Thirteen of the 14 pesticide samples analyzed by both staff and the certified laboratory, were negative for all analyzed pesticides. Sample 284A was determined by the contract lab to contain Endosulfan Sulfate at their detection limit of 100 PPTr. Since the staff analysis did not detect this pesticide at 20 ng/L, the certified lab was requested to verify the analysis and send copy of the pertinent chromatograms. While the detection was "confirmed" by the certified lab, the project QA officer's review of the chromatograms found a false positive. This determination is based on the pre- and post-sample standard injections of Endosulfan sulfate which had a retention time of 23.03 minutes, while the suspect sample peak was observed at 22.93 minutes. As shown in table A8, 3 spiked samples were shipped to the certified lab, with their mean recovery being comparable to those observed by project staff (table A7).

As proposed in the project quality assurance plan, laboratory control standards were utilized to verify the analytical results for the analysis of purgeable compounds. The mean, standard deviation and range of recoveries, were all well within the EPA 624 method acceptance criteria and shown in table A9, with a comparison to the results obtained during this study. Because of the difficulty in reliable spiking low concentrations of purgeable compounds, no spiked samples were prepared for the certified laboratory.

Table A9. EVALUATION OF PURGEABLE LABORATORY CONTROL STANDARDS. Results taken from 3 samples (n=3) and are given in µg/L (PPB).

As with the other major analyses, the method 625 semi-volatile or extractable analysis was initiated using EPA Water Pollution Quality Control Samples spiked into duplicate field collected samples at the designated concentration of 100 µg/L (PPB). Three spiked samples were prepared using both GC/MS Base Neutral II (Lot WP586) and GC/MS Acids (Phenols) (Lot GAC489). As shown in tables A10 the mean and standard deviation were well within the reported acceptance criteria for all compounds except 2-Methyl-4,6-dinitrophenol, which appears to be due to a typographical error since the standard deviation (S=93.2) is twice the range of the mean (53-100). It should also be noted that combining, and simultaneously analyzing, the base neutral and acid extracts, a method modification used during this project, produced no discernable analytical artifacts, even with the vary concentrated spiked quality control samples.

During the second phase of the quality control assessment, three duplicate samples were spiked with all of the method 625 analytes, at either 20 or 40 µg/L. The resulting values were multiplied by 5 or 2.5 respectively and compared to method acceptance criteria, which are based on the spiking of laboratory water at 100 µg/L, and are presented in tables A11. As previously suggested, 2-Methyl-4,6-dinitrophenol appears to exceed criteria due to a typographical error. Three other compounds, 2-Chloronaphthalene, Hexachlorobenzene, and 2,4,6-Trichlorophenol, are slightly out of acceptance criteria for the standard deviation.

Table A10 contd. EVALUATION OF HIGH CONCENTRATION SEMI-VOLATILE QUALITY CONTROL STANDARDS. Results from 3 samples and are in µg/L.

Analyte	Acceptance Criteria		Project Results	
	Range of Mean	S	Mean	S
Nitrobenzene	54.3-157.6	39.3	90	4.1
2-Nitrophenol	45.0-166.7	35.2	113	6.4
4-Nitrophenol	13.0-160.5	47.2	113	8.0
Pentachlorophenol	38.1-151.8	48.9	100	2.2
Phenol	16.6-100.0	22.6	50	1.22
2,4,6-Trichlorophenol	52.4-129.2	31.7	111	1.24

Given that acceptance criteria are normally based on 7 laboratory water extractions at higher concentrations, these variances do not warrant concern. Finally, sample 200A was collected in duplicate and both were spiked with 40 µg/L. They were then analyzed by either staff or the certified laboratory. The results are given in tables A12 and show a general agreement at levels above the CLP detection limits of 10 to 50 PPB. Sample 260A was analyzed by the contract laboratory and reported to contain 2-methyl phenol (o-Creosol) at 19 µg/L, while a duplicate analyzed by staff did not confirm the finding. The QA officers review of the contract labs analysis concurs with their findings. Since the two labs were in disagreement, only the staffs findings were reported in the report. However if this value had been included, the most significant change would have been in the total maximum value of phenols, which would have risen to 34 PPB while the Ocean Plan standard, with 5:1 dilution, is 150.

The quality assurance and quality control for the resin accumulation and ames assays were undertaken by staff under the direction of Dr. J. Froines. They generally followed EPA protocols and utilized blanks and controls. Further information on the specific efforts and results of those efforts can be obtained by contacting the author or Dr. Froines of the University of California at Los Angeles, School of Public Health.

A major emphasis of this study, was the estimation of bacterial numbers. All of the bacterial densities are expressed in terms of the most probable number per 100 ml of water. While some of the certified laboratory analyses actually used a membrane filtration method (primarily the enterococcus analyses), the distinction is irrelevant for the purposes of analyzing the results. Routine quality control followed the recommendations of the manufacturer Environetics (formerly Access Analytical), and included weekly culturing of Pseudomonas aeruginosa (a non coliform organism), the total coliform bacteria Klebsiella pneumoniae, and the primary fecal coliform microbe Escherichia coli.

During the project, 48 influent/effluent pairs were analyzed by both project staff and the contract laboratory for both total and fecal coliform organisms. The contract lab also analyzed their 48 pairs for fecal streptococcus as shown in table A13. Thus, 192 pair-wise comparisons can be made between the staff and contract laboratory analyses. Early in the study (see sample #173-175), the project QA officer became disturbed with discrepancies in the outcomes of these comparisons. Initially, the contract laboratory responded by adding additional blue ice to further chill the samples or by supplying more sturdy sample collection containers. However, these changes were generally short lived and even with frequent remainders from the QA officer, shortages occurred.

In order to define the source of these errors, EPA Microbiological Quality Control Samples were utilized. The Escherichia coli (lot series 121589), or fecal coliform, sample was diluted 1:99, then 7 sterile dilution bottles were inoculated with 1 ml from the first dilution bottle. Two of these seven were analyzed by each of the three staff members who performed the bulk of the bacterial analyses. The remaining seventh bottle was then poured into the whirl bag sample container and shipped to the certified laboratory marked as a spiked sample (300AS1). The analysis for total coliform was conducted using a Klebsiella pneumoniae quality control sample (lot series 060989) prepare in an identical fashion and marked as sample 300AS2. For both analyses the staff samples were all well within the 95% confidence interval for MMO-MUG type analyses. In the case of total coliforms, the staff mean was 490,000 organisms per 100 ml, compared to the EPA mean reported value of 510,000. The sample analyzed by the contract lab was reported to contain 2,400,000 organisms per 100 ml, and was outside of the 95% confidence interval. The results for fecal coliform were similar. The mean staff MPN was 320,000, with all enumeration in 95% confidence interval, while the EPA mean was 350,000 organisms per 100 ml. The certified laboratory analysis returned a value of 70,000 and was outside of the acceptance criteria confidence interval. It was also noted that after these results were reported back to the contract lab, the remaining analyses (sample numbers ≥310) more closely correlated with the results obtained by staff.

333B	11,000	790	240	330	1,700

* Sample 300AS1 is the mean of 540,000; 170,000; 240,000; 240,000; 540,000; & 170,000. EPA mean is 350,000; 95% CI 1,100,000-110,000.
** Sample 300AS2 is the mean of 920,000; 350,000; 170,000; 240,000; 1,100,000 & 170,000. EPA mean is 510,000; 95% CI 1,400,000-130,000.

In summary, all of the analyses in the Quality Assurance Plan were carefully evaluated to insure the quality of the results. Most of the analyses and analysts demonstrated their competence through the use of EPA Water Quality Control Samples. While any individual analysis maybe outside of the 95% confidence interval around the true value, there is no indication of any bias or significant inaccuracy. The data acquired by the project staff is of generally excellent quality and many of the primary conclusions of the study would not have been possible without the conscientious efforts of each analyst individually, and more importantly, as an analytical team.

OZONE DISINFECTION AND TREATMENT OF
URBAN STORM DRAIN DRY-WEATHER FLOWS

A PILOT TREATMENT PLANT DEMONSTRATION PROJECT ON THE KENTER CANYON STORM
DRAIN SYSTEM IN SANTA MONICA

TECHNICAL AND DATA APPENDICES

APPENDIX C

GLOSSARY

VOL 12

15824

Base Flow See Dry-weather Flow.

By-products Incidental products (chemicals) that are formed during a process, such as water disinfection, many of which are undesirable, but difficult to prevent from being formed.

Chlordane A technical (commercial) grade of chlorinated pesticide which contains many similar compounds that vary slightly in the number and placement of chlorines. Included in the mixture is heptachlor a pesticide that is sold in a more pure form. Chlordane was a popular and widely available pesticide for use in foundations for the control of ants and termites. Over the last 20 years it use has become more restricted and is now unavailable for use in the United States.

Chlorine Chlorine gas has been widely used for destroying disease causing organisms and can be credited with preventing many human epidemics. Recent studies have shown that it also generates many hazardous by-products. In this report chlorine disinfection refers to treatment by chlorine gas, chloramines, chlorine dioxide and other similar treatment compounds.

Coliform A group of bacteria that ferment lactose (milk sugar) and includes several genera in the Enterobacteriaceae family, such as Arizona, Citrobacter, Enterobacter, Escherichia, and Klebsiella. While some genera are found in animal intestines, many are also found free-living in soils and other media. For decades, total coliform organism counts have been used as an indicator of the effectiveness of disinfection of drinking water.

Dilution See Initial Dilution.

Disinfection A term originally used to describe methods used to remove or inactivate infectious or disease causing organisms, but also used to refer to the control of microscopic organisms in general.

Dry-weather Flow The flow observed from storm drains during the dry season and several days after storms. While the relative source contributions varies significantly, the flow is assumed to be composed of infiltration (leaks into the storm drain from groundwater or septic systems), runoff from lawns and other residential sources (pools, car washing, etc.), NPDES permitted facilities, and illegal floor drains, maintenance activities, and sewer connections. Many other sources have been observed.

Enteric virus As used here, see Human Enteric Virus.

VOL 12

1 5825

<u>Enterococcus bacteria</u> A subset of <u>Streptococcus</u> bacteria including S. <u>fecallis</u>, S. <u>faecium</u>, S. <u>avium</u>, S. <u>bovis</u>, S. <u>equnius</u>, and S. <u>gallunarum</u>, which have been isolated from the feces of mammals and birds.

<u>Fecal Coliform</u> A subset of the Coliform bacteria group, characterized by the ability to ferment lactose at elevated temperatures (> 39°C). <u>Escherichia coli</u> and some strains of <u>Klebsiella</u> make up this group and the former is commonly found in mammalian and avian feces. While generally a beneficial constituent of the human intestinal tract, the presence of fecal coliform in water maybe an indicator of sewage contamination and the presence of pathogenic (disease-causing) organisms.

<u>F-male Specific Coliphage</u> A virus that attacks and replicates exclusively in a specific (F-male) type of Coliform bacteria. Coliphage are indicative of fecal contamination and may be a good indicator of chlorine disinfection efficacy.

<u>Geometric</u> As used here, this refers to a statistical method whereby the logarithmic value (base 10) is calculated and used to estimate the mean and standard deviation. This method, which is commonly applied in bacteriology and to a lesser degree in environmental analysis, acts to reduce the statistical effect of unusually high events (spills) on the overall mean and standard deviation.

<u>Halogenated Compounds</u> Chemicals that contain Chlorine, Bromine, Fluorine or Iodine. Many are biologically hazardous.

<u>Heptachlor</u> A chlorinated pesticide that is available in a relatively pure form and found in pesticide mixtures such as Chlordane.

<u>Human Enteric Virus</u> Any virus found to replicate in humans and be present in the human digestive system. Many types are pathogenic (disease-causing) in humans.

<u>Humic Acids</u> Colloidal organic material derived from decomposing plant and animal matter. It often induces a brown color when dispersed in water and can exert a significant disinfectant demand during disinfection. Humic and Fulvic matter are believed to be significant sources of mutagen precursors in chlorinated water.

<u>Initial Dilution</u> is the process which results in the rapid and irreversible turbulent mixing of wastewater with ocean water around the point of discharge.

<u>Mutagens</u> Chemicals and processes that cause a change or mutation in the genome (DNA) of an organism. Some mutagens are also carcinogens, causing mutations that disrupt normally cellular growth and result in the rapidly cellular proliferation generically referred to as a cancer.

VOL 12

1 5827 L

NTU National Turbidity Units. A standardized scale based on the ability of matter in water to scatter incident light at a ninety degree angle. Comparable to Formazin or Jackson Turbidity Units (FTU or JTU).

O-xylene (1,2-Dimethyl Benzene) is present in gasoline and may be used as a solvent, but is less hazardous than benzene.

Ozone is a gas composed of three atoms of oxygen, while the oxygen humans breathe consists of only two atoms. Simplistically, ozone tends to "degrade" back to molecular oxygen, but the third oxygen atom may react with other compounds, especially organics with double bonded carbons. This process effectively attacks microbial membranes and kills the organism (bacteria).

PAH's or **PNAH's** are Polynuclear Aromatic Hydrocarbons and are essentially compounds containing multiple (commonly 3-5) benzene rings (6-carbons forming a ring with each carbon bonded to a hydrogen and the adjacent carbons). Benzene and many of the PAH's have been identified as mutagens and are likely carcinogens. They are formed during combustion processes and have been associated with soot and particulates from diesel engines among other sources. The list of compounds included in "Total PAH's" varies among regulators and analysts and care should be taken in making comparisons among different sources.

Pathogen An organism (normally microscopic) that cause diseases in other organisms (generally vertebrates and commonly humans).

Polio and **Polio virus** The common name and causative agent of the disease Poliomyelitis which is characterized by inflammation of brain stem and spine and results in loss of muscle control or death. During this study noninfectious or vaccine type polio virus were used to investigate disinfection efficiency.

TOC or **Total Organic Carbon** refers to an analytical chemical method to detect carbon atoms from sources that were of biologic (living) sources. This would include carbon from oil and hydrocarbon fuels such as gasoline

Total Coliform See Coliform.

Water Reclamation The treatment, transportation, and use of wastewater for a direct beneficial or controlled use that would not otherwise occur. While not technically a wastewater, storm drain dry-weather flows can exhibit many of the same undesirable qualities.

Wet-Weather Flows The relatively high flows from storm drains that occur during and after storms as water is conveyed away from areas in the upstream areas.

Foreword

Coping with a third consecutive dry year and studying ways to meet increasing future water demands were Metropolitan's primary concerns during fiscal year 1988-89. Although new water supplies were secured, analyses still indicated potential problems in the next century.

By augmenting dependable supplies of Colorado River water (CRW), Metropolitan improved long-term water reserves for Southern California's urban coastal zone. At mid-fiscal year, Metropolitan entered into an historic agreement with Imperial Irrigation District (Imperial), creating a $237-million water conservation program. The innovative water-saving program will improve Imperial's irrigation efficiency and supplement Southern California's future CRW supplies.

Under the agreement with Imperial, Metropolitan will pay Imperial about $92 million to build conservation facilities near the Salton Sea, while another $23 million will cover Imperial's indirect costs such as the loss of hydroelectric revenues. Metropolitan also will underwrite operating and maintenance costs totaling $14 million over the contract's first five years, and $3.1 million for each of the following 35 years. In return, Metropolitan gains approximately 100,000 acre-feet of conserved CRW per year, which will meet the annual water needs of approximately 1 million people. The water comes directly from the conservation program and does not impact agricultural supplies to Imperial farmers.

Another 100,000 acre-feet of water will be realized annually from lining the All-American Canal and Coachella branch of the All-American River. In October 1988, Congress approved Senate Bill 795, introduced by Senator Alan Cranston and cosponsored by Senator Pete Wilson, authorizing the canal lining. Metropolitan and other California agencies with CRW contracts will pay the costs to line the 66 miles of earthen-lined canals. Practically, however, only Metropolitan possesses the resources to cover the lining costs, estimated at $150 million to $200 million. Because only water saved through conservation will be added to the urban supply, the canal lining will not negatively affect farmers, and may indeed provide benefits through increased efficiency and reduced maintenance costs.

Additional measures to expand water supplies were pursued during the fiscal year. Metropolitan presented the results of its preliminary studies defining the need for additional reservoir storage space at a community meeting in Hemet where [illegible] potential reservoir sites are located. New reservoir capacity would permit Metropolitan to import more water during wet years.

Equally important, Metropolitan continued a wide-scale conservation campaign for Southern California's third consecutive dry year. Although Metropolitan's [illegible] were sufficient to meet Southern California's 1989 summer needs, the [illegible] population and dwindling supplies make conservation essential for the area. Among the campaign's components were an [illegible] media and public education program using television, radio and billboards; suggested local anti-waste ordinances, including landscape irrigation restrictions; distribution of plumbing fixture retrofit devices; and an expanded conservation credits program to help retail water purveyors finance water-saving projects. Metropolitan's long-term conservation goal is a savings of [illegible] acre-feet of water per year within the next 20 years.

Threats to Southern California's water reserves, however, came from the State Water Resources Control Board (SWRCB), which released a draft allocation plan in November 1988. The SWRCB plan calls for large releases of fresh water through the Sacramento-San Joaquin Delta (Delta) estuary and into the ocean to ostensibly improve fishery habitat. Currently, the Delta provides about two-thirds of California's fresh water.

If implemented, Southern California's State Water Project (SWP) deliveries from the Delta would be limited to 1985 levels in most years, despite the [illegible] population and reduced Colorado River supplies. The plan also means Southern Californians would be forced to implement stringent water [illegible] SWRCB has not shown that the region can achieve [illegible]. Metropolitan challenged the proposal and after [illegible] SWRCB withdrew the proposal and will resubmit a [illegible]. The plan concludes the first phase of hearings on the [illegible] Delta.

[illegible] the Delta plan [illegible] that it does not forthrightly advocate [illegible] that can increase water supplies and protect [illegible] even more acute in light of a Metropolitan report [illegible] $3 billion worth of new water facilities over the [illegible] September 1988, the review noted that existing [illegible] expanding and improving while new plants [illegible] reservoirs developed, and new pipelines to deliver [illegible]

The study's major findings include: population will increase 35 percent within Metropolitan's service area over the next two decades; water usage, while increasing 24 percent at the same time, will grow more slowly due to conservation and declining agricultural use; all five of Metropolitan's water treatment plants and much of its distribution system will operate at or near capacity during peak water demand periods; treatment capacity, increasing in the service area by 880 million gallons per day by the year 2000, could double to 4.5 billion gallons per day by 2030; more stringent water quality standards could reduce some treatment plants' capacities; more than 500,000 acre-feet of new reservoir will be needed by 2000, 1.1 million acre-feet by 2030, to fulfill seasonal, carryover, and emergency storage requirements; and, while Metropolitan's wholesale price of untreated water is expected to increase only slightly by 2010, its wholesale price of treated water used in homes and businesses will rise from its current $230 per acre-foot to $320 per acre-foot (in 1988 dollars).

In fiscal year 1988-89, water rates remained stable for the fourth consecutive year. By implementing its rate stabilization fund, Metropolitan's Board of Directors held rates at $197 per acre-foot and $230 per acre-foot for untreated and treated water, respectively; $153 and $186 for interruptible untreated and treated water, $591 and $624 for emergency untreated and treated water; and $84 for reclaimed water.

To finance planned improvements and expansions, Metropolitan's Board of Directors authorized a negotiated sale of $215 million in waterworks general obligation bonds, the largest issue in Metropolitan's history. Sale proceeds will be used to continue financing Metropolitan's $2.8 billion capital improvement program.

In another record year for water sales, revenues rose $32 million over last fiscal year, totaling $425 million on water deliveries of 2,095,079 acre-feet, up nine percent over last year's record deliveries. Revenues of $19 million were earned from the recovery of hydroelectric power, $1 million more than the previous fiscal year. *Ad valorem* property taxes, levied on all property within Metropolitan, earned revenues of $73 million, up $1.5 million from last fiscal year.

Secured property tax rates for fiscal year 1988-89 continued to fall slightly to 0.0110 of property value, Metropolitan's lowest rate in 54 years. These rates are in keeping with a 1984 policy calling for Metropolitan taxes to continue representing a decreasing percentage of its total revenue. Tax revenues are used to pay voter-approved debt service related to financing facilities.

CHAPTER 1

WATER SUPPLY

The Metropolitan Water District of Southern California (Metropolitan) was incorporated in 1928 to provide Southern California's coastal plain with a supplemental water supply. Municipal and industrial demand consume approximately 90 percent of Metropolitan-supplied water, with the remaining 10 percent being used for agricultural activities.

Metropolitan's service area spans 5,200 square miles, consisting of 27 member agencies: 14 cities, 12 municipal water districts, and the San Diego County Water Authority. Metropolitan currently supplies about half of the water used within its service area and is expected to deliver nearly all of the anticipated increase in future demands.

Southern California water supplies are obtained either locally or imported, vary widely from wet years to dry years, and are affected by multi-year periods of drought conditions. Metropolitan's two sources of imported water are the Colorado River Aqueduct, which diverted 1.18 million acre-feet (maf) in fiscal year 1988-89, and the State Water Project, which furnished 1.0 maf. Because of its lower cost and availability to Metropolitan, Colorado River water (CRW) continues as the primary supply source. Metropolitan's total dependable supply from the Colorado River and the State project equals only 1.65 maf per year.

Colorado River Supply

Entitlements

Metropolitan signed a contract with the United States Secretary of the Interior in the early 1930s for an allotment of 1.212 maf of CRW per year. Additionally, three California agricultural contractors signed with the Secretary, and maintain priority over Metropolitan for their CRW entitlement. In 1963, California lost a portion of its entitlement to the State of Arizona by U.S. Supreme Court decision. However, Colorado River sys[illegible] issued by the Secretary of th[illegible] Interior in 1931 [illegible] impact for 15 years. In March 1985 [illegible] Project (CAP) began supplying wat[illegible] to Arizona [illegible] from Lake Havasu. This reduce[illegible] Metropolit[illegible] supply to less than 550,000 acre-fe[illegible] per year [illegible] priority Indian and miscellaneous right[illegible] (3,000 [illegible] losses (50,000 acre-feet) further lower this [illegible] feet per year.

The Aqueduct System

The [illegible] Aqueduct was initially completed in 1941. Over th[illegible] to keep pace with increasing water needs, Metropoli[illegible] the Aqueduct to accommodate a full capacity of more than one mil[illegible] per year, which equals more than one billion gallons per day.

The Aqueduct spans 242 miles of desert and mountain ranges between its Lake Havasu intake and its terminal reservoir, Lake Mathews, near Riverside. Originally designed to convey an eight-pump flow of 1,605 cubic feet per second (cfs), the Aqueduct can actually carry flows 15 percent higher. The system currently delivers the dependable water supply as well as more than 500,000 acre-feet of surplus water when available. During the 1988-89 fiscal year, 1.2 maf of water was diverted from Lake Havasu into the Aqueduct. The average flow was 1,657 cfs, 103 percent of the Aqueduct design capacity.

To reach Metropolitan's service area, CRW rises 1,367 feet via five pumping plants. The W. P. Whitsett Pumping Plant, on Lake Havasu's western [illegible] elevates water from the lake 291 feet to Gene Wash Reser[illegible] Gene Pumping Plant raises the CRW an[illegible] Gene Reservoir to Copper Basin Reservoir [illegible] the Aq[illegible] point. The water then flows by gravity app[illegible] Iron Mountain Pumping Plant where it is ele[illegible] Mountains. Rolling another 147 miles, the [illegible] Pumping Plant which raises the water 438 [illegible] the water arrives at the Hinds Pump[illegible] plant elevates the water 441 feet [illegible] to bring the water the remaining [illegible] at Lake Mathews.

Each [illegible] pump[illegible] usly with eight pumps, a ninth [illegible] and provides additional or emer[illegible] nine-pump flow, the Aqueduct can carry [illegible] capacity, or 1,850 cfs. Because [illegible] each pump's capacity now exceeds [illegible] capacity.

Colorado River Water Supply Conditions

Colorado River runoff continued below average for a second consecutive year. End-of-year reservoir storage declined by about 3.8 maf from a year ago, reflecting the June 1 forecast of average runoff into Lake Powell of 47 percent for the April-to-July snowmelt period (Table 5).

As shown in Table 1, Lake Powell inflow reflected the drought conditions experienced in the Upper Colorado River Basin.

Table 1

Inflow to Lake Powell

(Million Acre-feet)

Inflow Source	Fiscal Year 1986-87	1987-88	1988-89
Green River at Green River, Utah	4.7	3.4	2.2
Colorado River near Cisco, Utah	7.0	3.9	2.9
San Juan River near Bluff, Utah	3.5	1.3	1.0
Miscellaneous	0.8	0.6	0.2
Total Inflow to Lake Powell	16.0	9.2	6.3

The river's gauged flow at Lees Ferry, Arizona, a few miles downstream of Lake Powell, was 7.7 maf for the fiscal year. This gauge lies just upstream of the Paria and Colorado River confluence. Downstream of the Paria is the Colorado River Compact point, where Upper Colorado River Basin releases to the Lower Basin are determined.

Releases from Lake Mead totaled 9.2 maf. CRW deliveries in the Lower Basin were 5.11 maf to California, including 1.18 maf to Metropolitan and 3.87 maf to the agencies supplying irrigation water; 2.08 maf to Arizona, 0.16 maf to Nevada; and 1.94 maf to Mexico.

Colorado River Aqueduct Power Requirements

Power required for Aqueduct pumping operations is delivered through a Metropolitan-owned transmission system consisting of 310 miles of high-voltage (230-kilovolts) power lines connecting the pumping plants to the Western Area Power Administration (WAPA) system and the Southern California Edison Company (SCE) system. WAPA's system delivers Metropolitan's power from Hoover Power Plant and the Parker Power Plant.

VOL 12 1 5 8 5 C

R0049155

TABLE 2

ELECTRIC ENERGY AVAILABLE AT HOOVER AND PARKER POWER PLANTS

Fiscal Year 1988-89

	(Kilowatt-hours)
Hoover Power Plant	
Total Hoover Energy	4 245 751 000
Total Hoover Energy Available to Metropolitan	1 231 206 000
Parker Power Plant	
Total Parker Energy	484 029 049
Total Parker Energy Available to Metropolitan	237 142 000

Total energy needed to divert the 1,185,803 acre-feet of water from Lake Havasu this fiscal year was 2.4 billion kilowatt-hours (kwh), and as shown in Table 3, the Hoover and Parker Power Plants provided 61.4 percent of the total.

To supplement the Hoover and Parker power resources, Metropolitan purchases power from different suppliers under various power contracts and agreements implemented since June 1987. Almost all of the supplemental power involved economy off-peak energy purchases: 13.5 percent were SCE purchases, and the remaining 86.5 percent came from various suppliers, including Arizona Public Services Company, Salt River Project, California Department of Water Resources (DWR) and WAPA's Navajo Project.

TABLE 3

METROPOLITAN'S ELECTRIC ENERGY USE

Fiscal Year 1988-89

Energy Source	Kilowatt-hours	Percentage of Total Energy Requirement
Hoover Power Plant	1 231 206 000	51.49
Parker Power Plant	237 142 000	9.92
Edison Benefit Energy	215 485 363	9.01
Exchange (SCE)	(27 764 000)	(1.16)
Supplemental Energy Purchases*	735 276 330	30.75
TOTAL	2 391 345 693	100.00

Note:

*Suppliers include Edison, California Department of Water Resources, Western Area Power Administration Navajo Project, Salt River Project and Arizona Public Services Company

Table 7 summarizes this fiscal year's total power costs for Aqueduct pumping operations. The composite of the supplemental power costs represents SCE's average power rate of 23.3 mills kilowatt-hour, and the other suppliers' average rate of 17.2 mills kilowatt-hour, with the difference providing substantial economic benefits. The operating conditions of the interconnected systems and the energy market usually dictate such supplemental purchases. For fiscal year 1988-89, the supplemental power cost savings totaled approximately $3.8 million.

Power Management

Boulder Canyon Project Administration

Staff attended the annual Boulder Canyon Project Contractor's meeting with WAPA and the Bureau of Reclamation (Reclamation). Items discussed included year-end Hoover energy accounting, proposed changes for administrative and operating procedures, progress on the uprating of Hoover generating units, Hoover-Mead substation consolidation, and status of the Hoover power rate and repayment studies.

Staff continues to work with WAPA concerning the cost estimates and methodology employed in WAPA's repayment studies. Based upon Metropolitan's recommendations, WAPA refined its final repayment analysis which significantly reduced its proposed rate adjustment on Metropolitan's current cost for Hoover power.

Sale of Metropolitan's Hoover-Mead Transmission Lines

A transmission line sales agreement between WAPA and Metropolitan was executed on August 29, 1988. Under the agreement, Metropolitan's two 230-kv transmission lines between Hoover Power Plant and Mead Substation were sold to WAPA for $3.5 million. All ownership rights in the lines as well as the property on which the lines reside were transferred to WAPA on the above date. Metropolitan's Hoover power is delivered at the Mead Substation interconnection with Metropolitan's transmission system. Under the agreement, WAPA is obligated to provide Metropolitan with 320 megawatts of transmission capacity between Hoover and Mead when needed in the future.

District-Edison Contracts

New administrative procedures were developed and implemented per the District-Edison 1987 Service and Interchange Agreement. These procedures cover energy scheduling, dispatching, transmission, metering arrangement, accounting, and billing. Staff continues to monitor conformity with this agreement's operational and monetary aspects to maximize the operational flexibility of the Aqueduct and minimize Metropolitan's overall power costs.

A letter was prepared and submitted to Edison requesting that negotiations be initiated between Metropolitan and Edison for an interconnection agreement for Metropolitan's Etiwanda power plant, construction of which is scheduled for 1991. Staff expects that the proposed interconnection agreement will be accomplished through an amendment of Metropolitan's current contract with Edison.

District-State Contracts

As required under the District-State Coordination Agreement, staff completed and submitted to the California Department of Water Resources (DWR) Metropolitan's estimate of its Aqueduct power operation for calendar year 1989 and indicated that no surplus Aqueduct energy will be available to sell to DWR nor will any energy be available for exchange.

Pursuant to the terms of Metropolitan's marketing contract with DWR, a letter agreement was executed specifying the unit rate to be applied for the sale of energy from Metropolitan's Phase I hydroelectric power plants to DWR during the six-year period from January 1, 1989 through December 31, 1994. Under the agreement, Metropolitan will receive 40 mills per kilowatt hour (kwh) during 1989, escalated by 3 percent per year during the succeeding five years. During this period, it is estimated that Metropolitan will receive an average of approximately 8.4 million dollars per year for the next six years.

Purchase Agreement for Supplemental Power

Aqueduct pumping demands can exceed Metropolitan's base-load energy resources available from Hoover and Parker power plants and Edison's benefit energy by up to one billion kwh of supplemental power annually. To supplement these base-load resources, staff has negotiated and signed economy energy agreements with WAPA, DWR, Salt River Project Agricultural Improvement and Power District, Arizona Electric Power Cooperative, Inc., Arizona Public Service, Nevada Power Company, Tucson Electric Power Company, and the city of Glendale. These agreements allow Metropolitan to purchase supplemental power for Aqueduct pumping on an hour-to-hour basis, depending on the power market conditions existing at the time.

Impact on Supply—The Central Arizona Project

While the Secretary has not yet limited Metropolitan's CRW diversions, CRW diversions by CAP increased to about 610,000 acre-feet this year. It is projected that diversions will total [illegible] acre-feet next fiscal year from CAP's Hayden-Rhodes, Salt-Gila, and Tucson Aqueducts.

Now scheduled for a 1991 completion, 87 miles of the Tucson Aqueduct are completed, with three pumping plants fully operational and six under construction. Construction is proceeding on five miles of pipeline and tunnel to deliver water to Tucson, and a contract has been awarded to build an eight-mile pipeline to serve the San Xavier Indian Reservation. A contract for an Aqueduct regulating reservoir will be awarded next fiscal year.

New Waddell Dam will serve as CAP's major regulatory storage facility. Three tunnels that will act as inlet, outlet, and diversion works for the reservoir have been excavated. With foundation excavation nearing completion, a contract to erect the dam embankment will be awarded next fiscal year. The new Waddell Pump Generation plant is under construction with operation to begin in 1994. Figure 3 shows where the major CAP facilities are located.

Colorado River Floodway

Metropolitan staff continued participating in a Colorado River Floodway Task Force created to advise the Secretary and Congress on issues related to establishing a floodway from Davis Dam to the southerly international boundary. In determining the floodway boundary, the Task Force adopted design criteria and mapping procedures. The floodway will encompass the area required to carry the one-in-one-hundred-year river flow or 40,000 cfs, whichever is greater. The one-in-one-hundred-year river flow has been determined to range from slightly greater than 35,000 cfs to nearly 50,000 cfs in different river reaches. Floodway boundary mapping was under way at fiscal year end.

State Water Project Supply

To meet its future demands, Metropolitan signed the first contract with DWR in 1960 leading to the State Water Project's (SWP) construction. Initially, the contract called for Metropolitan's ultimate water entitlement to be 1.5 maf per year, but later amendments raised this to 2.0115 maf per year. Metropolitan's entitlement equals half of the 4.218 maf per year contracted by all 30 SWP contractors. Metropolitan's contract with DWR reaches it maximum annual entitlement in 1990.

The SWP was designed so that additional conservation facilities to augment yield could be constructed as delivery demands increased. However, due largely to opposition from various sectors since the first conservation facilities were finished in 1967, no additional conservation facilities have been built. The total demand for State project water has been increasing since then, and two drought periods have also stressed the system (see Table 10). In the past, Metropolitan has received its maximum CRW entitlement to meet its needs. However, due to increasing demands and reduced Colorado River supplies, in the future Metropolitan will use greater amounts of State water than before. To enable Metropolitan to receive larger amounts of State project water, the California Aqueduct's East Branch is being enlarged. This project's status follows:

TABLE 4

EAST BRANCH IMPROVEMENT/ENLARGEMENT

As of June 30, 1989

STATUS	PROJECT
Complete	• Raise [illegible] lining [illegible] length of East Branch* • Construct [illegible] siphons • [illegible] foundation work at Pearblossom Pumping Plant and Devil Canyon Power Plant
Near Completion	• Raise [illegible] siphons • Design Devil Canyon Power Plant penstock shutoff valve
Construction Begun	• Check structure modification — Alamo to Pearblossom • Enlarge Devil Canyon Power Plant — fabrication and installation units 3 and 4 • Enlarge Pearblossom Pumping Plant — fabrication and installation units 7, 8, and 9
Contract Awarded	• Furnish and install second penstock at Devil Canyon Power Plant
Contracts Out for Bid	• Pearblossom Pumping Plant • Mojave Siphon Power Plant — turbines, generators and governors
Continuous	• Design — Mojave and Antelope Siphons • Design — Mojave Siphon Power Plant • Design — modifications to check structures from Pearblossom to Mojave Siphon Power Plant • Develop second afterbay at Devil Canyon Power Plant

Notes:

*A portion of the East Branch canal lining from Alamo to Pearblossom may have to be raised an additional foot pending hydraulic testing upon completion of the East Branch Enlargement.

Metropolitan first began receiving State project water in 1972 at Castaic Reservoir, the California Aqueduct's West Branch terminus. Under its contract, Metropolitan paid the State nearly $195 million before taking its first water delivery. Each of the 30 SWP contractors proportionately pays project costs based on the sizing of facilities required to deliver water to their respective areas. Metropolitan, located at the project termini, pays approximately two-thirds of all costs. Metropolitan's payments to DWR for State project water reached $232 million during the fiscal year, for a cumulative total of $2.32 billion through June 30, 1989 (Table 11).

Power for Pumping State Project Water

The SWP power supply system is managed and operated by the DWR. The major goals of DWR's power program are: (1) maximizing the benefits from existing SWP power resources, (2) developing and maintaining alternate energy sources thereby reducing dependence on power purchased from utilities, (3) securing transmission resources to efficiently supply power to SWP facilities and to provide access to areas where low cost power can be obtained, and (4) minimizing the impact on the SWP when major contractural arrangements expire in 2004.

The three largest sources of SWP energy are hydroelectric energy, exchange energy, and coal-fired energy. SWP hydroelectric energy resources include the Hyatt and Thermalito hydroelectric plants and on-aqueduct power recovery plants. Exchange energy is provided through contractual arrangements with SCE. Coal-fired generation is obtained from unit No. 4 at the Reid Gardner Power Plant in Southern Nevada. These energy sources accounted for 90 percent of the total SWP energy requirements in 1988. Other sources of SWP energy are purchases from a variety of public and investor-owned utilities, geothermal power, and wind generated power. Figure 2 shows the SWP energy resources for 1988.

The overall SWP energy mix is subject to annual variations, because precipitation amounts can vary substantially from year-to-year directly affecting both hydroelectric generation and pumping demands. The locations of SWP power resources and major transmission facilities are shown in Figure 4. Table 12 contains actual and projected energy and costs for 1988, 1990, and 1995.

Metropolitan's Share of SWP Power Costs

Metropolitan's average net power cost for pumping SWP water in 1988 was $99 per acre-foot for a total cost of $79 million. The projected pumping power cost for 1995 is $114 per acre-foot, with a total annual cost of $172 million.

Mojave Siphon Power Plant

Discussions were carried out between DWR and the State Water Project Contractors regarding the sizing, construction schedule, and cost allocation for the proposed Mojave Siphon Power Plant on the East Branch of the California Aqueduct. DWR recommended construction of a power plant having three 8 megawatt turbines, each rated at a maximum flow of 960 cfs. This design will allow the entire flow of the enlarged East Branch to pass through the power plant. Plant construction is expected to be completed by 1994, at a total estimated cost of approximately $38 million. The project will be financed through the sale of water system revenue bonds and repaid over a 35-year period.

South Geysers Power Plant

DWR presented a Geothermal Facilities Operation Plan to the State Water Contractors which describes DWR's long range plan for development, operation, and use of SWP geothermal facilities. These facilities include Bottle Rock and South Geysers power plants, the Francisco, Rorabaugh, and Binkley mineral leases, and associated well structures and equipment. Of specific interest is the South Geysers plant, originally designed as a 55 MW facility but which was never completed due to an inadequate steam supply. In March 1988 a plan was approved that calls for accepting bids for leasing the steam resource and the existing structure at South Geysers, and sale of most of the plant equipment. Currently, DWR is in the process of accepting bids on these resources separately or in combination.

Reid Gardner

Reid Gardner unit No. 4 is jointly owned by DWR which is entitled to 94 percent of the Unit's 250 MW output, and the Nevada Power Company (NPC). In March 1988 a settlement was reached in a long-running arbitration between DWR and NPC which involved the interpretation of each party's obligation for receipt of minimum coal deliveries from coal suppliers. The settlement, known as Memorandum of Agreement No. 56, set forth the minimum coal delivery obligations for both parties, established a common stockpile for coal at Reid Gardner, and provided for NPC to make a series of payments to DWR totalling approximately $12.4 million.

SWP Power Cost Computer Models

Staff implemented a plan to use computer models to track SWP power costs. DWR currently utilizes computer programs to model the operation of the California Aqueduct and associated project facilities. These models are used for a variety of purposes including scheduling water flows, balancing energy loads and resources, and allocating power costs among the contractors. The ability to use these programs will allow staff to more closely monitor SWP power operations and costs.

Issues Affecting Water Supply

Forecasting Agricultural Water Use

Metropolitan and the Colorado River Board of California have developed techniques for projecting agricultural CRW use in California outside Metropolitan's service area. As both techniques underestimated actual use in calendar year 1988, a consultant has begun refining Metropolitan's

forecasting model. Had Metropolitan's CRW use been limited in calendar year 1988, 65,000 acre-feet of unused agricultural priority water could have been scheduled for diversion by use of monthly forecasts.

Colorado Ute Indian Water Rights Settlement

Legislation to settle outstanding water rights claims between the Ute Mountain Ute and the Southern Ute Indian tribes and parties in Colorado was signed by the President. As introduced, House Resolution (HR) 2642 and Senate Bill (S) 1415 would have authorized the tribes to enter into water-use contracts to sell, exchange, lease, or dispose of water tributary to the Colorado River. Metropolitan and the States of California, Arizona, and Nevada sought bill amendments to prohibit off-reservation, out-of-state use of this water. As passed by Congress, the legislation prohibits sales, exchanges, leases, uses, or other disposal of water into or in the Lower Colorado River Basin unless water held by non-Federal, non-Indian holders of water could be marketed under State law, Federal law, interstate compacts, or international treaty. Such a determination would be subject to a Federal court's final order or pursuant to an agreement among the seven Colorado River Basin states.

Salinity Control

Implementation of the Colorado River Salinity Control Program continues, meeting numeric criteria for total dissolved solids concentration below Hoover and Parker Dams and at Imperial Dam adopted by each of the Colorado River Basin states. Numerous projects to prevent agricultural, point, and diffuse sources of salinity from entering the Colorado River or its tributaries have been completed or are under development by the Departments of the Interior and Agriculture. Projects in the Grand and Paradox Valleys and Lower Gunnison Basin and the Dolores Project and Meeker Dome areas of Colorado, the Uinta Basin in Utah, the Big Sandy River area in Wyoming, and Las Vegas Wash in Nevada remove 157,000 tons of salt annually. Another 1.1 million tons of salt per year must be removed by the year 2010 to meet Imperial Dam's numeric criterion.

San Francisco Bay/Delta Hearing

The State Water Resources Control Board's (SWRCB) three-year-long hearing process to review its 1978 water rights decision 1485 (D-1485) and related water quality control plans for the San Francisco Bay (Bay) and the Central Valley basins fell behind schedule this year.

Phase I concluded on February 1, 1988, and Phase II was scheduled to begin in July 1988. Prior to Phase II, the SWRCB was to issue a draft Water Quality Control Plan for Salinity in the San Francisco Bay/Delta Estuary (Plan) and draft Pollutant Policy Document (PPD). During

Phase II, the SWRCB was to receive comments on these draft documents. However, the draft Plan and draft PPD were not completed and publicly released until November 3, 1988.

In the drafts, SWRCB staff rejected or disregarded most of the Phase I recommendations of Metropolitan, the State Water Contractors (SWC), DWR, and other water agencies. The major concerns over the SWRCB staff recommendations include:

- The draft Plan would limit SWP and federal Central Valley Project (CVP) Sacramento-San Joaquin Delta (Delta) exports to 1985 levels.
- The draft Plan would hold the amount of water pumped at the Edmonston Pumping Plant to the 13 Southern California SWP contractors to the 1985 levels of 790,000 acre-feet annually (660,000 acre-feet for Metropolitan, about one third of its contracted entitlement).
- Additional Northern California water, above 1985 levels, could be pumped only during wet and above normal water years for off-stream surface storage and conjunctive use programs.
- The draft Plan would call the viability of the Coordinated Operations Agreement (COA) between DWR and the United States Bureau of Reclamation (Reclamation) into question.
- The draft Plan doubled Metropolitan's projected water conservation levels in its service area to one maf per year by the year 2010. No information submitted or discussed during Phase I justified such large projected savings.
- The Plan, based on very poor evidence of added benefits, would have greatly increased the amount of Delta outflow (1.5 maf) from April through July dedicated to fish and wildlife. A combination of water released from upstream reservoirs and SWP and CVP export curtailments accounted for the increase.
- The draft Plan specifically rejected the current D-1485 fish and wildlife Delta standards and the current resource management programs being implemented as unreasonable.
- Based on preliminary DWR staff analysis, it appeared that the Bulletin 160-87 plans for increasing SWP yield (Delta facilities, Los Banos Grandes Reservoir, interim CVP water purchases, and the Kern Water Bank groundwater storage) would not be feasible under the proposed draft Plan.
- The draft PPD would have left urban water agencies using Delta water completely responsible financially for trihalomethane (THM) treatment by recommending that "reasonable alternatives" other than treating THM sources be used; and
- The draft Plan would have required that Central Valley reservoir operating procedures be changed to release additional water from April through July.

SWRCB staff, in the draft documents, did not suggest specific outflow standards for San Francisco Bay but recommended further research and monitoring toward possible future outflow standards.

Finally, the draft Plan proposed a "California Water Ethic" as its major philosophical approach to solving the State's future water needs. Essentially, the "Ethic" called for Southern California to use less water to solve California's complex water resources problems. While Metropolitan places high priority on additional conservation efforts, conservation alone does not solve Southern California's future water needs. The SWRCB approach proved quite different from DWR's statewide water plan (Bulletin 160-87) in which conservation, fish and wildlife, and water management, along with new State project facilities, are all proposed to meet California's future growing water needs.

Subsequent to the release of the draft Plan and draft PPD, Metropolitan and other parties filed petitions with the SWRCB to reopen Phase I of the hearing, to set aside the two draft documents, and to schedule a special workshop in January 1989. The latter allowed participants to submit estimates of time needed to prepare and present additional evidence to respond to the draft documents' proposals and assumptions.

The SWRCB held the workshop and later directed its staff to develop a new schedule and work plan for the Bay-Delta hearing process. It also eliminated flows and export limits from the Plan and included objectives for salinity and possible water temperature only; export limits and flow requirements would be considered later during the water rights hearing. Workshops to facilitate greater interaction among the SWRCB staff and DWR and other interested parties will be held to help provide SWRCB staff the necessary data and analysis of impacts to revise the draft plan. A revised draft Plan and PPD are expected in late 1989. An overall Bay-Delta hearing proceedings completion date is not known.

California Urban Water Agencies Delta Drinking Water Study

Brown and Caldwell Consulting Engineers completed the final report on a two-year study evaluating alternatives to protect Delta drinking water quality. This study was funded by nine urban water agencies, including East Bay Municipal Utility District, Los Angeles Department of Water and Power, San Diego County Water Authority, city of San Francisco, Santa Clara Valley Water District, city of San Diego Water

Department, Municipal Water District of Orange County, Alameda County Water District, and Metropolitan.

The report concludes that constructing new water facilities would significantly improve the quality of Delta drinking water by dramatically reducing levels of dissolved solids and organic compounds that form THMs during water treatment. Of the six alternatives studied, the Peripheral Canal provides the most cost-effective way of improving Delta drinking water quality.

State Water Project Fishery Mitigation

In July 1985, negotiations began between DWR and the California Department of Fish and Game (DFG) over a new fishery agreement. This is required under the December 30, 1986 Banks Pumping Plant Fishery Mitigation Agreement before DWR can operate the plant at full capacity of 10,300 cfs. To improve the Delta fish population by offsetting direct fish losses at the Banks Pumping Plant, the 1986 agreement called for funding mitigation projects such as hatcheries, fish screens, and physical transfer of fish from Clifton Court Forebay back into the Delta.

CHAPTER 2

Delivering Metropolitan's Water Supplies

The Distribution System

Stretching about 200 miles along the Pacific Ocean, Metropolitan's service area runs from Oxnard to the Mexican border, and inland in some places for about 70 miles. It extends into six counties: San Diego, San Bernardino, Riverside, Orange, Los Angeles, and Ventura. Metropolitan delivered approximately 2.2 million acre-feet (maf) of water in fiscal year 1988-89, an average of almost 2 billion gallons each day.

The initial delivery point for Colorado River water (CRW) into Metropolitan's distribution system is Lake Mathews, while Castaic Lake and Devil Canyon provide delivery points for State project water. Utilizing 775 miles of pipeline, five filtration plants, eight reservoirs, numerous regulating structures, and 14 hydroelectric power recovery plants, Metropolitan supplies its member agencies, which subsequently deliver water to homes, industries, and agricultural users. Table 13 shows each filtration plant's location and capacity.

System and area control operators can remotely control any one of several hundred valves and monitor changes in water levels and pressure, thus regulating system flows. More sophisticated computerized control systems are being developed and integrated into the Area Control Centers to provide even greater monitoring and control.

Metropolitan delivers water to member agencies through 345 service connections located throughout the distribution system. Each connection usually consists of a turnout valve, turnout structure, and metering facility.

When a member agency requests a new or modified service connection, Metropolitan normally provides plans, specifications, equipment, and materials, then helps construct the connections.

TABLE 13

METROPOLITAN DISTRIBUTION SYSTEM
FILTRATION PLANTS

Plant	Process	Current Design Capacity Million gallons/day (mgd)
Jensen plant, Granada Hills	Filter State Project Water	400
Weymouth plant, La Verne	Filter Blend CRA/State Project Water	400
Skinner plant, Winchester	Filter Blend CRA/State Project Water	320
Diemer plant, Yorba Linda	Filter Blend CRA/State Project Water	400
Mills plant, Riverside	Filter State Project Water	75

This fiscal year, Metropolitan completed three new major service connections, made significant modifications to one connection, and enlarged another's capacity.

Service Connection LA-30, on the Sepulveda Feeder, was completed on March 29, 1989. This new connection has a design capacity of 100 cubic feet per second (cfs) and provides additional service to Los Angeles Department of Water and Power's Marina del Rey, Los Angeles Airport and Los Angeles Harbor areas.

Construction was completed May 18, 1989 on Service Connection CB-16, an untreated water service connection on the Rialto Pipeline, which will provide a design flow of [illegible] cfs to the Cucamonga County Water District's new water treatment plant.

Service Connection CB-12 was completed in August 1988, and provided water deliveries that same month to test the new Chino Basin Municipal Water District treatment plant. Full service began in September 1988.

On June 5, 1989, staff completed installing a 78-inch butterfly valve at DWCV-4, an untreated water service connection off the second barrel of the Colorado River Aqueduct (Aqueduct). As a result, Metropolitan can now isolate flows to the Desert Water/Coachella Valley's Service Connections DWCV-4A through 4D and the Whitewater hydroelectric power plant without affecting Aqueduct flow.

A treated water service connection on the Lower Feeder for the city of Brea, OC-29, was enlarged in December 1988. This service connection originally had a design capacity of 10 cfs; the expansion now provides treated water at a design capacity of 15 cfs.

Operational Planning

Metropolitan has a well designed, flexible water distribution system. Numerous pipelines distribute water to different portions of the system. While weighing each water supply's availability and the effect on State Water Project (SWP) operations, staff plans activities to maximize delivery of the least costly water. Continually deciding on increases and decreases in the quantities taken from each source, staff determines the extent to which terminal reservoir storage should be utilized to most efficiently accommodate demand changes. Plans are developed weekly and reviewed daily.

During the year, Metropolitan's Operations Planning staff continued to participate in the development and review of Colorado River and SWP operations. During the first eight months of the year, California's water supply situation was deteriorating and it appeared that Californians would suffer a third year of continuous drought throughout the State. While Southern California's situation was buffered by the U.S. Secretary of Interior's approval for Metropolitan to divert up to 1.3 maf of CRW through Metropolitan's Aqueduct, numerous SWP contractors were facing serious supply shortfalls. In February 1989, facing mandatory contractor cutbacks by the SWP, Metropolitan reduced its order for State project water by 200,000 acre-feet to approximately 1.17 maf. During March 1989, above-average rainfall was received in the Northern California region resulting in the recovery of State conservation reservoirs. The State approved all SWP contractor orders and eliminated the proposed reduction in the agricultural water deliveries.

Although the water supply situation remained poor throughout most of the year, Metropolitan continued delivering water to its member public agencies at record levels. By carefully monitoring Southern California's water supply situation, Metropolitan continues to develop strategies that minimize the potential for delivery shortfalls to member public agencies.

Shutdowns and Service Interruptions

Metropolitan's water operations also involve filtration plant, pipeline, or reservoir shutdowns and planned service interruptions. This year, major shutdowns and interruptions included:

- The Foothill Feeder from Castaic Lake to Magazine Canyon was shut down from November 29, 1988, to March 17, 1989, so that the Newhall Tunnel could be sealed with a 19-foot diameter, 1 2-inch thick welded steel liner. The liner was installed from the Newhall Siphon to Magazine Canyon Shaft (See "Maintaining and Improving the Distribution System" page 32)

- On November 9, 1988, the State Department of Water Resources (DWR) reported a break on the SWP's East Branch at the Mojave Siphon, upstream of Silverwood Lake. The East Branch was shut down and investigations indicated the break was caused by corrosion failure of the prestressing wire that reinforces the pipe. By utilizing Metropolitan's distribution system's flexibility, overall deliveries to member agencies remained unaffected. Deliveries through the East Branch resumed on November 27, 1988.

- Two concrete panels collapsed on the San Diego Canal near the Lake View Pipeline. Collapsed panels are not uncommon and occur particularly in areas of settlement or high groundwater. Metropolitan forces replaced the panels and restored service within 72 hours of the March 2, 1989, incident.

- On March 6, 1989, a shutdown of the Box Springs Feeder was made at DWR's request to examine a potential leak located near the turn-out structure on the State system. Further inspection revealed two major breaks and considerable corrosion on exposed portions of the prestressing steel wire. Metropolitan staff, in cooperation with DWR, restored the line's structural integrity and service was returned to affected member agencies on March 11, 1989. DWR later affected permanent repairs through an emergency contract.

- The West Valley Feeder was shut down March 28, 1989, to allow an [illegible] with Calleguas Municipal Water District to modify [illegible] on CA-2. The modification included install[illegible] butterfly valve on CA-2's discharge manifold.

Ensuring Deliveries—Emergency Preparedness

Operations remained [illegible] three earthquakes during the fiscal year:

- June 10, 1988, located near Gorman, California; registered a magnitude of 5.2 on the Richter Scale, causing major damage to DWR's Edmonston Pumping Plant switchyard.
- December 3, 1988, located near downtown Pasadena, California; registered 4.5.
- January 16, 1989, located eight miles south of Malibu, California; registered 5.0.

During each of the quakes, Metropolitan's Emergency Operations Center (EOC) was activated. Located in the most earthquake-resistant area of the Los Angeles Headquarters Building, the EOC's primary purpose is to assimilate system status from the Eagle Rock System Control Center and inform and coordinate damage assessment teams. The EOC also maintains communications with local media and offices of emergency services.

Optimizing the System—Power Recovery

Adding 14 hydroelectric power plants to the distribution system in recent years has increased Metropolitan's ability to minimize or recover some of the energy costs required in CRW and State project water pumping operations. As shown in Table 14, these hydroelectric power recovery plants produced a total of 356,020,600 kilowatt-hours (kwh) this fiscal year. Although power plant inspection and maintenance continued throughout the year, careful rerouting of system flows minimized generation loss.

Water Deliveries and Sales

Water sales for fiscal year 1988-89 totaled 2,095,078 acre-feet, up 9 percent over last year. Of the total sales, 64 percent was treated water, 35 percent untreated water, and sales of reclaimed water constituted the remainder. Monthly water sales varied from approximately 116,622 acre-feet in February 1989 to a high of 221,775 acre-feet in June. The June 1989 sales figure established not only a new sales record for that month, but the highest monthly sales record in Metropolitan's history. In this fiscal year, new monthly water sales records were set in nine out of the 12 months.

Table 15 summarizes water use by Metropolitan's member agencies, while Tables 16 through 18 detail the types of water deliveries made to the member agencies during the past fiscal year and over the last 48 years.

Approximately 63,000 acre-feet of water were sold under the temporary in-lieu program. The program enhances conservation of imported supplies by substituting Metropolitan deliveries with water produced by local sources, thus providing greater water storage for future use.

Groundwater replenishment was generally suspended from July to November 1988 due to water supply constraints, then re-established in December 1988 through April 1989. In May 1989, replenishment deliveries were again curtailed to ensure the filling of Lake Mathews Reservoir. Groundwater replenishment deliveries totaled 106,941 acre-feet.

The Interruptible Water Service Program encourages member agencies with reservoirs or groundwater basin supplies to hold water in reserve. When a member agency maintains reservoir or underground facilities capable of compens... for Metropolitan service interruption ...r reductions, it may p... the interruptible portion of its water su... at a lower rate. M... that replenish groundwater basin... spreading ... are also eligible. Similarly, member agencies ... buy ... deliveries made from surplus supplies at ... reduced ... In M... Metropolitan's Board of Directors determ... that all ... requests for interruptible water deliveries du... the ... could be met. Table 19 shows a 40-year hist... of ... member agencies for underground replenishme...

During N...ber 1988, in response to the State's continuing dry conditions, Metropolitan for the first time issued the required one-year advance notice to agricultural water users participating in the Interruptible Water Service Program that Metropolitan could be required to curtail service. The one-year advance notice allows agricultural users to adjust cropping patterns before interruption. However in April 1989 improved supply conditions enabled Metropolitan to cancel the notice.

After completing refurbishment work at LaVerne, an impeller and shaft assembly are ... one of Metropolitan's pump plants

- The Foothill Feeder Lining Project was started at the end of November 1988 and continued until mid-March 1989. Spanning 2,940 feet, the 19-foot diameter, welded steel liner was installed to prevent crude petroleum from continuing to seep into the tunnel from the surrounding oil-bearing strata. Since completing the liner installation and reactivating the Joseph Jensen Filtration Plant, no trace of petroleum odor or oil sheen has been evident in the plant's source water or anywhere throughout the plant.

- Installation of a security monitoring system at Pleasants Peak communication facility was completed in February 1989. Closed circuit television monitoring equipment was installed and placed in operation at the Eagle Rock and Soto Street facilities.

- The Board granted authorization in May 1989 to proceed with the preliminary design phase of the new Operations Control and Maintenance Center at Garvey Reservoir.

- Diemer Modification Project work included installing various piping, chlorine, and flow metering systems designed to increase the Robert B. Diemer Filtration Plant capacity.

Rehabilitating An Aging System

Colorado River Aqueduct Pump Rehabilitation Program

A 1985 evaluation of the condition of the five major pumping units that bring CRW to Metropolitan's service area revealed that many of the units installed during the original construction of the Colorado River Aqueduct were nearing the end of their useful life. As a result, last year Metropolitan began an extensive five-year program to rehabilitate each of the nine pump units at all five pumping plants. Restoring all the pump units to their original efficiency should result in approximately a 6 percent power or $2 million annual savings, based on delivery of 550,000 acre-feet of CRW. Transformer rehabilitation should generate an additional operating efficiency savings of approximately $88,000 annually.

Project Description

Each of the five pumping plants contains nine pump units and was designed to operate continuously with eight pumps. The ninth pump, serving as a spare and intended to permit maintenance without interrupting plant service, was also included to provide additional pumping capacity during peak periods.

Each pump unit consists of four major components (electric motor, centrifugal pump, suction valve, and discharge valve) and various auxiliary systems and equipment. The horsepower, rotational speed, pump size, and impeller shape are engineered to provide pumping capacity of approximately 200 cfs. Figure 7 identifies the components of a unit.

The size and scope of the Aqueduct Pump Rehabilitation program includes: (1) designing and purchasing equipment, and replacing up to 35 bronze impellers, including one spare impeller for each pumping plant, (2) rehabilitating pump motors, discharge valves, pump system components, and bearings, (3) replacing motor temperature instruments at all pumping plants, (4) replacing vibration monitoring instrumentation, (5) installing acoustic flowmeter transducers in delivery lines at all plants and totalizing flowmeters at two plants, and (6) rehabilitating 11 main transformers at four plants.

Project Schedule

Planned in nine phases, the Colorado River Aqueduct Pump Rehabilitation Project (CRAPRP) will be completed in 1992. Phase I was concluded in July 1988 and included Unit No. 5 at Intake, Unit No. 1 at Gene, Unit No. 3 at Iron Mountain, Unit No. 3 at Eagle Mountain, and Unit No. 1 at Hinds.

During the 1988-89 fiscal year, Phases II and III of the CRAPRP were completed. Phase II ran from September 6, 1988, to February 29, 1989. Phase III was started March 6, 1989, and completed on June 29, 1989.

Project Management

During Phase II, staff determined that the system used for documenting the time, equipment, and resources of the identified 800 individual tasks for each project phase was inadequate for the project's needs. Because of this, staff consolidated task progress sheets, used during Phases I and II to identify each step of the 800 repair procedures, to simplify tracking costs and project schedule development. Additionally, a new project scheduler program was implemented. Weekly coordination meetings were held as Phase II and III work progressed to adjust the schedule, as required, and plan remaining work.

In order to maintain the Phase II and III schedules, Metropolitan contracted for supplemental laborers, as was done in Phase I, to work with its crews at the pump plants and Metropolitan's shops in La Verne. The supplemental laborers included machinists, welders, and millwrights.

As with Phase I, the first major task facing the crews during Phases II and III involved installing a bulkhead in the discharge pipeline of each unit being worked on in that phase. Once installed, the bulkheads allowed

the other units on the affected delivery line to resume normal operations while preventing back flow into the plant and protecting the crews during the pump rehabilitation work.

Prior to the complete disassembly of each unit, alignment and tolerance checks were made and recorded to determine proper clearances. Workers removed the pump impeller assembly from the pump bowl and shipped it to Metropolitan's shops in La Verne. The new impellers were check balanced and corrected as required. Figure 8 outlines the major work completed on the pump and discharge valves.

While shop work was in progress, desert crews sandblasted then coated the pump bowls, and installed vibration monitoring probes and computerized monitoring equipment. Discharge valve bowls and plug valves were also sandblasted then coated. To provide additional protection to the plug and housing, corrosion protection devices were installed on the discharge valve plugs at Eagle Mountain and Hinds. Replacement stationary seal rings were bored in place in preparation for final impeller assembly installation.

Figure 9 outlines the major work completed on the motors. The main and pilot exciters were shipped to La Verne where they were cleaned, machined, balanced, and electrically tested. All rotors and stators were inspected, solvent cleaned, repaired, coated, and electrically tested.

Rehabilitation of the final General Electric transformer for Gene Bank 1 and the first of four Iron Mountain Bank 1 transformers was completed this year by McGraw Edison. The remaining three General Electric transformers at Iron Mountain are scheduled for rehabilitation by McGraw Edison during next fiscal year. For refurbishment, the transformer units are disassembled and the coils removed from the old core. Before the coils are reinstalled into the new core, the old core is structurally modified. The core and coil assembly is placed in an oven for three weeks to dry completely, then is tested and returned to service.

Testing and Evaluation

At the end of each phase, engineers, technicians, consultants, and workers conducted performance testing at each plant. Before starting a motor, a preliminary check ensures a free-running unit. Once the pump and motor have passed the checkout phase, performance testing begins. Over 270 measurements are taken to obtain data on suction and discharge pressure, vibration, flow, temperature, and electrical energy use.

Evaluation of the repairs made to the units during the first three phases revealed that repairs and modifications prevented future unit outages and increased Aqueduct flow by approximately 40 cfs.

Phase IV, scheduled to begin on August 28, 1989, will involve Intake Unit No. 1, Gene Unit No. 6, Iron Mountain Unit No. 2, Eagle Mountain Unit No. 6, and Hinds Unit No. 3.

F. E. Weymouth Filtration Plant Rehabilitation

The F. E. Weymouth Filtration plant was constructed in 1941, and expanded in both 1949 and 1962. In 1967 and 1973, modifications modernized the plant to filter State project water and helped rehabilitate the chlorination system, roads, and parking areas. But operating problems in the areas where the plant was not rehabilitated had been increasing due to equipment aging. Consequently, a study was undertaken to develop a plan for all work required to maintain operating reliability, improve process control, automate the plant, and bolster energy management. All equipment was inspected, the operating and maintenance history reviewed, and test and evaluations made prior to the final recommendations.

The study showed that some of the equipment was worn, vibrated too much, and required excessive maintenance, calibration, and part replacement. Equipment maintenance and repair posed a major problem due to the unavailability of spare parts. In addition, some of the old equipment is incompatible with plant automation.

Based on the detailed study, a modification program consisting of 30 projects was approved in late May 1985. Basically, all projects are concerned either with instrumentation, modernizing flow measurement devices, or handling emergencies to ensure noninterruptible service. Specifying the time required for the modification work proved extremely difficult because scheduling required plant shutdowns and close coordination with plant operations. But the project work was estimated to be accomplished over a five-year period. Metropolitan personnel oversee the design and purchase of materials and equipment and construction of the modification work.

During the fiscal year Metropolitan personnel continued with the design work, equipment and materials procurement, and installation and construction work at the plant. Of the 23 individual projects at the beginning of the fiscal year, six have been completed. Engineering design has been completed and the required equipment has been delivered or ordered for eight of the projects; construction is progressing for three of those projects. Design work is nearing completion for the remaining eight projects.

CHAPTER 3

Water Supply Management and Development

Colorado River Water

During the year, Metropolitan exchanged 56,506 acre-feet of Desert Water Agency (Desert) and Coachella Valley Water District (Coachella) State project entitlement water with an equal amount of Colorado River water (CRW) from its predelivery account, drawing it down to a balance of 436,236 acre-feet by June 30, 1989. Metropolitan did not predeliver CRW to Desert and Coachella for Coachella Valley groundwater basin storage during the year.

Also during the year, 65 acre-feet of San Bernardino Valley Municipal Water District State project water was delivered to Metropolitan for an equal amount of CRW extracted from Lake Havasu by the Havasu Water Company.

State Project Water

State Water Contractors

Metropolitan, together with 27 other State Water Project (SWP) water contractors, formed State Water Contractors, Inc. (SWC) to further its members' common interests. SWC mainly conducts its work through the various committees which regularly meet to study and offer solutions to problems arising from the California Department of Water Resources' (DWR) management of the SWP. The following are the major committees and some of the matters in which they are involved:

- The *Future Water Supply Committee* works on the State's plans for developing and maintaining an SWP water supply that includes Sacramento-San Joaquin Delta (Delta) water management programs, Los Banos Grande Reservoir, and interim and long-term water purchases

several water purchase sources including the Federal Central Valley Project (CVP) and a permanent agreement to purchase water from Yuba County.

Future Water Supply

DWR is actively planning to acquire further water supplies to increase SWP yield. Without additional water and facility construction to store the water the SWP will, in the very near future, be unable to meet water requests from the water contractors even in high or average rainfall years. The following are some of the most significant projects DWR is now examining.

- **Delta Facilities**—In the North Delta, DWR is seeking to provide a more efficient path for Sacramento River water through the Delta, reducing the water quality and fisheries problems currently associated with reverse flows. As the initial phase of the North Delta improvements, DWR proposes to increase the South Fork Mokelumne River flow capacity which will also provide flood control benefits for the surrounding Delta islands. In the West Delta, DWR, committed to meeting certain water quality standards, recommends constructing water conveyance facilities to the western portion of Sherman Island. Alternatively, DWR proposes to purchase island property and convert it to wildlife habitat. The South Delta's main problem lies in its channels' limited capacity, which leads to channel scouring when the SWP and CVP are maximizing their pumping simultaneously at a low San Joaquin River flow or at low tide. The low water levels also contribute to the poor South Delta water quality. Numerous alternatives are being studied, among them a modified Clifton Court Forebay gate, dredging in the channels, and a levee setback or enlargement of Clifton Court Forebay together with the channel enlargements. Other facilities which may be included in this project are various tidegate structures or a siphon at Tom Paine Slough, and connecting the CVP with Clifton Court Forebay.
- **Los Banos Grandes Reservoir**—An off-stream reservoir similar conceptually to San Luis Reservoir, this Reservoir is intended to store excess Delta flows, available primarily in the winter, for subsequent project use. DWR is currently refining its feasibility studies and will shortly be proceeding with the Federal and State environmental study process. A final Environmental Impact Report/Environmental Impact Statement (EIR/EIS) is expected in late 1991.
- **Article 10(h) Water**—Negotiations pursuant to Article 10(h) of the Coordinated Operating Agreement between the U.S. Bureau of Reclamation (Reclamation) and California, are continuing. Under the proposed agreement, Reclamation will provide an interim SWP water

supply of appro... feet per year. In turn, D... will wheel app... feet of CVP water. DWR a... Reclamation ... the environmental process a... a final EIR ... issued in mid-1991.

- Yuba Co... Yuba County Water Agency ha... begun ne... an interim water supply of up 200,000 a... the SWP from Yuba County Wat... Agency ... Reservoir.

Arvin-Edison Water Storage and Exchange Program

Arvin-Edison Water Storage District, a Kern County CVP contractor, and Metropolitan have proposed entering into a program whereby Metropolitan would ... a portion of its SWP entitlement to Arvin-Edison for storage in its groundwater basin. When needed, Metropolitan would then take Arvin-Edison's CVP surface water supply from the Delta and Arvin-Edison would pump the previously stored groundwater. The program would not adversely impact SWP operations or other SWP contractor entitlement deliveries.

DWR Business Information System

In developing a business information system, DWR plans to replace the present data processing system used in managing the SWP. The SWC has retained the two contractor auditing firms of Ernst & Whinney and Arthur Young to ensure that SWC needs for DWR information are handled by the new system. A joint report was prepared and transmitted to DWR ... The auditors will participate on DWR's internal ... staff to ensure that SWC needs will be considered ... and will provide assistance to DWR if required.

California Water ... Legislation

Legislation ... 1989 to reduce the SWP obligation to the C... ...bursing DWR for funds spent on recreation a... ...ancement facilities. In return, DWR will regul... ...transfers from the SWP to the California W... ...der of the obligation.

Suisun Marsh

The Montezu... Structure became operational in October 1988 and ... ...ed the control of Suisun Marsh salinity levels. Ad... ...plete the project, such as modifying the levees and ... be done in the coming year.

...P Financing

...n December 1988, DWR sold $9 million in Central Valley Project Water ...stem Revenue Bonds, Series E, to cover the reserve requirements for ...0 million bond issue Series D, sold in June 1988 to repay construction ...ts of various SWP facilities including the East Branch Enlargement. ...e Series E bonds are non-tax exempt since they are to be invested ...d held in trust over the life of the Series D bonds.

In March 1989, DWR sold $160 million in Central Valley Project Water System Revenue Bonds, Series F, to defease a portion of the Central Valley Project Power Facilities Revenue Bonds, Series G, which were for the Reid Gardner Project construction. This defeasance will reduce the debt service obligation of the SWP contractors by a present value of $12.2 million.

Regional Water Resources

Efforts to Expand the Use of Groundwater and Reservoir Storage

Member agencies received program assistance to expand current groundwater production to meet future regional needs. Expanded use of Southern California's groundwater and surface water storage is being accomplished through technical assistance to member agencies in five primary areas: water rates, local projects, cooperative conjunctive-use studies with member agencies, legislative and regulatory advocacy, and research and development funding.

Water Rates—Seasonal Storage Service

The Board of Directors has approved a permanent version of the Tem...rary In-lieu Program called the Seasonal Storage Service Program. ...offering water at a greatly reduced rate from October through April ...h year, the program provides incentives for member agencies to ...imize use of their local storage resources. The program is expected ...ead to the development of increased local production capacity by ...structing additional production, well-head treatment, spreading, and ...er facilities. Regional benefits include enhancing Metropolitan's ...ity to capture excess surface flows from both the State Water Project ...d the Colorado River and improving the region's capability to use ...re groundwater and reservoir storage during sustained droughts ...d emergencies.

Ground[illegible] Storage Programs

Chino Basin [illegible] Storage Program

Metropolitan [illegible] and held two public hearings for the [illegible] posed Chino [illegible] program. Comments made during the review focused primarily [illegible] program's influence on basin groundwater levels and groundwater [illegible], which has been deteriorating for many years and is predicted [illegible] continue to do so even without implementing the proposed program. The draft EIR helped alert local agencies to the groundwater quality problem's potential magnitude.

