Southern California and includes significant tributaries like the Santa Paula, the Sespe and the Piru Creeks.
The Santa Clara River Estuary is an important wetland habitat for numerous bird species including the endangered Least Bell's vireo and California least tern, and for Tidewater goby, a Federal candidate species. Other coastal wetlands in this area include McGrath Lake, Ormond Beach Mugu Lagoon. **Mugu Lagoon** is the prime coastal wetland in Region 4, with rich vertebrate and invertebrate fauna. The most common fish found are arrow gobies, topsmelt, staghorn sculpin and shiner surfperch. Threatened and endangered species of birds using the Mugu Wetlands include light-footed clapper rail, Belding's savannah sparrow, brown pelican and least tern.
The Sespe and the Piru Creeks, in their upper reaches, flow through the Las Padres National Forest(LPNF), the newly created "Wilderness and Scenic Area", and the Condor Sanctuary. According to the response from the LPNF District Ranger, the beneficial uses in the National Forest are consistent with their Land Resources Management Plan. Sespe Creek provides habitat for spawning and migration of Steelhead rainbow trout, endangered birds including California condor and least Bell's vireo, and for candidate species including arroyo southwestern toad and southwestern pond turtle.
Pine Canyon, Coldwater Canyon and Redrock Canyon are in wilderness areas, within Condor Sanctuary and there is no public access. **West Fork Sespe Creek, Trout Creek, Piedra Blanca Creek and Potrero John Creek** are important wildlife habitat, with spawning areas for anadromous fish.
Pyramid Lake and Castaic Lakes are parts of the State Water Project, with significant existing municipal, recreational, fisheries and hydropower usage. **Lake Piru** also provides habitat for threatened and endangered species of southwestern pond turtle and Santa Ana sucker.

Pyramid Lake and Castaic Lakes are parts of the State Water Project, with significant existing municipal, recreational, fisheries and hydropower usage. Lake Piru also provides habitat for threatened and endangered species of southwestern pond turtle and Santa Ana sucker. The release of water from Drinkwater Reservoir, in San Francisquito Canyon provides habitat for Threespine stickleback.

MALIBU HYDROLOGICAL UNIT

The Malibu Region is drained by Malibu Creek and its tributaries, and a number of small creeks, all draining the Santa Monica Mountains, directly into the Pacific Ocean. It also has some reservoirs (Lake Sherwood, Westlake Lake, Lake Eleanor, Malibu Lake), and three coastal wetlands (Dume Lagoon, Malibu Lagoon and Topanga Lagoon). The beneficial uses are partially affected by the Santa Monica Mountain Recreation Area (SMMNRA). The WILD designation for the Cold Creek, Medea Creek, East Fork Arroyo Sequit, are due to their location within the SMMNRA.

According to the responses from L.A. County Natural History Museum (Camm Swift) and California Trout (Jim Edmondson), there are historical and potential anadromous migration, spawning and rearing habitats in Zuma Canyon Creek, Las Virgenes Creek, Solstice Canyon Creek, Medea Creek, Triunfo Canyon. There are existing such habitats in the Malibu Creek, Topanga Canyon Creek, Arroyo Sequit Creek and upper reaches of Big Sycamore Creek.

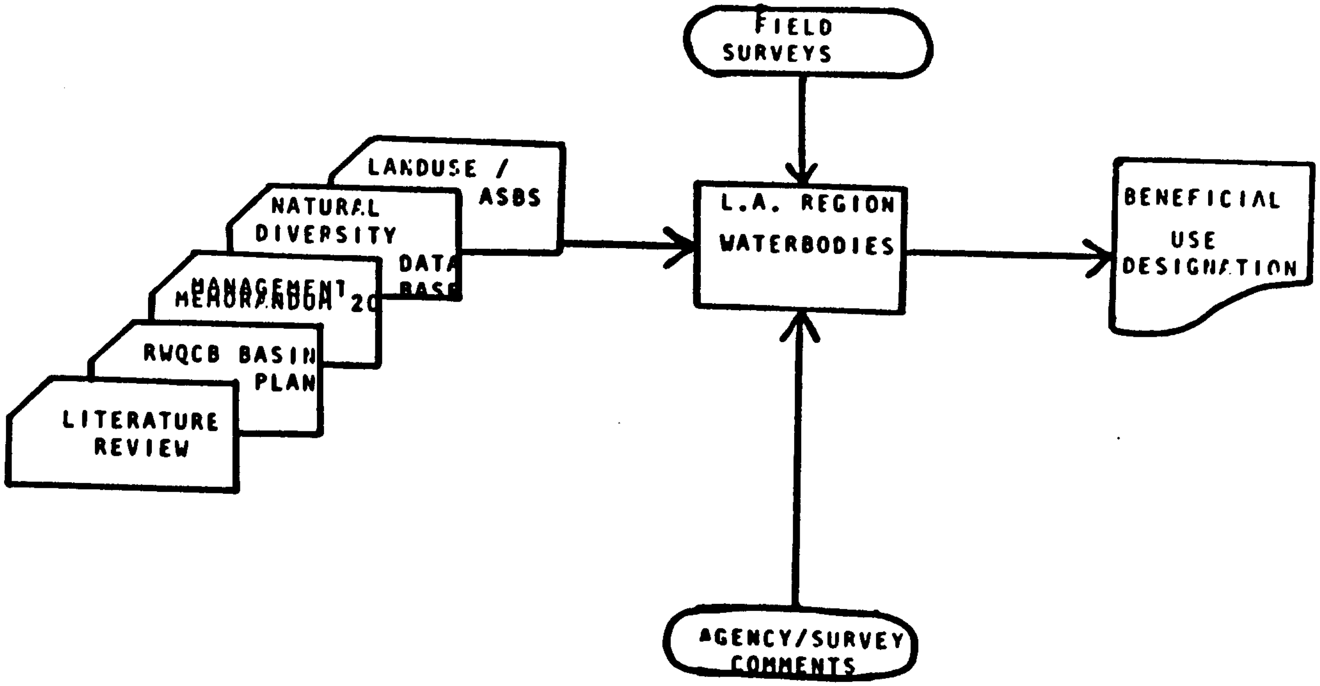
Malibu Lagoon is an important stopover and wintering area for migrating birds and a spawning and migratory route for Steelhead rainbow trout. It also provides habitat for California least tern, a state and federal listed endangered bird, and Tidewater Goby, a federal candidate for listing.

LOS ANGELES-SAN GABRIEL HYDROLOGIC UNIT

This includes the highly urbanized coastal plain, San Fernando Valley and San Gabriel Valley, where the rivers are largely channelized for flood control, and the headwaters of these streams in the rugged San Gabriel Mountains. The beneficial uses in the mountainous areas are affected by the Angeles National Forest Land Resources Mangement Plan and the SMMMNRA. The accessible rivers and lakes in the mountains have heavy recreational usage.

There are stretches of significant riparian wetlands in the soft bottomed channels of the Los Angeles and San Gabriel Rivers. Also, behind Whittier Narrows flood control dam there are lacustrine wetlands, with a high diversity of animal and plant life. These wetlands are also areas of heavy human usage, for recreational purposes. The wetlands in the urban coastal plain have undergone drastic reduction in size and distribution, as a result of flood control and agricultural practices. Overpumping of groundwater has lowered water table and diverted water supply from wetland areas. Should groundwater basins also have a WILD as a beneficial use?

VOL 12 1 8800



CSUF-LARWQCB WATERBODY I.D. & BENEFICIAL USE UPDATE	DECISION CRITERIA FOR BENEFICIAL USE DESIGNATION AND UPDATING OF WATERBODIES	FIG 8

TABLE 4.0

BENEFICIAL USE DEFINITIONS

Beneficial Use*	Abbreviation	Definition
Municipal and Domestic Supply	MUN	Usual uses in community or military water systems and domestic uses from individual water supply systems.
Agricultural Supply	AGR	Crop, orchard and pasture irrigation stockwatering; support of vegetation for range grazing and all uses in support of farming and ranching operations.
Industrial Service Supply	IND	Uses which do not depend primarily on water quality such as mining, cooling water supply, hydraulic conveyance, gravel washing, fire protection, and oil well repressurization.
Industrial Process Supply	PROC	Process water supply and all uses related to the manufacturing of products.
Ground Water Recharge	GWR	Natural or artificial recharge for future extraction for beneficial uses and to maintain salt balance or halt salt water intrusion into freshwater aquifers.
Freshwater Replenishment	FRSH	Provides a source of freshwater for replenishment of inland lakes and streams of varying salinities
Navigation	NAV	Commercial and naval shipping uses
Hydropower Generation	POW	Used for hydropower generation
Water Contact Recreation	REC-1	All recreational uses involving actual body contact with water, such as swimming, wading, waterskiing, skindiving surfing, sport fishing, uses in therapeutic spas and other uses where ingestion of water is reasonably possible.
Non-contact Water Recreation	REC-2	Recreational uses which involve the presence of water but do not require contact with water, such as picnicking sunbathing, hiking, beachcombing, camping, pleasure boating, tidepool and marine life study, hunting and aesthetic enjoyment in conjunction with the above activities, as well as sightseeing
Ocean Commercial and Sport Fishing	COMM	Commercial collection of various types of fish and shellfish, including those taken for bait purposes and sport fishing in ocean bays, estuaries, and similar non-freshwater areas
Warm Freshwater Habitat	WARM	Provides a warm-water habitat to sustain aquatic resources associated with a warm-water environment.
Cold Freshwater Habitat	COLD	Provides a cold-water habitat to sustain aquatic reasources associated with a cold-water environment.
Preservation of Areas of Special Biological Significance	BIOL	Preservation of Areas of Special Biolological Significance (ASBS) ASBS are those areas designated by the State Water Resources Control Board (SWRCB) as requiring protection of species or biological communities to the extent that alteration of natural water quality by even the slightest degree is undesirable.

VOL 12

TABLE 4.0. (CONTINUED)

BENEFICIAL USE DEFINITIONS

Beneficial Use*	Abbreviation	Definition
Saline Water Habitat	SAL	Provides an inland saline water habitat for aquatic and wildlife resources
Wildlife Habitat	WILD	Provides a water supply and vegetative habitat for the maintenance
Preservation of Rare and Endangered Species	RARE	Provides an aquatic habitat necessary, at least, in part for the survival of certain species established as being rare and endangered species.
Marine Habitat	MAR	Provides for the preservation of the marine ecosystem including the propagation and sustenance of fish, shellfish, marine mammals, waterfowl, and vegetation such as kelp.
Fish Migration	MIGR	Provides a migration route and temporary aquatic environment for anadromous or other fish species
Fish Spawning	SPWN	Provides a high quality aquatic habitat especially suitable for fish spawning
Shellfish Harvesting	SHELL**	The collection of shellfish such as clams, oysters, abalone, shrimp, crab, and lobster for either commercial or sport purposes.

* The beneficial uses designated in Table 2 apply to the main watercourse named and to all tributaries thereto, unless specific tributaries are identified which may have different beneficial uses, in each hydrographic unit, area, or subarea. These waters are to be protected to insure that the designated beneficial uses are preserved.

** The definition of "SHELL" is different from that adopted by the State Health Department in that it does not include mussels but does include shrimp, crabs and lobsters.

VOL 12 1 8803

TABLE 4.0 Continued

Provisional Definitions for New Beneficial Use Categories

Aquaculture	AQUA	All beneficial uses associated with waters used for the propagation, cultivation, maintenance, and harvestin of aquatic plants and animals for huma consumption or bait purposes. These operations include fish hatcheries, an other aquaculture or mariculture operations.
Wetland Habitat	WET	All beneficial uses associated with waters or contiguous areas which provid wetland habitat in marine, estuarine and freshwater areas. These uses include, but are not limited to the preservation and enhancement of wetlan ecosystems (balanced communities of fish shellfish, vegetation, waterfowl, shor birds, and other wetland wildlife), flood and erosion control, filtratio and purification of naturally occurrin contaminants in water, stream-bank stabilization and control of siltation Examples of these communities includ tidal salt marshes, mudflats, brackish marshes, freshwater marshes swamps, wet meadows, bogs, bottomlan hardwoods, seasonal wetlands, and verna pools.
Estuarine	EST	All beneficial uses associated with waters used to provide an essential an unique habitat for estuarine organism that serves to acclimate anadromous fishes which migrate between fresh an marine waters and provides for the propagation and sustenance of a variet of fish and shellfish, vegetation, waterfowl, shore birds, and marine mammals.

Request for Comments on Beneficial Use Designations for Waterbodies in Los Angeles and Ventura Counties

The California Regional Water Quality Control Board, Los Angeles Region, in conjunction with California State University, Fullerton, is conducting a survey of existing, potential and intermittent beneficial uses for all waterbodies in the Region (most of Los Angeles and Ventura counties). In order to obtain current information, we are surveying resource agencies and interest groups, and asking for assistance with this study. The results of this study will be used by the Regional Board to prepare their updates to the Basin Plans in 1993. Hopefully, your Agency will benefit from your participation in the Basin Planning process.

Enclosed you will find Tables 1, 2, and 3 which list all regional waterbodies and their designated uses, as published in the 1978 Basin Plans. We also have enclosed a regional map (Fig. 1) with the hydrological basins labeled for your reference. A list of beneficial uses and their definitions is also attached (Table 4). Please review the waterbodies in your geographic area and comment on the tables as necessary. Please keep in mind the following criteria when reviewing this information:

1. Existing beneficial uses have previously, or are presently in existence, and associated with the waterbody. If a beneficial use has been, or is presently in existence (E), it cannot be removed.

2. Intermittent uses (I) are designated under the assumption that they might only be present on a seasonal basis (based on presence of water).

3. Potential beneficial uses (P) are those which are desired on a waterbody, have a probability of occurrence, but may or may not exist.

1 8856

4. Beneficial uses can be added at any time, if they have been attained.

A survey form (Table 5) also has been included for your use in summarizing your comments. Please designate a contact person for your agency for further correspondence on these issues.

I would be grateful if you would send your comments to the above address by Monday, July 24, 1992. If you have any questions, please call me or Mr. Kwan Ihn at (714) 773-3267.

Thank you for your cooperation. We look forward to working with your agency or your group, and hope to make this study a valuable resource for all of us.

REEVALUATION OF BENEFICIAL USES IN THE 1978 BASIN PLANS

The objective of this survey is to review and update beneficial uses designated to waterbodies in the Regional Water Quality Control Board's (CRWQCB-LA) 1978 Basin Plans (most of Los Angeles and Ventura counties). The data from this survey will aid the CRWQCB in updating its Water Quality Control Plans (Basin Plans). As comments are received, we will make field verifications and review pertinent data to determine the validity and applicability of the recommendations. Please complete the following:

1. Review the beneficial uses listed in Tables 1, 2, and 3. Based on your best judgement, either add any additional beneficial use(s) and/or upgrade any existing beneficial use(s) (i.e., from potential to intermittent or intermittent to existing) for waterbodies under your jurisdiction or of interest to your group.* Do this directly on the tables, as shown in the example on the last page. Table 4 contains definitions for the 21 established beneficial uses. Figure 1 shows the locations of the hydrological areas listed in the left column of Tables 1, 2, and 3.

2. In Table 5, provide rationale for any recommended addition(s) or upgrade(s) made in Tables 1, 2, and 3. Moreover, if any gross errors are identified in these tables regarding beneficial use designation, indicate this and thoroughly explain why. Attach additional sheets as necessary.

3. If possible, provide references and/or enclose supplemental documents to support your recommendations.

4. If there are no comments, then indicate "no comments" in Table 5.

5. Please fill out the correspondence form on the following page and return it to the above address with the appropriate materials by July 24, 1992.

We appreciate your cooperation in our effort. If you have any questions, please contact me, Dr. Prem K. Saint, or Mr. Kwan Ihn at (714) 773-3267.

---

* According to federal and state regulations, beneficial uses can only be added or upgraded (not removed), except in extremely rare instances where it can be documented that a gross error was made in assigning these uses in 1975. Beneficial uses cannot be de-designated because of water quality impairment.

REQUEST FOR COMMENTS ON BENEFICIAL USE DESIGNATIONS FOR GROUNDWATER BASINS IN LOS ANGELES AND VENTURA COUNTIES

The California Regional Water Quality Control Board, Los Angeles Region, in conjunction with California State University, Fullerton, is conducting a survey of existing, potential and intermittent beneficial uses for all waterbodies including groundwater basins in the Region (most of Los Angeles and Ventura counties). In order to obtain current information, we are surveying resource agencies and asking for assistance with this study. The results of this study will be used by the Regional Board to prepare their updates to the Basin Plans in 1993. Hopefully, your Agency will benefit from your participation in the Basin Planning process.

Enclosed you will find Table 1 which lists all regional groundwater basins and their designated uses. We also have enclosed a regional map (Fig. 1) with the groundwater basins labeled for your reference. A list of beneficial uses and their definitions is also attached (Table 2). A survey form (Table 3) also has been included for your use in summarizing your comments. Please designate a contact person for your agency for further correspondence on these issues.

Please review the groundwater basins in your geographic area and comment on the tables as necessary. Please keep in mind the following criteria when reviewing this information:

1. Existing (E) beneficial uses have previously, or are presently in existence, and associated with the waterbody. If a beneficial use has been, or is presently in existence, it cannot be removed.

2. Intermittent (I) uses are designated under the assumption that they might only be present on a seasonal basis (based on presence of water).

3. Potential (P) beneficial uses are those which are desired on a waterbody, have a probability of occurrence, but may or may not exist.

4. Beneficial uses can be added at any time, if they have been attained.

5. If, possible, provide references and/or enclose supplemental reports to support your recommendations.

6. If there are no comments, then indicate "no comments" in Table 3.

7. In some basins, various aquifers are identified. In those that are not identified, please specify the names of aquifers or aquifer systems (upper, lower, etc.) currently under your agency's jurisdiction. If possible, please allocate beneficial uses according to aquifers or aquifer systems.

I would be grateful if you would send your comments to the above address by Monday, March 15, 1993. In case of a delay in meeting this deadline, we will welcome a response anytime thereafter. If you have any questions, please call me, Dr. Prem K. Saint, or Mr. Kwan Ihn at (714) 773-3267.

Thank you for your cooperation. We look forward to working with your agency, and hope to make this study a valuable resource for all of us.

REQUEST FOR COMMENTS ON BENEFICIAL USE DESIGNATIONS FOR COASTAL FEATURES (BAYS, BEACHES, HARBORS, LAGOONS, ETC.) IN LOS ANGELES AND VENTURA COUNTIES

The California Regional Water Quality Control Board, Los Angeles Region, in conjunction with California State University, Fullerton, is conducting a survey of existing, potential and intermittent beneficial uses for all waterbodies including coastal features in Region 4 (most of Los Angeles and Ventura counties). In order to obtain current information, we are surveying resource agencies and asking for assistance with this study. The results of this study will be used by the Regional Board to prepare their updates to the Basin Plans in 1993. Hopefully, your Agency will benefit from your participation in the Basin Planning process.

Enclosed you will find Table 1 which lists all coastal features and their designated uses. We also have enclosed a regional map (Fig. 1) delineating the hydrological areas and a coastal map (Fig. 2) with all coastal features proposed for inclusion in the Basin Plans. A list of beneficial uses and their definitions is also attached (Table 2). A survey form (Table 3) also has been included for your use in summarizing your comments. Please designate a contact person for your agency for further correspondence on these issues.

Please review the coastal features in your geographic area and comment on the tables as necessary. Please keep in mind the following criteria when reviewing this information:

1. Existing (E) beneficial uses have previously, or are presently in existence, and associated with the waterbody.

2. Intermittent (I) uses are designated under the assumption that they might only be present on a seasonal basis (based on presence of water).

R0052166

3. Potential (P) beneficial uses are those which are desired on a waterbody, have a probability of occurrence, but may or may not exist.

4. Beneficial uses can be added at any time, if they have been attained.

5. If, possible, provide references and/or enclose supplemental reports to support your recommendations.

6. If there are no comments, then indicate "no comments" in Table 3.

7. Please add other bays, beaches harbors, lagoons, etc. which are not listed and suggest appropriate beneficial uses for them. In addition, please label their locations directly on the coastal feature map (Fig. 2).

I would be grateful if you would send your comments to the above address by Wednesday, March 17, 1993. In case of a delay in meeting this deadline, we will welcome a response anytime thereafter. If you have any questions, please call me, Dr. Prem K. Saint, or Mr. Kwan Ihn at (714) 773-3267.

Thank you for your cooperation. We look forward to working with your agency, and hope to make this study a valuable resource for all of us.

Prem K. Saint, Ph.D.

APPENDIX 3. SUMMARY OF RESPONSES AND COMMUNICATION WITH AGENCIES, INTEREST GROUPS, ETC.

1. California Coastal Conservancy,
1330 Broadway, Suite 1100,
Oakland, Ca 94612-2530 Tel (510) 286-1015
Reed Holderman, Manager, Resource Enhancement Program

1.1. Response on March 19, 1993

1.2. Suggested addition of Venice Canals to Ballona Lagoon and added beneficial uses;
Also added beneficial uses to:
402.10 Ventura River Estuary
403.11 Santa Clara River Estuary.

1.3. Informed us of the following studies and reports:
(a) Ballona Lagoon/ Venice Canals:
Resource Enhancement Plan, 1992.
Hydrology, Water Quality Report by Phil Williams;
Biology Report by Wetland Research;
(Contact Person: Iylene Weiss, Ballona Lagoon Marine Reserve).

(b) Josselyn, Michael, 1993. Wetland Inventory and Restoration Potential: Santa Monica Bay Restoration Project Report.
(Contact Person: Paul Michel- (213) 266-7516.

(c) Santa Clara River Estuary: DPR Report
(Contacts: Steve Trainer or Virginia Johnson (805) 654-4611)

1 8873

2. California Department of Boating and Waterways,
1629 South Street,
SACRAMENTO, Ca 95814-7291 Tel (916) 445-6281
Bill S. Satow, Interim Director.

2.1. Response to Waterbody and Beneficial Use Survey (dated July 15, 1992):
"No Comment"

3. California Department of Fish and Game,
1416 Ninth Street, P.O. Box 44209,
SACRAMENTO, CA 94244-2090 Tel (916) 653-7664
Boyd Gibbons, Director

3.1. Response to Existing Waterbody and Beneficial Use Survey. (Response dated August 12, 1992).

3.2. Suggested additions of BU's to:
405.12 Long Beach Marina,
Alamitos Bay,
403.11 Nearshore Zone

VOL 12

3.3. Suggested further contact with Kris Lal, Richard Nitsos, Department Environmental Specialists, Long Beach

4. **California Trout,**
Region 5 Office, 9770 Sombra Terrace,
SHADOW HILLS, Ca 91040 Tel (818) 951-4015
Jim Edmondson, Regional Manager

4.1. Response to Existing Waterbody and Beneficial Use Survey. (Response dated July 27, 1992).
4.2. Suggested modifications to Beneficial Uses for:

404.36	Zuma Canyon Creek
403.11	Calleguas Creek
404.11	Topanga Canyon Creek
404.22	Las Virgenes Creek
404.44	Arroyo Sequit Creek
404.47	Big Sycamore Creek
404.32	Solstice Canyon Creek

4.3. Also provided references and copies of some reports.

5. **Crescenta Valley County Water District,**
2700 Foothill Boulevard,
LA CRESCENTA, Ca 91214. Tel (818) 248-1659
Michael Sovich, District Engineer

5.1. Response to Groundwater Basin Survey. (Response dated 4, 1993.

5.2. Suggested BU's for;
405.24 Verdugo Groundwater Basin

6. **Friends of Los Angeles River,**
Technical Advisory Board,
P.O. Box 292134,
LOS ANGELES, CA 90029 Tel (213) 223-0585
Jim Danza, Chair, Technical Advisory Board

6.1. Response to Beneficial Use Survey. (Response dated July 29, 1992.

6.2. Suggested changes and included justification for the following waterbodies:

405.12	Los Angeles River Tidal Prism
405.15	Arroyo Seco south of Devil's Gate Reservoir
405.15	Compton Creek
405.15	Los Angeles River to tidal prism
405.21	Los Angeles River
405.21	Sepulveda Flood Control Basin
405.20	San Fernando Valley Groundwater Basin

1 8874

6.3. Also provided documentation and photographs to support recommendations.
6.4. Follow-up discussions and a field trip with Jim Danza on FOLAR comments.

7. **Friends of Ventura River**
63 South Olive Street,
SAN BUENAVENTURA, CA 93001 Tel (305) 643-6074
Mark H. Capelli, Executive Director

7.1. Responses dated July 21, 1992, February 5, 1993 and June 9, 1993.
7.2. Suggested changes and provided justification for the following waterbodies:

401.00	Rincon Creek and other streams
	Javon Canyon
402.10	Lower Ventura River Tidal Prism
	Canada Larga
	Ventura River and tributaries
	Nearshore Zone
402.20	Murietta Canyon
	Matilija Reservoir
	East Fork Coyote Creek
	West Fork Coyote Creek
	Matilija Creek
	West Fork Matilija Creek
	Upper North Fork Matilija Creek
	West Fork Santa Ana Creek
	Mirror Lake
402.32	Reeves Creek
404.44	Arroyo Sequit

7.3. Also provided exhaustive documentation and copies of publications and reports.
7.4. Commented on June 9, 1993, in response to our coastal survey that "beneficial uses associated with Ventura River tidal prism appear to adequately cover existing uses". Cobble tide-pools in the Ventura River mouth are important shell-fish harvesting site.
7.5. Several follow-up phone conversations to get other information.

8.0. **Los Angeles County Department of Beaches and Harbors,**
13837 Fiji Way,
Marina Del Rey, Ca 90292 Tel (310) 305-9503
Gregory Woodell, Acting Chief, Planning

8.1. Response dated March 15, 1993, on coastal features.
8.2. Suggested changes to names of beaches.

VOL 12

8.3. Provided a map giving the location and names of beaches, in use by the L.A. Department of Beaches and Harbors.

8.4. No beneficial use changes suggested.

9.0 **Los Angeles County Department of Health Services**
2525 Corporate Place, # 150,
Monterey Park, ca 91754-7631 Tel (213) 881-4011
Jack Petralia, Director of Environmental Protection.

9.1. Response dated July 23, 1992:
" No comments".

10.0 **Los Angeles County Museum of Natural History,**
900 Exposition Boulevard,
Los Angeles, Ca 90007
Camm Swift, Fisheries Biologist

9.1. Responses dated October 30, 1992 and January 15, 1993.

9.2. Suggested changes and provided justification for the following waterbodies:

402.10	Ventura River Tidal Prism
402.12	Arroyo Las Posas
402.20	Ventura River and tributaries
403.11	Calleguas Creek Tidal Prism
	Santa Clara River Estuary,
	Nearshore Zone
403.12	Calleguas Creek
	Conejo Creek
403.21	Santa Paula Creek
403.32	Pine, Coldwater, Bear, Portero John, Tule Creeks
403.41	Santa Felicia Canyon
403.43	Gorman Creek
403.51	Drinkwater Reservoir
	San Francisquito Canyon
	Santa Clara River
403.54	Agua Dulce Canyon
403.62	Arroyo Las Posas
404.11	Topanga Canyon Creek
404.21	Cold Creek
404.23	Medea Creek
404.25	Triunfo Canyon
404.44	Arroyo Sequit
	East Fork Arroyo Sequit
404.47	Wood Canyon
	Lebrand Canyon
	Big Sycamore Canyon Creek
405.12	Alamitos Bay
405.13	Ballona Wetland
405.15	Ballona Creek
405.22	Pacoima Canyon Creek

18876

405.23 Big Tujunga Canyon Creek
Upper Big Tujunga Canyon
Fox Creek
405.27 Hansen Lake
405.41 Whittier Narrows Flood Control Basin
405.43 Bichota Canyon
Cattle, Coldwater, Cow Creek
East and North Forks San Gabriel
River, Devil's Canyon Creek

10.3. Also included references

11. **Los Angeles County Department of Public Works**
P.O. Box 1460,
ALHAMBRA, Ca 91802-1460 Tel (818) 458-5948
Gary Hildebrand, Supervising Civil Engineer

11.1 Response dated January 13, 1993.
11.2 Suggested changes and gave justification for these waterbodies:

405.13 Cetinella Creek Channel
Sepulveda Channel

12. **Los Angeles Department of Water and Power,**
111 North Hope Street,
Los Angeles, Ca 90051-0100 Tel (213) 481-8701
Dennis C. Williams, Engineer in Charge, Aqueduct Division

12.1. Response dated November 30, 1992
12.2. Suggested changes for these waterbodies:

403.51 Dry Canyon Reservoir: out of service
403.52 Bouquet Reservoir
405.13 Stone Canyon Reservoir
405.14 Hollywood Reservoir
Upper Franklin Reservoir
Lower Franklin Reservoir
Ivanhoe Reservoir
Silverlakes Reservoir
Elysian Reservoir
Encino Reservoir
Los Angeles Reservoir
Solado Reservoir
405.20 San Fernando Valley Groundwater Basin
405.25 Eagle Rock Reservoir

13. **Las Virgenes Municipal Water District**
4232 Las Virgenes Road,
CALABASAS, Ca 91302 Tel (818) 880-4110
Ane D. Deister, Director of Resource Conservation

VOL 12 1877

VOL 12 18878

13.1 Response dated July 23, 1992 and January 4, 1993
13.2 Gave status of beneficial uses for:
    404.21 Malibu Creek
    404.22 Las Virgenes Creek
13.3. Provided reports and documentation on water quality and groundwater.
13.4. Met with Ane Deister and other representatives, at the LVMWD offices to clarify locations and names of waterbodies in their district.

14. **NOAA National Marine Fisheries Service**
501 West Ocean Blvd., Suite 4200,
Long Beach, Ca 90802-4213 Tel (310) 980-4001
Gary Matlock, Acting Regional Director

14.1. Responses dated July 28, 1992 and January 21, 1993
14.2. Commented on general organization of BU tables; suggested addition of several additional BUs for groundwater basins, since groundwater withdrawal has eliminated several surface water habitats for fish. Also suggested addition of Estuaries and Wetlands to waterbodies, and expansion of definition of "nearshore zone," BIOL, WILD.
14..3. Specific suggestions on the following waterbodies:

403.11	Santa Clara River
405.12	Los Angeles River Tidal Prism
	Colorado Lagoon
	Alamitos Bay
	Las Cerritos Wetlands
405.13	Ballona Wetlands
406.00	Channel Islands

15. **Santa Clarita Water Company,**
P.O. Box 903,
SANTA CLARITA, Ca 91380 Tel (805) 259-2737
William J. Manetta

15.1. Response dated March 15, 1993
15.2 No Comments on the following groundwater basins:

EXECUTIVE SUMMARY

In order to prepare a wetland inventory for the Regional Water Quality Control Board, Region 4, a literature review and field surveys of rivers, lakes, reservoirs and estuaries of the coastal region of the Los Angeles and Ventura Counties were conducted from July, 1991 to January, 1993. Our study indicated the existence of at least 15 estuarine and coastal wetlands, 14 lacustrine wetlands and 79 rivers with stretches of riparian wetlands. The study period included the last two years of a six-year drought, and yet most of the rivers in the mountain reaches were flowing and supporting wetland vegetation. During the heavy rains of winter, 1993, several of the river mouth estuaries were breached by flood waters, allowing migration passage for anadromous fish like steelhead trout (*Oncorhynchus mykiss*).

Our study has concentrated on the estuarine, lacustrine, riverine and palustrine wetlands of the region, integrating these into estuarine, lacustrine and riparian categories. This is in agreement with the California Department of Fish and Game policy of placing riparian forests, woodlands and scrubs into riparian habitats.

In southern California, agricultural practices, followed by rapid urbanization had led to estimated losses of 90% of the coastal salt marsh. As a result of channelization and concrete lining of rivers, riparian habitats in the coastal floodplain has been reduced by 95 to 97%. Urbanization has not significantly affected the riparian wetlands in the mountainous regions, and has provided a net gain in lacustrine wetlands behind the flood control reservoirs. Many of the urban lakes, such as the Whittier Narrows Recreation Area, serve as "ecological islands" for many species of birds and fish. Several threatened and endangered species and species of special concern found in these artificial wetlands include: southwestern pond turtle (*Clemmys marmorata pallida*), at Lake Piru, Lake Sherwood, Lake Malibu, and Lake Casitas; Santa Ana sucker (*Catostomus santaanae*), at Lake Piru and San Gabriel Reservoir; and California least tern (*Sterna antillarum browni*), at Lake Machado and Harbor Lake.

The remaining riparian wetlands in the coastal region provide wildlife corridors. Malibu Creek, for example links various portions of the Santa Monica Mountains and the Santa Clara River provides a significant corridor for the rainbow and steelhead trout to migrate between the lower reaches of the river and spawning and rearing habitat in tributaries such as Sespe and Piru Creeks.

Our ranking system, using various wetland function criteria, has attempted to rank the coastal and riparian wetlands. We recommend a WETLAND designation for most of the waterbodies included in the Wetland report.

This project has been funded wholly or in part by the United States Environmental Protection Agency using Federal 201(G)(I)(B) grant funds under Assistance Agreement No. C9009532-90-2 to the State Water Resources Control Board and by Agreement No. 0-169-254-0 in the amount of $129,178 to conduct a Waterbody Identification and Update of Beneficial Use Designation study. The contents of this document do not necessarily reflect the views and policies of the U.S. Environmental Protection Agency and the State Water Resources Control Board, nor does mention of trade names or commercial products constitute endorsement or recommendation for use.

INTRODUCTION

Wetlands have been important to people in California since prehistoric times. Archeological middens indicate that coastal wetlands were important sites for food-gathering among some aboriginal groups. Riverine habitats, which were the source of fish (salmon in particular), also provided acorns, the second most important dietary staple for these groups. Lakes were also exploited for fish, waterfowl, and other food sources along with bulrush or tule which provided fiber for clothing and housing (Beals and Hester 1971).

Reduction of wetland acreage began with European settlement. Salt marshes were reclaimed for salt ponds, agriculture, and urbanization (Macdonald 1988). The great riparian forests of the central valley were cleared for flood control and agriculture (Katibah 1984). Hydroelectric projects and stream channelization further contributed to the loss of wetlands throughout the state.

In southern California, agricultural practices during the late 1800s, followed by rapid urbanization after World War II, led to dramatic reduction of wetland. Regulatory agencies such as the California Coastal Commission have estimated losses of coastal salt marsh to be as high as 90% (Ferren 1990). Riparian habitat in southern California floodplain areas has been reduced by 95 to 97% (Faber et al. 1989).

Lands which were once thought to be worthless swamps, marshes, or mires are now being appreciated as areas which equal tropical rainforests for productivity (Williams 1990). These same biotic communities are also being recognized as areas important to numerous types of vegetation and wildlife. Southern California salt marshes are home to numerous threatened or endangered species including the light-footed clapper rail (*Rallus longirostris levipes*), Belding's savannah sparrow (*Passerculus sandwichensis beldingi*), California least tern (*Sterna antillarum browni*), salt marsh harvest mouse (*Reithrodontomys raviventris*), and salt marsh bird's-beak (*Cordylanthus maritimus ssp. maritimus*). Inland coastal freshwater wetlands provide habitat for other threatened or endangered species. These are the unarmored threespine stickleback (*Gasterosteus aculeatus williamsoni*), bank swallow (*Riparia riparia*), and the slender-horned spineflower (*Centrostegia leptoceras*). Many other plants and animals which depend on salt or fresh water wetlands are candidates for listing as endangered or threatened. The protection and enhancement of all types of wetland habitats in California requires an accurate inventory of the wetland resources within the state.

The purpose of this study was to provide the Los Angeles Water Quality Control Board, with an update of the surface water resources over which it has regulatory responsibilities and powers. A significant portion of the study involved the identification and ranking of the significant wetlands within Region 4. These wetland resources are areas of increasing importance to humans and wildlife as urban practices increasingly have negative impact on the surface water resources of the Region.

Description of Wetland Systems

Although wetlands traditionally have been thought of as areas of standing water, such as ponds, marshes, and swamps; drier wetlands are now included in the designation. The inclusion of the drier wetlands habitats is based on their unique and crucial ecological role. In these areas, the soil may only be saturated for a brief period during the growing season and water only flows occasionally on the surface.

Classification of the vegetation associated with the surface hydrologic features within Region 4 is based in part on criteria used to define wetlands. For wetlands, the definition by Cowardin et al. (1979) was used:

> "Wetlands are lands transitional between terrestrial and aquatic systems where the water table is usually at or near the surface or the land is covered by shallow water. For the purpose of this classification, wetlands have one or more of the following attributes: (1) at least periodically, the land supports predominately hydrophytes; (2) the substrate is predominately undrained hydric soil; (3) the substrate is nonsoil and is saturated with water or covered with shallow water at some time during the growing season of each year."

By means of aerial photo interpretation, the U.S. Fish and Wildlife Service (1976) has developed a detailed hierarchical system of classifying national wetlands and has created sets of U.S. Geological maps showing the five classifications and wetland habitats. These include numerous intertidal and nontidal types, and vegetated and nonvegetated types. Subtidal deepwater habitats occur in the nearshore waters adjacent to intertidal wetlands. The wetlands and deepwater habitats are grouped into five principal systems.

Marine System. This type occurs seaward of coastal dunes, dune swales, sandy beaches, and estuaries. It includes nearshore subtidal deepwater habitats and intertidal wetlands on the shallow continental shelf and coastline where salinities usually exceed 30 o/oo. Wetlands along the intertidal cobble and sand margin of river deltas and the adjacent nearshore subtidal deepwater habitats are dominated by marine algae and angiosperms. The distribution of plants and animals in the marine system primarily reflects the differences in four factors: (1) degree of exposure of the site to waves; (2) texture and physicochemical nature of the substrate; (3) amplitude of the tides; and (4) latitude, which

VOL 12 1892

governs water temperature, the intensity and duration of solar radiation, and the presence or absence of ice. Marine wetlands are common along the entire coastline of Region 4.

Estuarine System. This type includes habitats commonly referred to as coastal salt marshes, bays, tidal channels and lagoons, and consists of subtidal deepwater habitats and intertidal wetlands usually confined to coastal embayments or other physiographic features that are open to the ocean at some time during the year. They also receive freshwater runoff, and are flooded by water with an annual low-flow salinity greater than 0.5 o/oo from ocean derived salts. Wave action is minimal. Estuarine wetlands and associated subtidal deepwater habitats occur at the Ventura and Santa Clara Rivers, Point Mugu, Malibu and Ballona Creeks. Former estuarine wetlands habitats associated with the mouths of the Los Angeles and San Gabriel Rivers have been greatly reduced or eliminated by channelization and dredging.

Riverine System. This type occurs in river and stream channels. It includes deepwater habitats and wetlands (submerged by less than 2 m or 6.6 feet of water) that are characterized by non persistent annual plants, when vegetated, and are flooded by water with an average annual low-flow salinity of less than 0.5 o/oo from ocean derived salts. The exposed channel margins and permanently flooded channels of the Ventura, Santa Clara, Los Angeles and San Gabriel Rivers belong to this system and occur upriver from estuarine wetland habitats.

Palustrine System. This type includes wetlands that in California are called "riparian" or "floodplain" vegetation and are characterized by persistent plant types (perennial emergents, scrubs, shrubs, and trees) when vegetated and that are flooded by water with an average annual salinity of less than 0.5 o/oo from ocean derived salts. If non persistent (above-ground annual) vegetation occurs, the habitat is not a riverbed or streambed. Palustrine wetlands are the most common type in the inland portion of Region 4 and include dune swales, freshwater marsh, scrub/shrub, and wooded or forested wetlands.

Lacustrine System. This type includes wetlands and deepwater habitats such as permanently flooded lakes and reservoirs with all of the following characteristics: (1) situated in a topographic depression or a dammed river channel, (2) lacking trees, shrubs, persistent emergents, emergent mosses or lichens with greater than 30% areal coverage, and (3) total area exceeds 8 ha (20 acres). Similar habitats totaling less than 8 ha are also included if an active wave-formed or bedrock shoreline feature makes up all or part of the boundary, or if the deepest water exceeds 2 m at low water. This system is well represented in Region 4 by man-made lakes and reservoirs.

Region 4 contains all five wetland systems. This study, however has concentrated on only the Estuarine, Riverine, Palustrine and Lacustrine systems. Riverine, which is not well represented in Region 4 and Palustrine have been combined under the classification of Riparian. This is in agreement with Orme (1990) who places riparian forests, woodlands and scrubs and associated floodplains into the Riverine category. All wetlands in Region 4 therefore fall into one of three classifications: Estuarine wetlands, Lacustrine wetlands, and Riparian wetlands.

Methods and Approaches

For purposes of the study, wetland habitats were defined, delineated, and described by application of a modified version of the definition and classification of wetlands by the U.S. Fish and Wildlife Service (Cowardin et al. 1979). The major criteria of identification were plants and hydrology. Soils were not used in wetland delineation. Another departure from the U.S. Fish and Wildlife Service system was that three, instead of five, wetland categories were used. Our three categories are:

1. Coastal: including estuarine and coastal palustrine,
2. Lacustrine: including lacustrine and palustrine,
3. Riparian: including riverine and palustrine.

A multifaceted approach was employed in determining location, areal extent, and quality of coastal, lacustrine and riparian wetlands within Region 4.

Information from the following sources was used in a hierarchical schema which generally followed the order in which they are explained:

Literature Search. The initial step was to assemble literature on wetlands in southern California including scientific literature (journal articles, proceedings of symposia, etc.), environmental impact reports (EIRs), documents by public agencies, and pertinent field guides for both floral and faunal wetland components.

National Wetland Inventory Maps. U.S. Fish and Wildlife Service 7.5 min National Wetlands Inventory maps were used as a primary source for location and areal extent of wetlands. These maps were consulted throughout the study. Before visiting a site, the Wetlands Inventory maps were consulted so that field proofing could be accomplished.

Field Visits. Hydrological, floral, and faunal components of candidate sites were observed and recorded during field visits conducted between July 1991 and November 1992.

Hydrological. Presence of water, depth, width, velocity, and approximate discharge were recorded for each site. This information was augmented by data from stream gaging stations

Channel characteristics and degree of erosion was also recorded.

Floral. Vegetation was sampled using a modified form of the releve approach of Mueller-Dombois (1974). Sites were reconnoitered by driving or hiking a large enough portion to familiarize the field investigator with the community or communities present. Stands best representing each community were then chosen and sampled. Sampling was by quadrat or belt transect for species composition by percent cover. Determination of species composition is a key element in wetland determination. The indicator status of various plant species is given in the *National List of Plant Species That Occur in Wetlands: 1988 California (Region 0)*, (Reed 1988). The formula used in determining the presence of hydrophytic vegetation is provided in the *Federal Manual for Identifying and Delineating Jurisdictional Wetlands* (Federal Interagency Committee for Wetland Delineation 1989). Photographs were taken of representative stands along with other significant features such as waterfalls and wildlife. 7.5 min USGS maps were used in the field to record sampling sites.

Faunal. Animal observation consisted mostly of bird sightings, which were recorded by species. Many species of birds are obligately tied to wetland habitats such as Belted Kingfisher (*Ceryle alcyon*) observed at San Antonio Creek near Ojai and Osprey (*Pandion haliaetus*) diving for fish at Lake Eleanor in Thousand Oaks. Presence of fish and amphibians was also recorded.

Rare Find and Pacific Coast Ecological Inventory Maps. Rare Find is the name of a computer database and accompanying maps (1:100,000 scale) available from the California Department of Fish and Game, Natural Diversity Database. These were used to locate endangered, threatened, and rare plants; endangered and threatened animals; and vegetation communities considered by biologists to be of special concern. Rare Find is updated on an annual basis. The database for the period of June, 1991 to June, 1992 was used in this study. The U.S. Fish and Wildlife Service, 1:125,000 scale, Pacific Coast Ecological Inventory Map (1981) was used as a complement to Rare Find.

Color Infrared Aerial Photograph Interpretation. Infrared photos were used to confirm the accuracy of National Wetland Inventory maps in conjunction with field visits. They were also consulted to make determination of areal extent of riparian wetlands where access was not possible. Infrared photos were also used to determine extent of vegetation zones around lakes.

Questionnaire Responses. Questionnaires were sent to various agencies (U.S. Forest Service, California Fish and Game, etc.) and local interest groups. Information from questionnaires and letters received from such groups provided important

VOL 12 18895

"local" information on many wetlands and associated populations of plants and animals. Field checks were carried out to confirm comments, or comments were followed up by telephone conversations where clarification was needed.

VOL 12

1 8897

Wetland Selection and Ranking Process

Waterbodies which met the conditions for wetland designation, were also ranked based on a number of criteria. The ranking of wetlands provides the Board with information regarding the relative quality of wetlands over which they have jurisdiction. The criteria, nine in all, included six habitat related criteria and three related to function.

Habitat

(1) **Disturbance** - consists of two components: physical and biological. Physical disturbance includes such things as the dredging of channels (Santa Clara River), sand and gravel mining operations (lower Ventura River), presence of debris dams or basins (Santa Anita Canyon and Winter Creek), and off road vehicle use (North Fork, San Gabriel River). Biological disturbance is characterized by the invasion of alien plants or animals whose presence is deleterious to native species. For animals, a typical example is the introduction of Large-mouthed Bass (*Micropterus salmoides*) and Carp (*Cyprinus carpio*) in the lower Ventura River where they now compete with native species for resources. For plants, giant reed (*Arundo donax*) and Eupatory (*Ageratina adenophora*) represent the most invasive plant species. Often, physical disturbance, such as dredging significantly alters habitat such that invasion by exotic species becomes possible.

(2) **Discharge regime** - considers the year round hydrological conditions for a given wetland. Perennial waterbodies typically are more valuable as habitat and as wildlife corridors than those which have water only during the rainy season. Many streams within Region 4 are "interrupted" meaning that portions contain water year round while other sections do not. San Franciquito Canyon Creek, due to year round water below Drinkwater Reservoir, maintains a significant population of the Unarmored Threespine Stickleback (*Gasterosteus aculeatus williamsoni*).

(3) **Botanical Diversity** - considers the plant species richness for a particular wetland. The botanical diversity is usually the function of a number of interrelated features: size, diversity of habitat types, and lack of disturbance. Size is typically measured as coverage in acres for coastal and lacustrine wetlands and as length for riparian wetlands. Mugu Lagoon and its associated salt marsh supports a much larger diversity of plants than does the Ballona wetlands due to larger size, more diversity of habitat and less disturbance. In a similar way, Eaton Canyon Creek which includes canyon live oak ravine forest, white alder riparian forest, southern mixed riparian forest, southern arroyo willow riparian forest, southern sycamore alluvial woodland and alluvial scrub has higher diversity of plants than does Medea Creek which is composed almost entirely of southern arroyo willow riparian

forest.

(4) **Wildlife Habitat** - is an extension of the three previous criteria: botanical diversity, hydrological regime, and disturbance. High botanical diversity supports high wildlife diversity as does year round water supply. The presence of invasive exotic plants, such as *Arundo donax*, displaces native willows which are important habitat for numerous bird species including the endangered Least Bell's Vireo (*Vireo bellii pusillus*).

(5) **Uniqueness** - consists of two components. The first is the relative rarity of the vegetation type or community. Walnut riparian woodland is restricted to only a few sites in all of region 4 whereas mulefat scrub is very common. The second aspect considered when evaluating uniqueness concerns features which make a given wetland unique. Designation of certain reaches of streams in Region 4 as wild trout streams would be an example of this aspect.

(6) **Wildlife Corridors** - considers the value to wildlife in providing corridors for migration. This is particularly important in maintaining gene flow between disjunct populations, thereby increasing genetic diversity. These corridors are most important where urbanization is encroaching upon and fragmenting habitat.

<u>Functional</u>

(7) **Flood Control** - considers the value of wetland vegetation and associated riparian vegetation in attenuating floods. By holding back flood waters and slowly releasing it to the environment, wetlands decrease potential damage from major flood events.

(8) **Groundwater Recharge** - considers the role of wetlands in providing a zone for the replenishment of groundwater supplies. The mouth of San Dimas Canyon, for example, is a significant recharge zone.

(9) **Water Quality** - considers the role which wetlands play in removing pollutants, sediments, and biochemical oxygen demand from water which is to be used for various beneficial uses.

The information on the wetlands of the Los Angeles Region has been tabulated as follows:

Included means that the waterbody was included in the 1978 Basin Plan of the Los Angeles Regional Water Quality Control Board.

@ The area includes the areal extent of the whole lake, reservoir or estuary, not all of which has wetland vegetation.

c Intermittent means that the lake or reservoir has seasonal water supply.

Explanation:

Names preceded with a 'p' are newly proposed waterbodies not included in previous basin plan.

Beneficial use designations that are underlined are unchanged from the previous basin plan. All beneficial use designations which are not underlined represent newly proposed beneficial uses.

E : Existing I : Intermittent P : Potential Beneficial Uses

TABLE W3.1. RANKING OF COASTAL WETLANDS

The criteria employed in the process of ranking the coastal wetlands of Region 4 is discussed in the section on "Methods and Approaches" in the general introduction to this wetlands report.

(A rank represents highest quality)

Coastal Wetland	Rank	Disturbance	Biotic Diversity	Habitat Quality	Uniqueness	Flood Control	Water Quality	Sediment Control
Mugu Lagoon	1	A	A	A	A	A	A	A

Coastal Wetlands

Coastal wetlands are the most heavily impacted type of wetland in Region 4. Dennis (1984) reports that Los Angeles and Orange Counties have lost 90% of their coastal wetlands. Historically, there were seven major coastal wetlands totalling 17,300 acres. The coastline between Newport Beach and Long Beach was considered to be one of the best habitats for game birds in the world.

In Los Angeles County no major coastal wetland remains. Ballona Creek Marsh was originally 1,550 acres, today 182 acres remain. Los Cerritos Lagoon totalled 2,400 acres and has been reduced by piecemeal filling for residential uses to 188 acres. Wilmington Lagoon was situated between the mouths of the San Gabriel and Los Angeles Rivers and covered 3,450 acres. Today, 5-6 acres of wetland are left. Alamitos Bay, a coastal wetland of 2,400 acres has been reduced to 50 acres of degraded marsh along New River Slough.

In Ventura County, wetlands historically were located at the mouths of the Ventura and Santa Clara Rivers. The wetlands at the mouth of the Ventura river have been filled such that only 10 acres remain. During the late 1800s, Mugu Lagoon covered approximately 3,000 acres, paralleling the coast for 4 miles. The U.S. Navy gained control of the area in the 1940s and through dredging has reduced the total to about 1,400 acres some of which are degraded.

Coastal wetlands serve many important hydrological and biological functions:

Flood Protection - coastal wetlands serve as spreading basins which can accommodate both upland and tidal flooding.

Water Purification - coastal wetlands have the ability to "treat" municipal wastewater and storm runoff. The broad, flat surface in a saturated condition provides a substrate for physical, chemical, and biological transformations. Sediments carried into the marsh from storm drains will settle out, adhesive forces can bind heavy metals, hydrocarbons and other constituents to the sediments. Microorganisms in the sediment can then degrade and recycle various chemical (organic and inorganic) compounds. Marsh vegetation can remove pollutants directly by taking up nutrients (nitrogen, phosphorus etc.) and heavy metals.

Shoreline and Bank Protection - marsh vegetation interrupts and absorbs the energy of ocean waves. In doing so, bank and shoreline erosion is reduced, providing protection for shoreline structures.

Primary Productivity - the primary productivity of an ecosystem is measured by the amount of plant material and algae which grow over an area of ground in a given amount of time. Because of exposure to full sunlight for photosynthesis and a plentiful supply of water, salt marshes have levels of primary productivity equaling tropical rainforests (Williams 1990). This productivity supports complex food chains and webs. Much of this productivity is "exported" by shorebirds when they move into other ecosystems.

Wildlife Habitat - Numerous organisms are dependant upon the productivity and shelter provided by coastal salt marshes and associated subtidal habitats.

Dense communities of invertebrates inhabit the shallow depths of the tide flats, tidal creeks and brackish marshes. These include worms, clams, crabs, shrimp, amphipods and insects. Some invertebrates undergo larval stages in the sheltered habitat provided within the salt marsh.

Coastal wetlands containing tidal creeks or other types of open water support fish populations. Staghorn sculpin, three-spine stickleback, California killifish, and topsmelt are some of the more common components of tidal estuaries (Dennis 1984). The nutrient rich water of many lagoons and tidal creeks attracts many transient offshore species. Eight foot blue sharks have been recorded in Mugu Lagoon at high tide (Macdonald 1976). Anadromous fish such as steelhead trout and salmon spend up to several months in river estuaries before migrating upstream to spawn.

Birds are the most conspicuous form of wildlife in coastal wetlands in Region 4. Those remnant coastal wetlands which remain provide important links along the Pacific Flyway for species migrating between nesting grounds in Alaska and wintering grounds in California and Central and South America. At Mugu Lagoon it is common to have up to 10,000 mud hens present at one time during periods of migration (Macdonald 1976).

Salt marsh and river mouth habitats are important to various endangered and threatened species including California clapper rail (*Rallus longirostris obsoletus*), Light-footed clapper rail (*Rallus longirostris levipes*), California least tern (*Sterna antillarum browni*), Belding's savannah sparrow (*Passerculus sandwichensis beldingi*), Salt-marsh harvest mouse (*Reithrodontomys raviventris*), and Salt-marsh bird's-beak (*Cordylanthus maritimus* ssp. *maritimus*). Candidate species such as tidewater goby (*Eucyclogobius newberryi*) also depend on estuaries.

Aesthetic and Educational Values - Coastal wetlands provide a refuge to many people living in the crowded urban environment of Region 4. Hiking, birdwatching, and photography, are just a few of the activities afforded by these areas so rich in biological diversity. They also are excellent educational resourses because of their proximity to many urban centers.