Metropolitan is assisting local Chino Basin agencies in developing approaches to improve basin management practices and deal with existing poor quality groundwater conditions. In this regard, Metropolitan has agreed to jointly fund a groundwater quality improvement study in the lower Chino Basin with the Santa Ana Watershed Project Authority (SAWPA). Also in response to a SAWPA "White Paper," the Chino Basin Municipal Water District and the Chino Basin Watermaster are attempting to expand the study to include the whole basin and incorporate groundwater quality monitoring. Additional efforts include jointly funding both a groundwater quality improvement study with the city of Pomona and the Santa Ana River Nitrogen study with numerous local and regional agencies. The most significant related effort, however, is the current development of Metropolitan's Seasonal Storage Program.

In the [illegible] additional basin management practices and improvement [illegible] developed, local agencies are acting individually [illegible] better use their groundwater resources. Metropolitan [illegible] participate with local agencies through its existing Chino [illegible] Storage Account, in which it has stored more than [illegible] Chino Basin Cyclic Storage Account which contains [illegible] state project water.

Calleguas Groundwater Study

Metropolitan and C[illegible] Municipal Water District (Calleguas) completed a draft report [illegible] improve groundwater resource use in the North Las Posas B[illegible] adjacent groundwater basins. A hydrogeologic evaluation [illegible] groundwater modeling study indicate that North Las Posas Basin [illegible] substantial storage capacity and that recharge and extraction are [illegible] feasible. Alternative means of replenishment and extraction were identified for staged expansion of existing facilities and development of new facilities. Analysis of the alternatives revealed that conjunctive-use programs would work effectively with application of Metropolitan's new seasonal storage service.

In related efforts, Metropolitan also provided technical assistance to [illegible]ct and store imported water in other Calleguas area groundwater [ba]sins. Working jointly with Calleguas and the city of Oxnard, Metropolitan initiated a small scale pilot injection test on the Oxnard Plain. Oxnard [pl]ans to use Metropolitan's new seasonal storage service to finance the project.

San Jacinto Basin Groundwater Storage Project

Metropolitan and Eastern Municipal Water District (Eastern) are jointly participating in a demonstration of groundwater spreading and storage in the San Jacinto Groundwater Basin. The project will involve groundwater recharge in the San Jacinto River bed and developing a groundwater model to assess quantitative and qualitative responses associated with conjunctive-use operations in the San Jacinto Basin. While coordinating the modeling study's joint funding options with Eastern and SAWPA, Metropolitan also is assisting Eastern in developing a phased construction plan for the recharge basins and a comprehensive groundwater monitoring plan to evaluate test operations. Eastern completed design of the spreading basin facilities connecting pipelines and monitoring wells and, at fiscal year end, had obtained all but one of the permits required for the project to proceed.

Conjunctive-Use Studies and Programs

Metropolitan and the Upper San Gabriel Municipal Water District are studying expanded use of the Main San Gabriel Basin under the *Main San Gabriel Conjunctive-Use Program*. A modeling study completed by a consultant demonstrated that the basin can physically accommodate significantly increased replenishment and extraction operations. Metropolitan assisted local basin agencies in reviewing the U.S. Environmental Protection Agency's (EPA) proposed plans to deal with extensive groundwater contamination under the Federal Superfund program. At fiscal year end, staff was formulating various conjunctive-use alternatives that would be compatible with EPA's program. Metropolitan also assisted the Main San Gabriel Watermaster with his appeal to the State Water Resources Control Board (SWRCB) to deny a permit for solid waste disposal in a gravel pit located in the basin's recharge area.

Under the *Raymond Basin Conjunctive-Use Study*, Metropolitan and the [city] of Pasadena have agreed to study the conjunctive use opportunities [in] the Raymond Basin. A consultant began collecting data describing [basi]n characteristics including basin geology, existing spreading facilities, [its] current operations of the basin's producers, and water quality [con]ditions in the basin. After completing a draft report on basin conditions [an]d background information, the consultant began identifying and [eva]luating conjunctive-use alternatives that will lead to better groundwater management in the [illegible] tives are being discussed [illegible] all of the basin wa[illegible] [illegible] which should be consid[illegible] further in Phase [illegible]

Metropolit[illegible] [illegible] Municipal Water District (Three Vall[illegible] and the cit[illegible] [illegible] studying expansion of La Verne's us[illegible] the Live Oa[illegible] [illegible] *Oak Conjunctive-Use Feasibility St*[illegible] A draft re[illegible] [illegible] geology consultant describes the bas[illegible] characteris[illegible] [illegible] condition. The parties are now formu[illegible] ing alterna[illegible] [illegible] recharge and extraction of imported water in light of the [illegible] institutional setting.

The [illegible] *Use Program* covers Metropolitan and Three Valleys evaluation of conjunctive use possibilities for the Glendora Basin high nitrate concentrations that have limited the city of Glendora's ability to produce groundwater. A basin management plan could allow Glendora to substitute local groundwater for imported Metropolitan water during drought years. A consultant is collecting and analyzing pertinent background information.

In coordination with the city of Glendale and the Crescenta Valley County Water District, Metropolitan is investigating means to increase Verdugo Basin groundwater production through the *Verdugo Basin* [illegible] Work progressed on developing an analytical model to evaluate the basin response to various conjunctive-use opportunities. [illegible] completed a conceptual model of the basin and is [illegible] model using historic data. Parameters to be [illegible] conductivity, specific yield, and boundar[illegible]

Metr[illegible] [illegible] to expand San Fernando Bas[illegible] conjunc[illegible] [illegible] that produce water from the bas[illegible] The EPA [illegible] [illegible] agencies to clean up contaminat[illegible] ground[illegible] [illegible] fund program. Conjunctive-u[illegible] scenari[illegible] [illegible] the clean up activities are bei[illegible] reviewed.

Water Exchan[illegible]

Sev[illegible] [illegible] arranged during the ye[illegible] tan a[illegible] [illegible] agreement between Metropo[illegible] of the late[illegible] Agency (SGPWA) to the Secreta[illegible] Metropolita[illegible] approved, the agreement perm[illegible] like amount [illegible] acre-feet per year of CRW for SGPWA with [illegible] water. This agreement provid[illegible] politan mor[illegible] otherwise receive and gives Metr[illegible] [illegible] water.

[illegible]scellaneous Projects

[illegible]etropolitan may establish a wheeling agreement with the Castaic [illegible] Water Agency (Castaic) through approximately seven miles of [illegible]ropolitan's Foothill Feeder. The agreement would allow Castaic to [illegible]ver part of its State project water entitlement to areas where Castaic [illegible] experiencing unprecedented growth through unused capacity in Metropolitan's system. Metropolitan would benefit by receiving revenue [illegible] its unused pipeline capacity. The price for wheeling the water is currently being evaluated and negotiations are underway with Castaic.

Metropolitan's role as a regional agency in groundwater management was presented at the Groundwater Information Management Workshop sponsored by the U.S. Geologic Service and at the Interstate Conference on Water Policy. Based on presentations and panel discussions, Metropolitan's activities place it at the forefront of establishing strategies for groundwater information management and sharing. While the smaller agencies were concerned with using computers to efficiently record and report data, the larger agencies focused on quality control in collecting and interpreting groundwater information.

Staff prepared a report on the Groundwater Remediation Activities in Southern California. Readily available information was collected and analyzed for 21 of the groundwater basins in Metropolitan's service area, described in individual basin profiles. Two major trends emerged: (1) an increasing number of groundwater contamination problems are being identified and (2) achieving successful groundwater remediation is increasingly difficult.

Metropolitan formed and hosted several meetings of the Groundwater Advisory Committee. The committee is composed of Metropolitan's management, groundwater resources staff, groundwater managers, and independent consultants from throughout Metropolitan's service area. At their bi-monthly meetings, participants evaluate and discuss political, managerial, water quality, and economic trends that impact regional groundwater production and management.

A research project was set up with the Orange County Water District [illegible]develop a practical and cost-effective method to remove nitrate [illegible]amination from groundwater. Biological denitrification is especially [illegible]ctive because it degrades nitrate into harmless compounds and does [illegible] require costly brine disposal facilities. Promising laboratory results [illegible] denitrification with a bench-top column colonized by autotrophic [illegible]eria led to the development of a pilot-scale laboratory test treatment [illegible] which will use local wellwater spiked with nitrate. To date, major [illegible]lusions find that hydrogen-based denitrification can be readily [illegible]ated and maintained under laboratory conditions and that nutrient[illegible]s found in typically high-nitrate groundwater will probably support

VOL 12 1588--

microbes with the [illegible] of phosphate. These findings constitute an important [illegible] consideration for both wellhead and in situ processes.

Metropolitan [illegible] three-year sponsorship of the University of California at Los Angeles [illegible] Engineering Research Center (ERC) which will highlight [illegible] cross-disciplinary solutions to hazardous waste problems. The ERC focuses research efforts on the most beneficial proposals in the areas of soil and groundwater remediation, treatment and disposal, and [illegible] risk evaluation. Metropolitan considers the ERC an excellent [illegible] for transferring technology between different sectors and exploring [illegible] to expand new technological applications.

Report No. [illegible] is progressing and will update groundwater quality conditions and project the impact of proposed legislation, including examination of Superfund-type sites on groundwater in Metropolitan's service area. After gathering data from every available source, including the EPA Superfund data base, staff will now use the data to evaluate groundwater conditions in the service area. The report will be released during [illegible].

The State Division of Safety of Dams completed its review of the Morris Dam seismic evaluation which was prepared as required under the agreement with Los Angeles County to transfer ownership of Morris Dam and Reservoir to it. Among other things, the review concludes that the dam should be stable during the maximum credible earthquake on the Sierra Madre fault and would sustain a full reservoir without uncontrolled [illegible]. It is now planned to complete the Agreement's remaining steps so that Morris Dam may be promptly transferred to the County.

Local Projects Program

The original Local Projects Program was initiated in late 1981, deferred in 1983 due to Metropolitan's [illegible] constraints, and reactivated and revised in early 1986. Under the [illegible] Program, Metropolitan provides financial support to [illegible] develop local water supply projects that reduce demand for Metropolitan's imported supplies. Metropolitan contributes to qualifying projects [illegible] an equivalent amount of [illegible] energy cost for pumping [illegible] water. This amount may change yearly subject to a minimum payment of $75 per acre-foot. The contribution for fiscal year 1988-89 was $75 per acre-foot, which will remain the same next fiscal year.

The financial contribution is transferred to a member agency through a Joint Participation Agreement in which Metropolitan guarantees to purchase a project's yield at a rate equaling the sum of Metropolitan's reclaimed water or other appropriate rate and the annually adjusted

avoided energy cost. Metropolitan then sells the yield back to the member agency at the reclaimed water or other appropriate rate, thereby transferring to the project a net contribution by Metropolitan equal to the annually adjusted avoided energy cost. Under the program, Metropolitan has participated in two groundwater reclamation projects and [illegible] wastewater reclamation projects with a combined total ultimate yield of [illegible] acre-feet per year. Currently, 15 projects with a total estimated yield of 33,500 acre-feet per year are in various stages of review.

Original Program

In 1982, Metropolitan entered into a Letter of Intent to participate in the SAWPA-sponsored *Arlington Basin Groundwater Desalter Project*. In October 1988, Metropolitan executed a Joint Participation Agreement with Western Municipal Water District of Riverside County and SAWPA to develop the project. Under this project, approximately 6,300 acre-feet per year of high-salinity groundwater from the Arlington Basin will be desalted for local use. SAWPA awarded contracts for the desalination equipment and well construction. The project will involve extraction wells, organics-removal facilities, desalting facilities and connections to local water distribution systems. When the project is completed, Metropolitan will retain a right to 61,000 acre-feet of groundwater in the Arlington Basin.

Revised Program

During the fiscal year, two projects were approved and Joint Participation Agreements were executed. Joint Participation Agreements for two additional projects, approved in the previous year, were also negotiated and executed.

The *Lakewood Water Reclamation Project* Joint Participation Agreement has been executed. The project is sponsored by the Central Basin Municipal Water District (CBMWD) and is owned and operated by the city of Lakewood. The project would deliver approximately 400 acre-feet per year of tertiary-treated reclaimed water from the Los Angeles County Sanitation District's Los Coyotes Water Reclamation Plant through the city of Cerritos' reclamation system for landscape irrigation.

The *South Laguna Reclamation Expansion Project* Joint Participation Agreement also has been executed. Sponsored by Coastal Municipal Water District, this project will be owned and operated by the South Coast Water District (South Coast). The project expands South Coast's existing South Laguna Reclamation Project to which Metropolitan contributed capital funds under the original program. The expansion project will produce approximately 700 acre-feet per year of additional reclaimed water from the Aliso Water Management Agency's Coastal Treatment Plant for park, golf course, residential greenbelt, school yard, and highway landscaping irrigation.

The *Fallbrook R[illegible]* Joint Participation Agreemen[illegible] executed Own[illegible] by the Fallbrook Sanitary District ([illegible]D). the project is [illegible] San Diego County Water Authority (SD[illegible]A). The project [illegible] to 1,200 acre-feet per year of tertiary-tr[illegible]ed reclaimed [illegible] Water Reclamation Plant No. 1 for irri[illegible]on of freew[illegible] golf courses, and nurseries within the comm[illegible]ty of Fallbrook and the cities of Oceanside and Carlsbad.

The *[illegible] Reclaimed System Extension Project* Joint Particip[illegible]on Agreement has been executed between Metropolitan, Las Virgenes M[illegible]cipal Water District (LVMWD) acting individually, and LVMWD and Triunfo County Sanitation District acting as a joint venture. The extension project, owned by the joint venture and operated by LVMWD, will produce approximately 700 acre-feet per year of reclaimed water from the joint venture's Tapia Water Reclamation Facility for landscape irrigation. The Expansion Project is an addition to the joint venture's existing Las Virgenes Reclamation Project to which Metropolitan contributed capital funds under the original program.

Of the 15 projects currently under review for inclusion in the program, the following five projects are in advanced review stages. These five projects with a total ultimate yield of 3,722 acre-feet per year, are expected to be approved by Metropolitan's Board of Directors next fiscal year.

Negotiations continued with the *Buena Sanitation District* for the proposed SDCWA-sponsored Shadowridge Reclamation Project. The project [illegible] approximately 350 acre-feet per year of reclaimed water from [illegible] Water Reclamation Plant for golf course and [illegible]

An [illegible] *Expan[illegible]* [illegible] evaluation of the *Glendale Reclam[illegible]* Glendale [illegible] city of Glendale was complet[illegible] politan [illegible] participation agreement with Me[illegible] imately [illegible] expansion project would yield app[illegible] Glendale [illegible] reclaimed water from the Los Ange[illegible] [illegible] park, and landscape irrigat[illegible]

Staff [illegible] for the prop[illegible] Ramona Municipal Water Dist[illegible] this project [illegible] *Santa Maria Reclamation Project*. W[illegible] receive abo[illegible] [illegible] water distribution system wou[illegible] Maria Water R[illegible] of reclaimed water from the Sa[illegible] would then be [illegible] raw water-reclaimed water ble[illegible] golf course and [illegible] irrigation and potentially for futu[illegible]

Discussions are [illegible] with the Trabuco County Water Distr[illegible] for the proposed *[illegible] Reclamation Expansion Project* sponsor[illegible] by the Municipal Water District of Orange County. The project wou[illegible]

[illegible]oduce approximately 672 acre-feet per year of tertiary-treated reclaimed [illegible]ter from the Trabuco Wastewater Reclamation Plant for landscape and [illegible]lf course irrigation.

Metropolitan and the city of San Diego are discussing the proposed [illegible]DCWA-sponsored San Pasqual Aquaculture Project which would supply [illegible]pproximately 600 acre-feet per year of reclaimed water through an [illegible]novative treatment process using water hyacinths. The reclaimed water [illegible]ould be used for landscape and nursery irrigation purposes.

Miscellaneous Local Projects

A survey was performed to determine the amount of reclaimed water use in Southern California. The survey documented 43 existing or under-construction reclamation projects in Southern California which will ultimately deliver approximately 197,000 acre-feet per year of reclaimed water. This represents an increase of 27 percent over the 155,000 acre-feet per year of re-use documented by a 1986 study.

Metropolitan and CBMWD jointly agreed to conduct an implementation study to develop a project providing reclaimed water along the Century Freeway and to six neighboring communities for landscape irrigation purposes. The implementation study, conducted by HYA Consulting Engineers, will identify a project, a lead agency, service area boundaries, institutional arrangements, capital facilities, preliminary costs, and the available financial alternatives.

Program staff is participating on the Bay Delta Reclaimed Water Sub-Work Group Committee organized by DWR at SWRCB's request. SWRCB asked the committee to compile a report which defines water reclamation and estimates the State's potential reclaimed water use by year 2010.

Two draft reports examining the potential for groundwater storage [illegible]rograms were prepared. The "Background Information for a Mojave [illegible]Water Agency Groundwater Storage and Exchange Program" explores [illegible]he feasibility of storing water in the Mojave River Groundwater Basin, [illegible]nd the "Background Information for an Antelope Valley Basin Ground-[illegible]ater Storage Program" examines the possibility of storing water in the [illegible]ntelope Valley Basin.

CHAPTER 4

Water Quality

…gislation and Regulations

The U.S. Environmental Protection Agency (EPA) and the State of California Department of Health Services (DHS) have been actively promulgating regulations under the federal Safe Drinking Water Act (SDWA) Amendments of 1986. Additionally, the California legislature …duced a number of water-quality-related bills.

On August 18, 1988, the EPA proposed a revised maximum contaminant level (MCL) for lead, a new standard for copper, and monitoring and public notification requirements for both. Compliance monitoring in the distribution system for lead and copper standards was originally proposed, but the EPA is now considering requiring monitoring at the homeowner's tap, which could significantly impact water utilities. The final regulation is expected in winter 1990.

The EPA proposed drinking water standards for 30 organic and eight inorganic chemicals on May 22, 1989. These 38 substances are among the 83 chemicals for which the SDWA requires regulation. Metropolitan had submitted comments at the public hearing in July 1988. The final regulation is expected January 1991.

The EPA finalized the Surface Water Treatment Rule (SWTR) and the Total Coliform Rule on June 29, 1989, establishing filtration and disinfection requirements for surface water systems, a revised MCL for total coliforms, and coliform monitoring requirements.

At the State level, monitoring and compliance regulations for organic chemicals became final on January 3, 1989. The DHS finalized MCLs for … chemicals on February 28, for 10 more on April 3, and for three more between January and July 1989. Through the Ad Hoc Committee of the California-Nevada Section of the American Water Works Association (AWWA), Metropolitan reviewed numerous DHS drafts of the State's version of the SWTR.

VOL 12

1,5884

Metropolitan ... for the California legislature's att... to pass a water ... and State primacy bill. Assembl... Byron Sher ... 21 on December 5, 1988. This bill ... amendment ... compromise among interested parties ... currently ... the legislature.

California ... attempted several times to incorporate p... agencies ... utilities into the warning requirements of the Safe Drinking Water and Toxic Enforcement Act (Proposition 65). Although the current bill ... 65 authored by Senator Kopp, is encounter-ing little opposition as it moves through the legislature, a similar bill was vetoed by Governor George Deukmejian last year.

In its 1988 session, the California legislature passed a bill establishing an environmental laboratory accreditation program, effective January 1, 1989. Under this legislation, public water system tests that are required by law must be performed by accredited laboratories. For currently certified laboratories, the accreditation requirement begins when the existing certificates expire. The renewal process will now cover a period of two years instead of three and will be self supporting through accreditation fees. Metropolitan is ... accreditation for its five treatment plant ... Water Quality Laboratory.

General Water Quality

Metropolitan ... of the DHS primary standards and EPA MCL ...

For the ... solids ... the fiscal year average of total dissolved ... from ... at Lake Havasu increased ... (Figure ... 1987-88 to 560 mg/L in 1988-... 10 year ... approximately 60 mg/L below ...

As shown ... Joseph Jensen ... TDS value for the influent to the ... TDS concentration ... plant) was 334 mg/L—the highest ... yearly increase ... years and the fourth consecutive ... Branch of the ... State project water from the West ... December ... at Castaic Lake. However, from ... came from the ... water used by the Jensen plant ... Aqueduct. This ... of Water and Power's Los Angeles ... lower than the ... averaged approximately 100-150 mg ... water.

As seen in ... East Branch water ... average TDS concentration ... TDS value recorded ... Lake, 350 mg/L, was the highest ... since Metropolitan began using ...

... Branch water. For treated water at the five filtration plants, the ...ghted average TDS value was 456 mg/L – the second consecutive yearly ...ease and the second highest TDS concentration in the past seven years.

...ince Metropolitan changed to chloramines, the bacteriological quality ...water in Metropolitan's distribution system has remained excellent ...shown in Table 20, distribution-system samples tested by the ...mbrane-filter technique for coliform bacteria produced monthly ...rages ranging from less than 0.001 to 0.028 coliforms per 100 milliliters ...falling considerably below the DHS standard, which allows a monthly ...rage of up to one coliform/100 ml.

Because nitrification again occurred in several locations within Metropolitan's distribution system and finished-water reservoirs, Metro-politan formulated a comprehensive plan to reduce nitrification occurrence and impact in its facilities and those of its member agencies. The primary nitrification control strategies to be implemented in the next fiscal year include temporarily converting to free chlorination and increasing the ratios of chlorine to ammonia when using chloramines.

In May 1989, a memorandum on the "Criteria for Accepting Treated Groundwater into Metropolitan's System" was issued, defining the criteria that member agencies must meet if they propose to send treated groundwater through Metropolitan's distribution system.

The laboratory information management system (LIMS) has been completely implemented, and the system has received most of the samples that entered the laboratory after December 1988. Successful LIMS demonstrations and interaction with the water quality data base were conducted in October 1988 and June 1989. Improvements in the system's operation are now being considered.

Trace Constituents

...n November 1988, Metropolitan analyzed source waters and filtration-...nt effluents for 16 metals (Table 23). All concentrations of primary ...d secondary standard metals were substantially lower than the MCLs. ...ough a new primary MCL of 1 mg/L became effective for aluminum ...February 25, 1989, aluminum concentrations in Metropolitan's source ...ers and filtration-plant effluents have historically been much lower ...n that value.

...etropolitan continued quarterly monitoring of source and treated ...ers for volatile organic compounds (VOCs) at the sample sites listed ...able 24. The EPA set MCLs for eight VOCs in 1988 and for an additional ...n in 1989. As required by the EPA and DHS, Metropolitan also ...itored for a number of unregulated VOCs. Table 24 lists the regulatory ...rmation and minimum reporting levels (MRLs) for the VOCs. Except

R0049189

for trihalometha[illegible] [illegible] regulated or unregulated V[illegible] were detected [illegible] list the results of other anal[illegible] of Metropoli[illegible]

As in p[illegible] [illegible] monitored pesticides and agricul[illegible] chemic[illegible] [illegible] waters (Table 28). The revised Stat[illegible] Califor[illegible] [illegible] Regulations (Title 22), effective Jan[illegible] 1989 [illegible] [illegible] monitoring for six pesticides (lind[illegible] endri[illegible] [illegible] Silvex) that were regulated b[illegible] [illegible] has one year of consecutive quarterly d[illegible] [illegible] three years for lindane, endrin, toxaphene, and me[illegible] [illegible] will satisfy part of the requirement. Quarterly monit[illegible] 2,4-D and Silvex began in March 1989. Quarterly monitoring of five [illegible] pesticides for which MCLs had been set, as well as eight unregulated pesticides, began in June 1989. Table 28 lists the regulatory information and MRLs for pesticides and agricultural chemicals. Except for the unregulated pesticide Dacthal, no pesticides or agricultural chemicals were detected in any of Metropolitan's supply sources.

A consultant began work to determine radon levels in water from 200 wells located within the major groundwater basins in Metropolitan's service area. In addition, selected homes that receive 100 percent groundwater will be tested to determine ambient air and tapwater radon levels. The study, to be completed in August 1989, will provide data to address the upcoming federal radon regulations. Such regulations may impact the planning of Metropolitan's conjunctive use programs as well [illegible] demands if member agencies should abandon wells [illegible]

THMs and Other Disinfection By-Products (DBPs)

Metrop[illegible] of 0.10 [illegible] comply with the EPA and DHS MC[illegible] annual [illegible] As shown in Table 29, the running average [illegible] distribution system's four quarte[illegible]

To a[illegible] monit[illegible] Metropolitan expanded the THM requir[illegible] DBPs. Five analytical fractions we[illegible] haloce[illegible] haloacetic acids (HAAs), fo[illegible] chloral[illegible] chloral hydrate, cyanog[illegible] formalde[illegible] and acetaldehyde. DB[illegible] The THM [illegible] and State project water blend[illegible] by the HAA[illegible] fraction of DBPs formed, follow[illegible] and th[illegible] [illegible]triles or chloral hydrate (Tables [illegible] or were not de[illegible] [illegible] were formed at very low levels [illegible] and acetaldehyde were occasionall[illegible]

WATER QUALITY

d[illegible]ted in State project source water and were found to incre[illegible] distribution system. Also, higher levels of cyanogen chlorid[illegible] d[illegible]ted when using chloramine disinfection than were present w[illegible] chlorine disinfection.

Additionally, in June 1989, Metropolitan completed a two-year n[illegible]nwide study for the DHS and the EPA on the occurrence of these s[illegible] 21 DBPs, and is completing a treatment and control study of these c[illegible]pounds for the EPA. The largest DBP fractions were composed of THMs (national median of TTHM sums = 39 μg/L) and HAAs (national median of HAA sums = 19 μg/L). Study results also showed that utilities using free chlorine as a disinfectant typically exhibited higher DBP levels than utilities using chloramines, with the exception of the DBP cyanogen chloride. Utilities employing ozone had higher levels of the nonhalogenated DBPs formaldehyde and acetaldehyde. Also, the presence of bromide in source waters shifted the distribution of some DBPs from chlorinated to brominated species.

The results of these studies may enable utilities to predict the particular DBPs formed as a result of source-water quality, seasonal factors, and treatment processes. In addition, the results will help both the EPA to define the best available technology to set DBP regulations and the water utility industry to select treatment processes to meet DBP regulations.

In February 1989, the final report on "Optimization and Economic Evaluation of Granular Activated Carbon for Organic Removal" was finished and submitted to the AWWA Research Foundation (AWWARF). This completed a two-year bench- and pilot-scale study by Metropolitan and James M. Montgomery, Consulting Engineers, Inc. (Montgomery), on the use of granular activated carbon (GAC) to lower THM and other DBP levels. In summary, GAC adsorption proved expensive as a means to control THMs. Metropolitan's capital cost to use GAC, based on a capacity of 2,970 million gallons per day (mgd), would be $730 and $[illegible] million to meet future THM MCLs of 50 μg/L and 5 μg/L, respectively.

[illegible]th Montgomery's assistance and an AWWARF grant, pilot-scale [illegible] continued to evaluate the effectiveness of ozone and PEROXONE, [illegible] combination of hydrogen peroxide and ozone for removing taste and [illegible] compounds, inactivating microorganisms, and controlling DBPs. [illegible]lts obtained this year indicate that PEROXONE was significantly [illegible] effective than ozone alone in controlling taste and odor compounds, [illegible]ically 2-methylisoborneol (MIB) and geosmin.

[illegible] equivalent removals of MIB and geosmin, the ozone dosage required [illegible] PEROXONE at the optimum hydrogen peroxide/ozone ratio equaled [illegible]ximately half that needed for ozone alone. Preoxidation with [illegible]OXONE or ozone, each followed by chloramines, was found to

A demo... oxidation facility with a capacity of 5.5 mgd is being ... evaluate the ozone and PEROXONE treatment processes ... first phase concluded in January 1989, a five-month ... study reviewed worldwide ozone technology and recommended ... approach for the demonstration plant. The design phase, which began in January 1989, is expected to be completed by October 1989. The ... oxidation demonstration project should confirm the results of the pilot-plant studies, evaluate processes and equipment for the country's first large-scale application of PEROXONE for surface water treatment, and provide the information necessary to retrofit Metropolitan's plants with ozone/PEROXONE. Critical issues to be addressed include ozone dosage, hydrogen peroxide/ozone ratio, contact time, and application methods and locations. Also, investigators will determine the impacts of ozone and PEROXONE on existing downstream conventional treatment processes. The 12-month construction phase of the project, if approved by the Board of Directors, is expected to begin in March 1990.

Reservoir Management

...kes Mathews and Skinner were once again affected by growths of ... blue-green algae that produce the malodorants MIB and geosmin. ... stem the growth of the taste- and odor-producing algae *Phormidium* ... and *Oscillatoria curviceps*, helicopters applied 86 tons of copper sulfate ... the lakes' shallow-water areas during the 1988 taste and odor season. As in past years, Metropolitan's divers conducted regular on-site inspection and sampling. Because of the efficient monitoring program and effective copper sulfate treatments, MIB and geosmin production remained low throughout the 1988 taste and odor season. Lake Perris, a California Department of Water Resources terminal reservoir for East Branch State project water, experienced very high levels of taste and odor compounds this season. Geosmin levels as high as 450 µg/L were produced during planktonic algae blooms. Consequently, water used by Metropolitan had to be withdrawn from the lakes' lower depths, where geosmin levels were much lower.

A testing program was initiated to determine whether chlorination effectively controls San Diego Canal algae growths, which reduce the canal's flow capacity. Previous work demonstrated that copper sulfate was ineffective.

Treatment-Plant Studies

In May 1989, a memorandum was issued entitled "Uniform Approach to Filtration-Plant Design Criteria," which defined process criteria for a "standard" Metropolitan filtration-plant process train. These criteria will be used in expanding existing plants, designing new plants, and reviewing the capacity ratings of existing plants.

... January 1989, Phase I studies, conducted jointly with the consulting ... CH2M Hill, Inc., began for the Robert B. Diemer Filtration Plant (...ner plant) uprating and the Henry J. Mills Filtration Plant (Mills ...t) expansion. The Phase I studies will evaluate existing plant facilities, ...s plant operation, and develop capacity ratings for the existing plants. ... results will be used in Phase II, which will evaluate the process ...rovements required to permanently uprate and maximize the Diemer ...'s rated capacity and will develop process design criteria for the ...her expansion of the Mills plant.

... April 1989, consultants Metcalf & Eddy completed the washwater ...mation study, and issued reports covering the results for the Jensen, ...ner, and Weymouth filtration plants.

In a related project, a pilot study was started in April 1989 to evaluate the Diemer plant [illegible] of filter air binding, which may limit the plant's uprated capacity. This study will evaluate the impacts of air binding on the filtration process with respect to supersaturation of dissolved air in the [illegible] entering the plant and the physical configuration [illegible] Diemer's filters.

In February 1989, staff began compiling a comprehensive data base of filtration performance (from 1982 to the present) at all of Metropolitan's filtration plants. These historical performance data bases will facilitate the plants' operation, upgrade, and conceptual design.

A project was initiated in June 1989 to determine whether Metropolitan's filtration plants will comply with the SWTR provisions that deal with water quality instrumentation, monitoring, and addition of coagulants to filter backwash water.

In December 1988, a Jensen plant study was finished, evaluating Jensen's filters with respect to turbidity removal, filter run length, headloss, and media condition. Results indicated that filter performance has declined over the past five to 10 years and that the filter media no longer meet Metropolitan's design specifications. To ascertain whether all of Jensen's filter media should be replaced, and to determine the optimal media configuration, a one-year test using four full-scale filters will begin at the Jensen plant in late 1989.

In April and May 1989, Jensen plant filter media were disrupted by hydraulic conditions created in the filter beds by operating the plant at high [illegible]. Recommendations were made to further [illegible] and develop a solution.

Operational Activities

A special data acquisition and transfer system utilizing microcomputers and specialized [illegible] developed to partially address the extensive SWTR filtration plant and water quality monitoring requirements. Each filtration plant laboratory is now equipped with a microcomputer, and plant personnel are evaluating software. A data transfer system for centralizing information within Metropolitan for assembly and submission to the DHS is expected to be operational by next fiscal year.

As required by the Federal National Pollutant Discharge Elimination System, 92 monitoring reports were prepared and presented to the Regional Water Quality Control Board concerning discharges of Metropolitan's water, wastewater, and sludge.

Assistance to Others

Metropolitan confirmed and recommended corrective measures to the City of Burbank, the Rowland Heights Water District, and the Municipal Water District of Orange County for nitrification problems occurring in their distribution systems or finished water storage reservoirs. Throughout the year, other member agencies and subagencies received assistance in resolving water quality degradation problems.

Approximately 100 people attended a seminar workshop presented by Metropolitan staff for two member agencies, the San Diego County Water Authority and the West Basin Municipal Water District, on the impact of nitrification on water quality and the effectiveness of nitrification control strategies.

Metropolitan organized and implemented regular meetings of the Member Agency Water Quality Directors to encourage information exchanges on water quality and regulatory matters between Metropolitan and its member agencies and subagencies.

Electric conduit work is done during the shutdown of the Venice Hydroelectric Power Plant

CHAPTER 5

Planning

Advance Planning Activities

System Overview Study

The Distribution System Overview Study (Report No. 971) was published and distributed in October 1988, and is a guideline for planning transmission, storage, treatment, and distribution facilities. The population within Metropolitan's service area is projected to increase from 14.5 million to 18.2 million, or 25 percent, over the next 20 years. By the year 2010, the demands on Metropolitan are expected to increase from the present use of more than 2 million acre-feet (maf) to almost 3 maf, primarily in treated water demands. In addition, new facilities and modifications to existing facilities will be necessary to meet these growing demands, to comply with more stringent Federal and State drinking water standards, and to maintain high standards of reliability throughout the growth period.

Area Studies and Facility Plans

Based on needs identified in the Distribution System Overview Study, area studies and facility plans are being conducted to evaluate key facilities in greater planning detail. Area water demand studies and facility plans are designed to determine the required facilities, estimate the capacity of those facilities, evaluate alternatives, and establish a project time-line and budget. The studies underway include expansion of the Henry J. Mills (Mills plant) and Robert A. Skinner (Skinner plant) Filtration Plants and construction of an Inland Feeder, an Eastside Reservoir, an Orange County treatment plant, and a Perris treatment plant. To effectively coordinate the planning and engineering work, multi-divisional task forces have been formed for each study.

Mills Area Study

Located in Riverside County, the Mills plant began service in 1978 with a capacity of 75 million gallons per day (mgd). The plant's first expansion was under construction this past year and will be placed int... rvice in the summer of 1989, doubling the Mills plant's total capacity. H... ever, Metropolitan's supplemental water demands are projected to i... crease by approximately 65 percent by 2010, and based on these pro... tions, the Mills plant will likely require expansion again in the mid-1990s.

Perris Area Study

The Distribution System Overview Report identified the need for a new treatment plant near Lake Perris to meet the increasing water demands in Riverside County and to supplement Mills plant activities. An area study to identify the location, size, and schedule for a new Perris treatment plant was initiated in June 1988.

After initially screening 26 potential treatment plant sites, staff selected five sites in an area south of Lake Perris for further analysis. Preliminary geotechnical assessments and reconnaissance level environmental studies have been conducted on the five sites. An engineering evaluation to determine the technical and operational feasibility of each site is currently underway.

South Riverside San Diego Area Study

The San Diego Canal and the Skinner plant serve the south Riverside San Diego area. The San Diego Canal, which currently has a capacity of 1,200 cubic feet per second (cfs), is being expanded to 1,70... cfs. The Skinner plant capacity is also being expanded, from 320 m... to 520 mgd. Both expansions are scheduled for completion in 1991.

According to studies conducted in 1986 by Metropolitan and the ... Diego County Water Authority (SDCWA), the expanded facilities w... adequately meet water demands until the year 2000 or beyond. However, the latest forecasts issued by the Southern California Associati... Governments (SCAG) and the San Diego Association of Governm... (SANDAG) indicate increasing population projections for sou... Riverside and San Diego counties. Water demand projections ind... that additional treatment and conveyance facilities will be ne... around 1997.

Currently underway, a study identifying near-term and long-range f... ity plans for the area is being closely coordinated with area mem... agencies to identify opportunities for joint operations and poter... groundwater development in southern Riverside County. Metropol... is also participating in SDCWA's Optimal Storage Study that will iden... ways to optimize reservoir facility use in San Diego County. This a... study is also coordinated with the Perris San Jacinto treatment pl... study and the Eastside Reservoir study.

Inland Feeder Study

Due to steadily growing water demands and projected reductions of Colorado River water deliveries, an Inland Feeder is needed to bring more State project water into Metropolitan's service area by the year 2000. Under study for some time, this facility has been an important element of Metropolitan's system development plans. The Inland Feeder will be a raw water conduit that will convey State project water from the expanded California Aqueduct East Branch to the Colorado River Aqueduct near San Jacinto. Through this feeder, Metropolitan can avail itself of additional State project or exchange water required to meet member agency needs starting in the year 2000. Furthermore, it will enhance system reliability by connecting major aqueduct systems and enable Metropolitan to blend State project and Colorado River supplies throughout greater portions of the service area.

The Inland Feeder Study originally identified 17 alternative alignments for the Inland Feeder. During the fiscal year, reconnaissance studies reviewed these alternative alignments, determining the relative merits of individual alignments and identifying five to be evaluated further. Reconnaissance studies included hydraulic analyses and seismic risk assignments of each alignment, biological land use and cultural resources surveys to support required California Environmental Quality Act (CEQA) documentation, and an operating analysis of deliveries through the Inland Feeder according to available State project supplies. Each of the five alignments consists of a series of tunnels and pipelines extending 35 to 40 miles in length. The routes transverse two counties, six water districts, and 18 cities.

Central Pool Augmentation and Water Quality Project

This project, which evolved from the south Orange County Study, will augment service to Metropolitan's central service area (Los Angeles, Ventura, and Orange counties) via additional conveyance and treatment capacity.

Project components include a second outlet tower at Lake Mathews, a pipeline tunnel into Orange County through the Santa Ana Mountains, and a new filtration plant located either at Lake Mathews or in south Orange County. This plant will relieve the Robert B. Diemer Filtration Plant (Diemer plant) of a large portion of its Orange County load, enabling it to serve other parts of the central service area. The new plant is expected to be on-line by 1998.

San Joaquin Reservoir Improvement Project

Located in Newport Beach, the San Joaquin Reservoir is a 3,000 acre-foot finished water reservoir jointly owned by Metropolitan and several-

VOL 12 1 5899

R0049204

local agencies. In recent years, frequent episodes of high bacteria counts have caused periodic bypassing of the facility. This project aims to improve reservoir water quality and to better integrate the water into Metropolitan's distribution system. Alternatives under consideration include: (a) a new filtration plant to treat reservoir effluent, (b) various types of reservoir covers, (c) replacing a new pipeline from the Diemer plant to the service connections at the Coastal Junction delivery point, (d) abandoning the reservoir, and (e) continuing operating the reservoir as at present.

Eastside Reservoir Study

Metropolitan has identified the need to virtually double its reservoir capacity in the next 40 years. Reconnaissance studies, initiated in 1987, have identified up to 19 alternative reservoir sites which either singly or in combination could meet this need. The reservoir sites have been evaluated against various engineering, cost, environmental, and operational criteria. From these studies, five potential sites have been selected for evaluation during detailed feasibility studies, which will include preparing an Environmental Impact Report (EIR). The five alternative sites, all in Riverside County, include the potential expansion of Lake Perris, a reservoir at Potrero Creek south of the city of Beaumont, a reservoir at the Domenigoni Valley southwest of the city of Hemet, the expansion of Lake Skinner, and the expansion of Vail Lake. These alternatives will be further evaluated and reduced in number near the end of 1989. During the studies, coordinated surface reservoir and groundwater operations also will be evaluated. Groundwater storage is expected to meet a portion of the total storage need.

Detailed land use studies indicate that several of the potential reservoir sites could be subjected to strong land development pressures during the study period. As a result, Metropolitan's Board of Directors authorized funding in November 1988 and again in May 1989 to acquire options or to purchase properties where development pressures could eliminate a site before reservoir studies could be completed. Negotiations to purchase lands have been initiated at the Domenigoni Valley and Potrero Creek sites. Studies are scheduled for completion in mid-1991 at which time a final reservoir site will be selected.

Weymouth Lake Mathews Area Study

Over the next 25 years, the Chino Basin area within western San Bernardino County is expected to continue its rapid population growth, projected to double by the year 2010, causing a corresponding rise in municipal and industrial water demands. These demands will substantially increase raw and treated water delivery requirements within the Weymouth Lake Mathews service areas. An Area Study currently underway will determine the scheduling for the Rialto Pipeline paralleling,

the need for the Chino Valley Pipeline, and expansion of F.E. Weymouth Filtration Plant (Weymouth plant). During the fiscal year, hydraulic evaluations of the existing raw water conveyance lines and the Weymouth plant were conducted. In addition, alternatives for increasing raw and treated water to the Chino Basin area have been initiated.

Water Quality, Supply and Demand Studies

Water Supply and Demand Models

The *MWD-MAIN water demand forecasting model*, originally developed for the U.S. Army Corps of Engineers and later calibrated for use by Metropolitan, is used within Metropolitan's service area. In forecasting demands, the model incorporates numerous demographic, econometric, and climatic variables, including the number and types of housing units (single- and multiple-family dwellings), housing density, housing values, and employment levels for more than 200 different industrial and commercial sectors. It also accounts for changes in water and waste water rates and various types of water conservation programs. The model provides disaggregated water demand forecasts for four major water-use categories: residential, commercial, industrial, and public/unaccounted. Additionally, these forecasts are further disaggregated into very specific water use categories to better understand the service area's water-use characteristics.

During 1988-89, four technical improvements were made in the model. First, its commercial and industrial water-use coefficients were updated to reflect a special recovery of water use by 3,000 commercial and industrial establishments in Metropolitan's service area. Second, the population, housing, employment, and land-use projections were updated to encompass the 1988 revisions made to regional growth plans by SCAG and SANDAG. Third, the residential demand equations were revised per a special study of 1,250 households in five southern California communities. Finally, the water conformation assumptions are being updated to indicate implementation of "best management practices" throughout the state.

Since climate influences water use, Metropolitan continued developing the *METROWATFORE model* to supplement the MWD-MAIN model to estimate *variations in water demands due to climate swings*. The demand fluctuation caused by weather variation has been estimated to be about 8 percent above and below the total normal MWD-MAIN model demand projection, at the 90 percent confidence level.

A short-term *monthly demand forecast model* was developed in 1988-8 that includes a population trend, a seasonal component for capturing the characteristic monthly water-use pattern, and climatic variables to show the effect of specific month-to-month rainfall and heat conditions. The monthly model explains more than 97 percent of the month-to-month demand variation, and allows staff to estimate short-term future demands and storage levels for various temperature and rainfall scenarios.

Used during the DROUGHT '88 campaign, the demand forecasting model showed that regional water use decreased by about 90,000 acre-feet during the 1988 summer months, an approximate 7 percent savings.

Staff developed a *computerized distribution system flow model* to route water through Metropolitan's delivery system and to assist in identifying the need for future system improvements and their scheduling. Specific projects now being analyzed include the Eastside Reservoir, Inland Feeder, and South Orange County Treatment Plant.

Regional Population and Water Demand Studies

In early 1989, SCAG adopted its Growth Management Plan, with revised forecasts of year 2010 population, housing, and employment within a six-county Southern California planning area. SANDAG had adopted its Series 7 forecasts in 1988. Metropolitan's staff has incorporated the revised forecast results into the MWD-MAIN water demand studies and facility planning. The key findings are that by the year 2010:

(1) the population of Metropolitan's service area will increase from the present 14.5 million to 18.2 million with two-thirds of the increase due to births over deaths,

(2) the number of housing units will increase from 2.8 million to 3.4 million,

(3) total employment will increase from 4.2 million to 5.0 million,

(4) the increase in population, housing, and employment will create a need for an additional 1 maf of water to meet municipal and industrial demands, and

(5) the demands on Metropolitan could increase by 700,000 acre-feet per year depending on weather conditions and Los Angeles Aqueduct supplies.

Water Resources Data (PINS)

Staff has developed a computerized data base and retrieval system called the Planning Information System (PINS). PINS contains data on

Metropolitan's daily system flows and monthly water sales, daily rainfall and temperature data, local water production, groundwater quality, and water supplies to Metropolitan, as well as population and demographic statistics. Accessible to all divisions, PINS data files are part of Metropolitan's corporate data base and provide data for analyzing seasonal and annual water demand forecasts, future delivery system requirements, and the Finance Division's annual water rate recommendations.

PINS software development is now 80 percent complete, and will be finished during the next fiscal year. PINS currently contains 3 million records of information, approximately 1 million additional records of information will be added every year.

Water Quality Studies

Metropolitan currently provides 55 percent of all the water used annually within its service area. Local ground and surface water and the Los Angeles Aqueduct meet the remaining demand.

However, the future availability of local water is affected by groundwater quality conditions and changing regulatory requirements. Metropolitan is now collecting data to update its 1986 Report No. 969, "Groundwater Quality and Its Impact on Water Supply in the Metropolitan Water District Service Area," a reconnaissance assessment of groundwater conditions. Beyond providing assessment of current groundwater quality conditions and changes since 1986, this updated study will evaluate how new and proposed water quality standards potentially affect groundwater availability. Study results will further define the supplemental water needs from the Colorado River and State Water Project.

Environmental Studies

Garvey Reservoir Operations and Maintenance Facility

Pursuant to CEQA, a Negative Declaration was prepared regarding constructing a new operations and maintenance facility on the Garvey Reservoir property. The new facility will accommodate additional administrative, operations, and maintenance activities of the Los Angeles Section staff. The Board of Directors approved the Negative Declaration on May 9, 1989. Final CEQA documents were subsequently filed with the appropriate State and local agencies.

Joseph Jensen Filtration Plant Expansion

Staff completed a Negative Declaration for the facilities needed to expand the Jensen plant's existing capacity of 350 mgd to a total capacity of

750 mgd. This expanded capacity will meet above-normal, peak-week demand for supplemental treated water in the Jensen service area. The Board of Directors approved the Negative Declaration on March 14, 1989, and the final documents were filed with the appropriate State and local agencies.

Environmental Documents in Preparation

At year's end, staff were actively involved in preparing seven EIRs. A Draft EIR was completed for the San Joaquin Reservoir Improvement Project. As CEQA requires, this document was transmitted for public review.

Notices of Preparation were completed and published for the Central Pool Augmentation and Water Quality Project, Arvin-Edison Water Storage and Exchange Program and Eastside Reservoir Study. A Notice of Preparation is a CEQA document that advises the public of an agency's decision to prepare an EIR. It solicits public comments on the EIR's scope and contents, and initiates the CEQA compliance process for the proposed project.

Environmental reconnaissance studies were initiated for the Perris Area Study, South Riverside-San Diego Area Study, and Inland Feeder Study. These preliminary investigations will help identify the scope of environmental compliance requirements for subsequent actions, develop project schedules and cost estimates, screen alternatives, modify project plans to mitigate significant adverse effects, and expedite the environmental compliance process for recommended alternatives.

Conservation and Water Management

Arvin-Edison Water Storage and Exchange Program

During the past year, Metropolitan and the Arvin-Edison Water Storage District (Arvin-Edison), a Federal Central Valley Project contractor in Kern County, progressed considerably in implementing the Arvin-Edison Water Storage and Exchange Program. Under this program, Metropolitan can accumulate an underground reservoir of about 800,000 acre-feet by storing available State project water in the groundwater basin underlying Arvin-Edison. During future dry years, Metropolitan would receive, through exchange, water that would otherwise be delivered to Arvin-Edison, increasing available dry-year supplies by about 100,000 acre-feet annually.

During 1989, progress was made on numerous difficult implementation issues. Responding to concerns of other State Water Contractors,

Metropolitan and Arvin-Edison agreed to develop their program such that it would not cause greater shortages of entitlement water available from the State Water Project (SWP). Working closely with the State Department of Water Resources (DWR), the two entities extensively studied the program's potential impacts and developed procedures to assure that program operations would not adversely affect other contractors. Based on the DWR studies, the Arvin-Edison program will allow DWR to deliver more than 1,000,000 additional acre-feet of water to Metropolitan in the future without negatively impacting deliveries of entitlement water to others.

In cooperation with Arvin-Edison and the U.S. Bureau of Reclamation (Reclamation), Metropolitan has also developed an approach to supplement the water rights permit held by Reclamation—a difficult step necessary for the program's ultimate implementation. In Kern County, the program will generate significant economic benefits but also raises local concerns about an agreement with urban Southern California. Thus, a series of public meetings are underway to provide information about program operations and benefits and to resolve the concerns of local residents, landowners, and others. Despite recent progress, a full program implementation may take more than two years.

Completed environmental documentation for the project is expected in spring 1990, with final design and facility construction to follow. Meanwhile, Metropolitan and Arvin-Edison have developed an interim program to allow for water storage while the long-term program is finalized.

Water Conservation

Regional Urban Water Management Plan

In 1983, the California Legislature passed the Urban Water Management Planning Act, AB 797. The Act required most retail urban water suppliers to prepare water management plans documenting existing and future water management activities, including water conservation. Although Metropolitan was not obligated to prepare a plan, it did so to assist its member agencies in developing their plans.

Per the Act, plans face revision after five years. During the year, work began on revising Metropolitan's Regional Urban Water Management Plan. The revised regional plan, which will be completed in 1990, will provide the framework for Metropolitan's future water management activities, as well as assist Metropolitan's members and sub-agencies in revising their plans.

Conservation Credits Program

To encourage member agencies to undertake aggressive water conservation programs, Metropolitan introduced the Conservation Credits

Program (CCP). CCP provides financial incentives for implementing conservation projects with verifiable water savings. Under CCP, Metropolitan will pay the lesser of one half of a conservation project cost or an amount per acre-foot of water saved based on the avoided cost of SWP aqueduct pumping, subject to a minimum pumping cost of $75 per acre-foot.

In 1989, Metropolitan and the city of Pasadena initiated the first CCP project. Under this pilot project, Pasadena will survey indoor and outdoor water use at 2,400 single-family homes to determine water savings potential and to implement appropriate conservation measures. A second program with Pasadena was initiated to distribute low-flow showerheads and toilet displacement kits to the entire city, or 34,000 single-family residences. This program is expected to save approximately 4,990 acre-feet of water during the project's five-year span.

In another CCP project, Metropolitan and the city of Santa Monica will replace high-flow toilets and showerheads in existing residences with ultra-low-flow toilets and showerheads. This will be the first such program implemented in Metropolitan's service area. Approximately 25 percent of the bathrooms in Santa Monica will be retrofitted over a five-year period, with a $100 rebate provided to homeowners for each bathroom retrofitted. To help finance the program, a surcharge of $0.50 per month will be levied on non-participants for each bathroom not retrofitted. Water use in participating households is expected to drop by about 70 gallons per day.

Metropolitan is entering into agreements with Municipal Water District of Orange County and its sub-agency, Irvine Ranch Water District, to conduct residential pilot water conservation studies in Orange County. Approximately 4,000 homes will be retrofitted with low-flow showerheads and toilet displacement devices, and complete indoor-outdoor home water surveys will be conducted on an additional 1,000 homes to determine the potential for large-scale water savings using these techniques.

Metropolitan and its member agencies are currently studying a variety of other proposals. The San Diego County Water Authority has proposed a large-turf water audit program, while the city of Los Angeles' Department of Public Works has submitted a proposal to retrofit 100,000 single-family homes with low-flow showerheads and toilet displacement devices.

Landscape Water Conservation

Metropolitan's third California Irrigation Management Information System (CIMIS) weather station was installed at Three Valleys Municipal Water District's treatment plant in Claremont. It joins the Irvine and

Hollywood Hills stations installed last year. A contract was also signed to install a CIMIS weather station at Mount Olivette Reservoir in the city of Santa Monica. Additionally, DWR has placed seven CIMIS weather stations within Metropolitan's service area.

To encourage using CIMIS weather data to schedule irrigation of large landscaped areas and improve irrigation systems, Metropolitan contracted with the University of California Cooperative Extension, the Ventura County Resource Conservation District (VCRCD), and the Irrigation Association to train irrigators of large landscaped areas. The training's purpose is to help irrigators evaluate their irrigation systems efficiency and apply CIMIS weather data to help schedule irrigations. About 300 irrigators were trained by the University and VCRCD during the year. Altogether, 1,500 of the largest turf irrigators in Metropolitan's service area will be trained to help them substantially reduce water use.

Residential Water Conservation Pilot Projects

Metropolitan's consultant project manager, Brown and Caldwell, Consulting Engineers, has completed the field survey work on several pilot projects, including residential water audits and a residential leak detection program. Initial results indicate that the pilot studies successfully demonstrated that these measures could be effective in saving water and money. Metropolitan will receive a final report once Brown and Caldwell has completed its analysis of study results.

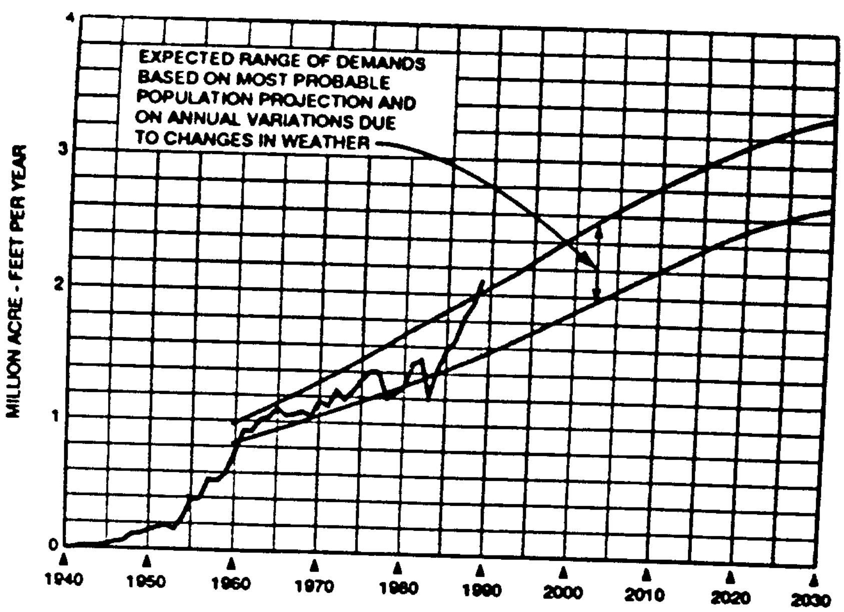

Figure 14 Total Projected Water Demand to be Met by Metropolitan

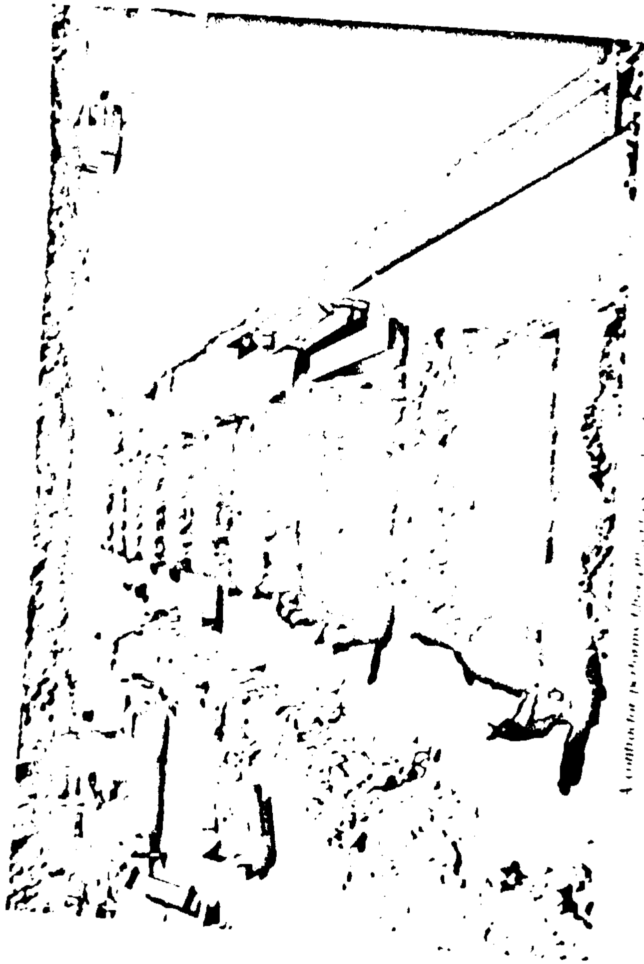

CHAPTER 6

Engineering

During fiscal year 1988-89, Metropolitan continued the third major engineering design and construction period in its history. The expanded work program answers the need to expand or modify existing facilities and to construct new facilities to meet increasing water demands in Metropolitan's service area. The 1988-89 engineering work program was based on facility requirements specified in the Planning Division's System Overview Study and those that meet anticipated State and Federal water quality standards. Design and construction programs dealt with water transportation, purification, storage, and distribution facilities, and included rehabilitation, expansion, modification, and new-construction work.

Under the expanded work program, both Metropolitan staff and outside consultants conducted a number of studies relative to project alternatives and feasibility and system design capacities.

Major ongoing activities included dam and reservoir investigations and surveillance, office automation, substructure investigations, corrosion control, materials evaluation, and metallurgy studies. Other significant programs under way during the year involved seismicity investigations and response, pipeline relocations, service connection constructions and refittings, and records of survey for pipeline and aqueduct survey maps.

The consulting firm of Touche Ross & Company completed a study and prepared a report examining Engineering Division staffing requirements and the division's operational strategies. The report provides recommendations for increasing production and improving operational efficiency and supports the current and planned increased use of professional consultants and temporary personnel to assist Engineering staff members during peak work-load periods.

Capital Projects

Capital expenditures for fiscal year 1988-89 totaled more than $54 million, an increase of about $25 million over the previous year. This figure covers work performed under contract and by Metropolitan, and includes

VOL 12 159C96

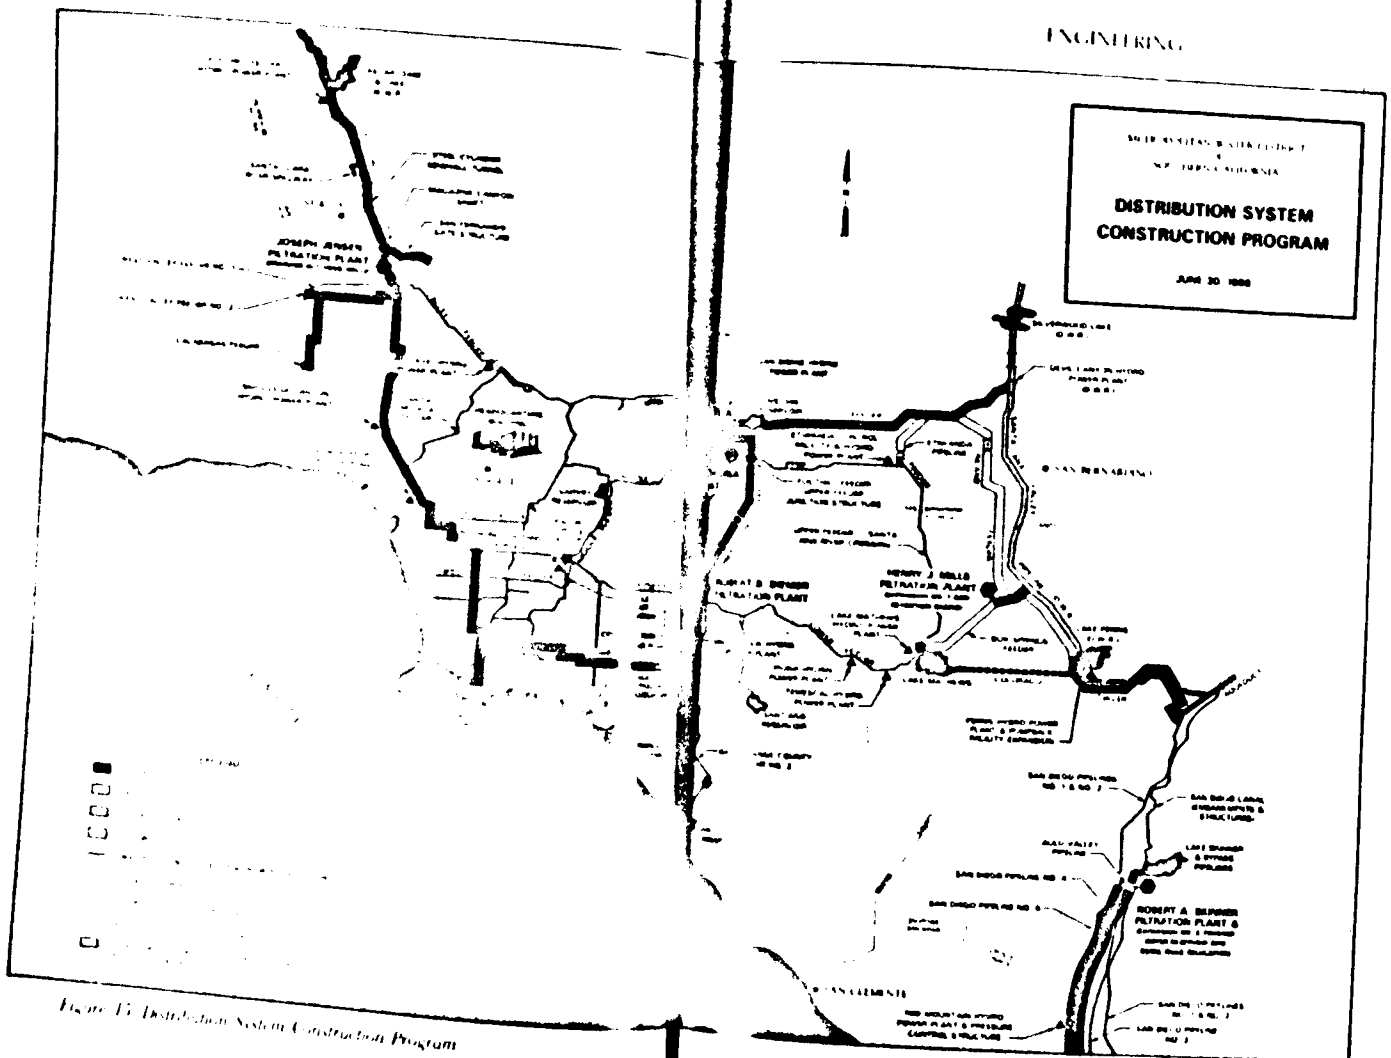

Figure 15 Distribution System Construction Program

equipment and right of way procurement, design, contract administration, inspection, and general administration. Metropolitan's existing and proposed facilities and pipelines are shown in Figure 15, while Table 3? summarizes projects in various design and construction stages.

Construction

Outside Contracts

During the fiscal year 17 construction contracts covering modifications, betterments, and expansions to existing facilities were in progress. Contractor earnings under these contracts totaled $20,532,361 during the fiscal year.

Additionally, the Board of Directors or the General Manager awarded nine construction contracts valued in excess of $71 million. Included in these contracts was the construction of Expansion No. 3 to the Robert A. Skinner Filtration Plant (Skinner plant), the Skinner plant's finished water reservoir and additional retention basins at the Henry J. Mills Filtration Plant (Mills plant). Eleven construction contracts were completed during the fiscal year with gross contractor earnings of $29,318,726. At fiscal year-end, six construction contracts valued at an estimated $70.8 million were progressing. Capital construction projects in progress at various times during the fiscal year included:

- Skinner Plant Expansion No. 3 — To better handle San Diego County's growing water demands, Metropolitan's existing facilities, including the Skinner plant, are being improved and expanded. This 200 million gallon per day (mgd) plant expansion will increase plant output from 340 mgd to 540 mgd and involves filtration modules, flocculation basins, chemical mixing and storage facilities, plant control units, and washwater reclamation facilities. Kiewit Pacific Company was awarded the construction contract at a bid price of $45.1 million in April 1989. Completion of this expansion project is presently scheduled for April 1991. Essentially, only mobilization operations were accomplished during the fiscal year.
- Finished Water Reservoir — Included in the major expansion of Skinner facilities, a 340-acre-foot finished water storage reservoir with a floating synthetic rubber cover will be constructed to improve supplies to the San Diego County Water Authority. This reservoir will ensure adequate disinfection contact time. A construction contract exceeding $20.5 million was awarded to Kiewit Pacific Company in May 1989; mobilization operations were progressing at fiscal year-end. All work required under the contract is currently scheduled for completion during February 1991.

- **Borel Road Relocation** — Relocating a portion of Borel Road was required for the Skinner plant expansion and construction of the finished water reservoir. McGrew Construction Co. completed relocation operations during December 1988.
- **Mills Plant Expansion No. 1** — Costing about $13.3 million, the 75-mgd expansion to the existing Mills plant was completed during June 1989. Prime contractor on the project was Dillingham Construction, N. A., Inc.
- **Retention Basins at Mills plant** — In connection with the Mills plant expansion, a $1.584 million contract to modify existing retention basins and construct additional retention basins was awarded to G. A. MacDonald Construction. This work will upgrade the plant's existing reclamation system to handle the increased water flow from the plant. Construction operations began in November 1988 and were 95 percent complete by the end of the fiscal year.
- **Floating Cover for Palos Verdes Reservoir** — Installation of this one-million-square-foot floating synthetic-rubber cover over the Palos Verdes Reservoir was completed during July 1988 by Gulf Seal Corporation at a final construction cost of $3,850,559.
- **Newhall Tunnel Liner** — Approximately 3,000-linear-feet of the existing Newhall Tunnel needed impervious steel lining to prevent continued seepage of crude oil into the water being transported from Lake Castaic to the Joseph Jensen Filtration Plant (Jensen plant). Installation of the 236-inch-diameter steel cylinders was completed by J. F. Shea Co., Inc. during May 1989 at a construction cost of $8,844,325.
- **Middle Feeder Relocation** — Part of the existing 83-inch-diameter Middle Feeder was relocated to accommodate construction of the proposed State Route 105 (Century Freeway). Advanco Constructors, Inc. completed relocating 1,100-linear-feet of pipeline during July 1988 at a cost of $1,478,595. This project is reimbursable by the State of California.

Details of various miscellaneous construction contracts awarded, in progress, or completed during the fiscal year are shown in Table 34. These projects consisted entirely of repairs and modifications to existing facilities and were located throughout Metropolitan's distribution network.

Metropolitan Construction

Major construction projects in progress during fiscal year 1988-89 by Metropolitan forces included rehabilitating Colorado River Aqueduct pump plant systems; structural modifications to the East Valley Feeder to improve operational reliability, facilitate maintenance and protect valves, installing operator-assisted automated control systems for the existing Mills filtration plant (Module No. 1) and the Mills expansion (Module No. 2), the Robert B. Diemer Filtration Plant (Diemer plant) and the Skinner plant (Modules Nos. 1, 2, and 3) and refurbishing F. E. Weymouth Filtration Plant (Weymouth plant) equipment to maintain operating reliability, improve water quality and energy management and automate the plant. Although design work is still under way to modify the Diemer plant to increase capacity, some construction work was also in progress during the year.

Engineering Design

Extensive design work was undertaken during the fiscal year. The following are major projects in design during the year:

- San Diego Canal Enlargement — The San Diego Canal will be enlarged to a 1,700 cubic feet per second (cfs) capacity to help meet the projected demand for San Diego County and the south part of Riverside County. The project will include raising canal banks and linings, weir walls, walkways, structure walls, and headwalls, and replacing radial gates where necessary to gain additional flow capacity. Design work was completed at fiscal year-end.
- Etiwanda Facilities — The Etiwanda Pipeline and Pressure Control Structure are being designed to deliver additional State project water from Devil Canyon into Metropolitan's distribution system. (The additional water will be made available by the California Aqueduct East Branch enlargement.) Extending about six miles from the Rialto Pipeline to the Upper Feeder in the Fontana area, the pipeline will contain a design capacity of 1,000 cfs and an inside diameter of about 12 feet. To control the pipeline's water flow, a pressure control structure and 450 acre-foot regulating reservoir are also being designed. Under the Etiwanda project, a 20-megawatt turbine-generator power plant is being designed to recover energy which would otherwise be wasted through the pressure control structure. The pressure control structure, power plant, and reservoirs will be located in the Rancho Cucamonga area. Design work on the pipeline and pressure control structure is scheduled to be completed by about February 1990, on the power plant, by June 1991.
- Jensen Filtration Plant Expansion No. 1 — The Jensen plant will be expanded from the existing 350-mgd capacity to a 750-mgd capacity to join with the Diemer and Weymouth plants in meeting increased water demands in Metropolitan's Central Pool area. Construction will include additional structures, mixing and settling basins, filter units, retention basins, a 50-million-gallon finished

water reservoir, and an additional 33-mgd washwater reclamation plant to handle expanded Jensen plant flow. Completed design on all phases of this project is expected by September 1990.

- Diemer Filtration Plant Modifications — The Diemer plant will be modified to increase plant capacity from the current 600 mgd to about 710 mgd to help meet the increasing Central Pool area water demands. The modifications will include raising the height of the launders and rejection weirs at the settling basins, adding equipment, enlarging service lines for the chlorination and chemical feed system, and expanding the washwater reclamation facility to accommodate the increased plant capacity. The design work is scheduled to be finished by January 1990.
- Weymouth Washwater Reclamation Plant Enlargement — Currently, the facility is undersized for treating Weymouth washwater when the plant is operating at high capacity. This enlargement project consists of constructing additional facility capacity, upgrading equipment in the north washwater reclamation facility module, and adding two sludge retention tanks. Design work should be completed by October 1989.
- Ozonation Demonstration Project — Under this project, a demonstration plant will be constructed at the Weymouth facility for verifying the technical feasibility and determining cost effectiveness of treating water with ozone or PEROXONE followed by chloramines. This project represents an effort to refine water quality in Metropolitan's systems to meet anticipated State and Federal water quality standards. Complete design work is expected by October 1989.
- Foothill Feeder Control Structure Expansion No. 1 — This structure will be expanded to 1,700 cfs to supply additional water from Lake Castaic to the expanded Jensen plant. The expansion will include installing valves in two existing branch lines. Design work should be completed about March 1990.
- During fiscal year 1987-88, preliminary design work was progressing on the Chino Valley Pipeline which will provide treated water to the Chino Basin service area under a conjunctive-use program. This year, design work was delayed while additional studies were conducted regarding Chino Basin conjunctive-use requirements.

Other design projects included Lake Skinner Bypass Pipelines Nos. 2 and 3 to provide operational flexibility during problem taste and odor episodes, expanding the Skinner plant administration building, constructing a maintenance building and expanding the existing administration building at the Mills plant, building vibration monitoring systems for hydroelectric plants, removing and replacing underground storage tanks throughout Metropolitan, and refurbishing Weymouth plant systems and equipment. (Design work was progressing on only portions of the underground storage tanks and Weymouth refurbishment projects – remaining portions of these projects are in construction phases.)

Service Connections

The reimbursable service connection program is an ongoing activity (See Table 13). Of six service connection projects under way during the year, three were under design by consultants and will be constructed by outside contractors. Metropolitan reviewed agency designs and provided construction inspection and cost monitoring.

During the year, two of the larger service connection projects in preliminary design were Service Connection LA-35 at the Jensen plant and enlargement of Service Connection OC-60 at the Diemer plant. LA-35 will connect Metropolitan's Foothill Feeder to the Los Angeles Department of Water and Power to increase water supply reliability. The OC-60 enlargement will help meet increasing water demands in southern Orange County.

Continuing Projects

Studies

Significant studies conducted during the year included a technical and operational feasibility study of possible sites for a new treatment plant near Lake Perris and a study of alternatives for improving San Joaquin Reservoir water quality and for better integrating the reservoir water into Metropolitan's distribution system. Of particular interest, studies were performed on water desalination processes and the technical and financial viability of constructing a seawater desalting plant in Southern California. Studies also were performed on possible energy sources for powering desalination processes including new generation nuclear power, fossil fuel, and coal. The nuclear studies focused on the modular, high-temperature, gas-cooled reactor concept.

Major studies conducted relative to system design capacities were a water distribution study for the Mills plant and Perris Reservoir sites, a flow test of the East Orange County Feeder No. 2 for the Central Pool Augmentation Project, and a test of the Weymouth plant's hydraulic capacity.

Investigation and Surveillance of Dams and Reservoirs

The ongoing surveillance program monitored the safety and structural performance of Metropolitan's 14 dams and reservoirs. This included daily inspections by operating personnel at all facilities and semiannual inspections by Metropolitan's dam safety engineers in which California Division of Safety of Dams (DSOD) engineers frequently participated. Seepage flows, piezometric pressures, and horizontal and vertical movements were and continue to be monitored and analyzed for each dam. During strong shaking from earthquakes, seismic acceleration time histories were also recorded instrumentally and analyzed. This fiscal year, five earthquakes of sufficient magnitude occurred to start the strong-motion accelerographs at various sites. None of Metropolitan's dams or reservoirs was damaged during any of these five earthquake episodes. Engineering reports were periodically provided to the DSOD, summarizing routine surveillance activities, periodic inspections, and analysis of all data collected from each dam.

The DSOD has formally concurred with the consultants' final conclusions that Morris Dam is stable and should be able to sustain the maximum credible earthquake shaking without uncontrolled loss of stored reservoir water. Document preparation is progressing to finalize the transfer of ownership of Morris Dam to the Los Angeles County Department of Public Works.

Office Automation

Computer use grew during the fiscal year, with applications for all facets of engineering design and construction. In construction administration, computers continued to help monitor construction contract progress, perform administrative tasks, and analyze survey data. Electronic surveying instruments and programs that perform survey calculations were used in field surveying. Additionally, two systems for monitoring and reporting dam and reservoir safety were implemented. One system completely automates collecting and processing settlement data while the other collects and processes piezometric data.

Both the Formtek and Auto computer-aided-drafting (CAD) systems helped prepare drawings for ongoing design projects and planning studies. Numerous programs to automate design-drawing production and improve CAD operator productivity continued to be developed.

Touche Ross & Company began reviewing engineering automation and information processing requirements to assist in selecting and implementing applications to improve engineering activity efficiency and effectiveness.

Staff began implementing a mainframe-based project management system which will help staff better manage projects and resources. This system offers managers current task-level information regarding project status and resource utilization.

Substructure Investigations

Substructure investigations review and analyze proposed utility and improvement projects to determine if they will interfere with existing and proposed Metropolitan facilities. During the fiscal year, staff received and answered 1,151 letters from outside agencies and developers regarding proposed new construction or modifications to existing facilities, and 225 notifications from the city of Los Angeles of proposed construction activities. Staff also reviewed 6,028 teletype notifications from "Underground Service Alert," a nonprofit computerized service notifying participating members of planned excavations or construction activities at or near their underground facilities. Additionally, approximately 404 street right-of-way notices to vacate were processed to ensure continued access to existing Metropolitan facilities.

Corrosion Control

Field Investigations

The ongoing program of monitoring and mitigating corrosion throughout Metropolitan's water transmission, storage, and distribution systems continued. Electrolysis and close interval potential surveys were completed on the Calabasas, Long Beach, and Torrance pipelines and the Lower, Middle, and Upper Feeder pipelines.

Staff monitored and maintained existing cathodic protection systems on a regularly scheduled basis. Several existing systems were modified and refurbished as required. New deep well anode cathodic protection systems were installed to provide corrosion protection for portions of the Inglewood Lateral and Rialto Pipeline. To mitigate the corrosive effects of cathodic interference from several petroleum conveying pipelines, a new deep-well anode cathodic protection system also was installed on the Second Lower Feeder.

Materials Evaluations and Research and Development

To stay current with new materials technology, materials evaluations continued, including short- and long-term testing of protective coatings, adhesives, linings, sealants, metal alloys, and other materials used for construction and maintenance.

Research and development projects undertaken this year included evaluating the effects of modified orthophosphate-based, potable-water corrosion inhibitors on reducing or eliminating the amounts of lead that can be leached from copper plumbing joined with lead tin solders. Testing was initiated to determine effects of chloramine-treated waters on elastomeric materials used in valves, meters, pumps, and back-flow prevention devices.

Data obtained from materials evaluations and research and development form the basis for materials selection and technical information for Metropolitan, its member agencies, and other water utilities.

Metallurgy

Failure analyses were conducted in both the metallurgical laboratory and the field to determine reasons for equipment failures at various locations. Resultant metallurgical evaluations have led to improved materials specifications, and modifications to operating parameters for both existing and proposed equipment.

In the metallurgical laboratory, complex metallurgical evaluations involving metal characterization (both destructive and nondestructive), failure analysis, alloy identification, and quality control can be performed. These capabilities are used by both the Engineering and Operations Divisions.

Seismic Investigations and Response Program

The Emergency Preparedness Task Force continued to coordinate Metropolitan's Earthquake Preparedness and Emergency Response Programs with those of State, counties, local cities, public and private utilities, and member agencies.

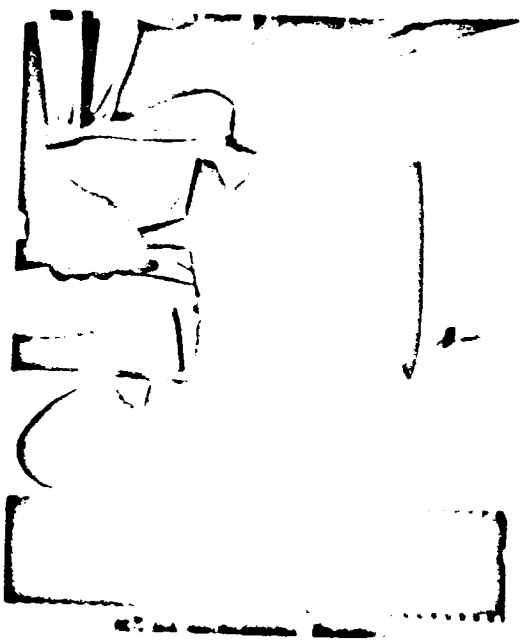
Several projects have been initiated under a long-range program to minimize the effect of a large seismic event. Consulting structural engineering firms analyzed the original maintenance shops at Metropolitan's La Verne facility and the Los Angeles Headquarters two-story buildings. Reports were prepared addressing proposed seismic upgrading to ensure these facilities continued functioning following a major earthquake.

Record of Survey Program

During the year, six Records of Survey covering 16 miles of pipeline and aqueduct rights-of-way were filed with County Records. Approximately 55 percent complete, this program monuments and records survey maps for public record.

Professional Consultant Activity

To keep pace with its accelerated fiscal year work program, Metropolitan relied on many outside sources to supplement its permanent work force. Professional consultants contributed significantly to this effort, and professional consultant activity increased about 61 percent from the previous fiscal year. As of June 30, 1989, 236 consultant agreements were in effect for services including feasibility studies, analyses, design, rehabilitation, program development and implementation, advertising, drafting, personnel training, forecasting, office automation, and administrative and clerical support work. Expenditures under these agreements totaled about $6,200,000; most of the services were engineering related.



Ensuring that slide gates can operate freely is a part of the maintenance process.

The decorative entrance to Metropolitan's first headquarters still beautifies downtown Los Angeles

CHAPTER 7

Legal

Metropolitan's legal staff represents Metropolitan, its Board of Directors, officers, and occasionally employees, in litigation and administrative proceedings. The staff provides the Board [and] Metropolitan officers with legal advice and written opinions, and [re]views contracts and other documents. Additionally, the staff follows [lit]igation and administrative proceedings to which Metropolitan is not [a] party but whose outcome could affect Metropolitan or the resources [o]n which it depends. By closely monitoring State and federal legislative proposals, staff recommends positions Metropolitan should take, if any.

Litigation

Water Matters

Chino Basin MWD v. City of Chino, et al

In November 1988, three agencies holding water rights in the Chino groundwater basin under a 1978 water rights adjudication filed a motion seeking, among other things, to invalidate a trust storage agreement Metropolitan had executed with the Chino Basin Watermaster in 1986. The agreement allows Metropolitan to store groundwater in Chino Basin in exchange for imported water Metropolitan delivers through Chino Basin Municipal Water District to the city of Ontario and Cucamonga County Water District.

The San Bernardino Superior Court, supervising administration of that [ad]judication, upheld the validity of Metropolitan's agreement in a tenta[tiv]e decision issued on May 11, 1989. Proceedings to finalize that ruling [we]re pending at fiscal year's end.

Imperial Irrigation District v. SWRCB

On July 8, 1988, the Imperial County Superior Court denied Imperial [Irr]igation District's (Imperial) motion for a new trial on the ade[quacy of] the State Water Resources Control Board's (SWRCB) 1984 Decision 1600. [Th]at Decision ruled that Imperial was wasting water it diverts from the

Colorado River. Imperial filed a notice of appeal on August 8, but [illegible] not filed the record on appeal by fiscal year end. The Court of App[illegible] ruled in 1986, in an earlier Imperial appeal, that SWRCB had jurisdict[illegible] to determine whether Imperial is wasting water.

Mono Basin Water Rights Litigation

During the year, major developments occurred in the five cases challenging the city of Los Angeles' rights to export approximate[illegible] 100,000 acre-feet of water annually from Mono Basin streams in the eastern Sierra Mountains. These cases are important to Metropolitan since Los Angeles will replace losses in that supply by purchasing additional water from Metropolitan.

Three of the cases assert Mono Lake public trust obligations and have been coordinated for trial by the El Dorado Superior Court. On June 15, 1989 that court issued a temporary restraining order directing Los Angeles to hold all of its Mono Basin diversions in storage there until the court would rule on requests from the National Audubon Society and others for a temporary injunction that would reduce Los Angeles' Mono Basin supply to 50,000 acre-feet through March 31, 1990. At Los Angeles' request, Metropolitan submitted staff declarations to the court describing potential impacts on Metropolitan of that type of injunction.

The two remaining cases assert California Fish and Game Code obligations to maintain fish flows below Los Angeles' dams and other diversion facilities in streams that flow into Mono Lake.

On January 26, 1989, the Court of Appeal ruled that SWRCB must revise Los Angeles' water rights licenses to include those obligations. Metropolitan and other water agencies supported Los Angeles' unsuccessful request to the California Supreme Court for review of that ruling. At the fiscal year end, the cases were pending before the Sacramento Superior Court to determine specific directions to SWRCB.

SWRCB advised that it would initiate Mono Lake public trust proceedings in conjunction with its mandated proceedings to add fish flow requirements for the Mono Lake tributary streams to Los Angeles' water rights licenses. SWRCB accordingly filed a request in mid-June 1989 to stay the three Mono Lake cases until it completes its proceedings. In late June, SWRCB distributed a draft work plan that indicates those proceedings will last three years.

Laughlin River Tours, Inc., et al. v. Bureau of Reclamation, et al.

Plaintiff John T. Talley, an operator of river tour boats in the vicinity of Laughlin, Nevada, sought in federal district court in Las Vegas, Nevada, both a temporary restraining order and a preliminary injunction to require

the U.S. Bureau of Reclamation (Reclamation) to release 10,000 cubic feet per second of water continuously from Davis Dam to facilitate river navigation. Both those applications were denied. Plaintiff complains that the river in this reach is non-navigable during certain times of the year due to Reclamation's limited water releases. Plaintiff alleges that under the Boulder Canyon Project Act, a first priority is accorded to navigation improvement and that the U.S. Secretary of the Interior is failing to adhere to that priority by regulating the river in a manner favorable to water users and power generation. The States of Arizona, California, and Nevada, as well as the Los Angeles Department of Water and Power, Metropolitan, and the Arizona Power Authority, have all intervened in this action. The Regional Director of the Lower Colorado River Region denied the administrative request by Laughlin to release water from Davis Dam for the sole purpose of facilitating navigation, a decision affirmed by the Commissioner of Reclamation. The federal district court will now review that administrative determination.

Coachella Valley Water District v. Metropolitan, et al.

In February 1989, the Coachella Valley Water District (Coachella) filed an action in the federal district court for the Southern District of California to challenge the validity of the Imperial Irrigation District-Metropolitan Water Conservation Agreement. Under the Agreement's terms, Imperial would undertake conservation measures intended to conserve 100,000 acre-feet of water per year, and agree to reduce its diversion from the Colorado River by a like amount. In return, Metropolitan would pay Imperial the costs of conserving that water. Coachella, through its lawsuit, asserts that under the law governing Colorado River water (CRW) use and allocation, it has a prior right, to the extent it can be put to beneficial consumptive use, to water conserved by Imperial. The suit was served on Metropolitan and others in May of 1989. The parties have agreed to extend the time to respond in the lawsuit while settlement discussions continue.

Environmental Defense Fund, et al. v. East Bay MUD

The Environmental Defense Fund, Sacramento County, and others have pursued this action for 17 years. The action's apparent purpose is to prevent the East Bay Municipal Utility District (EBMUD) from taking delivery of American River water from the Federal Central Valley Project's Folsom South Canal under a 1970 Reclamation water supply contract.

Trial began in the Alameda Superior Court on March 6, 1989. On June 12, the court issued a 139-page "preliminary tentative decision" for review and comments by the parties. When finalized, that decision will represent a significant development in establishing rules for applying the public trust doctrine to water rights issues, and in recognizing the importance of public health aspects of water supplies.

The tentative decision recognizes that California's public trust doctri requires balancing in stream flow needs and water supply diversion nee on the basis of economic, technological, and other feasibility factors ar reasonable use considerations. It also places major emphasis on th importance of protecting public drinking water supplies from public healt risks. More specifically, it concludes that American River water has muc better public health characteristics than does Sacramento-San Joaqui Delta water.

The tentative decision provides a physical solution which would allow EBMUD to proceed with its plans to divert 150,000 acre-feet of American River water from the Folsom South Canal, but would impose several significant conditions. Those conditions include Lower American River flows twice as large as previously recommended by the SWRCB.

The conditions also include a 60,000 acre feet annual storage reserve for fishery needs, a requirement that the water be used only for municipal purposes within EBMUD's service area, EBMUD funding of viable fishery and riparian habitat in the Lower American River, and appointing a special master to administer the physical solution.

Indian Claims and Litigation

Metropolitan, et al. v. United States, et al. (Indian Boundary Litigation)

The United States Supreme Court granted Metropolitan's petition for certiorari from the Ninth Circuit's decision ordering the case dismissed on the basis that the United States was immune from suit. In June of 1988, Metropolitan, along with Coachella, the States of Arizona and California, filed their brief on the merits. The United States and the tribes filed their briefs in mid August. In June 1989, the Supreme Court, evenly divided, affirmed the Ninth Circuit's dismissal of the lawsuit. The tribes will not receive any additional CRW as a result of this decision. Rather, another forum must be found to finally determine the Indian reservation boundaries.

Soboba Band of Mission Indians v. United States

On or about June 27, 1986, the United States filed a cross-motion for summary judgment to limit the tribe's claim to damages to pre-August 13, 1946, damages actually incurred based on crops that the tribe would have grown on up to 286 acres of reservation land and for the permanent diversion of water from 86 acres of land. This latter determination, the United States contends, should be based on the diminution in value of reservation land before and after 1946, or the difference in value before and after the alleged permanent deprivation of water. That deprivation is alleged to be in part due to the effect on local aquifers by Metropolitan's San Jacinto Tunnel construction. The tribe in its motion for summary

judgment had apparently requested an award of approximately $63 million. The Claims Court in June 1989 denied the cross motion of the United States and will allow the tribe to claim post-1946 damages. The case will now be scheduled for trial. If damages are awarded to the Sobobas, the United States might assert a claim against Metropolitan for reimbursement for a portion thereof. An action on behalf of the Sobobas could also possibly be brought for monetary damages or for a determination of the Sobobas' water rights or both.

Miscellaneous Matters

MWD v. NRC Construction; NRC Construction v. MWD

In September 1988 this case was settled by agreement under which Metropolitan received a total sum of $100,000 from NRC Construction. The dispute arose out of the construction of Metropolitan's Water Quality Laboratory located at the F. E. Weymouth Filtration Plant in La Verne, California. During construction, various disputes arose regarding the quality of work, specification, interpretation, and inspection procedures, and the failure of NRC Construction as general contractor to follow written directives. Metropolitan first withheld a progress payment and then suspended work on July 17, 1984. When NRC Construction took the position that the suspension constituted contract termination, and refused to complete the project, Metropolitan finished the project under separate contracts and filed suit against NRC Construction. NRC Construction filed a cross-complaint against Metropolitan for breach of contract and quantum meruit. By reason of the settlement, the parties have dismissed their respective cross-actions and this suit is now ended as to Metropolitan.

MWD v. Voith-Hydro, Inc.; Allis-Chalmers Corporation, et al.

Metropolitan reached a settlement in the suit it filed in June 1988 against Voith Hydro, Inc. (Voith), the contractor, as successor-in-interest to Allis-Chalmers Corporation, which supplied the turbine generator units for Metropolitan's Red Mountain and Valley View Power Plants. Metropolitan paid a total of $2,000,147 for the two turbine generator units. The Red Mountain Power Plant was plagued by a series of runner failures necessitating repeated tear-downs, repair, and re-assembly, and the current runner is considered unreliable and needs a newly designed replacement. The Valley View Power Plant also failed upon initial start up and was beset by repeated operating and control problems which have been remedied. Various and difficult contractual and evidentiary disputes arose between the parties which necessitated the litigation, particularly with regard to causation of the Red Mountain Power Plant runner failures. Under the settlement, Metropolitan dismissed its suit in exchange for the supply of a newly-designed runner for the Red Mountain Power Plant, the installation of that new runner by Voith forces, and a payment to Metropolitan by Voith in the sum of $50,000. This litigation is now closed.

Internal Matters

Staff was involved in various cases in which damages were claimed for death, personal injury or property damage, principally resulting from accidents involving motor vehicles. Staff also represented Metropolitan in various personnel matters involving disciplinary issues or discrimination claims.

Administrative Proceedings

State Water Resources Control Board Activities — Bay Delta Hearings

SWRCB San Francisco Bay/Sacramento-San Joaquin Delta Estuary (Bay Delta) water quality and water rights proceedings continued. In these proceedings, SWRCB will develop a document setting forth pollutant policy for waters of the State, adopting a water quality control plan identifying beneficial uses of Bay Delta waters, and determining reasonable levels of protection for those uses. It also will hold a water rights hearing to determine the need to condition water rights as a means to protect those beneficial uses. A wide variety of interests are represented in the hearings including the operators of State and federal water projects, State and federal fish, wildlife, and other resources agencies, agricultural and municipal/industrial water users, both in export areas and within the watershed, and environmental and other special interest groups. Metropolitan participates in concert with State Water Contractors, Inc. (SWC), an organization comprised of public entities with contracts for water delivery from the State Water Project (SWP).

In November 1988, SWRCB released a draft Water Quality Control Plan (WQCP) which effectively could have limited Metropolitan's supply of State project water to its 1985 supply level. Similar restrictions would have been imposed on other urban and agricultural water agencies relying on the Delta for their water supplies. However, as the result of petitions filed by Metropolitan and other parties, with SWRCB identifying numerous legal, factual, and policy errors in the draft WQCP, SWRCB withdrew the draft, revised its procedural work plan for the remainder of the proceeding and began preparing a revised draft WQCP.

Hearings on the pollutant policy document are scheduled to begin in October 1989, and it is anticipated that a revised draft WQCP will also be released in October, with hearings to commence thereon in mid-November 1989. SWRCB plans to adopt a final WQCP in July 1990 and the final pollutant policy document in August 1990. Adoption of that document will be followed by a scoping session and a water rights

hearing to review whether any water rights should be conditioned as a means of implementing the WQCP or otherwise protecting beneficial uses of Bay Delta waters.

The finally adopted WQCP and water rights decision could substantially impact the SWP's ability to store water and to export water from the Delta. This could in turn decrease the amount of water available for delivery to Metropolitan under its SWP contract. Nearly every urban area statewide and scores of agencies delivering water for agricultural purposes could also face reductions in available water from the Bay Delta watershed.

State Water Resources Control Board Activities — Emergency Drought Hearings

SWRCB held a series of hearings to determine the State water supply situation for 1988 (the second of two consecutive inadequate rainfall years) to establish contingency plans for a potential dry 1989, and to determine possible steps which water supply agencies could take to mitigate the impacts of a continued drought. Presentations were made by Reclamation, California Department of Water Resources (DWR), a number of other State agencies, agricultural, municipal, and industrial water users, including Metropolitan, and environmental interest groups. SWRCB issued a draft resolution containing its findings and determinations, which received substantial negative comment. Subsequently, SWRCB announced that it was indefinitely postponing any further proceedings on the drought hearings.

Interpretation of Shortage Provision of Metropolitan's State Water Contract

A controversy currently exists between Metropolitan, other State contractors, and DWR staff regarding water allocations under the various State water contracts in times of water shortage. Metropolitan currently relies on the SWP for approximately 50 percent of its supplies. In 1989, Metropolitan requested approximately 1,100,000 acre-feet of water from SWP; it had a right to request 1,961,000 acre-feet. Metropolitan contributes towards SWP's cost of conserving water on its right to receive water as distinct from its actual water delivery request.

The controversy relates to whether Metropolitan, in times of shortage, should, after certain initial deficiencies imposed on SWP agricultural users, be allocated available water based on its actual request or based on the amount of water it has a right to receive. Metropolitan ... that this water should be allocated on the basis of its right ... Such a basis enhances the reliability of the SWP's ... to Metropolitan.

Discussions on this matter are continuing with other State contractors and DWR.

SWRCB Imperial Irrigation District Water Conservation Proceedings

SWRCB adopted a 46 page order on September 7, 1988, implementing its 1984 Decision 1600 which ruled that Imperial is wasting water it diverts from the Colorado River. The order directed Imperial to initiate a program by the end of 1988 that will conserve an additional 100,000 acre-feet annually by January 1, 1994.

Imperial accordingly entered into a water conservation agreement with Metropolitan in December 1988 for a 35-year program to conserve that amount of water annually in Imperial Valley for Metropolitan's use. The agreement is subject to satisfaction of several conditions by the end of 1989.

Shasta Dam Storage Releases

In July 1988 and June 1989, Metropolitan, along with SWC, DWR and the Association of California Water Agencies filed memoranda with SWRCB in support of a Reclamation petition to rescind a waste discharge order of the Central Valley Regional Water Quality Control Board.

That order would establish a significant precedent by allowing regional boards to regulate Shasta Dam water storage releases into the Sacramento River as waste discharges, although SWRCB already regulates those discharges under water rights permits. The precedent could precipitate similar regional board regulation of other storage reservoirs such as those of the State Water Project.

On June 22, 1989, SWRCB directed its staff to initiate water rights proceedings to resolve the underlying factual issues. However, it had not determined by fiscal year end the manner in which it would rescind the regional board order.

Legislation

All legislation introduced in the California Legislature was examined to determine its interest to Metropolitan. Staff prepared a digest and recommendations as aids in reporting to the Board of Directors and others those items requiring a policy determination.

During the first half of the 1989-90 Legislative session, several bills were introduced dealing with the San Francisco Bay Delta Estuary. Three bills, Assembly Bill (AB) 2210, SCA 24 and SCA 28, sought to expand the existing statutory protection for water uses in the Bay Delta watershed. Metropolitan's Board opposed these measures since in each instance, the added protection would reduce the reliability of Metropolitan's SWP supplies.

The Board supported AB 1442, introduced by Assemblyman William Baker. This bill provides that monies the State General Fund currently owes the State Water Resources Development System, which includes the SWP, for project recreation and fish and wildlife enhancement benefits are to be offset against monies the System owes the California Water Fund (Fund). The bill also provides that future monies owed for recreation and fish and wildlife enhancement benefits would be used to reduce the Fund obligation. Two other measures, AB 609 and AB 610, introduced by Assemblyman Byron Sher, also dealt with Fund repayment. AB 609 requires the Legislature to annually review all reimbursements to the Fund to determine for what purpose the funds so reimbursed are to be used and AB 610 requires the SWP to reimburse the entire $432,800,000 owed the Fund by July 1, 1994. The Board opposed AB 610 and took no position on AB 609.

Metropolitan supported several measures dealing with water conservation. AB 325, authored by Assemblyman Steve Clute, would require cities and counties in California to adopt a resolution or ordinance on appropriate landscaping to further water conservation. AB 1571 and AB 1572, authored by Assemblywoman Maxine Waters, would provide State financial assistance for, or State participation in, constructing and improving local water storage and conveyance facilities. Senate Bill (SB) 1520, authored by Senator Robert Presley, would set new flushing standards for water closets for dwellings constructed after January 1992, while a similar bill, AB 2355 by Assemblyman Bill Filante, also would set stricter standards for water closets and associated flushometer valves.

Of several water quality bills, Metropolitan was particularly concerned with AB 2102, authored by Assemblyman Lloyd Connelly. This measure would require public water systems to notify consumers if the running annual average of quarterly samples for trihalomethanes (THMs) exceeds 25 parts per billion. The current primary drinking water standard for THMs is 100 parts per billion. The Board opposed this bill since it would require public notification even if THM levels lie significantly below the current primary drinking water standard and, therefore, would create confusion and undermine the public's confidence in its water supplies. The Board supported AB 21, authored by Assemblyman Sher, which would establish primacy for the State of California, under the federal Safe Drinking Water Act. The bill also would establish additional reasonable standard-setting requirements for maximum contaminant levels and recommended public health levels.

The Board also opposed AB 1767, authored by Assemblyman Moo[illegible]. This bill prohibits the Department of Health Services director from issuing an order requiring covering or draining a reservoir owned by a public water system unless no other alternative is technically feasible. If enacted, this measure could prevent installing reservoir covers even though a cover might best preserve water quality and ensure public safety.

[illegible]

Southern Californians long for plenty of winter snow to guarantee substantial spring runoff.

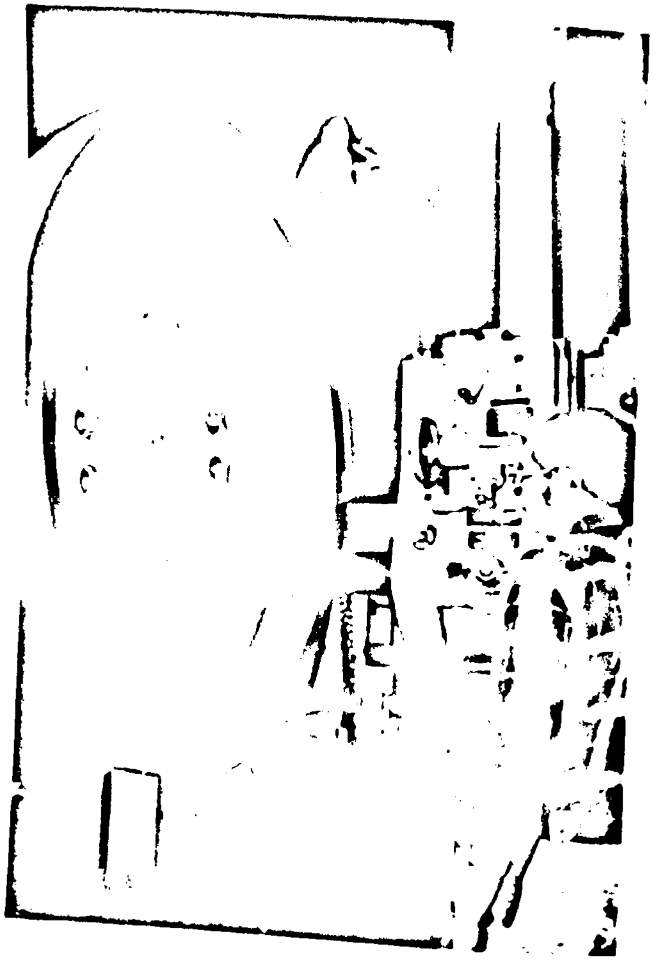
R0049228



Metropolitan assists others, such as by working on an impeller for the State Water Project.

CHAPTER 8

Finance

[illegible]neral Obligation Bond Sale

In June 1989, Metropolitan sold $215 million in Waterworks General Obligation Bonds, Election 1966, Series C, to raise needed capital funds. A negotiated sale occurred on June 15, 1989, after only 15 working days [of] preparation, and such sale was recommended to the Board to take [ad]vantage of the lowest rates available to insurers in the last 10 years. The [b]onds were sold at a net interest cost of 6.53 percent and a true interest [cost] of 6.65 percent. At the time of the sale, the 25-year index for AAA-rated G.O. bonds stood at 6.85 percent, the AA 20 G.O. bond index at 6.88 percent. Rating agencies rated the issue AAA/Aaa.

With the sale's proceeds, Metropolitan can continue funding its expansion program into 1991. Metropolitan's average cost of capital, including this sale, remains below 7 percent, noteworthy considering the credit markets' volatile nature over the last decade.

Long-Range Finance Strategy

In 1986, staff prepared a Long Range Finance Plan to identify the most [co]st-effective means of financing Metropolitan's capital improvement plan. During this fiscal year, staff developed a Strategic Finance Plan that [ad]dressed both Metropolitan's updated capital financing requirements [an]d how the future construction program will impact total costs and [fut]ure water rates. Staff continued developing and analyzing financing [tech]niques to lessen Metropolitan's future cost of capital while preserving financial integrity. The updated plan identifies [illegible] [strateg]ies for meeting Metropolitan's long range capital [illegible] year 2010.

[St]aff projects that capital improvements and [illegible] [distr]ibution and treatment systems through the [illegible] billion in 1989 dollars or $4.5 billion in escalated [illegible] recommends funding these expenditures [illegible]; however, projections indicate a possible [illegible] [capac]ity by 1997. To reduce bonding requirements [illegible] various financing methods to the Board during the year. Acting on [illegible] recommendations, the Board approved a revised pay-as-you-go prog[illegible], a revised working capital policy, and creating a Revolving Constru[illegible] Fund (RCF) during the year.

The Board authorized a pay-as-you-go objective of 20 percent of [illegible] construction program. This measure coupled with revenue bond s[illegible] should completely finance the construction program.

The new working capital policy sets a ceiling of $130 million for work[illegible] capital purposes through fiscal year 1993-94. The increased financ[illegible] flexibility now available to Metropolitan through short-term debt authority should hold working capital at this level for the next five years. Staff will periodically review working capital levels and water sales experience to ensure that Metropolitan can cover potential revenue shortfalls. To comply with statutory, bond covenant, contractual, and rating requirements, the revised policy will maintain sufficient funds; it also will help Metropolitan adjust to changing circumstances such as back-to-back annual water sale deficiencies.

In January 1989, the Board established the RCF with a $100 million loan from the Water Rate Stabilization Fund (WRSF). When bond funds are unavailable, the RCF balance would be expended on capital programs. The RCF would then be reimbursed from security sale proceeds. Using the RCF will enable Metropolitan to better time market entry for security sales and realize economic savings of up to 1.5 percent (the difference in interest rates between invested funds and long-term borrowed funds).

1989-90 Budget

Staff [illegible] Metropolitan's 1989-90 budget in a program-budg[illegible] format [illegible] statements of accomplishments, objectives and the [illegible] resources needed to continue a high standar[illegible] of service [illegible] member agencies. With the program-budg[illegible] format [illegible] division consolidates its activities and cost in an intern[illegible] evaluate performance against Metropolitan goals.

The 1989-90 [illegible] include optimally using Metropolitan's facilities, expanding [illegible] of Metropolitan's distribution system, upgrading and [illegible] treatment facilities, increasing dependable water supplies and [illegible] programs to reduce demands on Metropolitan's system, upgrading water quality standards, rehabilitating Colorado River Aqueduct [illegible] pumps with minimal service interruptions, and continuing to automate Metropolitan work activities. These expenditures are estimated to be $562 million in 1989-90.

FINANCE

[illegible]89-90 Revenue Requirements and Water Rates

In December 1988, the General Manager submitted [illegible] [illegible]surance Committee an estimate of total revenues [illegible] [illegible]es for fiscal year 1989-90, as determined under the Board's [illegible] [illegible]e policy. The General Manager recommended and the [illegible] [illegible]proved using up to $22 million from the WRSF to [illegible] [illegible]sts, and that revenues derived from 1989-90 water [illegible] at least [illegible]58 million. This formed the basis for setting the [illegible] water rates.

In January 1989, the General Manager submitted a recommendation [illegible] no change in water rates to the Water Problems Committee, leaving the rates unchanged since 1984. Following a public hearing, the Board adopted rates for 1989-90 as follows:

Noninterruptible		Interruptible		Emergency		Reclaimed
Untreated	Treated	Untreated	Treated	Untreated	Treated	
$197	$230	$153	$186	$591	$624	$84

Metropolitan's water pricing structure contains four service classes: noninterruptible, interruptible, emergency, and reclaimed. Noninterruptible service includes water sold for domestic, municipal, and other purposes, while interruptible service meets all noncontinuous demands, including groundwater replenishment and agricultural uses. Water sold for agricultural purposes at interruptible rates is provided only when not needed for municipal and industrial uses. Under certain conditions, such as temporary water shortages, interruptible water delivery can be reduced or discontinued. Agencies purchasing interruptible water must be able to sustain an interruption by using their local storage supplies. If they cannot, agencies may avoid customer service loss by purchasing water for domestic and municipal purposes, but at the substantially higher emergency rate. Reclaimed water (nonpotable water with limited uses) is sold at Metropolitan's lowest rate. Metropolitan's reclaimed water comes from rights received through financial participation in member agencies' [illegible]l reclamation projects.

[illegible]n Revenue

[illegible]entified as an objective in the long-range financ[illegible] [illegible]or more new sources of firm revenue will help [illegible] [illegible]ble water revenues as Metropolitan taxes and [illegible] [illegible]ne. During the year, staff compiled a report that [illegible] a firm revenue charge collected as a service [illegible] [illegible]ber agencies, and how a service charge would [illegible] [illegible]erential right to purchase water, the offset [illegible] [illegible]ctions, and changes in working capital req[illegible]

VOL 12 1 5925

Staff considered several factors in allocating a projected service charge among the member agencies. These included water demands, service connection capacity, acreage, population, and assessed valuations. Various levels of service charges were examined based on amounts collected sufficient to meet Metropolitan's total fixed costs, total capital costs, revenue bond debt service, or a combination of revenue bond debt service plus pay-as-you-go construction. The report illustrated how a service charge could be established at various levels and allocated among the member agencies under different methods.

Alternatively, staff investigated the relative merits of phasing in a water standby charge on individual land parcels within Metropolitan's service area. Imposed annually, the standby charge would be shown as a line item on county tax statements. The charge per parcel would be established by the Board; it may be allocated on such bases as acreage, land use, benefits received from the construction program, or the quantity of water used in the parcel's service area. Parcel information is gathered through each County Assessor's Parcel Number (APN) which is uniquely assigned to every parcel within the State. Extracting, modifying, and analyzing the APN data available from each County Assessor requires specialized technical expertise. A consultant assisted in continued studies of a standby charge revenue mechanism.

Investment Operations

State law requires Metropolitan's Treasurer to submit annually a statement of investment policy to the Board. The statement describes the Treasurer's investment authority, practices, and limitations, as established by the Government Code and Board policy. In order of importance, Metropolitan's basic investment policy's objectives are safety of principal, liquidity, and yield.

Interest earnings totaled $52 million, an increase of approximately $15 million over fiscal year 1987-88. At year end, the return on investments ranged from 7.5 percent to 10.5 percent with average weighted days to maturity of 215.7 days.

Examination of Metropolitan Bonds Held for Safekeeping and Escheatment of Coupons not Presented for Payment

A physical inventory of bearer bonds held for safekeeping by Bankers Trust Company in New York and Security Pacific National Bank in Los Angeles was performed using bank personnel. The two financial institutions are expected to resolve the minor discrepancies noted.

Financial Systems Automation

As one of its objectives, the Finance Division works through automation to deliver prompt financial information to respond to queries and to more readily support the decision-making process. Automated systems provide a means to capture, develop, store, and deliver this needed information. Staff is developing various systems within the division and also is creating various corporate information systems.

During the year, staff installed a local area network within the division, enhanced the *Electronic Timesheet System* (ETS), and implemented a general ledger query system. The query system will allow network users to access information from the general and appropriation ledgers. Work progressed on developing an enhanced cost accounting and budgeting system; testing an investment management system to assist the Treasurer in making, monitoring, and reporting investment decisions; and maintaining information through an on-line system on vendors who do business with Metropolitan.

Staff began testing the *Investment Management System*, which is designed to assist with analyzing, tracking, reporting, and accounting for Metropolitan's investment portfolio. Program coding and the system's initial testing phase have been completed.

Installed within the division this year, a *local area network* allows sharing of microcomputer resources, such as printers and software. The network will facilitate developing a financial data base integrating information related to investments, cash accounting, general ledger accounting, and accounts receivable records. All network users may review general ledger information via an application that was implemented during the year. In the near future, staff plans to activate the General Ledger and Cash systems in the network environment.

Electronic Timesheet System

The ETS was enhanced during the year to permit tracking of labor hours against work tasks. The new ETS captures data at more detailed levels than did its predecessor. Additionally, it will allow for full integration with the proposed Cost Accounting System. The staff also is revising the electronic approval process to improve ease and efficiency of use.

During the year, a more efficient on-line Vendor System replaced the manual method of maintaining information on Metropolitan's vendors. The information supports Metropolitan's purchasing and accounts payable functions. Eventually, the Vendor System will be a subsystem of the new Procurement System.

In September 1987, the Automation Overview Report (AOR) identified the Cost Accounting System and the reporting of cost information as needing improvement. The AOR recommended addressing this as a major application within the corporate information system. Additionally, the AOR encouraged improving the budget process and the current budget system in the areas of data accuracy, procedures, and systems.

The limiting factor with the current cost system is the cost accounting structure and the systems that relate to it, including budget, operating equipment, and labor. During the summer of 1988, a task force including staff from several divisions began reviewing the chart of accounts and the cost accounting structure. Its goal: to develop an integrated perspective and understanding of the information requirements of systems for cost, budget, project management, and other related systems, and to devise a flexible yet consistent structure. Phase 1, which provided a data model and requirements overview, was completed in November 1988. The second phase was initiated to further define the proposed system's data, interface, and processing requirements.

The second phase has been completed with the task force defining the requirements for a comprehensive cost and budget data structure. This structure and the related data model represent a significant portion of the "corporate data base" and a major milestone for the task force. With this proposed structure, staff can begin addressing many of the problems the original AOR identified.

Automation of Transmitting Payroll Information

The software necessary to electronically transmit payroll data to Security Pacific National Bank via computer was developed and successfully tested. Staff expects to put this process in production by December 1989.

Automation of Stop Payment Procedures

During the year, a system allowing computers to place stop payments on Metropolitan checks was implemented. This electronic method will reduce the cost of placing stop payments on checks by 50 percent. In addition, the length of time in which a stop payment may remain in place without being renewed was doubled.

Physical Inventory of Central Stores

The Controller's Branch annually performs a physical inventory of the Central Stores to verify the accuracy of Metropolitan's perpetual inventory records. In recent years, this occurred at an interim date (in March or April) to allow enough time to complete the inventory testing prior to fiscal year end.

The 1988-89 Central Stores inventory was taken as of April 30, 1989. A report was issued summarizing the results of the physical inventory counting process and quantified the reduction in inventory value based on the results of that counting. The report contained several recommendations for improving the physical inventory process. Staff concluded, after certain reconciliation procedures were performed, that the statistically projected total inventory value was, within a high degree of probability, approximately $8,557 less than the recorded inventory values (0.1 percent of the total inventory).

Operating Equipment

The 1988 operating equipment inventory is nearing completion. In conjunction with the inventory and to facilitate automating the inventory process in 1990, bar code tags were designed and attached to all operating equipment. Staff also developed new transfer reporting procedures for equipment.

Benefits Administration

Section 89 Compliance

Staff spent considerable time researching, collecting data, and running preliminary tests for legal counsel in preparation for compliance with Internal Revenue Service Code Section 89 requirements. Section 89 requires testing employee benefit plans that provide tax-favored benefits to "highly compensated" employees.

Deferred Compensation

Metropolitan administers a deferred compensation plan for its employees' benefit according to Section 457 of the Internal Revenue Code of 1986. This plan enables employees to defer portions of their compensation until retirement, disability, or death. The Director of Finance administers the plan, the Plan Coordinator maintains participation records, and the Treasurer invests the deferred funds in security [illegible]. As of June 30, 1989, the plan balance was $16.2 million compared to $13.6 million on June 30, 1988. Employees deferred [illegible] the fiscal year and investments yielded an average return of [illegible] percent.

Savings Plans

In accordance with Section 401(k) of the Internal Revenue Code, Metropolitan established two additional deferral arrangements to [illegible] employees (referred to as Savings Plans I and II). The Director of Finance [illegible]

VOL 12 1 5927

R0049232

administers the plans and the Treasurer acts as Trustee. Amounts deferred are transferred each payday to a third-party broker who invests them in authorized investment vehicles as each participant directs. Employees deferred a total of $601,743 in fiscal year 1988-89. Enrollment in the various plans increased 11 percent over last year, raising total enrollment to 931 participants.

Several provisions in the 1986 Tax Reform Act, which became effective January 1, 1989, necessitated plan amendments. The revisions proved technical in nature, were approved by the Board of Directors, and did not significantly affect Metropolitan's plan administration. The major changes reflect more rigid distribution requirements and revised limitations on the amounts participants can invest.

Pursuant to the Tax Reform Act of 1986 relating to Metropolitan's 401(k) Saving Plans I and II, the anti-discrimination test was modified for the plan years beginning after December 31, 1988, to further limit the disparity between elective deferrals made by "highly and non-highly compensated employees." The actual deferred percentage of the "highly compensated employees" (as defined by IRS) has been adjusted downward to ensure regulatory compliance.

Risk Management

The Risk Manager consulted with Resources Division personnel regarding insurance and indemnity related to water conservation negotiations and with Operations Division and Legal Division personnel regarding the Orange County Volunteer Emergency Preparedness Organization and Municipal Water District of Orange County programs.

The Risk Manager also completed an Annual Report on Risk Management, and audited the transactions reports for subrogated property losses.

Balance Sheet Highlights

Cash & Marketable Securities

Cash and marketable securities totaled $694 million and $613 million at June 30, 1989 and 1988, respectively, as shown in the following table.

TABLE 35

CASH AND INVESTMENT SCHEDULE

June 30, 1989 and 1988
(Dollars in Thousands)

	June 30 1989	June 30 1988
Cash and cash equivalents	$ [illegible]	$ 1,257

Local Agency Investment Fund	5,000	5,000
Total cash and investments	$694,189	$612,807
Less:		
Restricted portion	288,494	212,799
Employee deferred compensation fund	15,988	13,421
Unrestricted cash and governmental marketable securities	$389,707	$386,587

Cash and marketable securities are held under separate accounts (funds) to accomplish specific activities in accordance with special regulations, bond covenants, and Board policies. The funds are classified under general headings as "unrestricted" and "restricted." After necessary fund transfers are made to comply with bond covenants, the Board has complete discretion over the magnitude and use of unrestricted funds. Restricted funds are non-discretionary in use and pay for debt service on Metropolitan bonds and capital costs under the State Water Contract. In addition to unrestricted and restricted funds, Metropolitan maintains other funds as follows (also see Table 36):

- Revenue Bond Construction Fund
- 1966 Bond Construction Fund
- Revolving Construction Fund
- San Joaquin Reservoir Fund
- Deferred Compensation Fund

Plant and Equipment

Before accumulated depreciation, plant and equipment increased $68 million over 1988, to $1.4 billion in 1989, after depreciation, primarily because of construction program expenditures for water distribution and treatment plant facilities.

Participation Rights in State Water Facilities

Participation rights reflect unamortized capital expenditures made under the State Water Contract. Since Metropolitan does not own the State Water Project (SWP), the capitalized payments represent intangible rights (assets). The participation rights are amortized as Metropolitan receives State project water. For the fiscal year ending June 30, 1989, the asset account increased $118 million before amortization to $945 million net of amortization. This increase was directly associated with the revised costs for each State Water Contract component cost.

Deferred Water Rights

Metropolitan and other agencies have entered into several water exchange, storage, and reclamation project agreements, which reliably supplement Metropolitan's Colorado River and State project water supplies. Metropolitan is also actively pursuing other agreements both within and outside its service area, to provide additional water supplies.

The exchange and storage agreements generally provide for advance water delivery during periods when surplus flows and inexpensive energy for pumping are available. The reclamation project agreements effectively furnish Metropolitan funding to construct or improve reclamation facilities by local agencies to produce subpotable water for agricultural and industrial uses.

Cost associated with these agreements have been recorded as deferred charges and are amortized to the cost of water as the rights are exercised. At June 30, 1989 and 1988, deferred water rights totaled approximately $16 million and $17 million, respectively, based on volumes of 715,000 and 757,000 acre-feet respectively, as of such dates.

Bonded Debt

On June 30, 1989, $879 million in Metropolitan bonds was outstanding, consisting of $365 million in revenue bonds and $514 million in general obligation bonds (Table 37). Principal payments in 1988-89 reduced bonded debt by $16 million. Table 42 contains a five-year summary of Metropolitan's revenue bond coverage. The weighted average cost of all bonded debt outstanding, exclusive of the 1989 Series G general obligation bonds, was 5.57 percent at year end with an average bond life of 17 years.

Commitments and Contingencies

To provide power for transportation within the SWP system, the State Department of Water Resources (DWR) has financed construction of certain off-aqueduct power facilities. Construction on one such facility, the South Geysers Geothermal Power Plant, was suspended in 1987 pending

procurement of a steam supply sufficient to operate the plant at planned capacity. During the year ended June 30, 1989, DWR officials decided to dispose of the plant assets, if possible, by leasing the steam field and plant site, and selling the power plant equipment. As a result, Metropolitan's management determined, per provisions of Financial Accounting Standards Board Statement No. 5, that Metropolitan had incurred a contingent loss which must be recognized for financial reporting purposes. Therefore, the portion of unamortized participation rights attributable to the South Geysers Project, totaling $22 million, was written off as of June 30, 1989. Additionally, the estimated present value of $55 million of Metropolitan's remaining obligations to the State for debt service costs of South Geysers Project was recorded as a contingent liability.

Equity

Equity on June 30, 1989, stood at $2.1 billion, compared to $2.0 billion on June 30, 1988. The increase reflects net income of $115 million and $2 million more in contributions from member agencies to aid construction. Of retained earnings, $68 million was designated at fiscal year end for pay-as-you-go construction to reduce future debt requirements and to preserve revenue bond debt capacity.

Statement of Operations Highlights—Accrual Basis

Water Sales and Power Recoveries

Revenues of $425 million from water sales increased $32 million over last year (Figure 16). Water deliveries of 2,095,079 acre-feet rose 171,256 acre-feet over fiscal year 1987-88, marking the fifth consecutive year of record water sales. Hydroelectric power sales generated revenues of $19 million, $1 million more than the previous year.

Interest and Other Income

Interest earnings increased by $12 million for a total of [illegible] fiscal year 1988-89, reflecting higher interest rates on [illegible] Other income equaled $7 million, an increase of $1 [illegible] principally due to Metropolitan's sale of surplus [illegible]

Taxes and Annexation Income

As shown in Tables 40 and 41 and Figure 17, the total valuation of property subject to taxation for Metropolitan purposes was $597 billion in August 1988, representing a 5.7 percent increase over August 1987. Beginning in fiscal year 1988-87, unitary values for State Assessed utility properties were valued separately and excluded from the total taxable assessed valuations. The unitary value results in an average county-wide tax rate for property operated as a unit in a primary function. Therefore, the individual county determines an estimated revenue (tax) for Metropolitan's bond debt service accounts at a specified dollar amount which it remits to Metropolitan.

Proposition 13, adopted by voters in 1978, does not limit taxes levied by Metropolitan to pay voter-approved bonded debt, including payments under the State Water Contract and debt service requirements for Metropolitan general obligation bonded debt. Ad valorem property taxes and annexation charges collected on all property within Metropolitan totaled $73 million during 1988-89. For the fiscal year, Metropolitan's secured property tax rate was .0110 percent of assessed value; the unsecured rate was .0112 percent. This equals 4.4 cents and 4.5 cents per $100 of assessed value, respectively, as defined before Proposition 13, with assessed value recorded at one quarter of full value. Table 39 summarizes the tax rates over the past five years and Figure 18 shows regular tax levies.

Since 1978, Metropolitan has required newly annexing areas to pay charges on a cash basis. Prior to 1978, annexing areas could amortize their annexation fees over 30 years, and most areas chose this option. These areas must make essentially equal annual payments to Metropolitan until the debt is fully amortized. As a result, the applicable annexation tax rate varies yearly due to changes in the area's assessed valuation. Annexation charges levied this year totaled $6 million; total estimated future annexation charges amount to $28 million. Fiscal year income from cash annexations was $14 million.

Metropolitan does not record annexation receivables unless full amortization can be accomplished within 50 years following the amortization date by applying an annual tax rate of 0.1875 percent of assessed valuation or less, assuming that the annexed area's assessed valuation remains constant. As of June 30, 1989, annexation receivables of $46 million, including uncollected interest of $18 million, were not reflected as assets nor included in Metropolitan's equity.

Operating Expenses

Net operating expenses of $218 million increased $5 million over the previous year, reflecting State Water Contract credits totaling $25 million.

Depreciation and amortization expenses increased $19 million to $1.1 billion, because DWR increased the Water System Revenue Bond Surcharge charges. The amount of Participation Rights amortized is based on the total projected annual water deliveries divided into the total associated cost base. Bond interest expense, net of $5 million interest capitalized, was $46 million, a decrease of approximately $4 million.

Net Income

For fiscal year 1988-89, net income decreased $46 million to $115 million. The decline resulted primarily from recording a $76 million loss for financial reporting purposes attributable to the State's planned abandonment of the South Geysers Geothermal Power Plant.

Debt Service Coverage

Debt service coverage on the outstanding revenue bonds for fiscal year 1988-89 was:

TABLE 36

DEBT SERVICE COVERAGE ON OUTSTANDING REVENUE BONDS

For the Fiscal Year 1988-89
(Dollars in Millions)

	Accrual Basis*
Water and Power Sales	$ 443
Net Operation and Maintenance Expense	218
Net Operating Revenues	225
Revenue Bond Debt Service	26
Debt Service Coverage Ratio	8.49x

Note:
X = Times
* Any differences are due to rounding

Net Direct and Overlapping Bond Debt

Presented in Table 44 is a statement of direct and overlapping tax-supported bonded indebtedness within Metropolitan's boundaries on June 30, 1989, as prepared by California Municipal Statistics, Inc. Net direct and overlapping bonded debt totaled $10 billion, which amounts to a per capita debt of $673. As of June 30, 1989, Metropolitan's gross direct "general obligation" bonded debt stood at $514 million, which is approximately 0.09 percent of Metropolitan's 1988-89 assessed valuation of $553 billion (after deducting approximately $44 billion incremental assessed value associated with redevelopment agency activity).

Cash Flow Highlights (Cash Basis)

Cash Receipts

The following three sections contain dollar amounts based upon the cash basis of accounting, which reflects transactions only when cash is received or disbursed. Conversely, the dollar amounts shown for the Balance Sheet and Statement of Operations are recorded on an accrual basis of accounting. This manner of accounting indicates financial transactions are recorded when revenues are earned and expenditures are incurred, irrespective of actual receipt or disbursement during the fiscal year accounting period.

Cash receipts from water sales for fiscal year 1988-89 were $418 million. Tax receipts equaled $74 million and other revenues $64 million, for a total of $556 million, compared to an annual budget estimate of $462 million. This was mainly due to increased water sales which were $72 million over budget. Sales were 362,760 acre-feet over budget for the fiscal year.

Expenditures

Expenditures for the fiscal year totaled $446 million. This compared with an annual budget estimate of $449 million. Total net disbursements were $3 million below budget, mainly due to the following:

- SWP capital, OMP&R, and off-Aqueduct costs were lower than anticipated due to revised billings;
- State Water Control variable power costs were lower than anticipated after adjusting the variable cost component for prior year transportation charges; and
- Additional power credits were received from DWR due to changes in Los off-Aqueduct costs as well as bonded debt service coverage from prior years.

Cash-On-Hand at End of the Fiscal Year

Total cash on hand at fiscal year end equaled $555 million, excluding construction and trust funds totaling $139 million. Of this amount, $164 million was in restricted funds, with $25 million designated for self-insurance, and $68 million was in the Pay-As-You-Go Fund. Funds in the Water Rate Stabilization and Treatment Surcharge Stabilization Funds totaled $173 million and $20 million, respectively, and are designated to reduce future water revenue and treatment revenue requirements.

The July 1, 1988, working capital requirement, in accordance with current Board policy, was $105 million. On June 30, 1989, surplus funds of

$5 million and $6 million were transferred from the Water [illegible] Remainder Fund to the WRSF and Water Treatment Surcharge Stabilization Fund, respectively, in accordance with Board policy established in Metropolitan's Administrative Code.

Over the next decade, to the year 2000, staff is projecting use of all funds available in the water rate stabilization funds to mitigate water rate increases. The base noninterruptible and interruptible water rates are projected to increase over the period by less than 5 percent per year, assuming a complete draw down of the stabilization fund. The treatment surcharge is estimated to rise over the 10-year period at a rate slightly above the projected inflation rate, which is assumed to be 5 percent per year, taking into the account the use of PEROXONE or ozone to meet the anticipated revisions in the federal water quality regulations.

CHAPTER 9

Support Functions

Human Resources Management

Recruitment and Selection

The total number of Metropolitan's budgeted permanent positions increased by 68 to a total of 1,593 positions in fiscal year 1988-89. Staff continued in its efforts to enhance recruitment through the use of advertising, consulting services, and targeted recruitment sources to assure that qualified minorities and women were informed of all employment opportunities. During the fiscal year, 142 permanent positions and 166 temporary positions were filled, and at fiscal year end, Metropolitan's payroll comprised 1,569 permanent employees. The following is a five-year summary of Metropolitan's permanent employees.

End of Fiscal Year	Employees
1984-1985	1,330
1985-1986	1,374
1986-1987	1,416
1987-1988	1,506
1988-1989	1,569

Metropolitan employees are eligible to receive service pins after one year of service, and on every subsequent fifth anniversary. At three Service Award luncheons, hosted by the Chairman of the Board and the General Manager, 68 employees with 20 or more years of service were honored.

Assisted by the California Employment Development Department (EDD) in Los Angeles, the Summer Student Employment P[illegible] from increased minority and female employment [illegible] and resources to recruit and screen qualified candidates [illegible] while the Personnel Division supplied timely [illegible] clearances. The program employed a total of [illegible]

Classification, Compensation and Employee Insurance

Annually a salary survey of 11 agencies is conducted to obtain prevailing wage rates in the local labor market. In addition, other agencies have been utilized during specialized surveys to obtain data on managerial classifications. Staff also surveys various agencies on employee benefits to collect data used during bargaining unit negotiations.

Job audits ensure that Metropolitan's wage policy applies uniformly and that positions are classified appropriately. During the fiscal year, 54 job audits were conducted and numerous job descriptions revised to reflect current duties and responsibilities. New classifications were implemented as required.

Metropolitan employees receive a benefits package that includes medical, dental, and group term life insurance. They also maintain the option of enrolling in other insurance programs such as disability, accidental death and dismemberment, and cancer and intensive care.

Several changes occurred in medical insurance with the consolidation of three of Metropolitan's more prominent health carriers into one fee-for-service indemnity plan, "PERS CARE." In addition, another carrier with substantial enrollment, First Farwest, became insolvent. Employees subjected to these changes were given the opportunity to choose an alternate health carrier.

Employee Relations

The second year of the two-year agreement with Metropolitan's Employees Association became effective June 25, 1989. Changes include the following:

1. Salary increases of 5 percent,

2. An increase in Metropolitan's monthly contribution to medical insurance premium rates to $125 for employee only, $227 for employee plus one dependent, and $314 for employees with two or more dependents,

3. The amount of group life insurance for nonmanagement employees increased to $20,000, and

4. The choice to receive the Preretirement Optional Settlement 2 Death Benefit in lieu of the lump sum basic death benefit becomes available to spouses of employees deceased on or after July 1, 1989. For these survivors of active employees who die at or after age 50, this option provides a survivor's allowance calculated as if the employee had died while retired and had elected the most advantageous retirement benefit option.

Liability Claims Administration

The Liability Claims and Subrogation Program works to ensure equitable disposition of liability claims against Metropolitan under its self-insured program, to minimize economic loss experience as a result thereof, and to facilitate recovering damages to Metropolitan resulting from outside third-party negligence.

Employee Training and Education

Metropolitan expanded its Human Resource Training Section, adding a staff member to design and implement a human resource development program covering basic skills; management skills; and leadership, supervisory, and advanced management skills. Approximately 1,450 requests were received to attend more than 54 of the program workshops available. In addition to these program courses, 50 first-line supervisors participated in an eight-month training program; 145 employees received training in writing, editing, time management, meeting management, delegation, leadership and presentation skills, and six managers attended the University of Southern California's Professional Manager Program.

A computer program to assist Metropolitan in adapting to the increasing ...ultural diversity of its workforce was purchased and implementation ...egun.

VOL 12 1 59ME

R0049242

sessions during the fiscal year. Additionally, the section established data bases for the tuition reimbursement program, training vendors and materials, training enrollments, and scheduling.

Equal Employment Opportunity

A primary function of the Equal Employment Opportunity section has been the revision, implementation and monitoring of Metropolitan's Affirmative Action Plan. Now known as the Equal Employment Opportunity Program, the new plan is a more expansive program consistent with current laws, regulations, and guidelines.

Another critical function of this section involves processing and resolving discrimination complaints. In addition to internal complaints and inquiries, complaints from the U. S. Equal Employment Opportunity Commission, the California Department of Fair Employment and Housing, the U. S. Office of Federal Contract Compliance Programs, and the U. S. Civil Rights Commission are received and investigated. Technical assistance is provided to all employees in the work environment.

In reference to Metropolitan's statistics and procedures for recruitment and selection, staff has responded to several special requests from various entities that monitor equal employment opportunity, such as the Contract Compliance Unit of the Department of Fair Employment and Housing.

Throughout the year, Metropolitan was involved with various governmental and professional organizations, charitable functions, and community groups associated with equal employment opportunity.

The Equal Employment Opportunity Officer held regular meetings of the section's Advisory Committee, comprised of representatives from various minority organizations, the Vietnam Era Veterans Association, Metropolitan's Women's Association, and labor groups. Through the committee, members address relevant issues and exchange pertinent information on equal employment opportunity and affirmative action.

Environmental Safety and Health

Metropolitan's Environmental Safety and Health Program is promulgated on the California Occupational Safety and Health Act (OSHA) of 1973. The program assures compliance with standards of this act to ensure a safe and healthy work environment to prevent industrial illness and injury.

A multi-disciplinary Safety and Health staff effectively implements this program to train employees in safety and health practices, provide engineering, mechanical and physical safeguards to the maximum extent possible, and furnish appropriate personal protective equipment and

instruction on its application and maintenance. [illegible] surveys and investigations to determine corrective [illegible] necessary to eliminate unsafe workplace conditions.

This program has significantly advanced in [illegible] hygiene to evaluate conditions of potential hazard [illegible] and biological agents in the work environment [illegible] workplace ergonomics, material hazard control, and [illegible] construction safety consultation and compliance [illegible] projects by Metropolitan forces and major contract projects by various contractor services, and comprehensive training to heighten employee awareness of safety and health interests.

Metropolitan's accident experience comparison from January 1, 1988 to December 31, 1988, reflected 135 recordable injuries, 50 of which resulted in 1,082 lost work days and 748 restricted days. On average for a three-year period, employees experienced 119 recordable injuries, 46 of which resulted in 1,191 lost work days and 294 restricted duty days.

Based on this information, the following incident rates (Table 46) were computed and are compared to the U. S. Bureau of Labor Statistics rates for 1987 for the water supply industry.

TABLE 46

ACCIDENT INCIDENTS

	1988	1987	Average	Industry
Total Recordable Injuries/Illnesses	7.76	7.51	7.44	13.02
Lost Workday Cases*	2.87	2.03	2.88	6.20
Non Fatal Cases w/o Lost Workdays	4.88	5.97	4.56	6.86
Lost Workdays**	105.15	85.75	92.83	119.00

Note

Incident Rate = $\frac{\text{Number of Injuries/Illnesses} \times 200{,}000}{\text{Total Number of Hours Worked}}$

200,000 = Average Work Year in Hours for 100 Employees

* The lost workday cases rate includes cases which incurred a [illegible] duty workday

**The lost workdays rate includes lost and/or restricted [illegible]

Protective Services

Metropolitan's Protective Services Program provides professional [illegible] protection from natural, technological, and human threats [illegible] During the fiscal year, staff began implementing security [illegible] at the Joseph Jensen Filtration Plant, completed implementation of the site-specific security plan for the F. E. Weymouth Filtration Plant, initiated a program to identify and correct problems related to illegal uses of Metropolitan land, completed installing security systems at Pleasants Peak, Eagle Rock, and Soto Street facilities, established effective liaison and coordination with other key public safety and emergency service agencies, and maintained program emphasis on prevention, investigation, and consultation.

Detailed plans regarding response to emergency conditions at all of Metropolitan's facilities were developed and tested. Special emphasis was placed on Los Angeles Headquarters and City of Los Angeles requirements pertaining to emergency response capability.

Burns International Security Services continued to provide excellent contract guard services at Los Angeles Headquarters and selected field locations. All guards received ongoing training relative to emergency response, crime prevention, and public relations.

For incident management purposes, staff partially implements contingency plans via a limited Emergency Information System.

TABLE 47

Security Awareness Sessions	45	0
Security Improvement Recommendations	65	32
Consultations	84	43
Contacts with Outside Agencies	456	340

Workers' Compensation

Ensuring equitable claims disposition against Metropolitan under its self-insured program, the Workers' Compensation Program also minimizes economic loss experienced as a result thereof. In fiscal year 1988-89, 159 Workers' Compensation claims were filed compared to 126 in 1987-88.

Medical

The Medical Section protects Metropolitan employees by placing them in jobs for which they are medically fit without significant risk to themselves or co-workers. As shown in Table 48, staff accomplishes this goal through pre-placement medical evaluations which match the person with the job and vice versa, periodic medical surveillance to ensure that employees remain medically fit to effectively perform their job duties, job transfer evaluations to obtain all necessary medical data prior to transfer, audiometric testing for employees exposed at or above OSHA limits, and Return-to-Work evaluations to assess employee' ability to safely perform their jobs after serious or extended illness or injury.

To help employees become more responsible for their own health, staff educates employees to use available health services, emphasizing lifestyle changes designed to maintain health and prevent chronic illness. These goals are accomplished through individual employee counseling, wellness activities, and employee assistance services. A formalized Employee Assistance Program is currently being implemented. In addition, the executive physical program has been expanded to offer eligible employees the option of participating in community wellness activities in lieu of an annual examination.

Wellness Reimbursement	17	

Administrative Services

Purchasing

During the fiscal year, Metropolitan obtained $40,653,584 in materials, equipment, and services required for operation, maintenance, and minor construction in addition to purchasing large items under formal contracts. This total amount does not include electrical costs for water pumping or formal construction contract costs. The number of purchase orders issued increased about 8 percent over last fiscal year, with a total increase over the past two fiscal years of approximately 20 percent.

In other activities, an auction of used vehicles and assorted equipment reaped a total of $86,560 and sale by sealed bids of salvage material and surplus stock accrued $291,557. Colorado River and State project water treatment required purchasing 6,909 tons of liquid chlorine, 5,171 tons of liquid caustic soda, 5,072 tons of liquid alum, 1,471 tons of polymer, 1,206 tons of ammonia, and 211 tons of copper sulfate. This equals a 13 percent increase over last year's total chemical use.

Staff began customizing the Procurement System, a mainframe-based system which will automate creating, processing, and tracking purchase requisitions, purchase orders, and contracts, handle bid processing and analysis, and allow on-line receipt of material. Initial efforts have been focused on the Vendor, National Institute of Government Purchasing (NIGP) Commodity Code, and Stock Item sub-systems. The Vendor sub-system provides extensive information on vendors from both a Purchasing and Accounts Payable viewpoint, while the NIGP Commodity Code furnishes a cross-reference between vendors/bidders and the commodities they supply. Finally, the Stock Item sub-system allows maintenance and inquiry of stock items and links stock items to NIGP commodity classes and to the vendors that provide these commodities.

Procurement System use will be phased in to allow users access to sub-systems as they are completed, while development continues on the rest of the system. Throughout the fiscal year, Purchasing staff has used a microcomputer-based Automated Vendor/Bidder Commodity file system and Automated Bid Analysis system.

Warehousing

During the year, Metropolitan entered into three new annual agreements, totaling $69,350, for diskettes, respirators, and PVC pipe and fittings. This represents a 38 percent increase over the previous fiscal year's new agreements, and brings the number of Central Stores agreements to 32. Such agreements cost effectively reduce paperwork, labor, and procurement time over individual order processing.

Increasing $0.6 million over last fiscal year, inventory value of Central Stores stock at fiscal year end totaled $6.3 million. Total transactions (including transfers, issues, receipts, and debits) rose 10 percent during the fiscal year. As part of Metropolitan's continuing effort to eliminate and salvage excess and unusable personal property, staff sold 2,546 items of such materials and equipment, for a total value of $291,557. Items sold included scrap metal, office equipment and supplies, heavy equipment, and shop machines. This represented an increase of 2,498 items and $271,605 over the amount disposed of during the previous fiscal year.

Last fiscal year's use of drawer-type cabinets at Lake Skinner for rapid, over-the-counter issuing of small inexpensive items has been expanded to three additional outlying warehouses, which are now 80 percent converted to this system. The method has proven cost effective, reduces paperwork, and helps eliminate errors caused by repetitious issue procedures.

Office Automation

Metropolitan's office automation goal is to provide computer users with access to corporate applications and office functions on the central computer system. To that end staff implemented an Office System to handle daily office tasks such as sending and receiving electronic mail, sending notes and messages, scheduling meetings, and maintaining daily calendars. By fiscal year end, 200 employees were using the Office System with approximately 40 new users being trained monthly.

The original Automation Overview Study identified the need to provide on-line reference material. Toward the fiscal year end staff activated a pilot program using General Instructions (Metropolitan's policy and procedures documents) to evaluate a specific on-line reference package for the ease of both entering material and extracting it. Originators of various frequently-referenced materials determined how easy it was to enter documents, and other staff judged the ability to extract the information. The pilot program is expected to continue into the first quarter of next fiscal year.

Staff also implemented a Document Management System. Designed by a consultant to search for all types of documents, the system is currently tailored towards work progressing on the San Francisco Bay-Sacramento-San Joaquin Delta (Bay Delta) Hearings. The system will likely serve as a prototype of a generic document management system that can be adapted to meet any division's needs.

A project team was formed to investigate and analyze Metropolitan's costing needs and define the requirements of an appropriate costing system. What will evolve is a Cost/Chart of Accounts/Budget System.

VOL 12 159473

During the fiscal year, the team defined the entity diagram, delineating the system's heart and the relationship between the parts (see Chapter 8). Emphasis will be placed on the Budget portion during next fiscal year.

Microcomputer Training

Metropolitan continues to provide its computer users with in-house training, using a combination of instructor-led classroom courses, microcomputer and mainframe computer-based-training, and video courses. Classroom courses consist of basic, intermediate, and advanced curricula for various software products; data base concepts and design for the intermediate-level microcomputer user, and specialized curricula for support personnel within each division. During the fiscal year, the training program was expanded to cover the newly installed Office System, and staff began developing classroom instruction to support application training for users of Metropolitan's corporate on-line systems.

Data Processing

During the last quarter of the fiscal year, Metropolitan implemented a disaster recovery program. Defined by a task team of Metropolitan staff and an outside consultant, the plan ensures that, in case of emergency, staff will follow specific guidelines to recover previously identified key applications on Metropolitan's mainframe computers. Last fiscal year, the task team had interviewed certain division heads to identify and agree upon Metropolitan's key applications. This program produced a disaster recovery manual that provides a concise, highly structured format and identifies the personnel, policies, procedures, and provisions needed for a comprehensive data recovery plan. To ensure that the manual's information remains relevant, the plan was placed under a maintenance contract for annual updating.

To better meet the needs of the increasing numbers of users of Metropolitan's central computers, the Data Processing and Information Systems branches changed towards fiscal year end. Applications programming staff, previously a part of Data Processing, was transferred to Information Systems. As a result, Data Processing has become the technical operational arm of Metropolitan's information system, responsible for keeping the mainframe computer operating, installing and monitoring new mainframe software, troubleshooting user connectivity and operational problems, and monitoring system activity and response time.

Headquarters Services

The Los Angeles Headquarters Building again sustained minor cracks to drywall, plaster, and acoustical ceiling tiles when an earthquake shook

Pasadena in February 1989. As it had in 1987 [illegible] did comparable damage. Metropolitan employed [illegible] repairs with minimal effort and no disruption of [illegible]

Staff developed three new data bases for use by the Headquarters Services group. An Internal Shipping and Tracking data base allows users to keep abreast of packages and equipment sent through internal mails and to determine the status of the package or equipment in transit. For those participating in Metropolitan's Rideshare Program, the carpool parking data base maintains better control of assigned spots. Lastly, a Facility Management data base is being created to track, report, and project office space use in the Los Angeles Headquarters Building.

Office Services

A growing number of individuals have requested over the last few years the ability to merge text and artwork electronically for such things as treatment and hydroelectric plant operations manuals, pamphlets; various handbooks (i.e., timekeeping, communications, accounting for operating equipment, reports), and others. To meet that demand, Metropolitan will be installing a computer network capable of processing publishing and page artwork now being sent to outside vendors. During the fiscal year, staff developed a detailed plan and schematic for installing this network which is due during the first quarter of next fiscal year. The equipment will be compatible with existing systems both inside and outside Metropolitan.

Metropolitan augmented its computer graphics imaging system by providing needed support for creating maps and illustrations. The expanded software increases the number of type styles available, allows the mixture of typefaces on the same illustration, and rotates type for complicated artwork. Using this software greatly reduces artist design time since the old software created type only on a horizontal plane. With this software, staff can more easily devise maps, water quality charts, schematics for operational manuals, and illustrations for Planning and Water Conservation programs. This fiscal year, staff produced conceptual drawings of the Etiwanda Power Plant and the Desalination Plant projects, the Lake Skinner Operations Manual, and the Corona Hydro Power Plant Manual.