VOL 12

1891

Classification of Coastal Wetlands in Region 4

Coastal wetlands can be classified in various ways: (1) according to vegetation type and zonation, (2) freshwater versus saline, and (3) according to their physical attributes. In many cases the distinctions between types is clear cut; however in many other cases there is a continuum of types that suggests an inter-relatedness among estuaries and their associated biota.

Vegetation - Salt marsh vegetation in California has been divided into three types: San Francisco Bay area marshes, northern California coastal marshes and southern California coastal marshes (Macdonald 1988).

In San Francisco Bay, Mahall and Park (1976) found *Spartina foliosa* as the primary colonist on broad tidal mudflats and nearly pure stands of *Spartina* dominate the low marsh. A dense cover of *Salicornia virginica* replaces the *Spartina* at about Mean High Water (MHW) and dominates the high marsh. The *Spartina-Salicornia* ecotone is abrupt with an elevation change of as little as 7 cm sufficient for pure stands of *Salicornia* to replace pure stands of *Spartina*.

Northern California coastal marshes also have *Spartina* as the primary colonist of the tidal mudflats. *Salicornia virginica* shares dominance with *Spartina* in the lower marsh and in some instances *Salicornia* may act as the primary colonist. In the high marsh, *Salicornia* shares dominance with *Distichlis spicata*, and *Jaumea carnosa*.

Southern California coastal marshes begin at Mugu Lagoon and are found southward into Baja California. *Spartina* remains the primary colonizer of tidal mudflats and dominates the low marsh environment. Instead of *Salicornia virginica* succeeding the *Spartina*, however, a narrow zone dominated by *Salicornia bigelovii* and *Batis maritima* exists. *Batis* becomes more prevalent in winter when *S. bigelovii* (an annual) dies down.

The Physical Characteristics of estuaries recently have been classified by Ferren (1990) into four types, reflecting their origin, type of watershed, and relation to the marine environment. These types are: (1) river mouth estuaries with brackish lagoons; (2) canyon mouth estuaries with brackish or euryhaline (fluctuating salinity) lagoons; (3) bay estuaries with extensive deepwater habitats and intertidal basins; and (4) structural basin estuaries with steep watersheds, much sedimentation, and hypersaline conditions.

River Mouth Estuaries typically have some or all of the following features: (1) year-round freshwater runoff (sometimes consisting of treated wastewater) and occasional catastrophic flooding and flushing due to winter and spring storms; (2) sand bars which separate the lagoon from the open ocean except during periods of flushing following storms; (3) brackish water conditions throughout the estuary when the mouth is open, but with a freshwater to slightly brackish layer on the lagoon surface when the mouth is closed. The Ventura River Estuary is the best example of this type of estuary in Region 4. Other river mouth estuaries include the Santa Clara River, McGrath Lake, and Ballona Wetland and related complex.

Canyon Mouth Estuaries are quite variable in nature. Portions of California coastline are characteristically deeply cut, parallel canyons and arroyos which drain watersheds of the coastal foothills and mountains. These canyons empty into the ocean through small estuaries that vary in size, frequency of tidal flushing, salinity regimes and associated biota. Malibu Lagoon is the best example of this type of estuary in Region 4. Dume Creek Lagoon and Topanga Lagoon are also canyon mouth estuaries.

Bay Estuaries have large areas of subtidal habitat (bays) and usually extensive, low elevation salt marsh on the bay margins. The subtidal habitats often support beds of eel grass (*Zostera marina*). Intertidal mudflats adjacent to subtidal areas support a high diversity of invertebrate species. The margins of the intertidal mudflats are dominated by cordgrass (*Spartina foliosa*) as is the lower marsh where *Salicornia virginica* becomes important. *Salicornia virginica* and numerous other species (see above under southern California coastal marsh) share the middle and upper marsh habitats. Alamitos Bay and Los Cerritos Wetlands were historically sites of extensive bay and salt marsh habitats (2,400 acres each).

Structural Basin Estuaries occur where considerable tectonic activity has caused down-faulting or down-folding along the coast. The basins formed support small estuaries. There are no structural basin estuaries in Region 4.

Intermediate Estuaries are estuaries which exhibit characteristics of more than one of the above categories. Mugu Lagoon is an intermediate estuary which historically had a small watershed and received little runoff from the surrounding Oxnard Plain. The tidal prism was sufficient to keep the mouth of the lagoon open to the ocean (Onuf 1987). In 1884, Mugu Lagoon became an estuary, when Calleguas Creek was channelized, and directed into the lagoon which effectively expanded the watershed of the lagoon by 250 times over what it had been.

The type of vegetation present in coastal wetlands is determined by the hydrological regime, substrate, and frequency of disturbance for a given site. Region 4 contains three types of coastal wetlands.

VOL 12

1 8 9 / 4

Coastal Wetland Plant Communities

Southern Coastal Salt Marsh (Annual). Estuarine nonpersistent emergent wetlands generally lack aboveground persistent parts and are dominated by annual plants that regularly colonize seasonally exposed surfaces. Typically occurring in intertidal wetlands on exposed lagoonal bars and flats and also in the beds of shallow channels. These are not common in southern California most often associated with river mouth estuaries because of the presence of brackish or fresh water which is required for seed germination. Characteristic species include spear-leaved saltbush (*Atriplex patula*), coast goosefoot (*Chenopodium macrospermum*), salt marsh sand spurry (*Spergularia marina*), brass buttons (*Cotula coronopifolia*), and rabbitsfoot grass (*Polypogon monspeliensis*). The best example in Region 4 is at the Ventura River Estuary.

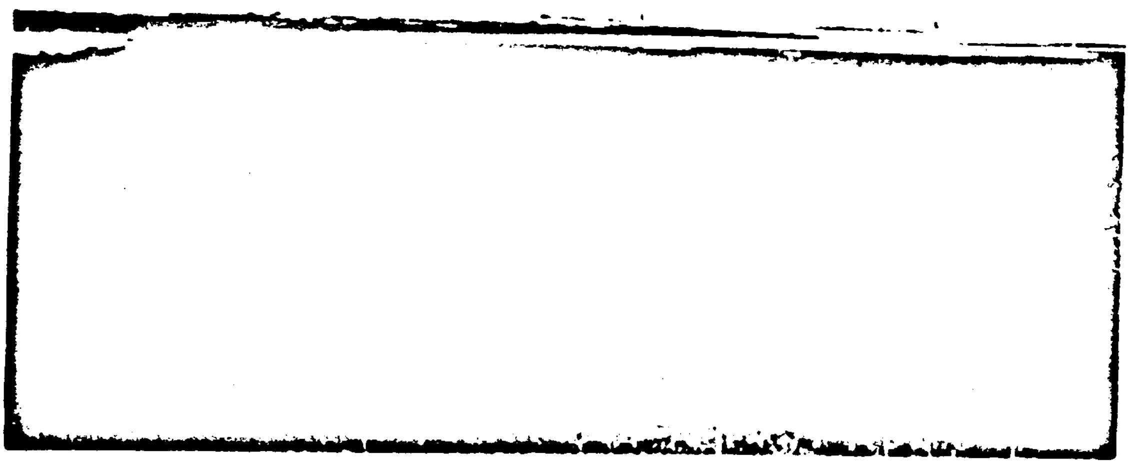
Southern Coastal Salt Marsh (Herbaceous Perennial). Is composed of persistent emergent, herbaceous vegetation which occurs on narrow to broad plains adjacent to bays or estuaries where tidal influences provide for typically saline or hypersaline conditions. Freshwater flushing occurs infrequently only following major winter or spring storms. The vegetation consists of succulent and suffrutescent perennials including pickleweed (*Salicornia virginica*), alkali heath (*Frankenia grandifolia*), fleshy jaumea (*Jaumea carnosa*), saltgrass (*Distichis spicata*), sea lavender (*Limonium californicum*), saltwort (*Batis maritima*) and arrowgrass (*Triglochin* spp.). Southern Coastal Salt Marsh also contains one annual species, *Salicornia bigelovii*. Mugu Lagoon is the best example of Southern Coastal Salt Marsh in Region 4 and in fact is the northernmost representative of this vegetation type. Other occurrances are at Anaheim Bay and at the Ballona Wetlands complex.

Coastal Brackish Marsh. Is dominated by perennial, emergent, herbaceous monocots to 2 m tall. Cover is often complete and dense. Similar to salt marshes and to freshwater marshes with some plants characteristic of both. Salinity varies considerably depending on interplay between tidal regimes and freshwater runoff. Most common along interior edges of coastal bays and estuaries where influx of freshwater is somewhat regular. In Region 4 characteristic species include narrowleaf cattail (*Typha domingensis*), broadleaf cattail (*T. latifolia*), california bulrush (*Scirpus californicus*), alkali bulrush (*S. maritimus*), and saltgrass (*Distichlis spicata*). This marsh type not widespread in Region 4. Localized occurrances are found at the Ventura River Estuary, Santa Clara River Estuary and Point Dume Creek.

Opposite Page Top: Coastal Salt Marsh at Mugu Lagoon, Ventura Co.

Opposite Page Bottom: Coastal Brackish Marsh, Point Dume, L.A. Co.

VOL 12



1 89/5

Coastal Freshwater Marsh. Is dominated by perennial, emergent monocots to 4-5 m tall. Cover is dense to complete. This type is similar to coastal brackish marshes. *Scirpus* and *Typha* are typically dominant. The sites are quiet, lacking significant current and permanently flooded by fresh water (rather than brackish, alkaline or variable). Prolonged saturation allows accumulation of deep, peaty soils. Characteristic species are wooly sedge (*Carex lanuginosa*), rough carex (*C. senta*), chufa (*Cyperus esculentus*), umbrella sedge (*C. eragrostis*), spikerush (*Eleocharis spp.*), whorled penny-wort (*Hydrocotyl verticillata*), northern mudwort (*Limosella aquatica*), common reed (*Phragmites australis*), bulrushes (*Scirpus acutus, S. americanus, S. californicus*), and cattails (*Typha domingensis, T. angustifolium, T. latifolia*). Uncommon in Region 4, best example at McGrath Lake in Ventura Co.

Coastal Saltbush Scrub. This type of scrub is transitional between saline influenced wetland types and upland habitats. Cover varies from sparse to dense. Understory is composed of grasses and forbs. Soils are typically saline clay soils which drain slowly and accumulate high concentrations of salt due to evaporation. Characteristic species include four-wing saltbush (*Atriplex canescens*), Lenscale (*A. lentiformis ssp. breweri*), Australian saltbush (*A. semibaccata*), sandbar willow (*Salix hindsiana*), arroyo willow (*S. lasiolepis*). Understory consists of various annual grasses such as *Bromus rubens*, salt grass (*Distichlis spicata*), and brass buttons (*Cotula coronopifolia*).

Coastal Wetlands: Ranking

The criteria employed in the process of ranking the coastal wetlands of Region 4 is discussed in the section on "Methods and Approaches" in the general introduction to this wetlands report.

Coastal Wetland	Rank	Disturbance	Biotic Diversity	Habitat Quality	Uniqueness	Flood Control	Water Quality	Sediment Control
Mugu Lagoon	1	A	A	A	A	A	A	A
Ballona Wetland	2	B	A	A	A	A	A	A

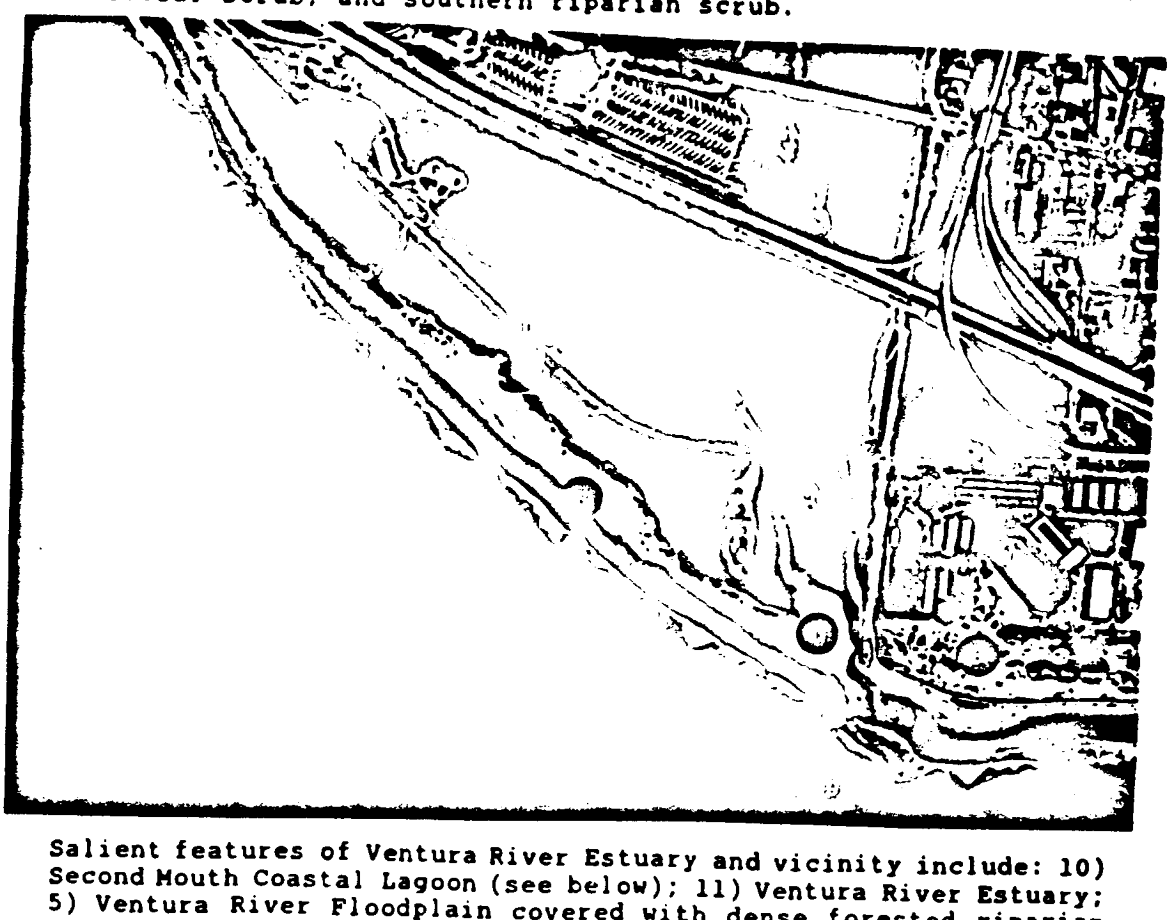
The Brackish lagoonal conditions along with a diversity of substrates and topography support a number of wetland community types which form a complex mosaic. The mosaic consists of southern coastal salt marsh dominated by pickleweed (*Salicornia virginica*) fleshy jaumea (*Jaumea carnosa*), and alkali heath (*Frankenia grandifolia*). At slightly higher elevations and intergrading with the salt marsh is a combination of dune swale wetland composed of *Salicornia virginica*, spiny rush (*Juncus acutus* var. *sphaerocarpus*), and bulrush (*Scirpus*); and scrub/shrub wetlands dominated by lenscale (*Atriplex lentiformis*), coastal goldenbush (*Isocoma veneta* ssp. *vernonoides*), and scrub willows (*Salix*). Along the west side of the estuary, between the railroad tracks and the beach is wetland dominated by nonpersistent emergent (annual) vegetation composed of coast goosefoot (*Chenopodium macrospermum* var. *farinosum*), spear-leaved saltbush (*Atriplex patula* ssp. *hastata*), and salt marsh sand spurrey (*Spergularia marina*). This is the only site for this vegetation type within Region 4. Other wetland types include southern arroyo willow riparian forest, alluvial scrub, and southern riparian scrub.



Salient features of Ventura River Estuary and vicinity include: 10) Second Mouth Coastal Lagoon (see below); 11) Ventura River Estuary; 5) Ventura River Floodplain covered with dense forested riparian vegetation.

W[illegible] the Ventura River estuary [illegible] which is only flooded during catastrophic [illegible] The area exhibits seasonal hydrological [illegible] high water [illegible] is at its highest when the main estuary [illegible] state. Coastal Wetlands: Santa Clara River Estuary

[illegible] at the mouth of the [illegible] sandbar willow [illegible] [illegible] widespread [illegible]

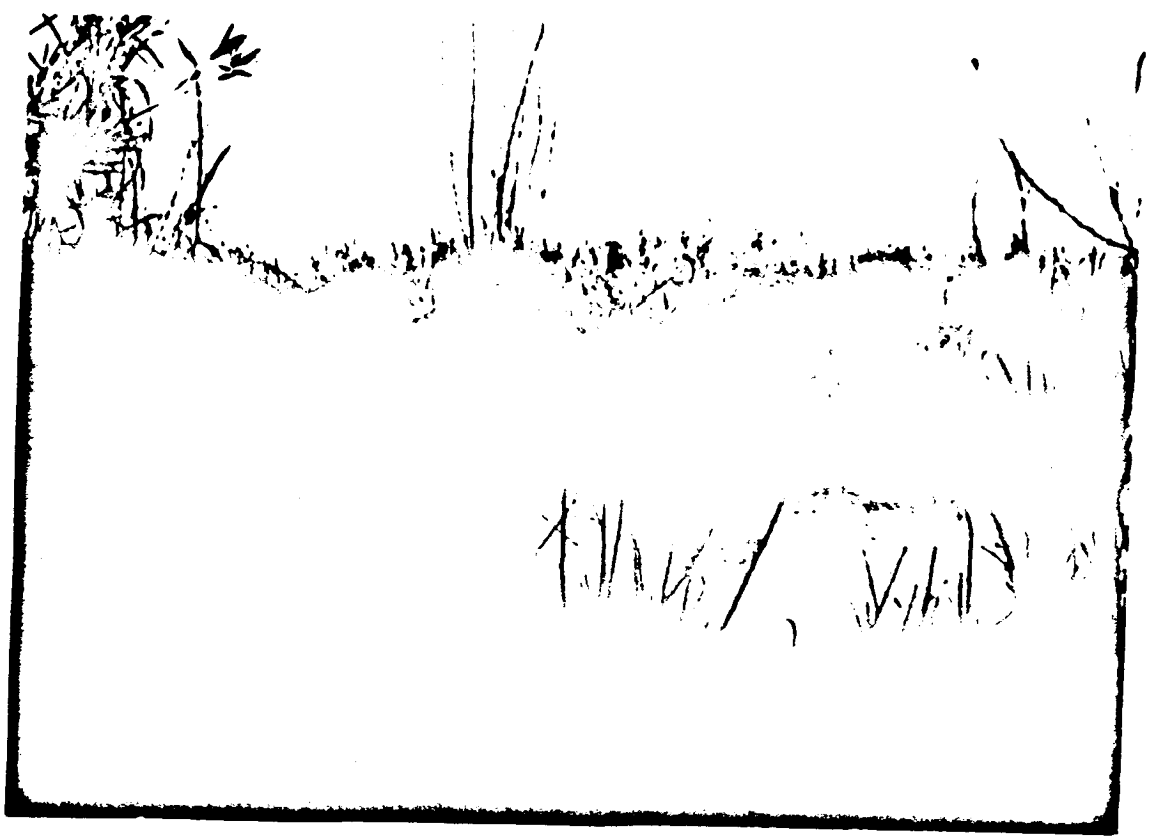

Photo: Santa Clara River Mouth, looking north at dense vegetation dominated by giant reed (Arundo donax)

The wetland covers approximately [illegible] acres and is in a significant state of disturbance due to the presence of giant reed. The giant reed displaces native vegetation, particularly the arroyo willow which is important habitat for numerous bird species including the endangered least Bell's vireo (Vireo bellii pusillus). California least tern (Sterna antillarum browni), which is a Federally listed endangered species, also nests at the river mouth. A habitat recovery plan for riparian vegetation also calls for the reintroduction of salt marsh bird's beak (Cordylanthus maritimus ssp. maritimus), a Federal candidate species, which had been extirpated from the area. Tidewater goby (Eucyclogobius newberryi), also a Federal candidate species, is found within the estuary.

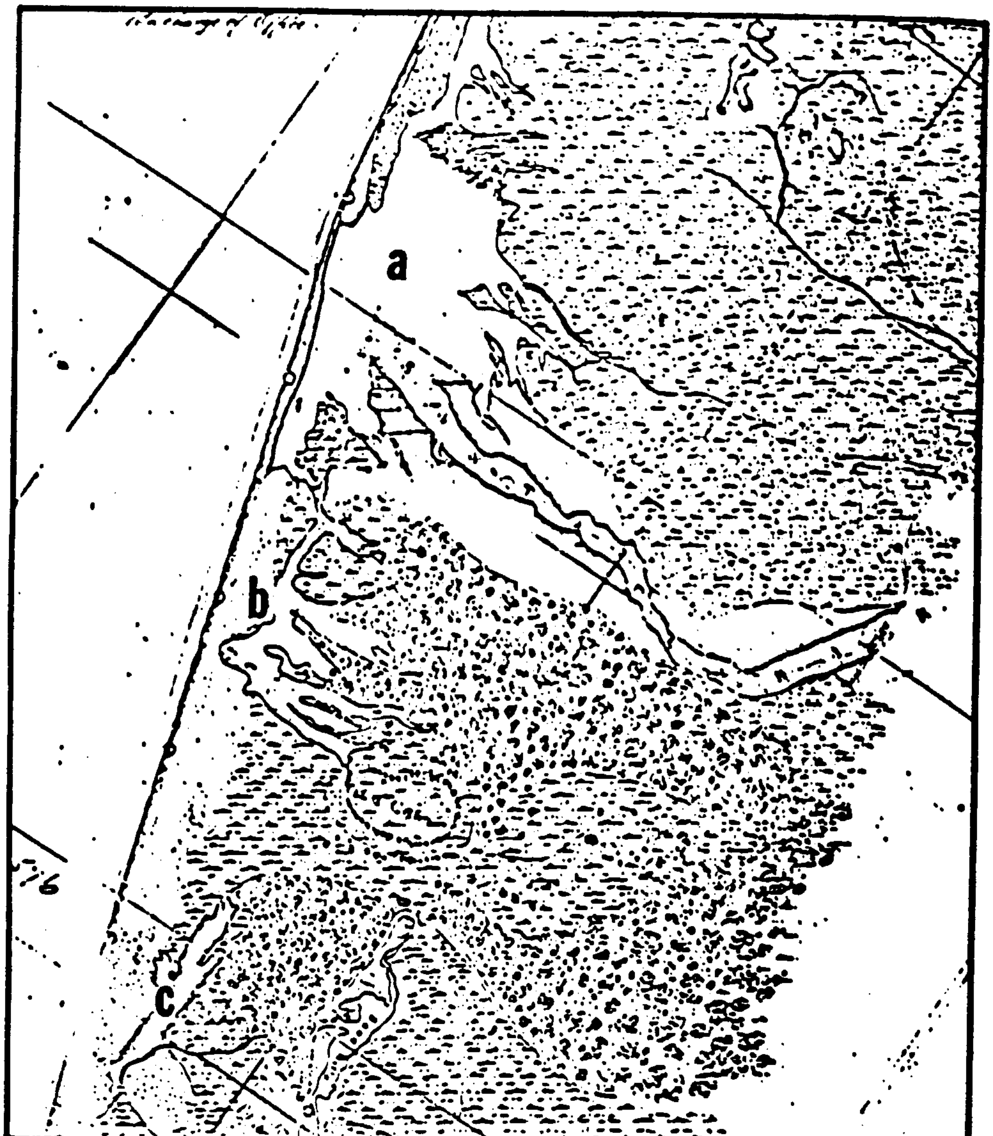
Santa Clara River Mouth from Oxnard USGS 7.5 min Quadrangle



Map: 1855 U.S. Coastal Survey Map. Significant points: a) Santa Clara River Mouth and approximate location of present Ventura Marina; b) approximate location of existing Santa Clara River mouth; c) estuary and present location of McGrath Lake.

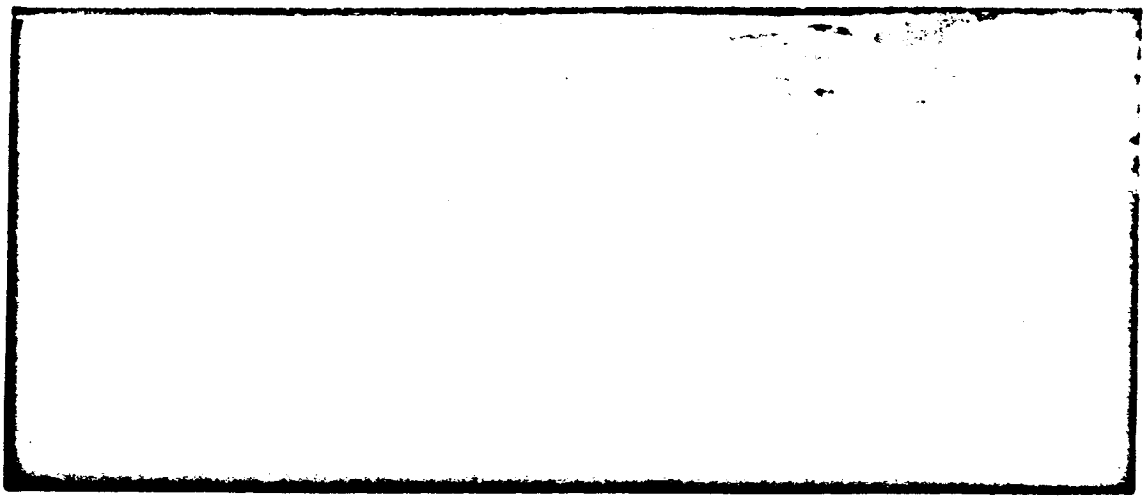


Photo: Santa Clara River Mouth, looking west at the sandbar at the mouth. Emergent vegetation in center of picture. Large monocultural stands of invasive exotic *Arundo donax* on both banks growing right to waters edge. Restoration of river mouth to native vegetation would entail eradication of *Arundo* which is an aggressive colonizer of disturbed riparian and wetland habitats. Flooding regimes favor *Arundo* over the native willows (*Salix*) because of extremely high growth rates and the ability to propagate vegetatively.

Coastal Wetlands: McGrath Lake

McGrath Lake (403.11) a 10.3 acre lake with surrounding marsh is the best example of a coastal freshwater marsh in Region 4. The Santa Clara River has migrated during the last 200 years and the location of McGrath Lake is at a former site of the rivermouth estuary. The source of water for McGrath Lake is from groundwater derived from the persistent high water table. The vegetation is not highly diverse with stands of hard-stemmed bulrush (*Scirpus acutus*) common along the bank. Saltgrass (*Distichlis spicata*) is the dominant ground cover often forming dense mats. Willows (*Salix* sp.) are present and provide habitat for bird species. Invasive exotic giant reed (*Arundo donax*) has become established and poses a threat to other native vegetation. Coastal strand elements such as sea rockets (*Cakile maritima* and silver beachweed (*Ambrosia chamissonis*) are common on the coastal strand between McGrath Lake and the Pacific Ocean.

VOL 12

L.A. Regional Water Quality Control Board
Coastal Wetlands: Ormond Beach

Ormand Beach (403.11) is coastal strand-coastal salt marsh complex in the city of Oxnard which covers approximately 15 acres. The complex includes coastal dunes which form a barrier enclosing two lagoons and interconnecting channels. The low, central portion of the complex is subject to tidal inundation and is dominated by salt marsh vegetation with fleshy jaumea (*Jaumea carnosa*) and salt grass (*Distichlis spicata*) co-dominant. Pickleweed (*Salicornia virginica*) is present but not abundant. The margins of the marsh contain lenscale (*Atriplex lentiformis*) and *Atriplex patula*. The lagoon margins support small stands of bulrush (*Sripus*). The dune vegetation is highly diverse containing sea rockets (*Cakile maritima*), silver beachweed (*Ambrosia chamissonis*), dune evening primrose (*Camissonia chieranthifolia*), ice plant (*Mesembryanthemum crystalinum*), and sea fig (*Carpobrotus aequilaterus*) which covers the back side of the dunes along the inlet (back) channel. The overall habitat is somewhat disturbed with many weedy species common including ripgut grass (*Bromus diandrus*), red brome (*B. madritensis rubens*), yellow sweetclover (*Melilotus indicus*), ragweed (*Ambrosia psilostachya*), annual barley (*Hordeum glauca*), and two particularly invasive plants giant reed (*Arundo donax*) and kikuyu grass (*Pennisetum clandestinum*), a particularly troublesome invasive grass in the Morro Bay area and other coastal dune/marsh areas.

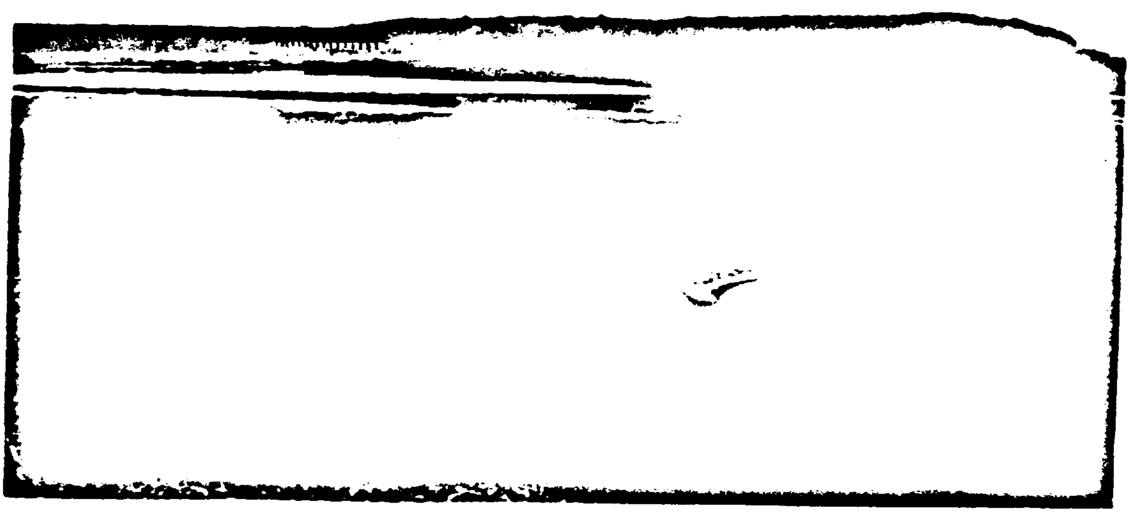
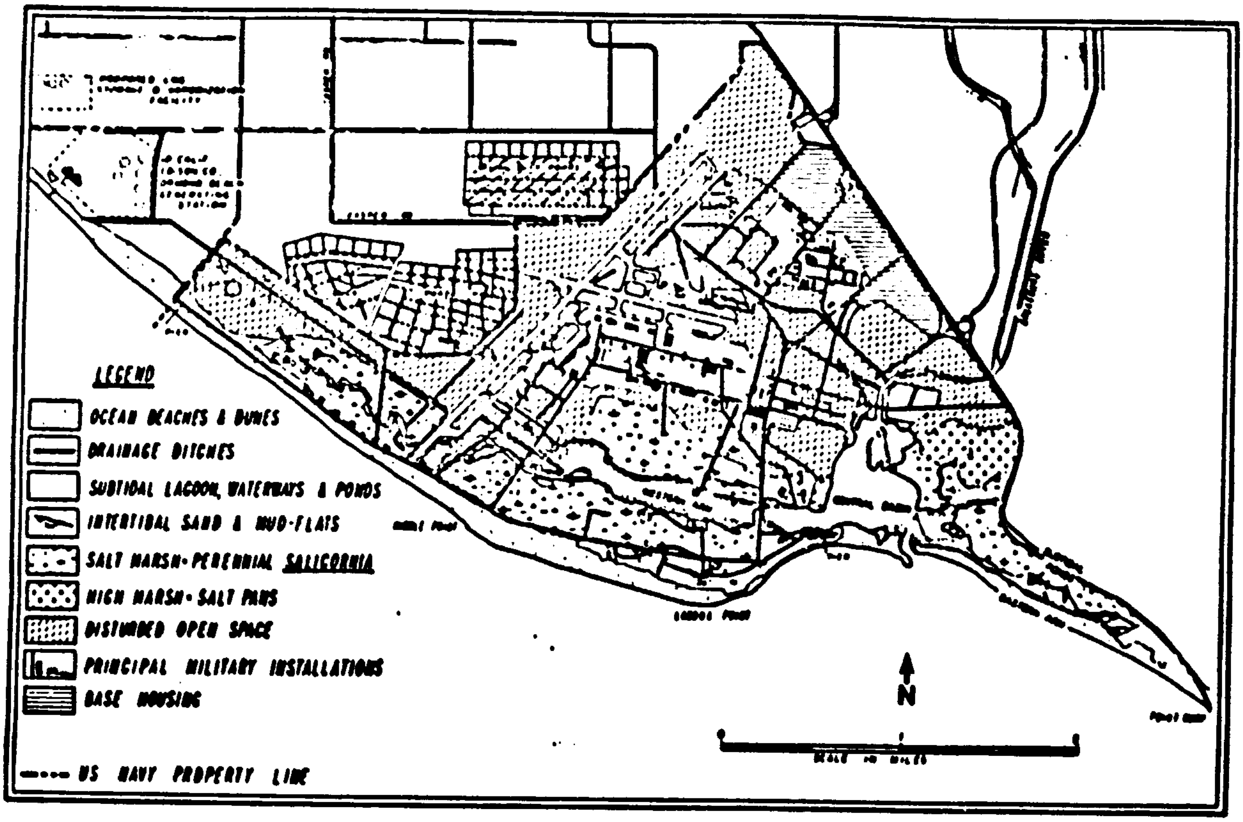
Coastal Wetlands: Mugu Lagoon

Mugu Lagoon is located on the coastal margin of the Oxnard plain in Ventura County 5[illegible] miles northwest of Los Angeles. It is the largest coastal wetland system between Elkhorn Slough, in Monterey County, and Bolsa Bay in Orange County. It is far and away the largest coastal wetland complex of Region 4 (Dennis et al. 1984). Historically the Lagoon and surrounding wetlands paralleled the coast for nearly four miles and covered approximately 3,100 acres (Macdonald 197[illegible]). In the early 1940s the U.S Navy acquired the lagoon and surrounding wetlands. In 1946 a Naval Air Station was established and became the Pacific Missile Range in 1957. A large portion of the central lagoon, which was shallow tide flats was dredged to a depth of 30 feet to provide fill for construction on the base. The dredging and construction destroyed over half of the wetland so that today 1,400 acres remain. Because of the need for military security, the area was fenced, resulting in protection for remaining marsh areas.



Mugu Lagoon, from Highway 101, showing high marsh, salt pans, and some disturbed open spaces in the foreground. There is a shallow water table at the mouth of Calleguas Creek to the right, offsite.



MUGU LAGOON WETLAND: LANDUSE AND ECOLOGICAL ZONES

The Wetland System of Mugu lagoon is conveniently described by dividing the site into three sections: the shallow eastern arms of the lagoon, the deeper central lagoon section and the shallow western arm. The eastern Arm is 1.4 miles long and between 300 to 1,000 yards wide. There are 34 acres of low marsh habitat which intergrade into tideflats along the northern shore. The Central Lagoon, which originally consisted of tide flats and salt marsh, was dredged to a depth of 30 feet in the 1950s. This is slowly being filled by sediments from Calleguas Creek and is being colonized by salt marsh vegetation. The Western Arm is farther inland and the largest marsh areas are associated with this portion of the site. It is 1.5 miles long and 1,000 yards wide. Flood control ditches and a tidal creek extend two miles beyond the western end of the lagoon and carry tidal flows to another 300 acres of salt marsh. Some upper portions of the western arm have been cut off from tidal flows by construction of roads.

The Vegetation - studies suggest that at the Mugu complex there are four zones or types of vegetation (Macdonald and Barbour 1974). the lowest zone, dominated by cordgrass (*Spartina foliosa*), annual pickleweed, (*Salicornia bigelovii*) and perennial pickleweed (*S. virginica*). Most of this has been eliminated by dredging. The majority of the marsh is now occupied by lower and upper vegetation types that are usually separated abruptly by physiographic features (sharp change of slope, etc.) at Mean High Water (MHW). The species composition of the higher marsh changes with elevation as the marsh grades into barren salt flats interspersed with strips of sinuous vegetation. Observations concerning the floristics at Mugu are extrapolated from studies performed in the eastern arm of the wetland.

The Lower Marsh is dominated by *Salicornia virginica* forming large monocultural stands. Scattered occurrances of *S.bigelovii*, *Jaumea Carnosa*, alkali heath (*Frankenia grandifolia*) and *Monanthochloe littoralis* are found in this zone. Following major storms in 1978 and 1981 there was an increase in biomass of *S. virginica* within this zone. According to Onuf (1987) the increase is due to stimulation of growth by the lowering of soil salinities due to flushing and also due to increased nutrients made available by deposition of fine sediments from surrounding watershed, much of which is agricultural and therfore high in fertilisers.

The Upper Marsh is dominated by *Salicornia virginica*, but unlike the lower marsh, other species contribute significantly to the biomass of the upper marsh. Onuf (1987) found the following composition based on 10 samples: *S.virginica* accounted for 44% of the total biomass; sea lavender (*Limonium californicum*), 21%; alkali heath (*Frankenia grandifolia*), 15%; fleshy jaumea (*Jaumea carnosa*) 14%, saltwort (*Batis maritima*), 5%; and arrow grass (*Triglochin maritima*), 2%. Along the uppermost portion of this zone Atriplex spp., seablight (*Suaeda californica*) and *Salicornia subterminalis* become more prevalent.

The Subtidal Zone historically contained large beds of eelgrass (*Zostera marina*). The intense storm of February of 1978 buried the beds and suffocated the plants. The eelgrass beds have not recovered since, with only a few small patches remaining, these identified by means of aerial photographs (Onuf 1987).

The Fauna is extreemly rich for both invertebrates and vertebrates. The tidal mudflats contain nurmerous species at high densities. Densities of 30.000 organisms per square meter have been reported (Onuf 1987). Thirty-nine species of fish have been identified from Mugu Lagoon of which the most common are arrow gobies (*Clevelandia ios*), topsmelt (Atherinops afinis), staghorn sculpin (*Leptocottus armatus*), and shiner surfperch (*Cymatogaster aggregata*). Census data for birds at Mugu Lagoon has not been published; however a list compiled by the Natural Resources Management Office for the Naval Air Station shows 198 species. Threatened and Endangered species which use the wetland are the light-footed clapper rail, Belding's savannah sparrow, brown pelican, and least tern.

VOL 12

L.A. Regional Water Quality Control Board
Coastal Wetlands: Dume Creek Lagoon

Dume Creek Lagoon (404.36) is a small freshwater lagoon of approximately 17.4 acres adjacent to Dume Beach in Western Los Angeles County. The size of the lagoon varies yearly with the amount of freshwater input. The biological value of this area is enhanced by the unique geographic position of Point **Dume**. This headland extends into Santa Monica Bay more than a mile **beyond** the rest of the Malibu coast, and is located on the **Pacific Flyway**. As a result the lagoon serves as a resting area for migr**atory** birds and also provides habitat for year round natives. **The surrounding** area is slightly degraded due to development on the overlooking bluffs. Further degradation could threaten the wetland due to increased sedimentation and runoff from areas of housing. The coastal area generally exhibits low intensity recreational use.

1 8936

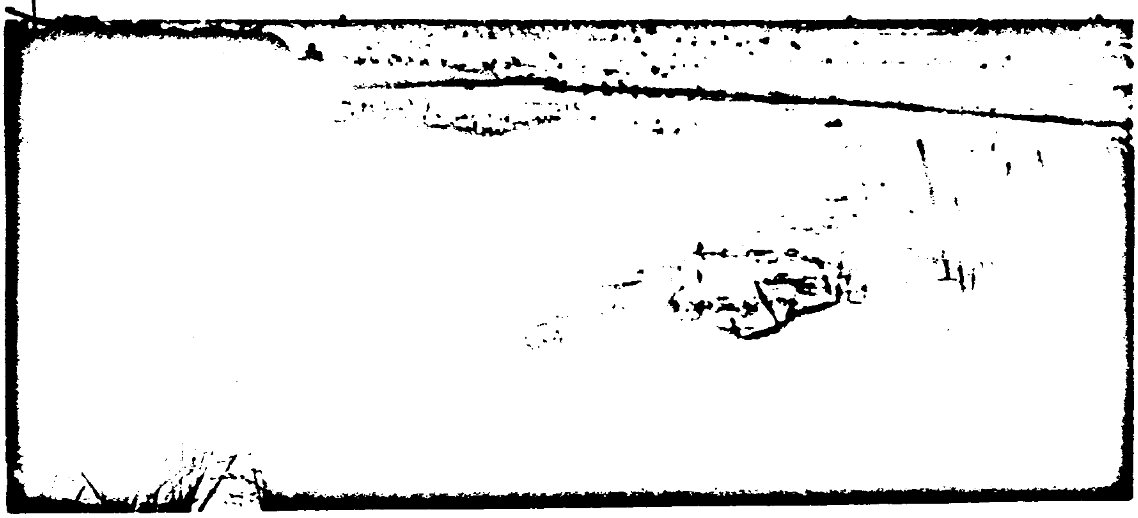


Photo: Dume Creek Lagoon, looking south toward sandbar which blocks connection with Pacific Ocean. Emergent cattails (*Typha sp.*) are in foreground with gulls and other shorebirds along the edge of the Lagoon.

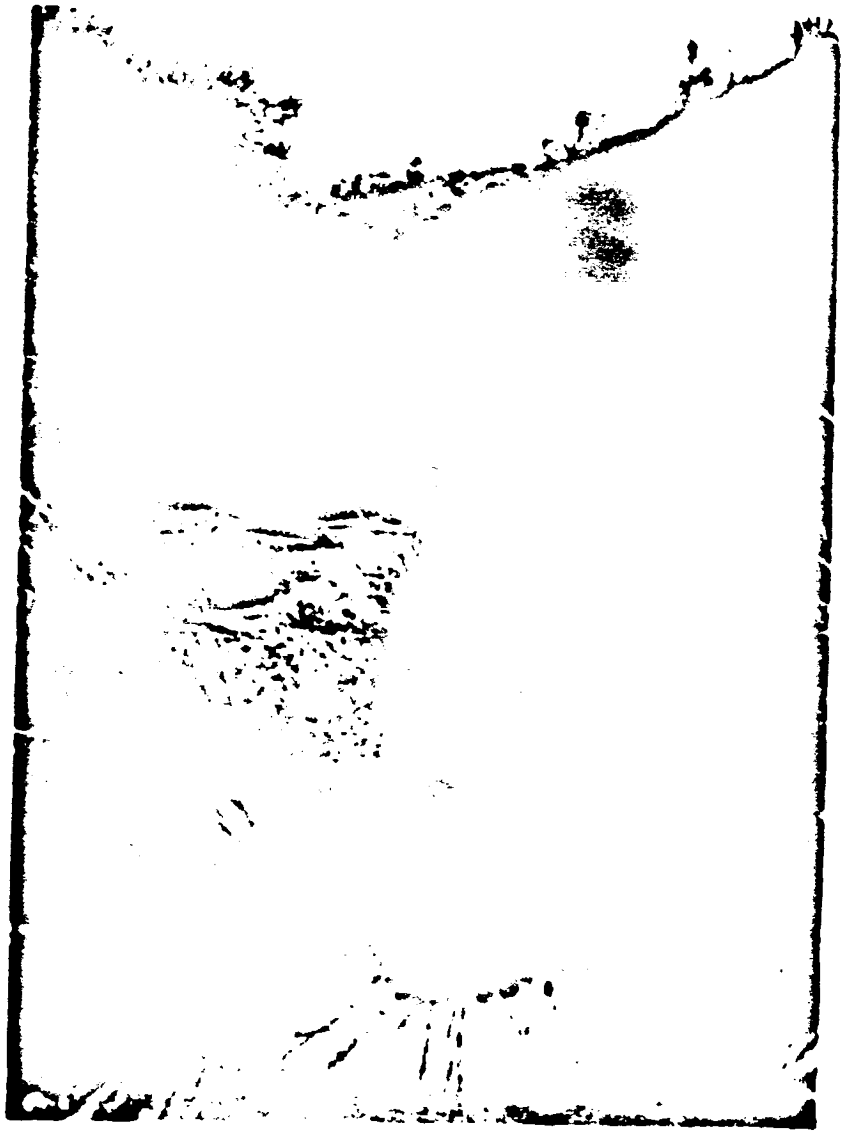
The Habitat: [illegible] Dume Creek [illegible] runoff. The vegetation [illegible] wetland [illegible] determined by the amount of water present. Species present in the wetland at the mouth of Dume Creek include cattail (*Typha latifolia*), California bulrush (*Scirpus californicus*), saltgrass (*Distichlis spicata*), and pickleweed (*Salicornia virginica*). After above average rainfall in 1991, watercress (*Rorippa nasturtium-aquaticum*) appeared in dense mats in Dume Creek. This is an excellent indicator that this area supports wetland vegetation. The density of the watercress indicates a large seed bank present in the soil. The rainfall, which occurred after 6 years of drought also raise the water table which was low due to the drought conditions.



The Photo: Looking upstream at Dume Creek from the mouth where it enters the wetland. This photo was taken November 16, 1992 after significant rainfall in February and March, 1991. The Channel is lined with arroyo willow (*Salix lasiolepis*) and the emergent vegetation in the streambed is cattail (*Typha latifolia*) and watercress (*Rorippa nasturtium-aquaticum*).

Opposite Page Photo: Same view as above, taken November 17, 1991. Caster bean (*Ricinus communis*) is indicitave of disturbed habitat. After the rain it was no longer present due to the presence of inundated soil.

Coastal Wetlands: Malibu Lagoon

Malibu Lagoon (404.21) is located in the town of Malibu, west of Malibu Pier, at the mouth of Malibu Creek. The lagoon covers 13 acres and contains roughly 2 acres of wetlands. It is one of the last remaining estuaries in Los Angeles County. Freshwater inflow through Malibu Creek is largely comprised of tertiary treated wastewater from the Tapia Water Reclamation Plant, five miles upstream. The lagoon is an important stopover and wintering area for migrating birds and is an essential nursery habitat for various fish species. Malibu Creek is presently the southernmost range extension of the anadromous steelhead trout (*Oncorhynchus mykiss*) which enters the lagoon to spawn upstream in Malibu Creek. The lagoon is readily accessible and receives heavy human use. A wetland restoration project, begun in 1983, has formed a permanent lagoon, a tidal marsh, and an upper marsh.

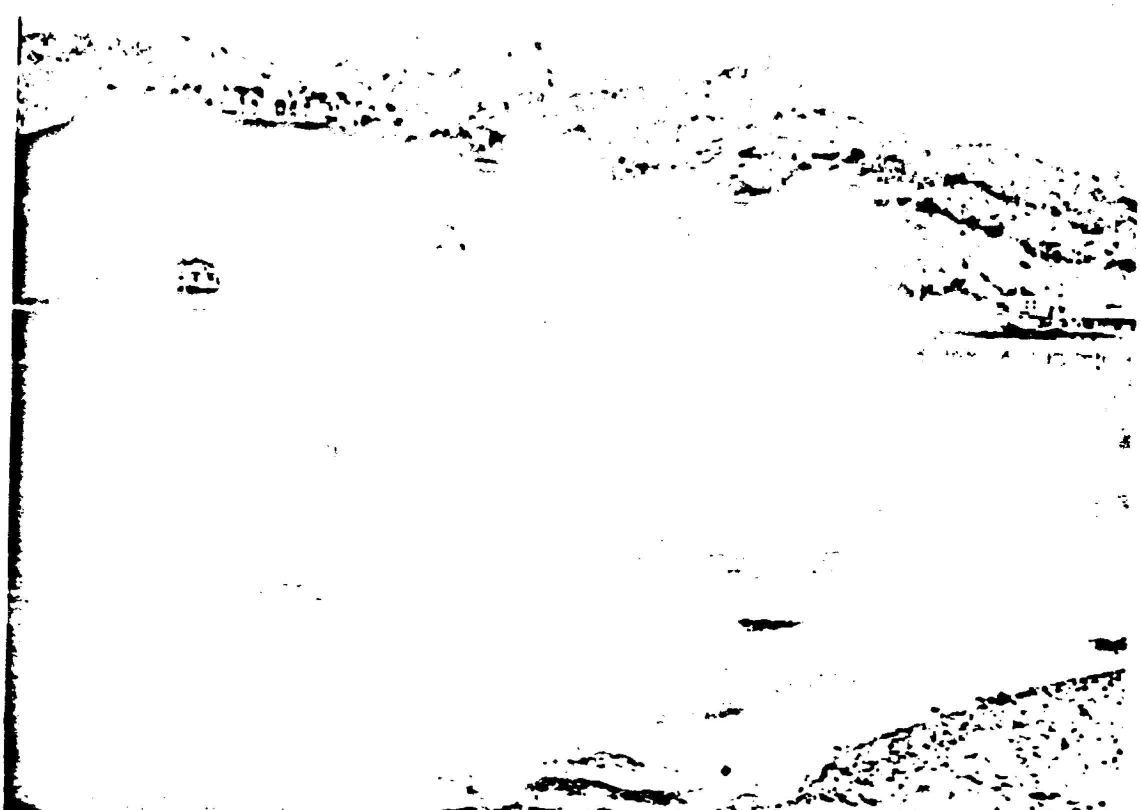

Photo: Malibu Lagoon facing north toward Pacific Coast Highway. Main lagoon, showing gulls, the most common of over 150 species which have been observed using the lagoon.

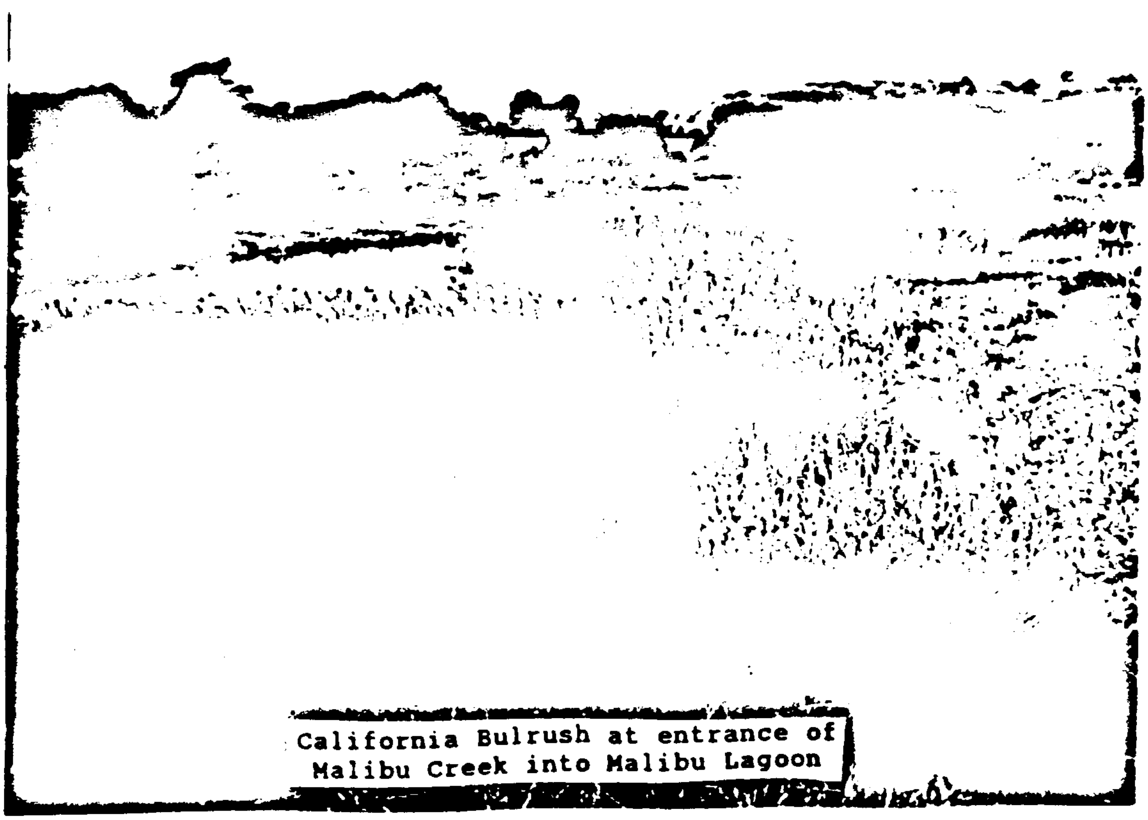
The Wetland Vegetation found at Malibu Lagoon is different from other tidal marshes in southern California. Typically, pickleweed (*Salicornia virginica*) is the first plant to establish dominance in salt marsh communities due to its ability to tolerate hypersaline soils. At Malibu Lagoon, fleshy jaumea (*Jaumea carnosa*) is the dominant low marsh plant and in some areas shares dominance with saltgrass (*Distichlis spicata*). This is probably due to two factors: (1) much of the substrate is sandy fill brought in during the restoration of the marsh. This soil drains quickly reducing the buildup of salt in the soils which favors pickleweed. (2) Pickleweed requires only a brief window of fresh water for germination, and when this is extended, germination rates fall. Jaumea germinates well in fresh water and has a competitive advantage over pickleweed in this estuarine environment which is subject to high amounts of freshwater influx. Other species found in the salt marsh include alkali heath (*Frankenia grandifolia*), *Limonium californicum*, dodder (*Cuscuta salina*), and arrow-grass (*Triglochin concinnum*). Bulrushes (*Scirpus californicus* and *S. robustus*) are found growing in the freshwater channel at the head of the lagoon. Past occurrances of *Astragalus Brauntonii*, a federal candidate 2 are recorded for the wetland area

The Animals which use Malibu Lagoon are numerous. There were recorded 151 different bird species between April of 1987 and March of 1988, including the California least tern (*Sterna antillarum browni*) which is listed as endangered (state and federal listings). Tidewater Goby (*Eucyclogobius newberryi*) a federal candidate for listing is also found in the lagoon.