Communications

Formed last fiscal year, a management-level task team assessed Metropolitan's automation needs given the rapidly changing work environment and steadily increasing workloads. Investigation results were published in the Automation Overview Report that discussed Metropolitan's existing communications network and its limitations for accommodating growth and future communication needs. The report disclosed the need for network enhancements that would provide improved disaster recovery capability and backup systems for the existing voice and data networks.

This year, Metropolitan developed a three-year communications strategy to support its business plans, control system, and information system requirements and their impact on Metropolitan's communications system. The plan was developed jointly by Arthur Young's Telecommunications Consulting Group and Metropolitan staff, and consists of conceptual and physical network designs and organizational support structure, estimated costs, and a three-year, phased implementation plan.

Public Affairs

California's continuing drought and the proposed allocations of Bay Delta waters dominated public awareness campaigns and water-related issues during fiscal year 1988-89.

With California entering its third consecutive critically dry year, Metropolitan renewed vigorous attempts to promote water conservation among consumers. A television advertising campaign ran District-wide from mid-July through September. The broadcasts were augmented by live presentations featuring conservation that appeared at county fairs and home and garden shows throughout Metropolitan's service area.

Following the original dissemination of more than 200,000 tent cards, a second conservation card was developed for distribution through the California Restaurant Association. Additionally, mirror stickers encouraging conservation were produced and dispersed via member agencies and several hotel and motel chains. *WaterScape*, a publication dedicated to conservation, reached a specially targeted audience.

Water Awareness Week ran May 1 through 7 this fiscal year, and was followed by a new water conservation advertising campaign based upon conservation becoming a way of life in Southern California. Using the theme, "Be Water Tight," the campaign incorporated television, radio, and outdoor billboards.

The State Water Resources Control Board (SWRCB) issued a draft water distribution plan for the Bay Delta, which generated substantial interest from the media and the public. Following its considerable involvement throughout the Bay Delta hearings, Metropolitan conducted a series of briefings for legislators, county supervisors, and city council members on the important need to modify the plan. Soon thereafter, SWRCB announced that it would redraft its original proposal.

Continuing negotiations between Metropolitan and the Imperial Irrigation District (Imperial) successfully forged an agreement for a dynamic water conservation effort in the Imperial Valley. Major media outlets statewide covered the story in-depth.

Government Relations

Metropolitan gained support for a water conservation proposal to line the All American Canal, with more than 80 cities, counties, business organizations, water agencies, and water associations indicating their backing. Combined tours of the Colorado River Aqueduct (Aqueduct) and the State Water Project (SWP) were conducted throughout the year for Federal, State, and local officials and their staff members to enhance understanding of these systems.

Staff arranged briefings for officials when concerns were raised regarding specific proposals, such as the impact of the Chino Basin Groundwater Storage Program on Chino's milk producers. A series of public meetings were conducted throughout Metropolitan's service area to discuss the importance of groundwater exchange proposals.

To maintain open communications and good relations with associations and organizations impacted by water issues, staff participated in the County Supervisors' Association of California annual conference, worked with chambers of commerce legislative committees, undertook grassroots efforts in Orange County regarding construction of transmission and filtration facilities, and made presentations to mayors and city councils regarding Southern California's 1989 water supply.

Community Relations

Strengthening public knowledge regarding the Aqueduct and SWP, the community relations staff continued its facilities inspection program as directors sponsored 40 Aqueduct and 11 SWP tours. The General Manager hosted another 12 Aqueduct and one SWP tour. Special and one-day tours numbered 20 for the fiscal year. Nearly 2,400 individuals were guests on these tours, while another 6,300 visited various filtration plants.

Staff planned and coordinated two Directors Emeritus luncheons and the annual Directors' Workshop; planned and participated in National Water Resources Association Municipal Caucus activities, the Association of California Water Agencies Public Affairs Committee, and the Southern California Water Conference Program Committee; assisted in planning and conducting the American Water Works Association annual conference held this year in Los Angeles; and participated in Colorado River Water Users Association activities, chairing the Public Affairs and Exhibits

committees. Additionally, staff participated in a joint association agency effort by chairing the Public Affairs Committee for the kickoff event of Water Awareness Week in the state capitol.

The Speakers Bureau was expanded to 53 participants. Members reached a total audience of about 16,000 people at a wide variety of club, association, society, chamber, and other appearances.

Publications

Throughout the year, more than 4,540 individuals and organizations asked to be added to the mailing list for Metropolitan's external publications, *Aqueduct* and *Focus*. Staff also sent extra copies of *Aqueduct* and *Focus* upon request to farmers along the Sacramento River, chambers of commerce, the city of Los Angeles wastewater management division, and realtors. Permission to reprint articles from both periodicals were received from and granted to numerous outside organizations and publications.

Employees were further advised about the SWRCB draft plan and other pertinent issues through the internal bulletin, *Watermark*. A brochure, "You Can Make a Difference," was updated to carry the theme that water conservation must become part of the Southern California lifestyle. Incorporating Metropolitan's new "Be Water Tight" conservation slogan, materials were developed that included a revised version of "25 Ways to Save Water," a redesigned plastic bag for fair presentations, plant tags, bumper stickers, and a postage meter mark displaying the slogan.

In addition to the regularly scheduled publications, more than 463,000 pieces of literature were distributed through exhibits, display racks, speaking engagements, Metropolitan's member agencies, and mail and telephone requests.

Media

While the drought held considerable media attention during the fiscal year, staff also attained expansive media coverage regarding the All-American and Coachella Canal linings, Metropolitan Imperial negotiations, trihalomethanes, Metropolitan's continuing program to cover water storage reservoirs, groundwater storage, Metropolitan finances, the lining of the Newhall Tunnel, and the Vail Lake enlargement.

Also receiving media attention were issues such as water rates, Metropolitan's reduction in SWP deliveries for 1989, record water-demand days in April, a U.S. Supreme Court ruling on Colorado River Indian water rights litigation, and the death of Board Chairman E. L. Balmer.

Throughout the year, staff provided info... and conservation in general and about sp... tan's affiliation with the California Coun... nomic Balance, upon request. Comprehensive... with the General Manager by the *Los Ang...* media outlets.

Education Programs

Elementary school students in the fourth and sixth grades gain early understanding about water resources through the "Admiral Splash" and "Water for Ursa" programs, respectively. Staff held orientation sessions for 878 teachers to receive program materials. Teachers throughout the Metropolitan service area were sent Metropolitan's *Splash* newsletter. Versions of the "Home Information Leaflets" that are part of the fourth- and sixth-grade classroom kits were translated into the Tagalog, Chinese, Vietnamese, Korean, and Cambodian languages.

Additionally, education staff made presentations at assemblies and other gatherings, reaching nearly 11,000 elementary school children. Materials were developed for the planned high school program which will begin in fall 1989. Metropolitan also continued its involvement in the Adopt-A-School program with El Sereno and Van Gogh elementary schools in Los Angeles County. Hands-on water science experiments were conducted at schools throughout the service area.

A 1989 "Water Is Life" calendar, featuring artwork created by elementary school students, was printed and distributed. Metropolitan also sponsored 10 stage performances of "Alice in Waterland" at area schools and prepared an activity package for elementary schools to use during Water Awareness Week.

Staff consulted with officials at Bonita High School and Van Gogh Elementary School regarding proposed drought tol... gardens at the schools.

Films and Exhibits

A new videotape, "Waterwise Gardening: B... Water," was funded in part by Metropolitan ... Films in cooperation with the American W... California Nevada Section. This video was sup... and selected subagencies throughout the se...

Metropolitan's film-loan program continued ... primarily by schools throughout the six countie... operates.

Throughout the year, Metropolitan presented live shows at major county fairs and home shows, and further reached the public with displays exhibited at malls, expos, and commercial locations. Metropolitan also provided xeriscape exhibits in various locations. For Water Awareness Week, a large outdoor display was erected at the State Capitol Building in Sacramento. Staff assisted the city of Glendale with a conservation exhibit and helped dedicate the conservation garden at the Los Angeles County Arboretum.

Right of Way and Land

Acquisition

Right of way acquisition activity focused on obtaining fee, permanent easement, and temporary easement property rights for the San Diego Canal Enlargement project, which extends approximately 17 miles from the San Jacinto area to Lake Skinner in western Riverside County. By the end of the fiscal year, two fee and 50 temporary easement purchases were consummated for this project.

Additional acquisitions, involving the Etiwanda Pipeline project, Detention Peak Microwave Site, and several miscellaneous easements containing exchanges for alternate access rights were completed. In the city of Fontana, one fee acquisition of 5.90 acres for the Etiwanda Pipeline project was acquired through Heritage Village and cost $1,746,000. Additionally, one permanent easement for access to Metropolitan's Detention Peak Microwave Site was closed this period. Staff provided acquisition services consisting of title encumbrance review, lease review, escrow coordination, and agreement review during negotiations for the Searl Ranch lands, which are included in the potential Eastside Reservoir Site in the Domenigoni Valley. Numerous property owners were contacted for entry permits for geotechnical survey purposes along the Etiwanda Pipeline alignment, the South Orange County Treatment Plant alternate sites, and the Domenigoni Valley, Potrero Creek and Vail Lake potential sites for the Eastside Reservoir. Division staff also monitored an independent contractor's acquisition of 400 entry permits for environmental observation purposes, 248 of which were acquired by fiscal year end at five potential Eastside Reservoir sites.

Approximately 122 parcels remain to be acquired for pending or completed projects, including San Diego Canal Enlargement (embankments and structures) project, Etiwanda Pipeline, San Diego Pipeline No. 4, Auld Valley Pipeline, Santa Monica Feeder, Corona Hydroelectric Plant, and Lower Feeder Service Connection. Advance acquisition

activities, including property owner conta[illegible] and [illegible] record and tract map surveillance and appraisal are continuing for [illegible] within potential Eastside Reservoir and South Orange County [illegible] Plant locations. A total of 62 fee, permanent easement, and [illegible] easement parcels were acquired for Metropolitan use this fiscal year. Table 50 shows the details of the year's right-of-way acquisition projects.

Land Management

Real Property Branch personnel are managing 152 separate secondary-use agreements on Metropolitan's fee-owned properties. Metropolitan collected approximately $273,630 in revenue from these uses, an increase of $9,530 over last fiscal period. Staff issued easements for secondary uses over Metropolitan's properties to governmental agencies, public utilities, and private individuals. Such easements usually apply to street widening, underground utilities, alternate access, and slope maintenance.

Metropolitan joined forces with various governmental agencies and utility companies in granting authority for special use of its properties for emergency purposes. Staff authorized fire department helicopter water pickup and landing sites at Lake Mathews and Lake Skinner, which will be used for water drop practice and/or emergency use.

The general construction boom in Southern California has created the need to grant easements to others for the above mentioned uses. Throughout the year, the Real Property Branch processed 75 to 100 documents, many of which are temporary in nature.

Occasionally, Metropolitan leases private property. Operating and maintaining Metropolitan's facilities requires staff to lease office space for government relations and legislative representatives in Washington, D.C., Sacramento, and Orange and Imperial Counties. To date, 12 leases permit Metropolitan to use private property for its needs. These leaseholds amount to approximately $32,000 annually.

Surplus Property

Surplus property sales activity stayed exceptionally low this fiscal period as staff concentrated on acquisition to expand existing or new Metropolitan facilities. Staff also participated in the planning [illegible] for proposed Metropolitan facilities.

Metropolitan sold one surplus parcel, [illegible] approximately [illegible] acres of land, for $9,000 in cash. Through [illegible] process staff publicly auctioned Metropolitan's F. E. Weymouth [illegible] Basin surplus Parcels H15-2-1, 3, and 7. The property placed on the market at its appraised value of $10,750,000 contains about 67.3 net acres of land and was sold for $13,550,000. However, the sale was never completed due to alleged

VOL 12 1 5944

municipal considerations which made the transaction too expensive for development. A thorough analysis of this sale has begun. Staff is also reviewing Metropolitan's overall surplus property marketing policies and will present its findings to the Board of Directors' Land Committee for review.

At fiscal year end, the eight promissory notes secured by deeds of trusts on properties previously sold were in effect. The fixed interest rates for these deeds of trust range from 10 to 12¼ percent. The principal balance of the notes outstanding at the end of the period amounted to $848,683, while the principal and interest payments received during the fiscal year amounted to $177,256.51. Metropolitan collected full payment on three promissory notes. Staff prepared full reconveyance documents for recording.

Relocation Assistance

No relocation assistance benefits were processed during the fiscal year, however staff is conducting preliminary surveys during project conceptual stages to determine the potential magnitude of displacing persons, farms, and businesses and replacement property availability.

Staff responded to inquiries related to relocation assistance and, furthermore, reviewed new legislation affecting relocation benefits and eligibility.

Real Estate Appraisal and Land Use Activities

Staff assisted contractors doing work for Metropolitan and the appraisal section, and completed appraisal reports for lesser valued parcels, rental rate surveys, and rental valuations for Metropolitan's use. Additionally, staff appraisers provided appraisal expertise and opinions along with recommendations to the General Manager and the Legal Department.

Staff Appraisals

Staff appraised 14 easement crossings and conducted four rental surveys, which will aid in determining market (economic) rental rates for tenant-occupied parcels. Right of Way personnel also completed 73 appraisals of fee and easement property rights for the San Diego Canal Enlargement Project. To update unsettled acquisition valuations, staff completed 18 re-appraisals of these parcels.

A preliminary value estimate was developed for the Planning Division on a 57 acre potential reservoir site east of the Robert B. Diemer Filtration Plant. Staff appraised two surplus parcels located along the Colorado River Aqueduct-Val Verde Tunnel, near Mead Valley, in Riverside County, as well as the Searl Ranch Property which includes 41 parcels and

... 346± acres (net) valued at $27,000,000 ... ...ty for advanced acquisition for a port... ...alley Reservoir site, near Hemet. Sta... ...t rental rates for 34 leases, licenses ... ...2 permanent easement parcels adjacen... ...nds, involving about 19.53 acres, for a ...

...ndependent Appraisals

Staff appraisers reviewed two appraisal reports submitted by outside ...gencies, which involved partial takings for lateral road crossing easements. One taking was by Caltrans to widen San Fernando Road, State Sign Route 126, across Metropolitan's Foothill Feeder in the city of Santa Clarita (Newhall). The other allowed the County of San Bernardino to cross the Yorba Linda Feeder, on a parcel in Chino Hills near the Phillips Ranch.

Staff conducted scoping and pre-submission conferences with all independent fee appraisers retained to perform acquisition appraisals as well as reviewed six appraisal reports submitted by independent appraisers. Staff also conducted a disposition appraisal review of independent appraisals on the Bolsa Chica Desalinization Plant Site, Huntington Beach, California, and an analysis of municipal assessments on an independent appraisal of F. E. Weymouth Sludge Basin surplus parcels.

Administrative and Consulting

Metropolitan entered into contracts with 20 independent fee appraisers regarding required land acquisitions and potential sales of surplus properties. One of the contracts calls for the appraisal of three potential spreading basins for the Arvin-Edison Water Storage District in Kern County, south of Bakersfield. An executive briefing was prepared on the proposed purchase of a land option at Potrero Creek Estates within the future Eastside Reservoir study area.

Land Use Studies

Staff completed several special land-use stud... ...d implementing potential projects:

- A preliminary estimate of both the original ... ...f 39 parcels (354+ acres) was developed ... ...-mile length of the Foothill Feeder, from C... ...oad. - A b... was prepared for a requested early termination of ... lease. GTE Sprint leased an area of Metropolitan's H... Plant fee Parcel 1640-1-1 for a microwave radio facility.

Annexation

... ed six annexations to Metropolitan, increasing the service area by 5,4?32 acres. Riverside County experienced four annexations: two to Eastern Municipal Water District (Eastern)—(Thirty-Sixth and Thirty-Eighth Fringe Areas), and two to Western Municipal Water District (Western)—(Twenty-First and Twenty-Second Fringe Areas). One annexation occurred in Ventura County to Calleguas Municipal Water District (Calleguas)—(Calleguas Annexation No. 28) and one annexation occurred in Los Angeles County to Las Virgenes Municipal Water District (Las Virgenes)—(Hidden Hills Annexation 87-1). The annexation charges totaled $375,122.30.

The city of San Diego annexed one area, which added 435.55 acres to Metropolitan. As of June 30, 1989, Metropolitan's total service area encompassed 5,137.89 square miles, increasing 1.47 square miles over last fiscal year.

The Board granted informal approvals for concurrent annexation of two areas to Western and Metropolitan, four to Eastern and Metropolitan, ... to Calleguas and Metropolitan. The Board granted formal ... for five concurrent annexations: Twenty-First and Twenty-... Areas to Western and Metropolitan, Fortieth Fringe Area ... Metropolitan, Calleguas Annexation No. 28 to Calleguas ... and Hidden Hills Annexation 87-1 to Las Virgenes ... tan.

... 30 redevelopment projects to determine their effect on ... tax base and facilities. Staff processed and paid 216 property ... for a total tax payment of $60,118.17. ...atement of Change of Boundaries

On December 30, 1988, Metropolitan ... Statement of Change of Boundaries with the County ... the six counties ... luded within Metropolitan's service area. ... summarizes ... changes in Metropolitan's member ... boundaries during the previous calendar year which changed Metropolitan's overall boundaries.

Automation

The changing work environment has led staff to increase their personal use of microcomputers, which decreased the duplication of efforts in specific areas, and saved man-hours. Staff also has enhanced their work's quality.

Most divisional staff is now computer literate. Staff is aware of, and is benefiting from, specialized software programs tailored to real estate and management applications.

An internal auditor prepares for an audit of one of Metropolitan's automated systems

CHAPTER 10

Internal Audit

Metropolitan's Audit Department performs internal auditing activities consisting of financial and compliance audits, as well as miscellaneous reviews or special audits. The Auditor reports directly to the Board of Directors through the Audit Subcommittee of the Finance and Insurance Committee. He works closely with Metropolitan staff, but is independent of Metropolitan's general management.

Internal audit assignments are usually selected by the Auditor and are occasionally requested by the Board of Directors or management. Performance of detailed audit testing is preceded by appropriate planning and coordination with management or staff. Upon completion of all significant audit assignments, a report is issued to the Board of Directors and copies are provided to management. In accordance with internal auditing standards, the typical audit report outlines the objectives and scope of the work performed, the audit findings noted, and any recommendations for corrections or improvements which the Auditor feels are warranted in the circumstances. In addition to internal audit assignments, the Auditor and his staff provide substantial assistance to Metropolitan external auditor in conducting quarterly financial audits and the year-end audit required by the California Government Code and Metropolitan bond covenants.

During fiscal year 1988-89, the Audit Department issued a variety of reports pertaining to financial, compliance, electronic data processing (EDP), or special auditing matters. Aside from the aforementioned assistance provided to the external auditors, major assignments completed and reported on during the year included (in chronological order of issuance):

- EDP Application Review—Bond Inventory System, dated July 29, 1988.
- EDP Application Review—Payroll System, dated November 22, 1988.
- Review of Payment Procedures for Engineering Consultants, dated April 13, 1989.

- Review of Metropolitan's Hydroelectric Power Program, dated April 27, 1989
- Review of Metropolitan Bond Records and Controls, dated April 21, 1989
- Review of April 1989 Physical Inventory of Central Stores, dated June 26, 1989
- Review of Metropolitan's Fiscal 1989-90 Annual Budget, dated June 30, 1989

The results of these audits, together with management's responses to the Auditor's recommendations, are discussed in detail with the Audit Subcommittee. The Audit Subcommittee met four times during fiscal year 1988-89.

In addition to the aforementioned assignments, a number of other meaningful assignments were completed during fiscal 1988-89 for which formal audit reports were not prepared. Instead, management and appropriate staff were provided with copies of memoranda summarizing the results of these reviews for their information and possible action. The following assignments fell into this category.

- Update Review of Bank and Check Reconciliation Systems.
- Survey Review of Automated Expense Reporting System.
- Review of Single Audit Act Compliance for Fiscal 1987-88.

At June 30, 1989, the following significant financial assignments, exclusive of EDP and many smaller assignments, were in progress:

- Review of the Official Statement for Metropolitan's 1989 Series "G" General Obligation Bonds
- Survey Audit of Reimbursables Section Activities.
- Review of Water Rate Adjustments Credits
- Review of District's Disaster Contingency Planning
- Review of October 1988 Operating Equipment Inventory.

In some instances, completion of these assignments was delayed due to other work priorities or other factors. All are expected to be completed during fiscal 1989-90.

In addition to the preceding assignments, Audit Department personnel participated in many other short-term or recurring assignments throughout the year. Recurring assignments include reviews of the Monthly Financial Reports, audits of submitted directors' and department heads' expense claims; audits of selected employees' expense claims; quarterly reviews of water inventory and deferred water rights computations and quarterly reviews of Budget vs. Cost Reports.

During fiscal year 1988-89, audit personnel also reviewed drafts of Metropolitan's comprehensive Annual Financial Report for the fiscal year ended June 30, 1988; tested the accuracy of the 1988-89 tax levy documentation; reviewed Metropolitan's compliance with its June 30, 1988, fund requirements, reviewed new overhead rate calculations that were effective July 1988; reviewed selected petty cash funds at Headquarters; reviewed quarterly lobbying reports which are required by the Fair Political Practices Act to be filed with the State, tested various work orders for propriety and compliance with Metropolitan's procedures; and reviewed security activities on a quarterly basis for matters having audit implications.

While the results of these recurring or short-term assignments were generally satisfactory, written comments on such reviews, including recommendations, if appropriate, are often provided to management or staff for their information and possible action.

Among the more significant of corporate-wide systems development projects that the department's EDP auditors are involved with include: (1) the Cost Accounting System; (2) the Procurement System, and (3) the Water Accounting and Classification Invoicing System. In addition, the EDP auditors are currently monitoring and testing the development of the following Finance Division systems: (1) the Investment Management System, (2) the Local Area Network, and (3) Accounts Receivable.

As a result of almost continuous involvement by the EDP auditors in various systems development activities, specific computer application reviews were not performed to the level anticipated during the year. While internal audit involvement in the development and testing of new automated financial systems remains a top priority, the review of some of the key computer applications is also a priority objective for the next year.

Foreword

With Southern California facing its fourth consecutive drier-than-normal year, Metropolitan continued its increased efforts toward ensuring future water supplies through additional water storage and water conservation agreements, by supporting reclamation projects, and by accelerating its conservation awareness programs.

Metropolitan authorized preliminary design of an innovative storage and transfer project that will provide additional water for Southern California. The project, between Metropolitan and the Arvin-Edison Water Storage District, will allow some of Metropolitan's unneeded supplies in wet years to be stored by Arvin-Edison in an underground aquifer in the San Joaquin Valley. In later dry periods, Arvin-Edison will use the underground reserve to irrigate crops. In exchange, water supplies that otherwise would be delivered to the agricultural district's farmers from federally operated storage reservoirs will be delivered to Metropolitan.

Supporting local water reclamation projects is another way Metropolitan ensures sufficient future supplies for cities and agricultural areas. Two reclamation projects that together will produce nearly 4 billion gallons of water annually for landscape irrigation purposes in Orange County were approved by the Board; one with the Moulton Niguel Water District, and the other with the city of San Clemente, the Tri-Cities Municipal Water District, and the Coastal Municipal Water District. A third project, the Trabuco Water Reclamation project in Orange County, will yield 260 million gallons of water per year; a fourth, with the City of Glendale, will produce nearly 196 million gallons of water to irrigate Glendale Forest Lawn Memorial Park.

In heightened conservation efforts, Metropolitan's Board of Directors called on municipal governments to adopt drought ordinances to help reduce the threat of water shortages and adopted a special rebate program aimed at rewarding communities and water agencies that cut back water usage by more than 5 percent. The Board also approved a $2,000,000 advertising campaign aimed at reducing water use in Southern California on a continuing basis by creating public awareness and providing valuable tips on how to curtail water use. The campaign, primarily radio and television commercials, is planned for the summer months when people are more conscious of the need for conserving water.

Furthering its involvement in the conservation effort, for the very first time, Metropolitan joined a private firm in calling for water use reductions. At fiscal year end, Metropolitan and Wells Fargo Bank launched a $3.4-million water conservation campaign "Helping California save water for a future we can all bank on." Aimed at saving more than 65 billion gallons of water over the summer, it includes not only radio, television, and billboard advertising but distribution of 1 million water conservation kits. Wells Fargo will distribute 70 percent of the kits at its 167 Southern California branches, the remainder will be disseminated by Metropolitan and its 27 member agencies.

Not stopping at its efforts on earth, Metropolitan is looking into outer space for assistance. Sophisticated analysis of photographs taken 450 miles above the earth will help plot outdoor water use patterns and guide Metropolitan to important water conservation opportunities in urban landscaping. The information will also be particularly useful in ongoing water allocation hearings before the State Water Resources Control Board.

Making sure that local water sources remain uncontaminated, Metropolitan, the Environmental Defense Fund, and local water agencies filed lawsuits during the year aimed at blocking a controversial garbage dump expansion in the San Gabriel Valley, seeking to reverse a ruling by the State Water Resources Control Board. The ruling would allow the Azusa Land Reclamation Company to dump more than 30 million tons of municipal garbage in gravel pits overlying the groundwater basin that provides drinking water for 1 million people. Metropolitan, EDF, and the local water agencies feared that the protective plastic liners installed at the dump would eventually leak, contaminating the groundwater basin which provides 90 percent of the valley's drinking water.

Metropolitan continues in the forefront on high standards of water quality, undertaking a six-month study of the occurrence of radon in Southland groundwater supplies in anticipation of an Environmental Protection Agency limit on radon expected later this year. The EPA advised that the maximum contaminant level (MCL) will be set somewhere between 200 and 2,000 pico Curies per liter (pCi/L). Findings from the study ranged from 93 to 1,538 pCi/L, with the majority of sites having radon levels between 200 and 500 pCi/L, indicating there could be significant impact on available water supplies in Southern California the more stringent the MCL.

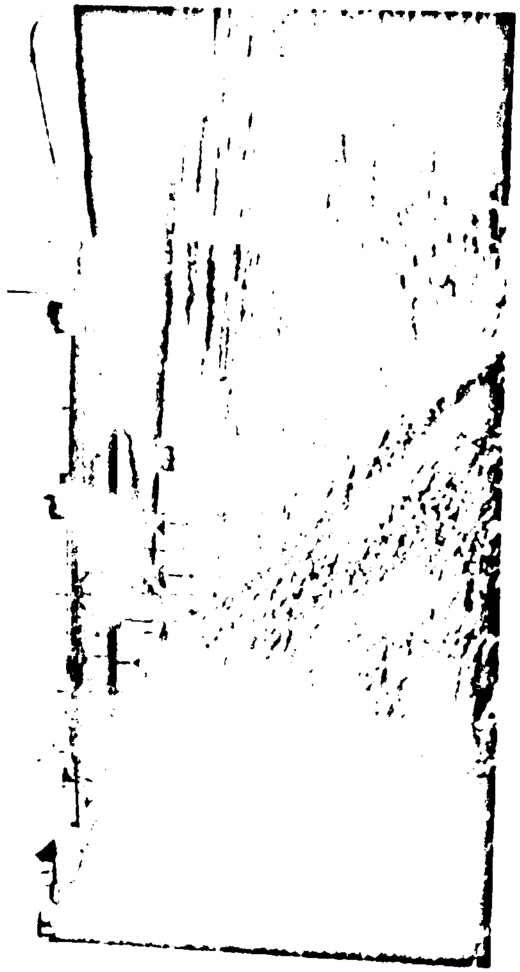
Water rates remained stable for the fifth consecutive year, keeping untreated and treated water at $197 per acre-foot and $230 per acre-foot respectively, interruptible untreated and treated water at $153 and $186, emergency untreated and treated water at $591 and $624, and reclaimed water at $54. A new class of service, Seasonal Storage, was added this year. Priced at $115 for untreated water and $135 for treated, Metropolitan hopes to encourage agencies to purchase water from October through April and

store it for summer use during peak demand on Metropolitan. This fiscal year, 18 member agencies took advantage of seasonal storage rates, buying 320,000 acre-feet, and staff estimates that about one-third would be used during the summer of 1990.

In yet another record year for water sales, revenues rose $62 million over last fiscal year, totaling $487 million on water deliveries of 2,511,375 acre-feet, up 19.8 percent over last year's record deliveries. Revenues from the recovery of hydroelectric power remained the same as last year at $19 million. The net amount of taxes for 1989-90 totaled $81.9 million.

Metropolitan's major expansion program moved forward throughout the year. Nineteen construction contracts with a total cost of $58,344,969 were in progress. The Board of Directors awarded 13 new construction projects with a value exceeding $129 million; 3 construction contracts were completed at a total cost of $2,160,529, and 16 contracts progressing at year end were valued in excess of $198 million. The major projects under construction during the fiscal year included Skinner Filtration Plant Expansion No. 3 and Finished Water Reservoir, enlargement of San Diego Canal, and Etiwanda Pipeline, Control Facility, and Reservoir. Major projects in design phases during the fiscal year included Jensen Plant Expansion No. 1, Foothill Feeder Pressure Control Structure Expansion, Diemer Plant Modifications, and the Etiwanda Power Plant.

Metropolitan continued rehabilitating its aging Colorado River Aqueduct pumping system, completing Phases IV and V during the fiscal year. Metropolitan staff also continued rehabilitation work at the F.E. Weymouth Filtration Plant, with completion anticipated during the next fiscal year.



Greater water conservation will be achieved by lining the earthen All American Canal and Coachella Branch

CHAPTER 1

Water Supply

Incorporated in 1928, the Metropolitan Water District of Southern California (Metropolitan) provides a supplemental water supply for Southern California's coastal plain. Municipal and industrial demand consumes approximately 90 percent of Metropolitan-supplied water; the remaining 10 percent is used for agricultural purposes and to prevent seawater intrusion into coastal groundwater basins.

Metropolitan's service area covers 5,200 square miles and 27 member agencies, which consist of 14 cities, 12 municipal water districts, and the San Diego County Water Authority (SDCWA) as shown in Figure 1 at the end of this chapter. Currently supplying more than half of the water used within its service area, Metropolitan is expected to deliver nearly all of the anticipated increase in future water demands.

Obtained either locally or imported, Southern California water supplies vary widely from wet years to dry years and are affected by multi-year periods of drought conditions. For imported water, Metropolitan relies on the Colorado River Aqueduct (Aqueduct), which diverted 1.24 million acre-feet (maf) in fiscal year 1989-90, and the State Water Project (SWP) which furnished 1.32 maf. As Metropolitan's total dependable supply from these two sources is projected to equal only 1.75 maf in 1995, various initiatives are being undertaken to increase that supply.

Colorado River Supply

Entitlements

In 1930, Metropolitan signed a contract with the Secretary of the Interior (Secretary) to receive Colorado River water (CRW). By annexing SDCWA's service area in 1946, Metropolitan's contractual CRW entitlement increased to 1.212 maf per year. However, Metropolitan lost some entitlement dependability in 1985 when the Central Arizona Project (CAP) began supplying water to central Arizona. This caused provisions of Colorado River reservoir operating criteria issued by the Secretary in 1970 to become effective. Annually, the Secretary determines whether sufficient water is available to satisfy water requests from contractors in Arizona, California, and Nevada. California's basic CRW apportionment is limited to 4.4 maf per year by a 1963 U.S. Supreme Court decision. Agencies supplying irrigation water hold a higher priority to reasonable beneficial use of 3.85 maf per year, less the amount of water made available to Metropolitan under its Water Conservation Agreement with Imperial Irrigation District (Imperial). Furthermore, water use by holders of higher priority Indian and miscellaneous rights (30,000 acre-feet) and conveyance losses (50,000 acre-feet) reduce Metropolitan's dependable supply delivered into the coastal plain. Metropolitan estimates that its dependable supply will increase from 476,110 acre-feet in 1990 to 576,110 acre-feet by 1996 as Imperial Valley water conservation projects are completed.

The Aqueduct System

Initial facilities on the voter approved Aqueduct were completed in 1941. As water needs increased, Metropolitan had expanded Aqueduct facilities by 1961 to a capacity of more than 1 maf per year, which equals more than 1 billion gallons per day.

The Colorado River Aqueduct covers 242 miles of desert terrain and mountain ranges between its Lake Havasu intake and its terminal reservoir, Lake Mathews, near Riverside. The Aqueduct, originally designed to accommodate an eight-pump flow of 1,605 cubic feet per second (cfs), can convey flows 15 percent higher. This sufficiently delivers the dependable water supply plus more than [illegible] acre-feet of surplus CRW when available. During the 1989-90 fiscal year, 1,243,064 acre-feet of water was diverted from Lake Havasu into the Aqueduct. The average flow was 1,720 cfs, 107 percent of the original Aqueduct design capacity.

Five pumping plants elevate CRW a total of 1,617 feet, taking it over several mountain ranges. The Whitsett pumping plant, on Lake Havasu's western shore, elevates water from the lake 291 feet to Gene Wash Reservoir located two miles inland. The Gene pumping plant raises the CRW an additional 303 feet to Copper Basin Reservoir, the Aqueduct's major flow control point. The water flows by gravity approximately 63 miles to the Iron Mountain pumping plant, where it is raised another 144 feet. After flowing another 41 miles, the water reaches the Eagle Mountain pumping plant which boosts it 438 feet. Following a 16-mile gravity flow, the water arrives at the Hinds pumping plant and is elevated 441 feet. The water continues by gravity the remaining 116 miles to Lake Mathews.

Each pumping plant was designed to operate continuously with eight pumps; a ninth pump facilitates maintenance and repairs and provides additional pumping capacity. With a nine-pump flow, the Aqueduct can carry flows 15 percent higher than design capacity, or 1,850 cfs. Because of modifications to pump and motor units, each pump's capacity now exceeds its original 200-cfs design capacity.

Colorado River Water Supply Conditions

Colorado River runoff continued below average for a third consecutive year. End-of-year reservoir storage declined by about 5 maf from a year ago, reflecting the June 1 forecast of runoff into Lake Powell of 31 percent of average for the April-to-July snow-melt period.

As shown in Table 1, Lake Powell inflow reflected the dry conditions experienced in the Upper Colorado River Basin.

TABLE 1

Inflow to Lake Powell
(Million Acre feet)

Inflow Source	Fiscal Year 1987-88	1988-89	1989-90
Green River at Green River, Utah	3.4	2.2	1.9
Colorado River near Cisco, Utah	3.9	2.9	2.2
San Juan River near Bluff, Utah	1.3	1.0	0.7
Miscellaneous	0.6	0.2	0.2
Total inflow to Lake Powell	9.2	6.3	5.0

The river's gauged flow at Lees Ferry, Arizona, a few miles downstream of Lake Powell, was 8.0 maf for the fiscal year. This gauge lies just upstream of the Paria and Colorado River confluence. Downstream of the Paria is the Colorado River Compact point, where Upper Colorado River Basin releases to the Lower Basin are determined.

Releases from Lake Mead totaled 9.0 maf. CRW deliveries in the Lower Basin were 5.2 maf to California, including 1.2 maf to Metropolitan and 3.9 maf to the agencies supplying irrigation water; 2.3 maf to Arizona; 0.2 maf to Nevada; and 1.7 maf to Mexico including saline waters bypassed to the Santa Clara Slough.

Colorado River Aqueduct Power Requirements

Power required for the Aqueduct pumping operations is delivered through a Metropolitan-owned transmission system consisting of 310 miles of high-voltage (230 kilovolt) power lines connecting the pumping plants to the Western Area Power Administration (WAPA) system and the Southern California Edison Company (SCE) system. WAPA's system delivers Metropolitan's share of power from Hoover and Parker Power Plants, shown in Table 2.

TABLE 2

ELECTRIC ENERGY AVAILABLE AT HOOVER AND PARKER POWER PLANTS

Fiscal Year 1989-90

	(Kilowatt-hours)
Hoover Power Plant	
Total Hoover Energy	4 067 847 000
Total Hoover Energy Available to Metropolitan	1 205 476 000
Parker Power Plant	
Total Parker Energy	469 699 522
Total Parker Energy Available to Metropolitan	230 545 000

This fiscal year, a total of 2.4 billion kilowatt-hours (kwh) of energy was needed to divert the 1,243,064 acre-feet of water from Lake Havasu. As shown in Table 3, the Hoover and Parker Power Plants provided 59.0 percent of the total energy required.

TABLE 3

METROPOLITAN'S ELECTRIC ENERGY USE

Fiscal Year 1989-90

Energy Source	Kilowatt-hours	Percentage of Total Energy Requirement
Hoover Power Plant	1 205 476 000	49.51
Parker Power Plant	230 545 000	9.47
Edison Benefit Energy	219 139 828	9.00
Exchange	24 [illegible] 000	1.02
Supplemental Energy Purchases*	754 629 485	31.00
TOTAL	2 434 567 313	100.00

Note

*[illegible] ... Project, Arizona Public Services Company, and the T[illegible]

To augment the Hoover and Parker power resources, Metropolitan and SCE integrated their electric systems under the District-Edison 1987 Service and Interchange Agreement. The agreement improves electric service reliability, conserves resources, and helps optimize efficiency for both parties. Specific benefits include energy interchanges and exchanges, supplemental energy purchases, and use of surplus generating capacity.

To secure the required energy for pumping operations, Metropolitan purchased supplemental power under various power contracts and agreements. Almost all of the supplemental power was "economy, off-peak energy" from various suppliers, including Arizona Public Services Company, Salt River Project, WAPA's Navajo Project, and the Tucson Electric Power Company.

Tables 4 and 5 summarize this fiscal year's total power use and costs for Aqueduct pumping operations. The composite of the supplemental power costs represents SCE's average power rate of 29.5 mills/kwh, and the other suppliers average rate of 16.7 mills/kwh. Such supplemental power rate differences provide substantial economic benefits by minimizing Metropolitan power costs. For fiscal year 1989-1990, the supplemental power cost savings totaled approximately $8.9 million.

TABLE 4

PLANT ENERGY USE

Fiscal Year 1989-90

Plant	Pump-Hours (Hours)	Energy Use (kwh)	Station Service (kwh)	Water Diverted (Acre feet)
Whitsett	61,910	423,187,481	898,861	1,243,064
Gene	66,265	447,553,908	5,706,434	—

Hinds	68,208	653,158,477	2,164,007	—
Total	332,795	2,381,519,997	14,178,463	1,243,064

Total Colorado River Aqueduct Energy Use (kwh):

Total Pumping Energy Use	2,381,519,997
Add Total Station Service	14,178,463
Add Transmission Losses	38,868,853
Total System Energy Use	2,434,567,313

Power Management

Boulder Canyon Project Administration

Metropolitan staff continued participating in meetings with other Boulder Canyon Project Power Contractors, WAPA, and the United States Bureau of Reclamation (Reclamation). Significant meetings attended included WAPA's 1990 Hoover Power Repayment Study, financial analysis of the Boulder Canyon Project, proposed changes on Boulder Canyon Project Power Contractors' Conservation and Renewable Energy Programs, and Hoover energy scheduling and accounting.

VOL 12 1597-2

[illegible]	24,[illegible]	[illegible]9.47*

[illegible]

[illegible] Benefit Energy plus Exchange Energy with SCE [illegible]

WAPA refunded approximately $9 million to Metropolitan, equaling Metropolitan's portion of funds that WAPA received from the Hoover power contractors which exceeded Boulder Canyon Project needs during the first 50 years (1937-1987).

WAPA has accepted Metropolitan's two-year progress report of its conservation and renewable energy program. The submission was required under the Hoover Power Plant Act and Section 9 of Metropolitan's Hoover Contract. The report described the progress made on rehabilitating Metropolitan's pumping plants during the last two years.

District [illegible]

Pursuant [illegible] Edison 1987 Service and Interchange Agreement [illegible] submitted to SCE Metropolitan's energy loads and [illegible] year 1989 through 2000. The submissions included [illegible] and estimated available Aqueduct power resources. Aqueduct [illegible] unused energy available to the SWP and benefit [illegible] deliver to Metropolitan.

Staff has also been [illegible] a preliminary interconnection agreement with SCE for Metropolitan's [illegible] Etiwanda Power Plant which is scheduled for operation in 1994. Under the proposed agreement, SCE would perform the necessary engineering, design, procurement, and construction of the interconnection facilities required to connect Metropolitan's Etiwanda Power Plant to SCE's electric transmission system.

Metropolitan-State Contracts

Per the provisions of the Power Coordination Agreement between Metropolitan and the California Department of Water Resources (DWR), staff completed and submitted to DWR Metropolitan's estimate of its Aqueduct power operation for the 1990 calendar year. Metropolitan anticipated that no surplus Aqueduct energy will be available to sell to DWR nor that any energy will be available for exchange.

On December 27, 1989, the San Diego Gas and Electric Company (SDG&E) submitted to the California Energy Commission a Notice of Intent (NOI) to construct a 460-megawatt combined cycle power plant at one of six possible California locations, including the Sun Desert site near Blythe, California. Metropolitan has been closely following the NOI process as it pertains to the Sun Desert location because of its potential obligation to supply cooling water from its Colorado River entitlement and its stake in DWR's acquiring viable and economic power resources. If SDG&E constructs the plant at the Sun Desert site before the year 2000, Metropolitan would be obligated, under an amended 1974 Letter of Intent, to annually provide 17,000 acre-feet of cooling water from its CRW entitlement through the year 2033. The letter of intent also obligates SDG&E to allow DWR to participate in the project up to 110 megawatts. DWR has notified SDG&E of its intent to participate in the NOI process.

Purchase Agreements for Supplemental Power

Pumping demands on the Aqueduct exceeded Metropolitan's base-load energy resources available from Hoover and Parker Power Plants and SCE's benefit energy in 1989-1990 by up to 750 million kwh. To supplement these base-load resources, the General Manager has executed new Economy Energy Agreements with WAPA, city of Burbank, and city of Pasadena in addition to existing Economy Energy Agreements with DWR; Salt River Project Agricultural Improvement and Power District; Arizona Electric Power Cooperative, Inc.; Arizona Public Service; Nevada Power Company; Tucson Electric Power Company; and city of Glendale. Due to the power market's dynamic nature, staff continually seeks opportunities to negotiate additional supplemental power resources for pumping on the Aqueduct at the lowest price. Metropolitan's history of energy use is listed in Table 6.

Impact on Supply — The Central Arizona Project

While the Secretary has not yet limited Metropolitan's CRW diversions, CAP CRW diversions increased to about 830,000 acre-feet this year. It is projected that diversions will total 1.15 maf next fiscal year from the CAP's Hayden-Rhodes, Salt-Gila, and Tucson Aqueducts.

TABLE 6

HISTORY OF METROPOLITAN ENERGY USE

Operating Year (June 1–May 31)	Hoover	Parker	Glen Canyon	Edison	Mohave	Total
[illegible]	[illegible]	[illegible]	[illegible]	[illegible]	[illegible]	[illegible]

Fiscal Year (July 1–June 30)	Hoover	Parker	Edison Benefit	Edison Exchange	Supplemental Energy Purchases	Total
[illegible]	[illegible]	[illegible]	[illegible]	[illegible]	[illegible]	[illegible]

Tucson Aqueduct construction has been completed, with three of its pumping plants fully operational and six under construction. Nearly four miles of pipeline and tunnel to deliver water to Tucson have been finished. Water deliveries to the city are expected to begin at the end of 1991 following construction of a water treatment plant. The Pima Reservoir, an operational reservoir off the Black Mountain Pipeline, has been completed. Construction of the eight-mile Black Mountain Pipeline to serve the San Xavier Indian Reservation and others is under way.

New Waddell Dam will serve as the CAP's major regulatory storage facility. Construction continued on tunnels that will act as inlet, outlet, and diversion works for the reservoir. With foundation excavation completed, erection of the dam embankment will begin early next fiscal year. Construction of the New Waddell Pump Generation Plant continued. Reservoir operation is scheduled to begin in 1994. Figure 3 shows the location of major CAP facilities.

Colorado River Floodway

Metropolitan staff continued participating in the Colorado River Floodway Task Force created to advise the Secretary and Congress on issues related to establishing a floodway from Davis Dam to the southerly international boundary. The floodway will encompass the area required to carry the one-in-one-hundred-year river flow or 40,000 cfs, whichever is greater. The Task Force adopted its report to the Secretary and Congress near fiscal year end. The report includes recommendations on means to restore and maintain the floodway, the necessity for additional floodway management legislation, whether specific cases of economic hardship resulting from impacts of the 1983 runoff on property outside the floodway should be compensated, and the potential application of the floodway on Indian lands.

State Water Project Supply

To meet future demands, Metropolitan signed the first contract with DWR leading to construction of the SWP in 1960. Although the initial contract called for an ultimate water entitlement of 1.5 maf per year for Metropolitan, later amendments raised this to 2.0115 maf per year. This is nearly one-half of the 4.218 maf per year contracted for by all 30 SWP contractors. Metropolitan's contract with DWR reached its maximum annual entitlement in 1990.

The SWP was designed so that additional conservation facilities to augment yield could be constructed as delivery demands increased. However, due largely to opposition from various sectors, no additional

VOL 12 1597-4

R0049279

conservation facilities have been built since the first ones were finished in 1967. The total demand for State project water has been increasing since then and two drought periods have also stressed the system as shown in Tables 8 and 9. In the past, Metropolitan has received its maximum CRW entitlement to meet its needs. However, due to increasing demands and reduced Colorado River supplies, Metropolitan will be using greater amounts of State project water than before. To enable Metropolitan to receive larger amounts of State project water, the California Aqueduct's East Branch is being enlarged. Table 7 shows the project's status.

Metropolitan first began receiving State project water in 1972 at Castaic Reservoir, the California Aqueduct's West Branch terminus. Under its contract, Metropolitan paid the State nearly $195 million before taking its first water delivery. Each of the 30 SWP contractors proportionately pays project costs based on the sizing of facilities required to deliver water to their respective areas. Located at the project termini, Metropolitan pays approximately two-thirds of all costs. Metropolitan's DWR payments for State project water reached $248 million during the fiscal year, for a cumulative total of $2.57 billion through June 30, 1990, shown in Table 10.

Power for Pumping State Project Water

Operating as an electric utility since 1983, DWR manages the SWP power system consistent with the following principles: (1) maximizing the benefit from existing SWP resources, (2) developing and maintaining alternate energy sources to provide flexibility in meeting water delivery requests and to reduce dependence on power purchased from utilities, (3) securing transmission resources to efficiently supply power to SWP facilities and to provide access to areas where low-cost power can be obtained and (4) minimizing the impact on the SWP when major contractual arrangements expire in 2004.

Hydro[illegible] provides the largest SWP energy share. Hydroelectric res[illegible] Hyatt-Thermalito generating plants, and the Gianelli[illegible] Castai[illegible] Alamo, Devil Canyon, Warne, and Mojave [illegible] In 1989 hydroelectric energy accounted for [illegible] 42 percent of the total resources. Coal-fired [illegible] Gardner Unit No. 4 (RG4) Power Plant in South[illegible] [illegible] source of SWP energy. DWR's [illegible] million kwh. [illegible] varies annually because precipitation [illegible] from year to year, directly affecting both [illegible] pumping demands. Table 12 lists projected [illegible] 1990, 1995, and 2000.

TABLE 7

EAST BRANCH IMPROVEMENT/ENLARGEMENT

As of June 30, 1990

PROJECT	STATUS
Complete	• Raising East Branch of canal lining* • Big Rock Siphon construction • R. C. Box Siphons 1, 2, & 3 construction • Parallel nine additional pipe siphons construction
Near Completion	• Devil Canyon Power Plant - Initial contract • Pearblossom Power Plant - Initial contract • Check structure modification - Pearblossom to Mojave Siphon Power Plant
Construction Begun	• Check structure modification - Alamo to Pearblossom • Devil Canyon Power Plant - Fabrication and manufacturing of Units 3 and 4 • Pearblossom Pumping Plant - Fabrication and manufacturing of Units 7, 8, and 9 • Furnish and install second penstock at Devil Canyon Power Plant
Contract Awarded	• Pearblossom Pumping Plant - Completion contract • Devil Canyon Power Plant - Completion contract • Mojave Siphon Power Plant - Turbines, generators, and governors
Contracts Out for Bid	• Mojave Siphon Power Plant - Initial contract
Continuous	• Design - Mojave and Antelope Siphons • Design - Mojave Siphon Power Plant • Develop second afterbay of Devil Canyon Power Plant • Design Devil Canyon Power Plant penstock shutoff valve

Notes

*A portion of the East Branch canal lining from Alamo to Pearblossom may have to be raised an additional foot pending hydraulic testing upon completion of the East Branch Enlargement.

Metropolitan's Share of the SWP Power Costs

Metropolitan's total power cost for pumping State project water in 1989, excluding cost adjustments for previous years, was approximately $104 million or $90 per acre-foot. The projected total pumping power cost for 1990 is $123 million or $90 per acre-foot.

South Geysers Power Plant

The 1989 SWP Geothermal Facilities Operation Plan describes DWR's long-range plan for developing, operating, and using SWP geothermal facilities. Consistent with this plan, DWR accepted bids to sell the South Geysers generating equipment, the steam resource, and the power plant building. In April 1990 four major lots of generating equipment were sold for $5.5 million. The remaining lots of equipment at South Geysers will be used as spares at SWP facilities. Efforts continue to market the steam field. The current outlook for the South Geysers plant building is to use it as a general archive and storage facility for the State of California.

Bottle Rock Power Plant

The DWR owned and operated Bottle Rock Power Plant is a geothermal facility located in the Geysers area of Northern California with an original design capacity of 55 megawatts. Due to a lower than anticipated steam supply, the Bottle Rock plant output has historically been considerably less than its rated capacity. As of March 1989 the plant was only generating about 8 megawatts, with expectations of continued decreased generation annually.

To increase plant steam production, DWR and the Northern California Power Agency (NCPA) reworked three wells in April 1990 with disappointing results. The costs and benefits of the redrilling effort are being equally shared by DWR and NCPA. NCPA has expressed interest in leasing the steam field and power plant, but no decision has been made. DWR is also considering shutting down the plant if a leasing arrangement cannot be negotiated.

Reid Gardner

RG4 is jointly owned by DWR and the Nevada Power Company (NPC). DWR is entitled to 90.4 percent of RG4's 250 megawatt output. During a scheduled plant outage in April and May of 1990, RG4's deteriorating concrete cooling tower was demolished and connections to a new wooden cooling tower were completed. In addition, the RG4 steam turbine was modified [illegible] the unit's output by 15 megawatts. DWR and NPC will [illegible] benefits and costs. Legal action is being taken [illegible] $13 million in damages to replace the structure [illegible] cooling tower.

Devil Can[illegible]

[illegible] the Devil Canyon Power Plant. Two 80- [illegible] added, bringing the plant's total gross [illegible]. The enlarged power plant should [illegible] Afterbay, with a storage capacity of [illegible] the Devil Canyon site. Benefits of the [illegible] include significant cost savings [illegible] reserve capacity and benefits [illegible] on peak energy production is

Issues Affecting Water Supply

Forecasting Agricultural Water Use

Metropolitan and the Colorado River Board of California have developed techniques for projecting agricultural CRW use in California outside Metropolitan's service area. As both techniques underestimated actual use in calendar year 1988, a consultant continued efforts to refine Metropolitan's forecasting model. Had Metropolitan's CRW use been limited in calendar year 1989, no unused agricultural priority water would have been available since use exceeded the 3.85 maf available under the first three priorities.

Salinity Control

Implementation of the Colorado River Salinity Control Program continues, meeting numeric criteria adopted by each of the Colorado River Basin states for total dissolved solids concentration below Hoover and Parker Dams and at Imperial Dam. Numerous projects to prevent agricultural, point, and diffuse sources of salinity from entering the Colorado River or its tributaries have been completed or are under development by the Departments of the Interior and Agriculture. Projects in the Grand Valley, Lower Gunnison Basin, and the Meeker Dome areas of Colorado, the Uinta Basin in Utah, the Big Sandy River area in Wyoming, and Las Vegas Wash in Nevada remove 168,500 tons of salt annually. Another 1.4 million tons of salt per year must be removed by the year 2010 to meet the numeric criterion at Imperial Dam.

San Francisco Bay-Delta Hearing

The State Water Resources Control Board (SWRCB) maintains regulatory authority over water quality and water rights within the State of California. The SWRCB's actions and decisions can significantly impact the SWP's facility operations and water supply reliability.

In July 1987, the SWRCB began regulatory review of its 1978 Water Rights Decision 1485 (D-1485) along with related water quality control plans for the San Francisco Bay-Sacramento-San Joaquin Delta Estuary (Bay/Delta) and the Central Valley water basins. After some delays, the SWRCB now projects adoption in late 1990 of the Water Quality Control Plan (WQCP) covering salinity in the Bay/Delta; the entire process will be completed in late 1992 with adoption of a water rights decision.

Metropolitan is coordinating its Bay/Delta Hearing involvement through State Water Contractors, Inc. (SWC). This effort consists of preparing testimony before the SWRCB and documents supporting Metropolitan and SWC's recommendations. During the 1989-90 fiscal year, this effort was directed towards analyzing the revised drafts of the heavily criticized 1988 draft WQCP. The SWRCB held workshops to receive public comments on the revised WQCP in February 1988 and scheduled hearings on the revised WQCP for August 1988.

In broad terms, the SWC is examining the revised draft WQCP assumptions and proposals from three directions:

- Are the directives in the Racanelli Decision being followed for water rights and water quality?
- Is there a reasonable balance of beneficial water uses among fish, wildlife, municipal, agricultural, and other purposes with supporting scientific evidence?
- Are pollution sources and adequate protection for drinking water quality addressed?

As part of the process, solutions must be found for the multiple existing Bay-Delta problems. SWC is supporting a broad examination and consideration of all options, including isolated Delta transportation facilities with appropriate guarantees.

State Water Project Fishery Mitigation

In July 1988, DWR and the California Department of Fish and Game (DFG) began discussions toward negotiating a new fishery agreement to mitigate SWP overall impacts on the Delta fishery. This new agreement is required by the December 30, 1986, Banks Pumping Plant Fishery Mitigation Agreement before DWR can operate the plant with four additional pumps at the full capacity of 10,300 cfs. The 1986 agreement was entered into to offset the direct losses of fish at the Banks Pumping Plant by funding mitigation projects such as hatcheries, fish screens, and physical transfer of fish from Clifton Court Forebay back into the Delta. It did not account for other [illegible] fishery caused by the SWP. Since discussions began, [illegible] in the negotiations with the hope of also [illegible] DFG for impacts caused by the Central Valley Pr[illegible]

CHAPTER 2

Delivering Metropolitan's Water Supplies

The Distribution System

Stretching 200 miles along the Pacific Ocean, Metropolitan's service area extends from Oxnard to the Mexican border and inland in some places for about 70 miles through six counties: San Diego, San Bernardino, Riverside, Orange, Los Angeles, and Ventura. In fiscal year 1989-90, Metropolitan's system met historical record-setting demands and delivered about 2.5 million acre-feet (maf) of water, averaging 2.27 billion gallons per day.

Our dependence on imported water is satisfied by the Colorado River Aqueduct (Aqueduct), described in Chapter 1, and the State Water Project (SWP) operated by the Department of Water Resources (DWR). State project water is transported from the Sacramento-San Joaquin Delta through the central valley to Southern California. State project water is introduced to Metropolitan's distribution system through the SWP's West Branch to Castaic Lake in the Santa Clarita Valley and through the East Branch to Silverwood Lake in the San Bernardino Mountains.

Utilizing 775 miles of pipeline, five filtration plants, eight reservoirs, numerous regulating structures, and 14 hydroelectric power recovery plants, Metropolitan delivers water to its member agencies, which subsequently supply homes, industries, and agricultural users. Table 13 shows each filtration plant's location and capacity.

Due to deteriorating water quality caused by nitrification, Metropolitan temporarily changed the disinfectant leaving the treatment plants from chloramine to free chlorine starting on June 26, 1989, at the Henry J. Mills Filtration Plant (Mills plant), and on July 10, 1989, at the Robert B. Diemer (Diemer plant), Joseph Jensen, Robert A. Skinner, and F. E. Weymouth (Weymouth plant) filtration plants. All of Metropolitan's treatment plants returned to chloramine disinfection on August 7, 1989.

Operational Planning

Metropolitan has a well-designed, flexible water distribution system involving numerous pipelines. Operations are planned to maximize delivery of the least costly water while weighing each water supply's availability and the effect on SWP and Aqueduct operations. Staff continually decides on quantity fluctuations taken from each source, and the extent to which terminal reservoir storage should be utilized to most efficiently accommodate demand changes. During the past year, Metropolitan's Operations Planning staff continued participating in developing and reviewing Colorado River and SWP operations. Due to a fourth year of continuous drought in California, the State imposed a 50 percent deficiency on agricultural deliveries in 1990; none were imposed on municipal or industrial contractors. Southern California's situation was further buffered by Metropolitan's ability to divert 1.243 maf of Colorado River water (CRW) during the fiscal year.

Metropolitan continued record-level deliveries to its member agencies, establishing monthly water sales records for nine out of the 12 months and delivering a total of 2,511,375 acre-feet during the fiscal year. By carefully monitoring Southern California's water supply situation, Metropolitan continues to develop operational strategies that minimize possible delivery shortfalls to its member agencies.

Seasonal Storage Service

In July 1989, Metropolitan's Board of Directors adopted a new service class known as seasonal storage. The three principal goals of seasonal storage service are to (1) achieve greater conjunctive use of imported and local water supplies, (2) encourage construction of additional local production facilities, and (3) reduce member agencies' dependence on Metropolitan summer deliveries. Generally, this discounted-rate service is to be offered October through April. To accomplish the goals, agencies are expected to store any water purchased under seasonal storage service for production at a time more advantageous to Metropolitan. Storage can occur in surface reservoirs or in groundwater basins either directly or by in-lieu means.

During fiscal year 1989-90, 18 of Metropolitan's 27 member agencies took advantage of seasonal storage service, which was available for the entire October 1 through April 30 period. Approximately 320,000 acre-feet were sold at seasonal storage rates, with about 133,000 acre-feet for direct groundwater replenishment, 95,000 acre-feet for in-lieu groundwater replenishment, and 91,000 acre-feet for reservoir storage. Staff estimates that about one-third of this total would be produced during the summer of 1990 to help offset the peak demand on Metropolitan.

"Drought Action Plan '90"

By spring 1990 it [illegible] that Southern California was into the [illegible] consecutive [illegible]. Anticipated supplies from Metropolitan's sources [illegible] well below normal and held the potentia[illegible] possib[illegible] projected demands. In response, Metropoli[illegible] Board of Directors approved "Drought Action Plan '90" in April [illegible]

The Drought Action Plan '90 goal [illegible] conserve 200,000 acre-feet of w[illegible] in calendar year 1990. It utilized $100 per acre-foot rebates as incentiv[illegible] to be credited to the accounts of member agencies that successfully redu[illegible] total water demands by more than 5 percent compared to adjusted 19[illegible] total water demands. Rebate crediting began June 1, 1990, and will continue through the summer. In the program's first month, approximately $241,[illegible] was credited to the member agencies.

Shutdowns and Service Interruptions

Filtration plant, pipeline, and reservoir shutdowns and planned service interruptions constitute another dimension of Metropolitan's water operations. This year, major shutdowns and interruptions included:

- On November 28, 1989, Garvey Reservoir was taken out of service and dewatered. During inspection, a 300-foot crack was found on the southwest slope near the junction with the reservoir's floor. The reservoir remains out of service.
- [illegible] Devil Canyon from December 1989 to [illegible] Metropolitan conducted maintenance and repairs to [illegible] Reservoir, and the San Dimas Power Pla[illegible] [illegible] Pipeline was shut down and dewater[illegible]
- [illegible] Feeder was shut down March 27, 1990, fro[illegible] Control Structure to San Joaquin Res[illegible] [illegible] Connection OC-63, providing water to t[illegible]
- [illegible] Feeder was shut down for four da[illegible] [illegible] Feeder Structure Modification Proje[illegible] [illegible] the last five years. The East Vall[illegible] [illegible] Calleguas Conduit, was purchase[illegible] [illegible] District in 1971 and was original[illegible] [illegible] vacuum, air-release, and shut-off valv[illegible] [illegible] surrounding structures. In March 19[illegible] [illegible] the $3.5 million rehabilitation pr[illegible] [illegible]

- The Santiago Lateral was shut down on May 18 and 24, 1990, for 12 hours each day to remove and replace the 24-inch butterfly valve at Service Connection A-8. The valve failed to seat properly, and did not completely shut off water flow to accommodate the city of Anaheim Hills performing work downstream.

Ensuring Deliveries—Emergency Preparedness

Operations remained normal following the February 28, 1990, Upland earthquake that measured 5.6 on the Richter Scale. Assigned personnel proceeded to Metropolitan's Emergency Operations Center (EOC) which, during an emergency, functions as the central point for evaluating the field's damage assessment reports. Located at Los Angeles Headquarters, the EOC is activated when an earthquake measuring at least 4.0 on the Richter Scale occurs in Metropolitan's service area.

In the event of an earthquake, Metropolitan's Emergency Response Plan requires that designated emergency field personnel proceed to their preassigned locations. According to the plan, the field's damage assessment reports are communicated to the Eagle Rock System Control Center and relayed to the EOC.

To ensure that its emergency preparedness efforts are current with industry trends, Metropolitan is reviewing its existing Emergency Response Plan and evaluating its entire emergency preparedness program.

Optimizing the System—Power Recovery

Adding 14 hydroelectric power plants to the distribution system in recent years has increased Metropolitan's ability to minimize or recover some of the energy costs required in the pumping operations of CRW and State Project water. As shown in Table 14, these hydroelectric power recovery plants produced a total of 404,498,600 kilowatt-hours (kwh) this fiscal year. Although power plant inspection and maintenance continued throughout the year, strategically realigning the distribution system flows minimized generation loss.

During the fiscal year, the Yorba Linda, San Dimas, and Sepulveda Canyon hydroelectric power plants were retrofitted with new Kingsbury thrust bearings. Early test results of the upgraded thrust bearings indicate reduced operating temperatures and less wear, resulting in extended operating periods.

Water Deliveries and Sales

Water sales for fiscal year 1989-90 totaled 2,511,375 acre-feet, increasing 19.8 percent over last fiscal year. Of total sales, 58 percent was treated water and 41 percent untreated water, with sales of reclaimed water constituting the remainder. Month[illegible] sales varied from approximately 150,[illegible] feet in February [illegible] to a high of 266,710 acre-feet in July 1989. The [illegible] established not only a sales record for the month of July, but the h[illegible] monthly sales [illegible] in Metropolitan's history.

Table 13 summar[illegible] water use by Metropolitan's member agencies. [illegible] ure 6 shows water demand by month. Tables 16 through 18 detail the t[illegible] of water deliveries made to the member agencies during the past [illegible] year and over the last 49 years.

The Interruptible Water Service Program encourages member agencies with reservoirs or groundwater basin supplies to hold water in reserve. A member agency with reservoir or underground facilities capable of compensating for Metropolitan service interruptions or reductions may purchase the interruptible portion of its water supply at a lower rate. Member agencies that replenish groundwater basins by spreading or injecting are also eligible. Similarly, member agencies may buy water for agricultural purposes from surplus supplies at the reduced interruptible rate. Table 14 shows a 50-year history of water delivered to member agencies for underground replenishment.

In July 1989, responding to the State's continuing dry conditions, Metropolitan issued the required one-year advance notice to agricultural water service users that Metropolitan may be required to curtail service in whole or in part beginning January 1991. The one-year advance notice allows [illegible] cropping patterns before interruption and helps [illegible] meet the domestic and municipal needs [illegible]

[illegible]ing the Systems

Maint[illegible]

[illegible]tribution System and Filtration Plan[illegible]

Main[illegible] regulat[illegible] Projects [illegible] [illegible]quire considerable time because [illegible] agencies, and operating restrictior [illegible] year included.

- The M[illegible] treatm[illegible] in July [illegible] 75 mgd [illegible] which was completed and commenc[illegible] and Western Municipal Water Distr[illegible] provides the service area an addition[illegible]

- Construction and installation was completed in August 1989 on the computerized control system at the Diemer plant. Started in 1982, this project required extensive rewiring of plant controls and installation of computerized equipment.

- The Operations Division, Field Services Section, coordinated in October 1989 with the Engineering Division and Corrosion Control Section to develop and schedule a systematic inspection program of all prestressed concrete pipe within Metropolitan's distribution system.

- November 14, 1989, marked the start of the first of six 14-day San Diego Canal Enlargement shutdowns. Deliveries to San Diego were maintained by ensuring an adequate storage level in Lake Skinner and utilizing San Diego Pipelines Nos. 1 and 2.

The Aqueduct System

Aqueduct pump plant personnel, involved with the plants' 24-hour operations, carefully plan, coordinate, and execute flow changes to meet supply requirements and maintain consistent pumping at each plant. They are responsible for continuous surveillance and control of pumping plant and power dispatching operations.

Additionally, skilled maintenance work must be performed regularly. Specialized Aqueduct pump mechanics repair, maintain, install, replace, and overhaul major electrical and hydraulic equipment such as valve regulators, pumps, and electrical motors. Lineworkers install, repair, and maintain more than 340 miles of power transmission lines and equipment. Workers routinely remove sand from the Aqueduct and inject liquid chlorine into the Aqueduct flow to reduce aquatic plant growth, thereby maintaining efficient water carrying capacity.

Rehabilitating An Aging System

Colorado River Aqueduct Pump Rehabilitation Program

Five major pumping plants lift CRW over several mountain ranges to transport the water to Metropolitan's service area. A 1985 evaluation of the pumping units' conditions revealed that many of the original units installed were nearing the end of their useful life. As a result, in February 1988, Metropolitan began an extensive five-year program to rehabilitate each of the nine pump units at all five pumping plants. Restoring all the pump units to their original efficiency should reduce power use by 6 percent, representing an annual savings of approximately $2.0 million.

This estimate is based on ... 550,000 acre-feet of CRW. Trans... rehabilitation should ... additional operating efficiency ... of approximately $...

Project Descripti...

Each of the ... plants has nine pump units and was des...ned to operate ... with eight pumps. The ninth pump, serving as a spare, ... intended to permit maintenance without interrupting plant service ... to provide additional pumping capacity during peak periods.

Each pump unit consists of four major components (electric motor, centrifugal pump, suction valve, and discharge valve) and various auxiliary systems and equipment. The horsepower, rotational speed, pump size, and impeller shape provide a pumping capacity of approximately 200 cfs.

The size and scope of the Colorado River Aqueduct Pump Rehabilitation Program (CRAPRP) includes:

1. Designing and purchasing equipment and replacing up to 35 bronze impellers, including one spare impeller for each pumping plant.
2. Rehabilitating pump motors, discharge valves, pump system components, and bearings.
3. Re... ...perature instruments at all pumping plants.
4. ...ing instrumentation.

Project Ma...

The new ... utilized dur... as Phase IV ... the remaining ... implemented during Phase III, w... coordination meetings were he... in order to monitor, track, and pl...

To maintain the Phase IV and V schedules, Metropolitan contracted for supplemental laborers, as in Phases I through III, to work with Metropolitan crews at the pumping plants and at shops in La Verne. The supplemental laborers included machinists, welders, and millwrights.

As with Phases I through III, the first major task facing the crews during Phase IV and V was installing a bulkhead in the discharge pipeline of each unit being worked on in that phase. Once installed, the bulkheads allowed the other units on the affected delivery line to resume normal operation while preventing back flow into the plant and protecting the crews during the pump rehabilitation work.

Testing and Evaluation

At the end of each phase, performance testing was completed at each plant. Engineers, technicians, and consultants worked for several days to perform the tests. Before starting a motor a preliminary check is made to ensure a free-running unit. Once the pump and motor have passed the checkout phase, performance testing begins. Over 270 measurements are taken to obtain data on suction and discharge pressure, vibration, flow, temperature, and electrical energy usage.

Evaluating repairs made to the units during the first five phases revealed that modifications prevented future outages of the units and increased Aqueduct flow by approximately 60 cfs.

Colorado River Aqueduct Transformer Rehabilitation Project

The remaining four General Electric 230-kilovolt (kv) transformers at Iron Mountain Bank No.1, including the spare transformer, were refurbished by McGraw-Edison this fiscal year. This completes a total of 12 230-kv Bank No. 1 transformers and three spares that have been rehabilitated at Gene, Eagle Mountain, Iron Mountain, and Hinds pumping plants during the last three years. The fourth spare is a newer model that did not require refurbishment. The transformer rehabilitation project targeted the original 230-kv transformers installed in the late 1930s. Transformer rehabilitation includes disassembling and refurbishing the primary and secondary coils, modifying the core structurally, drying, and testing before being returned to service.

Rehabilitation of the remaining 13 230-kv Bank No. 2 transformers, including the newer spare, is being studied to justify rehabilitation costs.

F.E. Weymouth Filtration Plant Rehabilitation

The Weymouth plant was constructed in 1941 and expanded in 1949 and 1962. In 1967 and 1973, modifications modernized the plant for State project water filtration and for rehabilitative work on the chlorination system,

VOL 12

15989

roads, and parking areas. Op[illegible] problems in the areas where t[illegible] plan was not rehabilitated had [illegible] increasing due to the equipme[illegible] age. Consequently, a study [illegible] to develop a plan for all work n[illegible] to maintain operati[illegible] improve process control, autom[illegible] the plant, and impr[illegible] management. All equipment was insp[illegible] the operating [illegible] history reviewed, and tests and evalu[illegible] were made prior to the final recommendations.

The study indicated that some equipment is worn out, has excessive vibration, and requires excessive maintenance, calibration, and parts replacement. A major problem with the maintenance and repair of the equipment is the availability of spare parts. In addition, some of the old equipment is not compatible with plant automation.

Based on the detailed study, a modification program consisting of 34 projects was approved in late May 1985. Generally, all projects are concerned either with plant process equipment instrumentation, modernizing flow measurement devices, water quality monitoring, or handling emergen[illegible] uninterruptible service. Specifying the time required for the [illegible] proved difficult because scheduling required plant shut[illegible] with plant operations. But the project work [illegible] over a five-year period. Metropolit[illegible] the design and purchase of materials and [illegible] of the modification work.

[illegible] Metropolitan personnel continued with the des[illegible] and materials, and installation and co[illegible] individual projects were complet[illegible] remain. Engineering design has be[illegible] has been delivered or ordered [illegible] for five of those projects. Des[illegible] remaining two projects. It is now ant[illegible] completed in fiscal year 1991.

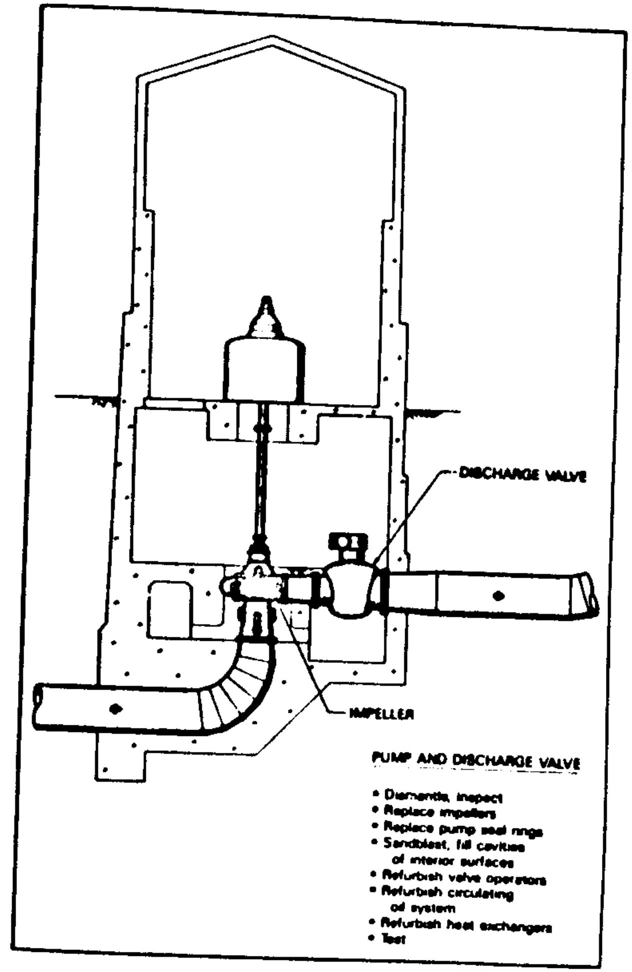

Figure 8. Rehabilitating a Pump and Discharge Valve

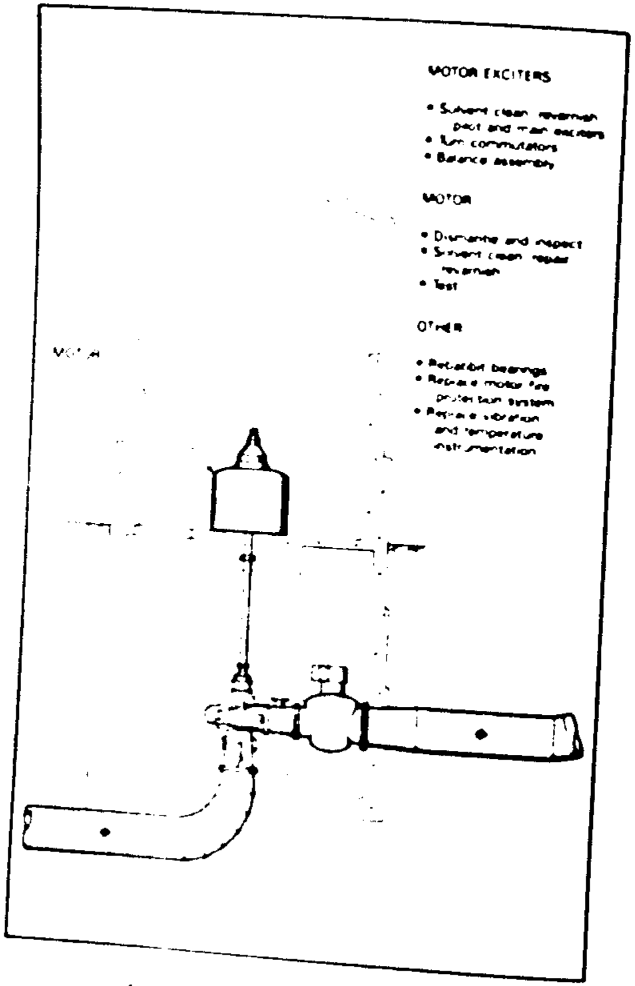
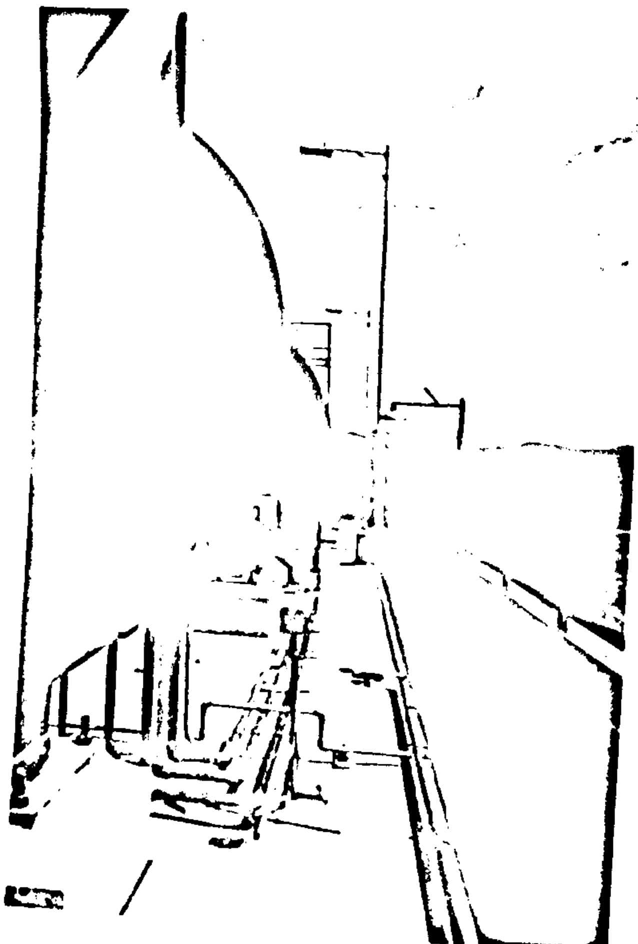


[illegible] a Pump Motor

Getting a head start on water issues thanks to Metropolitan's educational programs, these students at Brentwood School learn new lessons in geography.



New 55,000-gallon tanks at the Robert B. Diemer Filtration Plant safely store sodium hydroxide used to reduce pipeline corrosion.

CHAPTER 3

Water Supply Management and Development

Colorado River Water

With forecasts of insufficient State project supplies during future dry periods and Metropolitan's loss of half of its dependable Colorado River water (CRW) supplies, numerous water supply management and development programs are being undertaken. Although Metropolitan can expect to receive more than its dependable supply when surplus water is available or the agencies supplying irrigation water do not fully use their allocation, Metropolitan is working to develop additional supplies.

All American Canal and Coachella Branch Lining

Title II of Public Law 100-675 authorized the Secretary of the Interior (Secretary) to enter into agreements with the California agencies holding CRW delivery contracts to fund two canal lining projects: concrete lining of 28 miles of the All American Canal and concrete lining of 38 miles of the Coachella Branch. The U.S. Bureau of Reclamation (Reclamation) continued work toward publishing draft Environmental Impact Statements/Environmental Impact Reports (EISs/EIRs) next fiscal year on the canal lining projects.

To test the feasibility of lining the canals while they are operating, Reclamation awarded a contract to Kiewit Pacific Company last fiscal year to shape the canal prism and place a polyvinyl chloride and geotextile liner and concrete cover in 1.5 miles of the Coachella Branch. Subsequent complications in this first-ever underwater placement attempt required testing equipment modifications this fiscal year. Upon successfully completing the test, the contractor modified the equipment and will continue construction early next fiscal year. Metropolitan, Coachella Valley Water District (Coachella), and Reclamation are underwriting this demonstration project through an advance funding agreement.

Water Conservation Agreement with Imperial Irrigation District

This fiscal year, Metropolitan concluded negotiations with Imperial Irrigation District (Imperial), Coachella, and Palo Verde Irrigation District (Palo Verde) on agreements gaining Coachella and Palo Verde's approval of the Imperial-Metropolitan Water Conservation Agreement. Coachella had filed a complaint last fiscal year in Federal district court seeking to enjoin implementation of the Conservation Agreement. Coachella believed that Imperial was required to conserve water with or without Metropolitan funding and that such water should be available to it first under beneficial use priorities outlined in CRW water delivery contracts.

Under the Approval Agreement signed by the four agencies, Imperial is making available the water conserved by two Conservation Program Projects at no cost to Metropolitan. These two projects constitute the Augmentation Program and are estimated to conserve 6,110 acre-feet per year. Projects have been substituted into the Conservation Program so that the total water available equals 106,110 acre-feet annually. Should the Secretary require reduced use to offset use exceeding 3.85 million acre-feet, Metropolitan would reduce using conserved water at Coachella's request if Imperial did not exercise its option to do so. Coachella and Palo Verde would also reduce their diversions on a proportionate basis. If Metropolitan reduced its use of conserved water by certain amounts, the minimum term of the Conservation Agreement would be extended for a specified period. Imperial, Coachella, and Palo Verde would implement a public awareness water conservation program in any year in which Metropolitan might have to reduce its use of conserved water. These agencies would cooperate with Metropolitan in developing East Mesa groundwater resources in Imperial County.

Under a Supplemental Approval Agreement between Metropolitan and Coachella, Coachella would limit its net Colorado River diversions to 450,000 acre-feet per year except under limited circumstances. Coachella would not request that Metropolitan reduce its use of conserved water unless Imperial's net diversions exceeded certain amounts.

With project substitution, the capital costs of the conservation program in 1988 dollars are estimated to total $97.8 million, the indirect costs $23 million, and the annual direct costs $2.6 million upon full implementation. The three agreements' terms extend for a minimum of 35 years after full implementation of the conservation program, and continue until terminated.

With the approval agreements executed, Imperial began implementing the conservation program halfway through the fiscal year. By fiscal year end, 28 miles of canal were concrete lined, half day deliveries of irrigation water were taking place, and distribution system automation work was

progressing. Also, Z Reservoir design, the Plum-Oat Lateral Interceptor Canal siting, and on-farm water conservation plan preparation were under way.

Exchange Water Contracts

During the year, Desert Water Agency (Desert) and Coachella exchanged 57,010 acre-feet of State project entitlement water with Metropolitan for an equal amount of CRW from Metropolitan's advance delivery account. Metropolitan delivered 34,308 acre-feet of water to Desert and Coachella for Coachella Valley groundwater basin storage. The account balance on June 30, 1990, was 413,529 acre-feet, a reduction of 22,700 acre-feet during the fiscal year.

Also during the year, 59 acre-feet of San Bernardino Valley Municipal Water District State project water was delivered to Metropolitan for an equal amount of CRW extracted from Lake Havasu by the Havasu Water Company.

State Project Water

State Water Contractors

Metropolitan, together with 27 other State Water Project (SWP) water contractors, formed State Water Contractors, Inc. (SWC) to further its members' common interests. SWC mainly works through committees which regularly meet to study and offer solutions to problems arising from the California Department of Water Resources' (DWR's) SWP management. The following are the major committees and some of the matters in which they are involved:

- The Future Water Supply Committee works on the State's plans for developing and maintaining an SWP water supply that includes Sacramento-San Joaquin Delta (Delta) water management programs, Los Baños Grandes Reservoir, Kern Water Bank, and interim and long-term water purchases.
- The Joint Audit-Finance Committees concern themselves with all financial issues affecting the SWP, including procedures for allocating costs among the contractors. This committee also receives the reports of the DWR Technical Accounting Committee.
- The Contract Issues Committee watches areas which may require water service contract amendments. Currently, this committee is examining a contract amendment covering local projects.

- The Groundwater Committee mainly reviews DWR's activities in developing groundwater programs as SWP yield. At present, the Kern Water Bank program is being monitored.
- The Operations and Maintenance Committee provides DWR with the benefit of the water contractors' experience in operations and maintenance items. It is now examining the California Aqueduct sedimentation problem at Arroyo Pasajero.
- The Design and Construction Committee examines ongoing right-of-way acquisition and design and construction of SWP facilities. Currently, this committee is following the East Branch Enlargement and the planning of Los Baños Grandes Reservoir.
- The Energy and Power Issues Committees look at power supplies and cost allocations of power facilities, including evaluating the geothermal power plants and energy supply costs.
- The Table A Committee explores matters relating to each contractor's State project water entitlement.
- The Interim Water Purchase Committee reviews DWR's activities in acquiring interim water supplies. Working with DWR to develop an equitable method of collecting the associated costs, the contractors amended the water contracts to allow DWR to bill such water purchases as an operating cost in the Delta Water Charge. DWR is evaluating several sources of water purchase including the Central Valley Project (CVP) and a permanent agreement to purchase water from Yuba County.

Future Water Supply

DWR is actively planning to acquire further water supplies to increase SWP's yield. Without additional water and facilities to store it, the SWP will, in the very near future, be unable to meet requests from water contractors even in high or average rainfall years. The following are some of the most significant projects DWR is now examining.

- Delta Facilities. In the North Delta, DWR wants to provide a more efficient path for Sacramento River water through the Delta, thus reducing the water quality and fishery problems currently associated with reverse flows. In the initial phase of the North Delta improvements, DWR proposes to increase the South Fork Mokelumne River flow capacity which will also provide flood control benefits for the surrounding Delta islands. In the West Delta, DWR, committed to meeting certain water quality standards, recommends constructing water conveyance facilities to the western portion of Sherman Island. Alternatively, DWR proposes to purchase island

property and convert it to wildlife habitat. The South Delta's main problem lies in the channels' limited capacity which leads to channel scouring when the SWP and CVP are maximizing their pumping simultaneously with a low San Joaquin River flow or a low tide. The low water levels also contribute to the poor South Delta water quality. Numerous alternatives are being studied, among them a modified Clifton Court Forebay gate, channel dredging, and a levee setback or enlargement of Clifton Court Forebay together with the channel enlargements. Other possible project activities include installing tidegate structures, adding a siphon at Tom Paine Slough, and connecting the CVP with Clifton Court Forebay. Draft EIRs/EISs are expected in late 1990.

- Los Baños Grandes Reservoir—An off-stream reservoir similar conceptually to San Luis Reservoir, this reservoir is intended to store excess Delta flows, available primarily in the winter, for subsequent project use. DWR is currently refining its feasibility studies and will be proceeding with the Federal and State environmental processes. A Draft EIR EIS is expected in late 1990.
- Article 10(h) Water—Negotiations pursuant to Article 10(h) of the Coordinated Operation Agreement between Reclamation and DWR are continuing. Under the proposed agreement, Reclamation will provide an interim SWP water supply of approximately 150,000 acre-feet per year. In turn, DWR will wheel approximately 150,000 acre-feet of CVP water. DWR and Reclamation have initiated the environmental process and a final EIR/EIS should be issued in mid-1991.
- Yuba County Water—DWR and Yuba County Water Agency have been negotiating an interim water supply in the amount of up to 130,000 acre-feet per year for the SWP from Yuba County Water Agency's New Bullards Bar Reservoir.

Arvin-Edison Water Storage and Exchange Program

Arvin-Edison Water Storage District (Arvin-Edison), a Kern County CVP contractor, and Metropolitan may enter into a program whereby Metropolitan would deliver a portion of its SWP entitlement to Arvin-Edison for groundwater basin storage. When needed, Metropolitan would then take Arvin-Edison's CVP Delta surface water supply and Arvin-Edison would pump the previously stored groundwater. The program would not adversely impact SWP operations or other SWP contractors' entitlement deliveries.

DWR Business Information System

In developing a business information system, DWR plans to replace the present data processing system used in SWP management. The contractors have retained the auditing firm of Ernst & Young to ensure that the new system handles SWC needs for DWR information. The auditors are par ticipating on DWR's internal committee to ensure that system designers will consider SWC's needs. The auditors will provide assistance to DWR if required.

California Water Fund Offset Legislation

Legislation passed in September 1989 and signed by the governor reduces the SWP obligation to the California Water Fund by reimbursing DWR for funds spent on recreation and fish and wildlife enhancement facilities. In return, DWR will regularly schedule reimbursement transfers from the SWP to the California Water Fund for the remainder of the obligation.

Suisun Marsh

The Montezuma Slough Control Structure became operational in October 1988 and helped control salinity levels in the Suisun Marsh. Additional work to complete the project, such as modifications to the levees and boat locks, will be done in the coming year.

SWP Financing

In March 1990, DWR sold $100 million in CVP Water System Revenue Bonds, Series G, to (1) reimburse DWR for funds previously expended for SWP construction and planning costs, (2) fund a portion of the Debt Service Reserve Account, and (3) pay interest on the Series G Bonds to December 1, 1990, and pay costs of issuing the Series G Bonds.

DWR Technical Accounting Committee

The Technical Accounting Committee, chaired by the DWR Controller and including representatives of the auditing firms representing the water contractors, examines problems concerning SWP accounting and financing procedures. The main problem before the committee is resolving DWR's procedure for collecting SWP replacement costs from the contractors.

Water Conservation and Management

Best Management Practices

In response to SWRCB's 1988 Draft Water Quality Control plan, the Urban Water Conservation Task Force, which is comprised of representatives from urban water suppliers and various public interest groups, has been meeting to define and develop Best Management Practices (BMPs) for water

conservation. Metropolitan staff has played an important role on the task force and in developing the BMPs. Upon adoption by the coalition's membership, the BMPs will be submitted to SWRCB as publicly developed guidelines and standards for urban sector water conservation. The BMPs would be submitted through a Memorandum of Understanding in which the urban water suppliers and the various public interest groups would be the primary signatory parties.

Conservation Credits Program

In 1988, Metropolitan's Board of Directors adopted the Conservation Credits Program (CCP) to assist its member agencies in aggressively implementing conservation programs. Under CCP, Metropolitan's member agencies receive a financial incentive for conservation programs with verifiable savings. Metropolitan pays the lesser of one-half the program's cost or an amount per acre-foot of water saved times a flat rate of $154 per acre-foot.

Projects are selected for implementation based on anticipated effectiveness, verifiable results, economics, and financial need. Metropolitan staff may evaluate a program on its innovative merits to encourage development of new methods and technology.

To date, Metropolitan has funded a total of eight projects in its service area. These projects are anticipated to save 7,730 acre-feet per year, a total of 43,125 acre-feet over the lives of the projects. Because many of these initial projects are pilot in nature, the final total yields may vary from anticipated savings. This data will be used in developing future CCP standards and guidelines. Metropolitan's total financial commitment in fiscal year for 1989-90 was $3,454,150.

Regional Urban Water Management Plan

In 1983, the California Legislature passed the Urban Water Management Planning Act (Assembly Bill 797). The act required most urban water agencies to prepare a water management plan. Although exempted from the act's provisions, Metropolitan did prepare a Regional Urban Water Management Plan (RUWMP) for its own internal planning purposes and to assist its member agencies and sub-agencies in preparing their required plans.

This year, as in 1984-85, Metropolitan has prepared a RUWMP and this revised plan will be a significant part of Southern California's water management and conservation program planning. The RUWMP will document Metropolitan's existing and proposed water management programs, and provide a framework for a 10-year water management and conservation program.

Southern California Water Energy Conservation Partnership

During the year Metropolitan joined with Southern California Edison, Southern California Gas Co., and the Los Angeles Department of Water and Power to form the Southern California Water Energy Partnership (Partnership). This group serves to combine these agencies' efforts to conserve water and energy and to increase environmental protection and the quality of life in Southern California.

The agencies have agreed that where their mutual interests coincide they will cooperate in planning, funding, and implementing joint water energy conservation programs. Initially, the Partnership will implement a pilot toilet flapper retrofit program. The goal is to retrofit 32,000 Southern California homes.

CIMIS Program

Metropolitan continued its Southern California expansion of the California Irrigation Management Information System (CIMIS) program. The CIMIS program consists of two components, the CIMIS weather station network and the audit training module, and is intended to monitor and reduce growth in outdoor water usage. Metropolitan has provided CIMIS Audit training to 350 large landscape irrigators to teach them how to evaluate their irrigation systems efficiently, identify poor irrigation practices, and use the CIMIS weather data to schedule irrigation frequency and volume. This program is administered by the University of California Cooperative Extension in Los Angeles, Orange, Riverside, San Bernardino and San Diego Counties. The Ventura County Resource Conservation District administers the program within Metropolitan's service area in Ventura County.

Water Exchanges

Arvin-Edison—Metropolitan Water Storage and Exchange Program

During the past year Metropolitan and Arvin-Edison continued the joint effort to implement the Arvin-Edison Metropolitan Water Storage and Exchange Program. Under this program Metropolitan will be able to store about 800,000 acre-feet of SWP water in the groundwater basin underlying Arvin-Edison. During future shortage years, Metropolitan will receive, through the California Aqueduct, Arvin-Edison's CVP water. Arvin-Edison will, in turn, pump the water previously stored by Metropolitan to meet their demands. This will increase available dry-year supplies by about 10,000 acre-feet annually.

Significant progress was made on the EIR/EIS during 1989-90. The EIR/EIS was submitted to Reclamation for review. The public comment period is expected to be completed in December 1990. Adoption of the EIR/EIS by Metropolitan's and Arvin-Edison's Boards of Directors is scheduled for March 1991.

During 1990, Reclamation filed for a Change-in-Use Permit from SWRCB on behalf of Arvin-Edison. This permit will allow CVP water to be used in urban Southern California in exchange for Metropolitan's SWP entitlement water previously stored in the Arvin-Edison groundwater basin. SWRCB will convene a hearing on this permit in late 1990.

Metropolitan is continuing to work with DWR and the other SWC members to develop procedures to assure that the exchange program operations will not adversely affect the other SWP contractors.

Because 1990 has been a critically dry year, the Interim Arvin-Edison Metropolitan Water Storage and Exchange Program was not used this year. However, the Interim Program will be extended in the event an opportunity arises to put water in storage before the long-term program is finalized.

Groundwater and Regional Water Resources

Groundwater Resources

Throughout the year Metropolitan worked with its member agencies to protect and improve utilization of local groundwater resources. Groundwater represents roughly one-third of the annual water supply available to communities in Metropolitan's service area. Aquifers provide valuable storage of local and imported water vital to meeting seasonal, drought, and emergency demands. However, widespread contamination threatens existing groundwater production and is the primary obstacle to expanded conjunctive use. Metropolitan's activities focused on accomplishing the following objectives:

- Increased importation of surplus water through conjunctive use of groundwater storage.
- Increased groundwater production capacity.
- Protection and improvement of groundwater quality.
- Reduced peak demands on Metropolitan.

Actions taken toward accomplishing these objectives include:

Cooperative Groundwater Studies

Metropolitan participated with member and local agencies in 15 cooperative studies to maximize groundwater resource utilization. Reconnaissance-level reports identifying conjunctive-use opportunities in the Main San Gabriel Basin, the North Las Posas Basin, the Glendora Basin, the Raymond Basin, and the Live Oak Basin were completed. The remaining studies are in progress.

Metropolitan and local agencies formed the Chino Basin Water Resource Management Task Force. The Task Force's goal is to develop basin management practices that improve groundwater quality and expand conjunctive use. The Task Force established funding mechanisms, defined specific goals and initiated consultant investigations. Concurrently, Chino Basin agencies expanded local production capacity. New wells were drilled to quality for increased interruptible service and to offset declining agricultural pumping.

Metropolitan and Eastern Municipal Water District (Eastern) are jointly participating in a project to demonstrate spreading and storage of State Project water in the San Jacinto Groundwater Basin. Metropolitan assisted Eastern in developing a two-year replenishment test. The University of California at Riverside was retained to design and implement a groundwater monitoring program. Meanwhile, Eastern obtained all necessary permits and initiated construction of spreading basins in the San Jacinto River bed, connecting pipelines and nearby monitoring wells. Phased replenishment deliveries are scheduled to start in the fall. Development of a basin groundwater model was initiated through the services of the University of California at Los Angeles (UCLA). Model predictions will help guide future basin fill and extraction operations.

Research and Development

The city of Oxnard developed an innovative groundwater injection and recovery project and received technical support from Metropolitan. Oxnard successfully injected and stored imported water in the Oxnard Plain Groundwater Basin. Wells that had previously been shut down because of high total dissolved solids content were retrofitted. The wells were then operated to inject imported water during the winter of 1989-90 and to pump that water from groundwater storage during the following summer high demand period. The project showed the feasibility of recovering and serving high quality imported water injected into poor quality groundwater zones. Seasonal Storage Service pricing incentives offered by Metropolitan and Calleguas Municipal Water District (Calleguas) helped make the project cost effective. At year end, Calleguas and Metropolitan were

developing plans for another injection project that could eventually use 300,000 acre-feet of available storage capacity in the nearby North Las Posas Basin.

Metropolitan participated with the Orange County Water District (OCWD) in researching and developing biological procedures to remove nitrates from well water. The initial laboratory phase of investigation demonstrated promising applications for the autotrophic denitrification process. If perfected, this new technology would eliminate costly brine disposal associated with traditional reverse osmosis and ion exchange technology. The agencies are coordinating plans for a second phase of field testing on a production well.

Research conducted at UCLA and supported by Metropolitan led to advances in understanding contaminant transport processes in groundwater and in developing waste minimization technology for hazardous substances.

Regulatory and Legislative Advocacy

Metropolitan assisted member agencies in reviewing development proposals for solid waste landfill projects. Because landfills are potential sources of groundwater contamination, they require careful planning and management. Metropolitan identified certain sites as unsuitable and recommended improved design features for other projects to protect irreplaceable groundwater resources and major distribution pipelines from contamination. The following projects were investigated during the fiscal year: the Azusa Landfill, the North San Diego County Landfill, the North Orange County Landfill, Sunshine Canyon Landfill, and the Los Angeles County Solid Waste Management Plan. In finding the Azusa site unsuitable, Metropolitan, the Upper San Gabriel Valley Municipal Water District and other local agencies filed suit with the State Water Resources Control Board (SWRCB) to stop project expansion.

SWRCB began reviewing its Subchapter 15, Discharge of Waste to Land Regulations, which provide the criteria for developing and operating all California solid waste landfills. Metropolitan actively participated in strengthening the regulations to protect water quality. The review process continues into next fiscal year.

Metropolitan participated in the American Water Works Association Technical Advisory Group in reviewing proposed Federal legislation and regulations that would protect and expand groundwater use.

Groundwater Storage

This fiscal year, assignments totaling 28,725 acre-feet of the city of Ontario's and Cucamonga County Water District's Chino Basin safe yield water were executed. The groundwater was assigned to Metropolitan under its Trust

Storage Agreement with the Chino Basin Watermaster in exchange for delivery of equal quantities of imported water. Metropolitan is holding its Trust Storage water in the Chino Basin to use during shortages.

Metropolitan's Water Rates—Seasonal Storage Service

The Board of Directors approved a new class of water service, Seasonal Storage Service, on July 11, 1989. Under this program, water rates are discounted for water purchased from Metropolitan during specified periods and placed into groundwater or reservoir storage.

Seasonal Storage Service encourages member agencies to store Metropolitan's water when imported supplies are abundant and use the water during periods when Metropolitan's capability to provide service is less certain. The program encourages coordinating local storage resource operations with those of Metropolitan's and the State's importation facilities.

In brief, the regional benefits expected from the local development encouraged by Seasonal Storage Service are:

1. Storage of Metropolitan's water in the winter months of October through April better utilizes available imported supplies.
2. Increased local water production in droughts and peak-demand periods increases available supplies for non-groundwater agencies while providing adequate supplies for the agencies overlying groundwater basins.
3. The program decreases demands on Metropolitan's system during the summer months and increases system use during the low-demand season when facilities would otherwise be underutilized.
4. Increased local water production in the summer months lessens the drawdown of Metropolitan and State storage allowing higher carryover storage volumes to be held for droughts.
5. Seasonal regulation by local agencies extends the adequacy of Metropolitan's delivery system, ultimately leading to cost reductions for distribution system additions.
6. Improved local production capabilities could add to regional supplies following an earthquake.

OCWD established its Conjunctive Use Well Construction Program in response to the financial incentives available through Metropolitan's Seasonal Storage Service. Under the program, OCWD financially assists its

member agencies with new well construction. The OCWD goal is construction of 40 to 50 new wells by its member agencies to increase basin production capacity from 280,000 to 380,000 acre-feet annually.

Miscellaneous Projects

Report No. 991

Progress continued on Report No. 991, "Groundwater Quality and Its Impact on Water Supply in Metropolitan's Service Area." A database was developed that includes over 400,000 active groundwater quality values for approximately 3,400 municipal wells. Special software to use the data were developed and installed. At year end, work progressed on developing reporting formats and coordinating preliminary findings regarding groundwater quality in 15 major basins.

Brackish Water Study

Metropolitan began studying the potential water supply benefits associated with desalting brackish groundwater in its service area. The study would identify the quantity of brackish groundwater available, existing treatment technology, and production costs.

Morris Dam and Reservoir

A new draft lease was negotiated allowing the U.S. Navy to continue using the Morris Dam and Reservoir property. The lease reflects plans to transfer Morris Dam and Reservoir to the Los Angeles County Department of Public Works during the upcoming fiscal year. The existing lease expired on June 30, 1990. Under the County's ownership, the dam and reservoir will be operated to maximize flood control and water supply benefits. As a result, the Navy will no longer experience stable reservoir water surface levels. The new lease is expected to be finalized in the upcoming fall months. Metropolitan also prepared an agreement with the County to train County employees to operate Morris Dam to facilitate a smooth transition of ownership and to provide continuity in project operation.

Reclaimed Water and Local Resources

Development

Under the Local Projects Program (LPP), Metropolitan financially supports local agencies that develop water supply projects that reduce demands for Metropolitan's imported supplies. Metropolitan provides a

VOL 12 1 6004

R0049309

financial contribution for each acre-foot of water produced by a qualifyin reclamation project. The financial contribution is transferred to a membe agency through a Joint Participation Agreement in which Metropolita guarantees to purchase the project yield at a rate equal to the sum o Metropolitan's reclaimed water rate and the LPP contribution. Metropol tan then sells the yield back to the member agency at the reclaimed wate rate or other appropriate rate, thereby giving the project a net contribution equal to the LPP contribution.

The original Local Projects Program was initiated in late 1981, deferred in 1983 due to Metropolitan's financial constraints, and reactivated and revised in early 1986. Under the original program, Metropolitan provided capital funding for reclamation projects. With the 1986 program revisions Metropolitan contributed the avoided energy cost for pumping an equivalent amount of water through the SWP. The contribution to qualifying projects for fiscal year 1989-90 was $75 per acre-foot.

To meet the reclaimed water goal of 200,000 acre-feet of LPP water by the year 2000, staff members examined the adequacy of the energy-based LPP incentive. They determined that an LPP contribution of $154 per acre-foot would help facilitate goal implementation by more equitably sharing the costs of reclaiming water. The $154 per acre-foot contribution is based on Metropolitan's avoided costs to convey, treat, and distribute water and includes considerations of reliability and service area needs. This contribution is subject to a three to five year periodic review by the Board.

Under the original LPP, Metropolitan participated in two wastewater reclamation projects and one groundwater reclamation project with a combined ultimate yield of 9,000 acre-feet per year. Twelve wastewater reclamation projects and one groundwater reclamation project with a combined total ultimate yield of about 30,225 acre-feet per year are included in the 1986 revised LPP. Four of these wastewater reclamation projects were added this fiscal year. Currently, 15 projects with a total estimated yield of 49,714 acre-feet per year are in various stages of review.

Original Program

In 1982, Metropolitan entered into a Letter of Intent to participate in the Arlington Basin Groundwater Desalter Project (Project) sponsored by the Santa Ana Watershed Project Authority (SAWPA). The Joint Participation Agreement with Western Municipal Water District of Riverside County and SAWPA was executed in October 1988. Under this Project, approximately 6,100 acre-feet per year of high-salinity groundwater from the Arlington Basin will be desalted for local use. The Project will consist of extraction wells, organics removal facilities, reverse osmosis desalting facilities, and connections to the local water distribution systems. Currently under construction, the project will be operational in August 1990.

Revised 1986 Program

During the fiscal year, four projects were negotiated and Joint Participation Agreements were executed to provide a minimum LPP contribution of $75 per acre-foot.

The *Shadowridge Reclaimed Water System* Joint Participation Agreement between Metropolitan, the San Diego County Water Authority (SDCWA), and Buena Sanitation District (BSD) was executed in September 1989. The system will produce up to 375 acre-feet per year of tertiary-treated reclaimed water from BSD's Shadowridge Water Reclamation Plant to irrigate greenbelts and golf courses. BSD will own and operate the Shadowridge Reclaimed Water System.

The *Glendale Water Reclamation Expansion Project* Joint Participation Agreement between Metropolitan and the city of Glendale was executed in October 1989. The project will deliver approximately 600 acre-feet per year of tertiary-treated reclaimed water from the Los Angeles/Glendale Water Reclamation Plant for landscape irrigation. While the expansion project will be owned and operated by the city of Glendale, the reclamation plant is owned and operated by the city of Los Angeles.

The *Trabuco Canyon Reclamation Expansion Project* Joint Participation Agreement between Metropolitan, Municipal Water District of Orange County (MWDOC), and Trabuco County Water District was executed in November 1989. The project expands Santa Ana Mountain County Water District's (SAMCWD) existing Trabuco Canyon Reclamation project to produce approximately 700 acre-feet per year of additional reclaimed water for golf course and landscaping irrigation. This project will be owned and operated by SAMCWD.

The *Los Angeles Greenbelt Project* Joint Participation Agreement between Metropolitan and the Board of Water and Power Commissioners of the city of Los Angeles Department of Water and Power was executed in January 1990. The project will produce approximately 1,600 acre-feet per year of reclaimed water for landscape irrigation and will be operated by the city of Los Angeles Department of Recreation and Parks and the Department of Public Works.

Of the 15 projects currently under review for inclusion in LPP, four projects are in advanced stages of review. The following four projects, with a total ultimate yield of 19,600 acre-feet per year, are expected to be approved by Metropolitan's Board of Directors early next fiscal year.

- The proposed Santa Maria (Ramona) Reclamation Project will produce approximately 1,600 acre-feet per year of reclaimed water from the proposed Santa Maria Water Reclamation Plant for golf course and landscape irrigation. Sponsored by SDCWA, this project will [illegible] owned by the Santa Maria Water District.

- The proposed Molton Niguel Reclamation Project will produce abo[illegible] 8000 acre feet per year of reclaimed water for golf course a[illegible] landscape irrigation. MWDOC will be the sponsor, and the Molt[illegible] Niguel Water District the purveyor.

- The proposed San Clemente Reclamation Project will produce abou[illegible] 4000 acre feet per year of reclaimed water by expanding the existin[illegible] Advanced Wastewater Treatment facility. The reclaimed water wi[illegible] then be used to irrigate parks, golf courses, freeway areas, and greenbelts throughout the city of San Clemente's service area. This project is sponsored by Coastal Municipal Water District and will be owned and operated by the city of San Clemente.

- The proposed Rancho California Reclamation Project will produce approximately 6000 acre feet per year of tertiary-treated reclaimed water from the Rancho California treatment plants for landscape and golf course irrigation. The project is sponsored by Eastern and will be owned and operated by the Rancho California Water District.

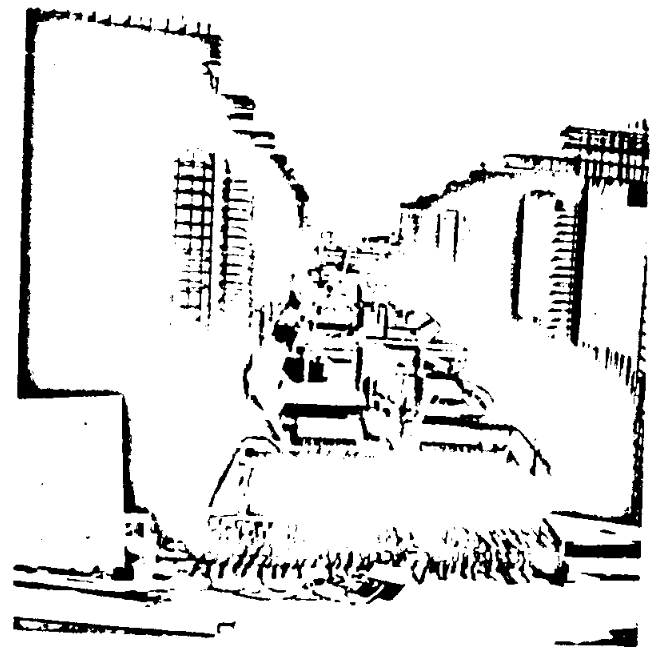
Other Activities

Metropolitan and Central Basin Municipal Water District conducted a study to formulate a project to provide reclaimed water along the Century Freeway and in six neighboring communities for industrial and landscape irrigation purposes. The Feasibility Study and Implementation Plan prepared by HYA Consulting Engineers, identified the service area boundaries, potential users, institutional arrangements, capital facilities, preliminary [illegible] available financial alternatives. The Plan outlines a reclam[illegible] which would serve approximately 4,000 acre-feet per year [illegible]

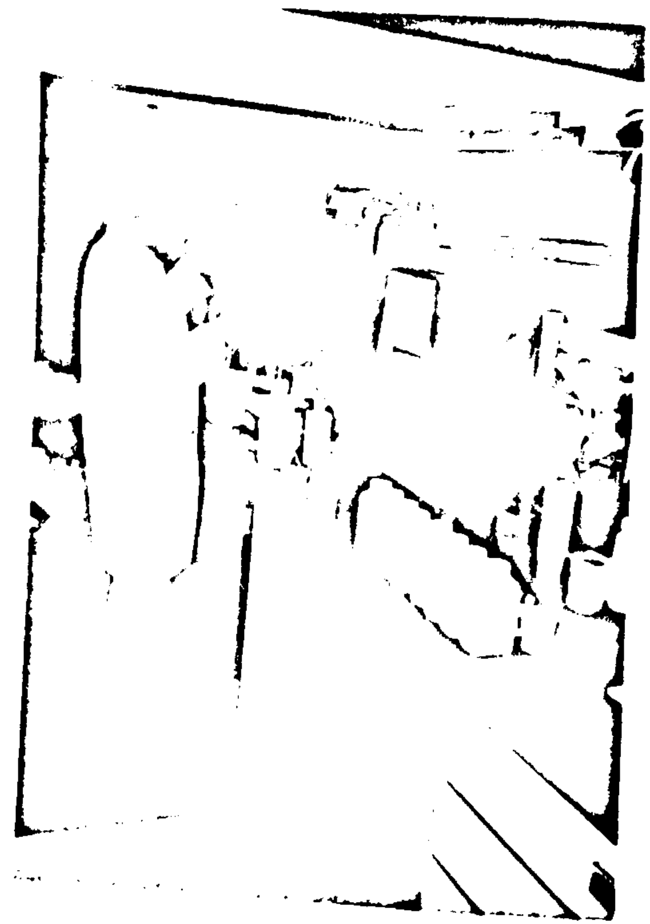
Metrop[illegible] West Basin Municipal Water District (WBMWD) initiated a [illegible] use of reclaimed water within WBMWD's service area. [illegible] conducted by HYA Consulting Engineers will identify po[illegible] reclaimed water supply alternatives develop a [illegible] and perform preliminary cost analyses.

LPP staff is par[illegible] on the San Francisco Bay Sacramento-San Joaquin Delta Es[illegible] Delta) Reclaimed Water Sub-Work Group Committee organized by DWR at SWRCB's request. The Work Group is preparing a rep[illegible] SWRCB that will estimate the State's potential reclaimed water use for the Bay Delta hearing process and will describe management practices and implementation and legislative needs for reclamation projects.

LPP staff is also participating on the State Water Conservation Coalition Reclamation Re-use Task Force organized by the Southern California Water Committee and the Committee for Water Policy Consensus, collectively known as the State Water Conservation Coalition. The Task Force is preparing a report on water reclamation in the State to present to SWRCB for use in the Bay Delta hearings.



Filter beds take shape at the Robert A. Skinner Filtration Plant expansion project.



Analyst determines ammonia-nitrogen concentrations in Metropolitan's treated water

CHAPTER 4

Water Quality

Legislation and Regulations

Considerable legislative and regulatory activity related to drinking water quality issues occurred during the 1989-90 fiscal year. Numerous regulations were proposed or promulgated by the U.S. Environmental Protection Agency (EPA) and the State of California Department of Health Services (DHS). In addition, the California legislature passed several bills affecting water utilities.

At the Federal level, Strawman rules—outlines of key regulatory concepts—were released for the disinfectant disinfection by-product (D/DBP) rule and the groundwater disinfection rule in September 1989 and April 1990, respectively. Metropolitan submitted comments to the EPA on the Strawman rules.

Additionally, the public water system primacy regulations were revised to incorporate the 1986 Safe Drinking Water Act amendments and became final on December 20, 1989.

The EPA is expected to issue final regulations for maximum contaminant levels (MCLs), monitoring, and public notification requirements for lead and copper in mid-1991. Also, the EPA's regulation for Phase II contaminants, which is expected to be finalized in January 1991, will establish MCLs and MCL goals for 30 organic and eight inorganic compounds and add 110 unregulated contaminants for monitoring purposes.

At the State level, public notification regulations for lead became final in February 1990. Additionally, final monitoring requirements for 48 unregulated contaminants were issued in March 1990. To assist the EPA in determining whether standards need to be set, these unregulated contaminants must be monitored quarterly for one year. DHS proposed MCLs for 12 synthetic organic chemicals on August 1, 1989. These regulated contaminants must be monitored quarterly for one year and, if none are found, may subsequently be monitored once every two years.

VOL 12 1 [illegible]

R0049312

Responding to a recent State regulation, Metropolitan prepared and m[illegible] available to the general public its first annual water quality report [illegible] assisted its member agencies in preparing their reports.

On April 3, 1990 DHS proposed surface water filtration requireme[illegible] which are expected to be finalized in January 1991. Metropolitan commen[illegible] on the proposed regulations at a June 13, 1990, public hearing.

Also, through the Ad Hoc Committee of the California-Nevada Sectio[n] of the American Water Works Association (AWWA), Metropolitan beg[an] reviewing drafts of the State's Total Coliform Rule (TCR) in June 1990.

During the year, the California legislature considered numerous drinking water quality issues. Assembly Bill 21, which provides for State primacy in making and enforcing stricter drinking water regulations, became effective on January 1, 1990. This bill significantly impacts water utilities, as it establishes recommended public health levels (RPHLs) for contaminants in water. These health-based standards require water utilities to evaluate contaminant reduction methods when the RPHLs are exceeded. Metropolitan is providing technical input to DHS on setting RPHLs.

General Water Quality

Metropolitan continued to meet all of DHS' primary standards and EPA's MCLs for drinking water.

For the [illegible] consecutive year, the fiscal-year average of total dissolve[d] solids (TDS) in Colorado River water (CRW) at Lake Havasu increased, rising from [illegible] milligrams per liter (mg/L) in fiscal year 1988-89 to 589 mg/L in fiscal year 1989-90, as shown in Figure 10. This TDS value is the highes[t] concentration in the past [illegible] years and is 19 mg/L below the 10-year averag[e] of 608 mg/L. Metropolitan continues to participate in the Colorado Riv[er] Basin Salinity Forum Work Group addressing concerns about future TD[S] increases.

As shown in Figure 11, the average TDS value for State project wate[r] from the California Aqueduct's West Branch at Castaic Lake was 351 mg/L—the highest TDS concentration in the past eight years and the fift[h] consecutive yearly increase. As seen in Figure 12, the average TDS for East Branch water from Silverwood Lake, 303 mg/L, was 47 mg/L lower than the 1988-89 fiscal year average. However, this value is the third-highest TDS average recorded during the 17 years since Metropolitan began using East Branch water. For treated water at the five filtration plants, the weighted average TDS value was 443 mg/L, a slight decline of 16 mg/L from the previous year's average of 459 mg/L.

The bacteriological quality of water in Metropolitan's system continues to be excellent. As shown in Tables 20, 21, and 22, distribution samples tested by the membrane filter technique for coliform bacteria produced monthly averages ranging from less than 0.001 to 0.054 coliforms per 100 milliliters (ml), falling considerably below the DHS standard of 1 coliform/100 ml. Beginning on December 31, 1990, total coliforms will be reported as a percentage of positive samples per the TCR, rather than as a monthly average of coliform colonies, as is currently required.

Metropolitan contracted with the University of California, Irvine, to evaluate the new coliform detection product's usefulness in complying with the TCR. Results of analyses indicated that whereas the new commercially available products (Colilert and Coliquik) were effective for detecting total coliforms, they underestimated the presence of *Escherichia coli*, a specific member of the coliform group the TCR regulates.

In July 1989 and again in May 1990, the disinfectant in the distribution systems of Metropolitan and its member agencies was changed for a one-month period from chloramines to free chlorine to control nitrification. As an additional nitrification control strategy, the chlorine-to-nitrogen weight ratio in Metropolitan's distribution system was increased from 3:1 to 5:1, by reducing the total ammonia-nitrogen concentration from 0.5 to 0.3 mg/L, beginning in August 1989. Increasing this ratio reduces the amount of free ammonia, which nitrifying bacteria require for growth. Collectively, these strategies have significantly reduced nitrification in the distribution systems of Metropolitan and its member agencies. Metropolitan also initiated a comprehensive one-year laboratory study, beginning in November 1989, to determine the disinfectant conditions necessary to prevent nitrifier growth.

The environmental laboratory accreditation program (ELAP) became effective on January 1, 1989. Under this program, analytical tests required by law for public water systems must be performed by accredited laboratories. For currently certified laboratories, the accreditation requirement begins when the existing certificates expire. As part of ELAP, the Water Quality Laboratory conducted quality performance evaluation analyses in May 1990 for general mineral and physical parameters, trace metals, volatile organic compounds (VOCs), pesticides, herbicides, trihalomethanes (THMs), and other DBPs.

In May 1990, the Occupational Safety and Health Administration promulgated a new standard entitled "Occupational Exposures to Hazardous Chemicals in Laboratories," which requires water utilities to implement a chemical hygiene plan by January 31, 1991. Metropolitan's Environmental Safety and Health Section has hired Clayton Environmental to assist in developing and implementing this plan.

The Digital Equipment Corporation (DEC) Varian laboratory informat[illegible] management system (LIMS) was completely implemented. Since increas[illegible] regulatory activity has required more analyses, a study to upgrade [illegible] current computer system's capacity was initiated. Additionally, becau[illegible] the DEC Varian software has been discontinued and full software supp[illegible] will no longer be available, other LIMS software packages are bei[illegible] evaluated.

In June 1989, staff from Arthur D. Little, Inc., returned to the Wat[illegible] Quality Laboratory and trained eight staff members for the flavor-profil[illegible] panel. Operations Division staff from the treatment plants also received introductory training in flavor profile analysis.

Trace Constituents

In November 1989, Metropolitan analyzed source waters and filtration plant effluents for 16 metals (Table 23). All concentrations of primary and secondary standard metals were substantially lower than DHS standards for filtration plant effluents.

Metropolitan monitored VOCs for one quarter at the sample locations listed in Table 24. Except for THMs, no VOCs were detected. Metropolitan has now completed four quarters of required monitoring, and, though required to monitor for VOCs every two years, will monitor VOCs twice each year to address the public's concerns.

In February 1990, Metropolitan completed the four consecutive quarters of required monitoring for pesticides and herbicides in source and treated waters. As shown in Table 25, none of the pesticides or herbicides for which analysis was done was detected.

Metropolitan [illegible] quarter of monitoring for base neutral and acid extractable [illegible] compounds in source and treated waters. None was detected as shown in Table 26. Tables 27 through 29 list the results of other analyses on Metropolitan's waters.

Metropolitan's [illegible] the Southern California radon survey. Black and Veatch, Inc., submitted its final report in January 1990. The study provided information on radon levels in groundwater to address upcoming federal regulations, which [illegible] probably establish the radon MCL between 200 and 500 picoCuries per liter (pCi/L). Although most wells tested had radon levels in this range, approximately 86 percent of the wells tested would exceed an MCL set at 200 pCi/L. By comparison, Metropolitan's source water radon levels are typically less than 10 pCi/L. If member agencies should abandon wells containing radon levels above the MCL, this could impact Metropolitan's conjunctive-use program planning and increase water demands on Metropolitan.

THMs and Other DBPs

Metropolitan continued to comply with the EPA and DHS MCL of 0.10 mg/L for total THMs. As shown in Table 30, the running annual average calculated from the distribution system's four quarterly averages was 0.066 mg/L. In the third and fourth quarters of 1989, Metropolitan continued to monitor for haloacetic acids (HAAs); haloacetonitriles; haloketones; chloropicrin; chloral hydrate; cyanogen chloride; 2,4,6-trichlorophenol; formaldehyde; and acetaldehyde in the distribution system. In general, DBP production increased with temperature and percent of State project water. The THMs constituted the largest fraction of DBPs based on weight, followed by HAAs as shown in Tables 31 and 32. The level of brominated DBPs increased as the percent of State project water increased in the blend because State project water contains a higher bromide concentration than does CRW [a result of seawater intrusion into the Sacramento-San Joaquin Delta Estuary (Delta)]. Metropolitan discontinued monitoring for these and other DBPs after the fourth quarter of 1989 to develop analytical methods for detecting ozone DBPs for the oxidant pilot plant and ozone by-product studies.

A draft report by the California Department of Water Resources (DWR), prepared with Metropolitan's review, demonstrates that agricultural drainage into the Delta is contributing approximately 45 percent of the State project water THM formation potential. These data have provided the impetus for the California legislature and DHS to request that the State Water Resources Control Board and the DWR find solutions to minimize DBP precursors from saltwater intrusion and agricultural drainage.

Five consecutive quarters of THM monitoring in Metropolitan's desert pumping plants' domestic treatment systems, completed in November 1989, indicate that all systems would have difficulty in meeting a new THM standard if it were set at 0.05 mg/L. A study currently being conducted by Brown and Caldwell Consultants will evaluate the treatment systems and recommend improvements to ensure compliance with the new regulations.

Metropolitan's Water Quality Division staff continued to manage and provide technical support for an AWWA D/DBP Technical Advisory Workgroup (TAW). The D/DBP TAW is providing input into the EPA's D/DBP and Groundwater Disinfection rules.

Through the D/DBP TAW's efforts, with analytical assistance from Metropolitan and funding from the AWWA, James M. Montgomery, Consulting Engineers, Inc. (Montgomery), is developing mathematical models to predict the types and amounts of DBPs that a utility may experience based on its raw-water characteristics and operational treatment practices. These models will allow a utility to investigate alternative treatments to control DBPs. In a related effort, Malcolm Pirnie, Inc., which originally developed a model for predicting THM formation, is determining wh[illegible]ther Metropolitan's member agencies will be able to comply with [illegible]ure disinfection and DBP regulations. Member agencies unable to meet [illegible]ure regulations may rely on Metropolitan to provide more treated wa[illegible]r.

In November 1990 bench-scale testing was initiated to evaluate the impact of optimized coagulation on THM precursor removal in State project water and CRW. THM formation potential test results indicated that high doses of alum (up to 100 mg/L), together with a cationic polymer, reduced THM precursors by 28 percent in State project water and 30 percent in CRW when the pH was not adjusted after alum addition.

Metropolitan is one of five utilities providing additional funding and analytical support for a project awarded by the AWWA Research Foundation (AWWARF) to the University of North Carolina to identify ozone DBPs and their occurrence in North America.

Pathogen Monitoring

In November 1990 Metropolitan contracted with the University of New Hampshire for a one-year study to develop gene probe methods for rapidly mon[illegible] viruses in Metropolitan's source waters. As part of the study, the University of Arizona is analyzing split samples by the [illegible] Albuquerque and Metropolitan will analyze them [illegible] gene probe procedure. To date, more and [illegible] has been observed between the gene-probe [illegible]

In De[illegible] Univer[illegible] initiated a collaborative study with th[illegible] Cryp[illegible] gene probes to detect *Giardia* an[illegible] These te[illegible] as common waterborne pathogens detection [illegible] decrease analysis time for pathogen [illegible] fluorescent antibody procedures.

Reservoir Manage[illegible]

Lakes Mathews [illegible] blue green algae [illegible] affected by extensive growths of benthic and geosmin. In Lake M[illegible] odorants 2-methylisoborneol (MIB) (T&O) producer, *Pho[illegible]* appearance of a new taste-and-odor began earlier in the season and lasted longer than in previous years. To stem this alga's growth, 3[illegible] tons of copper sulfate were applied to the lake. Diver inspections and laboratory experiments indicated that *Phormidium* is different from other T&O producers found in Metropolitan's source waters in that it grows at greater depth (up to 75 feet) and is more resistant to copper sulfate. To prevent the growth of T&O-producing *Oscillatoria* spp. in Lake Skinner, 105 tons of copper sulfate were effectively applied to the shallow areas. At Castaic Lake, geosmin levels as high as

250 nanograms per liter were produced by a surface bloom of a planktonic blue-green alga, *Anabaena* spp. Consequently, water used by Metropolitan had to be withdrawn from lower depths of the lake, where geosmin levels were much lower.

Metropolitan contracted with Paul Beatty and Associates to evaluate using grass carp for controlling aquatic plants and algae in its source waters and canals. The consultant indicated that grass carp would be ineffective in Metropolitan's source waters.

The U.S. Department of Agriculture completed a two-year study, partially funded by Metropolitan, to develop immunodiagnostic procedures to rapidly detect MIB and geosmin in environmental samples. Although antibodies to these compounds were successfully developed, the technique's sensitivity was too low to adequately detect these odorants in water without preconcentration.

Chlorination continued to be effective in controlling attached algae growths and biofilm formation in the San Diego Canal.

San Joaquin Reservoir (SJR), a 3,000-acre-foot, uncovered, finished-water reservoir serving communities in southern Orange County, was removed from service on three occasions (for a total of 34 days) because of elevated coliform activity in service connections receiving water from SJR. An Environmental Impact Report is being prepared to address options for improving SJR's water quality.

Oxidation Demonstration Project

With partial funding from the AWWARF and technical assistance from Montgomery, pilot-scale testing continued to evaluate the effectiveness of ozone and PEROXONE (the combination of ozone and hydrogen peroxide) for controling T&O compounds, microorganisms, and DBPs. Montgomery is preparing a report detailing the results obtained during the two-year pilot study, which was completed in June 1990, and it will become available from the AWWARF in early 1991.

Key issues examined during the study's second year included evaluating the impact of bromide in State project water on the production of brominated DBPs by ozone and PEROXONE, the production and removal of assimilable organic carbon (AOC), and the importance of ozone residuals in predicting the amount of *Giardia* cyst inactivation. With regard to the bromide issue, ozonation of State project water (dosed with added bromide to simulate severe saltwater intrusion into the Delta) yielded significant levels of bromoform and dibromoacetic acid. Ozone with ammonia addition or treatment with PEROXONE resulted in substantially lower levels of these compounds. In contrast, unamended State project water treated with PEROXONE produced higher bromate levels than it did when treated with ozone. The AOC analyses showed that without a secondary disinfectant added, the dual-media filter bed developed a biofilm capable of reducing AOC, formaldehyde, and selected brominated organic DBPs. However, when a secondary disinfectant was added before the filters, biodegradation of these undesirable compounds did not occur. Finally, disinfection results consistently demonstrated that ozone residual is the key to achieving adequate levels of inactivation of viruses and Giardia. These data were used to provide input to the EPA in developing disinfection regulations for ozone.

A 5.5-million-gallon-per-day (mgd) demonstration-scale plant is being constructed to further evaluate the ozone and PEROXONE treatment processes. The design phase of the project, completed in December 1990, was followed by a five-month bid-and-award period to select a construction contractor. The oxidation demonstration project's objectives are to confirm the results of the pilot-scale studies, evaluate processes and equipment, and provide the information necessary to retrofit Metropolitan's filtration plants with ozone/PEROXONE. The project staff expects that the ozone generation system and contactors will be on line by November 1991.

Treatment Plant Studies

Major emphasis was placed on developing and implementing an action plan to meet the upcoming Surface Water Treatment Rule (SWTR), which affects all Metropolitan filtration plants, including the desert pumping plants' domestic treatment facilities. The plan's key components include evaluating the filtration plants' process reliability, optimizing their washwater reclamation systems, developing emergency disinfection and operations plans, and evaluating the plants' pathogen removal capabilities.

In April and May 1990, conceptual design studies, conducted with the assistance of CH2M Hill, Inc., were completed for the Robert B. Diemer Filtration Plant (Diemer plant) uprating and the Henry J. Mills Filtration Plant (Mills plant) expansion. The Diemer plant study recommended improving the flash mixing, flocculation, and filtration processes to increase the design nameplate capacity from 400 to 518 mgd. The Mills study suggested modifications to improve the plant's reliability and performance. Recommendations for expanding the Mills plant included installing pumped-injection flash mixers, paddle-type flocculators, and tri-media filters.

Assisted by CH2M Hill, Inc., Metropolitan's staff initiated conceptual design studies in April 1990 for the new Central Pool Augmentation Filtration Plant and for uprating the F. E. Weymouth Filtration Plant (Weymouth plant). These studies will evaluate unit process requirements and recommend design criteria for the new plant and determine possible modifications to the Weymouth plant.

In June 1990, Metropolitan contracted with Montgomery to evaluate unit processes and recommend design criteria for a proposed filtration plant capable of treating water from Lake Perris. Adverse water quality conditions periodically experienced in the lake, including microbiological contamination from body contact and severe T&O episodes, could require enhanced ozone/PEROXONE feed capabilities and granular activated carbon (GAC) in addition to full conventional treatment.

A one-year study was initiated at the Mills plant in June 1990 to evaluate ferric chloride's effectiveness and feasibility as a coagulant for eventual use by Metropolitan.

In April 1990, groundwater from below and adjacent to the finished-water reservoir at the Joseph Jensen Filtration Plant (Jensen plant) was removed (and subsequently treated with ion exchange to meet discharge requirements) to prevent possible damage to the reservoir caused by a significant drawdown of water to meet water demands during a planned shutdown.

In June 1990, a treatment facility consisting of an oil-water separator and two 2,000-pound GAC absorbers was installed at the Magazine Canyon shaft to treat hydrocarbon-contaminated water, which began entering the Jensen plant from the Newhall Tunnel. The treatment reduced concentrations of organic contaminants to below detectable levels so the water could be returned to the Magazine Canyon shaft.

As part of the SWTR action plan, a tracer test was conducted at the Mills plant in October 1989 to determine hydraulic detention times, which will be used to assess the plant's ability to meet disinfection requirements. Results of the tracer test indicated that baffling would have to be installed to prevent the substantial hydraulic short-circuiting occurring in the flocculation basins.

Tracer studies were also conducted within the finished-water reservoirs at the Weymouth, Jensen, and Mills plants to determine actual hydraulic detention times. The results indicated that short-circuiting of flow occurs to varying degrees in all three reservoirs. This information will prove useful for future reservoir operation and for the design of additional facilities to provide sufficient disinfection contact time following chloramine addition.

Operational Activities

More than 60 monitoring reports were prepared and submitted to regulatory agencies concerning Metropolitan's water, waste water, and sludge discharges to comply with the 13 discharge permits or Board Orders issued to Metropolitan by the California Regional Water Quality Control Boards and other agencies. In addition, applications for four permit renewals were submitted, one special discharge permit was obtained, and more than 25 dechlorinations were conducted as part of various dewatering activities. Surveys conducted to identify unpermitted discharges from Metropolitan's facilities indicated that many new permits are needed.

Assistance to Others

Metropolitan provided analytical assistance with nitrification problems and recommended corrective measures to the city of Garden Grove, the Foothill Municipal Water District, and the Municipal Water District of Orange County. Throughout the year, other member agencies and subagencies received assistance in resolving water quality degradation problems.

Metropolitan organized and implemented regular meetings of the Member Agency Water Quality Directors to encourage information exchanges between Metropolitan and its member agencies and subagencies on water quality and regulatory matters.

Water Quality Publications and Presentations

During the fiscal year, Water Quality Division staff members were responsible as authors (or co-authors) for 11 feature articles published in professional journals such as [illegible] and [illegible] *[illegible] Science and Technology, Applied [illegible]* [illegible] the *Journal of Water Supply Research and Technology* [illegible] *Journal*. Water Quality Division personnel were also principal or secondary authors of 13 papers presented at professional conferences and symposia, including the AWWA's Annual Conference, Water Quality [illegible] Conference, and California-Nevada Section meetings, [illegible] Ozone Association's Pan American Committee Conference, [illegible] the Annual Meeting of the American Society for Microbiology.

CHAPTER 5

Planning

Advance Planning Activities

Area Studies and Facility Plans

Metropolitan's Report No. 971, the Distribution System Overview Study, outlined a plan of system improvements needed to meet Metropolitan's service area's future water quality and quantity requirements. A series of area studies and facility plans currently underway further evaluates and defines key facilities. These include the Central Pool Augmentation and Water Quality Project, Eastside Reservoir, Inland Feeder, Mills Area Study, Perris San Jacinto Area Study, San Diego Pipeline No. 6, and West Valley Area Study. Staff from Planning, Engineering, Operations, Water Quality, Resources, State Project Matters, and Right of Way have formed project study teams to facilitate coordination of all the area studies and facility plans. Corresponding environmental documentation is proceeding in each area.

Eastside Reservoir

For the past year, staff has been studying and preparing an EIR on five potential reservoir sites in western Riverside County to determine the feasibility of additional reservoir storage in the Metropolitan system. During this year, studies have included the collection and analysis of environmental, social, operational, cost, water quality, and engineering data to screen and reduce the total number of reservoir alternatives under consideration. Based on the information gathered to date, the Potrero Creek, Domenigoni Valley, and Vail reservoir sites have emerged as the most viable alternatives and are being studied in more detail. Results of the Lake Perris and Lake Skinner site studies will be presented in the EIR; however, neither is expected to be selected as a result of the feasibility study.

Beyond studying potential reservoir sites, staff conducted a refined assessment of reservoir storage needs and groundwater storage capability. These studies indicate that groundwater storage can meet a portion of the total storage need and that operating the reservoir within the delivery system, by temporarily storing imported deliveries in the reservoir, can facilitate groundwater basin deliveries. These studies also note that reservoir operation substantially increases the reliability of all imported supply sources by providing added capability to store imported supplies during the winter season when supplies are more abundant and aqueduct capacity is available.

During these studies, staff extensively evaluated potential mitigation sites and developed preliminary information regarding these sites' economic viability and acceptability. Using a habitat productivity model, staff quantified the effectiveness of the mitigation areas. The model compares overall habitat quality by measuring the habitat's physical characteristics as well as its ability to support various plant and animal species.

The Draft Feasibility Report and EIR are scheduled to be completed by February 1991; the final EIR will be submitted in July 1991.

Inland Feeder

The Inland Feeder will be a raw water conduit that will convey State Project water from the California Aqueduct's expanded East Branch to the Colorado River Aqueduct near San Jacinto. This facility is needed by the late 1990s to enable Metropolitan to optimally use State water supplies. It also will enhance system reliability by linking two of Metropolitan's main aqueduct systems and allow a more uniform blend of State and Colorado River water through much of Metropolitan's system.

The Inland Feeder Study is currently evaluating four alternative alignments. Each alignment encompasses a series of tunnels and pipelines that extend 40 to 50 miles. During the fiscal year, technical feasibility and environmental evaluations were begun and will continue into next fiscal year. The evaluations conducted include a preliminary geotechnical feasibility study of the tunnel portions, preliminary portal and spoil site evaluations, and a preliminary pipeline feasibility study. Environmental surveys were also initiated during the fiscal year in preparation for California Environmental Quality Act (CEQA) and National Environmental Protection Act (NEPA) documentation. The surveys are being conducted for sensitive habitat and species, and cultural and archeological resources. The draft EIR will be issued for public review next fiscal year.

Central Pool Augmentation and Water Quality Project

This project, which evolved from the South Orange County Area Study completed in 1988, will evaluate the facilities necessary to augment treated water service to Metropolitan's central service area (Los Angeles, Ventura, and Orange Counties). Lake Mathews provides the project's source water, which will be treated and conveyed into south Orange County, relieving the Robert B. Diemer Filtration Plant (Diemer plant) of much of its existing

demand. This will enable the Diemer plant to serve other parts of the central service area. The project will also enhance groundwater storage in the Main San Gabriel, Central, and West Basins.

Project components include a second outlet tower at Lake Mathews, a pipeline or pipeline tunnel conveyance system into south Orange County, and a new regional treatment plant located either near Lake Mathews or in south Orange County. Project completion is scheduled for 1998.

At the fiscal year beginning, staff had identified three potential treatment plant sites in south Orange County, one potential site near Lake Mathews, and several feasible lake outlet and conveyance system alternatives to meet the project's objectives. As staff members initiated the environmental documentation and analysis, they also conducted land-use studies to monitor development pressures which could threaten the feasible alternatives. Staff also continued to evaluate the technical feasibility of the alternatives based on planning refinements in related projects. The environmental and ongoing technical evaluations indicated that certain alternatives were indeed threatened, therefore another plant site near Lake Mathews and related conveyance system components were added to the study. Two of the three south Orange County sites were dropped from further consideration due to hydraulic and geotechnical constraints. The draft Environmental Impact Report (EIR) for the project is approaching completion and will be released for public review next fiscal year.

Mills Area Study

The proposed expansion of the Henry J. Mills Filtration Plant (Mills plant) in western Riverside County should meet regionally approved population forecasts and serve communities now using untreated water. Completed in summer 1989, the first Mills plant expansion doubled the plant capacity to 150 million gallons per day (mgd). This area study is being coordinated with the Perris San Jacinto Treatment Plant study to determine the capacity and timing required for the second Mills expansion. A capacity of about 300 mgd appears likely.

Perris San Jacinto Treatment Plant

This study is identifying the need, location, size, and schedule for a new treatment plant in the Perris Valley/San Jacinto Valley area of western Riverside County. Proposed facilities, including a new regional treatment plant and raw water conveyance pipelines, are planned to meet the increasing water demands and supplement activities at both the Mills and Robert A. Skinner Filtration Plants, and are being coordinated with the planning for the Inland Feeder and Eastside Reservoir facilities.

Reconnaissance studies, initiated in 1988, originally identified 26 potential treatment plant sites. By the fiscal year start, staff had screened the candidate sites down to five within the Perris Valley. However, as proposed developments threatened these sites' availability, additional sites were considered. During the year, five more sites in the San Jacinto Valley were evaluated.

Staff conducted detailed ranking evaluations of the facility alternatives, including technical feasibility, compatibility with the Inland Feeder and Eastside Reservoir systems, geotechnical and right-of-way investigations of plant sites and pipeline routes, cost estimates, and potential impacts to cultural and biological resources. Three sites will be included in the environmental documentation process. Also, due to strong land development pressures, staff began evaluating development activities and the potential need to secure properties where development could eliminate sites prior to final environmental documentation.

San Joaquin Reservoir Improvement Project

A 3000 acre-foot treated water reservoir near Newport Beach, the San Joaquin Reservoir is jointly owned by Metropolitan and several local agencies. As the reservoir has experienced periods of poor water quality, the improvement project is evaluating alternatives to improve water quality stored in and served from the reservoir and to better integrate the reservoir into Metropolitan's distribution system. Final environmental documentation was prepared during the fiscal year, including the EIR and the Plan Selection Report.

South Riverside San Diego Area Study

By identifying long range facility needs for south Riverside and San Diego Counties, this study looks to integrate Metropolitan's supplies with local storage plans and operations. Due to the area's rapid growth and increasing water demands, analysis has determined a need for San Diego Pipeline No. 6. The proposed pipeline, with a 500-cubic-foot-per-second capacity, will convey raw water. Staff has identified four alternate routes based on reconnaissance level engineering and environmental investigations, and has begun engineering feasibility studies and environmental field work.

Metropolitan is closely coordinating this study with area member agencies to identify opportunities for joint operations and potential groundwater development in southern Riverside County, and is also participating in San Diego County Water Authority's Optimal Storage Study to identify ways to optimize San Diego County reservoir facility use. This area study is also coordinated with the Perris San Jacinto Treatment Plant Study and the Eastside Reservoir Study.

West Valley Area Study

To determine the demands and identify the facilities needed to serve water in Ventura and western Los Angeles Counties, the West Valley Area Study initially identified nine alternative water conveyance alignments, which are now being evaluated. Preliminary technical feasibility studies and reconnaissance-level environmental surveys were started this year.

Seismic Risk Assessment of Local Water Production

This study assesses the availability of local supplies after a major movement along the San Andreas Fault. A seismic model was used to examine the vulnerability of local water production facilities (groundwater extraction wells) within Metropolitan's service area. The seismic analysis indicated that approximately 50 percent of groundwater extraction wells (or about 600,000 acre-feet per year of local water production) are located in areas of high ground-shaking intensities (Mercalli intensity 8 or more) where structural damages and underground pipeline breakages are expected. Additionally, the analysis found that approximately 40 percent of the extraction wells (about 500,000 acre-feet per year of local water production) are located in high liquefaction potential areas. These percentages are not additive because ground shaking and liquefaction areas overlap considerably. The data indicates that about 60 percent of the wells will be exposed to either high-intensity ground shaking or liquefaction.

Currently, a consultant is studying the probable damages to local water production facilities and Metropolitan's distribution system and the time needed for service restorations. Damages will be expressed in terms of typical failures or failure modes, and, given the damage scenarios, repair times will be estimated. The study will be completed by the end of summer 1990, and will provide information about emergency storage needs for the Eastside Reservoir Study.

Water Resources Data (PINS)

Staff has developed a computerized data base and retrieval system known as the Planning Information System (PINS). PINS contains data on the Metropolitan's daily system flows and monthly water sales, daily rainfall and temperature, local water production, groundwater quality, and Colorado River and State Water Project storages and supplies to Metropolitan as well as population and other demographic statistics. As part of Metropolitan's corporate data base, PINS data files are accessible to all divisions.

PINS is used for several types of studies. The distribution system flow data is used in facility planning studies by analyzing historic flow patterns and projecting when specific facilities will be operating at capacity. Water demand forecasts require the extensive use of climate, population, demographic data, and historic water-use patterns. The water-use modules, which includes data on Metropolitan's monthly water deliveries, are employed by the Planning and Finance Divisions to project water use and perform water-rate analyses. Additionally, the local water-use data has been applied by the Operations and Resources Divisions to evaluate how Metropolitan programs impact local water use and opportunities for conjunctive-use and coordinated operations.

Water Supply and Demand Studies

Urban Demands

The MWD-MAIN water demand forecasting model, originally developed for the U.S. Army Corps of Engineers Institute for Water Resources and later calibrated for use by Metropolitan's water demand consultant, is used to project municipal and industrial (M & I) water use within Metropolitan's service area. In forecasting M & I water demands, the model incorporates numerous demographic variables, including number and types of housing units, housing densities, population, and employment for over 200 industrial and commercial sectors, economic parameters including household income, housing value, price of water, and climatic data. The model also accounts for the effectiveness of urban water conservation programs. Water demands are disaggregated into four major use categories: residential, commercial, industrial, and public unaccounted. Additionally, these forecasts are further disaggregated into very specific categories to better understand the service area's water use characteristics.

During the past two years, four technical improvements were made to the model. First, its commercial and industrial water-use coefficients were updated based on an extensive Metropolitan water-use survey of over 3,000 service area commercial and industrial establishments. Second, the population, housing, employment, income, and land-use projections were updated to encompass the 1989 revisions made to the regional growth plans by the Southern California Association of Governments (SCAG) and the Series 7 forecasts of the San Diego Association of Governments (SANDAG). Third, the residential econometric demand models were revised based on specific Southern California agency water-use data. These new residential demand models were verified per a detailed Metropolitan household water-use study conducted to determine water-use behavior and characteristics of 1,000 households in five Southern California communities. Finally, the water conservation assumptions were revised to incorporate the 1981 and 1982 California building codes requiring low water-using fixtures in new construction, public education, and changes in retail level prices from 1980 to 1990. Metropolitan also is examining the

effectiveness of various "Best Management Practices" on further reducing service area water demands. Projected M & I water demands, under normal weather conditions, are expected to be 3.86 million acre-feet (maf) in year 2000 and 4.34 maf in year 2010. This compares to a current M & I use of 3.4 maf. These demands include the effectiveness of current conservation programs which are expected to reduce demands by 7 percent in year 2000 and 11 percent in year 2010.