California Bulrush at entrance of Malibu Creek into Malibu Lagoon

The Watershed drained by Malibu Creek is the largest in the Santa Monica Mountains comprising 67,000 acres. Malibu Lagoon forms at the terminus of Malibu Creek as a result of the fluvial processes of erosion, transportation and deposition of sediments. The winter and spring floods, typical of southern California, erode and carry the majority of yearly sediment load to the lagoon. The historic annual hydrologic cycles are currently disrupted by excessive non-seasonal domestic (tertiary treated) water most of which is from the Tapia Water Reclamation Facility of the Las Virgenes Municipal Water District. Tapia releases 8-10 million gallon per day into Malibu Creek.

The high influx of fresh water has a significant impact on the biota within the lagoon. Seawater salinity is typically 34-36 ppt. Measurements in the lagoon at various times and in various locations found salinities ranging from 2-35 ppt. There is often significant layering (saltwater lens formation) tied to the tidal cycles. As sediments flow into the lagoon, the mouth is closed, interrupting the influx of seawater. To mitigate the effects, Los Angeles County Department of Parks and Recreation periodically (once or twice a month) opens the mouth of the lagoon by bulldozing. During the rainy season, high flows associated with storms naturally breach the sediment at the mouth of the lagoon.

L.A. Regional Water Quality Control Board
Coastal Wetlands: Topanga Lagoon

Topanga Lagoon (404.11) is a 5.0 acre estuarine waterbody at the terminus of Topanga Canyon Creek where it discharges into the Pacific Ocean. There is no significant salt marsh associated with Topanga Lagoon. Vegetation around the lagoon is **indicitave** of a disturbed habitat and consists of grand reed (**Arundo donax**), tree tobacco (*Nicotiana glauca*). Some isolated willows (***Salix***) are present. California Trout lists the lagoon as potential habitat for anadromous steelhead, and lists Topanga Canyon Creek as actual habitat for trout. Overall the area is degraded by large amounts of trash and broken concrete.

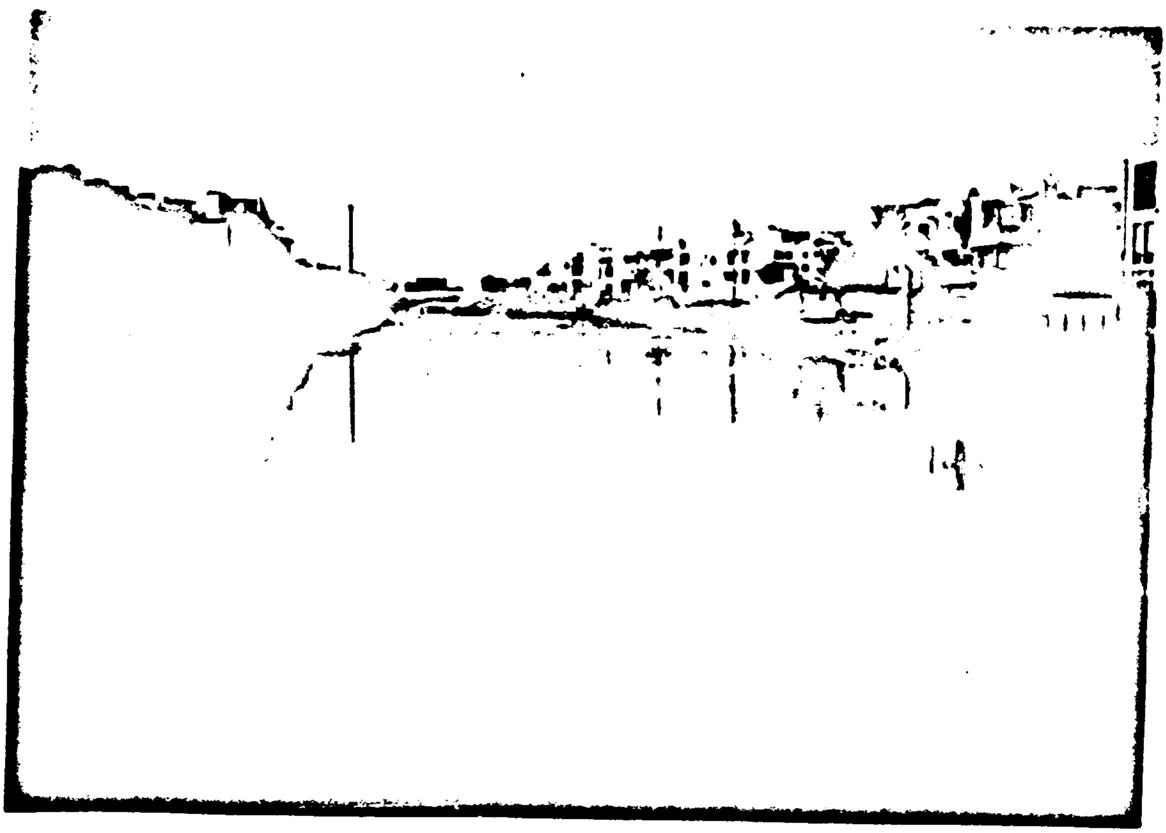
Coastal Wetlands: Ballona and Del Rey Lagoons

Ballona and Del Rey Lagoons are part of the coastal wetland complex [illegible] to the north and south of the channelized Ballona Creek. The Ballona wetlands constitute the rest of the complex. Historically, nearly [illegible] acres of wetlands, the Ballona Creek Marsh, were situated at this site. In [illegible] the major lagoons were drained and [illegible] of the land was converted to agriculture. In the 1960s the remaining [illegible] acres of salt marsh were developed into the Marina Del Rey residential marina project.

The primary source of water is the marina and the mouth of the harbor which are connected to the lagoon through tidal gates. The lagoons are surrounded by houses and streets which contribute fresh water. The lagoons provide habitat for over [illegible] species of waterbirds with peak densities during winter.

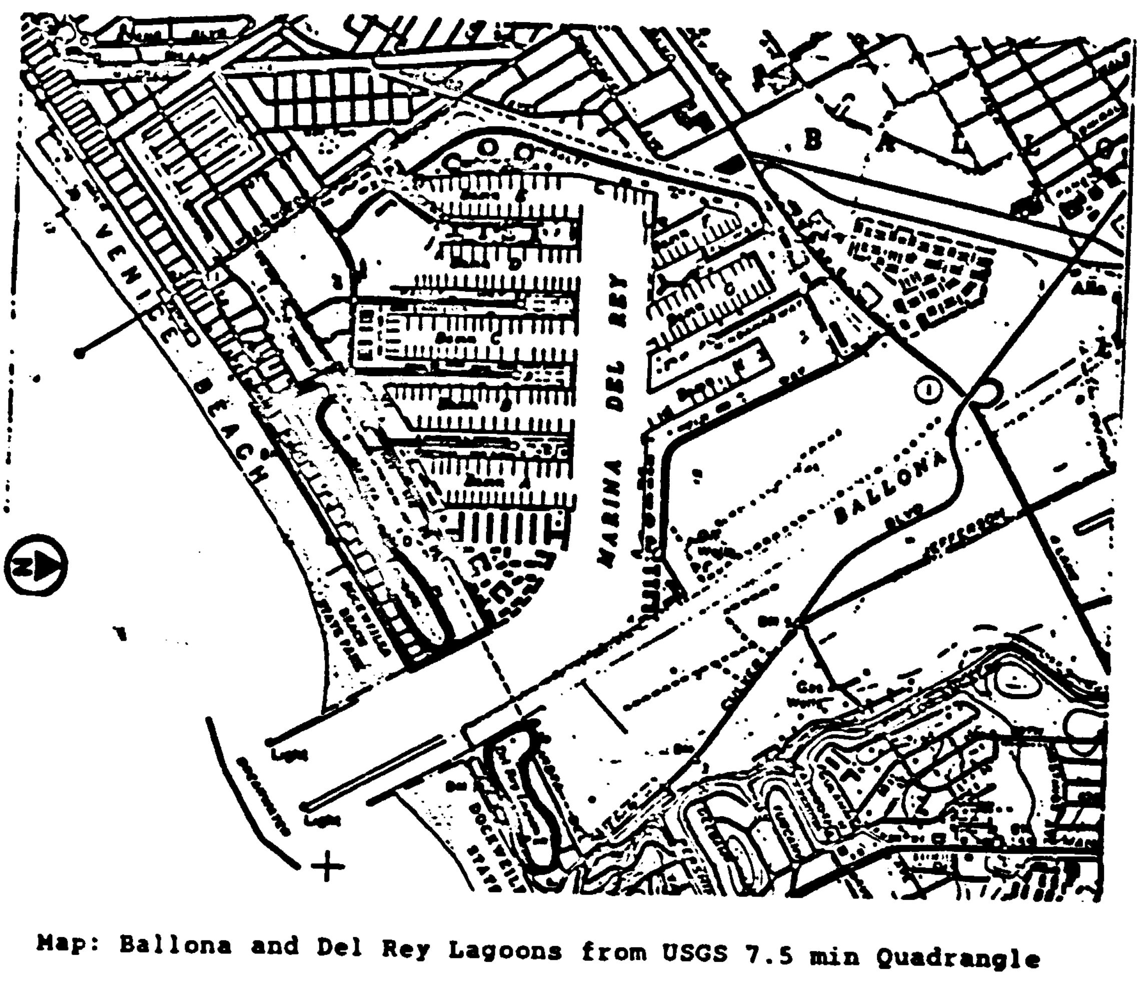


Ballona Lagoon, looking north from parking lot, near inlet from Marina Del Rey Harbor. The lagoon is surrounded by housing and slopes, some barren and some covered by iceplant (Carpobrotus sp.)

Ballona Lagoon (405.13) is located to the north and Del Rey Lagoon to the south of the channelized Ballona Creek. Ballona Lagoon covers 16 acres and has associated with it 1.5 acres of intertidal wetland vegetation mainly pickleweed (*Salicornia virginica*), and saltgrass (*Distichlis spicata*).

The Hydrology: The major source of water is marine water, derived from Marina Del Rey harbor entrance through the two tidal gates. There is also some fresh water derived from urban runoff, from a drainage are of about 290 acres which include the Venice Grand Canals to the north. At the site of seawater entrance from the south the water is saline.

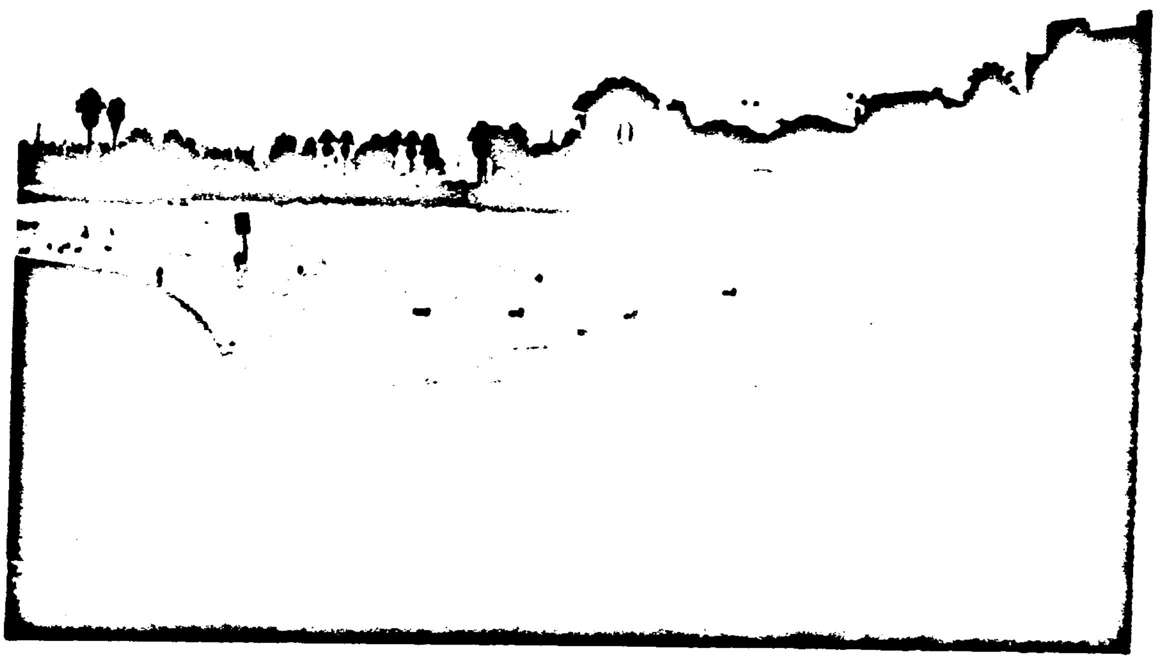
Occurrances of California least tern (*Sterna antillarum browni*), and the salt marsh skipper have been reported.



Map: Ballona and Del Rey Lagoons from USGS 7.5 min Quadrangle

Del Rey Lagoon is located to the south of Ballona Creek and to the west of the Ballona wetlands. There is no salt marsh vegetation, only iceplant (*Carpobrotus* sp.) which is used as a ground cover. Various waterbirds were observed during a field visit including a snowy egret (*Egretta thula*).

The Hydrology: The source of water is marine water which enters through the tidal gates located at the north of the lagoon. Some urban runoff from housing and streets to the east and west of the lagoon, and from irrigation waters for a park area in the south.



Del Rey Lagoon showing lack of vegetation.

Coastal Wetlands: Ballona Wetlands

Ballona Wetlands (405.13) is a [illegible] acre seasonal brackish and saline coastal wetland of which [illegible] acres are viable and are all that remains of an historical [illegible] acre salt marsh. It is located to the south of the channelized Ballona Creek and the harbor of Marina del Rey and is part of a larger complex which includes Ballona and Del Rey Lagoons. Shallow groundwater augmented by urban runoff is the main source of water. Tidal flows from Ballona Creek are blocked by tidal gates. The wetland presently is significantly degraded and restoration plans are proposed. These plans include creation of a freshwater marsh which will compensate for wetland losses. The marsh will be used for treatment of urban runoff and as wildlife habitat. Development of mid-tidal and full-tidal wetland systems is also proposed as a long-term goal.

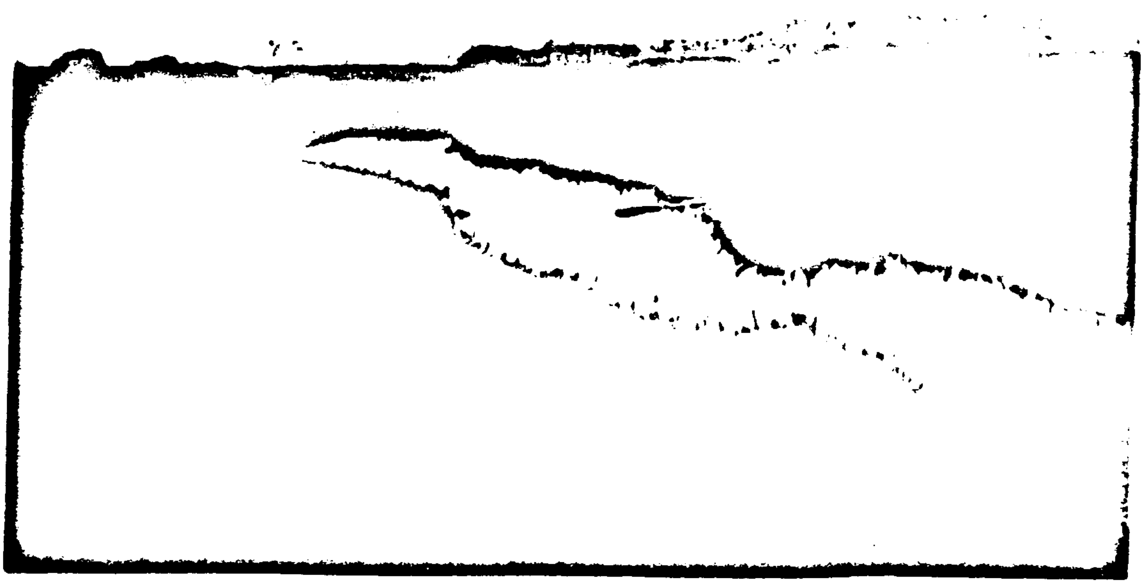

Photo: Ballona Wetland looking south from Ballona Creek. Pickleweed (*Salicornia virginica*) is the dominant herbaceous perennial. Willows (*Salix* sp.) can be seen in the background. Access to the site is limited by a fence.

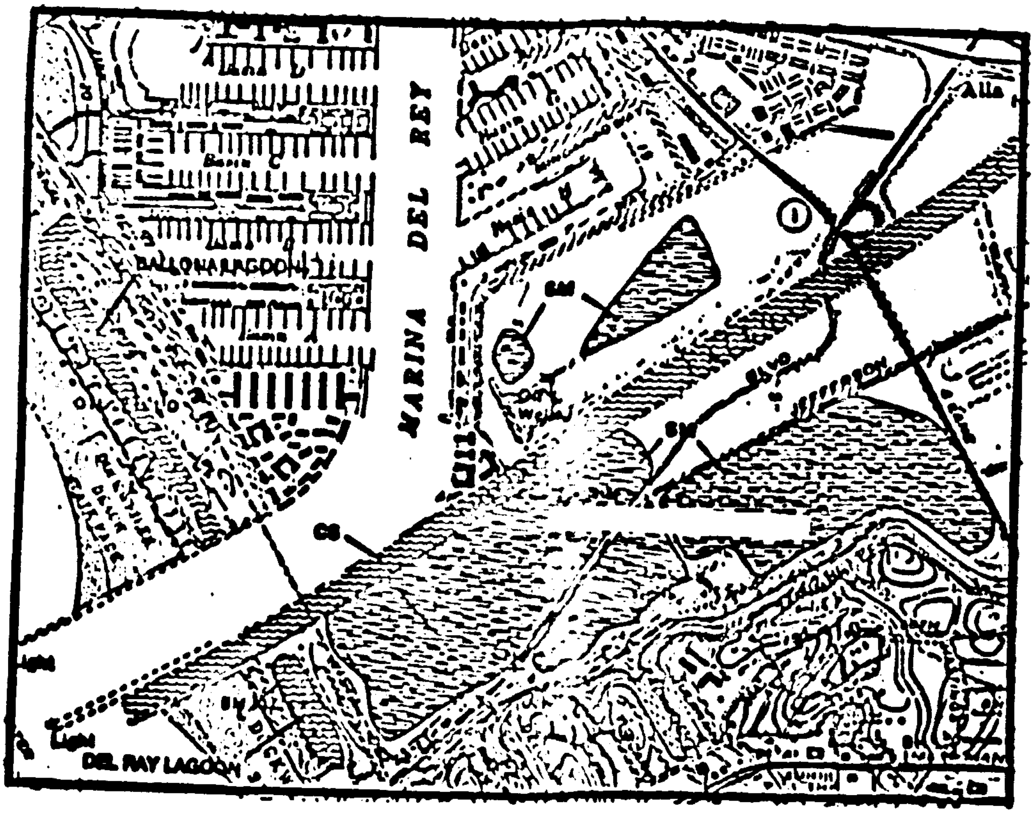
VOL 12

1 8949



BALLONA LAGOON, DEL RAY LAGOON AND BALLONA WETLAND COMPLEX

(from Josselyn and Chamberlain, 1993)

The Site consists of 182 acres of non-tidal coastal wetland and 50 acres of flood control channel. The wetland atea lies below 10 feet Mean Sea Level with a 2 to 5 percent slope. The surrounding soils are in the Oceano association and the soils within the wetland are alluvial and tidal marsh soils with high clay content.

Considerations for the site are as follows: (1) The Ballona wetland is the single largest coastal wetland system remaining in Los Angeles County and therefore represents an important resource. (2) Although there are various proposals for enhancement or restoration to both fresh and tidal wetlands there are contraints such as the need for flood control, the presence of underground gas storage facilities within wetland area, and the presence of underground pipelines which would need rerouting should tidal action be restored. Despite these constraints, the current landowner Maguire Thomas Partners is working with the National Audubon Society in developing restoration plans which would restore some level of tidal action to the wetland.

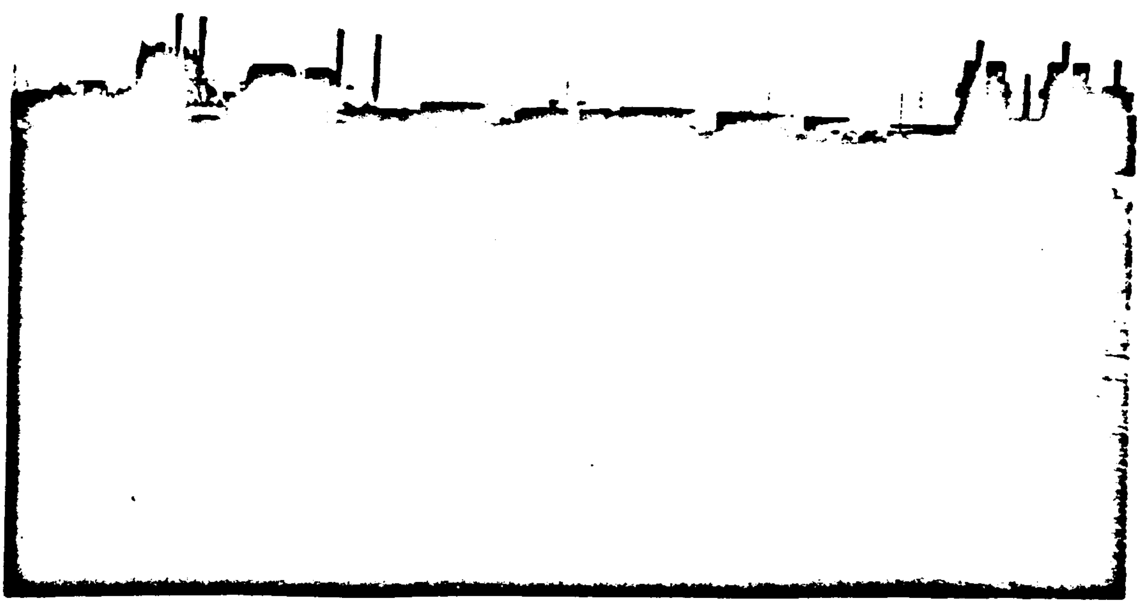
Coastal Wetlands: Los Cerritos Wetlands

Los Cerritos Wetlands (405.12) is a complex consisting of coastal salt marsh, intertidal channels, freshwater input and a fresh water pond. The area covers approximately 244 acres near the intersection of Pacific Coast Highway and Westminster Boulevard in Long Beach. The area south of Westminster Boulevard and the western portion north of Westminster Boulevard is an oil fiel and is largely degraded. The remaining portion of the northern section is a high quality coastal salt marsh. Within the northern, high quality portion of the wetland the vegetation is composed of cordgrass (*Spartina foliosa*) which is dominant in the tidal flats where periods of inundation are longest and extending to the lower portions of the marsh. At higher elevations, *Spartina* gives way to pickleweed (*Salicornia virginica*) which is dominant in the higher elevations. Salt grass (*Distichlis spicata*) is common throughout the complex. Cattail (*Typha latifolia*) and California bulrush (*Scirpus californicus*) are also present.

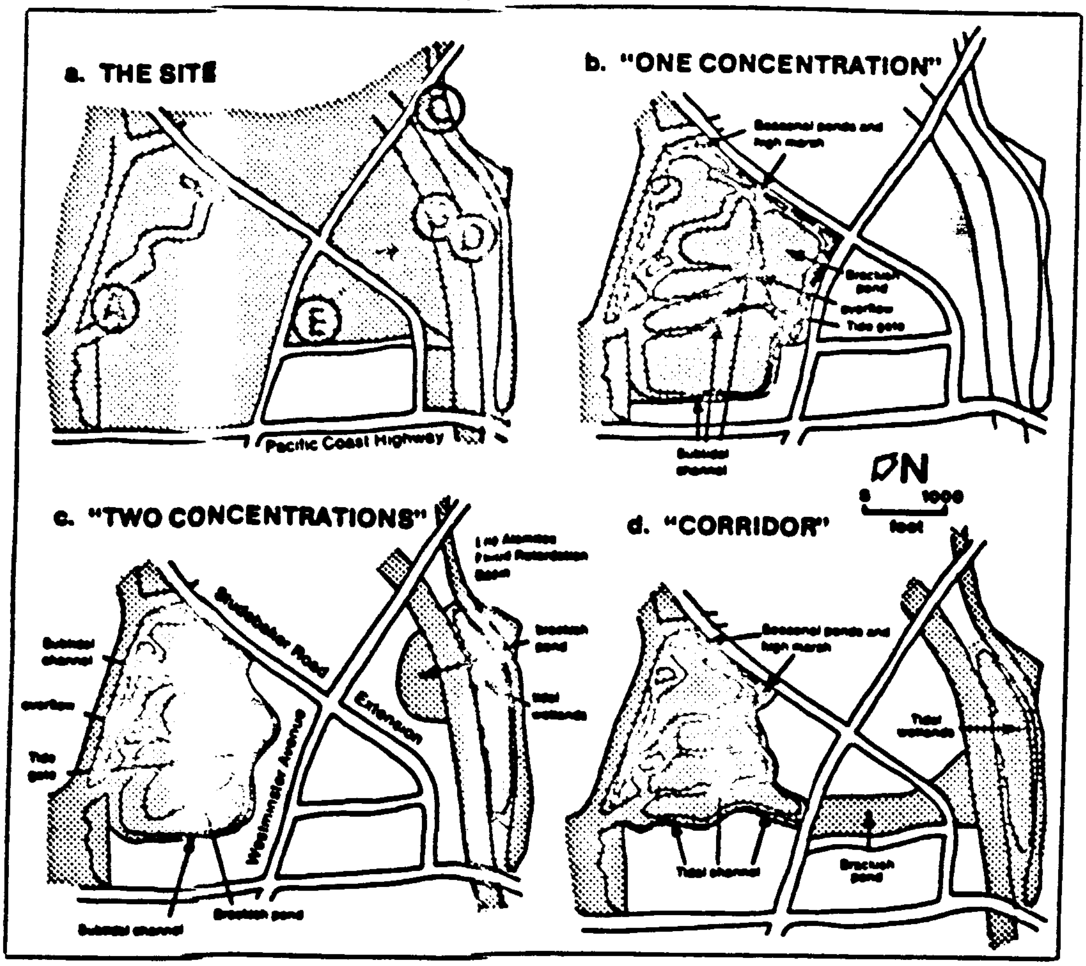


Northern Portion Los Cerritos Wetlands: Photo taken from south side of channel, across from marina. View is to the east showing extensive stands of cordgrass (*Spartina foliosa*). Power plant in background is on Studebaker Road.

18951

R0052256

Los Cerritos Wetland Restoration Alternatives.
(proposed by Sorensen and Associates)



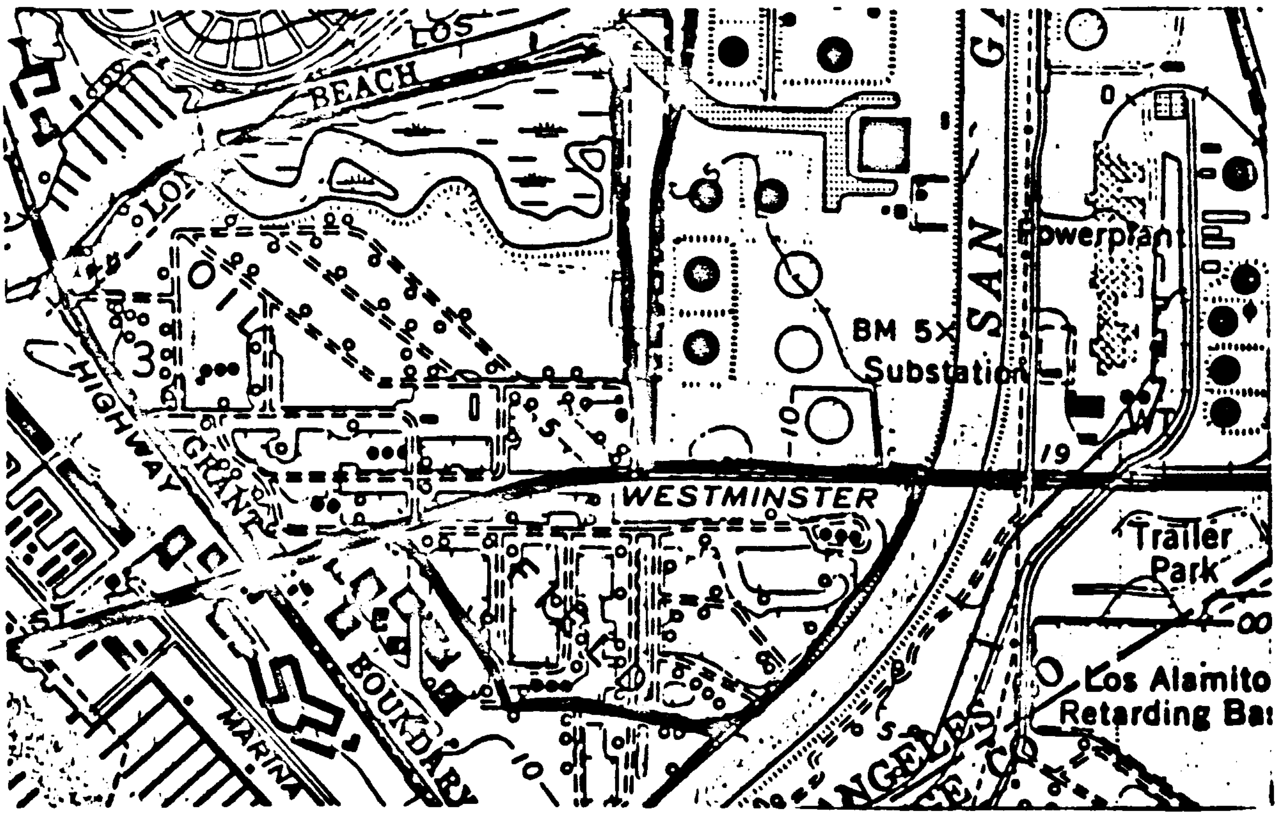
THE EXAMPLE OF LOS CERRITOS WETLAND RESTORATION

Alternative sketch plans for restoring Los Cerritos Wetlands (in Long Beach) were developed by Jens Sorensen and Associates. The restoration planning had the following features which were given at the onset:

- The site (Figure 7a) included 244 acres. Of this, 129.5 acres were to be restored as wetlands habitat; the remaining acreage would be developed.
- Studebaker Road was to be extended through the site.
- The site abutted another potential restoration project to the east.

Study of the area by the Department of Fish and Game and site inspection by scientists indicated that the following ecological assets already existed, although all were disturbed:

A. Intertidal channels, creeks, and marsh (functioning intertidal wetland)
B. San Gabriel River (aquatic habitat)
C. Power plant cooling-water intake (aquatic habitat)
D. Small intertidal channel and marsh connected to river by culvert
E. Artificially-built freshwater pond, heavily used by birds



Wetland Complex: High quality cordgrass/pickleweed salt marsh is separated from rest of complex by intertidal creek (in blue above and A below). Freshwater pond(s) (also in blue) support extensive stands of bulrush and cattail, and provide habitat for numerous birds.

Photo Opposite Top: Shows intermittent freshwater ponds on the southern portion of the complex which support large stands of California bulrush and cattail.

Photo Opposite Bottom: Intertidal Channel with stands of Pickleweed.

The complex is habitat for many bird species. Those observed during field visits were: great blue heron (*Ardea herodias*), green-backed heron (*Butorides striatus*), great egret (*Casmerodius albus*), willet (*Catoptrophorus semipalmatus*), kingfisher (*Ceryle alcyon*), and whimbrel (*Numenius phaeopus*). The complex is also potential habitat for Belding's savannah sparrow (*Passerculus sandwichensis beldingi*) and California least tern (*Sterna antillarum californicum*), both endangered species.

Lacustrine Wetlands

Lakes, and their associated lacustrine wetlands, typically occur in two physical situations: topographic lows and areas underlain by impermeable substrates. Topographic lows are created by a variety of erosional and depositional processes (Orme 1990). Southern California does not contain a large number of naturally occurring lakes. Another situation, namely the artificial impoundment of water behind dams, for purposes of flood control and water storage, provides for the formation of the majority of lakes in Region 4. Although artificial, many of the lakes and reservoirs have associated habitats which have the hydrology, soils, and vegetation which meet the criteria for wetland designation.

The rapid urban development in southern California since the 1930s has led to enormous losses, particularly of coastal wetlands and riparian wetlands of the coastal plain. During the same period, because of concerns regarding flood control and water storage, numerous reservoirs have been created, increasing the acreage of lacustrine wetlands. Many of these serve as "ecological islands" for many species of fish, birds and other vertebrates as well as many invertebrates. Large complexes, such as at the Whittier Narrows Recreation Area, provides habitat for numerous resident and migratory birds and waterfowl. Also significant is that many of these lacustrine wetlands occur along existing wildlife riparian corridors, enhancing the habitat and corridor value. Many threatened, endangered species and species of special concern utilize artificial lacustrine habitats. Examples include: southwestern pond turtle (*Clemmys marmorata pallida*), which is found at Lake Piru, Lake Sherwood, Lake Malibu, and Lake Casitas. Santa Ana sucker (*Catostomus santaanae*) is found at Lake Piru and at San Gabriel Reservoir. The threespine stickleback (*Gasterosteus aculeatus williamsoni*) is dependant on release of water from Drinkwater Reservoir in San Francisquito Canyon to provide flows required for maintenance of populations of this State and Federally listed fish. Bank swallows (*Riparia riparia*) utilize Lake Sherwood and occurrences of the California least tern (*Sterna antillarum browni*) have been recorded for Lake Machado and Harbor Lake.

As urbanization continues to exert pressure on the coastal and riparian wetland resources throughout the region, the importance of lacustrine wetlands can only become more significant. A thorough understanding of the hydrological and biological dynamics of lakes and reservoirs and their associated wetlands is necessary for the continued health of the habitat, for the maintenance of water quality (surface and groundwater), and the protection of the coastal areas from potential catastrophic flood events.

Description: Lacustrine Wetlands

Valley Freshwater Marsh is dominated by perennial, emergent monocots 4-5 meters tall often forming completely closed canopies. *Scirpus* and *Typha* are typically dominant. **Site factors** include quiet (lacking significant current), **permanent flooding** and freshwater. Prolonged saturation permits the **accumulation** of deep, peaty soils. Characteristic species include **chufa** (*Cyperus esculentus*), tall umbrella sedge (*Cyperus eragrostis*), ***Eleocharis*** spp., common reed (*Phragmites australis*), **black sedge** (*Scirpus acutus*), hard stem bulrush (*S. americanus*), California bulrush (*S. californicus*), narrow-leaf cattail (*Typha angustifolia*), southern cattail (*T. domingensis*) and broad-leaf cattail (*T. latifolia*). This type is found throughout Region 4. Good examples are found at Lake Eleanor, Century Reservoir, and Matilija Reservoir.

Stands of Cattail (*Typha*) and Bulrush (*Scirpus*) at Lake Eleanor.

Functional Values

Wildlife Habitat is of primary importance in any consideration of lacustrine wetlands. The lakes and associated vegetated wetlands provide resources in the form of food and shelter for numerous species of invertebrates (primarily insects) which are in turn major food sources for fish and bird species. These, in turn, are utilized by raptorial birds and other animals at the top of the food chain. As discussed above, there are many endangered, threatened, candidate or sensitive species associated with and often obligately tied to lacustrine wetland habitats.

Water Storage in the arid southwest is a way of life. In Region 4, many of the large lakes were constructed to store water imported from the Owens Valley, Sacramento Delta or Colorado River. Presently, nearly all of the lakes in Region 4 serve as reservoirs.

Groundwater Recharge zones are often below major reservoirs so that water can be released at a rate which allows for minimal losses of the water resources. Water released from Morris Reservoir near the mouth of San Gabriel Canyon is directed to spreading ground in the large alluvial deposits along the San Gabriel River in Azusa and Irwindale.

Flood Control is also provided by many reservoirs. In the late 1930s disastrous floods occurred providing the impetus for the construction of numerous dams throughout the region. Many of these reservoirs now serve a dual purpose, providing flood control and storage capacity. The storage of a permanent water supply has created wetlands in the form of freshwater marshes.

Lacustrine Wetlands: Matilija Reservoir

Matilija Reservoir (402.20) is the most extensive and best example of a lacustrine wetland in Region 4. The wetland is located at the upper end of the reservoir where Matilija Creek discharges into the lake. The wetland is a mosaic of vegetation types including extensive monocultural stands of cattail (*Typha*) which provide approximately 80% of the vegetative cover. Bulrush (*Scirpus*) contributes about 15% of the total cover and also occurs in dense stands. Willow woodland is dominant along the margins of the wetland and is dominated by yellow willow (*Salix lasiandra*) and arroyo willow (*S. lasiolepis*). Individuals of sandbar willow (*S. hindsiana*) are found throughout the wetland. Other species include cocklebur (*Xanthium strumarium*), and invasive exotic giant reed (*Arundo donax*) which forms dense stands, displacing native plants.

Lacustrine Wetlands: Century Reservoir

Century Reservoir (404.21) is a 6.0 acre lake reservoir in Malibu State Park. There is a small wetland at the dammed end of the lake consisting of dense, monocultural stands southern cattail (*Typha domingensis*). The cattail wetland intergrades into southern arroyo willow riparian forest dominated by *Salix lasiolepis*. The cattails are emergent and dominant in a narrow zone along the entire shore of the lake. Other species include sycamore (*Platanus racemosa*), mule fat (*Baccharis salicifolia*), mugwort (*Artemisia douglasiana*), and California bay laurel (*Umbellularia californica*). The area is subject to various types of recreational uses including fishing, hiking, jogging.

Century Reservoir: Malibu 7.5 minute Quadrangle

L.A. Regional Water Quality Control Board
Lacustrine Wetlands: Lake Eleanor

Lake Eleanor (404.25) is a [illegible] reservoir created by a dam on Eleanor Canyon Creek. At the southern end of the lake there is a high quality cattail (*Typha*) and bulrush (*Scirpus*) dominated wetland covering 3-4 acres which intergrades into southern arroyo willow riparian forest. The *Typha* and *Scirpus* form occassionally dense stands along the western shore of the lake while the eastern shore is dominated by mulefat (*Baccharis salicifolia*). Lake Eleanor demonstrates the importance of even small wetlands to certain species. During a field visit on 10 13 9[illegible] an osprey (*Pandion haliaetus*) was observered diving for fish in the lake. Also observed were coots (*Fulica americana*), pied billed grebes (*Podilymbus podiceps*), double crested cormorants (*Phalacrocorax auritus*), and a great blue heron (*Ardea herodias*). Though not large, this lake and associated wetland are significant habitat.

Lacustrine Wetlands: Harbor Lake

Harbor Lake (Machado Lake) (405.12) and its associated wetland is a 105 acre remnant of extensive freshwater wetlands which covered much of the southbay area of Los Angeles County. The lake is part of Harbor Lake Regional Park and is administered by Los Angeles County Parks Department. The area has been designated as Significant Ecological Area No. 35 for Los Angeles County. The wetland lies in the northern half of the park and also north of the park across Pacific Coast Highway. The entire area is surrounded by residential and commercial development. The wetland vegetation includes california bulrush (*Scirpus californicus*) southern cattail (*Typha domingensis*), mule fat (*Baccharis salicifolia*), arroyo willow (*Salix lasiolepis*) and yellow willow (*S. lasiandra*). The marsh supports numerous resident and migratory birds and waterfowl and the lakes supports various fish such as catfish, bass, and carp.

Harbor Lake with mulefat (*Baccharis salicifolia*) in foreground and large stands of southern cattail (*Typha domingensis*) and California bulrush (*Scirpus californica*) along far shore.

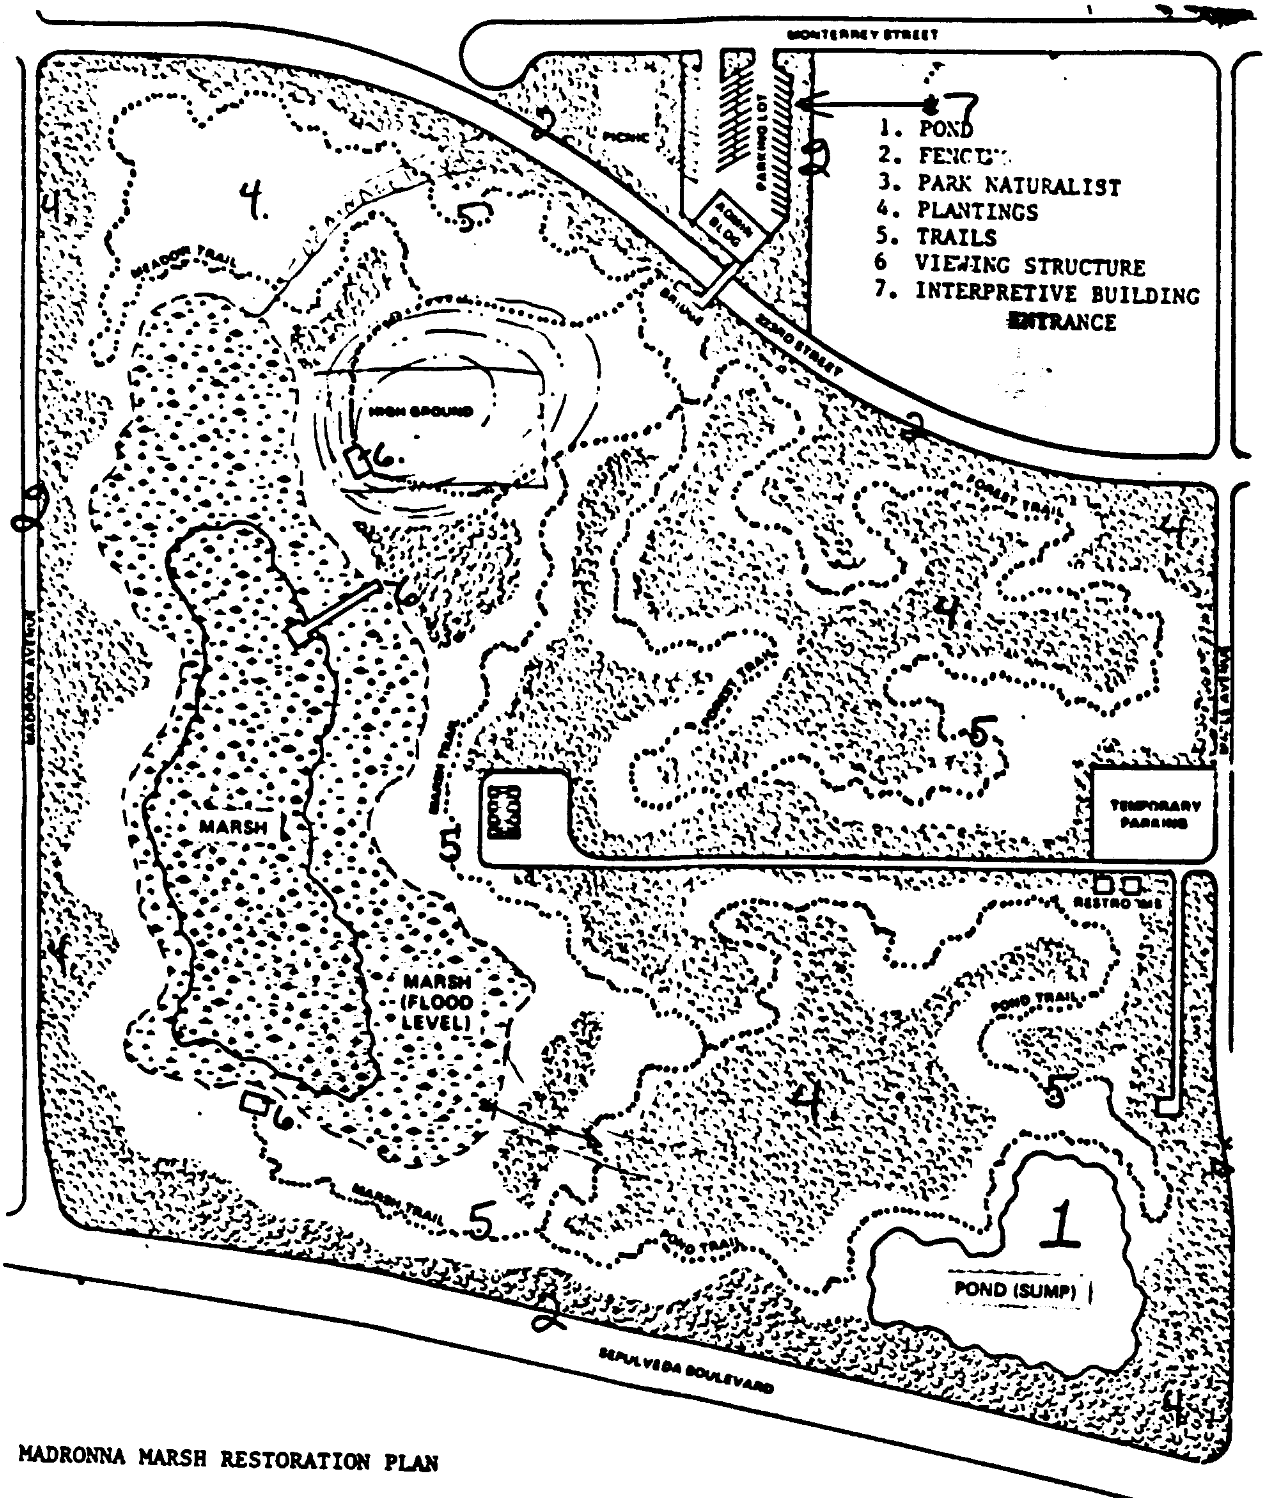
Lacustrine Wetlands: Madrona Marsh

Madrona Marsh (405.12) is an 8 acre remnant of extensive freshwater wetlands which covered much of the coastal plain in the southbay area of Los Angeles County. Madrona Marsh is Significant Ecological Area No. 23 in Los Angeles County. The surrounding area consists of residential, commercial and industrial development. The area covered by the wetland is currently being used for gas and oil extraction. The remaining natural areas are in resonably good condition or make excellent candidates for restoration/revegetation projects. Wetland vegetation includes willow (*Salix* spp.), mule fat (*Baccharis salicifolia*), cocklebur (*Xanthiw strumarium*), bulrush (*Scirpus* spp.), cattail (*Typha* sp.), spikerush (*Eleocharis* sp.), umbrella sedge (*Cyperus eragrostis*), and mosquito fern (*azolla filiculoides*). This small wetland has as great a diversity among hydrophytes as any in the region.

Madrona Marsh showing bulrush (*Scirpus*) and cocklebur (*Xanthium strumarium*). Oil extraction is occurring in background.



MADRONNA MARSH RESTORATION PLAN

VOL 12

1 8958

Riparian Wetland Plant Communities

Vegetation ecologists have described various vegetation types or communities which are associated with riparian habitats. Some, such as white alder riparian forest or various willow forests are normally indicative of wetland conditions. Others, such as coast live oak riparian forest, are indicators of wetland conditions in some instances. Some riparian types, such as scalebroom scrub Magney 1992), do not meet the conditions required by the Army Corps of Engineers to be protected under 404 permitting requirements. The initial descriptions of these vegetation types was by Holland (1986). California Department of Fish and Game has utilized (and modified as more detailed information becomes available) the original descriptions which have been centralized in the California Natural Diversity Database (CNDDB). The CNDDB is a statewide manual and computerized inventory of information on the location of threatened,endangered, and rare plants; threatened and endangered animals; and biotic communities which are considered sensitive or endangered by the scientific community. Taxa which are not listed as threatened, endangered, or rare, but are considered sensitive or limited in their distribution are also included (Shevock and Hennessy 1987). Region 4 contains thirteen recognized riparian plant communities. Descriptions generally follow Holland (1986) with modifications where repeated field observations warrant. Additional sources include Bowler (1990) for white alder riparian forest; Mullally (1992) and Quinn (1990) for walnut riparian woodland; Pavlik et al. for coast live oak riparian forest and canyon live oak ravine forest; Magney (1992) for scalebroom scrub; and Raven et al. (1986) for intermittent streambed.

Riparian Scrub

Southern Riparian Scrub. Typically dense stands of riparian thickets found along streams or washes dominated by mule fat (*Baccharis salicifolia*), and or shrub willows (*Salix*); varies in height from 4 to 12 feet. Usually without understory. Substrate is loose, sandy or gravelly alluvium deposited near stream channels during floods. Some stands of mule fat may be sparse over broad alluvial surfaces as in the lower Santa Clara River, Ventura Co. and in drainages below 2,000 feet throughout Region 4.

Mule Fat Scrub. A depauperate to sometimes dense, tall, herbaceous riparian scrub dominated by *Baccharis salicifolia*. This early seral community is maintained by frequent flooding. When flooding is absent, sycamore or cottonwood woodland will become established. It is the most common scrub type within Region 4 below 2,000 feet. Found along and in most intermittent streambeds. Associated species include arroyo willow (*Salix lasiolepis*), sandbar willow (*S. hindsiana*), giant nettle (*Urtica holosericea*), and cudweed (*Gnaphalium*).

VOL 12 1899

VOL 12

18970

R0052275

Alluvial Scrub - Open stands of evergreen and drought-deciduous shrubs associated with alluvial fans or riverine terraces. Vegetation is adapted to frequent flooding and coarse alluvial soils. Scale-broom (*Lepidospartum squamatum*) is the indicator species. Associated species include California sagebrush (*Artemisia californica*), California buckwheat (*Eriogonum fasciculatum*), laurel sumac (*Malosma laurina*), lemonadeberry (*Rhus integrifolia*), sugarbush (*R. ovata*) and holly-leaved cherry (*Prunus ilicifolia*). This type is poorly represented on the Santa Clara River in the Fillmore area, Ventura County. It is well represented in Big Tujunga Wash and the upper San Gabriel River, Los Angeles County.

Scalebroom Scrub - A sub-classification of alluvial scrub which has been proposed for addition to the California Natural Diversity Database Inventory of sensitive biotic communities (Magney 1992). Scalebroom scrub is an early seral stage of alluvial scrub which develops after flooding. *Lepidospartum squamatum* is the indicator species and associated species include burweed (*Ambrosia acanthicarpa*), western ragweed (*A. psilostachya*), *Bromus* sp., California bricklebush (*Brickellia californica*), Nevin's bricklebush (*B. nevinii*), hairy golden aster (*Heterotheca villosa*), wooly aster (*Corethrogyne filangifolia*), wooly star (*Eriastrum densifolium*), yerba santa (*Eriodictyon crassifolium* and *E. trichocalyx*), California buckwheat (*Eriogonum fasciculatum*), Cudweed (*Gnaphalium* sp.), and shrubby butterweed (*Senecio douglasii*). This somewhat herbaceous community is interspersed with California sycamore (*Platanus racemosa*), Fremont's cottonwood (*Populus fremontii*), and mule fat (*Baccharis salicifolia*). When flooding does not occur on a five to ten year cycle, woody upland species typical of alluvial scrub become established. Ventura County occurrences are along the Ventura River, Matilija Creek, upper and middle reaches of Sespe Creek and the lower half of Piru Creek. In Los Angeles County scalebroom scrub occurs at San Francisquito Wash, Big Tujunga Wash, Topanga Canyon (Raven et al. 1986), Eaton Canyon Wash, San Gabriel River, and San Antonio Creek. According to Magney (1992) this vegetation type does not fall within the U.S Army Corps of Engineers wetlands jurisdiction and is therefore often ignored as valuable habitat. More attention should be given to these and other similar habitats in environmental documents. Many areas of scalebroom scrub have already been lost to urbanization, recreational facilities, off road vehicle use, sand and gravel quarries, and flood control projects.

Riparian Woodlands and Forests

Southern Arroyo Willow Riparian Forest - Dense, low, closed canopy broadleafed winter deciduous forests dominated by *Salix lasiolepis*. This plant grows as a tree or as a large treelike shrub. The typically dense stands have little understory. Substrate is moist to saturated sandy or gravelly soil. Associated species include yellow willow (*S. lasiandra*), red willow (*S. laevigata*), mugwort (*Artemisia douglasiana*), giant nettle (*Urtica holosericea*), red top (*Agrostis alba*), smilo (*Piptatherum miliaceum*). This type is widespread in Region 4.

Southern Cottonwood-Willow Riparian Forest - Tall, opem, broadleafed winter deciduous riparian forests dominated by cottonwood (*Populus*) and several tree willows (*Salix*). Sub-irrigated and frequently overflowed lands along rivers and streams. This is provided after flood waters recede, leading to uniform-aged stands, but with vigorous vegetation reproduction from the roots, root-crowns, and fallen trunks. Characteristic species are mugwort (*Artemisia douglasiana*), mule fat (*Baccharis salicifolia*), wild cucumber (*Marah macrocarpus*), California sycamore (*Platanus racemosa*), Fremont's cottonwood (*Populus fremontii*), black cottonwood (*P. trichocarpa*), black willow (*Salix gooddingii*), arroyo willow (*S. lasiolepis*), and giant nettle (*Urtica holosericea*). Distributed along perennially wet streams and rivers of Region 4. A good example occurs on the Santa Clara River as viewed from Soledad Canyon Road, Los Angeles County.

Southern Mixed Riparian Forest - Tall, open, winter-deciduous and evergreen riparian forest composed of various combinations of tree willows (*Salix*), California sycamore (*Platanus racemosa*), coast live oak (*Quercus agrifolia*), and cottonwood (*Populus*). Understory of scattered shrubs or introduced grasses and forbs. Associated with low velocity flows, flood plains, and gentle topographywith deep alluvial soils and a high wate table. Best example on the Ventura River at Foster Park and Casitas Springs, Ventura County.

Opposite Page Top: Southern Arroyo Willow Riparian Forest, Big Tujunga Canyon, Los Angeles County.