Agricultural Demands

To project total regional water demands, agricultural water-use projections must be added to the MWD-MAIN's M & I demands. Metropolitan has conducted a special study on the service area's projected agricultural water use. In fiscal year 1988-89, agricultural water use in Metropolitan's service area was 384,000 acre-feet per year, or 10 percent of the total regional water use, with 194,000 acre-feet provided by Metropolitan. This yielded an annual gross crop value of about $2.0 billion. In total, agriculture contributes upwards of three times the crop value or $6.0 billion to the region.

The dairy industry in Riverside and San Bernardino Counties accounts for the largest category of agricultural activity in terms of crop values. Nursery products found throughout Metropolitan's service area run second. The largest amount of irrigated acreage is devoted to tree crops followed by row crops. With continued urbanization, agricultural water use is projected to decline to 310,600 acre-feet per year by year 2010, or 7 percent of total demands. Of this, Metropolitan is projected to provide 153,000 acre-feet per year; the remainder will come from local supplies.

Total Demands

The total regional decrease under normal weather conditions is projected to increase from a current annual use of 3.8 maf to 4.2 maf by year 2000 and 4.7 maf by year 2010. During periods of low rainfall and higher temperatures, demands would be greater than under normal weather conditions.

Distribution System Flow Model

A computerized system designed to route water through Metropolitan's distribution system, the Distribution System Flow Model (DSFM) evaluates the need and timing for future system expansion. Recently the model helped determine the amount of additional groundwater storage of Metropolitan's supplies that would be possible with the proposed Eastside Reservoir and Inland Feeder. Results indicated upwards of 300,000 acre-feet of additional storage may be achieved. Together with the DSFM, the System Information Graphics (SIG) program has been developed to graphically display the distribution system flow model results on a computer screen.

Short-term Demand Forecast Model

The short-term monthly water demand forecast model was developed to track water use in one-to-two year time frames given a set of population growth and climatic scenarios. It helps both the Planning and Operations Divisions to forecast the highest probable water demands on Metropolitan's system due to unusual climatic conditions. Model improvements include: (1) a climate "generator" was developed based on observed climate data to provide the possible rainfall and temperature extremes and their probability of occurrence; (2) models have been restructured to discern urban and agricultural water use; and (3) fully automated-and-interactive demand forecasting models for various member agencies have been constructed.

Drought '90 Water Use

As part of Metropolitan's Drought '90 campaign, staff obtained daily and monthly water-use data from key agencies. The data helped determine the effectiveness of Metropolitan and member agency conservation efforts. Company water use by these agencies for May, June, and July for 1990 and 1989 showed 8, 6, and 5 percent reductions respectively. Using the short-term demand forecast model to adjust for population growth and climate effects, staff estimated conservation savings of 6, 12 and 9 percent for May, June, and July over last year. The estimated agricultural savings in Metropolitan's service area would be 19,000, 40,000, and 35,000 acre-feet respectively for these three months. This monitoring program will continue through fall of next fiscal year to determine the conservation campaign's full effectiveness.

Regional Population and Water Demand Studies

The California Department of Finance has released its January 1, 1990, population estimates for the State of California, cities, and counties. Statewide population in 1990 is estimated to be 29.5 million, up 800,000 from the 1989 population of 28.7 million. Based on this data, along with supplemental data from county planning agencies, Metropolitan's 1990 population estimate is 14.9 million, an annual increase of about 373,000 over 1989's 14.5 million. Metropolitan's share of California's growth holds constant at about 50 percent.

In early 1989, SCAG adopted its Growth Management Plan, revising the population, housing, and employment forecasts for year 2010. SANDAG also adopted its revised Series 7 demographic and land-use forecasts in 1988. Together, these revised projections of demographic, economic, and land-use data for the six-county Southern California planning area have

been incorporated into the MWD-MAIN water demand forecasting model and facility planning studies. Key findings are:

(1) population will increase from 14.9 million to 18.2 million in year 2010, with two-thirds of the increase due to births over deaths;

(2) number of occupied housing units will increase from 5.2 million to 6.8 million in year 2010;

(3) persons per household will decline from 2.85 to 2.69 in year 2010;

(4) employment will increase from 7.1 million to 9.2 million persons in year 2010;

(5) employment is projected to grow at faster rates than population, indicating the percent of persons in the work force will be increasing; and

(6) growth rates of population, housing, employment, and income are greater in the inland Riverside and San Bernardino Counties compared to the other parts of Metropolitan's service area.

To assess how regional growth affects water demands, staff has been examining economic and demographic data such as population, house building activity, jobs, personal income, wages, and value of goods and services (economic output) in Metropolitan's service area. In a special study of population undercounts and undocumented immigrants, the Center for Continuing Study of the California Economy has determined that the 1990 Census population undercount in Metropolitan's service area could be about 601,000, occurring primarily in Los Angeles and San Diego Counties.

With the upcoming 1990 Census results, significant revisions are expected in the forecasting models regional governments use to project demographics. The regional governments will also be updating their land-use inventories to correspond with the 1990 Census.

Water Supply Data

Daily flow, storage, and water-delivery information covering the past six years have been entered into a computerized data base. With the historic and updated information, staff can closely monitor the use of Metropolitan's treatment plants, pipelines, and storage facilities and provide an early warning when flows approach system capacity. SIG will graphically display the information for easier interpretation. Currently, the data base is being expanded to include information from Metropolitan's distribution system control centers.

Water Use in Future Annexations

At the Board of Directors' request, staff identified the areas likely to seek future annexations to Metropolitan. These annexations would consist of "island areas" in west Riverside and San Diego Counties, the remaining part of the Oxnard Plain in southern Ventura County, and minor expansion of the easterly boundaries in San Diego County. Collectively, these areas would add about 2 percent to Metropolitan's land area over the next 50 or so years, and may increase demands on Metropolitan by up to 66,000 acre-feet per year by year 2010. Staff is working closely with the Board of Directors and member agencies to review water use in proposed annexation areas.

Environmental Studies

At fiscal year's end, staff was preparing 11 EIRs and three major environmental support studies. Environmental staff also led in establishing and coordinating two significant task forces to improve environmental performance in pertinent Metropolitan activities.

San Joaquin Improvement Project

Staff completed a Final EIR and Plan Selection Report for the San Joaquin Reservoir Improvement Project. This project would improve the quality of drinking water served from San Joaquin Reservoir and better integrate the reservoir into the Metropolitan's distribution system.

Arvin-Edison Water Storage and Exchange Program

To satisfy the provisions of both State and Federal environmental laws, staff prepared a joint Environmental Impact Report/Environmental Impact Statement (EIR/EIS) for the Arvin-Edison Water Storage and Exchange Program. Under this program, new facilities will be constructed to store up to 1 maf of water in the Arvin-Edison Water Storage District (Arvin-Edison). This water would be delivered to Arvin-Edison during wet periods in exchange for Arvin-Edison's Central Valley Project supplies to be delivered to Metropolitan during dry periods. The EIR/EIS will be submitted for public review next fiscal year.

Service Connection LA-35

Environmental Branch staff prepared a Negative Declaration and acquired a permit from the California Department of Fish and Game for Service Connection LA-35. This service connection will provide a permanent source of raw water to the Los Angeles Department of Water and Power at its Granada Hills facility. Final documents were filed with the appropriate State and local agencies.

Joseph Jensen Filtration Plant Expansion

An Addendum to the Negative Declaration for the Joseph Jensen Filtration Plant Expansion was prepared to address revisions to project plans made subsequent to the existing environmental documents. Construction will proceed as scheduled.

Environmental Compliance Handbook

To update specific procedures for the orderly review and completion of environmental requirements associated with both State and Federal laws, staff revised General Instruction 6A and prepared a complementary handbook for use by Metropolitan staff. This handbook also clarifies responsibility for compliance with applicable Government Code provisions.

Alternatives Report, Mills Area Study

To satisfy CEQA provisions as they relate to developing and analyzing alternative means to meet project objectives, staff identified and evaluated alternative treatment plant sites to accomplish Mills Area Study objectives. These studies will be used to complete an EIR for the proposed Mills plant expansion.

Regulatory Compliance Review Program

A regulatory task force was formed from the Engineering, Operations, Personnel, Planning, and Water Quality Divisions with representation from the Legal Department. The task force will make recommendations to management on measures to maintain compliance with health, safety, and environmental laws; to minimize major risk to the environment or public; and to prevent the imposition of civil and criminal responsibility on Metropolitan or its employees when statutory or regulatory requirements are violated.

At year's end, the task force agreed on program objectives and approach, and adopted an internal process to achieve consensus during program development. Further, the task force hired the consulting firm Dames & Moore to assess major risks at all Metropolitan facilities and to determine line-unit responsibilities for regulatory compliance. This work, to be completed next year, is the first of three steps leading to development of a Metropolitan environmental audit program. Steps two and three, implementing regulatory compliance and audit procedures for each line unit or division and implementing periodic oversight audits, also will be completed next year.

VOL 12 1 5025

R0049331

Air Quality Task Force

In April, Environmental Branch staff formed the Air Quality Regulat Compliance Committee to monitor and respond to proposed air-qua rules and legislation, and to develop procedures to comply with adop rules and laws. The committee is composed of representatives fr Engineering, Operations, Water Quality, Resources, Planning, Personn and Administrative Services Divisions with representation from the Le Department.

GIS Database

Staff retained Keller Environmental Associates to collect data for an environmental data geographical information system (GIS) study of Metropolitan's service area. The information will be integrated into a computerized GIS data base and used to evaluate the environmental effects of projects throughout Metropolitan's service area.

Environmental Documents in Preparation

During the past year, the CEQA compliance process was initiated for three projects as Notices of Preparation were completed and published for the Central Pool Augmentation and Water Quality Project, Eastside Reservoir Project, and the Mills plant expansion. These notices advise the public of an agency's intent to prepare an EIR and solicit comments regarding the type of information the EIR should include. Metropolitan's policy in each of these projects is to avoid and minimize impacts as a first priority, then mitigate to the extent practicable for unavoidable impacts. Advance mitigation is used as appropriate to ensure project schedules.

Environmental reconnaissance studies were undertaken for the Skinner Landfill Expansion, Perris Treatment Plant, and Westside Conveyance projects. These preliminary investigations will help identify the scope of environmental compliance requirements, develop project schedules and cost estimates, screen alternatives, modify project plans to mitigate significant adverse effects, and expedite the environmental compliance process for recommended alternatives.

To help conserve water, homeowners perform such simple tasks as replacing worn-out faucet washers and installing low-flow faucet heads.

CHAPTER 6

Engineering

During fiscal year 1989-90, the Engineering work program focused on continuing last year's projects to expand or rehabilitate existing or construct new major facilities for water treatment, distribution, and storage. These facilities will help meet the heightened demands on Metropolitan due to increasing regulatory requirements and rapid population growth in Southern California. The ongoing major-facility projects under construction this year included Robert A. Skinner Filtration Plant (Skinner plant) Expansion No. 3; Skinner Finished Water Reservoir; the San Diego Canal enlargement; expansion of the Weymouth and Diemer Washwater Reclamation Plants, the Etiwanda Pipeline, Control Facility, and Reservoir, and modifications to existing and construction of new retention basins at the Henry J. Mills Filtration Plant (Mills plant). The ongoing major-facility projects in design during the year included the Joseph Jensen Filtration Plant (Jensen plant) Expansion No. 1, expansion of the Foothill Feeder Pressure Control Structure, and modifications to the Robert B. Diemer Filtration Plant (Diemer plant). Other major ongoing projects included the Etiwanda Power Plant and the Orange County Feeder relocation.

During the year, many new engineering projects were initiated, most involved continuing efforts to comply with tighter State and Federal drinking water quality standards, increased concern with containment and safe handling of potentially hazardous substances, and improving internal telecommunications. In the water quality improvement effort, construction progressed on the Oxidation Demonstration Plant, and an investigative study began for a large-scale program to retrofit the filtration plants with ozonation facilities. Also during the year, the seismicity investigation and upgrade program expanded to include new studies and design work.

Capital Projects

Capital expenditures for fiscal year 1989-90 engineering activities totaled nearly $103 million, an increase of about $4.5 million over fiscal year 1988-1989. This figure covers capital work performed under contract and by Metropolitan, and includes equipment and right-of-way procurement, design, inspect[illegible] [illegible]d contract and general administration. Metrop[illegible] existing and r[illegible] [illegible]d facilities and pipelines are shown in Figure 15[illegible] Tables 34 a[illegible] [illegible]mmarize projects in various design and constr[illegible] stages.

Con

[illegible]struction contracts were in progress throughout the [illegible] year at a cost totaling $58,344,969; they are listed in Table 35. Thirteen [illegible] construction contracts were awarded by the Board during the year at a value exceeding $129 million. Three construction contracts, at a cost of $2,100,529, were completed during the fiscal year. At fiscal year end 16 construction contracts, valued in excess of $198 million, were progress[illegible]ing. Details of the major construction projects in progress during the year follow.

- Skinner Filtration Plant Expansion No. 3 — Construction of this 200-million-gallon-per-day (mgd) expansion to the existing 340-mgd Skinner plant continued through the fiscal year by the contractor, Kiewit Pacific Company, under a $48.1 million contract. The expansion [illegible] 52 percent complete by fiscal year end with all [illegible] currently scheduled for completion during May 1991.
- [illegible] Reservoir — Work continued on the 340-acre-[illegible]servoir and floating synthetic rubber cover. At [illegible] contractor, Kiewit Pacific Company, had [illegible] percent of the $20.5 million contract with [illegible] scheduled for March 1991.
- San Die[illegible] Enlargement — Enlarging approximately 18 mi[illegible] of the existing San Diego Canal, extending from San Jacinto Tun[illegible] to Lake Skinner, comes as part of Metropolitan's program to expa[illegible] facilities to provide greater water deliveries required by the San Die[illegible] County Water Authority. A $30.7 million construction contract [illegible] awarded to Kiewit Pacific Company in July. By fiscal year end [illegible] expansion project was approximately 61 percent complete, w[illegible] completion expected in August 1991.
- Oxidation D[illegible] Plant — This state-of-the-art 5.5-mgd wa[illegible] treatment p[illegible] the existing F. E. Weymouth Filtration Pl[illegible] (Weymouth pla[illegible] study large scale application of PEROXO[illegible] and ozone in water treatment processes. In March 1990, Me[illegible] Construction Engineers, Inc., was awarded a contract for $12.2 millio[illegible] Completion is scheduled in June 1991.
- Weymouth Washwater Reclamation Plant Expansion — Basically, th[illegible] expansion project involves constructing a 22-mgd water reclamati[illegible] plant and a 33-mgd coal removal flowsplitting structure, and modi[illegible]ing the existing 11-mgd washwater reclamation plant. The existi[illegible]

facilities do not have sufficient capacity to treat washwater when the Weymouth plant is operating at high capacity. In March 1990, a $7.7 million contract was awarded to C. W. Roen Construction Company. It is scheduled for a June 1991 completion.

- **Diemer Washwater Reclamation Plant Expansion** — Construction of this 25-mgd washwater reclamation facility is part of the Diemer filtration plant expansion. During June 1990, Kaweah Construction Co. was awarded a construction contract at a bid price of $6.7 million to expand the reclamation facility. The contract should be completed during October 1991.
- **Etiwanda Pipeline, Control Facility, and Reservoir** — These facilities are required to accept additional water deliveries available due to the expansion of the State Water Project's East Branch and then incorporate these increased deliveries into the existing distribution system. Two construction contracts were awarded near the close of the fiscal year; however, no construction had been started by fiscal year end. The Etiwanda Control Facility and Reservoir, required to regulate water flow into the system, will consist of a distribution and control facility and a 450-acre-foot reservoir. In May 1990, a contract to construct the control facility and reservoir was awarded to Advanco Constructors for a bid amount of $22.4 million. This contract is currently scheduled for completion during March 1992. A second Advanco Constructors contract, awarded in June 1990 at a bid price of $43.6 million, covers construction of 6.15 miles of 144-inch-diameter welded steel pipeline, including valve, meter, and relief structures, extending between the Rialto Pipeline and the Upper Feeder. The pipeline should be constructed by mid-1992.
- **Orange County Feeder Relocation** — In December 1989, Barnard Construction Co., Inc., received a contract for a bid price of $3.4 million to relocate approximately 5,800 feet of existing 46-inch-diameter pipeline owned by the Pomona-Walnut-Rowland Joint Water Line Commission and approximately 5,900 feet of existing Orange County Feeder Pipeline. These relocations, required per a Los Angeles County Sanitation District landfill project, are reimbursable by the county. This relocation project is scheduled for completion during December 1990.
- **Retention Basins at Mills Plant** — In August 1989, G. A. MacDonald Construction Company, Inc., completed modification of existing and construction of additional retention basins at the Mills plant at a construction cost of $1,634,763.

Figure [illegible] Construction Program

VOL 12 1 6CM2

R0049337

Design

The major facility projects in design phases during the fis[illegible] year included

- Jensen Plant Expansion No. 1 — The Jensen plant capacity [illegible] be expanded from 350 mgd to 750 mgd to help meet increasing [illegible] quality requirements and demands in Metropolitan's Central Po[illegible] area in conjunction with Diemer and Weymouth plant operations. The expansion work will include constructing additional structures: mix[illegible]ing and settling basins, filter units, retention basins, a 50-million-[illegible] finished water reservoir, and an additional 33-mgd washwater recla[illegible]mation plant. All design phases are scheduled to be completed by March 1991.

- Foothill Feeder Pressure Control Structure Expansion — The Foothill Feeder Control Structure regulates the water flow from Lake Castaic to the Jensen plant. Once the Jensen plant is expanded, it will have the capacity and requirement for additional Lake Castaic water. To meet the increased requirement, the pressure control structure will need to be expanded from the current 900 cubic feet per second (cfs) capacity to about 1,500 cfs. The control structure expansion will consist of installing sleeve and butterfly valves, pipe fittings, and related equipment. Design work is expected to be completed in October 1991.

- Diemer Plant Modifications — With a planned plant capacity increase [illegible] mgd to about 710 mgd, the Diemer plant enlargement will [illegible] increasing water quality requirements and Central Po[illegible] [illegible] conjunction with Jensen and Weymouth plant oper[illegible] [illegible] will include raising the height of the la[illegible] [illegible] at the settling basins, adding equipm[illegible] [illegible] for the chlorination and chemical feed s[illegible] [illegible] the washwater reclamation facility. The des[illegible] work sho[illegible] completed by January 1991.

- Etiwanda P[illegible] Plant — This proposed 19.5-megawatt capacity pow[illegible] plant will be [illegible] in Rancho Cucamonga to recover ener[illegible] that would otherwise be wasted through the Etiwanda Contr[illegible] Structure. The projected annual power generation for the first 10 yea[illegible] of operation is about [illegible] million kilowatt-hours, and the projecte[illegible] annual gross income from the plant's power generation is abo[illegible] $7,000,000. Design is scheduled for completion in mid-1992.

- Filtration Plant Ozonation Retrofitting — This project is one of severa[illegible] to be implemented under Metropolitan's Trihalomethane Action Pla[illegible] for reducing trihalomethane formation in drinking water. In this proj[illegible]ect, the five filtration plants will be retrofitted with oxidation systems using ozone or PEROXONE processes. Design work on this project is expected to be completed by July 1991.

Design was completed on various smaller-scale filtration plant projects. [illegible]hey include Skinner plant control room modifications and administra[illegible]tion building expansion, control system installations for Mills plant mod[illegible]ules Nos. 1 and 2, and rehabilitation of Weymouth plant equipment. Design [illegible]egan during the year on filter media replacements for Jensen plant filtra[illegible]tion systems.

Numerous distribution system projects were in design. Design was continued from last year on Skinner Bypass Pipelines Nos. 2 and 3 to provide operational flexibility during problem taste-and-odor episodes. Also, design was ongoing to relocate East Orange County Feeder No. 2 to accommodate the new Freeway 5/55 Interchange. An engineering study was under way to examine constructing a bypass canal in the Lake Mathews area to reduce potential lake pollution and provide emergency delivery capacity from Lake Mathews to the Lower and Upper Feeders. Design was completed for the following distribution system projects: installing chlorine solution lines and feed systems at Skinner East and West Bypass Pipelines and Bypass Pipeline No. 2 to eliminate taste-and-odor problems through periodic chlorination; replacing carbon dioxide cylinders within fire protection systems and rehabilitating controls at Units 1, 2, and 3 of the Colorado River Aqueduct (Aqueduct) pumping plants; relocating the Santa Ana Cross Feeder to accommodate a city of Santa Ana storm drain enlargement project; and modifying overhead bridge crane controls at Aqueduct pumping plants.

During the year, the previous study and design program for bulk storage containment measures expanded to include investigating, identifying, and recommending prevention measures for potential hazardous-substance spills and for implementing measures to safely handle potentially hazardous substances at Metropolitan facilities, including filtration and pumping plants, reservoirs, and maintenance areas. As a result of studies completed to date, design began for replacing caustic soda tanks at the Diemer plant.

Engineering design was completed during the year on the following telecommunications systems: (1) a telephone switch replacement and data networking equipment for Los Angeles Headquarters, (2) a telephone system for the Pasadena facility, (3) a CBX switch for the Weymouth plant, (4) ROLM-net for all facilities (a software program that provides alternate call-routing capability), and (5) PhoneMail systems for nine facilities.

Other projects in design during the year included hydroelectric plant vibration monitoring systems and enlargement of the chemical unloading facility located in the Lake Mathews area to accommodate increased chlorine delivery and storage requirements, as well as numerous miscellaneous projects. Design was completed for Phase III of the program to replace underground storage tanks at various Metropolitan facilities.

Continuing Projects

Corrosion Control

The ongoing program of monitoring and mitigating corrosion throughout Metropolitan's water transmission, storage, and distribution systems continued. Electrolysis surveys were completed on the Auld Valley and Lakeview Pipelines, the Burbank and Compton Laterals, and the West Orange County and West Coast Feeders. Also, surveys were conducted on portions of the Rialto Pipeline and the Santa Monica, Yorba Linda and East Orange County No. 2 Feeders. Corrosion was mitigated through regular maintenance and monitoring of existing cathodic protection systems and design and installation of several new systems. Projects included installing an impressed-current cathodic-protection system on the Lake Mathews forebay and headworks and the Mills plant influent gates and reservoir effluent structure. Deep-well anode groundbeds were installed to protect portions of the Orange County Feeder and West Valley Feeder No. 2.

Materials Evaluations and Research and Development

Restrictions placed on materials by government regulating agencies resulted in testing of several new products. Short- and long-term testing was conducted on protective coatings, adhesives, linings, sealants, and other materials used for construction and maintenance. Additionally, staff began evaluating how concentrated ferric chloride affected construction materials at the Mills plant, and an extensive report on the corrosion rates of metal alloys in Metropolitan's waters was completed. Test methods included accelerated weatherometer testing, infrared spectroscopy of test samples, and cathodic disbonding tests. Research and development projects included designing a new materials testing facility which will be operated in conjunction with the Oxidation Demonstration Plant, including cost analysis, process equipment product survey and acquisition, and design and construction of an ozone contact tower for diffuser and hydrodynamic studies. Data obtained from materials evaluations and research and development form the basis for materials selection and technical information for Metropolitan, its member agencies, and other water utilities.

Metallurgy

Failure analyses were conducted in both the metallurgical laboratory and the field to determine why equipment failed at various locations throughout Metropolitan's system. These included metallurgical inspection and failure analyses of hazardous materials containment, conveyance, and pumping equipment. Several power plant inspections were conducted and procedures recommended for weld repairs, heat treatments, and chemical cleaning and passivation. Also, ultrasonic testing procedures for inspecting and evaluating chlorine evaporators for flaws and corrosion were devised and implemented. Metallurgical evaluations by the metallurgy laboratory are used by both the Engineering and Operations Divisions and member agencies.

Investigations and Surveillance of Dams and Reservoirs

The ongoing surveillance program continued monitoring the safety and structural performance of the existing 14 dams and reservoirs in Metropolitan's system. This included daily inspections by operating personnel at all facilities and semiannual inspections by Metropolitan's dam safety engineers. Engineers from the California Division of Safety of Dams (DSOD) frequently participated in the dam inspections. Seepage flows, piezometric pressures, and horizontal and vertical movements were and continue to be monitored and analyzed for each dam. Seismic acceleration time histories are also recorded instrumentally and analyzed whenever any dam undergoes strong shaking during an earthquake. The Upland earthquake and some of its aftershocks, which occurred during this fiscal year, were of sufficient magnitude to activate strong-motion accelerographs at various sites. None of Metropolitan's dams or reservoirs were damaged by the Upland earthquake sequence.

Engineering reports were periodically provided to DSOD summarizing the results of all routine surveillance activities, periodic inspections, and analysis of all data collected from each dam.

The DSOD completed its review of plans and specifications on the 340-acre-foot treated water reservoir for the Skinner plant. DSOD gave final project approval in October 1989, and construction was subsequently started. Intensive liaison activities were, and continue to be, maintained between the DSOD, the outside geotechnical consultants, and Metropolitan's design and construction staff.

A ruling was obtained from the DSOD that the 450-acre-foot Etiwanda Reservoir does not fall under State jurisdiction, principally because its general configuration places most of the reservoir below the adjacent natural grade.

Staff reviewed the consultant's feasibility studies of the Eastside Reservoir siting. Numerous field and office reviews were made and liaison was maintained with the DSOD regarding all technical issues pertaining to that planned storage facility.

Subsequent to groundwater surfacing in the backyards of some Garvey Reservoir area homes, divers discovered a crack in the reservoir's bottom. As a result, the reservoir was taken out of service and drained in November 1989. An intensive effort was mounted to discover the cause of the ground cracking and to devise appropriate repair measures. Several consultants were retained to investigate the situation and to help design effective repairs.

Independently. DSOD retained Dr I M Idriss, Dr Clarence Allen, a
Mr J C Sciandrone as a consulting board to advise on all matters pertain
to incident causes and to the effectiveness of the proposed repairs. It is
anticipated that the repairs will be completed and the reservoir return
to service in summer 1991

Seismic Inspections, Investigations, and Upgrade Program

Biannual earthquake inspections were initiated by the Emergency Preparedness Task Force at Metropolitan facilities The investigations focused on the anchorage or lateral bracing of pipes, equipment, and electrical panels Preliminary design has been completed for seismic upgrading of several structures, and is nearing completion for lateral bracing of the discharge pipelines at the five Aqueduct pumping plants and for seismic upgrading of the plants themselves Design was completed on a seismic upgrade of part of the La Verne auto repair and utility shop and continues on the remainder Consultants have completed the preliminary seismic upgrade design for the two-story portion of the Headquarters Building and for the maintenance shop building at the La Verne facility A geotechnical consultant is preparing an investigative report on the stability of the slope directly behind the diversion structure at the San Jacinto Tunnel's west portal

Records of Survey

During the fiscal year four Records of Survey documents, covering four miles of pipeline and rights-of-way were filed with County Records Approximately 57 percent complete this program monuments and records survey maps for public record The survey maps are an accurate record of Metropolitan rights of way and land holdings. The work is currently completed using electronic surveying equipment and computer-aided engineering and drafting programs

Office Automation

A new Intergraph Computer Aided Design and Drafting system wa
acquired this fiscal year This sophisticated computer system will help auto
mate the design and drafting process of engineering projects in the ne
future The two initial phases of implementation—training an
standardization—have begun and will continue through fiscal yea
1990-91 A mainframe based project management system was als
implemented this year The system interfaces with the Electronic Time She
System to obtain up-to-date labor data Engineering managers and proje
engineers have access to project management reports via a terminal at the
desks The reports are interactive, which allows individuals to precisel
select the information they need to monitor and control the portions
the projects for which they are responsible Currently under way is a
enhancement to electronically retrieve cost data. This will provide complete

cost-monitoring capabilities within the Engineering Division. Computers continued to automate the collecting, processing, and analyzing of engineering data as well as to help perform administrative tasks.

Substructure Investigations

Substructure investigations review and analyze proposed utility and improvement projects to determine if they will interfere with existing and proposed Metropolitan facilities. During the fiscal year, staff received and answered 1,005 letters from outside agencies and developers regarding new construction that affected Metropolitan's existing and/or proposed facilities and rights-of-way, and 2,034 notifications and plans of proposed construction activities for the city of Los Angeles and Bureaus of Engineering and Street Maintenance. Also, 311 "Street Right-of-Way Vacation" notices were processed to ensure continued rights-of-access for operation and maintenance of existing Metropolitan facilities.

Service Connections

Under the reimbursable service connection program, which is an ongoing activity, 22 projects were under way during the year. The major projects in design stages included LA-35 to increase water supply from the Foothill Feeder to the Los Angeles area, in coordination with the Los Angeles Department of Water and Power; OC-64 to provide low-flow capability in the Santiago Aqueduct; EM-18 to supply additional water service from San Diego Pipeline No. 2 to the Rancho California area; enlarging EM-17 to increase water supply from the Auld Valley Pipeline to the Perris area, EM-12 to provide water service from the Mills plant to Moreno Valley; and USG-9 to furnish additional water service from the Middle Feeder to the Baldwin Park area. The major projects under construction included CenB-30 to provide water service from the Lower Feeder to the Santa Fe Springs area, CM-13 to supply water service from the Orange County Feeder to the Newport Beach area, and WR-24D to furnish water from the Sepulveda Feeder to the west part of Los Angeles.

Professional Consultant Activity

Fiscal year 1989-90 was another very busy year at Metropolitan. In order to meet project schedule requirements under the accelerated work program, Metropolitan continued to rely on many outside professional consultants to assist with projects requiring technical expertise. Professional consultant activity increased about 34 percent from fiscal year 1988-89, and 381 consultant agreements were active as of June 30, 1990. The heaviest uses were experienced by the Planning and Engineering Divisions, primarily with respect to drought and water conservation, water quality improvement, and facility expansion and construction for meeting the increasing demands on Metropolitan due to population growth. Fiscal year 1989-90 expenditures under the active agreements totaled about $21,561,811.

Board Chairman Lois B. Krieger presides over discussion at a lively Board of Directors meeting

CHAPTER 7

Legal

Metropolitan's legal staff represents Metropolitan, its Board of Directors, officers, and occasionally employees, in litigation and administrative proceedings. The staff provides the Board and Metropolitan officers with legal advice and written opinions, and reviews contracts and other documents. Additionally, the staff follows litigation and administrative proceedings to which Metropolitan is not a party, but whose outcome could affect Metropolitan or the resources on which it depends. By closely monitoring State and Federal legislative proposals, staff recommends positions Metropolitan should take, if any.

Litigation

Water Matters

Azusa Landfill Litigation

Metropolitan participated in State Water Resources Control Board (SWRCB) hearings supporting a petition by the Main San Gabriel Basin Watermaster to set aside a Los Angeles Regional Water Quality Control Board Order. That order allowed a major expansion of the Azusa Land Reclamation Company's municipal waste landfill in the San Gabriel Groundwater Basin's (Basin's) water recharge area. The California Departments of Water Resources (DWR) and Health Services (DHS), along with overlying water service agencies, locally elected legislators and other officials, and environmental and community groups also supported the Watermaster's petition.

The Basin provides drinking water supplies for nearly 1 million people within that portion of Metropolitan's service area. Additionally, Metropolitan stores imported water in the Basin and is actively studying a cooperative program for substantially expanding that storage.

Evidence adduced at the hearings indicated that the landfill expansion seriously threatens major contamination of the groundwater supplies and aquifers. The U.S. Environmental Protection Agency has already placed portions of the Basin on the National Superfund Priority List ... is currently formulating a billion-dollar remedial program, most of ... ch must be financed by local entities.

Nevertheless, SWRCB upheld the Regional Board's approval of the l... ... expansion with some modifications, including a conditional $20.5 m... ...on proposal by the landfill operator's parent entity, Browning Ferris Indus...es.

On November 8, Metropolitan, along with the Upper San Gabriel Valley Municipal Water District and the Environmental Defense Fund (EDF), filed an action in the Los Angeles Superior Court to rescind SWRCB's approval of the landfill expansion. The court consolidated the case with a similar action filed concurrently by the Watermaster. The actions assert that SWRCB's approval of the landfill expansion violates its duties under California's Water Quality Control Act, Solid Waste Management Act, and Environmental Quality Act (CEQA), as well as due process and other procedural requirements.

On April 20, 1990, the court rejected both actions. It ruled that SWRCB properly weighed conflicting needs for waste disposal and water supply and that the record indicates that any resulting groundwater impairment is reasonably remote. Additionally, the court ruled that the need for an Environmental Impact Report (EIR) on the expansion had not been adequately raised during the SWRCB proceedings and that SWRCB had nevertheless considered environmental issues.

Metropolitan and the other petitioners are appealing the Superior Court judgment, and a Court of Appeal ruling is expected within the next year.

Chino Basin ... Management Litigation

On July 31, 19..., the San Bernardino Superior Court issued a statem... of decision denying a motion by four Chino Valley water purveyo... challenging the validity of Metropolitan's groundwater storage exchan... agreement with the Chino Basin Watermaster and other aspects of t... Watermaster's management program.

Among other things, the decision holds that Metropolitan's agreeme... with the Watermaster fully complies with the letter and spirit of the 19... Chino Basin groundwater management judgment, and properly an... adequately safeguards the rights of the parties to that judgment. Th... decision also recognizes Metropolitan's right to participate in an... proceeding under that judgment that affects Metropolitan's real an... substantive interests without becoming a party to the judgment.

LEGAL

Imperial Irrigation District v. SWRCB

During the fiscal year, Imperial Irrigation District (Imperial) and SWRC... filed their respective briefs with the Court of Appeal in Imperial's continuing challenge of the validity of SWRCB's 1984 Water Rights Decision 1600. That decision concluded that Imperial's failure to develop and implement an adequate plan for reducing major losses in its Colorado River diversions violated the California Constitution's reasonable use requirements.

Expected to hear argument on the appeal in late 1990, the Court of Appeal previously upheld SWRCB's jurisdiction to adjudicate the reasonableness of Imperial's water management practices. The current appeal asserts that SWRCB did not comply with evidentiary and procedural requirements in issuing Decision 1600.

Mono Basin Water Rights Litigation

The Court of Appeal and the El Dorado Superior Court issued opinions and orders that significantly reduce the city of Los Angeles' 100,000 acre-feet Mono Basin water rights; these orders prevented Los Angeles from exporting any water from Mono Basin this past year. As a result, a substantial portion of the 155,000 acre-feet increase in Los Angeles' purchase of water from Metropolitan this fiscal year was used to offset this loss.

The Superior Court has issued preliminary injunctions that require Los Angeles to release substantial amounts of water for fishery purposes into Mono Basin streams that flow into saline Mono Lake, and to refrain from exporting any water from the basin until the Mono Lake level increases several inches.

In late June 1990, the Superior Court began lengthy evidentiary hearings to reconsider terms for extending the lake level preliminary injunction. Metropolitan's General Manager, Director of Planning, and Chief of Operations provided testimony describing the Mono Basin exports' importance to Metropolitan's service area.

Both preliminary injunctions are intended to maintain estimated fish flow and lake-level requirements until SWRCB completes a more precise re-evaluation, expected by the end of 1992, of Los Angeles' Mono Basin water rights licenses.

Coachella Valley Water District v. Metropolitan et al.

On January 26, 1990, the Coachella Valley Water District dismissed this action which challenged the validity of the Imperial/Metropolitan Conservation Agreement, with prejudice.

VOL 12 1 1607 3

American River Litigation

In December 1989, the Alameda County Superior Court finalized its decision in the American River litigation which EDF initiated 17 years earlier as *EDF v. East Bay Municipal Utility District* (East Bay). Of particular interest to Metropolitan, the decision applies the public trust doctrine by balancing instream flow uses with competing water supply needs, and concludes that providing high quality drinking water is a significant public policy objective in that balancing process.

The decision allows East Bay to export up to 150,000 acre-feet of water annually from the river under East Bay's Federal Central Valley Project water supply contract. However, the decision conditions that export on maintaining substantial instream flows. It also includes a physical solution to implement the decision, reserves continuing jurisdiction, and appoints a watermaster to aid in administering the physical solution.

Laughlin River Tours, Inc., et al. v. Bureau of Reclamation et al.

On December 29, 1989, the federal district court denied the request of Laughlin River Tours, Inc., for releases of water from Davis Dam for the sole purpose of facilitating Colorado River navigation. The claim for damages by Laughlin against the Federal government is still pending.

Indian Claims and Litigation

Arizona v. California III

After the U.S. Supreme Court affirmed the dismissal of *Metropolitan et al. v. United States et al.* (Indian boundary litigation), Metropolitan, joined by the States of Arizona and California and the Coachella Valley Water District, filed a motion to re-open *Arizona v. California* for the limited purpose of finally determining the boundaries and their attendant water rights, if any, of three Indian reservations along the lower Colorado River. The Supreme Court granted the motion and appointed a Special Master to hear the dispute and make recommendations to the Supreme Court.

Soboba Band of Mission Indians v. United States

This case has now been set for trial in February 1991 with regard to the damages issues. If damages are awarded to the Sobobas, the United States may possibly assert a claim against Metropolitan for reimbursement for a portion thereof. Additionally, an action on behalf of the Sobobas could possibly be brought for monetary damages or for a determination of the Sobobas' water rights or both.

Miscellaneous Matters

Mission Viejo Company v. MWD, et al.

This Los Angeles County Superior Court action asserts violations of CEQA and other statutes in purchasing properties for the proposed Eastside Reservoir, particularly the Searl Ranch property. It was brought by private developer Mission Viejo Company against Metropolitan, the Board of Directors, each individual Board member, and two staff members. On July 24, 1989, a preliminary injunction sought by plaintiff was denied. Causes of action against individual directors and staff members were severed and are currently the subject of a tentative judgment for dismissal. The remaining cause of action for writ of mandate has been ordered coordinated with a companion Riverside County Superior Court action (*Faulkner v. MWD*). The parties have engaged in extensive discovery pending designation of a trial court and trial date.

Faulkner, et al. v. MWD

On October 24, 1989, 22 individuals, subsequently reduced to 16 individuals, claiming to be resident owners of various land parcels located in or around the Domenigoni Valley in close proximity to the Searl Ranch properties, filed a petition for writ of mandate against Metropolitan in Riverside County Superior Court alleging violations of CEQA and other statutory provisions. That action is now at issue, extensive discovery has proceeded, and that action has been coordinated with a companion Los Angeles County Superior Court action for trial. The parties are continuing with discovery and await the designation of a trial court and trial date.

Mission Viejo Company v. Searl, MWD, et al.

On August 8, 1989, Mission Viejo Company filed and served its amended complaint in Riverside County Superior Court against the sellers of the Searl Ranch property and Metropolitan for specific performance, constructive trust, etc. with regard to the Searl Ranch properties. Discovery is proceeding and trial is set for November 1990.

Mission Viejo Company v. MWD, et al.

In addition to the pending lawsuits already described, on or about December 29, 1989, Mission Viejo Company filed a government tort claim against Metropolitan, all persons who were members of the Board of Directors in May 1989, and two staff members, claiming damages according to proof for Metropolitan's alleged tortious interference with contract in its purchase of the Searl Ranch property for the proposed Eastside Reservoir. Metropolitan denied the claim on February 9, 1990. By stipulation and agreement with Metropolitan, Mission Viejo Company has until September 9, 1990, to file suit on those alleged claims.

MWD v. Cucamonga Development Company et al.

This is an action in eminent domain filed by Metropolitan on December 12, 1989, to take a parcel of property consisting of approximately 80.51 acres located in the city of Rancho Cucamonga. Metropolitan obtained an Order for Possession of the property on December 27, 1989, and, based on an independent appraisal, deposited $8,767,500 with the court as compensation for the parcel. A trial-setting conference is scheduled for August 24, 1990. The parties have not yet exchanged valuation data; therefore, it is uncertain what amount, if any, beyond the deposit the defendant will demand.

Garvey Reservoir Leak

Due to an October 1989 leak at Garvey Reservoir, approximately 37 claims for personal injury and property damages have been submitted to Metropolitan by the city of Monterey Park and homeowners residing near the reservoir. Nineteen of those claims have been denied; nine are still under investigation; two offers have been submitted; and Metropolitan is prepared to submit offers to five additional homeowners as soon as they provide final estimates of property damage. Metropolitan offered to settle the claims submitted by Monterey Park, which denied the offer; there is one new claim. Of the 19 claims denied, 13 were denied because the claimants did not specify the extent of their damages; thus, Metropolitan was unable to act on those claims. The 45-day period for responding to such claims expired in May 1990.

Nine of the claimants live on Ransom Way in Monterey Park, and Metropolitan engineers have been unable to determine whether there is a causal connection between the Garvey Reservoir leak and their claimed damage. As a result, those claimants were notified that Metropolitan was still investigating their claims and, within 90 days from the notice date, Metropolitan would make a decision about those claims. To date, no one has accepted any of Metropolitan's offers.

Employees Association of The Metropolitan Water District of Southern California Local 1902, AFSCME, AFL-CIO v. The Metropolitan Water District of Southern California et al., Case Nos. BC 003912 and BS 001327

Near the end of the fiscal year, Metropolitan was served with a complaint for injunctive relief and was also served with a petition for writ of mandate in the above matters. Later, an amended petition was served. The Employees Association (Association) alleged that Metropolitan was committing unfair labor practices in its handling of a petition from a group of employees who wish to split from the Association and form a new employee organization. The petitioning group, made up primarily of maintenance, operations, and crafts workers located at Metropolitan's field facilities and calling itself the Field Employees and Technical Crafts

[Ass]ociation (FETCA), filed a petition signed by more tha[n] ... [th]e employees in the job classifications that it hoped to ... [Metro]politan's Employee Relations Officer determined, as ... [M]etropolitan's Administrative Code, that the group was an ... [u]nit" and scheduled an election to determine whether FETCA or the Ass[oci]ation will represent the unit.

The Association alleged that Metropolitan and certain named defendants dominated, interfered with, and encouraged the formation of FETCA in order to divide the Association and in retaliation for the Association's recent affiliation with the American Federation of State, County, and Municipal Employees. The complaint seeks a temporary and permanent injunction. The petition seeks damages, including punitive damages of $1 million, and an order enjoining Metropolitan from recognizing the new group for 12 months. The Los Angeles Superior Court denied the Association's request for a Temporary Restraining Order, and its request for a Preliminary Injunction. A tentative settlement resulting in dismissal of this action has been reached and will be presented to the Metropolitan's Board for approval on September 11, 1990.

Internal Matters

Staff was involved in various cases in which damages were claimed for death, personal injury, or property damage, principally resulting from accidents involving motor vehicles. Staff also represented Metropolitan in various personnel matters involving disciplinary issues or discrimination claims.

Administrative Proceedings

State Water Resources Control Board Activities—Bay Delta Hearings

The SWRCB San Francisco Bay-Sacramento-San Joaquin Delta Estuary (Bay-Delta) water quality and water rights proceedings continued.

In these proceedings, SWRCB will (1) develop a document ... [p]ollutant policy for waters, (2) adopt a water quality control plan ... [b]eneficial uses of Bay/Delta waters and determining reasonable ... [p]rotection for those uses, and (3) hold a water rights hearing ... [t]he need to condition water rights as a means to protect those ... [u]ses. A wide variety of interests are represented in the hearing ... [t]he operators of State and Federal water projects; State and Federal ... [w]ildlife, and other resources agencies; agricultural and municipal ... water users, both in export areas and within the watershed; and environmental and other special interests. Metropolitan particip...

concert with the State Water Contractors (SWC), a nonprofit corporation made up of public entities with State Water Project (SWP) water delivery contracts.

In January 1990, SWRCB released a partial Revised Draft Water Quality Control Plan (WQCP) for the Bay Delta that discussed alternative water quality objectives proposed by the parties to this proceeding and by SWRCB staff, and held hearings on this partial draft in February 1990.

A full Revised Draft WQCP was released in June 1990 which contains a variety of proposed water quality objectives. The WQCP does not include the large freshwater outflow objectives that were contained in SWRCB's November 1988 Draft WQCP, which was withdrawn as a result of petitions filed by Metropolitan and others. The withdrawn flow objectives, based on fisheries' purported needs, will instead be considered in the proceeding's water rights phase. However, the Revised Draft WQCP still contains objectives that, if adopted, could cause the loss of as much as 2 million acre-feet of water available for municipal, industrial, and agricultural purposes.

The SWRCB adopted its Pollutant Policy Document on June 21, 1990. That document is intended to set policy to prevent pollution in the Bay Delta as a guide for the San Francisco Bay and Central Valley regional boards in amending plans for their respective regions' basin plans.

The ultimate WQCP and water rights decision could have a substantial impact on SWP's ability to store and export Delta water. This could, in turn, decrease the amount of water available for delivery to Metropolitan under its SWP contract. Nearly every California urban area and scores of agencies delivering water for agricultural purposes could also face reductions in available water from the Bay Delta watershed.

Shasta Dam Storage Releases

On May 2, 1990, SWRCB adopted a water rights order which imposed additional terms and conditions on the U.S. Bureau of Reclamation's (Reclamation's) permits and licenses to divert and store water at its Shasta Dam and Keswick Dam facilities. The terms and conditions are intended to improve temperature conditions in the Sacramento River below Shasta Dam for fall run Sacramento River salmon.

The water rights proceeding followed SWRCB's rescission of a similar order by the Central Valley Regional Water Quality Control Board issued as a waste discharge order under its water quality authority. Reclamation—supported by Metropolitan, SWC and others—had successfully argued that the regional board's order was beyond its water quality authority and was a matter more properly before SWRCB under its water quality authority.

Both Reclamation and the Central Valley Project Water Association h... filed actions seeking to invalidate SWRCB's order asserting that the ord... (1) violates CEQA because it was issued without a completed EIR an... (2) violates California Water Code sections 1253 and 1257 because SWRC... modified Reclamation's permits without considering and balancing th... relative benefit and public interest in consumptive water uses. Reclamation... action was filed in Federal court, the water association's in State cour...

Legislation

All legislation introduced in the California Legislature was examined to determine matters of interest to Metropolitan. Staff prepared a digest and recommendations as aids in reporting to the Board of Directors and to others those items requiring a policy determination.

Metropolitan supported several water conservation measures during the 1989-90 session, some of which were enacted by the Legislature prior to the session's end. Assembly Bill (AB) 325 (Statutes of 1990, Chapter 1145), authored by Assembly Member Steve Clute, requires DWR to appoint and work with an advisory task force to adopt a model water-efficient landscape ordinance which local agencies could then utilize. This measure would encourage and facilitate local agencies to adopt landscaping ordinances which would reduce demand on Metropolitan. Senate Bill (S) 1520 (Statutes of 1990, Chapter 809), authored by Senator Robert Presley, excludes from income any rebate a taxpayer receives from a local water agency as reimbursement for installing a low flush toilet, thus encouraging consumers to participate in low flush toilet rebate programs. AB 2355 (Statutes of 1989, Chapter 1029), authored by Assembly Member Bill Filante, sets stricter standards for water closets and associated flushometer valves. In time, these lower water-use facilities should reduce per capita water demands in Metropolitan's service area, particularly in new growth areas.

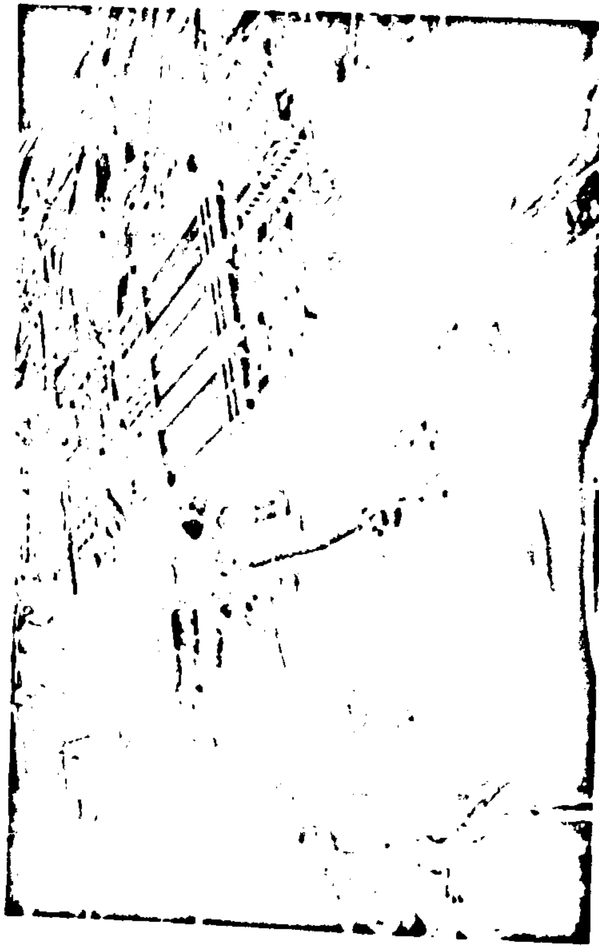
Of several water quality bills, Metropolitan was particularly concerned with AB 2158 (Statutes of 1990, Chapter 1182), authored by Assembly Member Jim Costa. The bill as enacted places all public water systems that have 15 or more connections under DHS's regulatory authority and requi... public water systems with 200 or more connections to pay $.50 for ea... connection. The $.50 fee is repealed as of July 1, 1991. After that date, pub... water systems will pay a fee based on the costs of service provided b... the DHS to the particular system. Metropolitan opposed S 65 (Statutes of 1990, Chapter 407) authored by Senator Quentin Kopp, amending t... Safe Drinking Water and Toxic Enforcement Act of 1986 to include publ... agencies, which include water utilities, under the warning and som... discharge requirements. S 65 will be on the November 1990 general election ballot as Proposition 141. If passed, water utilities will be required to warn their customers of chemicals in their water that are known to cause cancer or reproductive toxicity. Additionally, water utilities would not be allowed to use certain chemicals at "unsafe" levels and would have to either find replacement chemicals, lower the chemical's level or remove the chemical from their systems.

A package of bills intended to protect wetlands were introduced during the Legislative session's second half. The Board opposed some of those bills — S 2530 authored by Senator Milton Marks, AB 4231 authored by Assembly Member Byron Sher and AB 4327 authored by Assembly Member Phillip Isenberg — because they would impose additional restrictions, requirements, and costs on operating agencies, far exceeding existing Federal and State statutes or other measures necessary to protect wetlands. The Board adopted a position urging that the bills be amended to eliminate redundant permission and unreasonable mitigation requirements and to conform with Federal guidelines. The bills were not enacted during the 1989-90 session but are expected to be introduced again during the 1991-92 Legislative session.

Voice and data communications travel between Metropolitan's ... strategically placed microwave towers.

VOL 12

1 6047



Expansion at the Robert A. Skinner Filtration Plant will increase output by 200 million gallons per day to meet San Diego and Riverside Counties' growing needs.

CHAPTER 8

Financial Planning and Operations

Long-Range Financial Plan Strategy

Throughout the fiscal year, staff continued analyzing financial techniques to determine whether a more cost-effective means than presently strategized for financing Metropolitan's capital improvement plan may be advantageous. Current projections indicate that capital improvements and additions to the water distribution and treatment systems through the year 2010 will cost $4.3 billion in 1990 dollars, or $6.0 billion in escalated dollars after taking into account the construction schedule. The Finance Plan Strategy recommends financing these expenditures primarily from a combination of security sales and pay-as-you-go financing. The securities would include fixed- and variable-rate revenue bonds and commercial paper offerings.

Developing a new source of firm revenue would reduce reliance on variable water revenues as future Metropolitan taxes and water rate stabilization fund balances decline. During the year, staff continued reviewing charges as a firm revenue source. A consultant compiled information on parcel data from Metropolitan's six-county service area during the year; a model data base is being constructed to provide information on future revenue that could be derived from various levels of stand-by charges.

By law, Metropolitan's revenue bond debt capacity is limited to an amount equal to its equity as shown on its balance sheet. To confirm [illegible] revenue bond capacity will exist to finance the Capital [illegible] staff projected Metropolitan's financial statements and [illegible] each year to the year 2000 using an updated Consumer [illegible] The analysis, which took into account the Board's 20 percent [illegible] objective, reconfirmed that the projected revenue bond debt [illegible] Metropolitan's projected equity.

R0049352

VOL 12

1 6 C 3 4 8

In January 1989 the Board established the Revolving Construc[illegible] Fund (RCF) with a $100 million transfer from the Water Rate Stabilizat[illegible] Fund (WRSF). The RCF currently finances Metropolitan capital works [illegible]ich general obligation bond proceeds cannot be used. In 1993 the fu[illegible] [illegible]ll be closed and the $[illegible] million plus interest will be transferred to the WRSF.

Selection of Financial Advisor

[illegible] year Metropolitan sent requests for proposals to financial firm[illegible] consideration as financial advisor. Staff received requests for p[illegible] from 12 firms and conducted interviews with six. The firm of [illegible] Partners Inc. was selected to provide financial advisory services.

1990-91 Annual Budget

Metropolitan's budget for 1990-91 is $628 million. Projected revenue sources for the fiscal year are $444 million from water sales, $77 million from ad valorem taxes, $53 million from interest income, and $20 million from power sales. WRSF will be used to fund expenditures not covered by operating revenues.

Metropolitan's budget is organized in a program format which provides clear statements of accomplishments, objectives, and the cost of resources needed to continue the high standard of service Metropolitan provides its member agencies. With this format, each department and division consolidates its activities and costs in an interrelated document to evaluate performance against Metropolitan's goals.

The 1990-91 budget's major objectives include pursuing opportunities to increase dependable water supplies and formulate programs to reduce demands on Metropolitan's system, upgrading water quality, efficiently using existing facilities, expanding the distribution system's capacity, upgrading and enlarging water treatment facilities, rehabilitating Colorado River Aqueduct pumps with minimal service interruptions, and continuing the automation of work activities.

To monitor the budget throughout the fiscal year, Metropolitan p[illegible] a monthly variance analysis to track actual receipts and expenditures [illegible] the budget.

1990-91 Revenue Requirements and Water Rates

In December 1989, the General Manager submitted to the Fina[illegible] and Insurance Committee an estimate of total revenues required fro[illegible] water sales for fiscal year 1990-91 as determined under the Board's propo[illegible] rate policy. This formed the basis for setting 1990-91 water rates. In [illegible]ary 1990 the General Manager recommended no change in water rat[illegible] the Water Problems Committee, leaving the rates unchanged since 19[illegible].

FINANCIAL PLANNING AND OPERATIONS

Following a public hearing, the Board adopted the [illegible] per acre-foot for 1990-91 as follows:

Noninterruptible		Interruptible		Emergency		Reclaimed	Seasonal Storage	
Untreated	Treated	Untreated	Treated	Untreated	Treated		Untreated	Treated
$197	$230	$153	$186	$591	$624	$84	[illegible]	[illegible]

Metropolitan's water pricing structure contains five service classes: noninterruptible, interruptible, emergency, reclaimed, and seasonal storage.

Noninterruptible service includes water deliveries for domestic and municipal purposes, including groundwater replenishment, in-lieu groundwater replenishment, and storage, and is not subject to reduction or interruption. Interruptible service includes water deliveries for agricultural purposes in addition to the primary uses identified for noninterruptible service, but is subject to reduction or interruption upon notice. Agencies purchasing interruptible water for other than agricultural purposes must demonstrate the ability to sustain an interruption by using stored supplies not normally required for local area service. Alternatively, an agency unable to sustain an interruption may purchase emergency water at a higher rate. Water may be delivered for agricultural purposes when supplies are surplus to domestic and municipal demands.

Reclaimed water (nonpotable water with limited uses) is sold at Metropolitan's lowest rate. Through financial participation in member agencies' local reclamation projects, Metropolitan acquires rights to reclaimed water.

Seasonal storage service is discounted to encourage member agencies to purchase and place into local groundwater storage and surface reservoirs water available during the off-peak winter months. The agencies thereby reduce treatment demands on Metropolitan during on-peak summer months.

1989-90 Tax Levy

Metropolitan levies taxes each year to pay debt service on its general obligation bonds and a declining portion of the capital costs [illegible] its contract with the State for water. Installments are also collec[illegible] Metropolitan area annexations prior to June 6, 1978. The net [illegible] for 1989-90 totaled $81.9 million. Assessed valuations within Metropolitan's six-county service area amounted to $671.7 billion, an [illegible] percent over 1988-89.

Charges and Payments Under the State Water Contract

Metropolitan is one of 30 participants contracting with the State for a system to provide water throughout California. Metropolitan is obligated to pay part of the cost of system construction and operation through the year 2035 regardless of the quantities of water available. For fiscal year 1989-90, Metropolitan paid $248.1 million, or 67 percent, of the State Water Project (SWP) costs.

Indirect Cost Allocation Plan

Staff assembled data for the Indirect Cost Allocation Plan (ICAP) for fiscal year 1989-90 to update the ICAP overhead rate. The ICAP identifies the cost components to be included in establishing an acceptable indirect cost rate for federal cost reimbursement purposes. The new rate also is used as a provisional indirect cost rate for applicable projects in the subsequent fiscal year.

Establishment of the Iron Mountain Landfill Closure/Postclosure Maintenance Fund

Metropolitan operates a solid waste landfill facility at its Iron Mountain Pumping Plant, and therefore is subject to regulations under Government Code Section 66796.22. This statute requires landfill operators to evidence their financial ability to pay the closure and postclosure maintenance costs of their facilities. Last year, based on draft regulations, Metropolitan satisfied the Government Code's requirements by disclosing to the California Integrated Waste Management Board (CIWMB) the estimated costs of closure and postclosure maintenance of its landfill facility and certifying its ability to meet such costs.

In August 1989, the CIWMB issued amended regulations requiring Metropolitan to establish a separate funding mechanism to insure that sufficient monies will be available to pay the estimated costs of closure and postclosure maintenance of its solid waste site. Staff recommended establishing a separate enterprise fund to be invested and held by Metropolitan. The fund basically offers protection equivalent to a third-party trust fund, thereby assuring that all costs will be covered. Upon Board approval and adoption of the required resolution, $3.4 million, the engineering estimate of the costs (in 1990 dollars) for closure in the year 2030 and the postclosure period ending in the year 2045, was transferred to this newly established fund.

Revised Statement of Investment Policy

The Annual Statement of Investment Policy for 1990 was revised to reflect three changes:

(1) The portion of the portfolio that can be invested in repurchase and reverse repurchase agreements was reduced from 50 to 20 percent.

(2) The Treasurer was authorized to extend investment maturities beyond the standard two-year maximum term for the Iron Mountain Trust Fund.

(3) Qualified institutions with which the Treasurer may execute transactions were identified, each of which will be sent, and must acknowledge receipt of, Metropolitan's Statement of Investment Policy of investment objectives and parameters.

Banking Issues

An interim securities custodial agreement was executed on April 6, 1990, with Security Pacific National Bank (SPNB's) trust department following dissolution of SPNB's operational safekeeping unit. A request for proposals for permanent custodial services and other banking services should be issued by fall 1990. Staff is being trained on a new system which electronically notifies the custodian that a security has been purchased or sold with subsequent updating of the custody account. The system also enables the Treasurer to review the securities held in safekeeping.

In cooperation with SPNB, an audit is being conducted of Metropolitan's bearer bonds held for safekeeping at SPNB, Los Angeles, and Banker's Trust Company, New York. Upon completion, the exchange and co-paying functions performed by Banker's Trust will be consolidated into SPNB. Electronic transmission of payroll data to SPNB was fully implemented in October. Automated payroll deposits for crediting employee accounts at SPNB and other banks is now completed.

Deferred Compensation and Savings Plans

Metropolitan administers a deferred compensation plan for its employees' benefit according to Internal Revenue Code Section 457. This plan enables employees to defer portions of their compensation until retirement, disability, or death. The Director of Finance administers the plan, the Plan Coordinator maintains participation records, and the Treasurer invests the deferred funds in Metropolitan-authorized instruments. As of June 30, 1990, the plan balance was $18.8 million compared to $16.2 million on June 30, 1989. Employees deferred $2,017,638 for the fiscal year and investments yielded an average return of 8.943 percent.

In accordance with Section 401(k) of the Internal Revenue Code, Metropolitan maintains two additional deferral arrangements to benefit eligible employees (referred to as Savings Plans I and II). The Director of Finance administers the plans and the Treasurer acts as Trustee. Amounts deferred are transferred each pay day to a third-party broker who invests them in authorized investment vehicles as each participant directs. Employees deferred a total of $820,366 in fiscal year 1989-90. Enrollment in the plans increased 22 percent over last year, raising total enrollment to 1,137 participants. An employer-matching contribution for Plan I began in January 1990. Metropolitan contributions totaled $74,367.

At the Trustee's request, the Audit Department performed a limited review of the activities in Savings Plans I and II for calendar year 1988. Based upon the review's overall results, the existing internal controls over the Plans' records and documents are considered adequate and related accounting and administrative policies and procedures required to maintain such records are functioning properly in all significant respects.

Risk Management

The Risk Manager is developing a program to comply with the U.S. Environmental Protection Agency regulations which impose financial responsibility conditions on owners of underground storage tanks and, with Imperial Irrigation District's (Imperial's) insurance representatives, is setting up a system to ensure mutual compliance with the risk, insurance, and indemnity provisions of the Metropolitan Imperial agreement.

Accounting Operations

During the fiscal year, Finance's automation program continued contributing to operational effectiveness as new microcomputer and local area network based applications were implemented and staff continued to maintain and operate numerous applications vital to its daily operations.

Annual Tax Levy

The annual tax levy process involves accumulating assessed valuations from the Counties of Los Angeles, San Diego, Orange, Riverside, San Bernardino, and Ventura. The information and Metropolitan's annual tax levy requirement are processed to determine the tax levy rates that will be used to assess property owners in the counties. This information is presented to the Board of Directors each August for its approval, and then sent to each of the six counties for inclusion in their property tax bills. The process includes developing tables that list assessed valuations for

each of the geographical areas covered by Metropolitan's [illegible] This information is used to determine the number of directors [illegible] that each member agency has on the Board of Directors.

Inventories

Staff annually performs a Central Stores physical inventory to verify the accuracy of Metropolitan's perpetual inventory records. In recent years this occurred in March or April to allow enough time to complete the inventory testing prior to fiscal year end. The 1989-90 Central Stores inventory was completed by March 23, 1990. The Controller issued a report summarizing the results of the physical inventory counting process and quantified the reduced inventory value based on the counting results. The report contained several minor recommendations for improving the physical inventory process. Staff concluded, after certain reconciliation procedures were performed, that the statistically projected total inventory value was, within a high degree of probability, approximately $49,053 less than the recorded inventory values, or less than 1 percent of the total inventory.

Final results of the 1988 Operating Equipment Inventory were released. A biennial physical inventory of operating equipment verifies the accuracy of Metropolitan's equipment inventory records. The physical inventory resulted in a write-off of 363 pieces of equipment, with an original cost of $566,623, and a net book value of $101,784. The net write-offs as a percentage of the total net value of the operating equipment, over $12 million, is minor (less than 1 percent).

To improve the accuracy and timeliness of the 1990 operating equipment inventory, efforts are under way to revise the counting procedures and develop new programs used to process and report the inventory results. During the 1990 physical inventory, staff will also prototype, at selected locations, the bar code scanning system currently under testing.

Invoice Processing

A study was undertaken to develop methods for streamlining requisition and invoice processing. A joint task force of Operations, Purchasing, and Accounts Payable staff met and made 34 recommendations that were approved by management. A deadline of December 1, 1990 was set for implementing the recommendations. The study's [illegible] recommendation was to install a draft system for use by [illegible] which allows them to procure materials and one-time services [illegible] than $500 and pay the vendor directly. This draft system will [illegible] reduce the number of small payments that Accounts Payable [illegible] and improve vendor relationships. Verification controls are [illegible] oped to guard against system abuses.

Major inroads were made to improve Metropolitan's relationship with consultants. Staff analyzed the payment procedures and found that the growth of consultant contracts over the past five years exceeded Metropolitan's ability to process the invoices in a timely fashion. To correct the problem (1) An automated tracking system was installed that produces reports showing the status of invoices, and flagging invoices that exceed the agreement total, (2) written guidelines were developed for agreement administrators on how to process consultant invoices and how disagreements are to be handled, and (3) in an effort to provide feedback to agreement administrators on their payment record, an Accounts Payable report was produced on the average number of days required per agreement to pay an invoice for the last six months of 1989. Reports were then run quarterly for the remainder of the fiscal year, showing that the total processing time has been reduced from 25 to an average of 12 days.

Balance Sheet Highlights

Cash & Marketable Securities

Cash and marketable securities totaled $955 million and $694 million at June 30, 1990, and 1989, respectively, as shown in Table 39.

Cash and marketable securities are held under separate accounts (funds) to accomplish specific activities in accordance with special regulations, bond covenants, and Board policies. The funds are classified under general headings as "unrestricted" and "restricted." After necessary fund transfers are made to comply with bond covenants, the Board has complete discretion over the magnitude and use of unrestricted funds. Restricted funds are earmarked for payment of debt service on Metropolitan bonds and capital charges under the State Water Contract. In addition to unrestricted and restricted funds, Metropolitan maintains other funds as follows (also see Table 40):

- Revenue Bond Construction Fund
- 1966 Bond Construction Fund
- Revolving Construction Fund
- San Joaquin Reservoir Fund
- Deferred Compensation Fund
- Excess Earnings Fund
- Iron Mountain Trust Fund

Plant and Equipment

Before accumulated depreciation, plant and equipment increased $158 million over 1989 to $1.5 billion in 1990, after depreciation, primarily because of construction program expenditures for water distribution and treatment plant facilities.

Participation Rights in State Water Facilities

Participation rights reflect unamortized capital expenditures made under the State Water Contract. Since Metropolitan does not own the SWP, the capitalized payments represent intangible rights (assets). The participation rights are amortized as Metropolitan receives State project water. This fiscal year, the asset account increased $91 million before amortization to $982 million. This increase was directly associated with the revised costs for each State Water Contract component cost.

Deferred Water Rights

Metropolitan and other agencies have entered into several water exchange, storage, and reclamation project agreements, which reliably supplement Metropolitan's Colorado River and State project water supplies. Metropolitan is also actively pursuing other agreements both within and outside its service area to provide additional water supplies.

The exchange and storage agreements generally provide for advanced water delivery during periods when surplus flows and inexpensive energy for pumping are available. Under reclamation agreements Metropolitan funds a share of the construction or improvement of reclamation facilities by local agencies. Reclamation plants produce subpotable water for agricultural and industrial uses.

Costs associated with these agreements have been recorded as deferred charges and are amortized to the cost of water as the rights are exercised. At June 30, 1990, and 1989, deferred water rights totaled approximately $16 million for both years, based on volumes of 649,000 and 715,000 acre-feet respectively.

In addition to the above programs, Metropolitan and Imperial approved a major conservation program that will help improve Imperial's outdated distribution system. In all, 106,000 acre-feet of water a year will be made available for Metropolitan's use by 15 Metropolitan financed conservation projects. As of June 30, 1990, Metropolitan has deferred charges of [illegible] million for this program. Over the first 40 years of the program [illegible] year 2029 — nearly 4 million acre-feet (maf) of water will be made [illegible] to Metropolitan.

Bonded Debt

On June 30, 1990, $1.078 billion in waterworks bonds was outstanding, consisting of $361 million in revenue bonds and $717 million in general obligation bonds. Principal payments by Metropolitan in 1989-90 reduced bonded debt by $17 million. Table 42 contains a five-year summary of Metropolitan's revenue bond coverage. The weighted average cost of all bonded debt outstanding, including the 1989 Series G general obligation bonds, was 5.65 percent with an average bond life of 17 years.

Commitments and Contingencies

To provide power for transportation within the SWP system, the State Department of Water Resources (DWR) issued bonds to construct two off-aqueduct power facilities. Construction on the South Geysers Geothermal Power Plant was suspended in 1987 pending procurement of a steam supply sufficient to operate the plant at planned capacity. During the year ended June 30, 1989, DWR officials decided to dispose of the plant assets, if possible, by leasing the steam field and plant site and selling the power plant equipment.

Additionally, the Bottle Rock Geothermal Power Plant's steam supply has been steadily declining in recent years. This fiscal year, DWR determined it to be more economical to either suspend operations at this facility indefinitely or to contract with a private entity for plant operations, rather than continue operations under the present conditions. Regardless of the option selected, it is unlikely DWR will receive any significant future benefits from power generation at the Bottle Rock facility.

Because of these contingencies and a reading of Financial Accounting Standards Board Statement No. 5, Metropolitan has decided to recognize losses on these two geothermal facilities. The portion of unamortized participation rights attributable to the South Geysers Project, totaling $21.5 million, was written off as of last fiscal year. Similarly, the portion of unamortized participation rights attributable to the Bottle Rock facility, totalling $11.8 million, were written off as of June 30, 1990. Additional losses on the Off Aqueduct Power Facilities (OAPF) were recorded in the amounts of $115.8 and $55 million for the years ended June 30, 1990, and 1989, respectively. These additional losses represent the present value of Metropolitan's remaining obligations to the State through the year 2024 for the debt service costs of the South Geysers project and the Bottle Rock facilities which are now reflected as long term obligations on Metropolitan's balance sheet.

Equity

Equity on June 30, 1990, rose to $2.2 billion, compared to $2.1 billion on June 30, 1989. The increase reflects net income of $[illegible] million, $1 million in contributions from member agencies to aid construction, and $4 million in annexation commitments. Of retained earnings, $[illegible] million was designated at fiscal year end, $90 million was reserved, and the remaining $1.7 billion was undesignated.

Statement of Operations Highlights— Accrual Basis

Water Sales and Power Recoveries

Revenues of $487 million from water sales increased $62 million over last year (Figure 16). Water deliveries of 2.5 maf rose 416,000 acre-feet over fiscal year 1988-89, marking the sixth consecutive year of record water sales. Hydroelectric power sales generated revenues of $19 million.

Interest and Other Income

Interest earnings increased $24 million to $75 million during fiscal year 1989-90, reflecting higher interest rates and larger operating balances. Other income equaled $4 million, principally due to Metropolitan's sale of surplus lands and new annexation commitments which, since 1978, are paid in lump sum rather than on installment.

Taxes and Annexation Income

As shown in Tables 43 and 44 and Figure 17, the total valuation of property subject to taxation for Metropolitan purposes was $672 billion in August 1989, representing a 12.5 percent increase over August 1988. Beginning in fiscal year 1988-89, unitary values for State-assessed utility properties were valued separately and excluded from the total taxable assessed valuations. The unitary value results in an average county-wide tax rate for property operated as a unit in a primary function. Each County determines a specified amount which it remits to Metropolitan as its share of unitary value-based taxes.