VOL 12

1 89-75

R0052280

Coast Live Oak Riparian Forest - Open to locally dense evergreen sclerophyllous (hard-leaved) riparian woodlands dominated by coast live oak (*Quercus agrifolia*). This type appears to be richer in herbs and poorer in understory shrubs than other riparian communities. Found in bottomlands and outer floodplains along larger streams, on fine-grained, rich alluvium. Characteristic species include big leaf maple (*Acer macrophyllum*), mugwort (*Artemisia douglasiana*), toyon (*Heteromeles arbutifolia*), honeysuckle (*Lonicera hispidula*), California rose (*Rosa californica*), blackberry (*Rubus ursinus*), elderberry (*Sambucus mexicana*), and poison oak (*Toxicodendron diversilobum*). Common in canyons and valleys throughout Region 4. Good examples are found in Marshall and Little Dalton Canyons above Glendora in Los Angeles County.

Canyon Live Oak Ravine Forest - Dense evergreen sclerophyllous riparian woodlands dominated by canyon live oak (*Quercus chrysolepis*). Understory is typically sparse. Found in narrow canyons and ravines between 2,500 and 9,000 feet (Pavlik et al. 1991). Trees often with multiple trunks, probably from crown-sprouting after fires. Characteristic species vary with altitude and include incense cedar (*Calocedrus decurrens*), California bay laurel (*Umbellularia californica*), bigcone douglas fir (also called bigcone spruce) (*Pseudotsuga macrocarpa*), coffeeberry (*Rhamnus californica*), deer brush (*Ceanothus integerrimus*), and bitter gooseberry (*Ribes amarum*). Important community at headwater settings due to the provision of coarse particulate organic matter which supports the predominately heterotrophic community in headwater reaches (Knight and Bottorf 1984). Common throughout the San Gabriel Mountains above 2,500 feet.

Walnut Riparian Woodland - Typically similar to and intergrading with coast live oak woodland but locally dominated by California black walnut (*Juglans californica*). Mullally (1992) reports that in the Santa Susana Mountains, density of walnut woodlands increases along intermittent streams and in canyons which channelize rainwater during rain storms. In many of the canyon bottoms walnut is dominant or sometimes shares dominance with elderberry (*Sambucus mexicana*). Most commonly, walnuts occurring in riparian settings are in easterly flowing drainages. Associated species are coast live oak (*Quercus agrifolia*), flowering ash (*Fraxinus dipetala*), and California bay laurel (*Umbellularia californica*). Because of the open canopy the understory is dominated by introduced annual grasses, The best examples occur throughout the Santa Susana Mountains and at Walnut Creek in San Dimas in Los Angeles County.

R0052282

Intermittent Streambed - this designation refers to various communities composed of non-persistent herbaceous plants (annuals) within the banks of intermittent streams or channels. Perennials such as mule fat, scrub willow, etc., would be excluded. Many of the plants associated with this community share two common features: (1) adaptation to periodic flooding which often provides conditions required for the physical breakdown of the seedcoat (scarification) needed for germination, and (2) the deposition of nutrient rich sediments from upstream areas which enrich the typically nutrient poor sandy/gravelly soils commonly found in streambeds. Characteristic species include sprangletop (*Leptochloa uninervia*), sedges (*Carex* spp.), umbrella sedge (*Cyperus eragrostis*), mugwort (*Artemisia douglasiana*), dock (*Rumex* spp.), knotweed (*Polygonum* spp.), brooklime (*Veronica anagallis-aquatica*), rabbitsfoot grass (*Polypogon monspeliensis*), reed fescue (*Festuca arundinacea*), meadow fescue (*F. pratensis*), wild celery (*Apium graveolens*), water bent (*Agrostis semiverticillata*), and scarlet monkeyflower (*Mimulus cardinalis*).

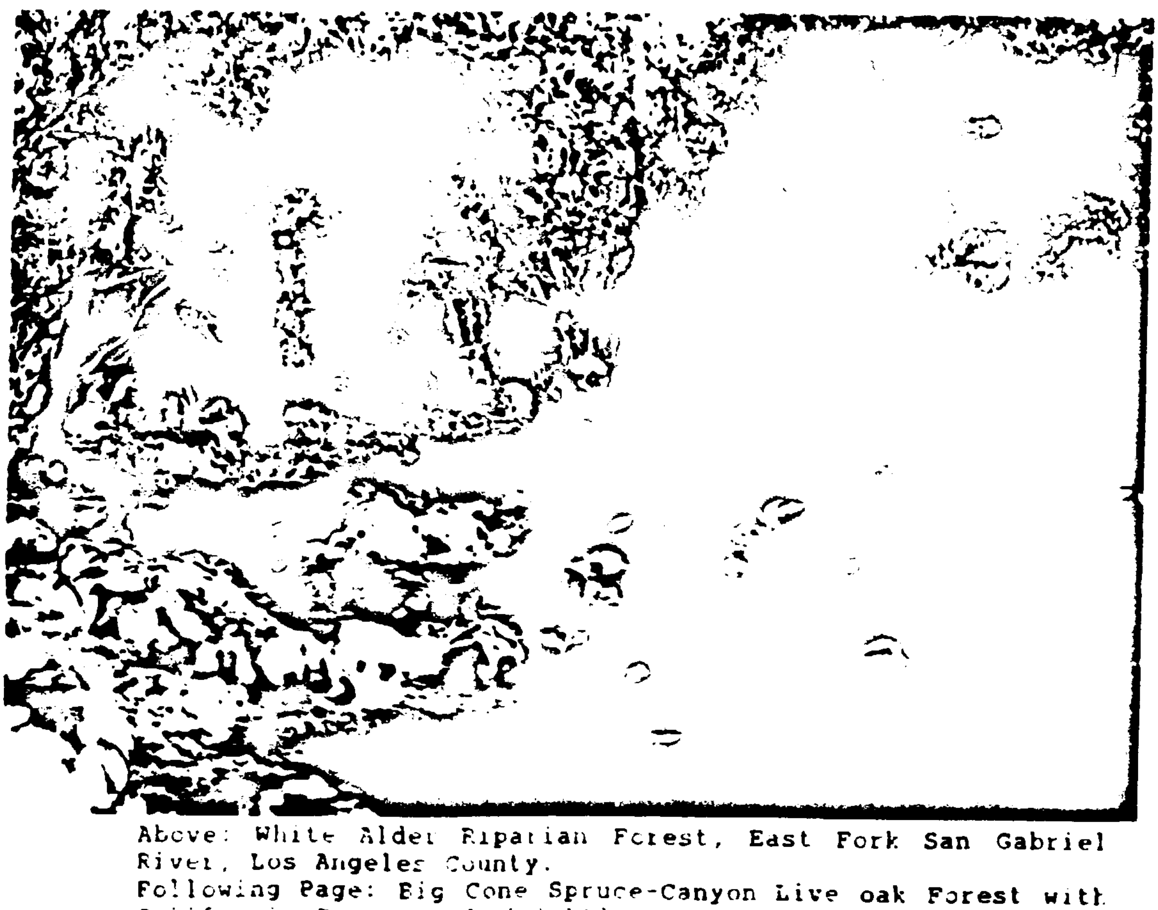
VOL 12

1 8978

White Alder Riparian Forest Medium-tall broad-leafed deciduous streamside forest dominated by Alnus rhombifolia. Other trees present include big leaf maple (Acer macrophyllum), California bay laurel (Umbellularia californica), and arroyo willow (Salix lasiolepis). Understory can be poorly represented to dense and consists of semi-woody shrubs and various herbs including eupatory (Ageratina adenophora), nightshade (Solanum douglasii), knotweed (Polygonum punctatum) and hedgenettle (Stachys bullata). Best developed along rapidly flowing, well aerated perennial streams with coarse beds that reflect high stream power during spring runoff. Typical in bedrock constrained, steep-sided canyons making the riparian zone narrow. Common along all perennial in the San Gabriel Mountains up to 6,500 feet. Also found in the central portion of the Santa Monica Mountains along perennial streams up to 1,000 feet. On larger perennial rivers like the East Fork of the San Gabriel River this type is bordered by alluvial or scale-broom scrub.

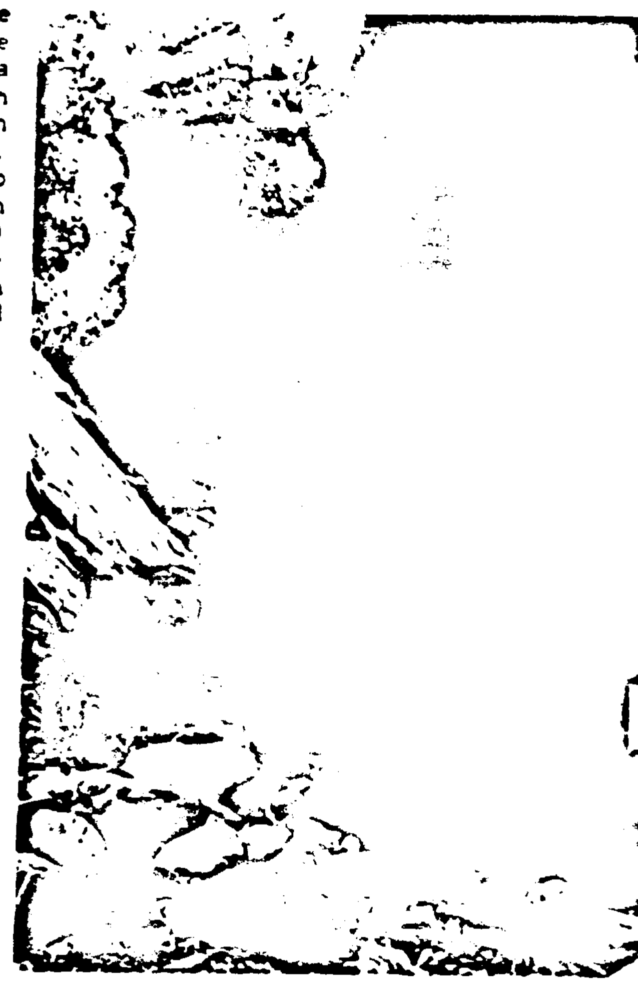


Above: White Alder Riparian Forest, East Fork San Gabriel River, Los Angeles County.
Following Page: Big Cone Spruce-Canyon Live oak Forest with California Bay Laurel (right), Big Leaf Maple and Big Cone Spruce in Background. From East Fork San Gabriel River

VOL 12

18979

Bigcone Douglas Fir-Canyon Live Oak Forest - Open to dense forest dominated by *Pseudotsuga macrocarpa* 50-80 feet tall with a dense subcanopy of canyon live oak (*Quercus chrysolepis*). Herbaceous layer is sparse to nonexistent. Most common on (though not restricted to) canyon sides where it intergrades with various riparian forests. Not a wetland indicator as a community but often providing significant canopy for riparian vegetation. Ecological importance is in providing shade and nutrients to the headwaters portions of numerous streams throughout Region 4. Associated species include big leaf maple (*Acer macrophyllum*), incense cedar (*Calocedrus decurrens*), mountain mahogany (*Cercocarpus betuloides*), coast live oak (*Quercus agrifolia*), poison oak (*Toxicodendron diversililobum*), and California bay laurel (*Umbellularia californica*). Found along upper reaches and headwater areas of many streams in the San Gabriel Mountains and also at the head of various canyons in the Santa Susana Mountains.



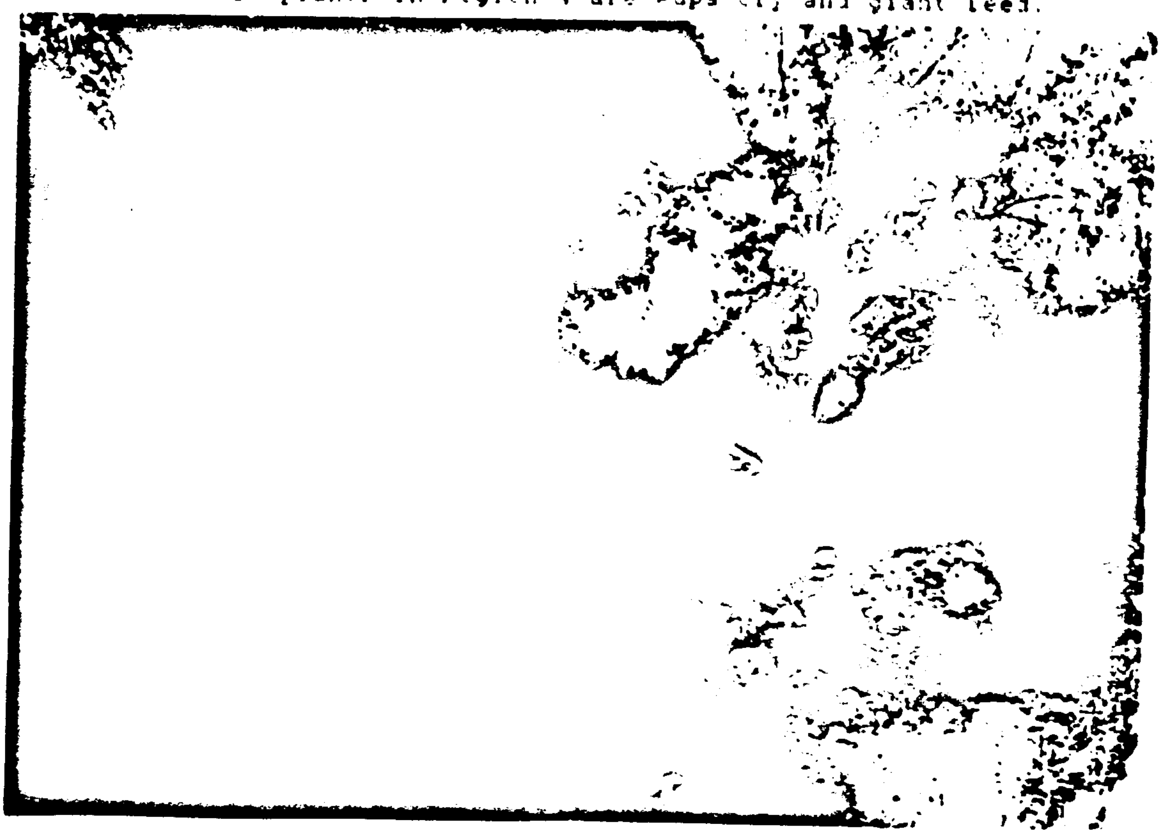
Southern Sycamore Alluvial Woodland - Tall, open winter deciduous woodland of streamsides and alluvial fans dominated by *Platanus racemosa*. This type seldom forms closed canopy forests, and may even appear as scattered trees in a shrubby thicket of evergreen and deciduous species. Lianas (sprawling vines) of wild grape (*Vitis girdiana*), blackberry (*Rubus ursinus*), and poison oak (*Toxicodendron diversilobum*), are common. Found in rocky, boulder strewn streambeds subject to seasonal high-intensity flooding. The flooding is at times quite violent, damaging or uprooting trees. Sycamores have well developed vegetative reproduction, giving the woodland a clumped appearence. Common species include mugwort (*Artemisia douglasiana*), smilo (*Piptatherum miliaceum*), mule fat (*Baccharis salicifolia*), coast live oak (*Quercus agrifolia*), elderberry (*Sambucus mexicana*), and giant nettle (*Urtica holosericea*). This type intergrades into white alder riparian forest where canyons narrow or where there is permenant water. Best example is in Big Sycamore Canyon in Los Angeles County.

VOL 12

Invasive Exotic Plants: Impacts to Riparian Communities in Region 4

The impact of invasive exotic plants to plant communities throughout California has recently been given much attention. The formation of the California Exotic Pest Plant Council (CalEPPC) in October of 1992 was in response to numerous invading species statewide. At a symposium, held at Morro Bay in October of 1992, which marked the beginning of CalEPPC, some emphasis was given to exotics which are invading riparian habitats. Giant reed (Arundo donax) and salt cedar (Tamarix sp.) were two such plants. In CalEPPC News Winter [illegible], the newsletter of CalEPPC, Nerium oleander and Ficus carica were cited as invaders of riparian communities of the Central Valley.

The riparian communities of region 4 are subject to invasion by many such plants. Edible fig (Ficus carica) is established in many of the canyons of the San Gabriel Mountains. English Ivy (*Hedera helix*), and periwinkle (*Vinca major*) have been planted as ground cover around cabins in Big Santa Anita Canyon and San Dimas Canyon. These have become the dominant vegetation in some of these canyons, replacing native herbaceous and shrubby plants. Currently, the two most significant invasive exotic plants in Region 4 are eupatory and giant reed.



Eupatory dominating understory in Rubio Canyon Riparian Woodland

R0052286

Eupatory (*Ageratina adenophora*) - is a native of mexico which escaped cultivation above Pasadena in the early 1900s (Abrams 1917). It has become a troublesome weed in other parts of the world including Australia, Hawaii, South Africa and the Philippines. It reproduces by seed and also vegetatively by means of stolons or runners. Because of the ability to propagate vegetatively, a single plant can become a dense mat or thicket within a few years. Eupatory is dominant, forming dense stands, in most front country canyons of the San Gabriel Mountains from Wolfskill Canyon on the east to Stough Canyon in the Verdugo Hills on the west. It appears to be limited by cold and does not extend above 2,700 feet in elevation. Eupatory is a federally listed noxious weed and is therefore subject to control efforts.

Giant Reed (*Arundo donax*) - is a native of the Mediterranean region and was originally imported for use as an ornamental plant. *Arundo* invades riparian habitats on the coastal plain and extends for a short distance into the mountain areas. *Arundo* typically becomes established after disturbance (natural or manmade) and outcompetes native vegetation due to extremely rapid growth rates (Rieger and Kreager 1999). Populations of native birds are often impacted because willow forests are often the most severely impacted by invasions of *Arundo*. Areas of significant infestation include the Santa Clara and Ventura Rivers, Big and Little Tujunga Canyons and the San Gabriel River.

Photo: Giant Reed (*Arundo donax*) along the upper Ventura River.

Riparian Wetlands near Pitas Point:
Rincon Creek and Javon Canyon Creek

Rincon Creek and Javon Canyon Creek are the westernmost riparian wetlands in Region 4. They are located between Pitas Point and Carpenteria. Rincon Creek demarcates the boundary between Ventura and Santa Barbara Counties.

Topographic Map: 30 X 60 min, Santa Barbara Quadrangle

L.A. Regional Water Quality Control Board
Riparian Wetlands: Rincon Creek

Rincon Creek (401.0) - defines a portion of the boundary between Ventura and Santa Barbara Counties. The creek originates within the Santa Ynez Mountains of the Los Padres National Forest at an elevation of about 3,000 feet. The wetland begins at 2,400 feet and extends 7.5 miles to the Pacific Ocean. A number of riparian forest woodland types are found along the creek, including southern arroyo willow riparian forest, southern mixed riparian forest, coast live oak riparian forest, and southern sycamore-alder riparian forest. Often these types intergrade and are difficult to distinguish. Individuals of California black walnut (*Juglans californica*) are fairly common along sections of the stream. The extensive riparian forests provide habitat (existing or potential) for a number of endangered, candidate, or species of special concern. The endangered species are least Bell's vireo (*Vireo bellii pusillus*) and southwestern willow flycatcher (*Empidonax traillii extimus*). Candidate species are California red-legged frog (*Rana aurora draytonii*), and southwestern pond turtle (*Clemmys marmorata pallida*). Yellow warbler (*Dendroica petechia brewsteri*) is the species of special concern.

VOL 12

L.A. Regional Water Quality Control Board
Riparian Wetlands: Javon Canyon Creek

Javon Canyon Creek (401.0) - emerges from one of a series of north-south canyons between the Ventura River and Rincon Creek and runs in a deeply incised channel with vertical walls ranging from 6 to 15 feet. The creek is an interrupted stream which is fed in part by seeps at points along the steep gully walls (Holmgren 1989). The bottom of the creek channel supports *Enteramorpha* sp. (a freshwater green alga). Wetland indicator plants at the site include arroyo willow (*Salix lasiolepis*) mulefat (*Baccharis salicifolia*), Douglas baccharis (*Baccharis douglasii*), lenscale (*Atriplex lentiformis* ssp. *breweri*), salt heliotrope (*Heliotropum curassavicum*), halberd-leaf saltbush (*Atriplex patula*), salt grass (*Distichlis spicata*), and California figwort (*Scrophularia californica*). Plummer's baccharis (*Baccharis plummerae*), which is included on the California Native Plant Society list of plants of limited distribution, grows on the vertical sides of the canyon (Capelli and Gardiner 1990). The availability of water makes Javon Canyon important habitat. Holmgren (1989) in two field visits counted counted 28 bird species, 7 mammal species and 1 lizard.

Riparian Wetlands: Lower and Upper Ventura River

The Ventura River (402.10 and 402.20) is the northernmost major river in Region 4, extending 21 miles north from the Pacific Ocean and draining approximately 226 square miles. The main stem, which is about 15 miles long, originates at the confluence of Matilija and North Fork Matilija Creeks. Upland portions of the watershed, which reach 6,000 feet in elevation, consist of the narrow steep canyons while the main stem flows through a broad valley. Major tributaries are Matilija Creek, North Fork Matilija Creek, San Antonio Creek, and Coyote Creek. The river terminates in a small river mouth estuary which is closed to tidal action by a sandbar during times of low flow. During periods of storm runoff in winter and spring the sandbar is breached and the estuary is subject to tidal influence.

The main stem of the Ventura River is an interrupted stream, consisting of perennial reaches with intervening intermittent reaches (Hunt 1991). Water is diverted to the Casitas Reservoir for use by industrial, agricultural and municipal use (Ferren et al. 1990). Perennial flow from below the confluence with San Antonio Creek is due to high groundwater in the vicinity of Casitas Springs, base flow from San Antonio Creek, and discharged effluent from the Ojai Valley Sanitary District.

Upper and Lower Ventura River from
Santa Barbara 30 X 60 min Quadrangle.

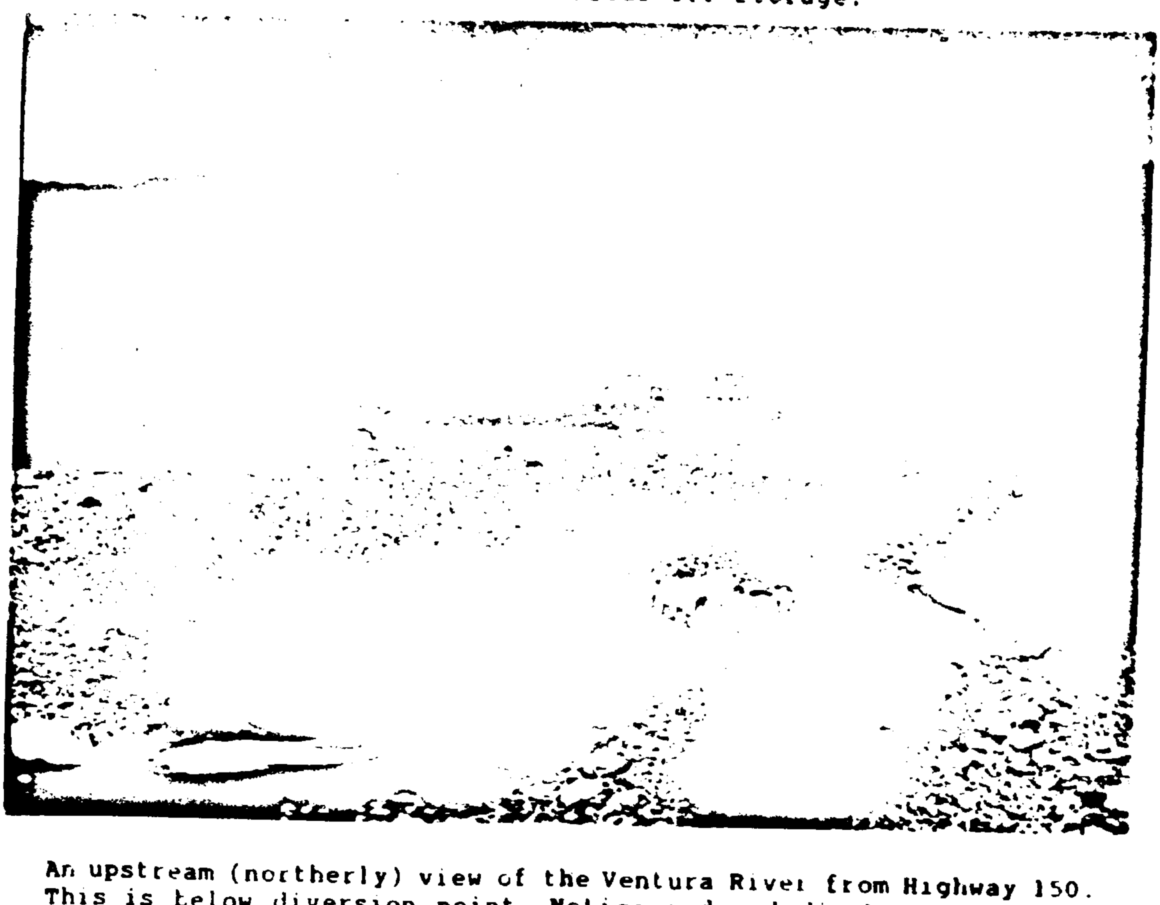
R0052292

Southern Pacific Milling Company currently maintains a sand and gravel mining operation near the junction of Highways 101 and 33. The site occupies 152.8 acres and stretches for about 1.6 miles along the floodplain. Hunt (1991) has determined that modifications to the habitat resulting from the operation have the following adverse impacts: 1) Reduction of wildlife habitat due to loss of vegetative cover; 2) Siltation of river bottom and estuary; 3) Increased water temperatures due to removal of riparian vegetation which provides shade and cover to river channel; 4) Reduction of aquatic and terrestrial insects due to removal of riparian and adjacent vegetation, thus diminishing and important food resource for fishes and other vertebrates; 5) Removal of spawning gravels utilized by anadromous fishes. Hunt (1991) has also found that the diversion of approximately 240,000 gallons of water per day for use in the mining process, which is accomplished by the use of a diversion dam and channel impacts the steelhead fishery resources by: 1) reducing the magnitude and duration of peak discharges; 2) reducing the duration and magnitude of between storm discharge; 3) increasing the duration and extent of desiccation of stream sections; 4) blocking or inhibiting the passage of adult steelhead to historically important spawning and rearing habitat in the major tributaries of the river; 5) reduction of freshwater inflows to the estuary and lagoon at the mouth of the river which may have negative impacts on the ability of the estuary to serve as fish nursery and spawning habitat, particularly for juvenile steelhead and adult tidewater goby.

The gravel mining operation has some indirect beneficial effects on wildlife resources. The constant disturbance of the habitat mimics the disturbance which is typical of flood events. This maintains the habitat in a number of successional stages which increases the diversity of small mammals (rodents) and therefore provides resources for predatory mammals and raptorial birds. These early successional stages tend to support higher numbers of browsing mammals such as rabbits and deer. The ponds which are used for sedimentation settling also provide habitat for some species of waterfowl.

Despite the beneficial impacts, the overall influence of the gravel mining operations in the Ventura River Floodplain and the diversion and impoundment of water for the mining operations, is negative. The destruction of riparian vegetation, modification of the channel, and reduction of discharge rates severely impacts the vertebrate resources on the site and also downstream continuing to the estuary.

The Upper Ventura River begins at the confluence of Matilija Creek and North Fork Matilija Creek and extends to just below Casitas Springs. The entire reach, which is 7 miles long, is designated as wetland. The vegetation of the upper portion is southern mixed riparian forest and southern sycamore-alder riparian forest. Below this the canyon empties onto a broad alluvial plain. The vegetation changes to southern arroyo willow riparian forest along the streambank with alluvial scrub dominating the adjacent sand and cobble terraces. The willow forest gives way to a sand and cobble bottom with little vegetation at the point where a significant portion of the flow is diverted to Lake Casitas. From the point of diversion to Casitas Springs, flows are greatly reduced and during the dry season this reach of the stream often has no water. Since 1958, the Casitas Municipal Water District has by-passed the first 20 cfs of low flow at the Robles Diversion. This has helped to maintain the surface flow between Casitas Springs and the estuary (Ferren 1990). The Friends of the Ventura River won a law suit in 1988 preventing the Casitas Municipal Water District from diverting the remaining flow into Lake Casitas for storage.



An upstream (northerly) view of the Ventura River from Highway 150. This is below diversion point. Notice reduced discharge compared with photo taken above diversion point. Photos taken 2-6-93.

The Lower Ventura River. Because of the protected 20 cfs, along with discharge from San Antonio Creek and effluent from the Ojai Sanitation District, it remains a perennial stream. This reach of the stream, despite significant alterations, contains favorable habitat for various native fish such as pacific lamprey (*Entosphenus tridentata*), arroyo chub (*Gila orcutti*), three-spined stickleback (*Gasterosteus aculeatus microcephalus*), and sensitive species including the tidewater goby (*Eucyclogobius newberryi*) and summer steelhead trout (*Oncorhynchus mykiss gairdneri*) (Hunt 1991). Up to 27 steelhead trout have in recent years been observed about 30 meters upstream from the Southern Pacific Railroad bridge (Leidy 1991). The perennial flow on this reach of the river allows access by steelhead to Coyote Creek, below Lake Casitas, and also to San Antonio Creek which provide suitable spawning and rearing habitat (Hunt 1991). The vegetation primarily consists of southern arroyo willow riparian forest including arroyo willow (*Salix lasiolepis*), Red Willow (*S. laevigata*), yellow willow (*S. lasiandra*), and some individuals of white alder (*Alnus rhombifolia*). Invasive exotic *Ludwigia uruguayensis* is the dominant understory plant upstream from the estuary. *Arundo donax*, another invasive exotic is common, often displacing willow forest.

Riparian Wetlands: Ventura River Tributaries

**San Antonio Creek, Santa Ana Creek, Coyote Creek
West Fork Santa Ana Creek, Ojai Wetland**

The Ventura River is an interrupted stream. One of the reaches of which has a perennial flow is between Casitas Springs and the Estuary. This area is important to many vertebrate species (see Ventura River section). Discharge from San Antonio Creek and Coyote Creek provide a significant portion of water to this reach of the Ventura River. The Santa Ana Creek complex drains into Lake Casitas and is therefore also part of the Lower Ventura River system.

Tributaries of the Lower Ventura River:
Santa Barbara 30 X 60 min Quadrangle

VOL 12 1991

L.A. Regional Water Quality Control Board
Riparian Wetlands: Santa Ana Creek and West Fork Santa Ana Creek

The Santa Ana Creek drainage (402.2) includes the main stem which is 3.4 miles long the North Fork which is [illegible].7 miles long and the 3.5 mile long West Fork which joins the North Fork to form the main stem. The headwaters originate at above 3,000 feet in the Santa Ynez Mountains of the Los Padres National Forest. The riparian habitat consists primarily of coast live oak riparian forest, southern sycamore-alder riparian forest and southern riparian scrub dominated by arroyo willow (*Salix lasiolepis*). the understory is rich in hydrophytes including lance-leaved frog fruit (*Phyla lanceolata*), iris leaved rush (*Juncus xiphioides*), umbrella sedge (*Cyperus eragrostis*), scarlet monkey flower (*Mimulus cardinalis*), smilo (*Agrostis miliacea*), and horsetails (*Equisetum* sp.). Fish were observed swimming in large pools and frogs were also observed.
Santa Ana Creek is important spawning habitat for resident rainbow trout, and trout residing in Lake Casitas. Historically Santa Ana Creek was important spawning and rearing habitat for steelhead trout. Birds observered during field visits included black phoebe (*Sayornis nigricans*), Hutton's vireo (*Vireo huttoni*), warbling vireo (*Vireo gilvus*), and the red-shouldered hawk (*Buteo lineatus*).

Photo: Mixture of Oak and Sycamore along Santa Ana Creek

VOL 12

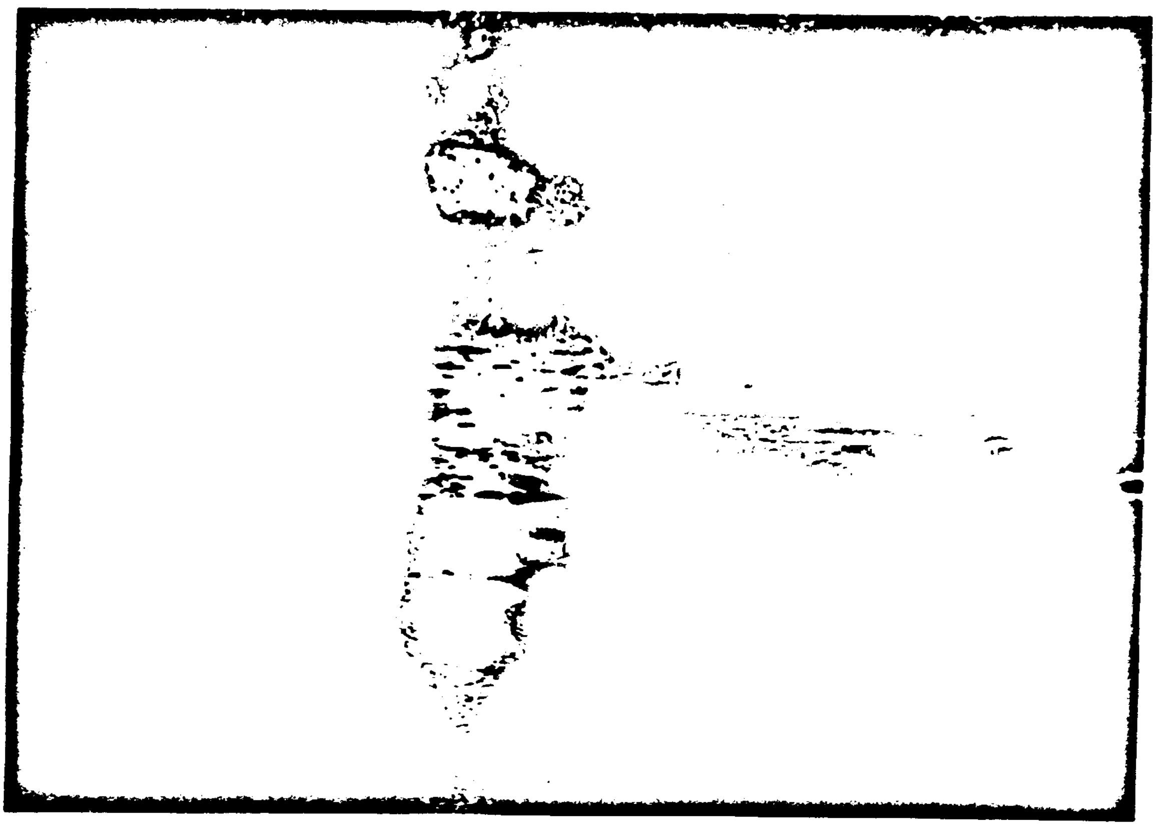
Riparian Wetlands: San Antonio Canyon Creek

San Antonio Creek (402.2 and 402.3) is a major tributary of the Ventura River. The Wetland begins at the confluence with [illegible] Creek and extends nearly 5 miles to the Ventura River. A variety of habitat types are found along the creek including southern arroyo willow riparian forest, southern sycamore alder riparian forest and coast live oak riparian forest. The understory is rich in hydrophytes including watercress (*Rorippa nasturtium aquaticum*), lance-leaved frog fruit (*Phyla lanceolata*), duckweed (*Lemna sp.*), umbrella sedge (*Cyperus eragrostis*), cattail (*Typha domingensis*), and barnyard grass (*Echinochloa crusgalli*). Wetland associated bird species observed during field visits were the common yellow throat (*Geothlypis trichas*), black phoebe (*Sayornis nigricans*) and belted kingfisher (*Ceryle alcyon*). San Antonio Creek is important spawning and rearing habitat for remaining populations of steelhead trout and also native populations of rainbow trout.



Southern Arroyo Willow Riparian Forest along San Antonio Creek, Ventura County

18993

VOL 12

L.A. Regional Water Quality Control Board
Riparian Wetlands: Coyote Creek

Coyote Creek (402.2) is a major tributary of the Ventura River which is interrupted by Lake Casitas. The headwaters originate below the Matilija Divide of the Santa Ynez Mountains within the Los Padres National Forest. The wetland extends from below the 3,000 foot elevation point to the Ventura River. The riparian wetland extends for 5.0 miles above Lake Casitas and for 3.1 miles below the lake. Tributaries to the main stem include the East and West Forks of Coyote Creek which are both 2.5 miles in length. The nearly 11 miles of riparian wetlands include southern sycamore-alder riparian forest, coast live oak riparian forest, and southern mixed riparian forest. Coyote Creek and its tributaries are important spawning and rearing habitat for resident rainbow trout and other trout residing in Lake Casitas. Historically, the Coyote Creek drainage was an important rearing and spawning area for steelhead trout. Presently the Coyote Creek system serves as an important wildlife corridor between the National Forest areas and the coast via the Ventura River.

Southern Mixed Riparian Forest typically found along Coyote Creek, Ventura County

18994

VOL 12

L. A. Regional Water Quality Control Board Riparian Wetlands: Matilija Drainage

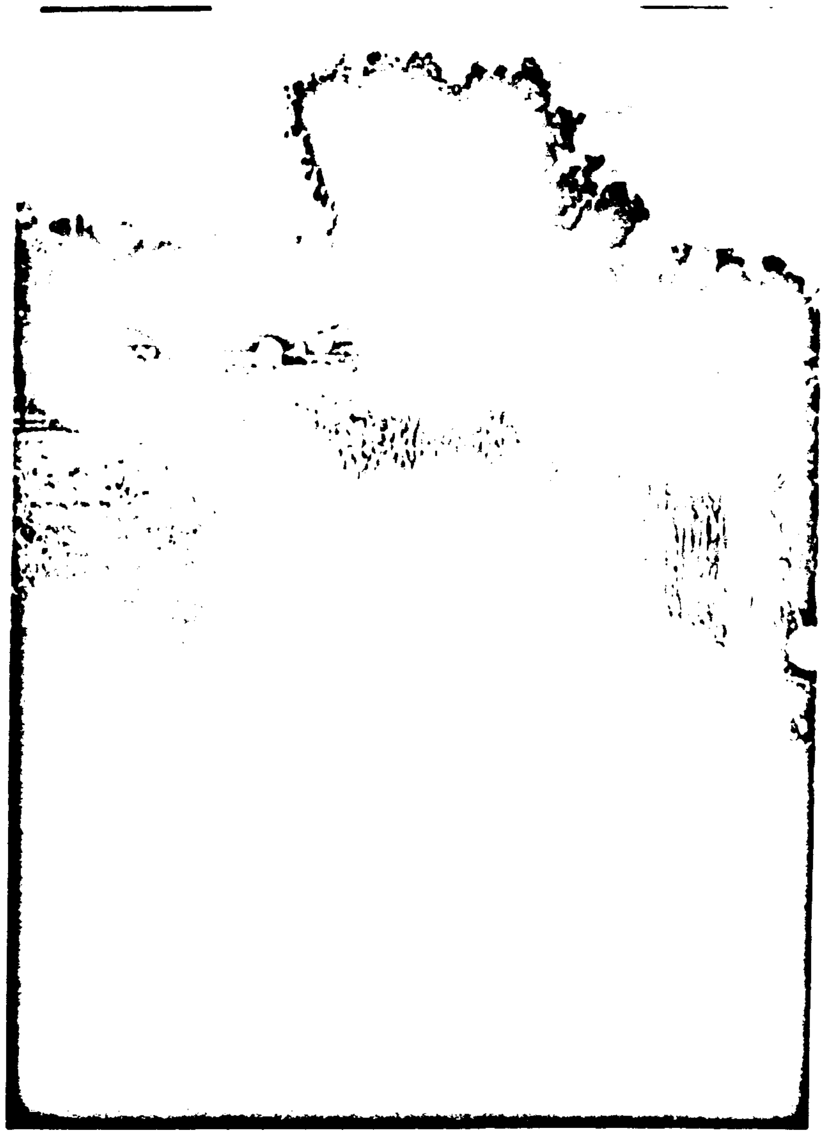
Matilija Creek (402.2?) and its associated tributaries which include Murietta Canyon Creek, Upper North Fork Matilija Creek, and Old Man Canyon Creek, are at the headwaters for the Ventura River. Murietta Canyon Creek is associated with approximately 3 miles of riparian wetland which begin at [illegible] feet and extend to the confluence with Matilija Creek. The wetland associated with the main stem of Matilija Creek extends approximately 7.0 miles from the [illegible] foot elevation level to the confluence with Upper North Fork Matilija Creek. The wetland associated with Old Man Creek begins at the [illegible] feet and extends [illegible] miles to the confluence with the Main Stem of Matilija Creek. The wetland associated with the Upper North Fork extends [illegible] miles beginning at [illegible] feet and ending at the confluence with the main stem. The vegetation is composed of various riparian woodlands including southern mixed riparian forest, southern sycamore-alder riparian forest, and coast live oak riparian forest. These riparian wetlands provide important spawning and rearing habitat and migration corridors for both steelhead trout and populations of native rainbow trout.

Southern Mixed Riparian Forest along North Fork Matilija Creek

1 8995

L.A. Regional Water Quality Control Board
Riparian Wetlands: Ojai Wetland

The Ojai wetland (402.2) is an area of freshwater marsh vegetation which originates at highway 33 between El Roblar and Nordoff High School and ends at the Happy Valley Drain. The total length is approximately one-quarter mile. The vegetation consists of 5 obligate wetland species including umbrella sedge (*Cyperus eragrostis*), wire grass (*Juncus sp.*), water cress (*Nasturtium officinale*), California bulrush (*Scirpus californica*), and narrowleaf cattail (*Typha domingensis*). The area adjacent to the the freshwater marsh is composed of naturalized annual grasses and a stand of eucalyptus trees. This wetland, while not significant at the regional level has been demonstrated by the California Department of Fish and Game to be important as a foraging area for various raptors including American kestrel (*Falco sparverius*), redtail hawk (*Buteo jamaicensis*) red shouldered hawk (*B. lineatus*), and black shouldered kite (*Elanus caeruleus*).



Ojai Wetland looking towards Highway 33. Narrowleaf Cattail (*Typha domingensis*) is the dominant vegetation.

1 8997

L.A. Regional Water Quality Control Board
Riparian Wetlands: Santa Clara River

The Santa Clara River is the largest river system in southern California and is one of the last which remains in a relatively natural state. The headwaters originate in the San Gabriel Mountains in Los Angeles County and below Mt. Pinos, the highest point of the watershed at 8,831 feet. The river traverses Ventura County and empties into the Pacific Ocean extending over 83 miles and draining a watershed of 1,600 square miles. All of the major tributaries originate in National Forest. Typical of southern California rivers, the stream flow is highly variable. Average daily discharge at Montalvo (about three miles from the coast) ranges from no flow (often for extended periods during the dry season) to winter flood peaks over 100,000 cubic feet per second.

Extensive, high quality riparian habitat is present along the length of the river. This habitat supports large populations of wildlife species, many of which are becoming rare as riparian habitats are destroyed, degraded or fragmented by development. Populations of many of these species are associated with the Santa Clara River system. The endangered California least tern (*Sterna antillarum browni*) nests at the mouth of the river and saltmarsh bird's-beak (*Cordylanthus maritimus maritimus*) which has been extirpated from the estuary is to be reintroduced to the site according to the species recovery plan. The recovery plan for least Bell's vireo cites the Santa Clara River as critical habitat.

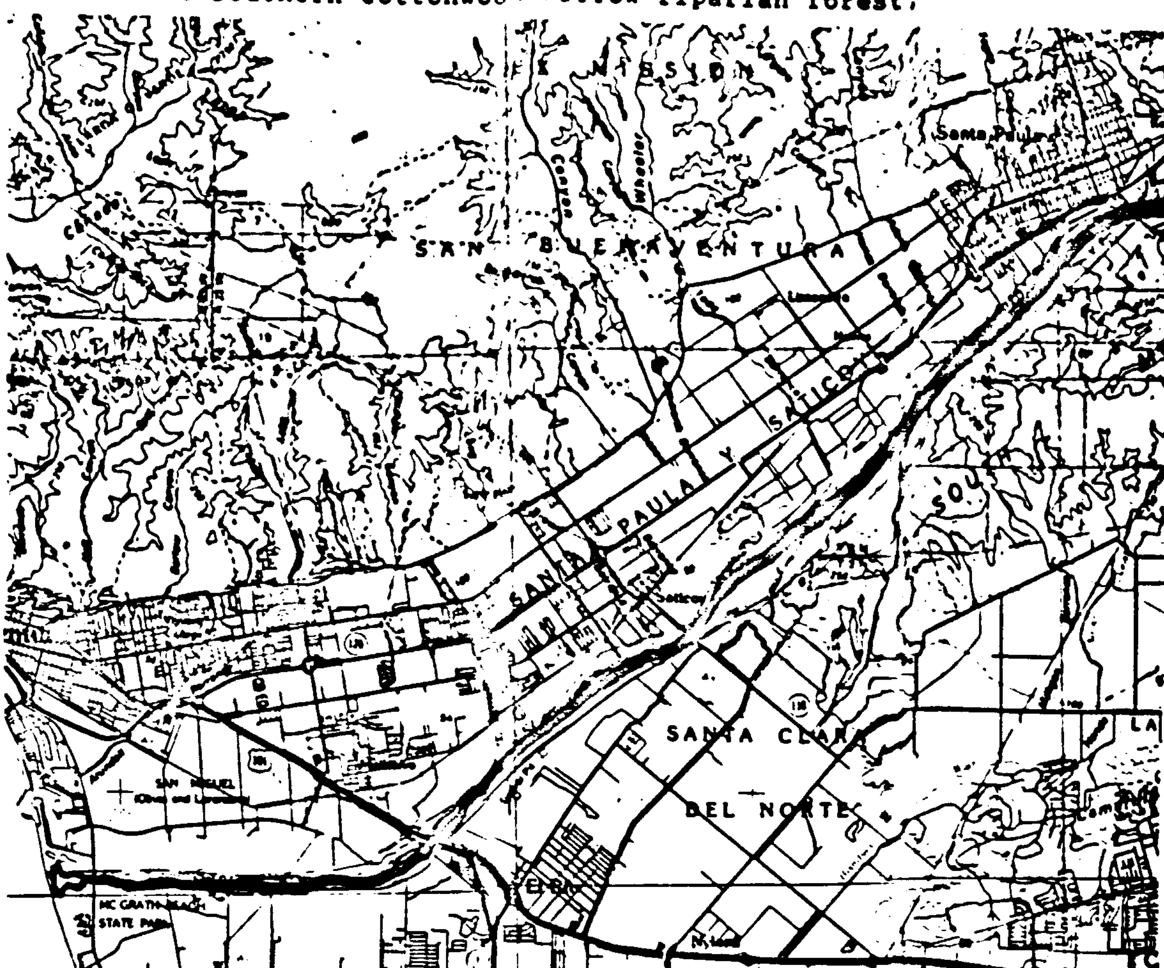
Riparian Wetlands: Santa Clara River

The Lower Santa Clara River (403.11, 403.21) extends 16.5 miles from the coast to just above the confluence point with Santa Paula Creek. Near the coast the habitat is southern arroyo willow riparian forest. Much of the willow habitat which is important to species such as least Bell's vireo has been invaded by giant reed (Arundo donax) which has invaded large stretches of this section of the river. The Arundo becomes established after flood events and reproduces very rapidly by means of vegetative growth. The willows are outcompeted and valuable habitat is lost. Other vegetation types found along this portion of the river include mulefat scrub and some southern cottonwood-willow riparian forest.



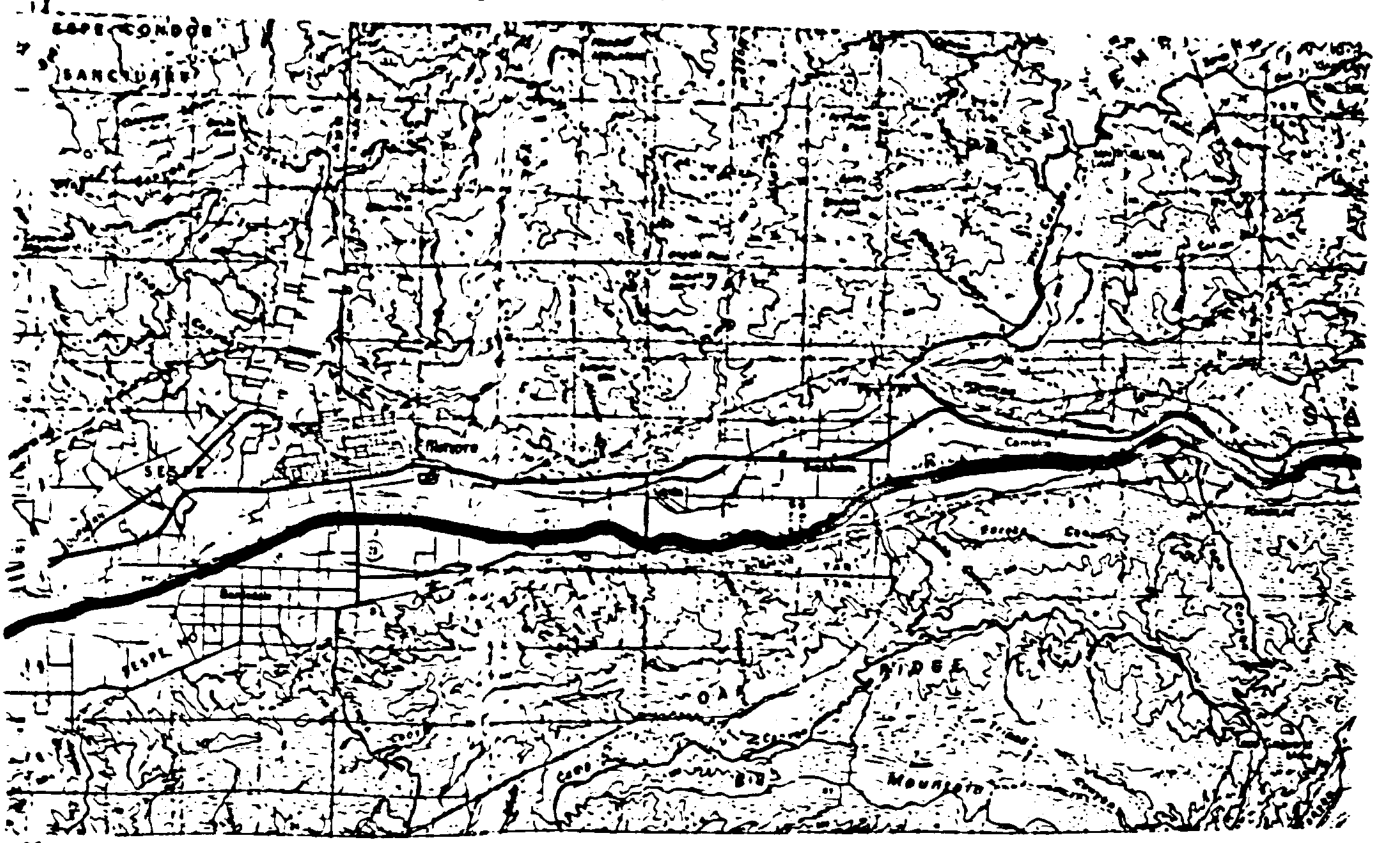
Lower Santa Clara River: Santa Barbara 30 X 60 min Quadrangle
Opposite Page: Lower Santa Clara River near Hwy 101 showing extensive stands of giant reed (Arundo donax) as dominant.

VOL 12

19002

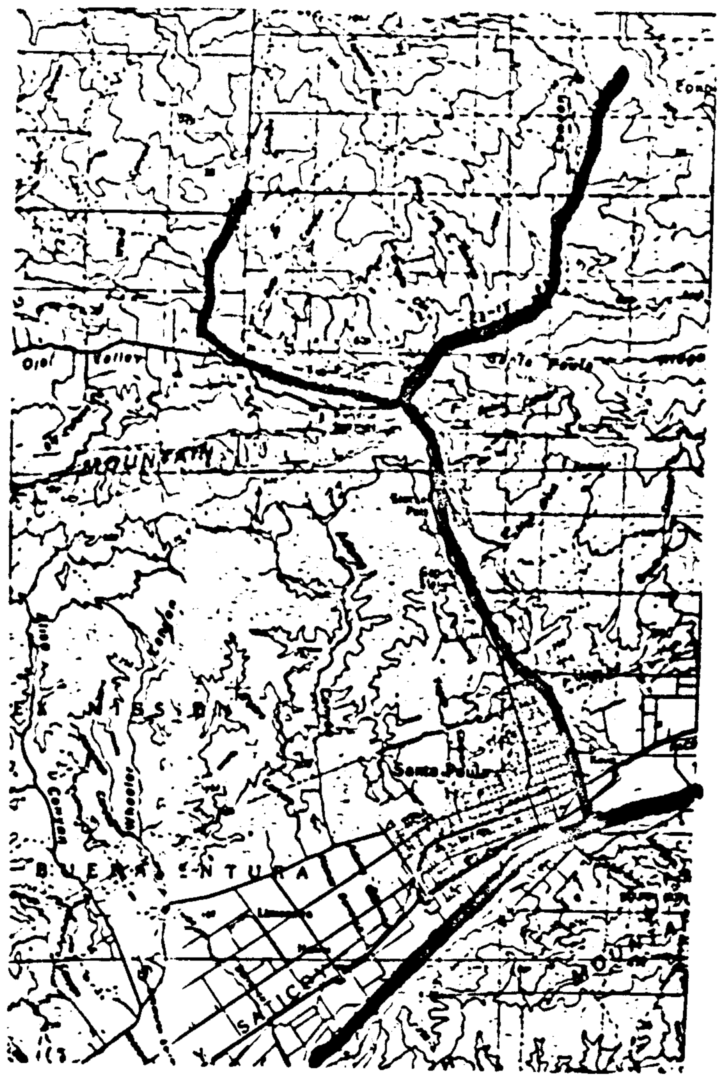
L.A. Regional Water Quality Control Board
Riparian Wetlands: Santa Clara River

The Santa Clara River (403.31, 403.41) extends 20.9 miles from Santa Paula to the Los Angeles/Ventura county line. Two of the river's major tributaries, Sespe and Piru Creeks empty into the river within about 4 miles of each other. The habitat consists primarily of southern cottonwood-willow riparian forest dominated by Fremont cottonwood (*Populus fremontii*), yellow willow (*Salix lasiandra*), and arroyo willow (*S. lasiolepis*). Alluvial scrub, dominated by scalebroom (*Lepidospartum squamatum*), borders the cottonwood-willow forest in most areas. This entire section of the river is wetland and provides a significant corridor for rainbow and steelhead trout to migrate between the lower reaches of the river and spawning and rearing habitat in tributaries such as Sespe and Piru Creeks. The threespine stickleback (*Gasterosteus aculeatus williamsonii*), an endangered fish, ranges from San Francisquito Canyon (which is upstream) to this section of the river. The fish requires clean, free-flowing perennial streams and ponds surrounded by native vegetation.



L.A. Regional Water Quality Control Board
Riparian Wetlands: Santa Paul and Sisar Creeks

Santa Paula Creek (403.21) is a major tributary of the Santa Clara River originating in the Los Padres National Forest at 5,000 feet. The topography of Santa Paula Canyon is quite severe and the canyon is generally narrow. The wetland begins at near the 4,000 foot level and extends nearly 15 miles to the Santa Clara River. The vegetation is a mixed riparian forest with the following species found during botanical surveys: red willow (*Salix laevigata*), mule fat (*Baccharis salicifolia*), Fremont cottonwood (*Populus fremontii*), white alder (*Alnus rhombifolia*), sycamore (*Platanus racemosa*), and coast live oak (*Quercus agrifolia*). Understory hydrophytes include watercress (*Rorippa nasturtium-aquaticum*), cattails (*Typha latifolia*), and willowherb (*Epilobium* spp.).



Sisar Creek (403.21 & 403.22) is a tributary of Santa Paula Creek which originates in the Los Padres National Forest at 4,500 feet. The wetland extends for 5.0 miles to the confluence with Santa Paula Creek. The vegetation is southern sycamore-alder riparian forest with white alder (*Alnus rhombifolia*) as dominant. Other species include coast live oak (*Quercus agrifolia*), sycamore (*Platanus racemosa*), California bay laurel (*Umbellularia californica*), and knotweed (*Polygonum spp.*) The habitat for both Santa Paula and Sisar Creeks is generally undisturbed.

L.A. Regional Water Quality Control Board
Riparian Wetlands: Sespe Creek

Sespe Creek (403.31 & 403.32) is a major tributary of the Santa Clara River which extends for 58.9 miles mostly on National Forest Lands. On June 19, 1992 President Bush signed into law the "Los Padres Range and River Protection Act" (PL-102-301) establishing 400,450 acres of new wilderness and 84 miles of "Wild and Scenic Rivers" in Los Padres National Forest. A significant part of Sespe Creek and its adjoining watershed was included with the new "Wilderness" and "Scenic Rivers" area. The following paragraph was added to and amended the Wild and Scenic Rivers Act (16 U.S.C. 1274(a)):

> "() SESPE CREEK, CALIFORNIA. --The 4-mile segment of the main stem of the creek from its confluence with Rock Creek and Howard Creek downstream to its confluence with Trout Creek, to be administered by the Secretary of Agriculture as a scenic river; and the 27.5 mile segment of the main stem of the creek extending from its confluence with Trout Creek downstream to where it leaves section 26, township 5 north, range 20 west, to be administered by the Secretary of Agriculture as a wild river"

Also added was part of Sespe Creek as a "Study River":

> "() SESPE CREEK, CALIFORNIA. --The segment from Chorro Grande Canyon downstream to its confluence with Rock Creek and Howard Creek, a distance of about 10.5 miles"

The wetland begins at Chorro Grande Canyon and extends the full length of the creek to the Santa Clara River. The vegetation is diverse along the length of the Sespe and includes most of the major riparian forest/woodland types found in Region 4. The area below Sespe Gorge is a mixed riparian forest with willows (*Salix lasiandra* and *S. lasiolepis*) being dominant. Also present is white alder (*Alnus rhombifolia*), and Fremont cottonwood (*Populus fremontii*). Hydrophytes *Typha* and *Scirpus* are also present. The area near the confluence with Piedra Blanca is cottonwood-willow riparian woodland dominated by *Populus fremontii*. The willows form a scrub understory to the cottonwoods. Lower Sespe Creek, north of Fillmore, is southern sycamore-alder riparian forest including white alder, sycamore (*Platanus racemosa*), willows and coast live oak (*Quercus agrifolia*). The broad alluvial floodplain below Little Sespe Creek is dominated by alluvial scrub vegetation including scalebroom (*Lepidospartum squamatum*), great basin sage (*Artemisia tridentata*), wild tarragon (*A. dracunculus*), yerba santa (*Eriodictyon crassifolium*), and California buckwheat (*Eriogonum fasciculatum*).

Sespe Creek provides unique habitat for anadromous fish including steelhead trout which historically used the Sespe and many of its tributaries as spawning and rearing grounds. Endangered animals include the California condor (*Gymnogyps californianus*) and least Bell's vireo (*Vireo bellii pusillus*). Candidate species include arroyo southwestern toad (*Bufo microscaphus californicus*), and southwestern pond turtle (*Clemmys marmorata pallida*).

VOL 12 1 9009

L.A. Regional Water Quality Control Board
Riparian Wetlands: Sespe Creek Tributaries

Sespe Creek (403.31 & 403.32) has numerous tributaries draining the newly designated Sespe Wilderness of the Los Padres National Forest. Based on comments by the District Ranger from the Ojai Ranger District of the Los Padres National Forest, the following waterbodies have been included as riparian wetlands:

Pine Canyon (403.32) Wilderness area within Condor Sanctuary, no public access.

Coldwater Canyon (403.32) Same as Pine Canyon.

Bear Canyon (403.32) Wilderness area with emphasis on recreation, fish and wildlife.

Redrock Canyon (403.32) Wilderness area and Condor habitat, no public access.

West Fork Sespe Creek (403.32) Wilderness area and Condor habitat. Also an important anadromous stream.

Rose Valley Creek (403.32) Management emphasis is on recreation and visual resources. Fish and wildlife habitat.

Timber Creek (403.32) Recreation emphasis. An important anadromous stream.

Lion Canyon (403.32) Management emphasis is wildlife, watershed, recreation, visual resources and wilderness. Importand anadromous spawning habitat.

Howard Creek (403.32) Management emphasis is recreation and visual resources. Includes important sensitive species habitat.

Trout Creek (403.32) Wilderness area with emphasis on wildlife. Anadromous spawning habitat.

Piedra Blanca (403.32) Same as Trout Creek.

Potrero John Creek (403.32) Same as Trout Creek.

Tule Creek (403.32) Management emphasis is on Water Yield enhancement. Non-motorized recreation and wildlife. Includes sensitive species habitat.

L.A. Regional Water Quality Control Board
Riparian Wetlands: Piru Creek

Piru Creek (403.41 & 403.42) is a major tributary of the Santa Clara River. The headwaters originate at over 5,000 feet in the Los Padres National Forest. The wetland begins near the headwater areas and extends nearly 60 miles to the Santa Clara River making it one of the longest riparian wetlands in Region 4. Because of its length there are a wide variety of riparian habitats associated with Piru Creek including southern coast live oak riparian forest, southern arroyo willow riparian forest, southern willow scrub, southern sycamore alder riparian woodland, and southern mixed riparian forest. Botanical surveys performed below Lake Piru found a mixed riparian habitat containing sycamore (*Platanus racemosa*), Fremont cottonwood (*Populus racemosa*), arroyo willow (*Salix lasiolepis*), with cattails (*Typha latifolia*), and mulefat (*Baccharis salicifolia*) in the understory. A large portion Piru Creek has been extended the status of "Study River" for purposes of inclusion in the "Wild and Scenic Rivers" legislation:

> "() PIRU CREEK, CALIFORNIA-- The segment of the main stem of the creek from its source downstream to the maximum pool of Pyramid Lake and the segment of the main stem of the creek beginning 300 feet below the dam at Pyramid Lake downstream to the maximum pool at Lake Piru, for a total distance of approximately 49 miles.

California Department of Fish and Game has designated 1.3 miles of Piru Creek as a "Wild Trout Stream" in California. Endangered or candidate species associated with Piru Creek include the California condor (*Gymnogyps californianus*), southwestern pond turtle (*Clemmys marmorata pallida*), and Santa Ana sucker (*Catostomus santaanae*).

Riparian Wetlands: Santa Clara River

The Santa Clara River (403.51) extends 23.8 miles from the Los Angeles/Ventura county line to Soledad Canyon. This section of the river is an interuppted stream with perennial water in portions only. Los Angeles county has designated the river, beginning at the county line and extending north to Arrastre Canyon, as Ecologically Significant Area No. 23 for Los Angeles County. This designation is primarily due to the presence of the threespine stickleback (*Gasterosteus aculeatus williamsoni*) which is an endangered species. The fish occurs only in this section of the Santa Clara river and in San Francisquito Canyon, a major tributary. The stickleback has survived due to a minimal amount of disturbance in these areas. The vegetation varies greatly depending on availability of water. Southern cottonwood-willow riparian forest is dominant where water is present or where the water table is high. Botanical surveys in the Valencia area found the following species in the cottonwood-willow forest: Fremont cottonwood (*Populus fremontii*), sycamore (*Platanus racemosa*), Mexican elderberry (*Sambucus mexicana*), yellow willow (*Salix lasiandra*), arroyo willow (*S. lasiolepis*), sandbar willow (*S. hindsiana*), mule fat (*Baccharis salicifolia*), and giant reed (*Arundo donax*). Other areas support little vegetation with only individuals of mule fat (*Baccharis salicifolia*) and salt bush (*Atriplex sp.*) well represented.

Riparian Wetlands: San Francisquito Canyon

San Francisquito Canyon (403 51[illegible]) is a riparian wetland which extends nearly 2[illegible] miles from the Santa Clara River to the confluence with [illegible] miles west of [illegible] Valley. The majority of San Francisquito Canyon lies within the Angeles National Forest and is designated as Ecologically Significant Area No. 1[illegible] for Los Angeles County. Two populations of the unarmored threespine stickleback [illegible] aculeatus williamsoni), which is now restricted to portions of the Santa Clara River and San Francisquito Canyon, [illegible] found [illegible] Reservoir and above Baird Canyon. This fish is on both State and Federal endangered species lists. San Francisquito Canyon is able to support these populations because the surrounding watershed is undisturbed, keeping sedimentation to a minimum and because of rich and healthy riparian forests. The habitat quality is also reflected in the designation of the stream as a an active trout fishing stream by USFS and CDFG. The riparian habitat consists of various types including white alder riparian forest, southern arroyo willow riparian forest, southern mixed riparian forest and coast live oak riparian forest. Currently, San Francisquito Canyon is the most favorable area for management of the endangered fish due to possibility of controlling development.

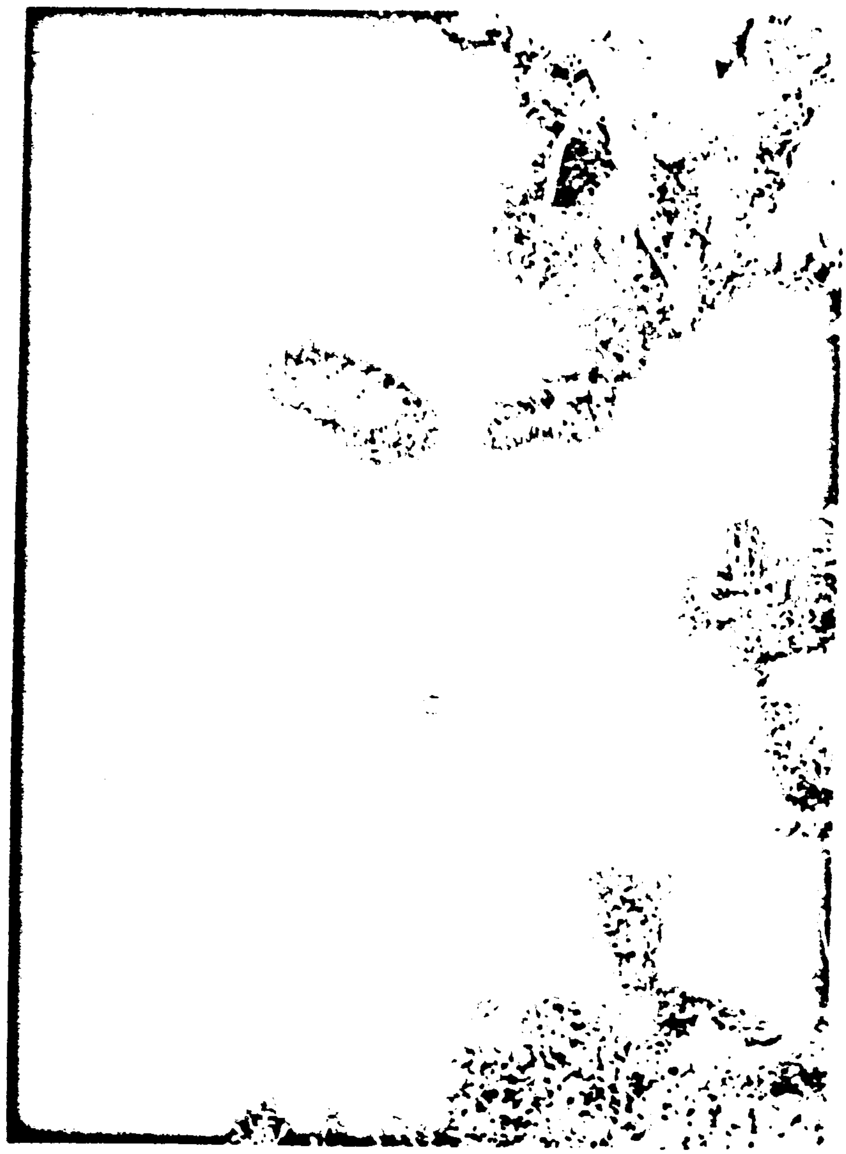
Riparian Wetlands: Bouquet Canyon Creek

Bouquet Canyon Creek (403.51) [illegible] wetland [illegible] [illegible] the Bouquet Reservoir [illegible] Santa Clarita. The habitat [illegible] with a mixture of riparian wetland and [illegible] forest. The stream is perennial [illegible] regulated [illegible] the dam for the reservoir. The vegetation types include southern coast [illegible] riparian forest and southern mixed riparian forest. Common species include Fremont cotton-wood (*Populus fremontii*), coast live oak (*Quercus agrifolia*), and sycamore (*Platanus racemosa*). Understory components include hydrophytes: watercress (*Rorippa nasturtium-aquaticum*), sedges (*Carex* spp.), giant nettle (*Urtica holosericea*), and mint (*Mentha spicata*).

At a site near Texas Canyon, southern arroyo willow riparian forest was dominant with understory [illegible] hydrophytes (*Typha* sp.) and sedges (*Carex* sp.). Giant reed (*Arundo donax*) is become established in the lower portions of the canyon and represents the major source of disturbance.



Above: Bouquet Canyon Creek with rich understory within Southern Mixed Riparian Forest

Riparian Wetlands: Soledad Canyon

Soledad Canyon (405.55) - The uppermost part of the Santa Clara River beginning approximately where Soledad Canyon Rd. joins the river. Soledad Canyon extends 21.5 miles and is an interrupted stream. Soledad Canyon is contained within Los Angeles County Ecologically Significant Area No. [illegible] which extends into Aliso Canyon. Areas with permanent water are habitat for the threespine stickleback (*Gasterosteus aculeatus williamsoni*), an endangered fish. The lower portion of Soledad Canyon consists primarily of southern cottonwood-willow riparian forest interspersed with southern arroyo willow riparian forest. Upper portions above Acton Camp contain significant stands of the diminishing alluvial scrub vegetation which extends into the lower reaches of Aliso Canyon and Kentucky Springs Canyon. Botanical surveys found scalebroom (*Lepidospartum squamatum*), great basin sage (*Artemisia tridentata*), rabbitbrush (*Chrysothamnus nauseosus*), bush senecio (*Senecio douglasii*), mule fat (*Baccharis salicifolia*), California buckwheat (*Eriogonum fasciculatum*) and *Eriastrum densifolium* to be most common.

19021

Aliso Canyon Creek (403.55) is a riparian wetland which originates at Aliso Spring near Mill Creek Summit at the 4000 foot elevation. The wetland extends for nearly 5 miles to the Angelus National Forest boundary at 3,000 feet. The upper reaches of Aliso Canyon is southern riparian scrub dominated by narrowleaf willow (*Salix exigua*), arroyo willow (*S. lasiolepis*), *Rosa woodsii* var. *ultramontana* and deergrass (*Muhlenbergia rigens*. Where the streamcourse widens california sycamore (Platanus racemosa) is interspersed with the riparian scrub. The scrub/sycamore association intergrades into southern mixed riparian forest. Species present were Fremont's cottonwood (*Populus fremontii*), yellow willow (*Salix lasiandra*), and white alder (*Alnus rhombifolia*). under-story elements included various sedges (*Carex*), and western goldenrod (*Euthamia occidentalis*). Aliso Creek is a major headwater tributary of the Santa Clara River.

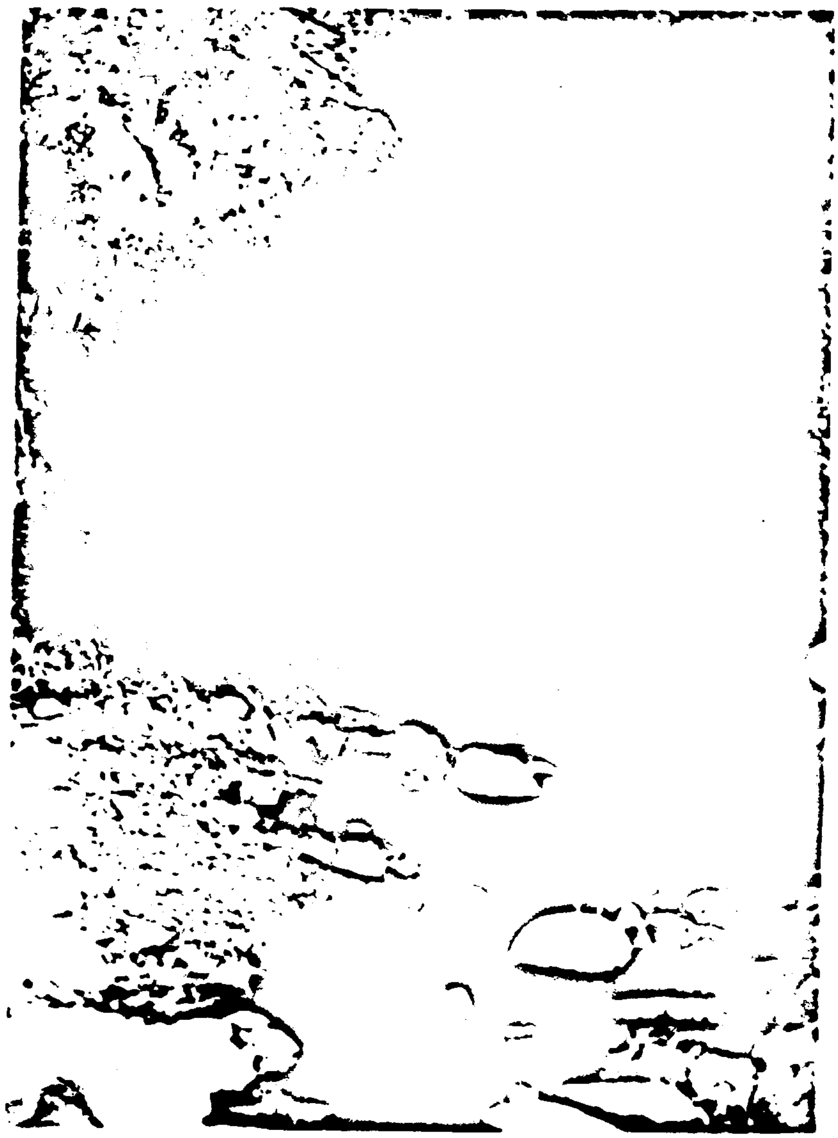
Riparian Wetlands: Malibu Creek

Malibu Creek (404.21) and its tributaries drain 105 square miles. Malibu Creek is fed by a complex of streams and lakes and it also receives treated wastewater. Regulation of the flow is controlled at Lake Sherwood Dam, Lake Eleanor Dam, Malibu Lake Dam, and Crag's Dam. Medea Creek and Triunfo Canyon Creek flow into Malibu Lake which is the headwaters for Malibu Creek. Las Virgenes and Cold Creeks flow directly into Malibu Creek. The headwaters of Las Virgenes and Medea Creeks originate in the Simi Hills. The wetland extends about [illegible] miles from Malibu Lake to the coast. Associated vegetation types include southern arroyo willow forest, coast live-oak riparian forest, southern sycamore alluvial woodland, and mulefat scrub. Malibu Creek is an important wildlife corridor linking various portions of the range. There is high species diversity including numerous hydrophytes, cattail (*Typha* spp.), umbrella sedge (*Cyperus eragrostis* and *C. odoratus*), and bulrush (*Scirpus* spp.). Giant reed (*Arundo donax*) is the most significant invasive exotic. *Dudleya cymosa* occurs on rocky cliffs along Malibu Creek and Tidewater Goby occurs in the estuary at the mouth of the creek. Both are candidates for federal listing.

Willow Riparian Forest along Malibu Creek, Los Angeles County.



Cold Creek (404.21) is a major tributary of Malibu Creek with the headwaters originating at the Arroyo Calabasas. The wetland extends [illegible] miles from Malibu Creek to Cold Creek Fire Road. Much of the wetland lies within the state owned Stunt's Ranch. The area receives heavy equestrian use. Two vegetation types characterize Cold Creek including coast live oak riparian forest (the most common type) and southern arroyo willow riparian forest. The oak forest has an unusually high level of diversity among the herbaceous understory and includes scarlet monkeyflower (*Mimulus cardinalis*), willow-herb (*Epilobium adenocaulon*), scouring rush (*Equisetum spp.*), goldenrod (*Solidago californica*), wild celery (*Apium graveolens*), and mugwort (*Artemisia douglasiana*). Lyons pentachaeta (*Pentachaeta lyonii*), which is listed as endangered, both federally and by the state, is found on Stunt Ranch as is the San Diego Horned Lizard which is a federal candidate species. The major source of disturbance is from giant reed (*Arundo donax*), and pampas grass (*Cortaderia atacamensis*).

Coast Live Oak Riparian Forest along Cold Creek, Los Angeles County. California Bay Laurel (*Umbellularia californica*): foreground, right.

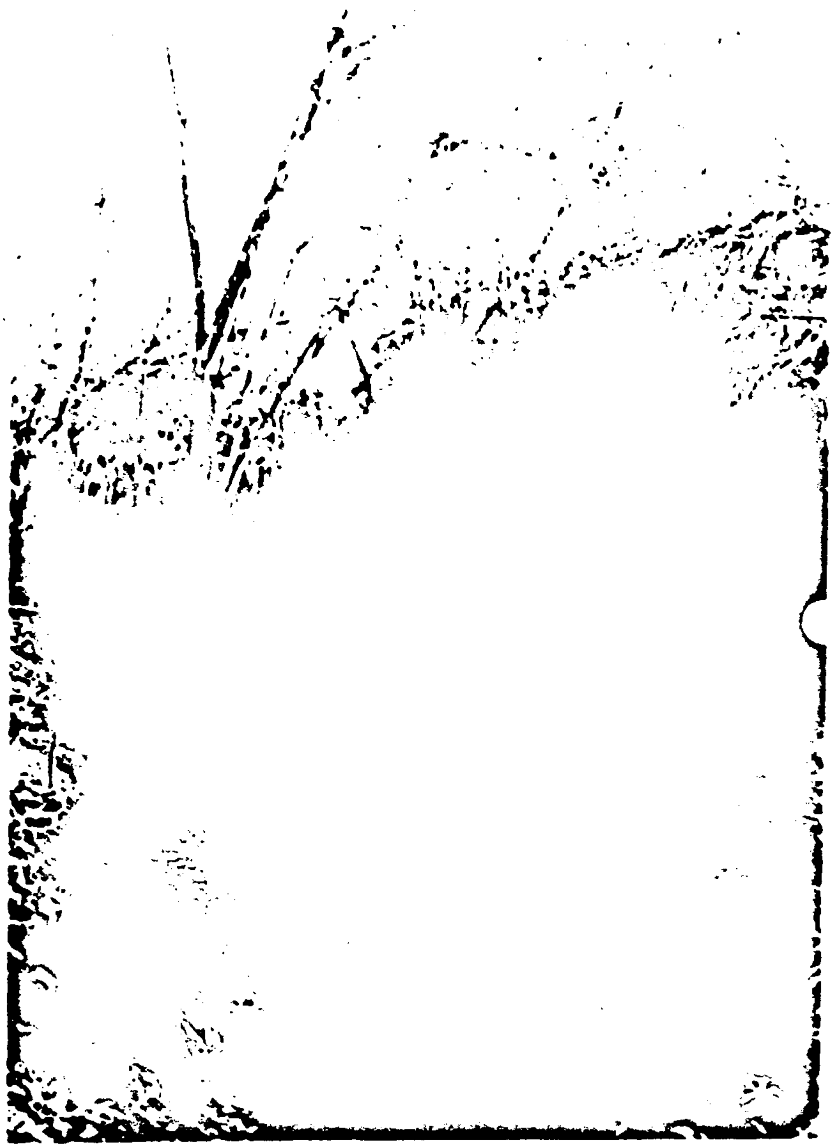
From Los Angeles 30 X 60 min Quadrangle

VOL 12

Medea Creek (404.23-404.24) begins in the Simi Hills and terminates in Malibu Lake which is the headwaters for Malibu Creek. The wetland extends from Malibu Lake to the confluence with Lindero Canyon Creek and Palo Comado Canyon Creek, just south of Highway 101. The wetland is 1.5 miles in length and consists of southern arroyo willow riparian forest. The understory is sparse containing mugwort (*Artemisia douglasiana*), giant nettle (*Urtica holosericea*), and blackberry (*Rubus ursinus*). Braunton,s milk vetch (*Astragalus brauntonii*), a candidate for federal listing, is found near the creek.

Las Virgenes Canyon Creek (404.22) - originates in the Simi Hills and empties into Malibu Creek. The wetland extends 7 miles from Malibu Creek to the confluence with East Las Virgenes Canyon Creek. North of Highway 101 is a mixture of coast live oak riparian forest, southern riparian scrub, and mulefat scrub. South of Highway 101 is southern arroyo willow riparian forest.



19028

L.A Regional Water Quality Control Board
Riparian Wetlands: Arroyo Sequit

Arroyo Sequit (404.44) is one of the best preserved small coastal drainages in Region 4. It lies partly within each of Ventura and Los Angeles Counties. The headwaters originate at over 2,000 feet below Sandstone peak. The wetland begins at the confluence of the East and West Forks of Arroyo Sequit and extends 3.2 miles to the Pacific Ocean. The habitat is primarily sycamore alluvial woodland dominated by Sycamore (*Platanus racemosa*). Scattered individuals of California black walnut (*Juglans californica*) are found throughout the drainage. The flow is interrupted but still supports a wide variety of native aquatic animals, including resident and migratory populations of rainbow trout and steelhead trout.

Riparian Wetlands: Big Sycamore Canyon

Big Sycamore Canyon Creek (404.47) is a premiere example of southern sycamore alluvial woodland within Region 4. It lies within Point Mugu State Park and the Santa Monica Mountains National Recreation Area. The wetland originates at 2,200 feet below Boney Mountain. The wetland begins at about 900 feet and extends 6 miles to the Pacific Ocean. The sycamore woodland has a dense understory of herbs and shrubs including mulefat (*Baccharis salicifolia*), blackberry (*Rubus ursinus*), smilo grass (*Piptatherum miliaceum*), cocklebur (*Xanthium strumarium*), laurel sumac (*Malosma laurina*), mugwort (*Artemisia douglasiana*), and willow (*Salix lasiolepis*). The riparian corridor has a network of trails which receive heavy use by hikers and mountain bikers. The riparian habitat is an important corridor for wildlife species within the Santa Monica Mountains providing access between the coast and interior portions of the range.

Riparian Wetlands: Los Angeles River

The Los Angeles River (405.21) is concrete lined for most of its 4[illegible].1 miles. Two sections remain soft-bottomed and contain significant riparian and wetland habitat. The first section lies below the Sepulveda Dam Recreation Area extending 2.3 miles. The second and larger of the two reaches, covering 7.0 miles lies between Riverside Drive on the west and Figuroa St. on the east. The habitat is quite variable and diverse. Much of the channel contains significant stands of yellow willow (*Salix lasiandra*) which is the largest of the tree willows native to southern California. Giant reed (*Arundo donax*) an invasive exotic has become established in the channel, and although it is largely removed during flooding it quickly becomes reestablished from underground rhizomes. Botanical surveys found numerous hydrophytes including arroyo willow (*Salix lasiolepis*), sandbar willow (*S. hindsiana*), cattails (*Typha domingensis* and *T. latifolia*), bulrush (*Scirpus spp.*), knotweed (*Polygonum spp.*), cocklebur (*Xanthium strumarium*), barnyard grass (*Echinochloa crus-galli*), joint paspalum (*Paspalum distichium*), and umbrella sedges (*Cyperus eragrostis*, *C. alternifolius*). Other hydrophytes include various species of wiregrass (*Juncus*) and sedge (*Carex*). The riparian vegetation is habitat for numerous birds both resident and migratory. Many shorebirds such as snowy egrets (*Egretta thula*) can be found feeding along the shallows and on sandbars within the river. The river bottom has invertebrate species upon which many of the large migratory birds feed. This portion of the Los Angeles River is an ecological island for many species which depend on this habitat in a highly urbanized region.

L.A. Regional Water Quality Control Board
Riparian Wetlands: San Gabriel River System

The San Gabriel River, including all of the major forks, is the longest river system in Region 4 covering 108 linear miles. The watershed contains the highest point in Region 4 which is Mount San Antonio (= Mt. Baldy) at 10,080 feet and is highlighted by some of the most spectacular scenery and pristine habitat in the region. All of the upper watershed drains National Forest lands and includes two wilderness areas, the San Gabriel and Mountain Sheep Wilderness Areas which provide habitat for Nelson's bighorn sheep.

The perennial nature of the streams, that make up the headwaters of the San Gabriel River, is due to two major factors: 1) geological substrate and 2) precipitation regime. The watershed is underlain by igneous rock which has been extensively fractured by tectonic forces through geologic time. Unlike most metamorphic rock, this highly fractured rock can store large quantities of water. The water enters the hydrologic cycle as precipitation, most of which falls between November and April, when the moisture laden air from Pacific storms pushes across the mountain barrier and drops moisture due to adiabatic cooling. The water percolates quickly due to the porous nature of montane soils. The water flows underground until is forced to the surface forming the many springs found throughout the mountains. The area around Crystal Lake has many such springs.

Examples of all of the major biotic zones within Region 4 are represented along the San Gabriel River beginning at the headwater areas and flowing ultimately into the Pacific Ocean. The top of Mount San Antonio is a mixture of talus and stunted limber pine forest (*Pinus flexilis*). Much of the precipitation that falls on such areas percolates into the coarse soils and run downhill. Below this zone, often where the water emerges in the form of springs, is lodgepole pine forest dominated by *Pinus contorta*. Below this zone where streams are more developed is the white fir-sugar pine forest with *Abies concolor* and *Pinus lambertiana* as co-dominants. *Pinus ponderosa* and *P. Jeffreyi* are the major components of yellow pine forest which can be found at the upper reaches of the North, Iron and Prairie Forks. Mixed conifer forest with *Pseudotsuga macrocarpa*, *Pinus ponderosa*, *Calocedrus decurrens* and also *Quercus kellogii* and *Q. chrysolepis* are below the yellow pine forest and can be found at the headwaters of the West Fork. Below these zones the riparian corridor is most typically dominated by white alder (*Alnus rhombifolia*). This is dominant on the East, West and North Forks above San Gabriel Reservoir. Below Morris Reservoir, mule fat scrub and southern arroyo willow riparian forest are widespread. Upon entering the coastal plain, alluvial scrub is dominant to the Santa Fe Reservoir complex. Below this the river is a mixture of willows interspersed with giant reed (*Arundo donax*) and annual weedy vegetation. This annual vegetation is dominant to where channelization begins between Firestone Blvd and Florence Ave in Downey. Hydrophytes such as *Scirpus olneyi* and *Juncus acutus* are found in the soft-bottomed tidal prism.

Riparian Wetlands: L.A. County Parks, San Dimas Vicinity

The Los Angeles County Park System has established numerous parks in natural areas for purposes of horseback riding, hiking, mountain bike riding, bird watching etc. Two such parks are located in the San Dimas vicinity and each is unique in its own way. Walnut Creek park begins at the 57 Freeway in San Dimas and extends into Covina. Marshall Canyon Regional Park is north of Baseline Avenue and includes an extensive trail system as well as a golf course. The streams associated with both parks have water year round.

Walnut woodland is dominant at the eastern end of the park and intergrades into a mixture of willow and oak woodlands at the west end of the park. Numerous invasive exotic plants have become established in the riparian corridor including milk thistle (*Silybum marianum*), sweet fennel (*Foeniculum vulgare*), dwarf nettle (*Urtica urens*) and giant reed (*Arundo donax*). The park is an important wildlife corridor within the Puente Hills and also serves as habitat for numerous birds and mammals. Mountain lions have been seen in the park. There is high diversity of plant species including large stands of blackberry (*Rubus ursinus*), poison oak (*Toxicodendron diversilobum*), California sycamore (*Platanus racemosa*), California black walnut (*Juglans californica*), black cottonwood (*Populus trichocarpa*), big leaf maple (*Acer macrophyllum*) and willow [illegible].

Riparian Wetlands Above Monrovia:

Monrovia Canyon, Fish Canyon, and Roberts Canyon Creeks

West of the San Gabriel River drainage and east of the Big and Little Santa Anita Canyon complex of streams, a number of smaller streams drain the front country canyons of the San Gabriel Mountains. These canyons are steep V-shaped canyons characterized by highly fractured rock which stores large amounts of water during the rainy season which is typically from November to April. The headwater areas for these canyons receive between 30 and 40 inches of precipitation annually. This water is then released slowly to the environment, making it available to plants and animals through the dry summer and fall.

Monrovia Canyon Creek (405.41) [illegible] steep canyon of the front country [illegible] the San [illegible] Mountains. The [illegible] waters originate in [illegible] separate [illegible] 4,000 feet [illegible] Clamshell and Rankin Peaks in the Angeles National Forest. The wetland begins at the 2,200 foot elevation level and extends [illegible] miles to the [illegible] basin below Sawpit Canyon Reservoir. The steep canyon is punctuated by a number of waterfalls. The lower portion of the canyon (approximately one mile is within Monrovia Mountain Park. The vegetation is white alder riparian forest with a dense canopy of California bay laurel (*Umbellularia californica*) growing on the margins of the stream and extending up the sides of the canyon. The understory is sparse due to the dense canopy. Escaped exotic eupatory (*Ageratina adenophora* has become well established in the canyon and forms dense stands in the bottom of the canyon. The flow regime in the lower portion of the canyon has been altered by the construction of sediment trapping debris dams. There is no trail system connecting this canyon with other areas of the San Gabriel Mountains, consequently this area receives use only by hikers.

Riparian Wetlands: East Fork San Dimas Creek

East Fork San Dimas Canyon Creek (4[illegible]44 [illegible] a riparian wetland [illegible] the [illegible] mountains. The headwaters [illegible] at Fallen Leaf Spring [illegible] 2,800 feet and [illegible] Canyon [illegible] feet. The stream [illegible] the West Fork San Dimas Canyon just above the San Dimas Reservoir. The Wetland extends from the upper end of the Reservoir to Fallen Leaf Spring ([illegible] miles) and also into Fern Canyon (4.[illegible] miles). Fern Canyon is a Research Natural Area. This area is sub[illegible] significant amounts [illegible] vehicular traffic due to numerous (60) cabins. Residents have planted English ivy (*Helix hedera*) and periwinkle (*Vinca major*) as ground cover. In many area this has grown into the stream course displacing native vegetation. Invasive exotics giant reed (*Arundo donax*) and eupatory (*Ageratina adenophora*) are present. The entire San Dimas drainage culminates in an important groundwater basin which begins at the mouth of the canyon. The groundwater basin is divided by faults [illegible] the San Dimas Basin, the Foothill Basin, and the Way Basin. The vegetation of the East Fork and including Fern Canyon is relatively undisturbed beginning at the point of confluence with Wolfskill Canyon. The vegetation consists of white alder riparian forest and intergrades into [illegible] forest.

Photo: White Alder Riparian Forest at Confluence with Wolfskill Canyon

L.A. Regional Water Quality Control Board
Riparian Wetlands: Little Dalton Canyon Creek

Little Dalton Canyon Creek (405.41) lies just west of the San Dimas Experimental Forest boundary, paralleling the boundary at a distance of about three [illegible]. The headwaters originate at [illegible] feet near Horse Canyon Saddle. The vegetation at the headwater area is canyon live oak ravine forest mixed with California bay laurel (Umbellularia californica). The lower reaches are typically white alder riparian forest and to a lesser extent canyon live oak forest. A mixture of southern arroyo willow riparian forest and mulefat scrub is dominant near Glendora Mountain Road. The section between Glendora Mountain Road and the debris basin contains large stands of giant reed (*Arundo donax*). The wetland begins at 2,000 feet and extends 2.1 miles to the debris basin. Most of the wetland area is white alder riparian forest with a dense understory of herbaceous perennial hydrophytes including hedgenettle (*Stachys bullata*), clustered docks (*Rumex conglomeratus*), cattail (*Typha domingensis*), iris-leaved rush (*Juncus xiphioides*), barnyard grass (*Echinochloa crusgalli*), and invasive exotic *Ageratina adenophora*. Hydrophytic annuals include scarlet and common monkey flowers (*Mimulus cardinalis* and *M. guttatus*).

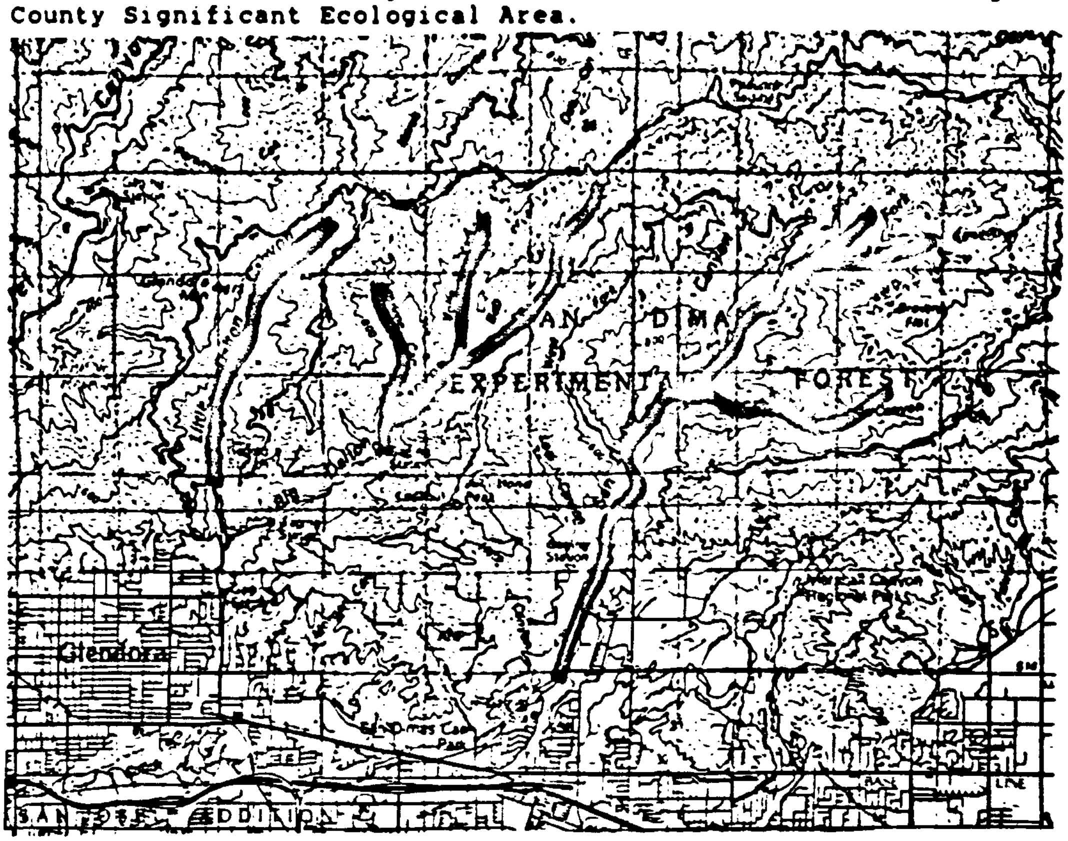
R0052366

L.A. Regional Water Quality Control Board
Riparian Wetlands: San Dimas Experimental Forest

East Fork San Dimas Canyon Creek, Wolfskill Canyon Creek
Big Dalton Canyon Creek, Little Dalton Canyon Creek

The San Dimas Experimental Forest lies above San Dimas and Glendora in the Foothill HSA (405.44). The topography consists of steep V-shaped canyons typical of the front range of the San Gabriel Mountains. Rainfall at the headwater areas of the major drainages is between 34-38 inches annually with the greatest (38 inches) occurring at the headwaters of Wolfskill Canyon. The geological history of the San Gabriels has been one of continuous upheaval leaving much of the underlying rock highly fractured. This fracturing allows for infiltration of large amounts of water. This water is slowly released back into the stream courses where it is available for use by vegetation and animals.

All of the Experimental Forest lies within the Angelus National Forest. San Dimas Canyon has been designated as a Los Angeles County Significant Ecological Area.



Map: Riparian Wetlands of the San Dimas Experimental Forest
From San Bernardino 30 X 60 min Quadrangle

L.A. Regional Water Quality Control Board
Riparian Wetlands: Big Dalton Canyon

Big Dalton Canyon (405.41) lies west of the San Dimas Canyon Creek drainage system within the San Dimas Experimental Forest. The Headwaters originate in Monroe Canyon, Wolfe Canyon and Bell Canyon which flow into Big Dalton Reservoir. Big Dalton Canyon begins at the Reservoir and extends to Glendora Mountain Road. The wetland area begins at 2,200 feet in both Bell and Volfe Canyons and extends about one mile in each canyon until they join. From the confluence point to the reservoir is 0.9 miles and from the reservoir outfall to the debris basin at Glendora Mountain Road is 2.5 miles for a total of 5.4 miles of riparian wetlands. These streams are interrupted streams which carry perennial water only in portions where geological conditions cause ground water to be pushed to the surface. In such areas, white alder riparian forest is common. Where surface water is not available year round coast live oak riparian forest and southern arroyo willow riparian forest are most common. Hydrophytic vegetation includes lance-leaved frog fruit (*Phyla lanceolata*), common monkey flower (*Mimulus guttatus*), scarlet monkey flower (*Mimulus cardinalis*), watercress (*Rorippa nasturtium-aquaticum*), and invasive exotic *Ageratina adenophora*.

L.A Regional Water Quality Control Board
Riparian Wetlands above Pasadena:

Big Santa Anita Canyon Creek, Winter Creek
Eaton Canyon Creek and Rubio Canyon Creek

Steep V-shaped canyons are typical of the frontal range of the San Gabriel Mountains. The canyons above Pasadena offer some of the most severe topography in the entire range. Eaton and Rubio Canyons are the most severe. Historically, these areas have been subject to heavy human use. Today they are still heavily used by hikers, mountain bikers, and backpackers. During a field visit to Big Santa Anita Canyon a group baptism was observed in the pool below Sturtevant Falls!

The perennial source of water in these canyons is due to highly fractured rock which stores large quantities of water. This water is released slowly, thereby providing a constant supply even during drought. The constant supply of water insures rich vegetation, typically white alder riparian forest. The rich vegetation provides habitat to numerous bird species as well as mammals, reptiles, and fish.

VOL 12

The Arroyo Seco ([illegible]) is one of the largest drainages of the [illegible] of the San Gabriel Mountains. The headwaters originate at about [illegible] feet near the Angeles Crest Highway above upper Switzer Camp. The wetland begins in the Angeles National Forest at [illegible] feet and extends over [illegible] miles to the Devil's Gate Reservoir. The habitat consists of white alder riparian forest, coast live oak riparian forest and southern arroyo willow riparian woodland. Hydrophytes include *Boykinia rotundifolia*, watercress (*Rorippa nasturtium-aquaticum*), common monkey flower (*Mimulus guttatus*), and invasive exotic *Ageratina adenophora*. Periwinkle (*Vinca major*) and English ivy (*Hedera helix*) have become dominate in some areas having been planted as groundcover around cabins many years ago.

White Alder Riparian Forest along the Arroyo Seco above Pasadena in Los Angeles County

19070

Bear Canyon (405.32) is the largest tributary of the Arroyo Seco and is possibly the most pristine canyon on the front range of the San Gabriel Mountains. The headwaters originate at [illegible],800 feet in the Angelus National Forest. The wetland is approximately 2 miles in length, ending at the confluence with the Arroyo Seco. The canyon is steep and narrow, containing a mixture of white alder riparian forest and big cone Douglas fir-canyon live oak ravine forest. The understory is sparse due to the dense canopy which in some areas consists of two layers. California bay laurel (*Umbellularia californica*), and big leaf maple (*Acer macrophyllum*) are also common.

Little Bear Canyon (405.32) empties into the Arroyo Seco about 600 feet below where Bear Canyon joins the Arroyo Seco. Little Bear Canyon is quite undisturbed due to a lack of access. The headwaters originate at about 4,000 feet and the wetland extends for one mile to the Arroyo Seco.

Riparian Wetlands: Pasadena Area

Arroyo Seco and Millard Canyon Creek

The Arroyo Seco and Millard Canyon are typical of most canyons of the front country of the San Gabriel Mountains. The canyons are steep and V-shaped. The highly fractured granite of this portion of the range is able to store large quantities of water which falls as rain and snow between November and April. The water is released slowly to the environment so that even during the dry summer and fall, or after years of drought, there is still sufficient water to support diverse plant communities. These plant communities provide important habitat for numerous vertebrates. This part of the range has historically received heavy human use. Fifty years ago the Arroyo Seco was one of the favorite vacation spots in the range (Robinson 1990). Today the area is used by hikers, runners, and mountain bikers.

Millard Canyon Los Angeles County

R0052378

L.A. Regional Water Quality Control Board Riparian Wetlands: Fish and Iron Forks, San Gabriel River

The Fish Fork of the San Gabriel River (405.43) originates below Pine Mountain Ridge in the Sheep Mountain Wilderness and on the western slope of Mount San Antonio at [illegible] feet. The wetland extends [illegible] miles from below the 6,000 foot level to the confluence with the East Fork of the San Gabriel River. The canyons of the headwater areas contain canyon live oak-big cone Douglas fir forest. The coniferous forest intergrades into white alder riparian forest with California bay laurel (*Umbellularia californica*) and big leaf maple (*Acer macrophyllum*) often sharing dominance with *Alnus rhombifolia*. The area is pristine habitat, subject to little disturbance due to lack of accessibility. This area is important habitat for Nelson's bighorn sheep (*Ovis canadensis nelsoni*).

The Iron Fork of the San Gabriel River (405.43) consists of two branches, the main stem Iron Fork and South Fork Iron Fork. The main stem originates below Mount Baden-Powell at 7,500 feet. The wetland extends 2.1 from the 5,600 foot level to the confluence with the South Fork. The South Fork drains South Mount Hawkins with the wetland beginning at 5,200 and extending [illegible] miles to the main stem Iron Fork. The upper areas contain canyon live oak-big cone douglas fir forest. The wetland area below the confluence point is white alder riparian forest and extends about 2 miles to the East Fork, San Gabriel River.

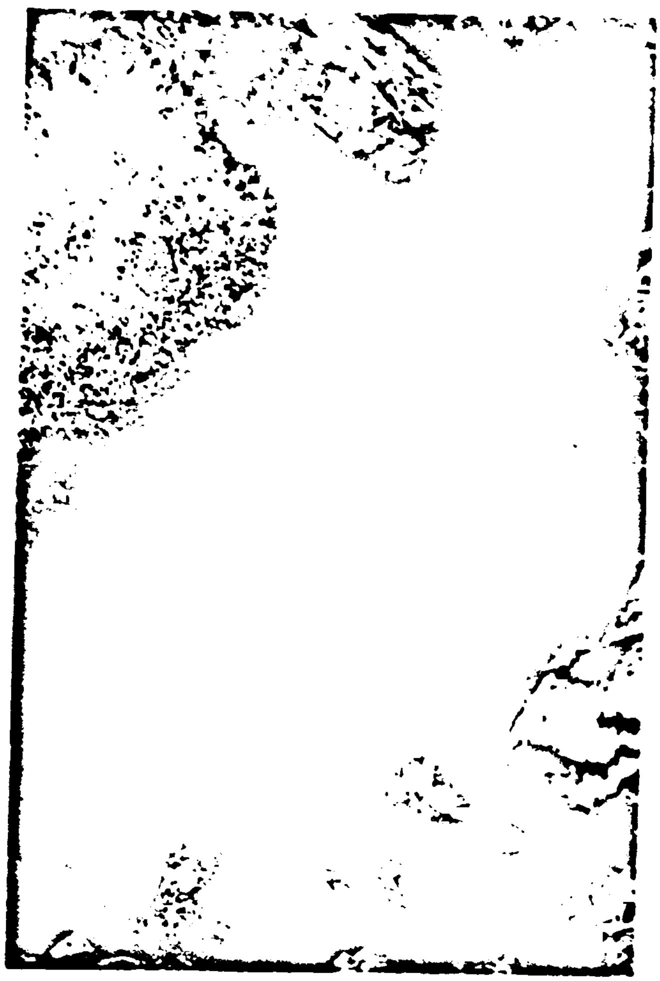
Riparian Wetlands: East and Prairie Forks, San Gabriel River

The East Fork of the San Gabriel River (405.43) originates at the confluence of the Prairie Fork of the San Gabriel River and Vincent Gulch at an elevation of 4,[illegible] feet. The wetland extends approximately 1[illegible] miles to the San Gabriel Reservoir. The vegetation is white alder riparian forest which is found in and immediately adjacent to the streambed. Outside the active channel is a broad zone of alluvial scrub dominated by scalebroom (*Lepidospartum squamatum*), California buckwheat (*Eriogonum fasciculatum*) and Our Lord's candle (*Yucca whipplei*). The area receives heavy use by gold miners. The primary method employed by the miners is panning which causes large amonuts of sediments to be put back into the stream. The impact of panning for gold on the biotic resources is unknown and needs to be studied. The East Fork is habitat to the Santa Ana Sucker (*Catostomus santaanae*) and Nelson's big horn sheep (*Ovis canadensis nelsoni*).



The Prairie Fork of the San Gabriel River (405.43) originates at 7,000 feet in the Sheep Mountain Wilderness. The wetland extends 6.2 miles to the beginning of the East Fork of the San Gabriel River. The vegetation at the headwaters is a mixture of white alder riparian forest dominated by *Alnus rhombifolia*. Occasional stands of big cone Douglas fir (*Pseudotsuga macrocarpa*) are found along the margins of the canyon and extending up the slopes. The canyon is a broad canyon and supports a number of plant communities including southern arroyo willow riparian forest which often takes on a stunted scrub-like appearence a[illegible] alluvial scrub.

Above: White Alder Riparian Forest in the Narrows Area of the East Fork, San Gabriel River.

L.A. Regional Water Quality Control Board
Riparian Wetlands: North Fork San Gabriel River

The North Fork of the San Gabriel River 405.43 originates in the Falling Springs area below the Crystal Lake Recreation Area in the Angeles National Forest. The wetland begins at 3,[illegible] feet at the confluence of Coldbrook and Soldier Creeks and extends 4.6 miles to the confluence with the West Fork of the San Gabriel River. The vegetation is primarily white alder riparian forest with occasional stands of big-cone Douglas fir. The lower areas are white alder riparian forest dominated by *Alnus rhombifolia* with occasional individuals of arroyo willow (*Salix lasiolepis*). The understory is sparse due to the dense understory with mugwort (*Artemisia douglasiana*) as the most common component. The white alder riparian forest is bordered by alluvial scrub including scalebroom (*Lepidospartum squamatum*), mulefat (*Baccharis salicifolia*), bush senecio (*Senecio douglasii*), California buckwheat (*Eriogonum fasciculatum*), California brickelbush (*Brickellia californica*) and *Heterotheca villosa* [illegible]. The area is subject to heavy use by picnickers who leave large amounts of trash including dirty diapers in the stream. This could have negative impact on water quality. The North Fork provides habitat for the Santa Ana sucker (*Catostomus santaanae*) and Nelson's big horn sheep (*Ovis canadensis nelsoni*).