Proposition 13, adopted by voters in 1978, does not limit taxes levied by Metropolitan to pay voter-approved bonded debt, including payments under the State Water Contract and debt service requirements for Metropolitan general obligation bonded debt. Ad valorem property taxes, annexation charges, and allocated county-wide taxes on utilities collected on all property within Metropolitan totaled $90 million during 1989-90. For the fiscal year, Metropolitan's secured property tax rate was 0.0121 percent of assessed value, the unsecured rate was 0.0110 percent. This equals 4.8 cents and 4.4 cents per $100 of "assessed value" respectively, as defined before Proposition 13 with assessed value recorded at one-quarter of full value. Table 46 summarizes the tax rates over the past five years, and Figure 18 shows regular tax levies.

Annexation charges levied this year totaled $6 million and total estimated future annexation charges amount to $25 million. Fiscal year income from cash annexations was $0.4 million.

Metropolitan does not record annexation receivables unless full amortization can be accomplished within 50 years following the amortization date by applying an annual tax rate of 0.0075 percent of assessed valuation or less, assuming that the annexed areas assessed valuation remains constant. As of June 30, 1990, annexation receivables of $45 million, including uncollected interest of $17 million, were not reflected as assets nor included in Metropolitan's equity.

Operating Expenses

Net operating expenses of $273 million increased $55 million over the previous year, reflecting State Water Contract credits totaling $9 million. Depreciation and amortization expenses increased $7 million to $123 million, because DWR increased the OAPF charge components. The amount of participation rights amortized is based on the total projected annual water deliveries divided into the total associated cost base. Bond interest expense, net of $7 million interest capitalized, was $57 million, an increase of approximately $11 million.

Net Income

For fiscal year 1989-90, net income decreased $37 million to $78 million. The decline resulted primarily from recording a $127.6 million OAPF loss attributable to the State's planned abandonment of the SWP South Geysers and Bottle Rock Geothermal Power Plants.

Debt Service Coverage

Debt service coverage on the outstanding revenue bonds for fiscal year 1989-90 was:

TABLE 38

DEBT SERVICE COVERAGE ON OUTSTANDING REVENUE BONDS
For the Fiscal Year 1989 90
(Dollars in Millions)

	Accrual Basis*
Water and Power Sales	$ 506
Net Operation and Maintenance Expense	273
Net Operating Revenues	233
Revenue Bond Debt Service	26
Debt Service Coverage Ratio	8.79X

Note
X = Times
* Any differences are due to rounding

Net Direct and Overlapping Bonded Debt

Table 47 presents a statement of direct and overlapping tax-supported bonded indebtedness within Metropolitan's boundaries on June 30, 1990, as prepared by California Municipal Statistics, Inc. Net direct and overlapping bonded debt totaled $11 billion, which amounts to a per capita debt of $733. As of June 30, 1990, Metropolitan's gross direct general obligation bonded debt stood at $717 million, which is approximately 0.12 percent of Metropolitan's 1989-90 assessed valuation of $619 billion (after deducting approximately $52 billion incremental assessed value associated with redevelopment agency activity).

Cash Flow Highlights (Cash Basis)

The following contain amounts based upon the cash basis of accounting which summarizes cash receipts and expenditures. Conversely, the amounts shown for the Balance Sheet and Statement of Operations are recorded on an accrual basis of accounting. This accounting procedure reflects both cash and non-cash transactions occurring in the fiscal year accounting period.

Cash Receipts

Cash receipts from water sales for fiscal year 1989-90 were $494 million. Tax receipts equaled $87 million and other receipts $68 million, for a total of $649 million, compared to an annual cash basis budget estimate of

VOL 12 1 6054

R0049359

$530 million. This was mainly due to drought conditions which increased water sales by 641,000 acre-feet over budget for the fiscal year. The receipts exceeded the budget estimate in total by $119 million.

Expenditures

Expenditures for the fiscal year totaled $543 million. This compared with an annual budget estimate of $562 million. Total net expenditures were $19 million below budget, mainly due to:

- Metropolitan operations and management expenditures were under the budget estimate due to a reimbursement of $9.0 million from the U.S. Bureau of Reclamation.
- Payments under a preliminary agreement with Imperial were budgeted to be paid in January and July of 1990, but because of a delay in reaching a final agreement only one payment was made in the fiscal year.
- Additional power credits were received from DWR due to changes in 1990 Off-Aqueduct costs. DWR bonded debt service coverage in excess of cash disbursement for debt service was returned to Metropolitan.

Cash-On-Hand at End of the Fiscal Year

Total cash-on-hand at fiscal year end equaled $674 million, excluding construction and trust funds totaling $281 million. Of this amount, $174 million was restricted, $25 million was designated for self-insurance, and $53 million was set aside in the Pay-As-You-Go Fund. Funds in the WRSF and Water Treatment Surcharge Stabilization Fund totaled $289 million and $23 million, respectively, and are designated to reduce future water revenue and treatment revenue requirements.

In accordance with current Board policy, the July 1, 1990, working capital requirement was $105 million with an additional $5 million for Imperial indirect payments. On June 30, 1990, surplus funds of $106 million and $14 million were transferred from the Water Revenue Remainder Fund to WRSF and Water Treatment Surcharge Stabilization Fund, respectively, per Board policy.

Over the next decade, the base noninterruptible and interruptible water rates are projected to increase by about 10 percent per year, assuming a utilization of the stabilization fund. The treatment surcharge is estimated to rise over the 10-year period at a rate of about 12 percent per year, taking into account the use of PEROXONE or ozone to meet the anticipated revisions in expanding treatment facilities and other enhanced treatment processes needed to meet Federal and State water quality regulations.

Metropolitan produces a myriad of materials to help teach elementary school students about water issues

CHAPTER 9

Support Functions

Human Resources Management

Recruitment and Selection

During fiscal year 1989-90, the number of Metropolitan's budgeted permanent positions increased by 109 to a total of 1,702 positions; the number of permanent employees increased to 1,667. Personnel staff filled 268 permanent positions and 209 temporary positions. Additionally, staff continued enhancing recruitment through advertising, consulting services, and expanded use of targeted recruitment sources to ensure that qualified minorities and women received employment information. Job Fair participation also attracted many qualified candidates, and thousands of inquiries were received by the Job Information Line on the PhoneMail system. To implement more timely and cost-effective selection processes, staff drafted procedures to use eligibility lists next fiscal year.

The following is a five-year summary of the number of permanent employees on Metropolitan's payroll.

End of Fiscal Year	Number of Employees (Actual)
1985-1986	1,371
1986-1987	1,416
1987-1988	1,506
1988-1989	1,569
1989-1990	1,667

Metropolitan employees are eligible to receive servic[illegible] of service, and on every subsequent fifth-year anniver[illegible] fiscal year, 72 employees with 20 or more years of ser[illegible] at a total of three Service Award luncheons hosted b[illegible] the Board and the General Manager.

Metropolitan's Summer Student Employment Program employed 61 students, including an increase in minority and female employment. Assistance was provided by the State's Employment Development Department in Los Angeles which again supplied staff and resources to recruit and screen qualified candidates for this program. Metropolitan's Personnel staff was also able to provide timely medical and security clearances for the program.

Classification, Compensation, and Employee Insurance

To obtain information on prevailing wages and benefits, the annual salary survey of 11 agencies was conducted. This and other survey information enabled Metropolitan to establish wages and benefits competitive with those in the local labor market.

Job audits continued to be a tool to ensure that Metropolitan uniformly applies its wage policy and classifies its positions appropriately. During the fiscal year, staff conducted 15 job audits resulting in the update of numerous job descriptions and implementation of new job classifications to reflect current duties and responsibilities. Additionally, consultants Becker and Bell, Inc., performed job audits for the engineering, electronic, and hydroelectric technicians and the communications series.

The Metropolitan employees' benefit package includes medical, dental, and group term life insurance. Employees also may enroll in other insurance programs such as disability, accidental death and dismemberment, and cancer and intensive care.

Health Fairs were conducted at five Metropolitan facilities during the Public Employees Retirement System (PERS) Open Enrollment period (May 1-31) for medical insurance. Representatives from most of the medical insurance carriers participated in the Health Fairs, providing informational materials and answering questions. Delta Dental, Metropolitan's dental insurance carrier, also participated. Meetings were held by Employee Benefits staff at seven Metropolitan facilities to offer employees open enrollment information and answer questions about medical insurance and other employee benefits.

Employee Relations

Effective October 1, 1989, new Memoranda of Understanding were signed, implementing three-year agreements with Metropolitan's Management and Professional Association, the Field Supervisors and Professional

Personnel Association, and the Association of [illegible] Individual contracts also became effective for [illegible] The agreements included:

1. **Salary increases of 4.5 percent** effective June 24, [illegible] **effective June 23, 1991.**

2. **An increased Metropolitan** contribution for medical insurance **rates: (a) $140 for employees only, (b) $264** for employees with one **dependent, and (c) $353 for employees** with two or more dependents **during the first contract year. During the** contract's second year, **Metropolitan's contribution will be based on 80** percent of the PERS-**CARE rate, and during the third year,** on 85 percent of the PERS-CARE **rate.**

3. **A change in the group life insurance benefit for unrepresented employees, employees represented by the Management and Professional Employees Association, and employees represented by the Association of Confidential Employees from 100 percent of annual salary with a maximum of $50,000 to a full 100 percent of annual salary, effective January 1, 1990.**

4. **A long-term disability (LTD) insurance benefit for unrepresented employees, employees represented by the Field Supervisors and Professional Personnel Association, and employees represented by the Association of Confidential Employees, effective January 1, 1990. LTD insurance provides a benefit of $1,000 per month (but not to exceed 60 percent of the employee's monthly salary) 180 days after the employee's disability begins and extends to a maximum of 2-1/2 years.**

5. **A matching contribution by Metropolitan** in the amount of 50 cents **for each dollar contributed to Metropolitan's 401(k)** savings plan, effective **January 1, 1990. The maximum contribution** for the year ending **December 31, 1990, will be 1 percent** of salary and for the year ending **December 31, 1991, the maximum contribution** will be 2 percent. **Commencing January 1, 1992, the maximum** matching contribution will **be 3 percent.**

Liability/Property Administration

The Liability Claims and Subrogation Program works [illegible] **disposition of liability claims against Metropolitan** and [illegible] **program, to minimize economic loss as a result** thereof [illegible] **recovering damages to Metropolitan** resulting from [illegible] **negligence. Staff processed 132 liability** claims and 59 [illegible] **fiscal year 1989-90.**

VOL 12 1 969--

Employee Training and Education

The Human Resource Training Section conducted 64 internal training classes covering basic skills, management skills, supervisory skills, and leadership. Approximately 913 employees participated. Beyond these programs, three four-day Project Management Workshops were held during the fiscal year involving 20 employees per workshop. Three workshops, involving approximately 58 employees, in Creating High Performance Teams were held at the request of the Management Development Club. A Team Achievement workshop also was held at Gene Village for 18 employees.

To provide a wider spectrum of available developmental resources, the Training Section purchased self-study video courses in writing skills and computer literacy, the two highest enrollment requests for the 1989-90 fiscal year. These are now available at Headquarters, and at field locations where formal workshops are impractical.

Metropolitan's Tuition Reimbursement Program financially assists full-time employees with a minimum of six months service who wish to continue their formal education. Under the program, 85 percent of tuition, books, and lab fees are reimbursed if the employee receives a grade of "C" or better per course. More than 300 applications were processed during this fiscal year.

During the second day of the New Employee Orientation Program, staff processed 179 new employees.

Equal Employment Opportunity

During the fiscal year, staff continued implementing and monitoring Metropolitan's Equal Employment Opportunity Program (Program) to assure compliance with current laws, regulations, and guidelines. Additionally, efforts to revise and enhance the existing Program continued.

Contract-initiated compliance procedures relative to Metropolitan's contractors and consultants were developed during this fiscal year. This effort's primary purpose was to ensure the participation of minorities and females as prime or subcontractors on construction contracts.

Another critical function of this section involves processing, investigating, and resolving internal discrimination complaints, as well as those received from the U. S. Equal Employment Opportunity Commission, the State of California Department of Fair Employment and Housing, the U. S. Office of Federal Contract Compliance Programs, and the U. S. Civil Rights

Commission. This year, 10 complaints were ... assistance and counseling concerning equal ... compliance was made available to all employees ... received individual counseling.

Responding to special requests from various ... employment opportunity, such as the Contract ... Department of Fair Employment and Housing, staff provided Metropolitan's statistics and procedures for recruitment and selection.

Throughout the fiscal year, Metropolitan was involved with various governmental and professional organizations, charitable functions, and community groups associated with equal employment opportunity.

The Equal Employment Opportunity Officer held regular meetings with the Equal Employment Opportunity Advisory Committee, comprised of representatives from Metropolitan's various minority organizations, the Vietnam Era Veterans Association, Metropolitan's women's association, and the employee bargaining units. This committee provides a forum for members to address relevant issues and obtain pertinent information on equal employment opportunity and affirmative action.

Environmental Safety and Health

Metropolitan's Environmental Safety and Health Program, which conforms to the California Occupational Safety and Health Act (OSHA) of 1973, is designed to promote a safe and healthy work environment and prevent industrial illness and injury.

Environmental Safety and Health issues were addressed through monthly safety training, industrial hygiene and construction safety support activities, and individual work group training sessions.

During the fiscal year, the Environmental Safety and Health staff continued to identify and evaluate health hazard situations, recommend and implement policies and procedures, and monitor work environments. Additionally, staff identified and assessed chemical, biological ... ical hazards throughout Metropolitan work areas and ... ment of proposed changes to Federal, State, and local ... Metropolitan's Environmental Safety and Health Program.

Metropolitan's accident experience in calendar ... 157 recordable injuries, 69 of which resulted in ... 424 restricted work days. Over a three-year period, Metropolitan ... 102 recordable injuries annually, 78 of which resulted ... days and 294 restricted duty days.

Based on this information, the following incident rates were computed and are compared to the Bureau of Labor Statistics rates for 1987 for the water supply industry

TABLE 49

ACCIDENT INCIDENTS

	1989	1988	Water Supply Industry
Total Recordable Injuries/Illnesses	8 99	7 76	12 36
Lost Workday Cases*	5 04	2 87	6 06
Non Fatal Cases w/o Lost Workdays	3 95	4 88	6 30
Lost Workdays**	126 42	105 15	138 00

Note

$$\text{Incident Rate} = \frac{\text{Number of Injuries/Illnesses} \times 200\,000}{\text{Total Number of Hours Worked}}$$

(200 000 = Average Work Year in Hours for 100 Employees)

* The lost workday cases rate includes cases which incurred a lost and/or restricted duty workday

** The lost workdays rate includes lost and/or restricted modified duty workdays

Protective Services

The Protective Services Program provides ongoing professional, quality protection for Metropolitan assets from natural, technological, and human threats. During the fiscal year, staff completed most of the Joseph Jensen Filtration Plant (Jensen Plant) security improvements; completed site-specific security plans for Lake Mathews, Lake Skinner, and the Robert B. Diemer Filtration Plant; expanded the program begun last year to identify and correct problems related to illegal use of Metropolitan lands; continued and expanded liaison with key public safety and emergency service organizations within Metropolitan's service area; and completed several specific-hazard contingency plans to protect Metropolitan facilities during a disaster or civil emergency.

Duber Security began providing contract guard services at the Los Angeles Headquarters Building (Headquarters) and selected field locations. Most of the security personnel employed under the previous Burns International Security Services contract were retained in the new contract, generating little loss of specialized training in emergency response due to the change.

Metropolitan's Protective Services Program emphasizes three broad areas of service: prevention, investigation, and consultation. This has resulted in reduced threats to Metropolitan's resources through greater involvement by its employees. The impact of these collective activities is reflected in Table 50.

Medical

The Medical Section safeguards Metropolitan employees by placing them in jobs for which they are medically fit without significant risk to themselves or to co-workers. As shown in Table 51, this goal is accomplished through pre-placement medical evaluations matching individuals with jobs, periodic medical surveillance to ensure that employees remain medically fit to effectively perform their job duties, compliance with OSHA requirements, job transfer evaluations to ascertain medical fitness to perform new duties, audiometric testing for employees exposed at or above OSHA limits, and return-to-work evaluations to assess employees' abilities to safely perform their jobs after serious or extended illness or injury.

Attempts are made to educate employees to become responsible for their own health by becoming informed consumers of available health services and by emphasizing lifestyle changes designed to [illegible] and prevent chronic illness. These goals were accomplished [illegible] employee counseling, wellness activities, and employee [illegible]. A formalized Employee Assistance Program was imple[illegible] 1989. In addition, the Executive Physical Program [illegible] eligible employees the option of participating in [illegible] activities in lieu of an annual examination.

Administrative Services

Purchasing

During the fiscal year, Metropolitan obtained $42,759,531 in materials, equipment, and services required for operation, maintenance, and minor construction in addition to purchasing large items under formal contracts. This total amount does not include electrical costs for water pumping or formal construction contract costs. The number of purchase orders increased about 13 percent over last fiscal year, with a total increase over the past two fiscal years of approximately 21 percent.

In other activities, an auction of used vehicles and assorted equipment brought a total of $72,368 and sale by sealed bids of salvage materials and surplus stock accrued $68,322. Colorado River and State project water treatment required purchasing 6,920 tons of liquid chlorine, 6,652 tons of liquid caustic soda, 5,349 tons of liquid alum, 3,682 tons of polymer, 595 tons of ammonia, and 576 tons of copper sulfate. This equals a 19 percent increase over last year's total chemical use.

Staff continued customizing the Procurement ... system which will automate creating, processing ... requisitions, purchase orders, and contracts ... analysis, and allow on-line receipt of material. ... were directed toward implementing the automated ... portions of this system.

Procurement system use will continue to be phased in to allow users to access sub-systems as they are completed, while development continues on the remainder of the system.

Warehousing

Decreasing $0.2 million over last fiscal year, inventory value of Central Stores stock at fiscal year end totaled $6.1 million. Total transactions (including transfers, issues, receipts, and debits) rose 8 percent during the fiscal year. Surplus stock and salvage items sold included office equipment, books, tires, wooden pallets, shop equipment and machines, and scrap metals. This represents a decrease of $203,235 from the amount disposed of during the previous fiscal year.

Last year's use of drawer-type cabinets for rapid, over-the-counter issuing of small, inexpensive items has been expanded to two additional warehouses, including the Gene Camp facility and Central Stores, which are now 25 percent converted to this system, and should be fully converted in fiscal year 1990-1991. This method saves money, reduces paperwork, and helps eliminate errors caused by repetitious issue procedures.

Headquarters Services

To accommodate new employees and relieve overcrowding at Headquarters, Metropolitan has conducted a major long-term and short-term office space allocation program, which includes the F.E. Weymouth Filtration Plant (Weymouth Plant) and Headquarters modification ... The ... increase has required leasing two floors (25,000 square feet) ... in Pasadena to accommodate 114 employees ... Administrative Services' Purchasing Branch ... in January 1990.

Metropolitan concluded negotiations on an additional ... of office space in the Pasadena building to ... additional employees from Headquarters and ... additional space needs until spring 1991 for ... Pasadena.

During a six-week period from March through April, the Headquarters floor arrangements were reconfigured to satisfy Los Angeles City Fire Code requirements. This reconfiguring included widening fire escape routes to 48 inches and removing obstacles such as tables and copiers from elevator lobbies and bookcases and file cabinets from aisles. When reinspected by the Los Angeles Fire Department, the building met Fire Code standards.

Office Services

During the fiscal year, staff expanded its services to accommodate the move of the Right of Way and Land and Finance Divisions and the Purchasing Branch to the Pasadena office facilities. This included placing a mail clerk at the facility to distribute and pick up mail and revising and updating 11 different business forms for Purchasing so that bids and other documents would be delivered directly to the Pasadena facility.

Staff converted Controller documents, deeds, and easements documentation into a micrographic retrieval system to protect these vital records from continued handling. A back-up copy of the film is stored in an off-site vital records storage vault. Staff also converted the deferred compensation hard copy files to the micrographic retrieval system to eliminate continued file growth and maintain an audit trail of compensation plan statements.

To meet the demand of reproducing reports and meeting deadlines, Metropolitan upgraded its in-house copying capabilities by installing three new state-of-the-art high-speed duplicators.

Fleet Management

During the last quarter of the fiscal year, 149 vehicles were added to the fleet at a cost of $2,184,566. An auction of 91 used vehicles netted $137,358. Future auctions will be held quarterly.

Regulation XV and the Trip Reduction Program require that employers reduce the number of vehicles commuting to the work site by promoting ridesharing participation through employee incentives.

Metropolitan's new Trip Reduction Plan has adopted a more aggressive approach toward reaching previously established goals by implementing several new policies. Among these are the Guaranteed Ride Home, which makes a Metropolitan vehicle available to any ridesharing participant in case of emergency or if required to work late. Several shuttle services have been initiated to provide efficient transportation and peripheral parking between Headquarters and other Metropolitan facilities, such as the Jensen plant, Weymouth plant, and Pasadena offices. A new service shuttles employees using public transportation (Amtrak at Union Station or the Blue Line at Pico Station).

Information Syst[illegible]

Office Automation

The automated Office System, in place [illegible] 450 users performing tasks such as sending [illegible] scheduling meetings, and maintaining daily [illegible] bulletin board informs staff of support services [illegible] and helpful hints on using the system. During the fiscal year, the office system became available to field locations.

A centralized Helpdesk was established in Information Systems to assist users in solving problems encountered while using office automation equipment. To track problems and associated solutions, a problem management system was developed and provides a repository for future reference.

The conversion from Wang to IBM workstations was completed, making it possible for users to access internal and outside information from a single workstation, saving the cost of leased equipment needed to access outside data.

Phase 2 of the Procurement System was implemented, permitting requisition of materials, products, and services through an on-line system. Routing of requisitions for review and approval is now done electronically, providing substantial time savings.

A program to account for all water in Metropolitan's distribution system and to produce invoices for water sold has been completed. Testing and implementation of this program will continue into the next fiscal year. The program enables auditing of all water distribution and invoicing transactions, as well as automatically enforcing invoice approval processes by both Operations and Finance Divisions. These and other features reduce errors, diminish the effort required to produce invoices and capture planning data, and create flexibility to accommodate new conservation programs.

Communications

Last year, Arthur Young Consulting and staff [illegible] three-phase communications plan. This year, [illegible] mented. State-of-the-art telephone systems were [illegible] ters and the Weymouth plant, producing [illegible] greater reliability, route optimization in case of [illegible] and improved disaster recovery capability. Al[illegible] all Metropolitan facilities.

Metropolitan's data network is being upgraded to meet future interconnectivity requirements between major computer systems. The increased capacity will support high data transmission volumes, water control systems, video teleconferencing, geographical information systems, and electronic data interchange systems. As part of the upgrade, a fiber-optic cabling system was installed at Headquarters and additional systems are scheduled for Weymouth and Gene facilities; these increase capacity, improve connectivity to user workstations, and support the new local area networks at Headquarters and planned for the Weymouth plant. Installing such new technologies as voice-mail, telemanagement software, digital microwave data network, and satellite systems provide the tools necessary to enhance, process, and manage Metropolitan's evolving communications network and user requirements.

Data Processing

The ability to support the expanding network of end-users of host computer services was substantially improved by installing an upgraded IBM Disk Storage System and Communications Controller as well as an Uninterruptible Power Source that will prevent data loss caused by power outages. Also, nearly 400 workstations were installed at Headquarters and at all field locations.

Preliminary plans for the Network Operations Center (NOC) recommended in the Strategic Communications Plan were completed. Phase I of the NOC plan was initiated in May 1990. The NOC will be located in a remodeled area of the Computer Operations Center on the seventh floor of Headquarters and will provide central performance monitoring of the communication network so that a reliable, continuous flow of information is maintained between users and the host computer.

Public Affairs

As California moved into its fourth year of drought, staff focused on providing information about water supply and management, drought conditions, and conservation and reclamation.

The $2-million water conservation campaign, "Be Water Tight," continued throughout the summer of 1989. Live performances at county fairs, school assemblies, and community functions augmented this campaign. Bumper stickers, restaurant tent cards, and conservation brochures were incorporated into Metropolitan's most far-reaching water conservation effort at that time.

May was declared Water Awareness Month [illegible] the water awareness of 30 million Californi[illegible] tens of thousands of brochures, magnet[illegible] materials for its member agencies and sub[illegible] Metropolitan's participation in Water Percepti[illegible] May. Co-sponsored with the Los Angeles Depar[illegible] this program drew business leaders from throu[illegible]

Water Awareness Month activities set the [illegible] ambitious $2.6-million conservation campaign for th[illegible] campaign designed to reinforce the need for water con[illegible] a way of life in Southern California. Television [illegible] advertising began in June. Working with Wells Fargo [illegible] conservation kits and literature were distributed through bank branch[illegible]

Government Relations

Staff provided local, State, and Federal officials with information needed for the decision-making processes in which they are involved. Activities included inspecting water facilities on the Colorado River and in Northern California, and participating in legislative briefings, scoping sessions, and conferences.

Issues addressed in detail by staff included siting of the proposed Eastside Reservoir, Garvey Reservoir repair and future operations, Metropolitan's opposition to expanding a controversial Azusa garbage dump which overlays a groundwater basin, the Central Pool Augmentation Project, and the effects of the drought.

Additionally, staff coordinated community breakfasts and luncheons. Opportunities to develop contacts, present Metropolitan's position on issues, and respond to special interest inquiries were gained by attending minority leadership conferences and industry and commerce conferences.

Community Relations

Staff coordinated and conducted inspection trips sponsored [illegible] of the Board of Directors and by the General Mana[illegible] [illegible] director-sponsored Colorado River Aqueduct (Aqueduc[illegible] Water Project (SWP) tours, the General Manager spon[illegible] Aqueduct and two SWP tours. There were 18 special [illegible] during the fiscal year. These included two special to[illegible] the Arizona state legislature and for executives of Ari[illegible] and associations who visited Southern California [illegible] [illegible]an's structure. A new directors' tour to Northern Cal[illegible] [illegible]nd conducted. Numerous groups, largely student[illegible] [illegible]tan's filtration plants. The total number of persons [illegible] during the year exceeded 10,000.

Metropolitan's data network is being upgraded to meet future interconnectivity requirements between major computer systems. The increased capacity will support high data transmission volumes, water control systems, videoconferencing, geographical information systems, and electronic data interchange systems. As part of the upgrade, a fiber-optic cabling system was installed at Headquarters and additional systems are scheduled for Weymouth and Gene facilities; these increase capacity, improve connectivity to user workstations, and support the new local area networks at Headquarters and planned for the Weymouth plant. Installing such new technologies as voice-mail, telemanagement software, digital microwave data network, and satellite systems provide the tools necessary to enhance, process, and manage Metropolitan's evolving communications network and user requirements.

May. Co-sponsored with the Los Angeles Department of Water and ... this program drew business leaders from throughout the metropolita...

Water Awareness Month activities set the stage for an even mo... ambitious $2.6-million conservation campaign for the summer of 1990, a campaign designed to reinforce the need for water conservation to become a way of life in Southern California. Television, radio, and outdoor advertising began in June. Working with Wells Fargo Bank, special conservation kits and literature were distributed through bank branches.

Government Relations

Staff provided local, State, and federal officials with information needed for the decision-making processes in which they are involved. Activities included inspecting water facilities on the Colorado River and in Northern California, and participating in legislative briefings, scoping sessions, and conferences.

Issues addressed in detail by staff included siting of the proposed Eastside Reservoir, Garvey Reservoir repair and future operations, Metropolitan's opposition to expanding a controversial Azusa garbage dump which overlays a groundwater basin, the Central Pool Augmentation Project, and the effects of the drought.

Additionally, staff coordinated community breakfasts and luncheons. Opportunities to develop contacts, present Metropolitan's position on issues, and respond to special interest inquiries were gained by attending minority leadership conferences and industry and commerce conferences.

Community Relations

Staff coordinated and conducted inspection trips sponsored by members of the Board of Directors and by the General Manager. There were 38 director-sponsored Colorado River Aqueduct (Aqueduct) and eight State Water Project (SWP) tours; the General Manager sponsored another eight Aqueduct and two SWP tours. There were 18 special and one-day tours during the fiscal year. These included two special tours for members of the Arizona state legislature and for executives of Arizona water agencies and associations who visited Southern California to investigate Metropolitan's structure. A new directors' tour to Northern California was planned and conducted. Numerous groups, largely students, toured Metropolitan's filtration plants. The total number of persons visiting Metropolitan during the year exceeded 10,000.

Staff assisted in planning, coordinating, and implementing meetings of the National Water Resources Association's Municipal Caucus and of the Southern California Water Conference and chaired the Public Affairs Committee and served on the Exhibits Committee of the Colorado River Water Users Association. Community relations activities at meetings of the Association of California Water Agencies, the California Water Resources Association, the National Water Resources Association, and the Colorado River Water Users Association were planned and conducted. Staff participated in forming the Colorado River Resources Coalition, an organization representing water users, farmers, municipalities, and power distributors working together to better inform the public and Congress of the Colorado River's many economic, industrial, and environmental values.

Two Directors' Emeritus luncheons, designed to update former Metropolitan directors on current issues, and a Directors' Workshop were planned and coordinated, and two Public Information Liaison Committee meetings were held to keep public affairs staff of member agencies and subagencies apprised of current activities.

Metropolitan's Speakers Bureau members spoke to more than 29,000 persons during the year. The most requested topic was the continuing drought. To publicize the Speakers Bureau, a brochure was developed that includes a request-for-speaker form. To provide updates to members, quarterly meetings were held, and two training sessions were conducted for new speakers. Staff developed a Speakers Bureau workbook to provide an overview of Metropolitan's history and issues past, present, and future.

Education Programs

Metropolitan's elementary program was distributed through in-services to 951 fourth- and sixth-grade teachers. These educators, new to the program, plus those who were resupplied with materials this year, taught the "Admiral Splash Water for Less" programs to approximately 90,000 students during the 1989-90 school year. The kindergarten through sixth grade assembly programs were rewritten and presented to some 15,300 students. Hands-on water science experiments were conducted with approximately 1,600 students during the year.

Three high school water education programs, "Water Quality," "Water Highways," and "Water Economics," were developed and produced. The units were presented to 83 teachers during the first month of availability. Implementation of the high school program officially begins during the 1990-1991 school year. The Water Quality unit was featured in a segment of the local CBS evening news in May 1990.

"Geography of Water" materials were introduced [illegible] four through eight, and approximately 2,000 teachers [illegible]. Teacher evaluations have been positive.

Staff conducted two college-credit classes, one for elementary and one for high school teachers, with a total of 100 educators participating. Topics covered included hydroelectric generation, water quality, water distribution, water politics and conservation. Teacher feedback was extremely positive.

Publications

Articles included in *Aqueduct*, Metropolitan's tri-yearly magazine, and *Focus*, its bimonthly newsletter, reflected the serious issues facing Metropolitan and the entire water industry today: urban and agricultural water use, long- and short-term water storage agreements, water quality regulations, environmental issues, water marketing, and conservation, among others. Several requests to reprint articles were granted to local, national, and international publications. Subjects included the drought, bottled water, growth, and water quality.

An education programs brochure was developed for use on Metropolitan inspection trips. "The Pacesetters," a brochure detailing the structure of the Board of Directors, and various water quality and conservation brochures were updated. The conservation newsletter *WaterScape* and the bimonthly internal *People* were also produced.

More than 500,000 pieces of literature, in addition to the regularly scheduled publications, were distributed through the exhibits program, display racks, speaking engagements, and member agencies' mail and phone requests.

Media

The drought continued to draw major interest from local, regional, state, national, and international media. Staff assisted radio and television stations with their efforts to produce water awareness programming. Drought stories promoted by Metropolitan news releases included the request for drought ordinances from the cities within the [illegible] and the possible wheeling of water into northern Ventura and Santa Barbara Counties.

The election of Lois Krieger as Chairman of the Board of Directors to complete the term of late Chairman E. L. Balmer was an historic [illegible] and produced wide interest.

Following the San Francisco Bay area earthquake, staff responded to media requests that centered on Metropolitan's ability to withstand a major quake and how repairs would be accomplished and water service restored.

News conferences were held to explain Metropolitan's position in attempting to block the expansion of the controversial Azusa garbage dump and to cover the historic signing of the agreement with Imperial Irrigation District (Imperial).

The discovery of a leak in the Garvey Reservoir floor also drew media attention. Public meetings, press conferences, and an opinion survey were conducted.

Additionally, information was provided to media outlets regarding the State Water Resources Control Board's San Francisco Bay Sacramento-San Joaquin Delta hearings, the seasonal storage program, the Eastside Reservoir project and related land acquisition, water reclamation, and water quality issues.

Staff also participated in visits to major Northern California newspapers. As a result of these meetings, several favorable editorials were published recognizing Metropolitan's and all of Southern California's efforts in water conservation and the positive action taken by Metropolitan in negotiating proposed agreements with Imperial and the Arvin-Edison Water Storage District.

Special inspection trips to the Imperial Valley, the Colorado River, and Mono Lake were conducted for local reporters.

Right of Way and Land

Acquisition

Right of Way activity reflected the increasing number of projects ranging from those still in planning stages to those certified for construction. Staff began acquiring parcels for the Etiwanda Pipeline connecting the Foothill Feeder to the Upper Feeder and traversing the cities of Fontana and Rancho Cucamonga. Although construction of the San Diego Canal enlargement is almost complete, nine additional temporary construction easements were acquired.

The major acquisition during the year was the 4,197-acre Searl Ranch, one of the sites under consideration for the Eastside Reservoir, for $26,500,000. Consultants working with staff provided mapping, title, and escrow coordination, document review, and administration of assigned leases subsequent to acquisition. Two additional parcels located within potential Eastside Reservoir sites also were acquired. One parcel comprising 227 acres was bought for $5,250,000 and the other, comprising 9.89 acres,

was purchased for $164,000. Additional prope[illegible] or appraised for acquisition. In addition to [illegible] several easements were obtained to preserve acc[illegible] surrounding land is developed.

Entry permits for pre-bid inspections were acquired [illegible] by the Etiwanda Pipeline. To assist project planning, staff obtained numerous entry permits for observation and geotechnical purposes on potential sites for the Eastside Reservoir, Lake Perris Treatment Plant and Reservoir expansion, and Eastside Reservoir mitigation. Staff also monitored the acquisition of 811 entry permits obtained by consultants in connection with site studies for the Inland Feeder and San Diego Pipeline No. 6.

During the last several months of the fiscal year, staff has been obtaining entry permits for observation of the Westside Conveyance Study project. Involving 185 parcels of land, the project consists of six study routes from Lake Castaic in north Los Angeles County, through the Santa Clarita Valley to the city of Fillmore, and south to the city of Thousand Oaks. Entry permits for observation purposes also are being obtained for the proposed Lake Mathews Treatment Plant, to be located west of Lake Mathews and east of Highway 15 in the Corona area of Riverside County, consisting of 23 parcels of land.

Advance acquisition activities are continuing for properties within potential sites of the Eastside Reservoir, South Orange County Treatment Plant, Westside Conveyance Project, Palo Verde Irrigation District, and various environmental mitigation areas. These activities include property owner contact, search of public records, tract map surveillance, mapping, title search, appraisal, writing of legal descriptions, and obtaining entry permits for observation and geotechnical purposes.

A total of 24 fee, permanent easement, and temporary easement parcels were acquired by direct negotiation with property owners. Table [illegible] lists the year's right of way acquisition projects.

Surplus Property

Surplus property sales activity remained low this [illegible] concentrated on acquisition and advance acquisition [illegible] tan sold one surplus parcel, containing approximately [illegible] for $27,000 cash. At fiscal year end, eight promissory note[illegible] of trust on properties previously sold were in effect. [illegible] of trust secure notes bearing fixed interest rates of 12[illegible] principal balance of the notes outstanding at the end [illegible] amounted to $778,559, while the principal and inte[illegible] ceived during the fiscal year amounted to $175,411.

Land Management

Currently, Real Property staff is administering 161 separate secondary uses of Metropolitan's fee property, generating $307,811 in revenue from these uses, an increase of $34,181 over last fiscal period. These secondary uses are granted to governmental agencies, public utilities, and private individuals, by granting easements or issuing licenses, leases, or entry permits for uses ranging from street widening, underground utilities, agriculture, or access. During last fiscal year, the property acquired for the proposed Eastside Reservoir included six existing leases which produce an annual revenue of $72,000.

Conversely, Metropolitan must occasionally lease private property for satellite offices, to operate and maintain its facilities, or for office space for its governmental representatives in Washington, DC, Sacramento, and Orange and Imperial Counties. There are seven such leases in effect, totaling $493,604 in annual rent payments.

Real Estate Appraisal and Land-Use Activities

Staff coordinated and reviewed appraisal work performed by contractors, and completed rental valuations for Metropolitan's use. Additionally, staff appraisers provided appraisal consultation services to the Planning, Engineering, and Operations Divisions, the General Manager, and the Legal Department.

Staff Appraisals

Staff conducted appraisals of secondary use, permanent pipeline, and temporary construction easements, and conducted rental surveys to aid in determining market rental rates for tenant-occupied parcels. Also completed were appraisals of fee interests required for Metropolitan projects, as well as fee interests of surplus properties. Staff prepared a planning-level cost analysis of a potential environmental mitigation area for the proposed Eastside Reservoir, westerly of Temecula. This mass appraisal involved 19 parcels totaling 5,665 acres of raw land. An update survey of vacant potential residential subdivision land sales, in the coastal Orange County area, was conducted by appraisal staff to review any market changes which would bear on the possible disposal of Metropolitan's Bolsa Chica property.

Independent Consultant Appraisers

Staff negotiated and processed 39 contracts to retain the services of independent real estate appraisers to value private ownerships comprising over 25,000 acres of land at the Domenigoni Valley, Vail Lake, and Potrero

Creek potential reservoir sites. Scoping and pr[illegible] were conducted with all independent consult[illegible]. Additionally, staff reviewed appraisal reports su[illegible] appraisers.

Standard general conditions were developed for attachment to appraisal contracts for acquisition appraisals. Special instructions were prepared to inform independent consultant appraisers of government code and evidence code requirements. Staff developed a final draft of division appraisal report procedures, which address staff appraisals and include descriptions of the minimum requirements for the various types of appraisal reports and consultations the division provides.

To facilitate the real estate appraisal and due diligence investigations of 18 separate ownerships to protect lands at potential Eastside Reservoir sites, staff retained the services of private consulting engineers to perform environmental, civil, and cost engineering services.

Land-Use Studies

A highest and best use feasibility study of property located within the potential Domenigoni Reservoir site was completed as a part of the Eastside Reservoir Study. The analysis investigated the property's potential susceptibility to the threat of development.

Staff completed a cost and planning study of vacant land surrounding the chemical unloading facility (CUF) for possible acquisition to provide a buffer zone to protect other uses in the area from the potential nuisance of CUF activities. The cost and planning study involved a land use feasibility study, land value range estimation, and acquisition cost estimation.

Staff completed an office availability study in the Pasadena, San Dimas, and La Verne areas of Los Angeles County.

Annexation

Eight annexations to Metropolitan were completed and processed increasing the service area by 1,724.52 acres. Seven annexations became effective in Riverside County; one became effective in Ventura County to Calleguas Municipal Water District. Total annexation charges amounted to $1,414,592.

Metropolitan's Board of Directors granted formal approval for 11 concurrent annexations and gave informal approval for [illegible] annexations.

VOL 12 1 5 9 7 - 9

R0049375

The city of Oceanside was able to annex one area, comprised of 876.46 acres, without Board approval because of its automatic annexation privilege. Metropolitan's total service area, as of June 30, 1990, consisted of 5,141.94 acres, an increase of 4.05 square miles from the previous year.

Staff reviewed 40 redevelopment projects to determine if either Metropolitan's facilities or tax base would be affected. Staff processed and paid 221 property tax statements for a total tax payment of $59,887, including an additional tax assessment of $1,315. This resulted from acquiring Parcel No. 145-1-25 for the portion of Eastside Reservoir property lying outside Metropolitan's boundaries. Also included were the escaped assessments for fiscal year 1983-84 amounting to $2,029. Street lighting and maintenance assessments of $10,035 on Metropolitan properties located within its boundaries were paid.

Statement of Change of Boundaries

Metropolitan filed the annual Statement Change of Boundaries with the State Board of Equalization and the County Assessors of the six counties in which Metropolitan's service area boundaries extend. Filed on December 29, 1989, the statement indicates any changes in the boundaries of Metropolitan's member agencies which amended Metropolitan's service boundaries during the previous calendar year.

Automation

Increased reliance on microcomputers and computer network systems to centralize data, decrease duplication of data and effort, and increase efficiency led to installing new hardware and software systems. These systems encompass word processing, mapping, real estate data spreadsheets, and legal description programs. To ensure the systems' efficient use, an on-going training program has been implemented to keep staff informed of and skilled in the use of new hardware and software.

The Information Retrieval System, a data base designed last year to provide essential facts and figures relevant to each Metropolitan-purchased parcel, has been completed and staff has formed a team to continuously update and improve the data base.

Survey and Legal Description Approval

This fiscal year, a Licensed Land Surveyor was added to staff to expedite the processing of legal descriptions set forth on documents used in acquisition and leasing. The surveyor processed 164 documents in addition to reviewing ALTA surveys of prospective acquisitions submitted by Metropolitan surveyors. He also established guidelines for legal descriptions and

maps for public agencies, corporations, an[illegible] permanent or temporary easements, leases, [illegible] politan property.

Project Management

Anticipating future growth, the consulting group of [illegible] conducted a study of the Right of Way and Land Division's automation needs to document current responsibilities and develop a man loading forecast. The study provided a timeline for 45 capital projects, identified five-year work force needs, suggested opportunities for both multi-division project management and exclusive Right of Way and Land Division project management, provided estimates of mapping capacity and appraisal capacity, and suggested historical data storage and retrieval methods. These recommendations are currently being reviewed for implementation.

During a Lake Mathews shutdown, workers perform scheduled maintenance to replace valve stems and add cathodic protection to the gate valves.

CHAPTER 10

Internal Audit

Metropolitan's Audit Department performs internal financial and compliance audits as well as miscellaneous reviews or special audits. The Auditor reports directly to the Board of Directors through the Audit Subcommittee of the Finance and Insurance Committee. He works closely with Metropolitan staff, but is independent of general management.

Internal audit assignments are usually selected by the Auditor and are occasionally requested by the Board of Directors or management. Detailed audit testing is preceded by appropriate planning and coordination with management or staff. Upon completing all significant audit assignments, a report is issued to the Board of Directors and copies are provided to management. In accordance with internal auditing standards, the typical audit report outlines the objectives and scope of the work performed, the audit findings noted, and any recommendations for corrections or improvements which the Auditor feels are warranted in the circumstances. Beyond internal audit assignments, the Auditor and his staff provide substantial assistance to Metropolitan's external auditor in conducting quarterly financial audits and the year-end audit required by the California Government Code and Metropolitan bond covenants.

During fiscal year 1989-90, the Audit Department issued a variety of reports pertaining to financial, compliance, electronic data processing (EDP), and special auditing matters. Aside from the aforementioned assistance provided to the external auditors, major assignments completed and reported on during the year included (in chronological order of issuance):

- Review of Metropolitan Bond Records and Controls—Follow-up Procedures, dated August 31, 1989.
- Compliance with IRS Restrictions on the Use of Revenue Bond Proceeds for Hydroelectric Facilities, dated October 31, 1989 (joint letter with General Counsel).
- Review of October 1989 Inventory of Gene Stores Warehouse, dated November 28, 1989.

- Review of Transmission of Payroll Automatic Deposit to Security Pacific National Bank, dated November 28, 1989.
- Review of Reimbursable Taxes Section Functions, dated December 28, 1989
- Review of Biennial Inventory of Operating Equipment as of September 30, 1988, dated January 19, 1990.
- Limited Review of the 401(k) Savings Plans, dated January 22, 1990.
- Review of March 1990 Physical Inventory of Central Stores, dated May 22, 1990
- Review of Metroplitan Compliance with the Federal Single Audit Act, dated May 23, 1990.
- Review of the 1990-91 Annual Budget, dated May 25, 1990.

The results of these audits, together with management's responses to the Auditor's recommendations, are discussed in detail with the Audit Subcommittee. The Audit Subcommittee met four times during fiscal year 1989-90.

In addition to the aforementioned assignments, a number of other meaningful assignments were completed during fiscal 1989-90 for which formal audit reports were not prepared. Instead, when applicable, management and appropriate staff received summaries of the results of these reviews for their information and possible action. The following assignments fell into this category:

- Review of the Official Statement for Metropolitan's 1989 Series "G" General Obligation Bonds.
- EDP Review of the Finance Division's Local Area Network (LAN).
- Review of Treasurer's Proposal to Replace Canceled Checks with a Bank Microfilm System.
- Compliance Review of Insurance Certificates Required for Construction Contracts and Consultant Agreements.
- Review of Security Contract Compliance.
- Review of the General Manager's Quarterly Reports to the Land Committee.

INTERNAL AUDIT

At June 30, 1990, the following significant financial a[illegible] of EDP and many smaller assignments, were in pro[illegible]

- Review of Water Rate Adjustments Credits
- Review of Metropolitan's Disaster Contingency Planning
- Survey and Review of Local Projects Programs
- Review of Selected Construction Contracts

In some instances, completion of these assignments was delayed due to other work priorities or other factors. All are expected to be completed during fiscal year 1990-91.

In addition to the preceding assignments, Audit Department personnel participated in many other short-term or recurring assignments. Recurring assignments include reviews of the Monthly Financial Reports, audits of submitted directors' and department heads' expense claims, audits of selected employees' expense claims, quarterly reviews of water inventory and deferred water rights computations, and quarterly reviews of Budget vs. Cost Reports.

During fiscal year 1989-90, audit personnel also reviewed drafts of Metropolitan's comprehensive Annual Financial Report for the fiscal year ended June 30, 1989; tested the accuracy of the 1989-90 tax levy documentation; reviewed Metropolitan's compliance with its June 30 and December 31, 1989, minimum fund requirements; reviewed quarterly lobbying reports which are required by the Fair Political Practices Act to be filed with the State; tested various work orders for propriety and compliance with Metropolitan's procedures, and reviewed security activities on a quarterly basis for matters having audit implications.

While the results of these recurring or short term as[illegible] generally satisfactory, written comments on such revi[illegible] recommendations, if appropriate, are often provided to [illegible] staff for their information and possible action.

Among the more significant of corporate-wide s[illegible] projects with which the department's EDP auditors we[illegible] fiscal 1989-90 include the Accounts Payable System [illegible] System, and the Water Accounting and Classification Fi[illegible] In addition, the EDP auditors are currently monitoring [illegible] development of the Investment Management System a[illegible] Expense System for the Finance Division. The EDP audit[illegible] a significant amount of time during the year working on [illegible] and security issues pertaining to the Wide Area Network in [illegible] the Finance Division LAN in particular.

As a result of turnover and almost continuous involvement by the EDP auditors in various systems development activities, specific computer application reviews were not performed to the level anticipated during the year. While internal audit involvement in the development and testing of new automated financial systems remains a top priority, the review of some of the key computer applications is also a priority objective next year.

PREFACE AND ACKNOWLEDGMENTS

This report represents Volume I from a series of four volumes of reports which form the basis of a pollution assessment and monitoring plan for Santa Monica Bay. Volume I describes storm drainage system land use statistics, catchment areas, existing water quality monitoring data, rainfall data, NPDES permit information for existing permits to storm drains, and contaminant mass emission estimates, based upon land use modeling. Volume II reviews sampling techniques, including sampling equipment, and other aspects associated with sampling such as a quality assurance plan. Volume III presents the proposed monitoring plan. Volume IV addresses best management practices as they apply to the Santa Monica Bay area. The first draft of this volume was issued in February, 1992.

The contract was performed by UCLA and Woodward-Clyde Consultants (WCC). Professor Michael K. Stenstrom of the Civil and Environmental Engineering Department, UCLA and Eric Strecker from WCC's Portland office were the project managers. There were several key individuals from both UCLA and WCC who assisted with the project; they include Sim-Lin Lau and Kenneth Wong (UCLA) and Lou Armstrong, Gail Boyd, Carol Forrest, and Joan Kersnar (WCC).

The contractors are grateful for the assistance of many individuals. The Santa Monica Bay Project and LA Regional Water Quality Control Board staffs were most helpful. We extend our special thanks to Dr. Guang-yu Wang, Ms. Catherine Tyrrell, Dr. Rainer Hoeinke and Mr. Xavier Swamikannu. Several public agencies were very helpful in providing data and information to us. The Los Angeles County Department of Public Works and the Southern California Association of Governments (SCAG) provided catchment area and land use data, respectively. We are also indebted to the members of the Technical Advisory Committee of the Santa Monica Bay Project and others who reviewed and commented on our draft reports.

ABSTRACT

This report describes the collection of data and land use information to estimate pollutant loads to Santa Monica Bay from stormwater runoff. A pollutant load is calculated by multiplying the flow rate or discharge of water by a pollutant concentration. The type of land use influences the pollutant load by either increasing or decreasing the fraction of impervious surface area (the higher the impervious area, the larger the runoff). The quality of stormwater runoff may also vary by land use. Therefore, pollution loading from a particular watershed can be formulated as a function of the areas of each of the various land use types that form it. Given this, a simple pollutant load model can be developed such that the sum of the products of the runoff from each land use type times the concentrations associated with each land use type equals the total load. The generic equation is of the form:

$$\Sigma M_a X_a = Y$$

where:

- X_a is the estimated runoff generated from land use "a"
- M_a is the estimated concentration for land use "a"
- Y is the calculated total load
- Σ is the summation over all land uses

To estimate the pollutant loadings of stormwater runoff from the Santa Monica Bay catchments, a form of the above equation was used. The methodology is similar to the methodology developed under the EPA's Nationwide Urban Runoff Program (NURP, EPA 1983), and was adapted to a simple spreadsheet model. This model uses available local data for rainfall, land use, and drainage area characteristics. It differs from the NURP methodology in that it uses different land use specific runoff pollutant concentrations for different land use types, where NURP used the same pollutant concentrations for all land use types.

The following steps are used in computing the annual pollutant loadings and concentrations:

- Organize rainfall data into storm events. The storm events data are then analyzed to estimate average storm volume, storm intensity, storm duration, time between storms, and number of storms per year. Spatial variability in rainfall between catchments is accounted for by calculating a rainfall correction factor to scale the storm statistics to from a single rain gage to all the catchment. Data from small rainfall events not expected to produce runoff (less than 0.1 inches) are eliminated.

- Determine land use characteristics. The drainage basins are divided into a series of catchments and the land use acreage is tabulated for each catchment. This was accomplished by use of a GIS system, where land use areas were calculated within the delineated catchments. For each land use type, the percentage of impervious area is used to estimate the runoff coefficient, the ratio of runoff to rainfall.

- Determine average storm and annual runoff. Total volumes and flow rates for each catchment are estimated by combining rainfall statistics, rainfall correction factors, runoff coefficients, and drainage area.

- Determine the pollutant concentration associated with each land use. The data collected by NURP were compared to local data by comparing the frequency distributions for both data sets. It was found that the 90th percentile concentration data from NURP (i.e. concentrations that were 90% higher than the rest) were approximately equivalent to the median concentrations (50% higher than the rest) collected in the Santa Monica Bay area.

- Multiply the runoff volumes by concentration. Concentrations of water quality parameters typically found in urban runoff, obtained from the NURP database, are multiplied by the runoff volumes to yield average annual pollutant loads for each land use area in each catchment.

- Calculate total loads. Total loads for each catchment are calculated by summing the loads for each of the land uses. The average concentration for each catchment is then estimated by dividing the total load for the catchment by the total runoff from the catchment.

The above methodology indicates that significant pollutant loads are coming from residential areas. This does not mean that residential areas are necessarily more polluted than other areas, but instead that, given the large amount of residential area in the Santa Monica Bay area, it contributes the most runoff. It does however suggest that cleaning up the residential areas a small amount will have the same affect in reducing loads as cleaning up a dirty industrial area a lot.

This report (Volume I) provides the information basis for the development of Volume III (monitoring plan development) and Volume IV (best management practices) of this project.

INTRODUCTION

Annual pollutant loadings are influenced by the spatial and temporal rainfall pattern, the total area of the drainage basin, and the distribution of different land use types in the drainage basin. The type of land use influences the total volume of runoff by either increasing or decreasing the fraction of impervious surface area (the higher the impervious area, the larger the runoff) and, as a result, the pollutant loads.

A number of studies have been conducted to investigate the concentration and loadings of a variety of pollutants in stormwater runoff. Urban runoff pollutant concentrations and loadings were studied in depth by the US Environmental Protection Agency's (US EPA) Nationwide Urban Runoff Program (NURP). WCC directed and completed a number of studies for the EPA under this program. The NURP program included the coordination of urban runoff pollutant studies at 65 urban sites across the United States, which included monitoring of over 2,000 storm events. In addition to the site-specific reports produced during this study, EPA published the Final Report of the Nationwide Urban Runoff Program (US EPA, 1983). The report summarized the findings of the research and presented a methodology for predicting pollutant loads from urban watersheds using a statistical approach. Other related studies conducted for US EPA include the analysis of detention basins for control of urban stormwater runoff quality (US EPA, 1986) and the development of a probabilistic, statistical methodology for predicting pollutant loadings and concentrations from stormwater runoff and their impacts on rivers and streams (US EPA, 1984). The oil and grease information used in this report is based heavily upon the work by Stenstrom et al. (1984) and Fam et al. (1987)

The Federal Highway Administration (FHWA) study analyzed the characteristics of pollutant loadings and concentrations found in highway runoff. This study involved the analysis of highway data collected from 31 highway sites throughout the United States and included approximately 1,000 storm events (Driscoll et al., 1990). As part of the study, a methodology for predicting pollutant loads and concentration from highways and street surfaces was developed (FHWA, 1987).

A small pollutant load study was presented in the State of the Bay report (SCAG, 1988). This study evaluated at loads from Ballona Creek, Malibu Creek, and the Pico-Kenter storm drain. The study calculated loads by using flow data and pollutant concentrations from 1983-84. The analysis is limited since only two years of flow data were used; furthermore, one year was very wet and the other year was dry. An addition limitation is the use of averaged dry and wet weather concentration data. This would tend to under predict the concentrations of the pollutants studied because wet weather concentrations tend to be higher than dry weather concentrations for most contaminants.

The goal of this study is to estimate the annual loads to Santa Monica Bay, in such a way that they can be used to easily identify catchments with the largest expected contribution of each pollutant. The catchments can be prioritized based on pollutant loadings and/or concentrations, and this information can be useful to others who might wish to prioritize the catchments on the basis of the receiving water's ability to assimilate the discharge. Monitoring sites and types and locations of best management practices (BMPs) can be targeted at those catchments having the highest levels of pollutant concentrations and loadings and the greatest potential for improvement. In addition to aiding in the

VOL 12

15084

To estimate the pollutant loadings of stormwater runoff from the Santa Monica Bay catchments, a modified version of the methodology developed under the US EPA's Nationwide Urban Runoff Program (US EPA, 1983) was adapted to a simple spreadsheet model. This model uses available local data for rainfall, land use, and drainage area characteristics. It differs from the NURP methodology in that it uses different land use specific runoff pollutant concentrations for different land use types, where NURP used the same pollutant concentrations for all land use types. The loadings for each of the catchments were calculated by multiplying the volume of runoff for each area with its associated land use concentrations. The loadings for each drainage basin were calculated by summing the results from contributing catchments.

2.1 RAINFALL STATISTICS

Average annual rainfall statistics were used to calculate the estimated pollutant loadings to the receiving waters for an "average" year. The amount of rainfall that the watershed receives annually, however, is quite variable from year to year. Hence, the pollutant loadings can vary appreciably from year to year.

In the Santa Monica Bay watershed, rainfall is measured at rain gage stations operated by the National Weather Service (NWS) and by local flood control and water supply districts including the Los Angeles County Department of Public Works (LACDPW). Table 1 lists those gages selected for detailed analyses in this study because of location, record completeness, and the availability of data in electronic format from the NWS. For each of these stations, the location (latitude and longitude), elevation, period of record, record completeness (in percent), and average annual rainfall are shown in the table. Figure 1 shows the location of gages in operation during 1988-89.

The rainfall record at the Los Angeles Airport (Station 5114) was analyzed to determine wet and dry seasons at Santa Monica Bay. The average monthly rainfall volumes and subtotals for each season are shown in Table 2, and the seasonal variation in rainfall is shown graphically in Figure 2. Based on average monthly rainfall volumes, the period from November through April is defined as the wet season and the remaining period is defined as the dry season for the study area. The wet season receives over 93 percent of the annual rainfall, as shown in Table 2. The analyses that follow focus on the wet season.

To illustrate the annual variation in rainfall, the wet season rainfall totals for selected gages are tabulated as shown in Table 3. The average wet season rainfall for the Los Angeles Airport gage is 10.72 inches with a standard deviation of 5.42 inches. Figure 3 shows the time series plot of the wet season rainfall for this gage. The horizontal lines in the figure represent the record average and one standard deviation above and below the average. Annual variations that have occurred at the other stations are similar.

To compute average runoff volumes at the site, data on rainfall duration, intensity, volume, and time between storms are required. Detailed analysis of the rainfall record of hourly data is performed using a statistical analysis program developed for the US EPA (US EPA,

VOL 12

1 6085

development of a stormwater quality management program, estimates of the annual pollutant load of the cumulative discharges to waters of the United States are required for Part 2 of the National Pollution Elimination System (NPDES) Stormwater Permit Application for municipalities. A description of the procedures used to estimate pollutant loads must also accompany the permit application.

This brief report summarizes the methodology and results of pollutant loading calculations for the Santa Monica Bay watershed. The general methodology, land use characteristics, water quality parameters, and intermediate results used to calculate the pollutant loadings are presented in the next section. Data collected by the various monitoring agencies were brought together and placed into a single ASCII data set. Summaries of the annual pollutant loading calculations by land use type and by drainage basins are given in the third section. The last section contains conclusions and recommendations based on these results.

Two appendices are provided. Appendix A summarizes the land use and annual pollutant loadings by catchment. Appendix B describes the collected data and a program provided to help sort the data for specific locations and parameters. A summary of the average dry and wet weather contaminant concentrations for 22 selected locations is also included in the Appendix B.

To estimate the pollutant loadings of stormwater runoff from the Santa Monica Bay catchments, a modified version of the methodology developed under the US EPA's Nationwide Urban Runoff Program (US EPA, 1983) was adapted to a simple spreadsheet model. This model uses available local data for rainfall, land use, and drainage area characteristics. It differs from the NURP methodology in that it uses different land use specific runoff pollutant concentrations for different land use types, where NURP used the same pollutant concentrations for all land use types. The loadings for each of the catchments were calculated by multiplying the volume of runoff for each area with its associated land use concentrations. The loadings for each drainage basin were calculated by summing the results from contributing catchments.

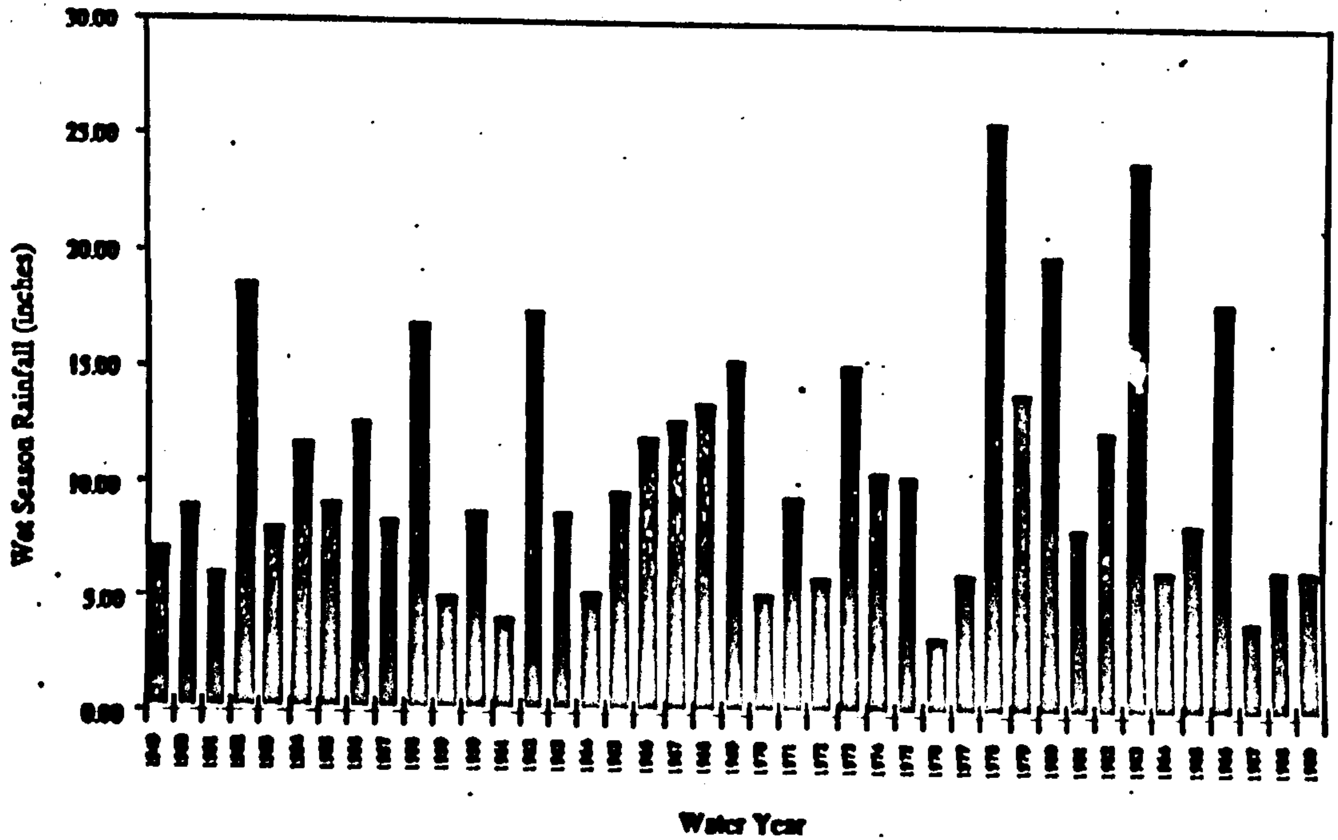

Figure 3. Wet Season Rainfall at Los Angeles Airport
(Station 5114)

1980) and updated by WCC for the US EPA and FHWA in 1989. The procedure used in the Synoptic Rainfall Analysis Program (called SYNOP) segregates the hourly rainfall record into discrete storm "events" by defining the number of consecutive dry hours that separate events (inter-event time). Then, for each "event," the total volume, duration, average intensity, and interval between storm event midpoints are computed. SYNOP performs a standard statistical analysis to compute the mean, standard deviation, and coefficient of variation for all of the event statistics.

Because only those rainfall events which produce runoff are of interest in this study, the minimum storm volume analyzed to produce average storm statistics is set at 0.10 inches. Therefore, all storm "events" with a volume of less than 0.10 inch are removed from the analyses based on evidence that these smaller events generally do not generate significant runoff volumes. A 6-hour inter-event time is also used to define the discrete storm "events". That is, hours of rainfall separated by 6 or more hours of dry weather are considered to be parts of separate events. These parameters have been used in other studies conducted by WCC in the Los Angeles area and in a national rainfall analysis prepared by WCC for US EPA (US EPA,1989). All computations are conducted for the wet season, a 6-month period ending on April 30 of the indicated year. The entire period of record is used for each of the gages, excluding partial years associated with the starting and ending dates of the records.

The results of the analyses for all storms in the period of record for the selected Santa Monica Bay rain gages are summarized in Table 4. The statistics shown in this table include storm volume, intensity, duration, and time between storm events (delta) averaged over all storms used in the analyses. The coefficients of variation for each of the summary statistics are also shown. For the Santa Monica Bay watershed, the average wet season storm volume varies from 0.67 to 1.09 inches with an average intensity of 0.061 to 0.101 inches per hour and duration of 10.5 to 14.2 hours. The time between storms varies from 198 to 258 hours (or 8 to 11 days) during the wet season. Approximately 16 storm events occur on average during each wet season.

There is a strong spatial variation in rainfall due to topographic influence in the Los Angeles area, which leads to uneven rainfall amounts over basins in the Santa Monica Bay area. Isohyetal maps (maps with contour lines of equal rainfall amounts) provide a good tool for identifying these rainfall patterns. The LACDPW publishes isohyetal maps of annual rainfall totals in the study area in its annual hydrologic reports. The 1988-89 seasonal total isohyetal map is shown in Figure 4. An isohyetal map of the 50-year, 24-hour rainfall event is also available from LACDPW and is shown in Figure 5. Figure 6 shows an isohyetal map of average storm volumes developed from the storm event analyses and the patterns found in the above mentioned isohyetal maps.

To assign rainfall characteristics to each catchment delineated for the Santa Monica Bay watershed, the statistics for one gage, the Los Angeles Airport gage, are used as the point-of-reference for all locations. Rainfall correction factors are used to scale the rainfall volumes for each catchment to reflect spatial variations within the watershed. The rainfall correction factor is essentially a modeling tool that allows a single reference gage to be used as input data. For each catchment rainfall volumes are calculated as the reference gage volume multiplied by the correction factor spatial variability in rainfall that occurs between catchments throughout the Bay drainage area. The rainfall correction factors for average storm volumes are computed using the Los Angeles Airport gage average storm volume of 0.68 inches as the basis. These factors are combined with the isohyetal map shown in Figure 6 to assign rainfall correction factors to each catchment. The results are shown in Figure 7. Average storm duration and number of storms per season do not vary as greatly as storm volumes and were assumed constant for all catchments.

2.2 LAND USE CHARACTERISTICS

Parameters used to compute the rainfall-runoff relationship and pollutant concentrations are based on land use categories. Land use data and acreage breakdown is available from the Southern California Association of Governments. The data were collected in 1987 by AIS under contract with Southern California Edison as part of a comprehensive coastal inventory. The land uses were photo interpreted then mapped. The complete data set covers approximately the area from Point Arguello to the United States/Mexico border and about 5 miles inland. The following categories are used:

- Single-family residential areas including duplexes and group quarters,
- Multi-family residential areas including mobile homes,
- Commercial areas including wholesale and retail trade and general services,
- Public lands including government offices and schools,
- Light industrial areas including manufacturing facilities,
- Other urban areas not included under the other categories,
- Open spaces including parks and undeveloped lands, and
- Unknown land use classification.

Drainage basins are defined as areas that drain to Santa Monica Bay and are made up of several smaller catchments. The land use acreage for each catchment are provided in Appendix A (Table A-1). Summaries for the drainage basins and the entire watershed are given in Tables 5 and 6. Open space represents the primary land use in the watershed (57 percent of the total watershed). Single-family residential areas represent the largest developed area (26 percent of the total watershed). Seven percent of the total watershed consists of multiple-family residential land use. Other urban land uses including commercial and light industrial uses constitute the remaining 10 percent of the total watershed area. As shown in Table 6, drainage basins 1 through 19 are more than 65 percent open, whereas drainage basins 18 through 28 are mostly urbanized (residential, commercial and/or industrial). Drainage basin 23 has the largest percentage of commercial/industrial land use (81 percent) and drainage basin 24 has the largest percentage of residential land use (85 percent).

The land use acreage for each catchment are used to determine the impervious area and runoff coefficient for each catchment. Impervious areas are those portions of a catchment where infiltration of rainfall cannot take place and surface runoff occurs. The overall average ratio of runoff to rainfall is the runoff coefficient which is used to convert rainfall data to estimates of runoff volume and runoff flow rate.

Prior studies (US EPA, 1983; FHWA,1987), which developed and analyzed rainfall-runoff characteristics using very large databases for both urban areas and highways, have indicated that the runoff volume and rate (and hence, the runoff coefficient) are strongly related to the fraction of impervious surface area within a predominantly urban watershed. The relationship used in this analysis to convert rainfall to subsequent runoff (the runoff coefficient) is based on the results from those studies. The equation expressing this relationship is (FHWA, 1987):

R0049408

$$RV = 0.007\,IMP + 0.1$$

where: RV = runoff coefficient
IMP = impervious area (expressed as a percentage).

In this study, the percentage of impervious surface area for a given land use category is taken or estimated from the Santa Monica Bay Drainage Basin - Drainage Area Characteristics (Los Angeles County Department of Public Works). For land use types not reported, an average of similar categories was taken. The Public and Other Urban categories were an average of the Multi-family and Commercial impervious surface values. The Unknown category was an average of the Single Family, Multi-family, Light Industry, Open and Commercial impervious surface values.

Table 7 lists the percentage of impervious surface area and runoff coefficient for each of the land use categories used in the Santa Monica Bay watershed. These values range from 0% impervious (runoff coefficient of 0.10) for open spaces and 92 percent impervious (runoff coefficient of 0.74) for commercial land uses. An average impervious area of 65 percent is used for areas with unknown land uses.

2.3 RUNOFF VOLUME

Storm runoff volumes and flow rates are calculated from the rainfall statistics and land use characteristics presented above. The Santa Monica Bay watershed is broken into 28 drainage basins, all of which drain directly to Santa Monica Bay. Each drainage basin is then made up of several smaller catchments. The computations are made for each catchment in the watershed and summed to produce the runoff data for each drainage basin and the entire watershed. The catchment data are included in Appendix A (Table A-1) and are summarized in Table 8. Average storm runoff was calculated by multiplying the average storm rainfall by the appropriate runoff coefficients. The annual average storm runoff was then calculated by multiplying the average storm runoff by the average number of storms per year. The amount of runoff from a drainage basin is primarily influenced by the size of the drainage basin. Drainage basins 12 and 21 represent 58 percent of the total watershed area and contribute an estimated 62 percent of the average annual runoff to Santa Monica Bay.

The computed runoff volumes can be compared to stream flow data to determine the validity of the method and parameters. Stream flow data are available for three gages located in the Santa Monica Bay watershed along Ballona, Topanga and Malibu Creeks. Information on the location, drainage area, period of record, and average annual stream flow is given in Table 9. The monthly average stream flow at each gage are summarized in Table 10. As shown in the table, the wet season total represents the majority of stream flow at each gage.

Table 11 shows a comparison of the wet season total stream flow at each gage and the computed storm runoff volume for the corresponding drainage basin. Because the stream gages are located within each drainage basin and measure a smaller drainage area than that used in the computations, the computed storm runoff volumes are adjusted in proportion to the drainage areas. As seen by the percent difference between the adjusted storm runoff and the recorded average wet season stream flow, the computed storm runoff volume for Topanga Creek is 48 percent less than the recorded stream flow.

Percent difference between adjusted storm runoff and recorded streamflow	7%	-19%	-48%

VOL 12

1 6109

The computed storm runoff volumes for Malibu Creek are 19 percent less than the recorded average wet season stream flow. Part of this error may be due to the fact that the model is only calculating runoff and does not consider base flow (base flow is any flow that is not derived from rainfall, such as flow from point sources).

The Ballona Creek computed storm runoff volumes are 7 percent higher than the recorded stream flow. A possible source of error in this comparison is that the stream gage data encompasses a drainage area of 89.5 square miles while the storm runoff is computed for a 130.1 square mile drainage area then adjusted for comparison. The drainage area in the model is slightly larger because it includes catchments which are downstream of the gaging station. Other errors in the runoff calculations are probably due to the simplicity of the model and the use of lumped parameters. These results indicate that the runoff coefficients and rainfall parameters reasonably represent actual conditions.