L.A. Regional Water Quality Control Board
Riparian Wetlands: Rio Hondo

Rio Hondo (405.41) is a river of the coastal plain of Los Angeles county. The headwaters originate high in the San Gabriel Mountains and the Rio Hondo begins at the confluence of two major drainages of the central portion of the range: Santa Anita and Eaton Washes. The river is concrete lined over most of its 11.1 miles. The notable exception to this is where the river flows through the Whittier Narrows Recreation Area. Here the river has remained in its natural state supporting a high diversity of native riparian vegetation along with a number of invasive exotic species as well as numerous weedy species. The wetland is 3.1 miles long, beginning south of Garvey Ave and extending to the Whittier Narrows Dam. The native riparian vegetation includes Sycamore (*Platanus racemosa*), Fremont cottonwood (*Populus fremontii*), black cottonwood (*P. trichocarpa*), arroyo willow (*Salix lasiolepis*), red willow (*S. laevigata*), yellow willow (*S. lasiandra*), California black walnut (*Juglans californica*), elderberry (*Sambucus mexicana*), and coast live oak (*Quercus agrifolia*). Understory species include mule fat (*Baccharis salicifolia*), cattails (*Typha* spp.), knotweed (*Polygonum* spp.), and cocklebur (*Xanthium strumarium*). Wild grape (*Vitis californica*) which is a vine , forms dense mats as it grows up into the canopy. Weedy species include various annual grasses (e.g. *Bromus* sp.), castor bean (*Ricinus communis*), tree tobacco (*Nicotiana glauca*), horehound (*Marrubium vulgare*), and most importantly giant reed (*Arundo donax*). *Arundo* has virtually taken over large portions of the Whittier Narrows Recreation Area. It forms dense monocultural stands, reproducing by underground rhizomes and excluding most native vegetation. This exclusion results in a loss of significant amounts of quality habitat upon which numerous native birds depend.

The area is used heavily for swimming and wading during those times when water is plentiful. The channel is heavily littered with various sorts of trash much of which is most probably washed from upstream areas which receive the same types of use.

The wetlands (both riparian and lacustrine) within the Whittier Narrows Recreation Area provide important habitat to numerous birds, both resident and migratory. It is an ecological island within a highly urbanized region and as such is indispensible in the maintainance of numerous bird and other vertebrate species throughout Region 4.

L.A. Regional Water Quality Control Board
Riparian Wetlands: Cattle Canyon and Tributaries

Cattle Canyon Creek (405.43) is a major tributary of the East Fork of the San Gabriel River. The headwaters originate at the 8,000 foot level of the south-west slope of Mount San Antonio and from Big Horn Ridge. The wetland extends 8.0 miles from about 5,400 feet to the East Fork of the San Gabriel River. The headwater areas consist of canyon live oak-big cone Douglas fir forest with willow scrub as understory. The lower portions are white alder riparian forest interspersed with southern arroyo willow riparian forest. Alluvial scrub occurs in those areas where the canyon broadens. Botanical surveys found a high diversity of trees in the riparian forests including *Alnus rhombifolia*, *Acer macrophyllum*, *Umbellularia californica*, *Fraxinus velutina*, *Quercus agrifolia* and various species of willow (*Salix* spp.). Cattle Canyon is habitat for the Santa Ana sucker (*Catostamos santaanae*), and Nelson's bighorn sheep (*Ovis canadensis nelsoni*).

Coldwater Creek (405.43) is a tributary of Cattle Canyon Creek originating from a number of branches draining the San Antonio Ridge. The wetland begins at 4,600 feet and extends nearly 6 miles to Cattle Canyon. Canyon live oak-big cone Douglas fir is dominant in the upper reaches and white alder riparian forest becomes dominant at lower elevations. Nelson's bighorn sheep (*Ovis canadensis nelsoni*) occurs here.

Cow Canyon Creek (405.43) is a tributary of Cattle Canyon Creek originating below Lookout Mountain at about 5,000 feet. The wetland extends 2.2 miles from the 3,600 foot level to Cattle Canyon. Big cone Douglas fir forest is overstory to willow scrub at the headwater areas and white alder riparian forest and southern arroyo willow riparian forest are dominant in the lower portions. Nelson's bighorn sheep (*Ovis canadensis nelsoni*) is present here.

Allison Gulch (405.43) is a tributary of the East Fork, San Gabriel River. The headwaters originate below Iron Mountain at 6,600 feet. The wetland extends 1.5 miles from above the Allison Trail to The East Fork, San Gabriel River. The canyon is steep and narrow and is dominated by bay laurel (*Umbellularia californica*), and big leaf maple (*Acer macrophyllum*). The upper part of the canyon is canyon live oak-big cone Douglas fir forest. Allison Gulch is within the Sheep Mountain Wilderness and is habitat for Nelson's bighorn sheep (*Ovis canadensis nelsoni*).

1991

EXECUTIVE SUMMARY

Marina del Rey, is the largest manmade marina in the world, containing 5,800 boat slips, and a terrestrial resident population of almost 11,000 people. There are 28 restaurants many shops, four hotels and two motels which draw patrons to the dock area, in addition to the small boat operators who use the launching ramps.

The Marina is a surprisingly good habitat considering the impacts it receives, which largely originate in the urban area virtually surrounding it. Since about ninety percent of the natural wetlands of the Los Angeles area have been lost, protecting the modified wetlands such as bays and harbors, including the Marina, is critical to the health and productivity of adjacent shallow water coastal habitats. Continuing efforts are essential to maintain and improve conditions in the Marina in order for it to serve as a fish nursery and a productive benthic community.

WATER QUALITY

The water quality of Marina del Rey is influenced by a number of factors: these include potential impacts of recreational and residential usage such as oil seepage, illegal disposal of wastes, trash and caustic substances, use of bilfouling compounds, and boat scrapings. Impacts originating outside the Marina appear to have the larger effects; these include the meteorologic and oceanographic conditions affecting the Southern California Bight, and the impacts of urban runoff.

The period of October 1989 to September 1990 was strongly influenced by the lack of significant rainfall over the past several years. Small storms serve to transport refuse and sediments, to which trace metals and pesticides are attached, into the Marina via storm drains and flood control

VOL 12 1992

TEMPERATURE, RAINFALL AND DISSOLVED OXYGEN

Water temperatures during the monitoring period were subject to extremes; October and November were colder than usual, followed by a warmer period, then cold in February, and an unusually long, warm summer. The highest record during monitoring was 25.3°C.

The combination of low rainfall and high temperatures may have been responsible for the large number of low dissolved oxygen (DO) values recorded during the year. Regulatory agencies regard 5.0 ppm DO as the minimum level for the protection of fish species, although most can survive with less, and many invertebrate species require far less. No episodes of zero DO were recorded, which would cause production of toxic hydrogen sulfide. Pelagic fish tend to leave the warm waters for cooler coastal waters during the summer, but very warm temperatures and low DO could impact resident fish such as those in the shallow sea grass beds in Basin D. Low DOs also were widespread in the inner Marina in November and December 1989, in April 1990 following a rainstorm, at the Marina entrance in May, and at scattered inner stations in the summer of 1990.

NUTRIENTS

Nutrients support a high level of phytoplankton production, at times creating bloom conditions, but providing oxygen and food for some fish species. In general, concentrations of ammonia, nitrate and nitrite, phosphate and silicate follow a pattern of being low near the ocean and higher in the inner Marina. They also tend to be higher in winter when phytoplankton densities are reduced by cooler temperatures and lower light intensities. However, high levels of ammonia which persisted during the summer of 1990 were unusual and correlated with low dissolved oxygen channels but are insufficient to flush accumulated contaminated sediments into Santa Monica Bay.

Dry weather flow in Oxford Flood Control Basin carries a large burden of pollutants and bacteria for the volume of water involved. This may have been the source of polychlorinated biphenyls (PCBs) that entered the Marina in 1988-1989, perhaps due to excavations of highly contaminated sediments during construction on property near the Marina. Sediments may have drained into Oxford Basin and been flushed into the Marina.

Ballona Creek Flood Control Channel flow mixes with tidal waters upstream, and on a falling tide carries trash, particularly plastic refuse, to the mouth of the stream. On a rising tide, some of that material will be drawn into the Entrance Channel of the Marina where it may accumulate in an eddy. Figure *i* shows trash accumulating inside the breakwater, and Figure *ii* shows debris collected along the outer end of the south jetty after a 0.5 inch rainfall in April, 1990. While a boom has been installed upstream on Ballona Creek, it does not catch all of the trash and illegally dumped materials. Its efficiency depends in part on frequent cleaning. Neither can it solve the problem when higher tides sweep the jetty rocks of trash and organic material from fishermen who spend long hours there without sanitary or trash disposal facilities and organic wastes from dogs that are exercised there.

Wet weather flow of large volume tends to cleanse the sediments deposited in the Creek bed, but the trash barrier is opened during major storms so that it will not impede storm flows or be torn loose to cause damage.

TEMPERATURE, RAINFALL AND DISSOLVED OXYGEN

Water temperatures during the monitoring period were subject to extremes; October and November were colder than usual, followed by a warmer period, then cold in February, and an unusually long, warm summer. The highest record during monitoring was 25.3°C.

The combination of low rainfall and high temperatures may have been responsible for the large number of low dissolved oxygen (DO) values recorded during the year. Regulatory agencies regard 5.0 ppm DO as the minimum level for the protection of fish species, although most can survive with less, and many invertebrate species require far less. No episodes of zero DO were recorded, which would cause production of toxic hydrogen sulfide. Pelagic fish tend to leave the warm waters for cooler coastal waters during the summer, but very warm temperatures and low DO could impact resident fish such as those in the shallow sea grass beds in Basin D. Low DOs also were widespread in the inner Marina in November and December 1989, in April 1990 following a rainstorm, at the Marina entrance in May, and at scattered inner stations in the summer of 1990.

NUTRIENTS

Nutrients support a high level of phytoplankton production, at times creating bloom conditions, but providing oxygen and food for some fish species. In general, concentrations of ammonia, nitrate and nitrite, phosphate and silicate follow a pattern of being low near the ocean and higher in the inner Marina. They also tend to be higher in winter when phytoplankton densities are reduced by cooler temperatures and lower light intensities. However, high levels of ammonia which persisted during the summer of 1990 were unusual and correlated with low dissolved oxygen levels. These results were consistent with water that has experienced significant breakdown of organic material, suggesting high levels of input of organic waste into the Marina or death of phytoplankton blooms, followed by microbial breakdown of the organic compounds.

BACTERIAL CONTAMINATION

In Oxford Basin, there were a number of violations of Public Health standards for coliform and fecal coliform organisms, possibly of animal origin, and of enterococcus standards, which are indicative of human fecal contamination. Oxford Basin is not a body contact water area, but since it drains into Basin E where boaters or maintenance people might be in contact with the water, these episodes of violation are of concern. In December 1989, bacterial counts were also in violation in Ballona Creek at Stations 12 and 1.

RAINFALL EFFECTS

Impacts of a small rain storm were well illustrated when about 0.5 inches fell in the Los Angeles Basin on 4 April 1990, followed by monitoring on 5 April. Almost the entire Marina was in violation of bacterial standards from runoff. Ammonia levels were high in Oxford Basin and in Ballona Creek, as were nitrates and nitrites, and phosphates. Biochemical Oxygen Demand (BOD) was high, indicating the input of organic materials which would be broken down chemically or by bacteria in processes using up oxygen. Dissolved oxygen was low only in the inner Marina, probably because bacterial degradation had not yet been completed, and also because turbulence at the breakwater may have increased the level of dissolved oxygen.

VOL 12 1996

SEDIMENT CHARACTERISTICS AND CONTAMINANTS

Sediment grain size changed from the previous year, in particular at Station 2, at the entrance to the Marina, with a large increase in very fine sediments that have accumulated at the sandbar. These fine sediments carry a large proportion of the pollutant trace metals and pesticides adsorbed on or complexed to them.

Stations 9, 10 and 11 in the Marina, and 12 in Ballona Creek scored as the most contaminated by total trace metals. Based on criteria newly developed by the National Oceanographic and Atmospheric Administration (NOAA), sediments at most stations monitored are sufficiently contaminated with copper, lead, mercury and zinc to pose a low range level of effects (ER-L) on fish and/or invertebrates, especially larval or juvenile stages. Several stations are sufficiently contaminated to fall in the median range of effects (ER-M) from lead and zinc, and a few stations are in the range called the apparent effects threshold (AET). Falling in the AET for copper was Station 10 in Basin E, and for zinc, Stations 2, in the Entrance Channel and 9, 10 and 11 in the inner Marina; Station 12 was in the AET group for zinc, and Station 13 in Oxford Basin was in the AET for lead and zinc. Regulatory agency standards are not yet in place for sediment contaminants, except for dredge disposal permits issued on a case by case basis by the U.S. Army Corps of Engineers (COE) and the Environmental Protection Agency (EPA).

There is no direct correlation between any single trace metal or pesticide parameter for which analysis is conducted with the benthic or fish populations. The synergistic effects of contaminants are difficult to evaluate, and previous bioassays conducted have shown chronic inhibitory effects but not lethal effects of Marina sediments on selected indigenous organisms.

Tributyltin, the highly toxic antifouling agent that was banned in September 1987, has continued to decrease in Marina sediments, indicating good compliance with the ban. This may be related to the return of intertidal crustaceans and mussels which had almost disappeared from pilings and riprap.

The situation for pesticides and chlorinated hydrocarbons is of concern; levels of Chlordane were above the median effects range and the apparent effects threshold (AET) except at Stations 6 and 8, which have the lowest terrestrial drainage. The total DDTs were above the median effects range at all stations. Levels are sufficient to damage liver function or reproduction in sensitive species and inhibit the larval and juvenile stages of hardier species.

Polychlorinated biphenyls (PCBs), banned for years but formerly used in transformers, as lubricants in motors and pumps and in other industrial processes, had been absent from the Marina in 1985-1988. Highly toxic forms, the Aroclors 1254 and 1260, were found in October 1989, when Aroclor 1260 occurred at the Administration dock (Station 25) and in Ballona Creek. Aroclor 1254 was found in all other Marina Stations except Stations 1 and 3, with by far the highest level at Station 2 in the Entrance Channel where the finest sediments accumulate. This indicated that the introduction(s) had been long enough prior to the annual survey to become widely spread.

To verify the occurrence of Aroclor 1260, which is not common, a second survey was made in January 1990, at which time Aroclor 1260 was found to be more widely distributed, with peaks at the Administration dock and in Oxford Basin. This suggests separate introductions. Soils inland of Admiralty Way near the head of the Main Channel are known to be heavily contaminated with PCBs, including Aroclor 1260, at levels more than 1000 times higher than those in the Marina. Extensive grading and excavation inland of Marina del Rey appears to have been contaminating the Marina by runoff that is potentially highly toxic to fish and invertebrates.

FISH TISSUE BODY BURDENS

Concern for the levels of PCBs and DDTs in the Marina led to a special study to determine whether the fish caught in the Marina, especially at the fishing pier, might be hazardous to human health. Muscle tissues from 22 fish, representing 12 species, and 3 sets of liver/gonads were sampled and analyzed. Results indicated that the fish muscle tissues were well below Public Health limits for human consumption.

Concentrations varied greatly, with the high levels under 300 ppb of PCB in California halibut, California barracuda, white croaker and shiner surfperch. The same species tended to have the highest levels of DDTs and the effects are probably cumulative. Liver and gonads, which are gutted before human consumption, had much higher levels in some species, indicating possible impairment of liver and reproductive functions. The California lizardfish, which had very low levels in body tissue, had extremely high levels in the liver. Widely ranging fish may ingest these pollutants during feeding elsewhere in the Bight or in the Marina. Fish from off Whites Point and the south side of Palos Verdes Peninsula may contain much higher levels than those found in the Marina, and therefore white croaker are banned from commercial catch there. Content varies seasonally since chlorinated compounds are complexed to fats, which are transported from muscle and liver to eggs that are shed, lowering the body burden. These special studies are continuing in 1989-1990.

BENTHIC FAUNA

The benthic fauna consists primarily of polycheate annelid worms, which prefer the fine grained sediments and can tolerate contaminants. Molluscs, crustaceans and echinoderms that might be expected in the Marina environment are scarce, perhaps reduced or eliminated by the high levels of contaminants in the sediments which inhibit reproduction and impact larval and juvenile stages.

The long term mean number of benthic species in October surveys is 31, but the means have been below that in the last three years. Similarly the mean number of individuals has been lower in the last three years than in 1986. This may reflect the low rainfall and the lack of flushing which may be needed to stimulate populations or to remove inhibitory substances. There have been no major sewage or other spills of record during this year.

Of particular concern are benthic conditions at stations 9 and 11, which had by far their lowest populations ever, lower than would have been expected due to the change from open water to boat slips.

FISH FAUNA

In all over ninety species or taxa of fish have been recorded in the Marina during the monitoring surveys. Of these, 12 species have occurred in all spring surveys since 1984, one of which, the striped mullet, is uncommon in the southern California Bight, making the Marina an important habitat for that species. The mean number of species from all surveys since the 1970s is 40, with a range of variation from 33 to 47.

The Marina appeared to be relatively in stable condition in the October 1989 and May 1990 surveys, recognizing that the larger numbers of individuals are more likely to occur in May than in October. The larger numbers represent smelt, pelagic fish that move in and out of the Marina, and thus greatly influence the total numbers by their movements. The numbers of species caught by gill net has been reduced in surveys since May 1988 and the numbers of ichthyoplankton have been reduced following the October 1988 survey. These might be related to the PCBs spillage or drainage that occurred into the Marina sometime after the sediment chemistry survey of October 1988.

I. INTRODUCTION

HISTORICAL BACKGROUND

Marina del Rey, California is the largest manmade small craft harbor in the world, constructed on degraded wetlands of the former Ballona Creek Estuary in 1960-1962. Ballona wetlands historically extended inland through the Venice area to the north, to the San Diego Freeway area on the east, northeast toward downtown Los Angeles and southeast around Westchester bluffs and the Palos Verdes Peninsula, to join the wetlands of the Los Angeles River. At times when the Los Angeles River changed course, it exited at Ballona Lagoon (Bancroft, 1884; Beecher, 1915).

La Ballona area was several times seriously considered as the site for the Port Los Angeles but was finally rejected in favor of improving Los Angeles Harbor, in part because Ballona was poorly protected from prevailing wind and wave patterns.

In the 1920s and 1930s the rivers and creeks of the Los Angeles basin were channelized and lined with concrete in efforts to control the massive flooding and destruction that occurred during major winter storms. Thus Ballona Creek became part of the Los Angeles County Flood Control system.

When the Marina was constructed, large areas of the Ballona Creek wetlands had already been drained, cut off from tidal inundation, and filled to create farm lands, gas fields, salt pannes and informal trash disposal landfills (Figure 1). Public health control of mosquitoes and black flies was also an objective for draining "useless swamps".

Channeling Ballona Creek cut off access, except through tide gates, to Ballona Lagoon on the north, which had been the major drainage channel of the wetlands and source to the Venice Canals, as well as Del Rey Lagoon and the remaining wetlands on the south side. These lagoons lay inland of

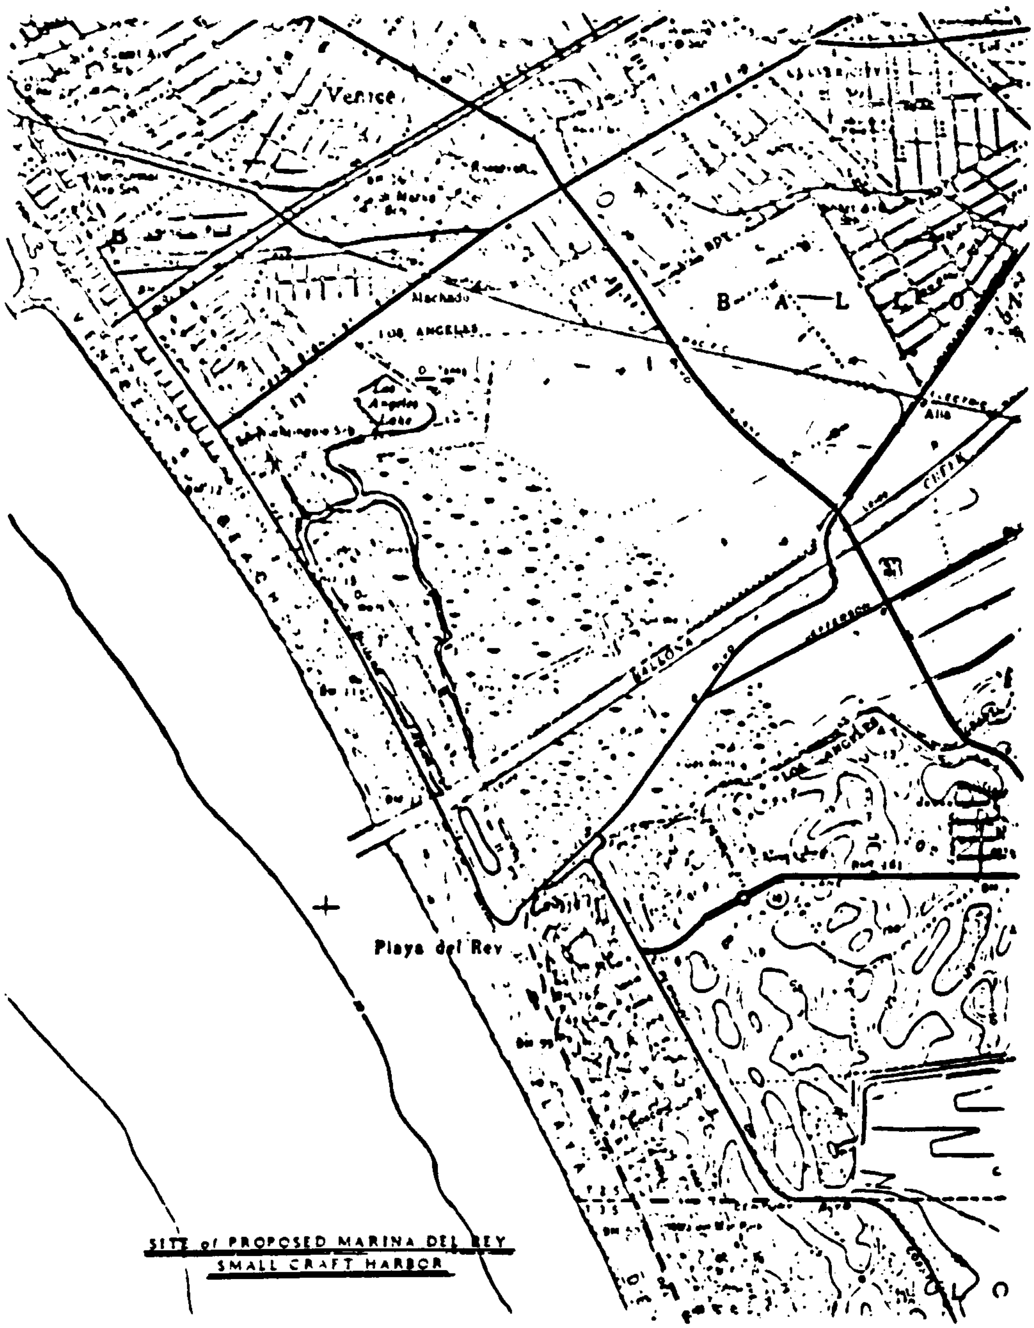

Figure 1. Ballona wetlands area prior to construction of Marina del Rey circa 1960.

the historic barrier beach. Design of the Marina placed the drainage pond known as Lake Los Angeles at the end of Basin D, now Marina Beach. The history of the wetlands and construction of the Marina were discussed and illustrated with photographs in detail in Soule and Oguri, 1990.

ENVIRONMENTAL STUDIES

No environmental inventories were undertaken before or after construction of the Marina and of the breakwater. In July 1976 through June 1979, baseline surveys were undertaken by the University of Southern California Harbors Environmental Projects under funding from the Sea Grant Program and the Los Angeles County Department of Small Craft Harbors (now the Department of Beaches and Harbors). An extensive program of physical, chemical and biological sampling at 13 stations (Soule and Oguri, 1980) provided a detailed picture of the Marina, not only as a recreational site but as a natural resource providing habitat in a region depleted of protected shallow water environments.

Limited surveys were resumed in 1984 in the spring and fall periods, with sampling that included monthly water quality measurements of water quality, biannual surveys of benthic organisms, fish and annually of sediment contaminants. Surveys were then reduced to one period a year, October, November and December (Soule and Oguri, 1985, 1986, 1987, 1988).

In 1988, year round monthly water quality surveys were resumed and four more stations were added (Soule and Oguri, 1990). Special studies have also been undertaken of the effects of tributyltin, bioassays of contaminated Marina bottom sediments, the incidence of coliform-enterococcus pollution, and the DDT and PCB body burdens of fish caught in the Marina as they might affect public health and fish reproduction. In 1989, one more station was added at the site for a potential entrance to a new marina basin. Figure 2 illustrates the western Los Angeles area where Marina del Rey is located, and Figure 3 gives the water quality station pattern in the Marina. Station descriptions are as follows:

STATION LOCATIONS AND DESCRIPTIONS

MDR-1. Located midway between the breakwater at the east entrance to the Marina and the beach, at the mouth of Ballona Creek Flood Control Channel. The area is subjected to discharges from the creek, to severe impacts from storm water flow and to deposition or erosion from storm wave action. Depth irregular, 2-6 meters.

MDR-2. At the entrance of the Marina, midway between the two Marina jetties. The area is protected from most storm waves but subject to weak coastal currents. Sands have been deposited from storms and blown from the adjacent beach resulting in severe, irregular deposition. Heavy flow in Ballona Creek flood control channel also carries sediment and debris into the mouth of the Marina. Dredging was undertaken in February 1987 to reestablish the channel. Depths 4-6 meters.

MDR-3. On the north (west) side of the entrance channel, in front of the tide gates to Ballona Lagoon and the Venice Canal system. Protected from all but severe storm waves, the site is subjected to discharge of waters from the canal system. Shell mounds present during the 1976-1979 surveys disappeared, replaced first with fine sediment and then sand. Depths 3-6 meters.

MDR-4. Seaward of the Administration/ Coast Guard dock on the south (east) side of the entrance channel at junction with main channel. Subject to heavy boat use. Protected from most surge, the area was heavily damaged by 1983 storms and docks were rebuilt in 1985. Depths 3-6 meters.

MDR-25 Between the Administration - Life Guard docks and the public fishing dock.

MDR-5. In the center of the Main Channel, subject to heavy boat traffic. Depth 3-6 meters.

MDR-6. At the innermost end of Basin B; protected from westerly winds by seawall, circulation reduced. Depth 3-5 meters.

MDR-7. At the end of Basin H near the work yard dock. Large storm drain present; exposed to afternoon westerly winds. Depth 3-4 meters.

MDR-8. Off the swimming beach in Basin D near first slips. Exposed to afternoon winds. Depth 3-4 meters.

MDR-9.	At the innermost end of Basin F. Large storm drain present; protected by slips and sea wall. Depth 2-4 meters.
MDR-10.	Innermost end of Basin E; subject to daily flushing from the Oxford Flood Control Basin through tide gates and to storm water runoff. Depth 3-4 meters.
MDR-11.	At end of Main Channel; subjected to storm drain flow and to influx from Station 10; impacted by reduced flushing due to increased slip capacity. Depth 3-5 meters.
MDR-12.	Ballona Creek, sampled from beneath the Pacific Avenue foot bridge. Subject to tidal flushing and continuing freshwater discharge into the flood control channel; also subjected to illegal dumping of trash upstream and to sewage overflow. Depths 1-4 meters.
MDR-13.	Inside tide gates of Oxford Flood Control Basin; subject to minimal daily tidal flushing, storm water runoff and drainage, surface only. Inaccessible at times.
MDR-18.	Twenty meters off wheelchair ramp in basin D perimeter of swimming area. Depths 1-3 meters
MDR-19.	At end of wheel chair ramp, surface only.
MDR-20.	At innermost end of Basin E where Oxford Basin flow enters Marina. Depths 1-4 meters; flow partially obstructed by large vessel docked there.
MDR-22.	Inner end of Oxford Basin at Washington Blvd. culvert, surface only.

Depths vary according to a number of factors including tidal stage, irregularities in the substrate due to storm deposition or erosion of sand, runoff, tide gate flow, and propeller wash.

SANTA MONICA BAY RESTORATION

Concern for water quality in Santa Monica Bay, and federal funding for restoration of the Bay, are focused heavily on controlling pollution from non-point sources, to which Ballona Creek contributes heavily. Documentation of conditions in the Marina, as they are influenced by the Ballona Creek and the Oxford Flood Control Basin, provides a major contribution to understanding the impacts of urban drainage on shallow coastal waters.

II. PHYSICAL WATER QUALITY CHARACTERISTICS

INTRODUCTION

Physical factors affecting water quality and the biota of the Marina that are measured monthly include temperature, salinity, dissolved oxygen, hydrogen ion concentration (pH), and light transmittance; water turbidity and color, tide, wind and weather are also recorded. The 1989-1990 period was the second year since the 1970s studies by USC that the full year was monitored monthly rather than a seasonal segment.

Biochemical Oxygen Demand is determined from water samples taken along with nutrient and coliform samples. BOD_5 is an indicator of the presence of natural and manmade substances in the water column which are oxidized by microbial action when they are released into the water column, a process that removes dissolved oxygen from the water, potentially depriving the biota of adequate oxygen supplies.

METHODS

Monthly measurements of temperature, salinity, dissolved oxygen and pH are made using a Martek remote probe, and light transmittance is measured with a transmissometer having a self contained light path. Observations of light penetration are made with a Secchi disk and color is determined by the Forel-Ule (FU) scale. Biochemical Oxygen Demand is determined according to Standard Methods (APHA, 1985), modified for sea water, by dilution of samples and incubation in air tight bottles for five days at 20°C. Complete physical water quality data are recorded in Appendix B.

TEMPERATURE

The most extensive comparative temperature data base in the Marina is for the months of October, November and December. As shown in Figure 4, the 1989 October surface to 2 m temperatures were cooler at the Ballona

Creek and Entrance stations and at the inner Marina stations than in any year measured except 1986. The El Niño event of 1982-83 extended into October of 1984 in southern California, making temperatures higher than usual. The temperature range was wider in the 1980s than in the 1970s, from 18.1°C to 21.5°C, as shown in Figure 5.

The November 1989 surface to 2 m temperatures were lower than in the rest of the 1980s surveys (Figure 6) and also lower than in the 1970s surveys (Figure 7). Comparison shows that 1985 and 1976 were the warmest of the Novembers surveyed. In spite of the cool water in October and November 1989, the warmer water in the inner Marina in September 1989 (Soule and Oguri, 1990) gave the autumn 1989 period a wider range in temperatures, from 15.4 to 23.4°C, than in the previous year, with the warmest value 2.0°C higher (Table 1, below). September 1990 was even warmer.

Table 1. Temperature Ranges ($^{\circ}$C) by Season and Year in Marina del Rey*

	Spring Mar, Apr, May	Summer Jun, Jul, Aug	Autumn Sep, Oct, Nov	Winter Dec, Jan, Feb
1976		20.3-23.0	19.2-20.9	16.0-18.3
1977	15.7-18.3	19.8-22.0	16.1-19.7	15.0-15.9
1978	17.1-20.7	18.9-22.6	18.2-19.7	12.8-14.1
1979	16.4-18.4	19.3-20.9		
1984	17.7-20.2[1]	19.4-23.3[2]	16.8-25.5	
1985			18.0-21.8[2]	12.4-14.3[1]
1986			16.5-20.8[2]	14.5-16.5[1]
1987			17.2-21.4[2]	15.3-16.6[1]
1988			15.9-21.4[2]	11.2-14.3
1989	14.1-22.9	15.6-24.0	15.4-23.4	11.8-16.2
1990	14.0-20.8	17.4-25.3	16.6-23.6[1]	

[1] = one month only
[2] = two months only
* = excluding Station 22, inner Oxford Basin

December 1989 surface to 2 m temperatures were intermediate in comparison with other 1980s temperatures (Figure 8), being more similar to 1986 and 1987 than to the colder years of 1985 and 1988. Figure 9 illustrates temperature differences, with 1976 being much warmer than 1978 in December.

Temperature ranges in winter months (December 1989, January and February 1990) were warmer than in the comparable period the previous year (Table 1); the low was 0.6°C higher and the high was 1.9°C higher. While this was referred to as another El Niño in the press, it did not continue into the spring period, where the range was about 2.0°C lower. However, the summer months were also warmer in 1990 than 1989, with the highest temperature, 25.3°C, of those recorded in the USC monitoring studies. For comparative purposes, data from Station 22, at the innermost end of Oxford Basin is excluded, since it was not monitored before 1989 and is relatively isolated from the rest of the Marina.

The temperatures at 0-2 m and bottom for each monthly survey are illustrated in Figures 10 to 21. In general, waters are well mixed with little evidence of a thermocline through the winter months. Beginning in March, a small thermocline existed in the Entrance and Main Channel which became more pronounced during the summer months, culminating in the widest range in September.

There was evidence of upwelling in August, when Station 1 showed an unusually low temperature and high salinity at the bottom of 17.4°C (Figure 17).

The minimum, average and maximum temperatures without regard to depth are shown in Figure 22. This also illustrates the more uniform conditions

VOL 12

1 9/1/6

in the winter and early spring and the wider ranges in July, August and September.

SALINITY

Salinity varies in the Marina according to the water masses entering Santa Monica Bay from the north or south, and according to the rainfall or dry weather flow into the flood control systems. Since measurements on a given day are taken over about three to four hours in the morning, tide phase also affects salinity by determining the influx of bay waters and mixing with Ballona Creek freshwater. The flow from Oxford Basin is of a lesser volume and thus may have less effect on salinity over a large area.

In 1990, most of the surveys were conducted during falling tides or near high tide followed by falling tide, in contrast to 1989 when most surveys were conducted on rising tides (Soule and Oguri, 1990). The exact time at which a station was occupied and the time of high tide are given in Appendix A, Cruise Logs, and Appendix B, Physical Water Quality Data.

Table 2 presents the low and high salinity values for each monitoring period and the stations showing the extremes, along with the tide phase. It can be seen that Stations 12 in Ballona Creek and Station 22 in Oxford Basin were generally the sources of low salinity water. There is apparently only a small surface intrusion of low salinity water into the Entrance Channel under dry weather flows in Ballona Creek, as is also evidenced by the floating trash that originates from the Creek and collects in the Entrance Channel. Bay waters mix with Creek waters at Station 1, with higher salinity water entering as a wedge on the bottom of Ballona Creek and the Marina. Complete salinity data are given in Appendix B.

The inner basins such as Stations 7 and 9 (Table 2) sometimes have the highest salinities, probably representing the residence time of water there and the evaporation due to insolation. Where the higher salinities occurred in the outer Entrance Channel they were in bottom waters but were generally mixed in the inner Entrance Channel and Main Channel, as is seen in January, February, April and June 1990. When highest salinities are in the Main Channel, coupled with the basins, it may represent mixing with basin waters or incursion of bay waters farther into the Marina, depending on tide stage and runoff.

Table 2. Salinity Ranges in Parts per Thousand (ppth) in Monthly Surveys, October 1989-September 1990

Month	Low	Station	High	Station	Tide Phase
October	24.7	12	32.1	3	rising
November	27.0	22	32.3	7	high, falling
December	16.4	12	32.0	7	falling
January	31.2	22	32.6	1,2,3,4,25	falling
February	30.7	12	32.6	1,2,3	falling
March	31.2	12	32.6	3,4,5,6,9	falling
April*	4.6	22	32.2	1,2	falling
	9.3	13			
	24.4	12			
May	29.6	12	31.5	2,3,5,7,9	low, rising
June	30.6	22	32.3	1,2	falling
July	28.1	12	32.0	7	rising
August	32.0	1	33.0	1,7,8	high, falling
September	31.9	22	32.5	2	high, falling

* one day after rainfall

Salinities in April at Station 12 in Ballona Creek and Stations 13 and 22 in Oxford Basin reflected runoff after about 0.5 inches of rain in the Los Angeles Basin the previous day, with a halocline at most stations. High tide had been about two hours prior to the start of monitoring at Station 12. Lowest Marina salinities were on the surface at Stations 1 through 5, probably reflecting the earlier incursion of Ballona Creek runoff waters during the rising tide, and at Stations 7, 9 and 11, where

VOL 12

1/9/18

storm drains enter the Marina. At the same time, the highest salinities were at the bottom at Stations 1 and 2.

In August, on a falling tide, salinities at Station 12 were higher than at the surface of Station 1, but bottom water at Station 1 was unusually cold and of high salinity, which suggests upwelling in Santa Monica Bay.

Figure 23 illustrates the maximum, minimum, and average salinities for the entire Marina during each monthly survey. The maxima did not vary greatly, but the minima varied considerably. The minimum in December was most influenced by Station 12, and represented a large freshwater flow in Ballona Creek during dry weather from an unknown source. The April minimum was in Oxford Basin and followed the day after a 0.5 inch rainfall.

DISSOLVED OXYGEN

Dissolved oxygen (DO) along the open coast usually ranges from 6.0 ppm to 8.5 ppm, depending on whether waters have become supersaturated due to turbulence or to phytoplankton blooms. Regulatory agencies state that 5 pp. is the minimum level of DO for survival of fish species, although invertebrates may exist on very low levels of DO, and some species have alternative anaerobic metabolic pathways for survival (without oxygen).

Waters in the Marina in 1989-1990 had DO values ranging from 12 ppm down to 1.6 ppm. Saturation varies according to salinity and temperature, decreasing as temperature increases. The tendency of Marina waters to show a thermocline during the summer months, restricting mixing, and the elevated temperatures in the basins lead to depleted oxygen levels at times in bottom waters. Also, when phytoplankton (single celled plant) blooms are expanding, DO increases rapidly due to photosynthesis.

Depletion of DO can occur at night when a large bloom continues to take up oxygen during respiration while photosynthesis cannot continue in the absence of light. When the bloom dies off, bacterial degradation exerts a large oxygen demand. Organic detritus and inorganic chemicals, including ammonia, originating in the Marina or carried into it may also exert a significant oxygen demand, discussed under Biochemical Oxygen Demand.

Comparison of the October - December periods in the 1980s for which the largest data base exists indicate that at the 0-2 m depth DO was higher in October than in any year since 1984, except at Stations 12 and 1; bottom water DO averages were also high except at Station 12 (Figures 24 and 25). These profiles are more similar to those of the 1977 period than to other years monitored (Figures 26 and 27). The 1976 and 1978 DO profiles were lower in general in both surface and bottom waters.

There was a distinct shift in November 1989, with the DO at both the average 0-2 m and the bottom being distinctly lower than the other years in the 1980s, with few exceptions (Figures 28 and 29). The DO levels were more similar to the 1976 and 1978 levels (Figures 30 and 31), which were years with much more rainfall than in 1989.

In December 1989, DOs were high in the Entrance Channel and outer Main Channel, but were below 5.0 ppm in the inner Main Channel and the basins in both surface and bottom waters, making the averages at surface and bottom lower than those in other years in the 1980s (Figures 32 and 33). These values were not as low as those in December 1976 and 1978 (Figures 34 and 35). In the latter year there was more than 2.4 inches of rain in December, no doubt creating a high Biochemical Oxygen Demand on Marina waters.

In Figures 36 to 47, plots of surface and bottom DO at each station by month in 1989-1990 are shown. The highest DO values were usually at Stations 1, 2 or 3, decreasing toward the innermost stations. Disregarding the Oxford Basin Stations 13 and 22, outside the Marina, there were a number of low DO episodes during 1989-1990, primarily in the inner basins. These occurred in November and December 1989, and during May through September. The effect on the shallow area in Basin D during the summer may make the area unacceptable for the fish that commonly inhabit the sea grasses there, causing them to move out of the marina into deeper water, a normal phenomenon in shallow coastal waters. As the thermocline became more pronounced in July, lower DOs occurred in the outer Marina but values did not fall below 5 ppm.

RAINFALL EFFECTS

A modest rainstorm of about 0.5 inches in the Los Angeles Basin the day before monitoring in April 1990 illustrates the effects on DO values; Stations 1 had a DO maximum at the bottom of 10.5 ppm with high salinities, probably reflecting ocean storm turbulence. BODs were very high at Stations 1 through 5, reflecting Ballona Creek runoff. There were DO values between 4.0 and 5.0 ppm layered at the surface and/or on the bottom with higher values between at Stations 5, 25, 9, 10, and 11, and low values in the mid-water column at Stations 7 and 8. BODs at those stations were not high, mostly below 2.0 mg/l, indicating that the oxygen demand from runoff had already been exerted.

Waters in Oxford Basin had DOs below 2 ppm and very high BODs of 15 mg/l (= ppm) or above, at Stations 13 and 22. While Oxford Basin receives waters from a smaller drainage area than Ballona Creek, it empties into such a small area, which normally has low flushing, that it may exert a disproportionate influence on the Marina. Ballona Creek waters are mixed

VOL 12

1 9/2/1

near the mouth and in the bay, but BODs ranged up to 12.0 ppm at Stations 1 through 4, without, however, depleting the DO because of the high levels due to ocean turbulence.

BIOCHEMICAL OXYGEN DEMAND

The interaction between dissolved oxygen (DO) and Biochemical Oxygen Demand during a rainfall runoff event was discussed above. The lowest BODs are usually below 1.0 ppm in the Marina, and these occur most often in areas of low runoff, such as Station 6, and Station 18. Station 11 also has low BODs at times, possibly for a different reason that may be related to toxicity of sediments and the very low benthic productivity there.

In general, BODs were below 2.0 ppm in the winter and above 2.0 ppm in summer, probably reflecting water temperature, and in the absence of the usual winter rainstorms in 1989-1990.

Maximum BODs ranged from 1.4 ppm in January to 15.5 ppm in April, and minimum values ranged from 0.3 ppm to 1.0 ppm. The monthly profiles are illustrated in Figures 48 to 59, and the data are presented in Appendix B.

In October 1989 through April 1990 there were few values above 2.0 ppm, at Stations 5, 7, and 9. In November, other than a maximum of 10.2 ppm in Oxford Basin, most stations were below 2.0 ppm. The December high of 2.4 ppm was in Ballona Creek, with most values below 1.0 ppm. The January high was also in Ballona Creek, at 1.4 ppm.

The February profile (Figure 52) showed a relatively large peak of 4.9 ppm at Station 3, the entrance to Ballona Lagoon, and may reflect activities associated with construction in the Lagoon. March (Figure 53) may have reflected earlier rainfall in mid-February or some other event in having a peak of 10.1 ppm in Ballona Creek and 9 ppm at Station 2, no doubt associated with Ballona Creek. The April rain event discussed above

VOL 12 1922

deviated strongly from the pattern of relatively low BODs.

May and June 1990 showed evidence of BOD originating in Ballona Creek or Oxford Basin, which may have been associated with earlier rainfall in April and May, or with dry weather flow. There were a number of stations with values above 2.0 ppm, but the maximum values were only 4.1 and 5.3 respectively. July's peak of 6.2 ppm was in Oxford Basin, as was the August peak of 4.9 ppm. The September peak of 5.1 ppm was at Station 19, at the wheel chair ramp, suggesting a human associated origin, as indicated by the high enterococcus value there at that time (see Microbiology section).

HYDROGEN ION (pH) CONCENTRATION

The pH of the open ocean generally ranges from 7.5 to 8.4 (Sverdrup et al., 1946). The range in the Marina in 1989-1990 was from 7.0 to 8.4, but all the low values occurred in Oxford Basin, except in July 1990 when the low of 7.9 occurred at the bottom in Station 10, concurrent with a low DO of 3.5 ppm. and a BOD of 4.8 ppm. A similar possible coupling of low pH, DO and elevated BOD occurred in June and September, both in Oxford Basin. This was not always the case, however.

Higher pH values can result from significant phytoplankton photosynthesis, resulting in uptake of carbon dioxide and a shift in the carbonata equilibrium. This activity may serve to buffer some of the lower pH potential due to chemicals introduced into Marina waters in runoff.

As illustrated in Figure 60, the maximum values and the average values for the entire Marina by month do not vary greatly but the minimum value do. In each case in this profile the lowest values in December and April reflect the effect of Stations 13 and 22 in Oxford Basin.

None of the pH levels were low enough to be harmful to organisms, but they could influence the very complex chemistry that determines the availability of toxic metals that are sorbed on particulates.

FOREL-UHL (FU) COLOR SCALE

Water color is an indicator of physical, chemical and biological factors such as depth, substrate, tide phase, turbulence, suspended particulates, bacteria and phytoplankton. Color is measured in the Forel-Uhl scale, which consists of a series of small, numbered glass vials filled with marine colors or shades which are compared to the seawater viewed above a white Secchi disk suspended at the surface. Numbers range from 1 to 3, deep sea blue; 4 to 5 are blue green, 5 to 11 are progressively darker greens; 12 to 15 are greenish browns, and 16 to 22 are progressively darker browns.

Colors of 3 to 5 rarely occur in the Marina; one 5 was observed at Station 1 in October 1989. The greens ranging from 6 to 9 usually occur in the Entrance Channel and the rest of the Marina stations usually range up to 14.

In 1989-1990, the minimum range was from about 5 to 10 (Figure 61), and the average was from about 9 to more than 13. The maxima were correspondingly higher, with a range from about 12 to 19, the latter value occurring after the rain in April 1990. Even excluding the April peak, the waters were more greenish to brown than in 1988-1989 when the peak was 15 at Station 9 in July 1989.

LIGHT TRANSMITTANCE

Water transparency is determined in two ways; one is by the self-contained light path in the transmissometer and the other is by visual observation of a white Secchi disk lowered in the water column, in the shade of the vessel if possible, to the depth in meters of disappearance.

VOL 12 1924

The latter method is traditional but can vary greatly according to the observer so that it is best if the same person always performs this.

The two methods produced somewhat different profiles of the maxima, minima and average values in the Marina in 1989-1990. While the lowest values obtained by transmissometer (Figure 62) and Secchi disk (Figure 63) were in April after the rain and in May, the curves for the minima and maxima were quite different, One might expect light transmittance to be inversely related to the color values, but that was the case only in a few instances. In October, the maximum Secchi disk value was related to the minimum FU color value of 5, and on 5 April 1990 the minimum transparency by both methods was related to the maximum color of 19 in Ballona Creek due to turbidity associated with rainfall runoff. Otherwise color and turbidity were not necessarily well related.

CONCLUSIONS

The wide range of temperatures in 1989-1990, with a cool fall, warm December and January and cold March, was followed by a very warm summer. This, coupled with very low seasonal rainfall which did not flush the Marina but served only to carry organic matter and trash into it, probably led to the more extensive low oxygen episodes (below 5.0 ppm) than seen in the recent past. There were no zero oxygen levels recorded, however; the lowest DO in the Marina proper was a 1.6 ppm at Station 8 in June. High temperatures and reduced oxygen levels probably cause fish to leave the inner Marina for deeper, cooler waters, but would probably not affect benthic fauna. Zero DOs would change the bottom sediment chemistry, and produce hydrogen sulfide, which is toxic.

III. NUTRIENTS

SOURCES AND FATES

Marine microscopic plants, the phytoplankton, are the most abundant form of plants in many aquatic systems. These planktonic plants depend on a supply of inorganic nutrients and energy from sunlight for growth. The major inorganic nutrients include nitrogen (usually in the form of nitrate, nitrite or ammonia), phosphate, silicate (for diatoms which have a silicon shell or frustule), and carbon from carbon dioxide. Trace metals are also necessary, but normally in much smaller quantities.

In the oceanic environment, nitrogen is often the nutrient that is in least supply and therefore most likely to regulate the growth of the phytoplankton, but in bays and estuaries the rate of supply of nutrients is less likely to limit phytoplankton growth due to input from terrestrial and/or anthropogenic sources. Often the phytoplankton in bays and estuaries are more likely to be limited by the light availability that is strongly affected by the turbidity in the water column (Kirk, 1983).

Within the ocean the nutrient supply primarily derives from natural processes of recycling. The organic nitrogen found in plants and animals is recycled by animals and microorganisms which break down the organic matter generated by the phytoplankton, releasing nitrogenous compounds. Ammonia nitrogen may be taken up directly by the plants to synthesize new organic matter or it may be oxidized first to nitrite, then to the more stable form of nitrate. Plants may take up nitrogen in any of these forms, but ammonia is often more readily taken up than the oxidized forms of nitrogen because it can be directly incorporated into amino acids.

Organic phosphate, which is used for energy transfer, for proteins, and for nucleic acids, is rapidly cycled within the water column since the form in which it occurs most frequently within organisms, ortho-phosphate, is also the form that is most abundant in seawater. Dissolved ortho-silicate comes from both recycling and river input.

METHODS

Water samples were obtained at all stations with a Naumann sampler, a PVC self-closing sampler, at two meter intervals beginning at the surface. One subsample was immediately acidified in the field with concentrated hydrochloric acid and held for later laboratory analysis with an Orion ammonia electrode. A second sample was immediately frozen in dry ice for later analysis in the laboratory. This sample was thawed and analyzed for silicate, phosphate, nitrate, and nitrite on an AlpKem RFA-300 automated analytical chemistry instrument using methods described by Whitledge et al. (1981). Complete nutrient data are presented in Appendix C.

AMMONIA-NITROGEN

Ammonia nitrogen is formed by the breakdown of organic material and recycled into inorganic nitrogen. In most ocean waters, it occurs at very low concentrations of less than 1 *ug-at/l* (1 *ug-at/l* = 17 *ug/l*). In southern California, higher concentrations (up to 25-30 *ug-at/l* may be observed. These high concentrations are usually due to anthropogenic sources such as ocean outfalls, (e.g. Eppley et al., 1979; Jones et al., 1990) and therefore are often indicative of sources of pollutants. When ammonia nitrogen is present, it is the most energetically effective form of nitrogen for the phytoplankton to use.

The ammonia-nitrogen concentrations within the Marina are generally higher than the concentrations observed in Santa Monica Bay and the adjacent ocean waters, except near the Hyperion and Whites Point sewage outfalls. Minimum concentrations within the Marina during October 1989 to September 1990 were 2-3 *ug-at/l* and occurred within the Main channel and at the breakwater (Station 2). The distribution patterns that are observed in ammonia concentration are similar to the patterns observed in the bacteriological samples (see Microbiology section).

The general spatial pattern is that the highest concentrations are observed within the Oxford Basin (Stations 13 and 22) and in Ballona Creek (Station 12). Ammonia concentrations were high within Oxford Basin in every sampling period, and had the highest ammonia concentrations except in October 1989 and August 1990. The ammonia concentrations within Ballona Creek were usually higher than within the Marina during the period of October through April, except in March 1990. The other areas that tended to have higher concentrations were the stations located at the end of the basins where tidal exchange is at a minimum (Stations 6, 7, 8, 9, 10, 11, 18, 19 and 20). There was not a clear relationship between the ammonia concentration at these stations and the concentrations within the Oxford Basin or Ballona Creek.

Ammonia concentrations were generally lowest within the Entrance Channel and the outer Main Channel (Stations 1, 2, 3, 4, 5, and 25). Presumably, these are regions where tidal flushing is most effective. It also suggests that there may not be a large exchange between the Ballona Creek outflow and the Marina inflow. However, this may be dependent on the tidal phase because Ballona Creek must be sampled near high tide due to the shallow water depth at Station 12. Observations suggest that material may be carried outside the breakwater on a falling tide and carried into the marina on the next rising tide.

Monthly profiles are shown in Figures 64 to 75, at the end of this section. During the October 1989 - September 1990 sampling period there were two periods when the average concentration of ammonia was relatively high within the Marina, excluding the samples from Oxford Basin and Ballona Creek (Table 3).

* Excluding Oxford Basin and Ballona Creek: Sta 12, 13, 22.

The first period was during the late fall and winter of October 1989 through January 1990 (Figure 76). The second period of higher average ammonia concentrations occurred during the summer, June - August 1990. This contrasts with the observations from the previous twelve month period

(Soule and Oguri, 1990), when concentrations were relatively low during the summer period except after the 4 July 1990 weekend. The cause of the elevated concentrations during summer is unknown but might have resulted from increased recreational use of the Marina. Freshwater inflow resulting from rainfall, which would increase the concentrations, was at a minimum and high summer water temperatures would result in potentially higher phytoplankton growth rates and higher ammonia oxidation rates, which would normally minimize ammonia concentrations during the summer period.

Maximum concentrations occurred in November 1989, and in April, July and August 1990. The November, April and July maxima occurred in Oxford Basin. The August maximum was observed at Station 11 at the northern end of the main channel. Two of these maxima, in April (99.3 *ug-at/l*) and July (74.3 *ug-at/l*), exceeded the maximum of 61 *ug-at/l* observed in the previous year. These two maxima also exceed all other maximum concentrations within the USC data set from 1984-1990. The April maximum was probably due to a significant freshwater inflow resulting from approximately 0.5 inchs of rain on April 4, the day preceding the sampling. The seasonal rainfall was low and therefore a single rainfall event would carry high nutrient concentrations from the storm drains and runoff.

In comparison to previous years (1984-1988), the October 1989 ammonia concentrations were on average the lowest observed and also showed the least amount of variability between the sampling sites. The November observations were similar to those of previous years, except for much higher ammonia concentrations observed in Oxford Basin in 1989. For December the ammonia concentrations were comparable to those observed in December 1988 and higher than the concentrations observed during the three

VOL 12

1955

years preceding 1988.

NITRATE PLUS NITRITE-NITROGEN

Nitrate (NO_3) is usually the most abundant form of inorganic nitrogen in the ocean. Most of the NO_3 in the ocean is found below the upper layer, where it is present at concentrations up to more than 40 *ug-at/l*. In the San Pedro-Santa Monica Basin, NO_3 concentrations reach 35 *ug-at/l* at depths of 600 m (Williams, 1986). Surface concentrations are often much less than 1 *ug-at/l* due to the uptake by phytoplankton and a limited supply rate from below. However, surface concentrations may reach values of 5-30 *ug-at/l* in coastal upwelling regions such as occur along much of the California coast. Coastal upwelling is not a dominant process within Santa Monica Bay but occurs predictably off Point Dume and Point Fermin when winds are favorable for upwelling. Within Santa Monica Bay, concentrations may be 10-20 *ug-at/l* at 20 meters depth and can be brought to the surface either by wind induced mixing or by localized upwelling. The concentration of nitrate plus nitrite in sewage wastewater and sludge are two to three orders of magnitude less than the concentration of ammonia (Morel and Schiff, 1983). The impact of ocean outfall effluents on the coastal ocean nitrate plus nitrite concentrations is therefore much less than for ammonia (e.g. Jones et al., 1991, in press).

The measurement technique for nitrate requires that the nitrate first be converted to nitrite (NO_2) which is then measured colorimetrically (Whitledge et al., 1981). The NO_3 concentration is derived from this by correcting for the efficiency and of converting NO_3 to NO_2 and correcting for the ambient NO_2 concentration. Since NO_2 concentrations are generally much less than 1 *ug-at/l* the correction is generally not large. In the text that follows, nitrate will be used in place of nitrate plus nitrite for brevity.

The general spatial pattern is that the nitrate concentration is lowest at Station 2 at the breakwater and increases toward the inner Marina basin and into Ballona Creek (Figures 77-88). The low values at Station 2 (and sometimes Station 1) may reflect the influence of coastal Santa Monica Bay where the nitrate concentration is low except during mixing or coastal upwelling periods. When the average concentrations within the basin are less than 2 *ug-at/l*, as during May through September (Table 4), the nitrate

Sep-90	0.1	5	3.5	13	1.4	1.3

* Excluding Oxford Basin and Ballona Creek: Sta 12, 13, 22.

concentrations within the Entrance Channel and outer Main Channel (Stations 3, 4, 5, and 25) generally are less then 1 *ug-at/l*. Higher concentrations of nitrate are often observed at the end of the basins, similar to the patterns observed in ammonia.

The highest NO_3 concentrations usually occur in Oxford Basin and/or Ballona Creek. The highest concentrations in May, June and July 1990 occurred at Station 20 within the Marina next to Oxford Basin at the tide gate rather than in Oxford Basin or Ballona Creek. A large, live-aboard vessel is docked there, partially obstructing flow from Oxford Basin.

The highest seasonal average concentrations of nitrate occurred within the Marina during November, December, and January (Figure 89). A nitrate peak occurred again in April, as observed in the ammonia concentration. The April peak was probably due to the rainfall on April 4. The highest concentration observed during the year (exceeding 100 *ug-at/l*) occurred in Oxford Basin during the April sampling. This is far in excess of the natural concentrations observed outside of the Marina in Santa Monica Bay, or in most of the open ocean.

High winter concentrations could result from increased flow in the storm drains, washing down significant amounts of organic waste which are oxidized as they are transported. However, the winter rainfall during 1989-1990 was very low. The higher concentrations might also be affected by reduced phytoplankton growth and nutrient uptake rates resulting from lower temperatures and lower available light levels. The low NO_3 concentrations during May through September probably reflect the reduced inflow from storm drain sources and high phytoplankton productivity within the Marina resulting from increased light availability and possibly higher temperatures. The difference in uptake of NO_3 compared to that of ammonia,

VOL 12

1957

which is usually low in summer, may be due to the phytoplankton species that dominated during the unusually warm summer. During this period the concentrations in both Ballona Creek and the Oxford Basin also were much lower than they were during winter.

In comparison to the previous five years of observations, the concentrations during October 1989 were low, as they were in 1984 and 1987. The November 1989 observations are very similar to the observations from the preceding five years. Nitrate concentrations were generally low at Station 2 (<5*ug-at/l*) and increased toward 10 *ug-at/l* in the inner basins of the Marina. The Ballona Creek concentrations in November 1989 were very low (<2 *ug-at/l*) Creek during the previous five years when concentrations ranged from 5 to 24 *ug-at/l*. The December observations are very consistent with preceding five years of observations. Concentrations were high in Ballona Creek, low at Station 2 and increased toward the inner basins, and were high in Oxford Basin.

Nitrate concentrations were, on average, less than the ammonia concentrations observed for each sample period. The April observations are the notable exception to this when nitrate concentrations were mora than 10 *ug-at/l* within the main channel and ammonia concentrations were generally about 5 *ug-at/l*.

TOTAL DISSOLVED INORGANIC NITROGEN

Total dissolved inorganic nitrogen (DIN) is calculated as the sum of the measured concentrations of nitrate, nitrite and ammonium rather than measured directly. The concentration of DIN is important for water quality because it represents necessary nutrients for phytoplankton growth and productivity, and it is an indicator of the input into or regeneration of nitrogen in the Marina. The monthly profiles are shown in Figures 90-101.

The seasonal pattern of dissolved inorganic nitrogen is given in Table 5 and shown in Figure 102. Ammonium concentrations were high during the winter months of November through February, as were the concentrations of nitrate and ammonium. The DIN concentration also shows the April peak following the April 4 rainfall. During the summer period (May-September) the DIN concentrations were generally low, but reflected the increase from June to August observed in ammonia.

Table 5. Total Dissolved Inorganic Nitrogen, October 1989 to September 1990.

Month	Min.	Sta.	Max.	Sta.	Average	Average*

* Excluding Oxford Basin and Ballona Creek: Sta 12, 13, 22.

The range of DIN concentrations observed during October 1989 through September 1991 was similar to the concentration range observed during the previous year. The maximum concentration of DIN during this period was higher then the previous year, but not excessively so.

PHOSPHATE

Inorganic phosphate in the ocean of the Southern California Bight region ranges from more than 3.5 *ug-at/l* at depths of 800-900 meters in the basins to less than 0.5 *ug-at/l* in surface waters (Williams, 1986). As with the other nutrients local variations may be mediated by ocean outfalls, coastal upwelling and turbulent mixing processes. Unlike nitrate, phosphate is seldom depleted in the surface waters of the ocean and it is unlikely that phosphate limits the primary production of phytoplankton. Phosphates are readily used by the bacteria, as well as by phytoplankton. Phosphorous is important for proteins, nucleic acids and energy transfer within organisms.

The general pattern of phosphate distribution within Marina del Rey region (Figures 103-114) was similar to the patterns for nitrate and ammonium. High concentrations were always observed in Oxford Basin. Concentrations were relatively high at the surface at Station 12 in Ballona Creek during the fall and winter months (October-February, and again in April. The lowest concentrations within the study area usually occurred at Station 1 or 2, near the breakwater. Within the Marina phosphate concentrations were usually higher at the inner basin Stations (6, 7, 8, 9, 10, 18, 19, and 20) than in the Main Channel. The notable exception to this pattern occurred in April when, apart from Ballona Creek and Oxford Basin, the highest concentrations occurred in the Main Channel at Stations 3, 4, and 5.

Phosphate concentrations (Table 6) had the least amount of seasonal variability of the measured nutrients. The average concentrations within

VOL 12 1960

the basin (excluding Ballona Creek and Oxford Basin) ranged from 0.6 to 1.4 *ug-at/l* (Figure 115). This was much less than the relative range of the

Table 6. Phosphate-P, Ranges in Concentration October 1989 to September 1990.

average concentrations for either nitrate or silicate. Average phosphate concentrations were higher during winter (November 1989 - February 1990) than during summer (May - September 1990). The minimum average concentration occurred in March, and the maximum occurred in April, simultaneous with high average concentrations of nitrate and ammonia.

In comparison to the previous five years of observations, the October 1989 concentrations were lower than in any of the preceding years. The October 1989 observations were also the lowest overall concentrations observed within the October 1989 - September 1990 data set. The concentrations in November 1989 were comparable to the concentrations in previous years, and the December 1989 observations were low for the six year range.

SILICATE

Silicate concentrations in the ocean surrounding Los Angeles are often relatively low at the surface, ranging from nearly unmeasurable concentrations to several microgram-atoms per liter. In the deep basins, silicate concentrations may approach 100 *ug-at/l* at depths of 800-900 meters (Williams, 1986). Low silicate concentrations in the upper layer result primarily from uptake by diatoms when nitrate and phosphate are sufficient to promote their growth (e.g. Broecker and Peng, 1982). It is in the oceanic euphotic zone to find residual silicate concentrations of 2-5 *ug-at/l* after phytoplankton have reduced the available nitrogen to nanomolar (nanogram-atoms per liter) concentrations. Silicate concentrations are usually high in freshwater inflows into the coastal environment.

The spatial patterns for silicate (Figures 116-127) were similar to the general spatial patterns for the other nutrient variables. Concentrations were high in the Oxford Basin and at the surface at Station 12 in Ballona Creek. Silicate concentrations within the Marina were generally low at Station 2, near the breakwater, and increased toward the inner basins.

The average silicate concentrations within the Marina peaked in December 1989 and declined through April, despite the rainfall on April 4, the day preceding the April sampling (Table 7; Figure 128). The minimum

average silicate concentration, excluding Ballona Creek and Oxford Basin was 4.1 *ug-at/l*, comparable to the minimum average concentrations for ammonia. However, the maximum average (20.9 *ug-at/l*) was more than twice the maximum average for ammonia. Summer concentrations averaged between 11 and 17 *ug-at/l*, except for June. These high summertime concentrations paralleled the high ammonia concentrations most of the summer, but contrasted with low phosphate and nitrate concentrations. This difference may result from the phytoplankton species that dominated the community during the summer. The warm, stratified conditions that characterized the Marina during the summer are conducive to dinoflagellate blooms. Dinoflagellates do not require silicon and therefore, if they dominate the phytoplankton community, could deplete the available dissolved inorganic nitrogen and phosphorus with little depletion of the available silicate.

Silicate concentrations and distributions during October-December 1989 compare with observations from previous years. Both the general spatial patterns and the magnitude of concentrations are similar. The primary difference appears to occur in the December 1989 data set, particularly at Stations 10, 19 and 20. At these stations the SiO_4 concentrations (30-40 *ug-at/l*) were significantly higher than in the rest of the Marina and exceed concentrations at these stations in previous years.

CORRELATIONS WITH OTHER VARIABLES

In the ocean, the relationships of one nutrient with another and of nutrients with physical variables such as temperature and salinity are usually predictable. For example, nitrate concentrations usually increase linearly with decreasing temperature below some threshold value, particularly below the euphotic zone (e.g. Zentara and Kamykowski, 1977; in the local coastal ocean the threshold temperature is ~13°C). An important question in understanding the processes within the Marina is whether or not the nutrients can be correlated with other variables in a predictable way that would provide a better understanding of their fluctuations.

The relationship between nutrients and temperature in the Marina is not as clear as it is for coastal and open ocean situations. During October 1989 through September 1990 the average nitrate concentration within the Marina was below 2 *ug-at/l* when temperatures were warmer than 18°C. At temperatures cooler than 18°C the average nitrate concentrations varied from 1 to 10 *ug-at/l*), but not in a predictable pattern. The phosphate temperature/relationship was similar to the nitrate/temperature

VOL 12

1 9/64

relationship, except in August 1990 when an average phosphate concentration of more than 1 *ug-at/l* occurred at an average temperature above 23°C.

Ammonia and dissolved oxygen appear to be correlated. High average ammonia concentrations occurred at the lowest average oxygen concentrations and decreased as dissolved oxygen concentrations increased. Low oxygen/high ammonia conditions are consistent with water that has experienced significant breakdown of organic material. Bacterial oxidation of the organic matter would consume oxygen and release ammonia in the process of breaking down nitrogenous organic matter. Thus, in the months where the dissolved oxygen is low and the ammonia concentrations are high there has probably been a significant input of organic waste into the Marina or into the waters flowing into the Marina, such as in April when there was significant rainfall runoff and during normal winter months (November and December). A similar pattern is observed in the relationship between phosphate and dissolved oxygen, which is to be expected. However, the phosphate pattern was more scattered than the ammonia pattern. Correspondingly, the average phosphate concentrations are relatively well correlated with the average ammonia concentrations.

CONCLUSIONS

There are several generalizations that summarize the October 1989-September 1990 nutrient data in Marina del Rey. These conclusions are separated into the three categories of spatial patterns, seasonal patterns, and general relationships.

The spatial patterns of nutrient distribution within Marina del Rey tend to show similar patterns for each of the nutrients. The lowest concentrations are generally observed at Station 2 near the entrance of the

Marina. This probably reflects the mixing with Santa Monica Bay which often has low nutrient concentrations in the surface layer. Concentrations in the Main Channel may increase from the values observed at Station 2, but are usually lower than the concentrations observed within the inner basins. This gradient may result from the tidally induced mixing between the water of the inner basin stations and the low nutrient water from Santa Monica Bay. The inner basin stations generally have the highest nutrient concentrations within the Marina itself. However, the highest nutrient concentrations are nearly always observed in Oxford Basin and Ballona Creek.

The seasonal patterns show that the highest average concentrations occurred in the winter period of November 1989 to February 1990. These high concentrations may result from lower rates of phytoplankton growth due to cooler temperatures and lower integrated light available for photosynthesis. The rainfall event on April 4, one day prior to the April sampling, demonstrates the impact of rainfall on nutrient concentrations. Each of the measured nutrients showed a maximum on April 5. This maximum in nutrient concentrations no doubt resulted from the runoff from storm drains and the surrounding land. Summertime nutrient concentrations tended to be variable except for nitrate which was low throughout the summer.

Examination of the relationships between nutrient concentrations and other measured variables showed two distinct relationships. The monthly averages of ammonium and phosphate were negatively correlated with dissolved oxygen, consistent with the coupling of their variability with the oxidation of organic matter, and hence the input of organic matter into the Marina. This input can be from direct sources within the Marina, from runoff through Ballona Creek and Oxford Basin, and from rain-derived runoff as demonstrated in the April 1990 data set.

Nitrate variability appears to be coupled with temperature variability, which may simply be a seasonal phenomena. Nitrate concentrations are less than 2 *ug-at/l* during the summer months (May-September 1990) when Marina temperatures exceed $18^{\circ}C$.

Nutrient variability within the Marina is relatively uncoupled from nutrient variability within Santa Monica Bay. The concentrations of nutrients that are found within the Marina generally exceed the concentrations expected in the near-surface waters of the Bay. In addition, the nutrient/temperature (or nutrient/salinity) relationships that are observed within the Marina do not correspond with the typical patterns observed within Santa Monica Bay.

IV. SEDIMENT COMPOSITION AND CONTAMINATION

GRAIN SIZE

The sediment grain size of Marina del Rey was originally dictated by development of the Marina in a degraded wetlands, with the consequent perturbation of historic beach sands and the accumulation of eroded terrestrial sediments overlaying them. In low energy environments such as marinas, fine sediments are deposited as they drop out of the water column, whereas in high energy environments fines are carried out to sea to become suspended in turbidity currents and carried ultimately to other areas of low energy environment. Thus the Marina inner basins tend to be composed of much higher percentages of fine grained sediments than one would expect in the outer Marina, where flushing is greater.

There is an exception to this in the Marina, where the deposition of sand at Station 2, at the Entrance Channel, created a sand bar. This area was partially dredged in 1987, reducing the barrier but leaving sufficient deposition to cause the accumulation of contaminated, very fine grained sediments in the area, and greatly changing the character of the habitat.

The lack of heavy rainfall in the past few years has also reduced flushing; runoff from low rainfall or dry weather flow seems to have moved some of the finest sediments from the inner basins out as far as the Main Channel (e.g., Station 5) but has not carried them out of the Marina.

PROCEDURES

Grain size is a relative size determination made by sieving sediments through a series of screens with various mesh sizes. The greater the screen size number, the finer the sediments are that pass through it. Sediment samples for grain size determination were taken from Campbell grab samples that were used to determine benthic fauna and sediment chemistry.

Table 8. Percent Sediment Grain Size in Marina del Rey, 20 October 1988 (Particle size decreased with increasing mesh size)

RESULTS AND DISCUSSION

Results of grain size tests show that there have been a number of changes in the last year. Tables 8 and 9 show the grain size for October 1988 and October 1989 for comparison.

At Station 2, the buildup of the finest size particles (less than 200) has increased dramatically, rising from 38.7 percent to 70.86 percent in one year, while the medium sized particles (60) increased at adjacent Station 1 and fines decreased at Stations 1 and 3. This is, no doubt, the reason for the increase in contaminant burden at Station 2, because pollutants adsorb and complex more with finer particles, since they have a larger surface to volume ratio, than with large particles. The Station 2 area is due to be dredged in the fall of 1991.

At Station 4, which last year showed signs of having formed a depression which collected fines, the size has shifted to slightly larger particles from 79.96 percent particles of <200 to 32.3 percent 200 size.

There was little change at most of the inner stations; Station 6 sediments showed decreases in the larger particles (35 and 60 mesh) and in the finest size, with an increase in the 200 mesh size, as did sediments (25 and 35 mesh) at Station 7. At Stations 8 and 9, the already high percent of the finest sediments increased, and at Stations 10 and 11 there was little change from the already very high levels of the finest grained sediment.

Station 5 showed a slight shift downward in all sizes except for the finest, which increased slightly. That station seems to accumulate fine sediments and contaminants in the middle of the Main Channel when rainfall and dry weather flow is low into the inner basins.

Station 13, inside the Oxford Flood Control Basin, showed decreases in fine sediments and increases in the larger grain sizes. The reasons for

VOL 12 1996

this are not clear; the finest materials may have been tidally flushed away following erosion control efforts, but the water exchange is generally not of sufficient velocity to move the larger particles, resulting in sorting that was further influenced by low rainfall runoff.

SEDIMENT CONTAMINANTS

SOURCES

Contaminants attached to fine particulates enter the Marina from a number of sources: dry and wet weather drainage from parking lots and facilities in the Marina; the Ballona Creek Flood Control Channel; Ballona Lagoon, which enters the Marina at Station 3; and the Oxford Flood Control Basin, which drains an urban industrial and residential area into the end of Basin E. Ballona Lagoon is linked tidally to the Venice Canal system.

Ballona Creek drains much of the western and central Los Angeles area, bringing normal runoff but also carrying a burden of garden debris, trash, plastic food wrappings and grocery bags, all testifying to the amount of illegal dumping that occurs into the channel. A new screen boom in the channel, near Culver Blvd. traps trash during dry weather flow, but the boom is released prior to expected rainstorms, when the largest quantity of trash is brought downstream. In the past, overflows from Los Angeles City sewage processing sometimes overflowed into Ballona Creek, but measures to control that have apparently been successful. Oil and grease from streets, discarded motor oil and traffic accident spills are sometimes carried into the creek channel. High tides also sweep the jetties, carrying trash left by those who fish from the rocks, along with feces from humans and dogs, into the waters. Channel flow is partially reflected off the breakwater and is carried back into the Marina on incoming tides. Conversely, if Ballona Creek levels are low, it is possible for material originating in the Marina to move up the creek and be deposited as far inland as the sand bar near Culver Blvd, inland from Station 12.

STANDARDS

There are presently no Federal or State criteria or standards for sediment content of pollutants such as trace metals and pesticides but research has been directed toward developing them. Bulk analyses were not effective in determining impacts so bioassay determinations of sediment effects from a given site were substituted and compared with those from a so-called pristine site. Some factor was then applied such as 125 percent or two standard deviations, on a case by case basis, to determine whether sediments could be ocean dumped or had to be landfilled (EPA, 1988).

The problems of developing standards or criteria are complex, since data derived from different research laboratories, using differing protocols, organisms, exposure times and methods of dosing sediments have been difficult to integrate into a collation of reasonably predictive measurements. Recently the National Oceanic and Atmospheric Administration (NOAA) has issued a Technical Memorandum compiling nationwide information using several approaches: Comparison of background levels in pristine areas; sediment-water equilibrium partitioning; spiked-sediment bioassays (adding known amounts of chemicals to pristine sediment); and several methods of correlating field data for organisms with co-occurrences of contaminants in sediment (Long and Morgan, 1990). These data were then developed into: Ranges from threshold to the tenth percentile for Effects Range-Low (ER-L); an Effects Range-Median (ER-M); and an Apparent Effects Threshold (AET) to indicate sites with high potential of causing effects on biota. The National Research Council (NRC, 1989) also published a study on threshold values developed by EPA, the US Geological Survey and others.

According to Long and Morgan (1990), it has been assumed that water quality criteria were sufficient to protect infauna when applied to interstitial water of sediments. Physical/chemical principles are now used to predict chemical concentrations that would occur in interstitial water in equilibrium with concentrations sorbed on sediment particulates, recognizing that the distribution between the two phases is highly influenced by the amount of total organic carbon or acid volatile sulfides present. Past studies have indicated that the bulk analysis data for sediment concentrations are poor predictors of the bioavailability of those chemicals.

BIOAVAILABILITY

Most metals attached to marine sediments are not bioamplified by passage through the food chain to top consumers (Carpenter and Huggett, 1984; Jenkins and Brown, 1984; Peddicord, 1984). Bioaccumulation, the sequestering of metals and/or pesticides in certain body tissues, may or may not be detrimental to the organism itself. Of particular concern are those chemicals such as chlorinated hydrocarbons (pesticides and PCBs) that are sequestered as lipids (fats) in liver and reproductive organs or eggs, which can cause liver pathologies or reproductive failure in some species.

Synergism between certain metals species may suppress or enhance their toxicities. Marina sediment bioassay tests in 1987 (Soule and Oguri, 1988) indicated that there were no acute toxicities to representative test organisms, but there was evidence of long term stress from sediments at the most contaminated stations. At that time, Station 2 had been partially dredged, and hence it was not among the highly contaminated stations.

PROCEDURES

Sediment samples were taken for chemical analysis from benthic

Campbell grabs on 12 October 1989. Subsamples for metals were taken with plastic containers from an area of the sample that had not been in contact with the stainless steel grab, and pesticide subsamples were similarly taken with glass containers. These were frozen with dry ice in the field and kept frozen in the laboratory until analyzed by Associated Laboratories of Orange, California. Analytical techniques were those specified by the Environmental Protection Agency or Standard Methods (APHA, 1985).

RESULTS AND DISCUSSION

METALS

Based on the analytical data, the 14 stations sampled were ranked in order of the amount of each parameter from 1, the lowest, to 14, the highest. These scores were summed for each station and a relative ranking given to each station. This is only an approximation, since the actual toxicity of each parameter is not definitively known. As in the past (e.g., Soule and Oguri, 1989, 1988), Station 10, where the Oxford Flood Control Basin is flushed tidally into the Marina, was the most polluted (Table 10, below).

Table 10. Ranking of Stations by Sediment Contaminants and Trace Metals.

VOL 12

19201

Data from contaminants and heavy metals are presented in Table 11, and the distributions of the individual metals in the Marina on 12 October 1989 are illustrated in Figures 130 to 148, at the end of this section.

Station 12, in Ballona Creek, and Station 2, at the entrance of the Marina, tended with some exceptions to be the highest in the non-metal parameters such as oil and grease, volatile solids and organic nitrogen, whereas Stations 10, 9, and 11 tended to be highest in metals, but followed closely in rankings of non-metals.

Examination of the data of Long and Morgan (1990) gives some insight into the relative effects of trace metals, based on integration of results from a variety of field and laboratory tests. Table 12 gives the ranges

Table 12. Concentrations of Trace Metals Producing Biological Effects : Units are Effects Range-Low (ER-L)[1], Effects Range-Median (ER-M)[1], Apparent Effects Threshold (AET)[1], and EPA Threshold (NRC)[2]. Marina del Rey ranges and stations exceeding the ER-L, ER-M and AET are listed.

Parameter (ppm)	ER-L	ER-M	AET	NRC	MDR Range 1989-90	Stations Equal/Exceeding ER-L	Stations Equal/Exceeding ER-M	Stations Equal/Exceeding AET
Arsenic	33	85	50	33	1.13 - 10.8	----	----	----
Chromium	80	145	--	--	11.40 - 85.2	----	----	----
Copper	70	310	300	136	8.19 - 333	12,2,8,6,13, 25,5,7,11,9	10	10
Cadmium	5	9	5	31	<0.26 - 2.12	----	----	----

19202

of low effects (ER-L), median range of effects (ER-M), apparent effects threshold (AET) (Long and Morgan, 1990), and threshold effects given in NRC (1989). These values are compared with ranges in concentrations found in the Marina, and stations that fall within and above the various ranges are listed in increasing order of concentration.

NOAA and NRC did not include tributyltin (TBT) in their studies of ER-L and ER-M values because of inconclusive data. Soule and Oguri (1988) reported extensively on the effects of TBT and on bioassays using Marina organisms and sediments.

In the Marina, TBT in sediment was down considerably from the October 1988 sampling; levels at that time were recalculated and ranged from below the limits of detection to 5.57 ppm (reported in Soule and Oguri, 1990, page 102 as being in ppt in sediment, whereas ppt levels occurred only in the water samples tested). In 1988, TBT was below the limits of detection at Stations 2 and 3; Station 12 was not sampled. Station 11 had the highest level, and the mean of 10 Stations where TBT occurred was 1.71 ppm.

In October 1989, TBT sediment levels were below the limits of detection at Stations 1, 3, 8 and 13, and the range was from 0.1 to a high of 0.4 ppm at Station 10. The mean of 10 stations where TBT was found was 0.22 ppm. This indicates that there has been an order of magnitude reduction at the highest stations in that highly toxic form of tin used in antifouling paints, indicating the success of the State ban in September 1987. Figures 148 and 149 compare the 1989 TBT concentrations with the 1988 concentrations, respectively.

Comparison of the rankings of stations by total contaminant levels in Table 10 with the stations that exceed the apparent affects threshold (AET) limits in Table 12 show that there is agreement on classification of Stations 9, 10, 11 and 12 as the highest contaminated group. However, based on the AET limits, Stations 2 and 13 should be added to that group because of their high levels of zinc and copper, respectively.

Table 13 compares the ranges of contaminants and trace metals for various years. The 1989 ranges were more similar to those in 1985, being higher than in the intervening years for most parameters. This may be due to the lack of significant rainfall, prior to the sampling. Exceptions were the peak sulfide at Station 12, a station not sampled in 1988.

METALS CONCLUSIONS

Since the data indicate that most stations would fall within the low effects range (ER-L) for some species, this may account for the absence of more sensitive species; hence the findings of low diversity in the Marina.

The median effects range (ER-M) indicates that populations are at risk from concentrations of copper, lead and zinc. Copper has been historically used in antifouling compounds, and all three metals occur in street runoff from industrial areas and from highways. Station 12, in Ballona Creek, and Station 13 in Oxford Basin indicate the major sources of the pollutants; Station 2 is at the sandbar near Ballona Creek that traps contaminants, and Station 10 is near Oxford Basin. Stations 9 and 11 also are near storm drains and, with Station 10, are poorly flushed. The data do not suggest why Stations 9 and 11 should have such poor benthic fauna as compared to that of Station 10. Station 2 had the lowest Shannon Wiener diversity index in the Marina, in keeping with the sediment quality there.

As in the past, there is no direct correlation between benthic numbers and trace metals, although the inner Marina stations are the most polluted, have the poorest flushing, and have the lowest benthic quality.

PESTICIDES AND CHLORINATED HYDROCARBONS

Data for chlorinated hydrocarbons, including the polychlorinated biphenyls (PCBs) and pesticides, have been used to rank the stations, based on station scores as was done for metals. However, scores are lower since levels below the limits of detection were not counted. The following rankings of stations (Table 15) can be made:

Table 15. Ranking of Stations by Total Chlorinated Pesticides.

High Group		Medium High Group		Moderate Group		Low Group	
Station	Score	Station	Score	Station	Score	Station	Score
2	52	7	38	4	16	1	9
12	51	9	36	6	15	8	6
11	43	5	35			3	1
10	43	25	30				
		13	27				

The pesticide data (Table 14, opposite) indicate that the levels in sediment in the Marina are excessive and are cause for concern, according to the ER-L and ER-M values and the NRC values (Table 16, next page). It is not possible to correlate the excessive levels of pesticides at Station 2 with the high benthic faunal diversity and numbers found there. It is quite possible, however, that Station 2 would have a completely different fauna if it did not contain the burden of contaminants it presently has. If it returns to a primarily sandy substrate after dredging, there may be a return of some molluscs, echinoderms and crustaceans.

CHLORDANE

Chlordane, which is at least as toxic as DDTs, increased markedly at Station 2, from 238 ppb in 1988 to 630 ppb in 1989; also the mean for the entire Marina rose from 78.33 ppb to 148.17 ppb. Since this substance is banned for most uses, its sources are of concern. Station 12 (Figure 150) the next highest level, suggesting that it is being transported into the Marina from Ballona Creek and deposited at Station 2. Lesser peaks occurred at Station 25 where parking lots of the Administration Building and a restaurant drain into the Marina, and at Station 10, which probably represents deposition from Oxford Basin.

Table 16. Concentrations of Chlorinated Hydrocarbons Producing Biological Effects Range-Low (ER-L)[1] and Effects Range-Median (ER-M)[1], with Apparent Effects Thresholds (AET)[1], and EPA Thresholds (NRC)[2] as compared with ranges and stations exceeding the ER-L, ER-M and AET.

[1] = Long and Morgan, 1990 (NOAA)
[2] = National Research Council 1989 (NAS)
** = ER-L, ER-M and AET calculated for total Aroclors;
-LD = less than limits of detection

Chlordane concentrations at all stations exceed the ER-L and ER-M values except at Stations 6 and 9, where it was below the limits of detection. Only Station 3, with 17 ppb, was slightly below the NRC value for threshold effects.

<u>DDTs</u>

Ranges in most of the chlorinated hydrocarbons increased in 1989 after decreasing over the years of monitoring; Dieldrin, however, had disappeared by 1987 (Table 17). Total DDTs measured in 1978 ranged from none detected to 589 ppb. Total DDTs were considerably lower in 1985 and 1987, with total peak values of 146.7 and 197 ppb, respectively, but in 1988 tests the peak had increased to 284.8 ppb (Soule and Oguri, 1990) and 317 ppb in 1989. The peak 1989 p.p'DDT value was 200 ppb at Station 12.

in Ballona Creek, suggesting a terrestrial origin, but a significant increase over the 1985-1988 range. Figures 151 to 153, at the end of this section, show distributions of the DDTs.

TERRESTRIAL DDT

Some terrestrial soil analyses in February 1990 from the hotel site on Admiralty Way and from building sites on Ballona Lagoon showed peak values for total DDTs of 488 and 220 ppbs respectively. It is disturbing to see an increased influx of total DDTs; since DDT has been banned for about two decades, but it is either still being obtained or has been buried in filled land, to be eroded after excavation at a later time.

Although well below the ER-L given by NOAA, the acute toxicity of DDT in seawater listed in the California Ocean Plan (SWRCB, 1989) is 0.011 ppb. DDT is bioconcentrated and 3 to 4 mg/g in fish ovarian tissue is known to inhibit reproduction (Cross and Hose, 1988).

According to Pollock et al. (1990) of the California Department of Health Services, who quoted EPA, currently available epidemiological data on the carcinogenicity of DDTs is inadequate for complete evaluation. A human carcinogenic potency factor of 0.34 mg/kg per day (340 ppb) was calculated based on rodent studies.

POLYCHLORINATED BIPHENYLS (PCBs)

In general, the higher the last two digits of ARoclor, the higher percent chlorine it has (from 16 to 60), and the greater the toxicity, although there is some question about Aroclor 1260, according to the American Conference of Governmental Industrial Hygienists (ACGIH, 1986).

PCBs, as Aroclors, were produced from 1920s until 1977 for use in electrical systems, pumps and compressors, in hydraulic fluids and plasticizers. They are stable, with the appearance of light oil.

According to the Agency for Toxic Substances and Disease Registry of the US Public Health Services (USPHS, 1987) few tests have been performed on Aroclor 1260, as 1242 and 1254 were more commonly used. These tests indicate carcinogenicity in humans at an intake of mg/kg body weight per day, considerably above any normal oral intake. Acute toxicity in rats was in the 1.3 to 10 g/kg range, a level reached only under test conditions. Pollock et al. (1990) indicate that the EPA (1990) gave 7.7 mg/kg/day as the carcinogenic level based on rat diets of 100 ppm/day for 16 mo, 50 ppm/day for 8 mo and 10 ppm/day for 5 mo. Female rats surviving for 18 months had a 91 percent incidence of hepatic carcinoma. The USPHS gives carcinogenicity in humans, based on rat studies, at 1.3 to 10 mg/kg/day, far above normal human consumption levels.

Although Long and Morgan (1990) indicate a moderate level of confidence in the ER-L and ER-M data for PCBs, which are not discriminated by chlorine numbers, there are very large differences in the field toxicity data by several orders of magnitude. They state that PCBs in field-collected sediments may be highly particle bound and not bioavailable and/or they may have a relatively minor role in causing biological effects such as acute mortality relative to other co-occurring contaminants.

The occurrence of PCBs in the Marina was thought to have ceased between the 1970s surveys and the 1980s surveys, although the detection limits were greatly improved by 1986; in 1978 the peak value of Total PCBs was 1,247 ppb. None was detected again until October 1989, when they were found at all stations except Stations 1 and 3, both of which are cleaned by tidal action (Figure 154).

Aroclor 1260 occurred in October 1989 at Station 25 at 200 ppb and at Station 12 at 130 ppb; this suggested either an origin near Station 25 or simply deposition in a low spot on the Main Channel. None was detected at

VOL 12 19232

the other stations (LD=<1.0) Aroclor 1254, which may have been a degradation product of Aroclor 1260 or a separate introduction, occurred at most stations, making it difficult to propose a source point. The highest level of Aroclor 1254 was 330 ppb at Station 2, followed by 150 ppb at Station 10 and 110 ppb at Station 11. It was not detected at Stations 1, 3, 12 and 25. No other Aroclors were detected. Selected replicate samples were sent to State laboratories for verification.

The reappearance of PCBs was so unexpected that a second benthic sediment sampling survey PCBs was undertaken in January 1990. This indicated that a new pulse of Aroclor 1260 had spread through the Marina, for it was found at all but Stations 3, 4, and 10 (Figure 155). By October 1990, both Aroclors were widely distributed, but distributions of Aroclor 1260 and 1254 did not coincide (Figure 156). This will be discussed further in the 1990-1991 report.

POTENTIAL TERRESTRIAL SOURCES OF PCBs

Some terrestrial soil near the Marina is known to have an extremely high level of Aroclor 1260, up to 22,200 ppb, inland from the Oxford Basin at the head of the Main Channel near Admiralty Way. A grassy area inland of Oxford Basin might have received sediments in runoff that drained into the Marina via parking lot drains near Station 11, or via Oxford Basin and into the Marina. There has been extensive grading and excavation inland of the Marina periphery which may have exposed contaminatied soils. Other storm drains are potential pathways, and it is also possible that runoff carrying contaminated soils has drained into Ballona Creek and moved into the Marina from that direction.

There were no PCBs in sediment samples taken at the hotel site under construction near Station 1 nor at Ballona Lagoon where construction was also underway. It is, of course, possible that some sort of leaking transformer or pump was dumped or sank in the Marina at an unidentified time and place, but the PCBs were so widespread as to be puzzling.

PCBs AND CHLORINATED HYDROCARBON CONCLUSIONS

Pesticides and other chlorinated hydrocarbons, including PCBs, are a continuing problem in the Marina, if not an increasing one, based on the limited sampling data obtained. Levels are not hazardous to human health but are potentially sufficient to inhibit some infaunal species and to reduce reproductive capacity in some fish species. The Marina provides sheltered, warm waters for larval and juvenile fish, with turbidity to protect them from predators and an ample food supply, but the environmental function if inhibited by the presence of pollutants.

V. FISH-TISSUE ANALYSES FOR PCBs AND DDTs

POTENTIAL CONTAMINATION

Because fishing dock and jetties are used to catch fish for human consumption, the Los Angles County Department of Beaches and Harbors was concerned about potential public health exposure to the PCBs identified as present in sediments for the first time in recent years.

To determine body burdens of PCB 1260, fish were obtained on 25 January - 2 February 1990 by trawl and by purchase or donation of fish from recreational anglers on the public dock. Samples were frozen with dry ice in the field and muscle tissue was dissected in the laboratory in preparation for chemical analysis by Associated Laboratories, Orange, California.

Because DDT body burden had not previously been examined, tissues were also analyzed for DDT, DDD and DDE. Liver and gonads of several specimens were analyzed separately.

RESULTS AND DISCUSSION

Muscle tissue from 12 species, represented by 32 specimens of fish, were analyzed and 3 liver/gonad tissues were analyzed separately. Table 18 presents the results of the analyses.

Body burdens varied considerably among individuals of the same species or between species, indicating variation in exposure and bioaccumulation. Lee (1984) noted the great differences between species, with some able to metabolize DDTs and others storing it. The fish used for analysis herein were all small, young specimens.

Since liver and gonads are discarded when fish are cleaned for consumption, levels in those tissues are not usually relevant to human health. They are important however, relevant to the health of the local fish population if they impair the liver and reproductive capacity.

The range in muscle tissue for Aroclor 1260 were 15 to 298 ppb while liver/gonad samples showed a range of 548 to 4,270 ppb. The PCB in edible muscle portions did not approach the 2 ppm level for action under public health regulations.

There is a seasonal variation in the chlorinated hydrocarbons in muscle tissue and in liver and gonads. Cross (1986) demonstrated that DDT and PCBs are concentrated in the lipids in liver and gonads of white croaker in the months prior to spawning, and after spawning the body burdens are much lower (Figure 157).

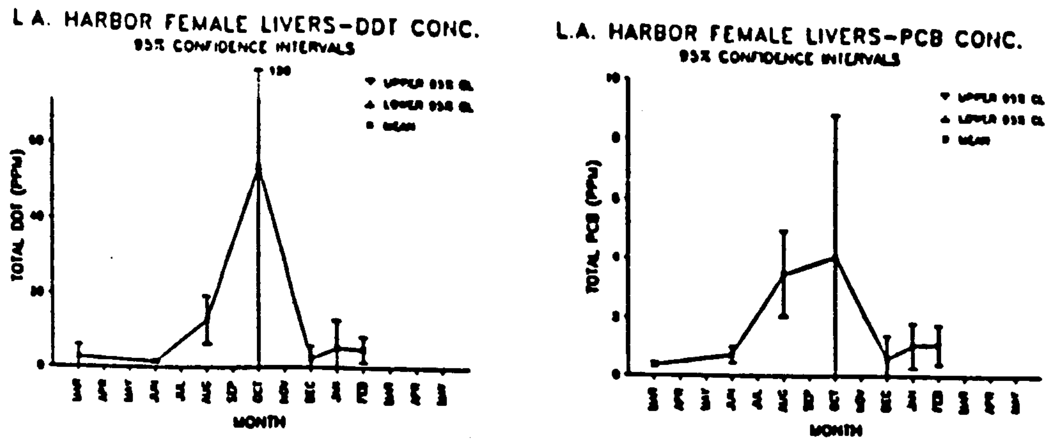

Figure 157. Mean total DDT and total PCB concentration (mg/kg wet weight =ppm and 95% confidence interval in the liver of female white croaker collected in outer Los Angeles Harbor from March 1985 through May 1986. N=5 per sampling period (Cross, 1986).

Because Marina fish sampling was performed in January - February 1990, at a period of theoretically low level of body burden, it was considered important to repeat the survey in October, which may be the peak body burden period, and in May 1991, a presumed low period.

Comparison of body burden with fish from off Whites Point and Santa

Monica Bay can be made with Table 19, from NRC (1989). Concentrations of DDT in ppm, were much higher from off Whites Point than from Santa Monica Bay, but PCB levels are less distinct.

CONCLUSIONS

It is clear that levels of metals, especially copper, lead and zinc, are excessive and capable of causing chronic damage to marine organisms. Since reproduction is most often compromised, this reduces the secondary productivity of the Marina. The more sensitive organisms such as echinoderms, crustaceans and molluscs are inhibited by chronic toxicity and species diversity is thus reduced.

Chlorinated hydrocarbon levels are excessive and the sources are not known. DDTs are very persistent in the environment, but non-degraded p,p'DDT should not be appearing, unless fresh inputs or excavation of previously unexposed contaminated sediments are the cause. Chlordane has been banned for most uses, and DDTs and PCBs have not been manufactured for many years. Natural flushing would have removed residual deposits by now if new material were not being introduced.

The January - February 1990 tests of fish tissues indicated that fish are not harmful to anglers under normal levels of consumption. The levels are, however, inhibitory to fish reproduction. To follow the levels of PCBs and pesticides, additional sampling was to be performed in October 1990 and May 1991. Chlordane will also be analyzed, since it probably is cumulative in effects with the DDTs. Muscle tissue may have a lower burden in October due to movement of lipids, in which chlorinated hydrocarbons are complexed to liver, reproductive organs and eggs prior to spawning.

VI. MICROBIOLOGY

PUBLIC HEALTH CONCERNS

Marina del Rey is not primarily a body contact water area, but does contain one beach, variously known as Marina Beach, Baby Beach and Mothers' Beach, located in Basin D. Following major sewage spills into adjacent waters in 1987, extensive monitoring of bacterial counts was undertaken by the Los Angeles Department of Health Services to determine when beaches could be reopened. However, counts did not recede as expected and an extensive study was undertaken by the Department of Beaches and Harbors to determine the sources. The beach was closed from October 1987 for more than a year. During this time a number of possible sources such as sewer or storm drain leaks were ruled out.

The major contributor to coliform contamination was identified as the seagull population that rested on the beach, especially during the cool weather months when there are few beach visitors to disturb them. The solution was similar to that used locally in some of the sanitary landfills to fend off hordes of gulls. Monofilament line, and later polypropylene line, was strung between a few poles at strategic locations. This seems to interfere with their flight pattern and keeps the gulls away but does not interfere with the smaller numbers of wading birds (Soule and Oguri, 1989; Charness and Smith, 1990).

Another significant source of coliforms is rainfall, which carries fecal material from transients, discarded diapers, dogs runs, and in some localities, drainage from horses, into the storm drains and flood control channels. Rainfall carries these materials into embayments and coastal waters, where the fecal bacteria persist for several days. Swimming after a rain should therefore be avoided for two to three days.

STANDARDS

Total coliform bacteria counts have for many years been used to measure the presence offecal material in water supplies. They were believed to be harmless, and are easier to culture in the laboratory than more dangerous pathogenic bacteria. Fecal coliform counts were added later, as being a more accurate measure of enteric contamination, and finally enterococcus counts were determined to be still more effective. The problem of identifying human contamination from illegal waste disposal, leaking sewers, vessel holding tanks and the like is that coliform bacteria also occur naturally in soil, and fecal coliforms occur in warm blooded animal feces, thereby confusing the results.

Enterococcus are really part of a group of *Streptococcus* species that occur in warm blooded animals. The enterococcus test eliminates those *Streptococcus* strains from cattle, horses and fowl, especially chickens, but it is not exclusive to humans. Because enterococcus do not generally survive long outside their hosts, they are supposed to be indicators of very recent contamination. None of the methods are truly accurate but can provide indicators of risk to public health; coliform tests have been in use for so many years that they represent the best historical data base for comparative evaluations. Research for better indicators is a continuing objective of public health agencies.

Federal (EPA), State and Los Angeles County standards for total coliforms in recreational waters stipulate that no single sample, when verified by a sample repeated within 48 hours, shall exceed 10,000 MPN (most probable number) per 100 ml (SWRCB, 1989). If daily monitoring were

VOL 12

1929

done, not more than 20 percent of samples taken in a 30 day period could exceed 1,000 MPN per 100 ml, but sampling is not normally done with that frequency.

Federal and State standards for fecal coliforms provide that not more than 10 percent of samples within a 60 day period may exceed 400 MPN per 100 ml. Since the USC surveys were done monthly, and the County Department of Health Services (DHS) monitoring is irregular, the 400 MPN per 100 ml standard is applied.

The EPA and DHS standard for enterococcus has been a geometric mean of 35 colonies (C) per 100 ml, or that no single sample may exceed 100 C per 100 ml. The State has proposed a standard of 24 C per 100 ml (SWRCB, 1989).

The County Department of Health Services in 1988 began to post beaches immediately after rains as being unsafe for swimming, based on results of monitoring in past years. Bacterial tests require incubation for several days before fecal contamination can be determined, and thus the waters could not be posted until after the risks had diminished if the County waited until the presence of contamination was confirmed.

METHODS

Surface water samples were taken in conjunction with sampling for nutrients and BOD_5 with the Naumann self-closing sampler. Samples were chilled and transported to Associated Laboratories of Orange, California for culture and counting according to Standard Methods and/or EPA approved protocols.

RESULTS AND DISCUSSION

Results of the monthly surveys are documented in Tables 20 to 25 and illustrated in Figures 158 to 169. The figures are plotted linearly in distance from the breakwater along the main channels, so that stations in the basins are positioned off the principal line. Station 12 is in Ballona Creek and Station 1 is at the mouth. Stations 8, 18 and 19 are relatively closely spaced in Basin D, where body contact is most likely to occur near the bathing beach and the wheel chair ramp; kayaking also occurs there. Station 13 is in Oxford Basin at the tide gate to Basin E and Station 22 is at the shore in inner Oxford Basin, where values are affected by runoff. Public Health standards are shown on the figures as solid transverse lines to indicate when contamination levels exceed the standards mentioned above.

BALLONA CREEK

Violations of standards have often occurred at Station 12 in the past (Soule and Oguri, 1990). There were none in October and November, but on 7 December 1989 there were fecal coliform and enterococcus violations at Stations 12 and 1 although it had not rained for two weeks (Figure 160). The tide had been +5.2 feet at 0431 hours on 7 December, which may have brought material down the channel and off the jetties. However, there were no violations there in January 1990, when tides were even higher (+6.3 ft).

There were no further violations observed in Ballona Creek during monthly monitoring until 5 April 1990, the day after about 0.5 inches of rain inland. All three parameters were in violation, but enterococcus was especially high, 3,100/100 ml, at Station 12. Total coliforms were in violation throughout the Marina, and fecal coliforms were in violation from Station 12 to Station 3. No violations occurred on subsequent monthly monitoring during the year. The June 1990 survey occurred ten days after heavy rains, but no bacterial effects could be noted in Ballona Creek.

BASIN D

Station 8, located at the innermost boat slip off the beach basin is the oldest of the survey stations in Basin D. Stations 18 and 19 were added in 1987 at the perimeter rope for the swimming area and at the end of the wheelchair ramp respectively. The only violations at Station 8 occurred for total and fecal coliforms after rainfall in April 1990. There were no violations at Station 18 throughout the year, while at Station 19 there was a very high enterococcus value on 10 May 1990. This may represent a human episode, perhaps of diaper contamination. A high fecal coliform in September may have been from birds.

OXFORD BASIN

Station 13, inside the basin at the tide gate, is frequently in violation of coliform standards; this is not a body contact area and thus is not a threat in itself, but waters from Oxford Basin, tidally flushed, can affect Station 20, on the Marina side of the tide gate, and/or Station 10, at the end of the first boat slip. Station 22 is at the inland end of Oxford Basin and receives drainage from a low grassy area which is used for recreation such as soccer but does not have sanitary facilities.

At Station 13, violations of fecal coliform standards occurred on 5 October 1989, 11 January 1990, 8 February, 8 March, 10 May, 2 August, and 6 September; total and fecal coliforms were in violation on 9 November 1989, 5 April, and 7 June 1990. The only enterococcus violation was after the rain, on 5 April 1990. The total and fecal coliform contamination may represent the neighborhood dog, wild rabbit and bird populations but the enterococcus violation may well represent human wastes.

At Station 22, violations of total and fecal coliform standards

VOL 12

19252

occurred on 9 November 1989; violations in fecal coliforms only occurred on 7 December 1989, 2 August 1990 and 6 September 1990. Enterococcus violations occurred on 7 December, 8 March, 5 April, and 7 June. Water was too low to be accessible for sampling on 5 October 1989 and 10 May 1990.

Station 20, where a large vessel is docked near the tide gate, has been a problem area in the past for bacteria and also ammonia levels. It was in violation of fecal coliform and enterococcus standards in October and December 1989, with both parameters exceeding those at Station 13 by an order of magnitude. All three standards were violated in April 1990, but this also occurred in most of the Marina following the rainfall. Total and fecal coliforms were in violation in May and June, when Station 13 levels were also high. The problem of probable human waste contamination at the dock was not evident as frequently as in previous years.

CONCLUSIONS

The only stations in the Marina proper not affected greatly by rainfall runoff are Station 6, in Basin B, and the Basin D beach stations, Stations 18 and 19. If further evidence were needed of the effects of rainfall on bacterial contamination from runoff, the profile (Figure 164) and data (Table 23) for 5 April 1990, the day after a 0.5 inch rain, would be illustrative.

Causes of other episodes of standards violations are not clear, as for example on 7 December 1989, when there were violations in Ballona Creek and Oxford Basin. Rainfall had occurred about two weeks earlier, and enterococcus should not have been able to persist for that long an exposure. Violations in Oxford Basin in May and June were also two weeks or more after rainfall. Recreational use of the area may be contributory

VOL 12

19253

to the problem. Violations from vessels does not seem to be a problem, other than the possible contamination at Station 20 in October 1989.

VII. BENTHIC ORGANISMS

INTRODUCTION

Benthic organisms, those living in or on the bottom (benthos), are very important components of the fauna of soft bottomed estuaries and marinas. The fauna usually consists largely of polychaete annelid worms, molluscs and crustaceans, although in polluted or disturbed areas the diversity in major groups may be reduced to polychaetes and other worms such as nematodes and oligochaetes.

Benthic organisms are good indicators of environmental stress, since they are predominantly sedentary, sessile or attached, and thus subjected to any environmental insults. Larvae of some species are planktonic, moving about with water exchange, which provides a mechanism for recolonization following impacts.

PROCEDURES

Field sampling was conducted on 12 October 1989 from the University of Southern California research vessel *Golden West*. A Campbell grab (modified Van Veen) which samples 0.1 m^2 of surface was used at 12 stations. While the Reineke box corer is a more accurate sampling device, it is not possible to operate a large enough vessel to accommodate it within the narrow confines of the innermost areas of the basins where many water quality stations are located.

Samples were washed through a 0.5 mm screen and preserved with 10 percent buffered formalin in the field. They were rough sorted to major taxa from debris and transferred to 70 percent ethanol in the laboratory prior to identification and enumeration by taxonomists. Numbers of individuals are multiplied by 10 for calculation of the numbers per m^2 of bottom sampled.

1 9256

Species were ranked according to the most numerous taxa for each station, so that results can be compared with previous years (Soule and Oguri, 1977, 1980, 1985, 1986, 1987, 1988, and 1990). The species diversity index (SDI), a measure of how varied the fauna is, was calculated by two methods, the Shannon-Wiener SDI and Gleason's SDI. Gleason's SDI was used during the 1970s and Shannon-Weiner SDI was addeo in 1984. Gleason's Index is more influenced by large numbers of individuals of a given species than is the Shannon-Weiner Index.

RESULTS AND DISCUSSION

Complete benthic data are presented in Appendix D. The following discussions summarize the results.

POPULATION DENSITY

The mean number of individuals per m^2 in 1989 was about the same as that in 1988, although the numbers do not approach those found in 1986 or earlier, in 1977 (Table 26). Numbers were increased in 1989 at Station 2, but the increase consisted primarily of Nematoda (roundworms), indicating a disturbed environment. Numbers decreased by about 50 percent at Station 6, by 57 percent at Station 11, and by about 68 percent at Stations 7 and 9. The total number of individuals was 151,190, up from 124,480 in 1988 due to the large number of nematodes and also to the addition of two stations.

The station, Station 25, located between the Administration building docks and the fishing pier, showed a surprisingly good benthic population even though it is located where it might be affected by the daily operations of the Life Guard's and Sheriff's Department vessels. There is far greater activity at that location than there would be at a recreational dock in terms of possible oil and gas contamination, and also there are many birds resting and feeding at the adjacent fishing pier, while washdown

water from parking lots drains into the area. However, it is not located in a deadend basin, and therefore water circulation is better.

Station 12, in Ballona Creek, has been sampled in some years but in other years it has not been possible to sample due to debris accumulation or to low tides which make the station inaccessible for benthic sampling. Station 12 had the highest levels of volatile solids, total organic carbon, chemical oxygen demand, oil and grease and organic nitrogen of all stations sampled.

NUMBERS OF SPECIES

The mean number of species for the eleven stations previously surveyed dropped slightly, from 30 per m^2 in October 1988 to 26 in 1989 (Table 26). If the new station, Station 25, and the Ballona Creek station, Station 12, are added, the mean number increases to $27/m^2$. The decrease is due in part to a decrease from 74 species to 34 species/m^2 at Station 2, and to decreases in the inner basins, particularly in Basin E at Station 10. There were substantial increases at Station 3 and 7.

Reasons for the declines at Stations 2, 9 and 10 are not readily apparent, but may be linked to the lack of heavy enough rainfall runoff in recent years to leanse the Marina and Ballona Creek by carrying the finest sediments, to which pollutants complex or adhere, seaward.

Sand deposition and uneven dredging at Station 2 has led to a buildup of polluted sediments at the entrance to the Marina. Station 10 has had a history of high metals contamination and Stations 2 and 10 have had high pesticide levels (Soule and Oguri, 1988; 1990). Populations at Station 11 had already decreased greatly between the 1987 and 1988 surveys, following construction of new docks in a formerly open area there. Stations 10, 9, 11, and 2 are the most polluted in descending order, within the Marina. In all, there were declines at 7 of 11 stations.

The total number of species or taxa in October 1989 was 164, up from 148 in the 1988 sampling and 117 in 1987. More than 40 of the 164 were single occurrences (count of 10/m^2), however. The species, or higher taxa if not identifiable to species level, are listed in Appendix D according to station occurrence and numbers of individuals calculated per square meter.

Figure 170 illustrates the general pattern of species numbers for all surveys in the 1980s, indicating the lower numbers of species per station in the inner basins, with several stations in 1989 having lower numbers than in prior years. Variation has generally been greatest at Stations 1 through 3. Figure 171 shows similar patterns and ranges for autumn surveys during 1976-1979, but with a large drop in numbers at Station 3 in 1977, suggesting some perturbation from Ballona Lagoon.

SPECIES DIVERSITY

The species diversity index (SDI) decreased slightly under both the Shannon-Weiner (S-W) and Gleason's methods. Although the Marina soft bottom habitat environment probably leads to a lower SDI than some other habitats might, the Marina SDIs remain low. The hypothetical S-W SDI would range from 2.4 to 4.3, and some Entrance Channel stations (3, 4) achieve the lower level, but the inner basins do not, and thus the means are lower.

One would expect the Marina to maintain a mean S-W SDI of at least 2.00, as it did in 1984 and 1986, but it has not, dropping gradually from 2.14 in 1984 to 1.88 in 1988 to 1.81 in 1989 for the 11 Marina stations or 1.76 for 13 stations. There were increases in the S-W SDI at six stations and decreases at the rest (Table 27).

Figure 172 illustrates the wide range of variation that has occurred over the 1980s monitoring periods in S-W SDI at Stations 1 through 3, as well as the decrease at Station 8 in 1989. In Figure 173, the S-W SDI

VOL 12

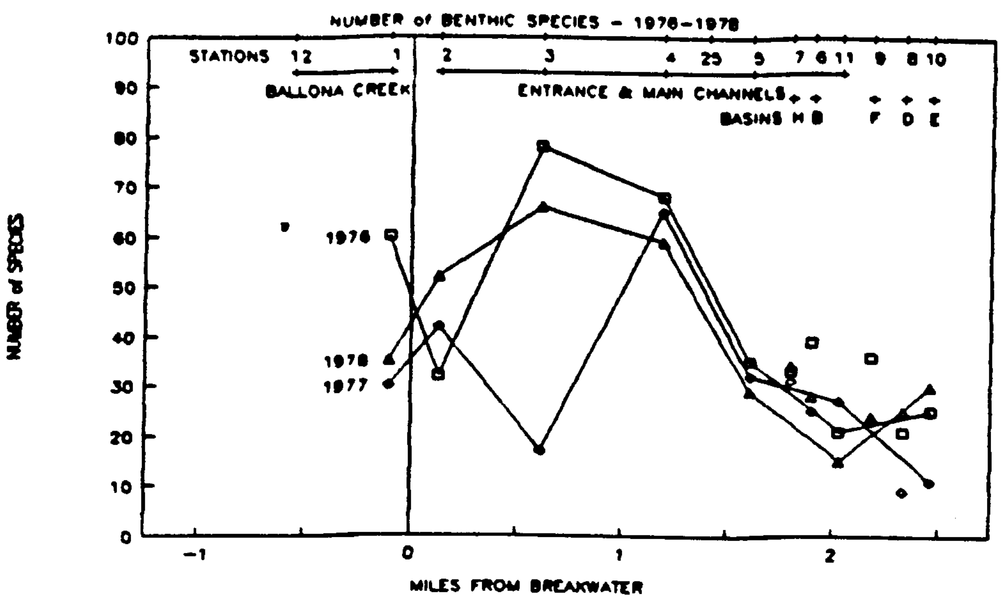

Figure 171. Numbers of benthic species per station, 1976–1979.

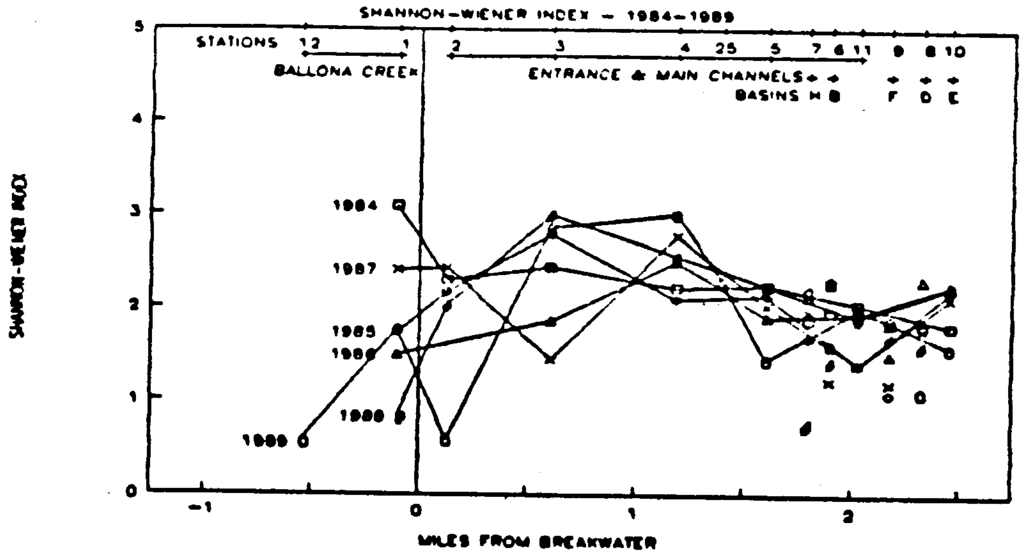

Figure 172. Shannon-Wiener Species Diversity Index, 1984-1989.

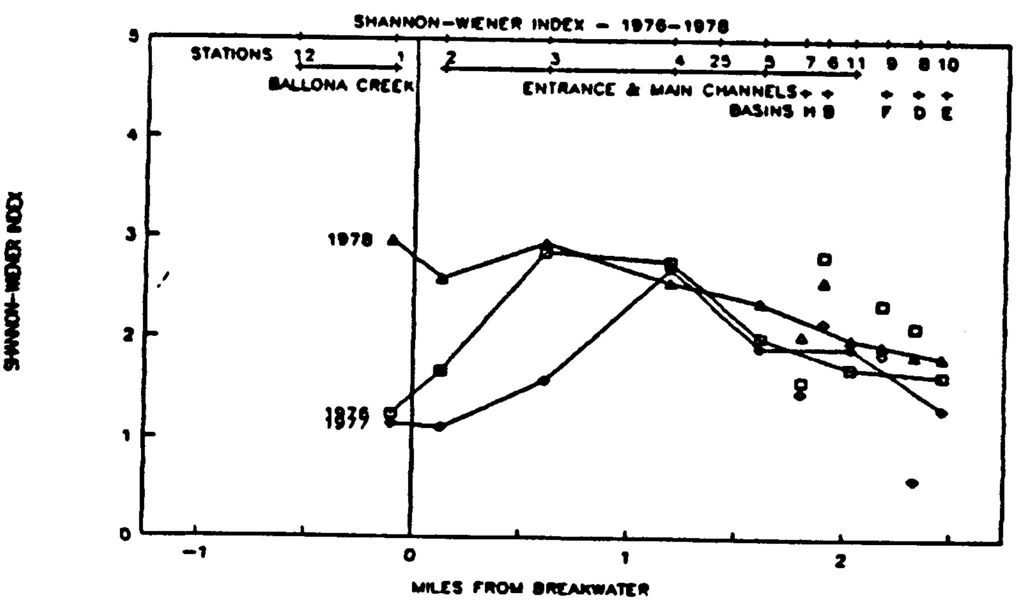

Figure 173. Shannon-Wiener Species Diversity Index, 1976-1979.

showed lower values in 1976 and 1977 in the Entrance Channel and higher values in Basin B, Station 6.

The Gleason's SDI has ranged from 2.90 in 1987 to 3.81 in 1986, with an October 1989 value of 2.92 for 11 stations and 2.99 for 13 stations. There were increases at five stations, but this was masked by large decreases at Stations 2 and 5.

Increases in the SDI agreed under both methods at Stations 1, 4, 6, and 7. Decreases agreed under both methods at Stations 2, 5, 8, and 10. The Gleason's SDI has in the past appeared to follow the pattern of higher values in the Entrance Channel, followed by the Main Channel and inner Basins more consistently than did the S-W SDI, but the deterioration at Station 2 in 1988 and 1989 has altered the channel pattern. Station 10, which has had a higher SDI than expected since 1985, given the runoff from the Oxford Flood Control Basin, has declined since then and now has an SDI little different from that in the other inner basins.

SPATIAL DISTRIBUTION AND DOMINANT SPECIES

The numerically dominant species for October 1989 are listed in Table 28. The large numbers of nematodes and oligochaete worms at Station 2 dominated the counts in the entire Marina. Surface sediments at Station 2 have become much less sandy and more organic in the last few years as the sand deposited there formed a trap for fine sediments and pollutants following dredging, and lack of heavy rainfall runoff has not carried material seaward. The highest Volatile Solids, Total Organic Carbon, Chemical Oxygen Demand and Oil and Grease values occurred at Stations 12 and 2, suggesting a spill during the year in Ballona Creek. High Chlordane and Aroclor 1254 levels probably originated through drainage or dumping directly into the Marina rather than from the creek (See Sediment

Contamination section.

Nebalia pugettensis, a shrimplike crustacean that is common in shallow coastal waters, occurred in large numbers at Station 12, in the creek bed. Most of the numbers are otherwise dominated by polychaete worms, with a few crustacean and molluscan species.

If the species are listed in order of the number of occurrences in the Marina, the nematodes and *Nebalia* drop far down the list into the 90 species that occurred only at one station in October 1989. Forty of these were collected as single specimens (counted as 10 individuals when calculated to the square meter). Table 29 shows species ranked by number of station occurrences (righthand column), with *Mediomastus ambiseta* occurring at all stations except Stations 12 and 1, and *Psuedopolydora paucibranchiata* occurring at all except at Stations 12, 1 and 2. Most species in the higher ranks are again polychaetes, with a few crustaceans and molluscs in the groups with three or more station occurrences. Interestingly, the arrow goby (fish) *Clevelandia ios* was taken in the grab sampler at three stations.

Station 1

Station 1 is located at the mouth of Ballona Creek where it mingles with waters from the Marina inside the breakwater and the ocean. The Creek is a flood control channel for a large urban area of the western and central Los Angeles area, receiving urban runoff, accidental spills of various sorts, and illegally dumped trash or waste. Tidal flow carries waters up the creek and tidal exchange flushes the Marina into Santa Monica Bay, all of which influence conditions at Station 1.

The number of species decreased by 20 percent at Station 1 in October 1989, and the number of individuals decreased by 86 percent, but the cause is unknown, and the pollutant loading is relatively low. A vessel has been

VOL 12

1 9 2 7 4

anchored nearby for a number of months. The fauna was again dominated by *Armandia bioculata*, although it had decreased from 84 percent of the fauna to 50 percent. Nematoda, which represented 5 percent of the fauna in 1988 sampling, were not found at the site. For the first time, two crustaceans, the cumacean *Leptocuma forsmani* and the amphipod *Synchelidium shoemakeri* appeared in the most numerous taxa at this location. The dominant taxa are as follows:

Species	Percent
Armandia bioculata	50.00
Apoprionospio pygmaea	24.39
Leptocuma forsmani	6.10
Synchelidium shoemakeri	2.44
Microspio maculata	1.83

Station 2

Located at the entrance of the Marina between the north and south jetties, this station has deteriorated faunally in recent years due to a buildup of organic matter at the sandbar inside the entrance and along the south jetty. Lack of significant rainfall has kept the fines from being carried out into the ocean, as would normally occur during storm periods. The grain size has shifted to >70 percent fine silt, approaching conditions in the inner basins, and these have high levels of Total Volatile Solids, Total Organic Carbon, Immediate Oxygen Demand, Chemical Oxygen Demand, Oil and Grease, Lead, and Organic Nitrogen.

The dominant species are as follows:

Species	Percent
Nematoda, unid.	85.41
Oligochaeta, unid.	11.17
Schistomeringos longicornis	0.99
Neanthes acuminata	0.57
Armandia bioculata	0.39
Capitella capitata	0.25

In October 1988, the fauna was dominated by 35.53 percent Oligochaeta

VOL 12 1975

but few Nematoda. In October 1989, nematodes had increased to form 96.56 percent of the population, and the three clam species found in 1988 (Soule and Oguri, 1989) had virtually disappeared.

Station 3

Located at the tide gate buoy marking the entrance to Ballona Lagoon, Station 3 has a comparatively large grain size and is the cleanest station based on trace metal and pesticide concentrations. Flushing through the tide gate no doubt helps to reduce buildup of fine materials and organics.

In 1987 nematodes dominated this station during excavation in Ballona Lagoon for construction, forming 63.3 percent of the fauna, but in 1988 a more diverse fauna was found. The number of species increased in 1989 and the population more than doubled from the previous year, but the total number has not risen to those found in 1986 and 1987. Two crustaceans, the corophiid *Rudilemboides stenopropodus* and the amphipod *Mayerella banksia* were found. The dominant species are as follows:

Species	Percent
Pseudopolydora paucibranchiata	33.31
Rudilemboides stenopropodus	7.06
Exogone sp. *A*	6.97
Saccocirrus sp.	6.36
Oligochaeta, unid.	4.37
Mayerella banksia	4.00
Prionospio heterobranchia	3.92

Station 4

Located off the embankment riprap in front of apartment houses and west of the Coast Guard dock, this station continued to show lower numbers than it did in the 1977, when it had 67 species and 28,700 individuals/m^2, or in 1984, when it had 43 species and 9,750 individuals/m^2. In October 1988, this station had the highest Chlordane and DDT levels in the Marina. By 1989, the sediment carrying this burden had moved down to Station 2, and

VOL 12 1 9276

a mixture of DDT, DDD and DDE were present there, with the result that Station 4 was among the cleaner stations.

There was little change in the faunal numbers, with a slight increase in the number of species and a slight decrease in number of individuals. The crustacean *Hemigrapsus oregonensis*, found in 1988, had disappeared by October 1989, leaving a dominant fauna of polychaetes, as follows:

Species	Percent
Minuspio cirrefera	12.68
Mediomastus ambiseta	10.87
Lumbrineris ? tetraura	9.78
Cossura candida	8.33
Euchone limnicola	7.61
Pseudopolydora paucibranchiata	6.88

Station 25

Station 25 is a new station, added between the Life Guard and Sheriff's patrol docks at the County Administration Building and the public fishing dock at Fisherman's Village. It is the site of the entrance to the proposed new Playa Vista Marina. It receives drainage from restaurant and Administration parking lots, and is subjected to potential oil and grease seepage from frequently operated vessels. However, those levels were low, but the Chlordane level was among the highest, suggesting terrestrial input from adjacent wood buildings or ornamental plantings.

Benthic fauna was moderately good, with 43 species and 8,530 individuals/m^2. The number of species was higher than at the seaward Station 4 and at Station 5. Dominant fauna were polychaetes and oligochaetes, as follows:

Species	Percent
Mediomastus ambiseta	28.37
Pseudopolydora paucibranchiata	23.09
Lumbrineris lagunae	11.25
Minuspio cirrifera	6.45
Euchone limnicola	4.57
Oligochaeta, unid.	4.57

VOL 12 1927

VOL 12

1 9278

Station 5

Station 5 is located in the middle of the Main Channel between the entrance of Basins B and H at a buoy. When storm rainfall is low, sediments that are flushed from the basins may be carried only as far as midchannel and not move farther down channel. Station 5 is a depositional area, ranked third in the amount of the finest grained sediments, with 97.65 percent. The 1989 levels of Chlordane dropped from 151 ppb to 93 ppb but DDT increased from 17.8 ppb to 80 ppb. In theory, DDT in the Marina should have long ago been degraded to DDD or DDE following the ban on its use in the USA, but either fresh applications have been made on land or deposits that have not been degraded are being uncovered and washed into the Marina. However, it is puzzling that populations were better in the 1970s when these chemicals were in widespread use.

The fauna in 1989 was typical of the polychaete species found elsewhere in the Marina, but *Pseudopolydora paucibranchiata* increased from 33.33 percent in 1988 to 61.7 percent in 1989, decreasing the species diversity indices substantially (Table 27). The dominant species were as follows:

Species	Percent
Pseudopolydora paucibranchiata	61.70
Cirriformia spirabrancha	17.45
Lumbrineris lagunae	5.11
Leitoscoloplos elongatus	2.55
Leptosynapta sp.	2.55
Mediomastus ambiseta	2.13

Station 6

Station 6 is located in the inner end of Basin B and is less polluted than most of the basins sampled, probably because it has a lower percentage of the finest grain size sediments or receives less contaminated runoff.

The polychaete *Tharyx* continued to dominate this station, the only location in the Marina where it does. In 1987 *Tharyx* provided 73.6 percent of the fauna; in 1988 it decreased to 55.55 percent and in 1989 it provided 58.9 percent. The crustacean Caprellidea, unidentifiable, dropped from the species list there, and the mollusc *Cylichnella inculta* decreased from 640 to 80 individuals. The dominant species were as follows:

Species	Percent
Tharyx sp.	58.93
Pseudopolydora paucibranchiata	15.05
Euchone limnicola	4.86
Mediomastus ambiseta	3.92
Schistomeringos longicornis	3.45
Leitoscoloplos elongatus	2.98

Station 7

Station 7 is located at the inner end of Basin H at the buoy off the launch ramp. It receives runoff from a large parking lot and a large storm drain as well as contamination which may be flushed from maintenance and boat yards.

The number of species rose at Station 7 from 16 in 1988 to 26 in 1989, but the number of individuals dropped from 14,700 to 4,590. While *Hydroides elegans* is often found in the Marina, it seldom occurs in such large numbers as it did in 1989. The dominant species were as follows:

Species	Percent
Hydroides elegans	36.82
Pseudopolydora paucibranchiata	15.25
Euchone limnicola	7.84
Lumbrineris lagunae	7.63
Tharyx sp.	6.97

Station 8

Located off Marina beach, otherwise known as Mother's Beach or Baby's Beach, this station lies outside of the sandy swimming area and seaward of the seagrass beds that border it near the innermost boat slips. The bottom is fine grained sediment with moderate levels of trace metals, including

VOL 12 1979

the highest value for mercury.

The number of species dropped from $35/m^2$ in 1986 to 21 in 1987, 16 in 1988 and 13 in 1989. The peak population was in 1986, 14,950 individuals $/m^2$, while the low was in 1988, 1,990, and there was an increase to 2,740 in 1989. The population was dominated by *Cirriformia spirabrancha*, with 71.53 percent, giving the station a low species diversity. That species formed only 6.53 percent of the population in October 1988. The dominant species are as follows:

Species	Percent
Cirriformia spirabrancha	71.53
Phoronis sp.	13.14
Pseudopolydora paucibranchiata	5.11
Euchone limnicola	2.92
Lumbrineris lagunae	2.19

Station 9

Located at the inner end of Basin F, Station 9 receives runoff from storm drains and has poor circulation, resulting in the second highest level of very fine sediment in the Marina, 98.73 percent. It had the highest DDT level within the Marina and the second highest pollution score in October 1989. The benthic fauna at this station has deteriorated, along with that at Station 11, since the new docks were constructed at the latter, creating a depositional area, although there may be no cause and effect relationship. Lack of heavy rainfall in recent years also has meant that pollutants are carried into the Basin F by stormdrain runoff but not out of it.

Station 9 has had low production of benthic fauna subsequent to 1986, when it had 18 species and 11,150 individuals$/m^2$. The population reached a new low of 780 individuals with 12 species$/m^2$ in October 1989. Dominant species were the usual polychaetes, except for the echinoderm holothurian *Leptosynapta*; holothurians are present in highly organic sediments, including places receiving human waste. Station 9 had the highest sulfide values, which increased in 1989. Dominant organisms were as follows:

Species	Percent
Pseudopolydora paucibranchiata	33.33
Lumbrineris lagunae	25.64
Cirriformia spirabrancha	14.10
Leptosynapta sp.	6.41
Mediomastus ambiseta	5.13
Leitoscoloplos elongatus	5.13

Station 10

Station 10 is the most polluted station in the Marina based on total levels of all contaminants. Located at the inner end of Basin E, near the tide gate from the Oxford St. Flood Control Basin, the area receives runoff from a large urban area. The tide gate is open to the Oxford Basin at all times except when a storm is expected, and it is cleaned of debris and reopened after a rain. Station 10 had high levels of Chlordane, DDE, tributyltin (TBT) and the PCB Aroclor 1254. PCBs had not been found in the Marina since the 1976-79 survey until 1989, when alarmingly high levels were found to have entered, perhaps through the Flood Control Basin from excavation of contaminated sediments for development on adjacent property in Los Angeles City or from Ballona Creek, or an unknown spill into the Marina. PCBs have since been carried throughout the Marina and deposited in areas of low flushing and fine sediment.

In October 1989, the number of species had declined by 44 percent and the population declined by 75 percent from October 1988. The dominant fauna were as follows:

Species	Percent
Cirriformia spirabrancha	51.87
Phoronis sp.	23.24
Pseudopolydora paucibranchiata	7.05
Euchone limnicola	4.98
Lumbrineris lagunae	2.49

VOL 12

<u>Station 11</u>

Station 11 has the highest percentage, 99.26, of the finest sediments in the Marina. Located at the inner end of the Main Channel, this area was open water until the installation of new floating docks in 1987. It is high in DDT, DDE, TBT and most metals.

Since 1986, benthic fauna has decreased at Station 11 from 22 species and 6,120 individuals/m^2 to 10 species and 360 individuals/m^2. The dominant species are as follows:

Species	Percent
Euchone limnicola	27.78
Cirriformia spirabranchia	16.67
Lumbrineris lagunae	16.67
Mediomastus ambiseta	13.89
Cylichnella inculta	8.33
Tharyx sp.	5.56

<u>Station 12</u>

Station 12 does not lie in the Marina, but is located in Ballona Creek at the footbridge. In some years it has not been possible to sample due to debris in the creek bed or to insufficient water level to gain access with a large enough vessel to operate the grab sampler. The grain size at the time of sampling in October 1989 had 49.54 percent very fine sediment, lower than most Marina stations except Stations 1, 3 and 4.

The number of species was fairly high, and the number of individuals exceeded those at Marina stations except at Stations 2 and 3. This would have been decreased substantially had there been a heavy rainfall prior to sampling. A shrimplike crustacean common to shallow coastal waters and mudflats, *Nebalia pugettensis*, dominated the fauna, which indicates that the freshwater flow is not sufficient to dominate the bottom fauna. It provided 89.3 percent of the fauna, giving a low S-W SDI value of 0.55; the

1 9 2 8 2

other dominant species were polychaetes, as shown as follows:

Species	Percent
Nebalia pugettensis	89.30
Neanthes acuminata	3.44
Schistomeringos longicornis	3.06
Microphthalmus sp.	1.36
Ophiodromus pugettensis	0.87

LONG TERM TRENDS

Previous monitoring records were examined to determine long term trends. In the current studies, benthic species were ranked according to the total number of individuals per square meter throughout the entire Marina (Table 28), and in Table 29 they were ranked according to the number of stations at which they appeared in October 1989. Records of monitoring in October 1976 and in September 1977 and 1978 were then sorted and compared with those in October of 1984-1988 to note the most numerous species for each year for the nine years of fall sampling. The number following the total count in Table 29 is the number of years surveyed in which the species has occurred.

There were 17 species or other taxa that appeared in all nine autumn surveys, of which two are fine sediment molluscs; the others were Nematoda, Oligochaeta and other polychaete worms. Eight other species were present eight out of nine years, of which two were molluscs, two crustaceans and the rest worms. This indicates that there is a resident core of species characteristic of the soft bottom marina environment. There were an additional 143 species present in at least 50 percent of the time periods sampled.

The taxonomy of nematodes and oligochaetes has not been adequately enough advanced in the literature to permit more precise identification of those groups and each is listed as a single entity, which may result in other dominant species were polychaetes, as shown as follows:

Species	Percent
Nebalia pugettensis	89.30
Neanthes acuminata	3.44
Schistomeringos longicornis	3.06
Microphthalmus sp.	1.36
Ophiodromus pugettensis	0.87

LONG TERM TRENDS

Previous monitoring records were examined to determine long term trends. In the current studies, benthic species were ranked according to the total number of individuals per square meter throughout the entire Marina (Table 28), and in Table 29 they were ranked according to the number of stations at which they appeared in October 1989. Records of monitoring in October 1976 and in September 1977 and 1978 were then sorted and compared with those in October of 1984-1988 to note the most numerous species for each year for the nine years of fall sampling. The number following the total count in Table 29 is the number of years surveyed in which the species has occurred.

There were 17 species or other taxa that appeared in all nine autumn surveys, of which two are fine sediment molluscs; the others were Nematoda, Oligochaeta and other polychaete worms. Eight other species were present eight out of nine years, of which two were molluscs, two crustaceans and the rest worms. This indicates that there is a resident core of species characteristic of the soft bottom marina environment. There were an additional 143 species present in at least 50 percent of the time periods sampled.

The taxonomy of nematodes and oligochaetes has not been adequately enough advanced in the literature to permit more precise identification of those groups and each is listed as a single entity, which may result in underestimation of species diversity. Nematodes appear in large numbers intermittently, as noted in Table 30, being significant in 1977, 1986 and 1989 at a single station each time.

In 1976-1978, 96 species appeared one or more of the three autumn surveys which were not recorded in the 1980s; 62 of these occurrences were in one period only. There were 364 species present in one or more of the six autumn surveys in 1984-1989, 126 of which were not identified as present in the 1970s; 125 taxa were recorded only in one period.

Of the total of 460 taxa reported in all autumn surveys, 187 species, or about 41 percent of the taxa, were recorded only one time; some of these were unusual for the area, some were juveniles unidentifiable to species, or otherwise unrecognized taxa. A few represented bottom fish not usually caught or freshly deposited fauna from boat scrapings. Some of these records also may be artifacts of identifying more recently described species, whereas each revision of a taxon is included under a single name to avoid duplication.

The benthic fauna is thus about 50 percent a stable group of species or taxa and about 50 percent incidental. The numbers of individuals varies greatly in response to a number of factors including localized impacts and natural succession. The opportunistic species, those that reproduce year around, can usually outcompete others with seasonal reproductive periods, and may dominate the fauna for short or long periods.

There was a decrease in the so-called pollution indicator species *Capitella capitata* in the 1980s, but other species of similar habitat preferences, though perhaps not as pollution tolerant, dominate the present benthos. The highest mean number of species in the 1970s autumn sampling occurred in 1978, when 37 species/m^2 were found, but only 9,040 individuals/m^2 were counted (Soule and Oguri, 1980). In contrast, in

1986, when 38 species were found, counts were 34,635/m^2.

CONCLUSIONS

The benthic fauna are influenced by many factors, including normal water temperature changes, the timing and magnitude of rain events, pollutant burden, accidental spills, localized disturbances such as propeller wash excavations, dumping of household cleaning products and holding tank chemicals.

There is a large natural variation in the presence and population numbers of the dominant species, and a greater variation in the presence/absence of non-dominant species.

No single parameter of pollutant measured correlates directly with the low incidence of species and populations in the innermost basins.

The areas of poorest fauna are in those areas with poor flushing; however, the large and continuing decreases at Stations 9, 10 and 11 suggest that impacts are due to other factors as well. The degradation associated with construction of new slips at Station 11 might be due to reduction in flushing alone, or to chemicals present such as those used in construction and/or vessel antifouling. It is clear, however, that Station 11 has been heavily impacted by that change.

The trend toward increased moorings and decreased open water suggests that benthic fauna will continue to decline, especially in years with little heavy rainfall or oceanic storms.

VOL 12 1986

Table 28. Dominant benthic species in Marina Del Rey, 12 October 1989. Species are rank ordered by total count per square centimeter in the entire Marina, with counts of individuals given for each station. Stations are listed in order of distance from the breakwater, with Station 12 located in Ballona Creek and Station 1 off the mounth of Ballona Creek.

VIII. FISH FAUNA

INTRODUCTION

The fish fauna of Marina del Rey were surveyed by Harbors Environmental Projects of the University of Southern California five times during 1977-1979 (Soule and Oguri, 1980), providing the first baseline studies of the area. Various techniques were tested to determine the most effective methods of sampling. Surveys were resumed, mostly on a semiannual basis, in 1984 with the *Vantuna* Research Group of Occidental College under the direction of Dr. John S. Stephens, Jr. and his staff.

During the 15 periods surveyed, a total of 95 species or taxa of fish has been identified from fish trawls, ichthyoplankton trawls, gill netting, beach seines and diver surveys, with an average of about 40 species present at any one time.

The importance of the Marina as a local shallow water habitat cannot be overlooked (Soule and Oguri, 1990), since about 90 percent of the wetlands in Los Angeles County have been lost (U.S. Fish and Wildlife Service, 1972). The Marina has hosted 15 important backbay wetlands species, most of which are rare in the open coast shallow water. Some species have been present only as young-of-the-year (YOY) and not as adults, and some were found only as eggs or larvae. Larvae of a deep water Mictophidae were found once in 1984.

PROCEDURES

Fish surveys reported herein were performed on 11 October 1989 and 17-18 May 1990. The techniques and equipment were the same as those used since 1984. The otter trawl is a 15 ft semiballoon trawl which is towed for ten minutes at three locations (Figure 174). A 100 ft multimesh gill net is deployed at three locations for 45 minutes each, and a 100 ft beach

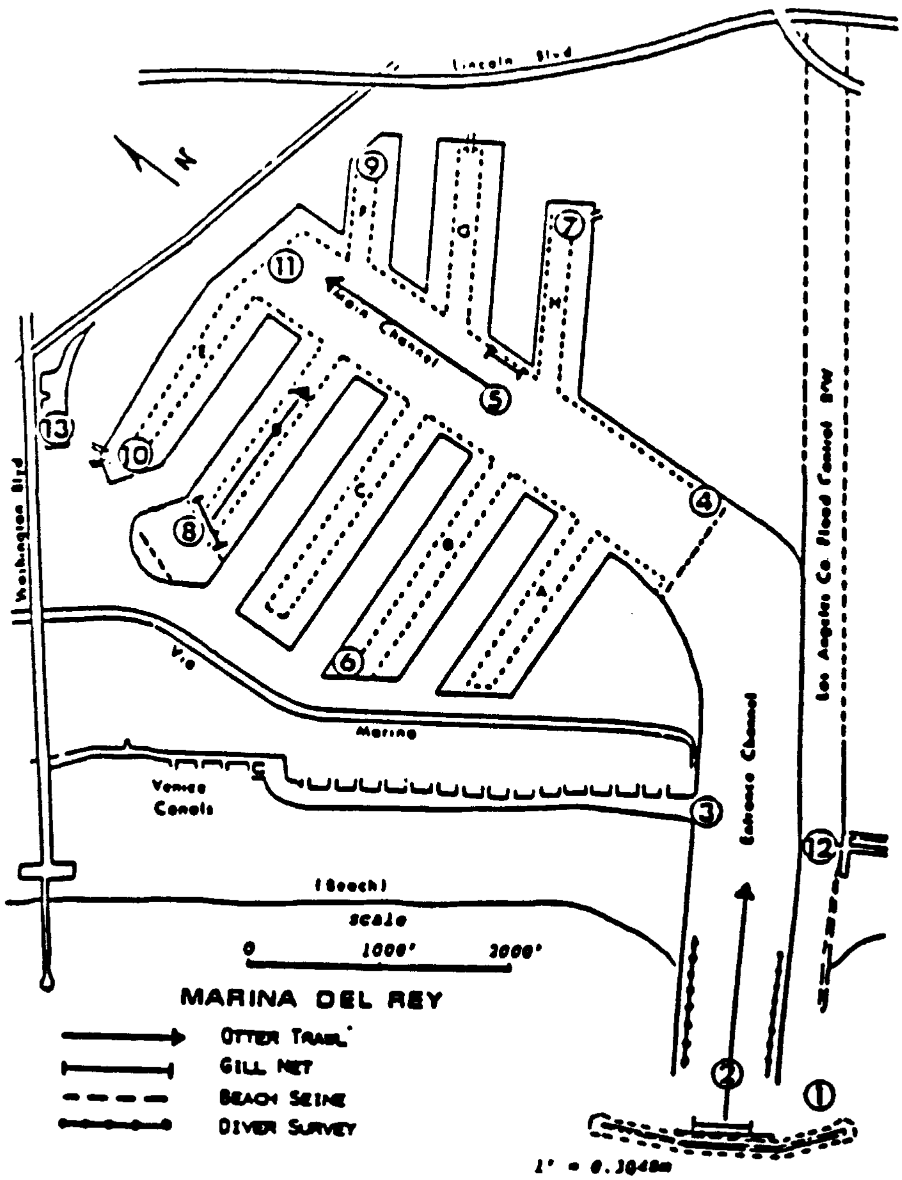

Figure 174. Fish Sampling Stations for Marina del Rey

VOL 12

1 9294

seine is deployed in 8 ft of water about 30 yds from the beach in Basin D near Station 8 and fished to the beach. Diver surveys are performed at the entrance breakwater and along the entrance jetties. Ichthyoplankton (eggs and larvae) are collected by towing a 333um mesh plankton net at 1 m depth for two minutes and on the bottom for three minutes.

RESULTS AND DISCUSSION

11 October 1989

A total of 35 species were identified in the October 1989 survey: 22 from diver observations, 7 from beach seines, 8 from otter trawls, 2 from gill nets and 3 from ichthyoplankton samples of eggs and larvae. This is five less than the total of 39 species in the October 1988 collection, and the lowest total for an autumn collection (Table 31); there were only 33 species in the May 1988 survey, the lowest total of all surveys.

Diver surveys in October 1989 identified the most species of all the sampling techniques, as has been usual in past surveys. The number of species in both the gill nets and ichthyoplankton collections were low, as they were in May 1989. Similarly the yield of these two techniques were at the lowest levels of all autumn collections.

Once again the total numbers of fish collected were predominantly due to the *Atherinops affinis* collected in the beach seine (Table 32). October ichthyoplankton results are presented in Table 33. Numbers of ichthyoplankton were very low, totaling 151, which was similar to the low in 1986.

The gobies *Clevelandia ios* and *Quietula y-cauda* returned to the beach seine station, but not in large numbers (Table 34). Those species were absent in October surveys in 1978 and 1988, and *Quietula* was also missing in May 1989. Both were missing in October of 1984 and 1985 as well, and

S = surface B = bottom

these were all periods of warmer waters (See Physical Water Quality).

The October 1989 reduction in total number of species, especially those from gill net and ichthyoplankton samples, suggests a decline in conditions within inner Marina del Rey. This might be linked to the PCB Aroclor 1260 drainage into the inner end of the Marina, possibly from land development to the north in the City of Los Angeles, sometime between October 1988 and October 1989.

Conversely, the diver surveys showed a healthy fish population at the mouth of the harbor with many juvenile fish present. Also, the top smelt population from the inner harbor contained many young of the year.

17-18 May 1990

In the spring survey conducted on 17-18 May, 1990, 38 species were identified: 13 from diver observations, 8 from beach seines, 12 from otter trawls, 2 from gill nets and 14 from ichthyoplankton samples of eggs and larvae. The total is 5 less than in the spring of 1989 (Table 31) and it is below the 41.6 mean (Standard Deviation = 5.73) for previous spring surveys. The mean of 41.6 is below the projected equilibrium number of 46 species calculated for an embayment of Marina size by Horn and Allen (1976).

The only method of sampling that produced a drop in species numbers in the 1990 spring survey was the diver transects, which dropped by 9 species, to 13 from 22 in May 1989. This may have been the result of a low tide (-0.4) which was ebbing, causing a strong current along the north and south points at the Marina mouth, very poor visibility, and reduced substrate availability.

Based upon diver observations at the entrance, the Marina would have been considered in very poor condition, but it was, at least in part, the result of poor sampling conditions rather than environmental deterioration. With respect to the rest of the survey, species numbers per sampling technique were relatively good, but gill netting has been poor since 1988. This could possibly be related to the PCB spillage or drainage into the Marina sometime between October 1988 and October 1989.

The total fish abundance, 3,846 individuals, was almost three times the numbers of last spring (1,327) but a little more than a quarter of the May 1988 total of 14,295 (Table 32). However, these numbers are not necessarily related to the abundance within Marina del Rey, but are almost directly proportional to the amount of smelt, *Atherinops affinis* and *Atherinopsis californiensis*, caught each year. Excluding the smelt, abundance of other species has remained relatively stable.

Importantly, the gobies *Ilypnus gilberti* and *Quietula y-cauda* have returned to the beach seine station at the end of Basin D. Their absence in May 1989 may have been a reflection of the collapse of the biota in this area of Marina del Rey due to disruption of the sea grass habitat when a bubbler was used in an attempt to reduce swim beach coliform counts. *Ilypnus* and *Quietula* were absent in October surveys in 1985, 1987 and 1988. *Typhlogobius californiensis* reappeared in the Station 2 ichthyoplankton sample after being absent since May 1986.

The May 1990 fish abundance data are summarized in Table 35 for beach seine, gill net and otter trawl while ichthyoplankton abundance data are presented in Table 36. Gill net results were considerably better than in any previous year, indicating recovery of the beach area. A survey of the sea grass bed of *Ruppia maritima* in Basin D in March 1990 was made by Domenic Gregorio which showed a very patchy bed below mean lower low water outside the swimming beach safety line from the south end to beyond the handicapped ramp. This is good habitat for small forage fish and juveniles.

LONG TERM RECORDS

In all, 95 species or taxa have been reported in the total surveys conducted since 1977, as is illustrated in Table 37 by sampling period. There were three additions to the list in May 1990, all larvae: Clinidae A, *Oxylebius pictus*, and Sciaenidae complex 2. *Oxylebius pictus* is a cold water species and its temperature preference is below that generally found in Marina del Rey. The one *Oxylebius pictus* was collected at Station 8, although it is possible that it was spawned elsewhere.

Twelve species have occurred in all of the spring surveys since 1984. Of these, *Mugil cephalus* (striped mullet) remains uncommon in the Southern California Bight. This makes it an important resident of the marina. Only one fish, *Halichoeres semicinctus* (rock wrasse) which has appeared in all of the surveys since 1984 was not found this year, and *Sardinops sagax* (Pacific sardine) which had been present since 1984 has not appeared since May 1989. *Halichoeres semicinctus* adults have been observed on the diver transects. If their larvae were to be found, then it would be during the fall survey. *Sardinops sagax* is a pelagic fish and its absence from the Marina may be significant to the Bight, but not necessarily related to the health of the Marina.

CONCLUSIONS

The mean number of species for all surveys since 1976 is 40, with a range of variation between 33 and 47. The mean in 1989-90 was 36.5. The Marina appeared to be in stable condition in October 1989 and May 1990, recognizing that the larger numbers are most likely to appear in May than in October. Very large numbers of individuals reflect the presence of smelt, which move in and out of the Marina and serve as forage fish for the numerous birds and larger fish in coastal waters.

The mouth of the Marina appeared to be in poor condition in May 1990, but this may have been the result of a strong ebbing minus tide, resulting in a lower total number of species. However, the beach seine station appeared to be healthier, with the reappearance of the gobies. This is encouraging, since a PCB Araclor 1260 spillage or drainage into the inner end of the Marina sometime between October 1988 and October 1990 created cause for alarm and may have inhibited those fish normally caught in the gill net. More frequent sampling would have been needed to determine whether there was a true trend. Aroclors are known to be toxic to larvae, but since the fish populations are so linked to smelt, no conclusion can be made on numbers of individuals. PCBs sometimes create an oily sheen on the water, which may keep pelagic fish away from an area.

Although otter trawl catch since 1984 has not approached the numbers caught in the 1970s, it peaked in the 1988 surveys and has since shown moderately stable levels. Marina del Rey does not appear to have deteriorated since 1984, recognizing the cyclic nature of the population, which is influenced by natural and non-natural factors

High 0807 5.6 ft

SAMPLING STATIONS: WEATHER:

Left Dock 0810 Overcast Campbell Grab

Station	Time	Depth	Procedure	Comments
12	0837		Bottom sediment coliform, metals, pesticides. Benthic org.	1st grab smells of sulfide, lots of small creatures. 2nd grab very heavy, too large to put through sieve
1	0906		Bottom sediment coliform, metals, pesticides. Benthic org.	Poor sample, sandy
2	0925		Bottom sediment coliform, metals, pesticides. Benthic org.	Lot of debris, strong sulfide odor, oily
3	0948		Bottom sediment coliform, metals, pesticides. Benthic org.	Very sandy, trouble sieving, large number of shells. Took 4 grabs to obtain sample
4	1020		Bottom sediment coliform, metals, pesticides. Benthic org.	Silty, lots of small crustacean and tubes
25	1040		Bottom sediment coliform, metals, pesticides. Benthic org.	Silty, very oily. Many pieces of plastic wrap
5	1115		Bottom sediment coliform, metals, pesticides. Benthic org.	Black, silty mud

VOL 12

1935

CRUISE: 12 October 1989 cont.

Station	Time	Depth	Procedure	Comments
6	1135		Bottom sediment coliform, metals, pesticides. Benthic org.	Black, silty - lots of worms
8	1205		Bottom sediment coliform, metals, pesticides. Benthic org.	Strong sulfide smell Black, silty mud
10	1250		Bottom sediment coliform, metals, pesticides. Benthic org.	Black, silty mud
11	1328		Bottom sediment coliform, metals, pesticides. Benthic org.	Black, silty mud
9	1343		Bottom sediment coliform, metals, pesticides. Benthic org.	Black, silty mud
7	1417		Bottom sediment coliform, metals, pesticides. Benthic org.	Black, silty mud
13	1424		East end Oxford Flood Control	Chemistry only Hand sampled from shore

CHEMICAL CONTAMINANT RELEASES INTO SANTA MONICA BAY

I. THE NEED FOR AN ADVOCACY MODEL BASED UPON EMPIRICAL SCIENTIFIC RESEARCH

Modern lifestyles are replete with and have been dependent upon the use of toxic chemicals harmful to both the environment and human life. In the United States alone, petroleum products, synthetic food additives, pesticides, plastics and other chemicals are marketed at a rate currently estimated at a thousand new chemical compounds a year.[1] Indeed, between 1950 and 1985 the annual production of synthetic, organic chemicals in the United States increased ninefold from 24 billion to 225 billion pounds.[2] Toxicants are ubiquitous and have been integrated into our society's economy and environment.

American Oceans Campaign believes that toxic contamination of the marine environment poses a serious threat to both the ecosystem and to human health. It is estimated that approximately 25 million gallons of untreated runoff flows into Santa Monica Bay every day. The flow of runoff increases to ten billion gallons a day during a rainstorm.[3] However, there has been relatively little empirical data and modeling done to develop applicable standards to assess the risk which these compounds pose to both human health and the ecosystem.

This pilot study, funded by Environment Now, the City of Santa Monica, the Santa Monica Bay Restoration Project, and American Oceans Campaign, and carried out by preeminent research scientists from the UCLA School of Public Health,[4] represents not only a unique public/private partnership but a model for the future, particularly relevant to solving environmental problems. All too often, environmental laws and policies are promulgated in a political vacuum either without science or without using scientific data specifically developed in relationship to the policy in question. Such an ad hoc approach routinely avoids setting adequate environmental policies, regulations and guidelines based upon empirical scientific evidence.

This study focuses on the chemical composition of hazardous effluent to Santa Monica Bay through the storm drain system in Los Angeles County. A parallel study which addressed the aquatic toxicity study of dry weather flow was performed at the same time with funding from the Santa Monica Bay Restoration Project. Their report will soon be available. By releasing the results of this study, American Oceans Campaign hopes to create a decision making process capable of responding to environmental threats by giving policymakers empirical scientific evidence that defines the nature of the environmental threat and creates a basis for formulating practical solutions.

II. TOXIC CHEMICALS ROUTINELY ENTER SANTA MONICA BAY THROUGH STORM DRAIN RUNOFF, WHICH IS CAUSE FOR CONCERN.

There are approximately sixty storm drains which flow into Santa Monica Bay. The vast majority of these storm drains are artificially created, with the exception of Malibu and Topanga Creeks which are naturally flowing discharge channels into the Bay. These natural creeks, act like rivers flowing into estuaries or other receiving waters.

A wide variety of chemical substances, as well as heavy metals[5] and pathogens (bacteria and viruses),[6] enter the Bay through the storm drain system. Limited studies have begun to identify those toxic chemicals which routinely enter Santa Monica Bay through storm drain runoff.[7]

This study, designed to become a part of existing literature identifying pollutants entering the Bay sampled effluent from the following five storm drains: Pico-Kenter, Ashland, Sepulveda Channel, Ballona Creek, and Centinela. These storm drains were specifically chosen because they were examples of highest flow areas, previously studied areas with existing background data and good comparisons of small and large drains. Water samples from all five drains were collected over a six month period. An analysis of these samples identified a soup of approximately 160 toxic chemicals entering the Bay through the storm drains. Some of these chemicals bioaccumulate (build up in the bodies of living organisms). Some of these chemicals are carcinogens, some are reproductive toxicants, and others are known or suspected to have acute or chronic toxicity. While this is obviously cause for concern, and while these findings unequivocally suggest that swimmers, waders, and people fishing in the Bay stay out of the storm drains themselves and away from the mouth of drains which discharge into the Bay, it was beyond the scope of this study to actually quantify the risks to either human health or the ecology of the Bay. Additional studies therefore will be needed to assess these risks.

To date, the bulk of pollution control efforts throughout the Santa Monica Bay region have focused on point source reduction from industrial and sewage wastewater treatment plants. Efforts to control storm drain runoff have not been given adequate attention both due to the diffuse nature of the problem and the expense associated with toxic testing. Yet, as this study shows, there are very real stormwater risks to both users of the Bay and the ecology itself which must be evaluated and quantified if we are to properly inform our citizens and protect Santa Monica Bay.

VOL 12

III. TOXICANTS IDENTIFIED BY THE STUDY

Because of the limited scope of this study, a protocol was designed to evaluate some of the most serious chemical compounds--carcinogens, reproductive toxicants, and other acute toxicants. The study demonstrated that many of the compounds identified are in fact carcinogens, probable carcinogens, possible carcinogens, reproductive toxicants and compounds having chronic and acute toxicity that are capable of absorption through dermal contact as well as by inhalation or ingestion. Chemical contamination was found in samples from all five storm drains in this study.

A minimum of 50 trace organic compounds were identified in each storm drain tested (with over 120 compounds found at the Ashland storm drain). Compounds found with toxicologic significance were polycyclic aromatic hydrocarbons (PAHs), phthalates, polychlorinated biphenyls (PCBs), chlorinated pesticides, chlorinated hydrocarbons, phenols, and other carcinogenic organic compounds and organophosphate pesticides. In addition, 33 volatile organic compounds were found in the effluent from all five storm drains.

In this study references are made to the California Ocean Plan and to Drinking Water Standards promulgated by the U. S. Environmental Protection Agency (EPA). These references are used for comparison's sake as indicators of potential problem pollutants. The study found significant levels of toxicants in excess of California Ocean Plan Standards in all five storm drains sampled. The study also found levels of methylene chloride, bis(2-ethylhexyl)phthalate and benzo(a)pyrene in excess of EPA Drinking Water Standards.

The chemicals identified by this study enter the body through two pathways: dermal absorption (through the skin) and bioaccumulation (through the food chain, i.e. eating fish and shellfish).

The California Ocean Plan was designed to provide water quality standards to protect human health and enjoyment and preserve aquatic ecosystems in ocean waters. Because many of our storm drains discharge directly across our beaches and people swim or wade in this runoff, the California Ocean Plan should be applied to storm drain effluent as well as point source discharges.

A. POLYCYCLIC AROMATIC HYDROCARBONS (PAHs)

Seventeen PAHs in excess of California Ocean Plan standards[8] were identified in all five storm drains studied. Seven of the PAHs, five of which were found in all five storm drains,[9] are identified as carcinogens under California's Proposition 65[10] and are listed as possible carcinogens by EPA.

1 940

PAHs are not derived from point sources. They represent products of an urban society which emphasizes the use of petroleum-based transport. They are often products of incomplete combustion and are found throughout the environment. They may emanate from exhaust, tires, used motor oil, or other transport-related processes, as well as from industrial sources, and outdoor barbecues, all of which create products of incomplete combustion.

The greatest concentration of PAHs found at Sepulveda were the benzo(a)pyrene, chrysene, and pyrene concentrations (all 3 of which are carcinogenic), which were 1,803 ng/l, 2,016 ng/l and 956 ng/l, respectively. These numbers can be compared to California Ocean Plan standards which seek to limit PAH concentrations to 8.8 ng/L

The primary health risk associated with PAHs in the water would probably derive from dermal contact. The carcinogenicity of this class of compounds was originally recognized as a result of studies which focused on dermal contact. Although the scope of PAHs sampled in this study was limited, it is reasonable to believe that other more potent PAHs (6-nitrochrysene an order of magnitude more potent than benzo(a)pyrene, dibenzopyrenes approximately 10 times more potent carcinogens than benzo(a)pyrene) may also be present in Santa Monica Bay storm drains. Because PAHs are potent toxicants, their presence in all five storm drains is cause for significant concern.

B. POLYCHLORINATED BIPHENYLS (PCBs)

PCBs were identified in all the storm drains studied, although the highest concentrations were found at the Ashland site. PCBs are found in aerosols and the ambient air. They are used for insulation purposes (in transformers) and they are virtually indestructible in the environment. They also bioaccumulate in living systems. The California Ocean Plan standard for PCBs is 0.019 ng/l. Many of the PCBs identified in this study exceed that value by a factor greater than 1000. (The total PCBs found in the Ashland drain were 451 ng/l; assuming a background of approximately 125 ng/l, the concentration of identified PCBs is approximately 325 ng/l, which is 17,000 times the California Ocean Plan limit.)

PCBs are listed as chemicals known to cause cancer and reproductive toxicity under Proposition 65. PCBs are considered probable carcinogens by EPA[11] and the International Agency for Research on Cancer (IARC). PCBs can enter the body through dermal contact. PCBs also bioaccumulate in the environment. Bioaccumulation through the food chain may represent the most important route of exposure to humans of PCBs. PCBs will concentrate in fish and other sea life and the risk associated with ingestion will increase as bioaccumulation occurs. The existence of PCBs in the studied storm drains is one of the <u>most</u> important discoveries of the study and is a serious concern to both humans and the ecology of Santa Monica Bay.

C. PESTICIDES

The finding of pesticides in the storm drains represents an important element of the study. Chlorinated pesticides, like PCBs, are very toxic, persistent and bioaccumulate in the environment.

The organophosphate pesticide diazinon was identified in water from Centinela, Ashland, and Pico-Kenter, while dimethoate was found at Ballona. (These are commonly used pesticides, and it is not surprising that they were identified.) Their persistence in the environment is a matter of concern and an area for further study.

The finding of alpha-chlordane, (at all five sites) and dieldrin (Pico-Kenter) represents an important finding in this study. These substances are of particular significance because of their potential toxicity, persistence, and potential for bioaccumulation in the environment. Chlordane is considered a possible carcinogen by IARC.[12] Chlordane and dieldrin are listed as carcinogens under Proposition 65 in California.

D. OTHER TOXICANTS IDENTIFIED BY THE STUDY

1. Phthalates

Six Phthalates[13] were present in the storm drain effluent from all five sites. Phthalates are widely used in industrial applications . They exist wherever plastics are found. They are generally considered ubiquitous contaminants, and are recognized to be laboratory contaminants as well. The phthalates present as laboratory contaminants were accounted for by analyzing appropriate controls.[14]

The most important compound identified was bis(2-ethylhexyl)phthalate (DEHP). DEHP is classified as a carcinogen and reproductive toxicant under California Proposition 65. It is also classified as a probable human carcinogen by the U.S. EPA and IARC. It is considered a chemical teratogen and may damage the testes. Repeated exposure may also result in neurological consequences. It has acute toxicity and produces irritation of the eyes, nose and throat. Exposure to DEHP can occur through inhalation, ingestion or dermal contact. The maximum contaminate level (MCL) established for DEHP in drinking water by EPA is 4 parts per billion (ppb). The California Ocean Plan limit is 3.5 ppb. The average concentration found for DEHP in this study was 6.6 ppb. The greatest concentration, 14.8 ppb, was found at Ashland, and the lowest concentration was found at Sepulveda. Because of their toxicity and potential impact to humans through dermal absorption, the presence of phthalates found in all five storm drains is significant.

2. Phenols

Seven phenols were identified as being present in the storm drain effluent in this study. Phenols are benzene derivatives which possess acute toxicity and there is evidence of some having chronic effects. Phenol and 2-nitrophenol were found at all five sites, 4-methyl phenyl was found at three sites. 4-chloro-3-methyl phenol, 2-methyl phenol, 4-nitrophenol, and 2,4-dimethyl phenol were found at one site.

2-methyl phenol is classified as a possible human carcinogen by EPA. There is evidence from animal studies of reproductive toxicity associated with exposure to phenols, and phenol is classified as a reproductive toxicant under Proposition 65. The presence of these compounds in Santa Monica Bay storm drains is a matter requiring further evaluation to assess the impact on both the ecology of the Bay and human health.

3. Other Carcinogens Identified

Two probable human carcinogens, azobenene, and 1,4-dichlorobenzene were identified at all five sites. N-nitrosodiphenylamine and N-nitrosodin-propylamine were present at three sites. These compounds are considered to be carcinogens under Proposition 65 and are classified by EPA as probable human carcinogens They were found in trace quantities and further study will be required to evaluate their continued presence.

4. Volatile Organic Compounds (VOCs)

Thirty-three volatile organic compounds were found in the effluent from the five sampled storm drains.[15] VOCs are low molecular weight hydrocarbons, aromatics and chlorinated hydrocarbons. VOCs were included in the study because they are found in solvents routinely used in dry cleaning and common household functions. A number of VOCs recognized as being potential human carcinogens or reproductive toxicants were identified in all five storm drains. All these are capable of absorption through dermal contact, as well as by inhalation or ingestion. The identified compounds; benzene, bromochloromethane, bromodichloromethane, bromoform, chloroform, 1,1-dichloroethane, 1,2-dichloroethane, methylene chloride[16] , trichloroethylene, and perchloroethylene are classified as chemicals known to cause cancer under Proposition 65. The concentration of VOCs, however, was low in relation to the other identified toxic contaminants, thereby failing to indicate evidence of illicit dumping.

VOL 12

5. The Chemical Soup

A myriad of other, yet to be analyzed, chemicals were present in the water samples studied.[17] Preliminary research indicates that some of the compounds in this chemical soup may be traceable to illegal dumping.[18] These chemicals need to be quantified and evaluated for toxicity before the risk to human health and the ecology can be properly assessed.

IV. RECOMMENDATIONS

A. THE NEED FOR FOLLOW UP STUDIES

This study evaluated dry weather flow of organic toxicants. In order to provide a basis to assess the potential health and ecologic risks associated with urban runoff into the Santa Monica Bay several other studies must be conducted.

1. Expanding the Scope of this Study to Include Wet Weather and Dry Weather Flows