2.4 WATER QUALITY PARAMETERS

Key water quality parameters that are of concern to urban nonpoint source runoff and required for Part 2 of the NPDES Stormwater Permit Application are included in this study. The water quality parameters that are included in this study consist of total suspended solids (TSS); 5-day biochemical oxygen demand and chemical oxygen demand (BOD_5 and COD); nutrients (total Kjeldahl nitrogen (TKN) and nitrite-nitrate nitrogen (NO_2+NO_3) and total and soluble phosphorus); total metals (copper, zinc, and lead), and oil and grease.

The following is a brief description of the pollutants used in the model:

- **Total Suspended Solids (TSS).** The term "suspended solids" is descriptive of the organic and inorganic particulate matter which is of a size and type that allows the particles to stay suspended in water. The sediment load in a water body is influenced by a number of factors including but not limited to: particle size, stream flow, climate, geology, and vegetation of each drainage system. The conditions under which suspended sediments are considered a pollutant is a matter of definition. In general, suspended solids are considered a pollutant when they significantly exceed natural concentrations and have a detrimental effect on water quality and/or beneficial uses of the water body. Suspended sediments are often used as a surrogate for other contaminants which bind easily with fine particulate matter, including heavy metals. Open areas are assigned the highest concentrations for TSS in the model.

- **Oxygen Demand.** Oxygen demand refers to the amount of oxygen that will be consumed by biological or chemical reactions involving organic compounds. In general, moderately high dissolved oxygen content is necessary for the maintenance of healthy aquatic ecosystems. The relationship of oxygen-consuming discharges to the amount of dissolved oxygen in a receiving water body, therefore, is fundamental to the maintenance of environmental quality in natural water bodies. The oxygen demand parameters are about equal for all the land use areas, except BOD_5 for Open areas. This is probably due to pollutants such as fertilizers, animal wastes and other organics.

  Biochemical Oxygen Demand (BOD). The BOD test provides an indirect measure of the quantity of biologically degradable organic matter in water in terms of the amount of oxygen required by microorganisms to oxidize it to carbon dioxide and

VOL 12

1 5 1 1 0

water. The decomposition of biodegradable materials by natural soil and water bacteria draws upon the dissolved oxygen resources of a water body. This process is countered by natural re-aeration processes that all water bodies possess to varying degrees. Significant reductions in dissolved oxygen concentrations can result when the demand rate exceeds the rate of replenishment through re-aeration.

Chemical Oxygen Demand (COD). The COD test provides a more rapid measure of oxygen demand. The consumption of oxygen from a strongly oxidizing chemical agent is measured by this test. As a result, it typically measures appreciably higher levels of oxygen demand than will be produced by biological decomposition because it oxidizes some organic compounds that are not biodegradable, and may also react with inorganic compounds as well. In urban stormwater, for example, COD levels are typically found to be about 8 times greater than BOD levels.

Nutrients. Nutrients are necessary for the growth and support of biota in natural water systems. Excessive quantities can result in the over-stimulation of biological growth and the creation of objectionable water quality conditions. Runoff from fertilized areas and discharges of sewage or industrial wastes are frequently sources of significant quantities of nutrients. Other sources include urban stormwater runoff and direct atmospheric deposition to water body surfaces. In general, the most important nutrient factors causing an acceleration in algal production are nitrogen compounds and phosphorus. Again, the Single Family has the highest concentration of nutrients. This is probably due to pollutants such as fertilizers, animal wastes and other organics. The high value for TKN can be attributed to the increased amount of foliage entering stormwater from this land use type.

Nitrogen. Among the potential major point sources of nitrogen which enter water bodies are municipal and industrial waste waters, and septic tank and feed-lot discharges. It is unlikely that the latter two are significant contributors to the system. Nonpoint sources of nitrogen include lawn fertilizers, leachate from waste disposal in dumps or sanitary landfills, atmospheric fallout, nitrite discharges from automobile exhausts and other combustion processes, and natural sources such as mineralization of soil organic matter, and farm-site fertilizers and animal wastes. Many water treatment methods have no significant effect on nitrate removal from water (Dunne and Leopold, 1978).

Two forms of nitrogen have been analyzed extensively in stormwater runoff water quality studies. These are nitrite plus nitrate ($NO_2 + NO_3$), and total Kjeldahl nitrogen (TKN). The latter, named after the analytical test procedure, provides a measure of ammonia and organic nitrogen forms that are present. The former ($NO_2 + NO_3$) provides a measure of the inorganic nitrogen. Both NO_3 and TKN are analyzed in this study.

Phosphorus. Phosphorus is used by algae and higher aquatic plants and may be stored in excess of use within plant cells. With decomposition of plant cells, some phosphorus may be released immediately through bacterial action for recycling within the biotic community, while the remainder may be deposited with sediments. Much of the phosphoric material that combines with the consolidated sediments within the bottom of a water body is bound permanently, with a low likelihood of being recycled into the water column.

Phosphorus enters waterways from many of the same sources as nitrogen. Domestic sewage contains significant concentrations of phosphorus, which is

VOL 12 1 6

contributed by detergents and human wastes. Primary and secondary treatment processes remove only about 20 to 30 percent of this element from sewage (Dunne and Leopold, 1978). Fertilizers and the erosion of soils rich in phosphorus can also be a potential source.

Two forms of phosphorus have been routinely analyzed in stormwater runoff water quality studies. These include total phosphorus (TP) and soluble phosphorus (SP). This study analyzes both of these parameters.

- **Metals.** Heavy metals such as copper, lead, and zinc are naturally released in very small quantities by the weathering of exposed soils and mineral deposits, corroding metal surfaces, decomposing paints, and certain corrosion-control compounds. Heavy metals tend to have comparatively low solubilities and are often mobilized by forming soluble complexes with humic materials or by becoming attached to clay particles.

  These metals are present in the biosphere as trace elements and are micronutrients necessary for plant and animal growth. Heavy metals are of concern because elevated concentration levels of soluble forms in natural water bodies can produce toxic effects in biota. Sources include domestic and industrial point-source discharges, urban stormwater runoff, and direct atmospheric deposition. In this study copper (Cu), lead (Pb), and zinc (Zn) have been chosen for analysis because stormwater runoff water quality studies conducted at other urban locations have indicated that these metals are almost always present, and are at concentrations which tend to be elevated, relative to other heavy metals. They also can be used as surrogates for other heavy metals, as they tend to display similar transport characteristics. Copper and lead are often associated with automotive emissions and leaks which is possibly why they are higher in the Santa Monica Bay area. Industrial and Commercial areas are assigned the largest concentration of zinc.

- **Oil and Grease.** Oil and grease is a prevalent constituent in urban runoff. In a study of oil and grease concentrations in urban runoff in Richmond, California, Stenstrom et al. (1984) found that oil and grease concentrations in runoff from commercial properties and parking lots are about three times higher than from residential and open areas. The NURP program did not address oil and grease. Due to the very limited data base on oil and grease concentrations, it was not possible to accurately model this constituent. Accurately measuring oil and grease is very difficult, especially due to its affinity for coating sampling bottles. Eganhouse and Kaplan (1981) measured oil and grease concentrations in the Los Angeles River and found that concentrations were generally lower during storm events than during dry flows. The State of the Bay report (SCAG, 1988) estimated that urban runoff accounted for about 3 percent of the total input of oil and grease to the Bay. The oil and grease concentrations are the same for all land use types except the Open and Single Family categories, which are lower (Stenstrom et al., 1984).

To quantify the pollutant characteristics of runoff from a given area and the surrounding vicinity, it is desirable (and sometimes possible) to use site-specific data or local data. However, the data set must be extensive enough to adequately characterize urban runoff water quality from each land use type. When extensive amounts of data are not available, as is the case for Santa Monica Bay, an alternative approach is to use the NURP database for characterizing typical runoff concentrations.

VOL 12

1 5 / 1 / 2

2.5 LOCAL DATA COLLECTION

One of the tasks of this project was to assemble all the available runoff water quality data. In this way an additional source of data beyond the NURP data would be available for accessing inputs to Santa Monica Bay. In theory this data could be more accurate than NURP data because they were collected from inputs to the Bay, as opposed to many different runoff sources. It was also planned to make the data available for other Santa Monica Bay Restoration Project purposes

Data collection was begun in 1990 and completed in 1991. At the beginning of the collection process all agencies that routinely monitor or have monitored stormwater runoff (point source data were excluded from the goals of this project, since the data are accessible by other means) were contacted either by telephone or letter. A total of 15 potential data sources were found.

After identifying the data sources an assessment of the quantity and quality of the data was made. Of the 15 original sources 9 were deemed to be suitable for inclusion. The other six sources were not included because the data were too few in number, collected by unconventional techniques, duplicative of other sources, or collected at points not discharging into Santa Monica Bay. Most data were collected in machine-readable format; some data, such as the data from SCCWRP were coded from printed material. It is important to note that data gathered from a variety of sources such as those contributing to this data set are less reliable that data collected from a single source or data collected through a sampling program with quality assurance (QA) and quality control (QC) programs. No rigorous analysis of the data was performed. If the parties responsible for collecting the data introduced errors, then they will also exist in this combined data set. Table 12 shows the sources of data. Further information on each source is provided in Appendix B, along with other material describing the data set.

Many of the data sources contained data collected from several places. There were a total of 47 different locations. Table 13 shows the locations. They are coded by longitude and latitude. Two sources have missing locations and are unavailable. Many of the various locations were collected from source 11 through US EPA STORET records. The location name shown in the table is the most accepted name known to us, although some agencies have different names for specific locations. There is no standard naming convention for the locations.

A data set was constructed of all the records and integrated with SAS (1985) on the UCLA IBM 9000/900 computer. The SAS program was used to calculate various statistics as well as to divide the data into subsets, such as data collected under dry and wet weather conditions. All parameters were coded by STORET number. A separate data set is included which can be used to decode the STORET numbers into water quality parameters. Table 14 shows a subset of the STORET codes used later in the text of the report. There are a total of over 11,000 STORET codes.

The locations were not correlated to any particular rain gauge, flow gauge or discharge location. This is because the data were collected by several agencies who had no reason to perform a systematic monitoring plan. Furthermore, much of the data was collected for purposes other than accessing inputs to Santa Monica Bay.

Table 15 shows the number of observations at each sample location. Also included are the periods of observation, number of parameters monitored, and number of observations below detection limits. The earliest observations were made in 1967. The most recent were made at the end of 1990. The reason there are no observations in 1991, even though the

data was obtained from the agencies in 1991, is probably the lag between collection, analysis and reporting. The full data set includes the detection limits when they were reported, the sampling technique (e.g. grab, composite, flow-weighted composite, etc.). Sampling technique, flow rate and mass emissions were included in the data set if they were provided. Few flow rates were provided and this is most likely because of the difficulty in measuring stormwater and dry weather flows.

Approximately 90% of the collected observations were coded as to wet or dry weather conditions. In order to classify the remaining observations, the date of collection and the occurrence of rainfall were noted. All of the USGS rainfall gauges in the runoff area were used. If 5 or more of the gauges showed rainfall more than 0.1 inch, the observation was classified as wet weather; otherwise it was classified as dry weather.

Table 16 shows selected data for locations that had sufficient data to perform a statistical evaluation. They are included to illustrate how the parameters for the model were selected. The parameters shown in Table 16 were selected because they match the NURP parameters used in the model, and therefore could be used to compare the Santa Monica Bay drainage area to the national averages (NURP). Refer to Table 14 to determine the units of the parameters shown in Table 16.

The left hand most columns of Table 16 show the parameter concentrations occurring at specific probabilities. For example, at Ballona Creek at Inglewood, the cadmium concentration was less than 1.175 ug/L 25% of the time, less than 2.24 ug/L 50% of the time, less than 6.98 ug/L 75% of the time, and less than 21.94 ug/L 90% of the time. The probability concentrations are more robust than the mean concentrations and are frequently more useful in comparing one data set to another.

For this study, local data were inadequate for use in the model due to the limited amount of data available. However, it was possible to use the available data for comparison with the NURP data. The NURP database includes estimated concentrations for several different land use types, including residential, commercial, mixed, and open. By comparing the median site concentrations (50% probability) of the available Santa Monica Bay data, to the concentration distribution of NURP data, the most representative NURP data can be selected for use in the model.

A comparison of the NURP site median results and actual data collected in the Santa Monica Bay watershed are presented in the plots included as Figure 8. The graphs in Figure 8 present the probability distribution of pollutant concentrations (the median value of the event mean concentrations at each site) in urban runoff at the Santa Monica Bay sites, while the NURP land uses represent the distribution of the site median concentration for the various sites tested. The data used for comparison are from sampling station 41 (Ballona Creek at Sawtelle Blvd.) and sampling station 12 (Ballona Creek at Inglewood Ave.). These two stations were chosen for comparison because they had the most data points for comparison. It should be noted, however, that a significant portion of the Santa Monica Bay data were collected as grab samples while most of the NURP data were collected as composite samples. As shown in the graphs, the spread of the data for the Santa Monica Bay locations is quite large. However, the concentration medians of the Santa Monica Bay data generally fall in the upper range of the NURP site median concentrations. Therefore, for the purposes of this study, the 90th percentile values of the NURP data are used to estimate pollutant concentrations for Santa Monica Bay. By using these concentration values, this study is assuming that the Santa Monica Bay watershed has more stormwater pollution than 90% of the other urbanized areas in the United States. These concentrations are shown in Table 17. Possible reasons for pollutant concentrations being higher in the Santa Monica Bay area are:

(a) 90th percentile values for median event mean concentrations for each site in a land use category (EPA 1983); data for commercial sites used for public, light industrial, other urban and unknown land uses.

1. The longer dry period between storms which allows a larger build up of pollutants.

2. Air pollution levels (and therefore airfall deposition of pollutants) in the Los Angeles Basin are probably higher than other urban areas.

It should be noted that the concentration used for lead may be high for present conditions. The values used in this study are based on the analyses of samples collected during NURP. Much of the stormwater quality data for the Santa Monica Bay watershed was also collected during this period. Decreased use of leaded gasoline may have reduced lead concentrations in stormwater runoff.

Oil and grease concentrations are taken from Silverman et al. (1988). These estimates are developed from stormwater runoff studies conducted in the San Francisco Bay area. Average concentrations of oil and grease determined for residential, commercial/industrial and undeveloped areas are shown in Table 17. Undeveloped areas contribute little oil and grease to stormwater runoff, whereas developed areas having large impervious areas and high vehicular use contribute a disproportionate fraction of oil and grease loadings.

VOL 12

1 6123

Using the previously described methodology for predicting runoff volumes and pollutant concentrations from individual land use areas, pollutant loadings and average concentrations can be calculated for each catchment in the watershed. Appendix A contains detailed tables of the calculations performed in this study including land use and hydrology (Table A-1) and pollutant loadings and concentrations (Table A-2). The drainage basins can be categorized in the following way:

Drainage basins 1-19 make up the North Bay.

Drainage basins 20-22 make up West Los Angeles.

Drainage basins 23-28 make up the South Bay.

To aid in analyzing the results of the modeling, rankings based on pollutant loads and concentrations were calculated. The rankings are based on the model results and are not based on other factors, such as coastal resources, which may also be important. The overall rankings assume that all the pollutants are weighted equal. This assumption is reasonable given that the affects of the modeled pollutants on the environment in Santa Monica Bay are not fully understood. The results are summarized in two formats: by land use categories and by drainage basins.

3.1 SUMMARY BY LAND USE

The annual pollutant loadings from each land use category are presented in Tables 18 and 19. Table 18 reports the loads for each land use in each basin. Table 19 reports the results for the total watershed in pounds per year, as a percentage of total, and in kilograms per hectare per year (KG/HA/YR). A ranking of the land use categories based on annual pollutant loadings (mass) was developed and is shown in Table 20. A ranking of 1 corresponds to the highest average annual pollutant loading for a given pollutant and a ranking of 8 corresponds to the lowest average pollutant loading for the pollutant. Ranking of the average of individual rankings for each land use category provides an overall ranking assuming equal weighting of each pollutant. A ranking of land use by pollutant concentration is not presented because the concentration data by land use was used as input data. As shown in the above tables, single-family residential contribute approximately 50 percent of the annual load of the oxygen demand and nutrient pollutants. The single family land use also ranks first in annual loads of metals. This does not mean that single family residential areas have a higher concentration of metals, but instead that, given the large amount of residential area in the Santa Monica Bay area, it contributes the most runoff. The modeling results also show that the largest load of TSS comes from open areas, and the biggest contribution of oil and grease is from the multi-family and commercial areas. The overall ranking shows that residential areas and open areas contribute the largest loads to Santa Monica Bay. These results may be misleading however, unless one considers the fact that these two land uses comprise 90 percent of the total watershed and contribute 82 percent of the total runoff.

3.2 SUMMARY BY DRAINAGE BASIN

Tables 21 through 23 summarize results of the pollutant loadings model for each drainage basin. These tables report the results in pounds per year, percentage of total loadings, and average pollutant concentrations in milligrams per liter (mg/L).

In a fashion similar to the summary by land uses, a ranking of the drainage basins was developed using both average annual pollutant loadings and concentrations. The results are given in Tables 24 and 25. For this ranking, a ranking of 1 corresponds to the highest average annual loading (or concentration) for a given pollutant and a ranking of 28 corresponds to the lowest average annual loading (or concentration) for the pollutant. As shown in Table 24, the two largest drainage basins (12 - Malibu Creek and 21- Ballona Creek) contribute the largest pollutant loads to Santa Monica Bay (about 65 percent when combined). It should be noted however, that these two basins also contribute approximately 67 percent of the total runoff. When looking at the pollutant concentrations, calculated as the load divided by the total runoff, these two basins rank 8th and 18th respectively. A closer inspection of the concentration rankings (Table 25) reveals that drainage basins 24 through 28, in the urbanized southern section of the watershed, have the highest average annual pollutant concentrations, whereas drainage basins 1 through 5, in the undeveloped northern section of the watershed, have the lowest concentrations.

Table 26 is a comparison of the loads model for Ballona and Malibu Creeks in the State of the Bay report and this loads model. The Ballona Creek comparison shows that the model predicts higher pollutant mass loads to the Bay at reduced flow rates. This discrepancy is possibly a result of the fact that the State of the Bay model used concentration data which was an average of wet weather and dry weather data. The one exception to this would be the lead value which is approximately an order of magnitude higher.

The Malibu creek comparison shows that the flows used in the model are approximately 74 percent lower than the flow used in the State of the Bay report. As a result, it is very difficult to compare the results of the two models. The comparison would tend to suggest, however, that the BOD, COD, and copper data are approximately equal and that the lead and zinc data are high. Oil and Grease data was not presented for Malibu Creek in the State of the Bay report. The model results would not predict flow contributions from any point sources on either Ballona or Malibu Creek. The possible contributions to both flow rates are reported in Section 4.

3.3 SOURCES OF UNCERTAINTY

The average pollutant loading estimates presented above are based on limited data and should be viewed as preliminary. Actual pollutant loadings are anticipated to be highly variable. Factors influencing actual pollutant loadings include:

- Number and intensity of storms
- Length of dry period before storms
- Land use characteristics
- Basin activities including construction and accidental spills

R0049443

Deviations of any of these factors from average conditions will result in variations in the annual pollutant loads. Factors specifically influencing the results for Santa Monica Bay include the following:

- Only storm flows were considered in the analyses; base flows, illicit connections, and illegal dumping may contribute to pollutants loads. Also, only storms with 0.1 inches of rain were considered in this study.
- Uneven rainfall patterns over a particular basin was estimated and based on catchment boundaries, i.e. uneven rainfall within a catchment was not considered.
- Existing BMPs were not co...dered; any water quality improvements due to these BMPs were not modeled.
- Flows and concentrations were based on typical values of percent imperviousness and runoff concentrations.
- The Santa Monica Bay water quality data was collected by grab samples whereas the NURP data used for comparison were collected as composite samples. Also, the NURP data were site median concentrations whereas the Santa Monica data were event median concentrations.
- The land use data was collected in 1987 and may no longer be valid in some areas. Also, for some of the categories such as Other Urban, which consists of urban areas not distinguishable by aerial photography, and Unknown percent impervious values were estimated.

Also, it should be noted that the pollutant concentration levels selected for this study are higher than values seen from other stormwater studies. The values selected for the model were based on the few data available for Santa Monica Bay. The concentration values should be adjusted after more extensive monitoring to better reflect actual pollutant runoff concentrations.

The impact of potential errors in the water quality parameter estimates, land use or area estimates, is linear. The model is linear in the parameters. Therefore a hypothetical 5% error in a water quality parameter would have a 5% error when the parameter is used in the model calculations.

4.0 COMPARISONS TO POINT SOURCES

It is interesting to compare the wet weather flow rates to the dray weather flow that results from permitted discharges. There are a number of permitted dischargers that are allowed to discharge their effluent directly into one or more storm drains. Two examples of allowable practices are the discharge of cooling tower blow-down or bleed-off (a portion of circulating cooling water is purposefully discharged and replaced with tap water to prevent salt build-up), and ground dewatering (pumping of shallow groundwater to prepare sites for construction. Normally these flows are not contaminated and are not though to pose a problem. There is a concern that these low flows may flush accumulated materials in the storm drains to the ocean, or may mask an illegal discharge.

In order to determine the magnitude of permitted flows to storm drains, a database of the Los Angeles Regional Water Resources Control Board's permits was created. The database was then used to develop total discharge estimates. Table 27 shows the results of the database development. The maximum allowable flow to Ballona Creek, from these permits is approximately 1,410,000 gallons per day, or approximately 2.18 cu ft/sec. This flow rate is negligibly small during an average storm event (see Table 7) but can impact the overall yearly discharge. For Malibu Creek the permitted discharges may be as much as 15% of the flow measured in the State of the Bay report, or more than 50% of the predicted flows (model results).

The discharges represented in Table 27 are maximums. There may have been no discharge during the periods reviewed; the permit represents the maximum allowable discharge.

No comparisons to large treatment plant discharges (e.g. Hyperion) were made, since they were beyond the scope of this study. Such comparisons would be useful and could be helpful in determining the benefits of both increased treatment plant removal efficiency and stormwater best management practices.

As noted in the introduction, estimates of the annual loads can be used to identify catchments with the largest expected pollutant loads, site stormwater quality monitoring stations, and select types of and locations for applying source control and structural BMPs. Estimates of the annual pollutant load of the cumulative discharges to waters of the United States are also required for Part 2 of the application for NPDES Stormwater Permits for municipalities. It should be noted, however, that areas which contribute a large quantity of runoff, often times are identified as being the largest pollutant load source. This is not an indication that the area is excessively polluted, just that it contributes a large quantity of stormwater to the receiving water body. This point becomes apparent when dealing with large open areas.

Based on the estimates of annual pollutant loads, the model shows that, overall, single-family residential areas contribute the largest loads of pollutants to the Bay. Again, this due to the large area that this land use makes up. However, higher concentrations of oxygen demand and nutrients are also associated with single-family residential areas. Therefore, public education and awareness about stormwater pollution may be considered as a Best Management Practice (BMP) for residential areas.

The loads model also shows that the urbanized South Bay and West Los Angeles drainage basins (20 through 28) have high loads as well as high concentrations of pollutants. These areas should also be targeted in the stormwater monitoring program and BMP design. Basin 21 (Ballona Creek) had the overall highest pollutant load ranking, although this can be misleading due to its size. Basins 24-28 had the highest 5 pollutant concentration rankings, in respective order. This indicates that these areas may require more structural and pollutant abatement oriented BMPs and should be considered candidates for early action BMP programs.

Beyond the general BMPs mentioned above an Illicit discharge and Illegal dumping elimination program should be considered for the highly urbanized basins.

Although some data are available, hydrologic and water quality data collected in the stormwater monitoring program should be used to update the estimates of annual pollutant loadings with site-specific data. A monitoring program that helps characterize the pollutant concentrations associated with the various land uses should be developed. Stream stations, which drain mixed land uses should also be monitored to help calibrate the model. A model such as this one is only as good as its input data, and the more data available for calibration the better. It is also recommended that the results of this model be used for comparison with and, where appropriate, to update the status and trends of pollutant loading to Santa Monica Bay.

VOL 12

This appendix describes the data collection of 15 small data sets which were used in building the overall compiled larger data set (Data Set A). A description of the Santa Monica Bay Urban Runoff Database (SMBURD) and summary of the average dry and wet weather contaminants concentrations for 22 selected locations of Santa Monica Bay Watershed are also included.

9.1 DATA COLLECTION

Data were collected or obtained from others for this study for major Los Angeles storm drains during both storm-flow and low-flow discharge. The period of observation for the various data sets ranged from November 20, 1967 and December 4, 1990. Trace metal concentrations and organic chemical concentrations in the discharge (runoff) are reported and analyzed. Table B-1 summarizes 15 data sets characterizing inputs to Santa Monica Bay. Some of the data sets are parts of reports and some are raw data sets. Several data sets have many observations and were useful in building our overall data set describing inputs to the Bay. Data sets which have no value for this project are excluded. Detailed descriptions of these 15 data sets are given in Section 9.2.

There are 42,370 observations in the final data set named "Data Set A" which includes data sets from 9 different sources with 47 sampling locations covering much of the Santa Monica Bay Watershed. Table B-2 gives the location (longitude and latitude) of these 47 sampling locations. A general description of the completed Data Set A is given in Table B-3. A smaller data set named "Data Set B" which includes 22 STORET parameters and is sorted by STORET code was extracted from Data Set A. This data set includes observations of special interest, or for locations which had a sufficient number of observations to warrant statistical analysis.. A description of these 22 STORET parameters is shown in Table B-4. Rainfall data for ten National Weather Service gages which are in or near the Santa Monica Bay Watershed were used to separate samples from Data Set B which were not explicitly know to be "wet" or "dry". . A value of 0.2 inches of rain was used as the difference between a "wet" and "dry" day. Results of "wet" and "dry" data are summarized in Section 9.3.

9.2 DATA DESCRIPTION

An IBM compatible PC program named SMBURD for IBM compatible PC was written and can be used to extract data from the final data set - Data Set A. Figure B-1 is a flowchart which illustrates the main features of SMBURD Program. The installation procedures of SMBURD ver 1.01 for most IBM compatible PCs and a description of SMBURD's output data format are described below. An output sample format at SMBURB is shown in Table B-5.

Table B-1. Status of Individual Data Sets

Source Number	Agency	Data Set or Report Name	Status Code
1	City of Los Angeles and Engineering Science	Santa Monica Bay Stormwater Pollutant Reduction Study	1

Note Variable names are not included in the output data files. Some of the above variable names are abbreviated.

9.2.1 Santa Monica Bay Urban Runoff Database (SMBURD) Program Installation

To install SMBURD 1.01 from the disk drive

1. Create a sub-directory on the hard drive.
   For example, at the command prompt C:\, type md smburd and press ENTER.

2. Insert the SMBURD 1.1 disk into a floppy drive, and change to the drive letter of the floppy drive.
   For example, to switch to the A drive, at the command prompt A:\ and press ENTER.

3. At the command prompt A:\, copy all files to the hard disk.
   For example, at the command prompt A:\ , type copy *.* C:\smburd and press ENTER.

4. Uncompress the data file named file.zip using pkunzip.exe.
   For example, at the command prompt C:\smburd, type pkunzip file.zip and press ENTER.

Running the SMBURD Program

1. Type Runoff and press ENTER. A series of menu will be presented.

```
SANTA MONICA BAY URBAN RUNOFF DATABASE PROGRAM
              Version 1.01
  *******    WELCOME TO MAIN MENU    ************
  ***********************************************
  * Menu  1: Location Code Menu                 *
  * Menu  2: Storet Code Menu                   *
  * Menu  3: S.M.B. Runoff database Menu        *
  * Menu  4: Return back to DOS                 *
  ***********************************************
```

Menu 1: To view the Location Name, Location Code, Latitude and Longitude.
Menu 2: To view the Storet Code and its description.
Menu 3: To view the SMB Runoff Databse.

Note: There are 42,370 observations and 13 variables in each observation. Each variable is separated by one or more blank space. Variables are output in the following order: Storet, Concentration, Detection Limit, Location Code, Date, Time, Source, Method, Quality, Storm, Flow rate, Interval, Mass.

2. Format:

   Concentration: Most of the data in this database are in µg/L.
   For bacteria, use MPN or CFU per 100 ml.
   - MPN = Most Probable Number - statistical method. (Most of the data)

VOL 12

1 5298

- CFU = Colify Forming Units - actual count of cells. (SMBRP data)

Detection Limit:	in µg/L.
Time:	Hour:min. Example, 1310 = 1:10 pm.
Source:	See attached sheet
Method:	1 = Grab Sample; 2 = Composite Sample over 24 hours.
Quality:	1 = Best available data; 2 = Medium; 3 = Lowest.
Storm:	0 = Dry weather flow conditions; 1 = Wet weather flow conditions; 2 = Not specified.
Flow rate:	Units are in CMS (cubic meters per sec).
Interval:	To be used with flow rate.
Mass:	Units are in grams. Mass = Concentration*Flow rate*Interval.

Note: Variable = -2 or -2.000 means missing data.
Concentration = -1 or -0.000 means not detected.

9.3 RESULTS AND DATA ANALYSIS

9.3.1 Wet annd Dry Data Analysis

Twenty-two STORET parameters have been selected and merged with rainfall data from ten National Weather Service gages in order to extract true "wet" weather data from Data Set A which has unspecified "storm" or "no storm" conditions. A new variable NSTORM (NSTORM = 1) is used to indicate the additional "wet" weather data extracted from Data Set A. As a results, an additional 829 "wet" weather observations are gained to give a total of 1,129 "wet" weather observations for the 22 selected STORET parameters. Statistical analysis is performed on these "wet" weather data and the results are shown in Table B-6.

In addition to the "wet" weather data, "dry" weather data were also extracted from Data Set A and statistical analysis is also performed on these data (Table B-7). Statistical analysis can only be done on limited locations as there is insufficient number of observations on most sampling locations to warrant this analysis.

9.3.2 Sample Histograms

As mentioned in the above sections, Data Set B consists of the extracted data of 22 different STORET parameters in 47 sampling locations of Santa Monica Bay Watershed. Based on the obtained results ("wet" and "dry" weather data), histogram was plottedfor each STORET parameters (Figures B-2 -23).

Table B-6. Statistical Analysis of Wet Weather Data (cont'd).

Source Number	1
Title of Data Set or Report	Santa Monica Bay Stormwater Pollutant Reduction Study
Prepared by	Engineering-Science Inc.
Prepared for	City of Los Angeles, Wastewater Program Management Division
Date of Sampling	Throughout 1988
Date Study Released	6/1/89
Sampling Sites	Ballona Creek, Figueroa Street and 12th Street, Adams Blvd and Hope Street, Windsor Blvd (500 feet north of 12th Street), Cimarron Street and 29th Street, Bronson Avenue
Number of Samples	64
Sampling Frequency	Dry Weather Flow: 24 hour composite samples of 24 discrete 1 hour samples Stormwater Samples: grab samples from throughout the storm event
Parameters Tested	TSS, oil and grease, metals, PCBs, herbicides, dioxins, PAHs and enterococcus (includes loading rate calculations)
Applicability For Our Use (high, medium or low)	High
Comments	Data were colected expressly for the purpose of identifying pollutant emissions for various types of land uses, but do not correspond directly to any discharges to the Santa Monica Bay. Detection limits are high, since official EPA analytical techniques were used; consequently many of the observations are less than detection limits.

Title of Data Set or Report	Santa Monica Bay Coliform Database
Prepared by	Science Applications International Corporation (SAIC)
Prepared for	California Regional Water Quality Control Board
Date of Sampling	9/1/87 through 7/1/90
Date Study Released	August 1990
Sampling Sites	17 shoreline stations from the City of LA treatment plant (Hyperion), 7 shoreline stations from the LA County Sanitation Districts treatment plant and 30 stations from streams and stormdrains from the County of Los Angeles Department of Public Works
Number of Samples	1 sample collected during each sampling
Sampling Frequency	Daily or about twice weekly at each station at each site
Parameters Tested	Total coliform, fecal coliform and enterococcus
Applicability For Our Use (high, medium or low)	High
Comments	Data from shoreline stations do not characterize inputs to the Bay. Data from the Department of Public Works was provided from their STORET database and is included in the data set from Source Number 11.

Title of Data Set or Report	Surface Water Quality Survey – Santa Monica Bay Inputs
Prepared by	California Regional Water Quality Control Board
Prepared for	Same as above
Date of Sampling	Once or twice annually from 1986 to present
Date Study Released	N/A
Sampling Sites	14 sites throughout Santa Monica Bay drainage basin (concentrated along Ballona Creek)
Number of Samples	20
Sampling Frequency	1 to 2 grab samples per site
Parameters Tested	VOCs, metals, herbicides, pesticides, COD, BNAs, acetone, PCBs, petroleum hydrocarbons and cyanide
Applicability For Our Use (high, medium or low)	High
Comments	Well documented location on topographic maps. Usually no flow data, except rough estimates in some cases. Few observations above detection limits. Not all points are inputs to Santa Monica Bay.

Title of Data Set or Report	Advisory Warning – Discharges from Storm Drains into Santa Monica Bay
Prepared by	County of Los Angeles, Department of Health Services
Prepared for	County of Los Angeles, Department of Beaches and Harbors
Date of Sampling	July through September, 1986
Date Study Released	7/28/86
Sampling Sites	Discharges from the following storm drains: Ballona Creek, Imperial Avenue, Pulga Canyon Creek, Ainsworth Avenue, Ashland Avenue, Kenter Canyon at Pico Blvd, Santa Monica Canyon Creek, Santa Monica Pier and Avenue I
Number of Samples	9 samples per site
Sampling Frequency	Weekly from 7/21/86 to 9/3/86 and twice weekly through 9/18/86 for coliforms, twice weekly from 9/3/86 through 9/18/86 for enterococcus
Parameters Tested	Total coliform, fecal coliform and enterococcus
Applicability For Our Use (high, medium or low)	High
Comments	Samples were collected in the surf zone at the mouth of the storm drain and at 10, 25, 50, 80 and 150 yards on each side of the storm drains. Only data from samples collected at the point of discharge are to be incorporated into this database.

Prepared by	Santa Monica Bay Restoration Project
Prepared for	Santa Monica Bay Restoration Project
Date of Sampling	August and September 1989
Date Study Released	June 1990
Sampling Sites	Outfall from the Kenter Canyon (at Pico Blvd) and the Ashland Avenue storm drains
Number of Samples	15 at each site
Sampling Frequency	Once or twice weekly from 8/10/89 to 9/29/89
Parameters Tested	Total coliform, fecal coliform, enterococcus and enteric viruses
Applicability For Our Use (high, medium or low)	High
Comments	Data collected specifically to determine the existance of human fecal material inputs to the storm drains. Resulus were positive.

Title of Data Set or Report Search for Mutagens and Carcinogens in Pico-Kenter Storm Drain -- Final Report

Prepared by County Sanitation Districts of LA County at their San Jose Creek Water Quality Lab

Prepared for County of Los Angeles, Office of the Chief Administrative Officer

Date of Sampling October 1980

Date Study Released 12/1/80

Sampling Sites Kenter Canyon drain at Pico Blvd

Number of Samples 2

Sampling Frequency Samples taken 16 days apart

Parameters Tested Analysis of HPLC fractionated samples resolved more than 600 compounds

Applicability For Our Use (high, medium or low) Low

Comments This data will not be included in our data set since they do not characterize discharges into the bay. Ames tests were performed and the results suggest that only the whole residue and non-polar fractions were mutagenic. The two samples were quite different in their molecular characterization.

Title of Data Set or Report	Untitled at this time (tentative title: Ozone Pilot Plant Demonstration Project for the Treatment of Urban Stormdrain Dry Weather Flows)
Prepared by	City of Santa Monica Department of Engineering (Gerry Greene)
Prepared for	The EPA and the Santa Monica Bay Restoration Project
Date of Sampling	11/20/89 to present
Date Study Released	In progress (projected for 1991)
Sampling Sites	Kenter Canyon drain at Pico Blvd
Number of Samples	3 samples collected during each sampling
Sampling Frequency	Daily to weekly
Parameters Tested	Among the numerous parameters tested are: flow rate, total coliform, fecal coliform, TS, TDS, TSS, setteable solids, turbidity and metals
Applicability For Our Use (high, medium or low)	Medium
Comments	This data set has more observations for a single point than any other data set. Unfortunately it does not correspond to a discharge location. Never-the-less, these data should be useful in estimating stormwater variability.

Title of Data Set or Report	LA County Department of Public Works surface water monitoring program data
Prepared by	LA County Department of Public Works
Prepared for	Same as above
Date of Sampling	1971 to present
Date Study Released	N/A
Sampling Sites	The following storm drains: Ballona Creek at Fairfax Avenue, Ballona Creek at Sawtelle Blvd, Centinela Creek at Centinela Blvd, Corral Canyon Creek at PCH, Dume Creek at Zuma Beach, Kenter Canyon drain at Pico Blvd, Malibue Creek at Cross Creek Road, Santa Monica Canyon at Short Street, Sepulveda Channel at Culver Blvd, Topanga and Canyon Creek at PCH
Number of Samples	Varies with site and year
Sampling Frequency	Typically monthly or anually
Parameters Tested	A wide spectrum of parameters were measured; irregular frequency
Applicability For Our Use (high, medium or low)	High
Comments	A varity of different analytical techniques, different laboratories, and different sampling techniques were used. The data have been placed in a publically readably STORET file. More recent data have been provided by the Department in FOCUS database form. Flow rate data have not been included which makes mass emission rates difficult to estimate.

Title of Data Set or Report	Deposition and Processing of Airborne Nitrogen Pollutants in Mediterranean-Type Ecosystems of Southern California
Prepared by	Pacific Southwest Forest and Range Experiment Station, Forest Service, US Department of Agriculture
Prepared for	Environmental Science and Technology, Volume 19, Number 9
Date of Sampling	March 1982
Date Study Released	September 1985
Sampling Sites	From a stream site in each of the following canyons in the Santa Monica Mountains: Deer, La Chosa, Trancas, Ramirez, Solstice, Corral, Carbon and Upper Santa Ynez
Number of Samples	8 (one from each stream)
Sampling Frequency	Samples were collected once on 3/25/82
Parameters Tested	Stream water nitrate concentrations following a major storm
Applicability For Our Use (high, medium or low)	High
Comments	This paper suggests that atmospheric deposition of nitrate might be as high as 7.0 mg/L in runoff from undeveloped land in the San Gabrial Mountains. Nitrate in runoff from undeveloped land the Santa Monica Mountains was much lower, generally less than 0.2 mg/L. If true, estimates of nitrogen and possibly other pollutants from undeveloped areas will need to be dramatically changed in urban runoff/land use models.

May, 1993

VOL 12

PREFACE AND ACKNOWLEDGEMENTS

This report represents Volume II from a series of four volumes of reports which form the basis of a pollution assessment and monitoring plan for Santa Monica Bay. Volume I describes storm drainage system land use statistics, catchment areas, existing water quality monitoring data, rainfall data, NPDES permit information for existing permits to storm drains, and contaminant mass emission estimates, based upon land use modeling. Volume II reviews sampling techniques, including sampling equipment, and other aspects associated with sampling such as a quality assurance plan. Volume III presents the proposed monitoring plan. Volume IV addresses best management practices as they apply to the Santa Monica Bay area. The first draft of this volume was issued in September 28, 1992.

The contract was performed by UCLA and Woodward-Clyde Consultants (WCC). Professor Michael K. Stenstrom of the Civil and Environmental Engineering Department, UCLA and Eric Strecker from WCC's Portland office were the project managers. There were several key individuals from both UCLA and WCC who assisted with the project; they include Sim-Lin Lau and Kenneth Wong (UCLA) and Lou Armstrong, Gail Boyd, Carol Forrest, and Joan Kersnar (WCC).

The contractors are grateful for the assistance of many individuals. The Santa Monica Bay Project and LA Regional Water Quality Control Board staffs were most helpful. We extend our special thanks to Dr. Guang-yu Wang, Ms. Catherine Tyrrell, Dr. Rainer Hoeinke and Mr. Xavier Swamikannu. Several public agencies were very helpful in providing data and information to us. The Los Angeles County Department of Public Works and the Southern California Association of Governments (SCAG) provided catchment area and land use data, respectively. We are also indebted to the members of the Technical Advisory Committee of the Santa Monica Bay Project and others who reviewed and commented on our draft reports.

VOL 12

ABSTRACT

This report is a literature review of surface water and wastewater sampling techniques, with an emphasis on applications for storm drain sampling. The report discusses sampling program objectives, statistical approaches, sample types, sampling equipment, flow measuring techniques, special problems in sampling specific biological, chemical, or physical parameters, and quality control/quality assurance plans. A variety of sampling equipment is reviewed, such as bottle samplers, messenger-activated samplers and automatic samplers, among others. Additionally several case studies are presented. The case study review is based upon Woodward-Clyde Consultants' previous experience in monitoring storm drains or developing monitoring programs.

This volume complements Volume III of this four-volume report series. Volume III provides more specific information on the development of a storm drain monitoring program for the Santa Monica Bay watershed.

1.0
INTRODUCTION

1.1 OBJECTIVES

This review outlines methodologies for sampling storm drains (urban runoff). It is not intended to address any site-specific sampling requirements. A general overview is provided, followed by several case studies of specific programs and their associated procedures and sampling equipment. It was produced as part of a contract to develop a storm drain monitoring program from the Santa Monica Bay Restoration Project to team comprised of the Civil Engineering Department at UCLA and Woodward-Clyde Consultants (WCC).

The following chapters address the sampling program, statistics, sample types, sampling equipment, sample storage and preservation requirements, flow measurement, special techniques required for certain contaminants (e.g., oil and grease), and quality assurance/quality control plans.

1.2 SAMPLING PROGRAM - OVERVIEW

The main objective of any sampling program is to collect a sample which is representative of the state of the media under study. A sample is considered to be representative if the sample possesses the same qualities or properties as the media being sampled at the point and time of collection. A set of representative samples is considered to be valid if it provides a true representation of the temporal and spatial variations of the quantity of the water body for the duration of the measurement program (Wilson, 1982).

No single sampling program can apply to all types of samples (e.g., surface water, ground water, coastal wastes, municipal wastes, etc.). However, each sampling program should consider at least the following criteria (Krajca,1989; Barcelona, 1988; US EPA, 1982) :

- objectives of sampling program
- analytes of interest
- location of sampling points
- frequency and time of sampling
- sample collection, e.g., selection of sampling equipment, sampling methods (grab or composite), etc.
- sample handling, e.g., preservation,
- field determinations, e.g., in situ analysis of unstable constituents, flow measurement, etc.
- sample storage and transport
- quality assurance/quality control (QA/QC)
- health and safety cost

In addition to the above mentioned criteria, the validity of samples in terms of the sampling sites, number of samples, time and frequency of sampling should be considered based on a statistical approach if the objective is to accurately characterize pollutant loadings and/or concentrations.. The above mentioned criteria is not all inclusive. Additional components

1

may be added into the sampling plan depending on the objective of the project. The following section discusses the basic required criteria of sampling program.

1.3 SAMPLING PROGRAM OBJECTIVES

The objective(s) of a sampling is the first step in planning of a sampling program. In general, there are four major reasons for sampling and analyses program: planning, research/design, process control, and regulation (including detection, verification and enforcement). A comparison of the sampling program based on these four different objectives are discussed by the US EPA (1982) and is summarized in the Table 1-1. For the purposes of this report, the objective of the sampling program is to provide good monitoring procedures for the evaluation of the pollutant load to Santa Monica Bay from storm drain and runoff flows. A work shop held in conjunction with this project concluded that the proposed monitoring plan should have two objectives: assessing the mass emissions to the Bay, and providing more information on the land-use pollutant runoff characteristics. Thus, the sampling plan , which involves the selection of the types of samples (grab and composite samples), sampling techniques, sampling equipment (manual or automatic), sample preservation, field analysis (e.g., *in situ* analysis, flow measurement), etc., should be based on this objectives.

1.4 ANALYTES OF INTEREST

The selection of constituents of interest to a particular study depends on the objectives of the monitoring program. Examples of the water quality parameters (which include organics, heavy metals, nutrients, etc.) are given in the Appendix A. In cases where insufficient information is available, a staggered program is usually implemented. A full suite of parameters is generally carried out during the initial phase of the monitoring program (or during the first several storms). A reduced suite of analyses can be performed if the results of the preliminary sampling show the absence or low levels (as compare to applied criteria) of specific parameters. In addition to the parameters given in Appendix A, other constituents can also monitored if their presence is expected in the storm water.

Once the analytes of interest are chosen, appropriate analytical methods for specific parameters must be selected. This consideration is not only important for proper sample collection and handling procedures and cost minimization, but also to avoid matrix interferences for certain types of samples. In addition, the minimum sample volumes and types of sample preservation and handling procedures also depend on the detail and specificity of the proposed analytical program (Barcelona, 1988). For example, the sample volume needed for organic analyses differs from those for inorganic analyses.

The selection of methods of analysis generally is left to the experience of the analyst. General guideline for the selection of analysis method were discussed by Mancy and Allen (1982) as follows:

- total number of analyses,
- frequency and geographical scope of analysis,
- required rapidity of analysis,
- sensitivity and detection limit,
- selectivity and interferences,
- constraints on accuracy and precision.

Table 1.1 Sample Program Objectives (EPA, 1982).

Objectives	Planning	Research Design	Process Control	Regulatory
Scope	General	Specific	Specific	Specific
Goals	Establish trends Benchmarks Background levels	New developments Modifications Improvements	Operation quality control	Verification compliance enforcement
Effort	Non-intensive and unlimited	Intensive and limited	Non-intensive and limited	Non-intensive and limited

VOL 12

1 6339

The above mentioned requirements give an insight into whether the analysis should be carried out in the laboratory or in the field. In general, in situ analysis is carried out if the conditions of the analyte of interest are unstable and need direct measurement at the sampling sites. These unstable determinads include temperature, pH, dissolved gases (dissolved oxygen).

In addition, the sampling modes, either manually, automatically or through a remote sensing system, can also be determined based on the costs and availability of manpower and equipment. Comprehensive discussion of this topic is given the *Examination of Water for Pollution Control* (1982).

1.5 SAMPLING LOCATIONS

The sampling program objectives usually define the approximate locations for sampling, e.g., the confluence of two stormdrains drains. However, the stated objectives give only a general indication, e.g., when the effect of an effluent on river water quality is of interest.

The quality of water varies from place to place in most water systems. Therefore, locations appropriate to the information needs of a particular program must be selected so that the samples collected from various sampling points can be representative as a whole of the system. No specific guidelines can be given due to the extent and nature of spatial heterogeneity that may vary with time and also differ from one system to another. However, certain general points still have to be considered when the selection of sampling locations is make.

The selected sampling locations must be representative sites. Factors influencing the selection of sampling locations are (US EPA, 1982; Wilson, 1982) :

1. Homogeneity of the water, wastewater or stormwater.
   Homogeneity is generally enhanced by the turbulence and good mixing resulting from a hydraulic jump or flow over a weir.

2. Non-homogeneity or heterogeneity of the water , wastewater or stormwater.
   Generally caused by poor mixing (e.g. vertical, thermal stratification of lakes and reservoirs), and non-homogeneous distribution of the chemicals caused by their different densities (e.g., floating oils or settling suspended solids), and also certain chemical or biological reaction (e.g., pH changes caused by the growth of algae in upper layers of a body of water).

3. Convenience and accessibility of the sampling locations.
   For stormwater such considerations include impact of vandalism, safety to workers, such entering confined spaces (e.g., manholes), and accessibility in all types of weather. Sampling in confined spaces always requires multiple team members and additional safety equipment. Another important consideration for stormwater sampling is the distance among sampling locations. Widely spaced locations may be best from the standpoint of collecting the most representative samples, but may be expensive because of travel time or the need for additional sampling teams.

4. Flow measurement.
   Flow measurement presents a particularly difficult challenge for stormwater monitoring. Often there are no provisions for measuring flow rates.

Conventional flow measuring equipment such as weirs or flumes is usually unsuitable for stormwater because of the increased head loss (resistance to flow) that the weir or flume causes. The increased head loss decreases the maximum capacity of the storm drain that may result in a loss of flood protection.

5. Other considerations
Sampling locations near the boundaries of water systems generally should be avoided except when these regions are of direct interest. Coastal stormdrains are often affected by tidal flows, which makes representative sampling nearly impossible due to the dilution of salt water. Stormdrains are often located in areas which have higher probability of violent crimes and vandalism. Extra precautions are required.

Generally, a preliminary investigation needs to be carried out to assess the degree of non-homogeneity of the proposed stormwater location. If such tests show that quality is homogeneous, one position for sampling may suffice; if heterogeneity is present, two approaches can be used to select the appropriate sampling locations (Wilson, 1982). The first alternative is to sample and test different locations until a suitable homogeneous location is found. For the second alternative, the location originally selected is used, and samples are routinely taken from several positions chosen so that they are properly representative of the quality at the location; the individual results are then weighted and averaged according to a suitable procedure (e.g., volume or flow weighting, etc.). The first alternative is usually preferable due to simplicity.

For the consideration of the spatial distribution of sampling positions, the hydraulic conditions can be characterized approximately as homogeneous, stratified, plug-flow, showing longitudinal mixing, showing lateral and longitudinal mixing, and patchy (e.g., in the distribution of photo plankton). The hydraulic conditions must be considered when selected both the location and number of samples. The number of sampling positions needed to obtain the required information tends to be smallest for homogeneous conditions and greatest for patchy conditions (Wilson, 1982).

1.6 FREQUENCY AND TIME OF SAMPLING

Frequency of sampling will be site specific and no general rules can be provided. However, several important considerations exist for determining sampling frequency: economics, regulatory requirements, and timing. The frequency of sampling is the most significant cost multiplier in a sampling operation. Certain frequencies of sampling are set by regulation and therefore, the required sampling frequency cannot be followed, even though there may be powerful incentives to modify sampling frequency. In general, if the environmental value or quality interest varies with a certain frequency, the sampling frequency must be at least twice the frequency of that variation. In addition, if the process is cyclic in nature, samples should be collected during at least one complete process cycle, or an integer number of process cycles.

For stormwater, monitoring programs often designate a specified number of storms to be sampled and a specified number of flow-weight averaged, composite samples. To obtain the required number of samples, prediction of the number of storms and the length of the storms is required. Such predictions are far from precise and some latitude and variability of sampling is necessary.

VOL 12

1.7 SAMPLE COLLECTION METHODS

Selection of correct sampling technique for collecting samples is very important in order for the collected samples to be representative. A good sampling collection method generally involves selection of the correct sampling techniques and equipment, trained personnel to perform the sampling procedures and correct handling of samples. This section will only discuss some general criteria involved in the selection of correct sample collection method. Detailed discussion of the types of sampling equipment available for water sampling, sampling methods (either grab or composite) and the correct sample handling (e.g., preservation, transport and storage) are discussed in the later sections of this report.

Samples can be collected either manually or with automatic samplers. Manual sampling involves minimal initial cost, but it is only suitable for collection of a small number of samples. For routine and large sampling programs, manual sampling can be costly and time consuming. Automatic samplers are increasingly being used to monitor water quality due to their cost effectiveness, minimal labor requirement, and ability to sample at greater frequency. Selection of the correct sampling collection mode, either manually or automatically, still depends on the needs of sampling programs (see Chapter 4).

In addition to the correct selection of sampling equipment, types of sample collected can be divided into two categories, i.e., grab (or discrete) and composite samples. A grab sample is defined as an individual discrete sample collected at a particular time and place, whereas a composite sample is defined as a sample formed by mixing discrete samples taken at periodic points in time or a continuous proportion of the flow (US EPA, 1982). Factors involved in the selection of sample types are discussed in the Chapter 3. The types of sample collected are also determined by the regulatory agency. In general, composite samples are required for the NPDES permit. However, grab samples may be allowed when compositing samples is difficult due to reasons such as the absence of flow during dry weather season, or analytical requirements (grab samples for certain analysis such as oil and grease or volatile organic compounds).

Poor sample collection procedures can seriously bias chemical results (Barcelona, 1988). Analyses of blanks and controls should be carried out simultaneously with samples collected from the sampling sites so that any errors, such as contamination, poor handling of sampling equipment, etc., that arise during the sampling and analytical procedures can be monitored. The efficiency with which the operator can control the operation of the sampling equipment, maintain stable, reproducible operation conditions, and recognize a malfunction all play a significant part in minimizing these errors.

Materials selection of sampling equipment can also cause unwanted bias results. Appropriate materials used for the sampling equipment should be based on the most sensitive (i.e., volatile, and reactive) chemical constituents under investigation so that any interaction of material used with the chemical constituent of interest (e.g., leaching, sorption, etc.) can be avoided.

1.8 FIELD PROCEDURES

The sampling program must also specify the various analyses to be performed on the sampling sites. Generally, determinands such as flow rate measurement, and unstable parameters such as dissolved gases, pH, temperature, and conductivity are determined on the field. Greater number of analyses can be performed in the field if a mobile laboratory is available. The mobile laboratory is especially useful when sample degradation is fast, or when immediate analysis is required, such as tracking a spill.

In addition to the collection of representative sample, field procedures must also include proper handling and preservation of samples, good housekeeping and appropriate chain of custody procedures. Factors that are commonly considered to insure good housekeeping of the field operations include (US EPA, 1982):

- written instructions on field sampling procedures should be completed beforehand.
- sampling equipment should also be checked prior to use in order to insure good operating conditions and cleanliness. After the sampling has been completed, the equipment should be cleaned and stored properly.
- all sample bottles should be checked to avoid possible contamination. Prior to collecting the samples, sample bottles usually should be rinsed several times with sample water.
- records of breakdown in the sampling operation, the problems encountered with different equipment and how they were resolved should be maintained.

More detailed procedures are provided by the US EPA (1982).

Conditions at the time of sampling, such as climatic conditions, hydrologic conditions, hydrogeological conditions, should also be noted during the field operations. Sampling from streams and reservoirs can be influenced to a considerable extent by variations in such things as flow rate, sediment and bed loads, temperature regime, and stratification. Sampling problems can also be caused by sudden changes of climatic conditions such as intensity and type of precipitation, air humidity, temperature and pressure, wind and speed direction. For example, intense precipitation can affect the composition of sample through direct contact with the water to be sampled, resulting in dilution or contamination (Krajca, 1989). Therefore, conditions at the time of sampling should be observed.

The safety and hygiene of those collecting the samples also need to be considered. The correct handling of sampling equipment and chemicals used during sampling operation to protect sampling personnel have been discussed by Krajca (1989). Stormwater, while usually not as contaminated with pathogenic organisms as wastewater, should be treated with the same precautions as wastewater. In sampling for many trace compounds, human contact or contact of safety equipment (e.g. rubber gloves) with the sampled water is required not only for personnel safety, but also to prevent sample contamination.

1.9 SAMPLE HANDLING, STORAGE AND TRANSPORT

Correct sample handling should be performed to avoid any unwanted contamination. Most of the Quality Assurance (QA) and Quality Control (QC) guidance manuals provide sound guidance for planning the procedures for sample preservation and handling. Selection of appropriate materials of sample containers, preservation methods, maximum holding times, and sample volume are discussed in the Chapter 5.

In general, the following guidelines for sample handling and preservation should be considered (US EPA, 1982):

VOL 12

1 6343

- minimize the number of people handling the sample
- if possible, have the same individual perform all operations when repetitive operations are conducted
- store the sample in a manner which insures that the parameters to be analyzed are not altered, and use appropriate preservation method(s) and holding time,
- make sure the container material does not interfere with the analysis of the specific parameters.

Efforts should also be made to handle and preserved field control samples (i. e., blanks and spikes) in the same manner as the samples collected. This precaution provides more effective identification and control of post-sample collection errors.

2.0
STATISTICAL APPROACH

The number of samples and frequency of sampling need to be considered carefully while planing any monitoring program so that samples collected will be representative. The aim of this Chapter is to give a general review of the statistical approach generally employed in determining an appropriate number of samples and sampling frequency. Detailed explanation on basic statistics is beyond the scope of this study. Information of basic statistics can be found in a numbers of statistics textbooks. References such as Montgomery and Hart (1974), US EPA (1982), and Schaum Series -Statistics are also useful.

2.1 BASIC STATISTICS TERMS

Basic statistics terms that are generally used for the determination of the number of samples and frequency of sampling include the following:

1. arithmetic mean
2. median
3. standard deviation (s)
4. variance (σ or s^2)
5. coefficient of variation (CV)
6. confidence level (α)
7. Normal distribution
8. Chi-square distribution

2.2 DETERMINATION OF NUMBER OF SAMPLES

Two methods have been described by Montgomery and Hart (1974) to determine the number of samples. The first is based on the allowed sample variability while the second is based upon the accuracy of the sample mean. Examples of these two methods also describes by US EPA (1982). Standard deviation and coefficient of variation (CV) of the concentration of the constituents are needed to determine the number of samples. These two parameters are usually obtained from the previously collected data. In the absence of such information, and sometimes in spite of such information, the number and frequency of samples are controlled by cost.

2.3 FREQUENCY OF SAMPLING

As mentioned in Chapter 1, frequency of sampling generally is site specific and no specific rules can be provided. In general, if the environmental value or quality interest varies with a certain frequency, the sampling frequency must be at least twice the frequency of that variation. In addition, if the process is cyclic in nature, samples should be collected during at least one complete process cycle. A detailed description of the procedure for

VOL 12 1 6345

determining frequency of sampling is described by US EPA (1982) and Wilson (1982). Various forms of time-series analysis such as harmonic and spectral analysis have also been used to study the nature of variability of water quality. This type of analysis can be found in references such as Thomann (1967), Fuller and Tsokos (1971), Shastry et al (1972) and Edwards and Thornes (1973).

Most of the time the frequency of sampling for the monitoring program is restricted by the availability of costs, regulatory or permit requirements and sampling objectives. Monitoring programs for stormwater sampling are much newer and less information is known. Therefore a tiered sampling approach is often followed, with the objective of the program to develop appropriate sampling frequency. In such programs a certain number of storms is selected for sampling in the first period (e.g. first year or storm season). The initial number of storms must be greater than the expected number of storms to sampled in the final plan. After completion of the initial period a statistical analysis can be performed to determine the impact of reducing sampling frequency. This analysis can be as simple as analyzing a subset of the data and comparing means and variance to the full data set. The increase in variability using a smaller set of data (e.g. less sampling frequency) can be compared to the added costs of more frequent sampling. Formal methods for making such evaluations are also available and are described in several of the previously cited references.

3.0 SAMPLE TYPES

Samples collected for any monitoring program generally can be divided into two types: grab samples - those taken from a single point as individual - and composite samples - which are mixed or poured together. The distinction between these two types of sample are summarized in the following sections. Detailed descriptions and procedures are given by US EPA (1982) and ASTM (1989).

3.1 GRAB SAMPLE

A grab sample is defined as an individual discrete sample collected over a period of time (generally not exceeding 15 minutes). A grab sample represents the conditions existing only at the point and time of sampling. When the source is known to be fairly constant in composition over a considerable period of time or over a substantial distances in all directions, a grab sample may be said to represent a longer time period or a larger volume, or both (Standard Methods, 1989). Generally, the collection of a grab sample is appropriate when it is used to :

- characterize water quality at a particular time,
- provide information about minimum and maximum concentrations,
- allow collection of variable sample volume,
- corroborate composite sample,
- meet a requirement of a discharge permit.

In addition, grab or discrete sampling can also be used when (US EPA, 1982):

- the stream does not flow continuously or a spill is suspected,
- the water or waste characteristics are relatively constant,
- the parameters to be analyzed are subjected to changes with storage (e.g.micro biological parameters, dissolved gases, soluble sulfide, residual chlorine, oil and grease, purgeable organics, and pH),
- information on maximum, minimum or variability is desired,
- the history of water quality is to be established based on its state over relatively short time intervals,
- the spatial parameter variability is to be determined (e.g., the parameter variability throughout the cross section and/or depth of a stream or large body of water).

A grab sample sometimes is also called a discrete sample, spot sample, or catch sample. Sampling is considered discrete if no further sampling is planned. If a number of discrete samples are collected in sequence in time and/or space to produce a set of samples, the sampling is considered to be a repetitive sampling. The variation of determinands in time and/or space can be obtained through a repetitive sampling. Examples of repetitive sampling include zonal sampling and chronological sampling (Krajca, 1989). Zonal sampling is applied to a repetitive collection of samples which are taken from a series of horizons or levels in a source (e.g., reservoir, borehole, swallow hole or lake). When samples are taken from a single source at fixed time intervals so that changes with time can be identified, the sampling process is considered to be chronological sampling. The time interval between successive sampling depends upon the purpose of the analysis, the dynamic character of the determinand, and often the flow regime and flow rate at the sampling point.

Spot samples, another form of grab sample, are usually acquired by filling the sample container or sampler once. They can be used to determine repeatability of non-recurrent, zonal or chronological sampling.

3.2 COMPOSITE SAMPLE

A composite sample is defined as a sample formed by mixing discrete samples taken at periodic points in time or a continuous proportion of the flow. Composite samples are most useful for observing average concentrations that will be used, for example, in calculating mass/unit time loading . Composite samples should not be collected over a period exceeding 24-hours, and care must be taken to prevent the deterioration of the sample during the period of collection by using preservatives, refrigeration, storage in the dark, or other means. Preservatives are normally put into the sample container prior to sampling, so that all sub-samples are preserved at the time of collection. Generally, composite samples should be avoided for the bacteriological/microbiological examination, radiological examination (e.g., short-lived radionuclides), or for constituents/analytical components that are subjected to significant and unavoidable changes on storage (e.g. dissolved gases, purgeable organics, residual chlorine, soluble sulfide, temperature, and pH) (Standard Methods, 1989; ASTM, 1989). Analyses for those constituents that are subjected to changes should be carried out on individual samples as soon as possible after collection and preferably at the sampling points (Standard Methods, 1989; Krajca, 1989).

The number of discrete samples which make up the composite depends upon the variability of pollutant concentration and flow. Generally there are two types of composite samples, i.e. time-interval and flow-proportioned (or flow-weighted) composite samples. A time-interval composite sample is collected in a series of small aliquots in which each aliquot was collected over a fixed interval of time. Sometimes a series of periodic grab samples is collected into an individual containers and then composited to cover a longer time period. This type of sample is called a sequential composite sample. Most of the composite samples are collected using automatic samplers (see Chapter 4). Current automatic samplers can be obtained with a built-in timer, flowmeter and rain gauge. Therefore, time-interval and flow-weighted composite samples can be programmed prior to sampling.

A frequent mistake made with automatic samples is to rely to heavily upon automation. No currently marketed samplers (Stenstrom and Strecker, 1993) can be remotely programmed to collect suitable volumes over suitable intervals for varying size storms and runoff periods. This must still be done manually. Automatic samplers require electric power and may need telemetry (e.g., a phone line connected to a modem). Many stormwater locations are not easily reached with power and phone lines. Rechargeable batteries are one alternative to electricity but can be used only for short storm events.

VOL 12 1 6348

There are six methods which can be used to composite samples (Table 3-1). Choice of composite type is dependent on the program and relative advantages and disadvantages of each composite type. For a constant volume/time proportional composite samples, previous flow records can be used to determine an appropriate flow volume increment so that a representative sample is obtained without exceeding the bottle capacity or supply. In addition, composite samples can also be prepared from time constant/variable volume discrete samples in various ways. Examples of these flow-weighted composite samples preparation are given by US EPA (1982).

3.3 BLANKS

The most commonly used analytical tools for assessing and controlling sample contamination are blanks. Blanks may be defined as samples that are expected to have negligible or unmeasurable amounts of the substance of interest. Nomenclature associated with blank samples is far from consistent in the literature, and distinguishing one type of blank from another is sometimes difficult except by context or by a more detailed description (Lewis, 1988). Generally, blanks can classified into two types: field blanks and laboratory blanks. Field blanks, which include equipment blanks and transport blanks are used to provide information about contaminants that may be introduced during sample collection, handling, storage, transport and preparation. Laboratory blanks, which include system/instrument blanks, solvent/calibration blanks, and reagent blanks, are reliable tools for assessing and controlling sample contamination that occurred in the laboratory (Black, 1988; Lewis, 1988).

3.3.1 Field Blanks

Equipment Blanks

An equipment blank is used to estimate incidental or accidental contamination of a sample during the sample collection procedure. It is also can be used to verify the effectiveness of cleaning procedures. Capped and cleaned sample containers are taken to the sample collection site. After a sample is obtained, the sampling equipment is cleaned according to the standard operating procedure prior to taking another sample. At that point, the sampling equipment is rinsed with deionized water, which is collected in a sample container for later analysis. If a preservative is used, then an equal amount is put into the container with the blank. Generally, one equipment blank should be allowed per sampling team per day per sampling equipment.

Transport Blanks

A transport blank is used to estimate sample contamination from the container and preservative during transport and storage of the sample. It is also called trip blank, travel blank or matched-matrix blank. A cleaned sample container is filled with deionized water, preservatives used in the sample are added and then the blank is stored, shipped, and analyzed with its group of samples. This blank is more important when shipping and storage consumes several days or weeks because leaching of the material from the container can become significant. One transport blank should be allowed per day per type of sample.

VOL 12 1 6349

Table 3.1 Sample Compositing Methods (EPA, 1982).

Sample Mode	Compositing Principal	Advantages	Disadvantages	Comments
Continuous	Constant pumping rate	Minimal manual effort, requires no flow measurement	Requires large sample capacity; may lack representativeness for highly variable flows	Practical but not widely used
Continuous	Sample pumping rate proportional to stream flow	Most representative especially for high vaiable flow; minimal manual effort	Requires accurate flow measurement equipment, large sample volume, variable pumping capacity, and power	Not widely used
Periodic	Constant sample volume, time interval between samples proportional to stream flow	Minimal manual effort	Requires accurate flow measurement or reading equipment; manual compositing from flow chart	Widely used in automatic as well as manual sampling

Table 3.1 Sample Compositing Methods. (continued)

Sample Mode	Compositing Principal	Advantages	Disadvantages	Comments
Periodic	Constant time interval between samples, sample volume proportional to total stream flow since last sample	Minimal instrumentaion	Manual composition from flow chart in absence of prior information on the ratio of minimum to maximum flow, there is a chnace of collecting either too small or too large individual discrete samples for a given composite volume	Not widely used in automatic samplers but may be done manually
Periodic	Constant time interval between samples, sample volume proportional to total stream flow at time of sampling	Minimal instrumentation	Manual compositing from flow chart. In absence of prior information on the ratio of minimum to maximum flow, there is a chance of collecting either too small or too large individual discrete samples for a given composite volume	Used in automatic samplers and widely used as manual methods

3.3.2 Laboratory Blanks

<u>System Blanks</u>

A system blank is also known as instrument blank. It is not really a blank at all in the sense of simulating a sample. A system blank is a measure of the instrument background, or baseline, response in the absence of a sample. System blanks are often used in gas and liquid chromatographic methods to identify memory effects, or carry-over from high concentration samples, or as a preliminary check for system contamination.

<u>Solvent Blanks</u>

A solvent blank consist only of the solvent used to dilute the sample. It is used to identify or correct for signals produced by the solvent or by impurities in the solvent. Depending on the analytical technique, the solvent blank may be used as a calibration blank. A calibration blank is used directly to set the instrument response to zero, or is used directly as one of a series of calibration standards, where the blank represents an analyte concentration of zero.

<u>Reagent Blanks</u>

In addition to solvent, the reagent blank contains any reagents used in sample preparation and analysis procedure. These reagents may include color development reagents, reagents used in sample digestion steps, reagents used for pH adjustment, preservatives, or other reagents depending upon the analytical method. The reagent blank is carried through the complete analytical procedure in the same manner as an actual sample. This procedure should include all steps involved in sample preparation, such as cleanup, filtration, extraction and concentration. Because it is carried through the complete analytical method, the reagent blank is also sometimes called a method blank. It can also use to determine the lower limit of detection. A reagent blank is analyzed for each 20 samples and analyzed whenever a new batch of reagents is used. The preferred outcome of reagent blanks is a less than detection limit result for all of the analytes of interest.

3.4 CONTROLS

Basically there are two types of control samples : (1) controls used in quality control procedures to determine whether or not the analytical procedure is in control, i.e., calibration control standard, laboratory control standard and matrix control, and (2) controls used to determine whether or not a factor of interest is present in a population (e.g., a group of environmental samples) under study but not in the control, i.e., control sites (local, area, national, background) (Black, 1988).

3.4.1 Calibration Control Standard

A calibration control standard is also known as quality control calibration standard (CCS) or calibration check standard. In most laboratory procedures, this control is a solution containing the analyte of interest at a low but measurable concentration. The precise concentration of this standard need not to be known. The first sample analyzed after an instrument is calibrated is a CCS, and the result should be plotted on a control chart. Another CCS is analyzed after each 20 samples, or after each shift if fewer samples are analyzed per shift. The standard deviation of the CCSs is a measure of the instrument precision unless the CCS is analyzed as if it were a sample, in which case the CCS is a measure of the method precision.

3.4.2 Laboratory Control Standard

The laboratory control standard (LCS) is a certified standard, generally supplied by an outside agency. This standard is used to determined whether or not an analytical procedure is producing results comparable to other analytical laboratories. The National Bureau of Standards (NBS) is a good source of LCSs in which a variety of standard reference materials containing certified concentrations of elements or compounds. The Environmental Monitoring and Support Laboratory of the U.S. Environmental Protection Agency in Cincinnati is another useful source of organic standard in water or organic solvent solutions. An LCS should be analyzed with every batch of samples until 7-10 results are available. If those results are within the control limits specified by the program protocol, the frequency may then be reduced to one per day. However, several LCSs should be analyzed any time the analytical instrument is recalibrated. The mean value of all LCS results is a measure of the method bias.

3.4.3 Matrix Control

Matrix control is commonly known as field spike. A field spike may be required to obtain an estimate of the magnitude of those interferences due to a complex mixture of a sample matrix (e.g., sediments, sludges). The losses from transport, storage, treatment, and analysis can be assessed by adding a known amount of the analyte of interest to the sample during collection in the sampling site.

3.4.4 Control Sites

In addition to the controls that are used to measure the precision and bias of sampling and analysis, a control site or a control population is also very important so that the results of a study of a given area can be judged as high, low, or insignificant. For example, if the contribution of pollutants from an urban area to environmental pollution is to be assessed, then the contribution of pollutants from sources other than the urban area must be known. However, if the environmental impact of a given facility, such as a waste disposal site, is to be assessed, then the environmental levels in the absence of that facility must be known. The sites or populations that can supply control samples can be classified as local, area, or national, depending on the location selected (Black, 1988).

<u>Local Control Site</u>

A local control site is a control near in time and space to the sample of interest. Factors to be considered in the selection of local control sites include the following:

- local control sites should be upwind of the facility most of the time,
- local control sites should be upgradient from the facility with relation to surface and groundwater flow,
- the potable water source should not be affected by site effluents,

- travel between the control site and the facility should be minimal because of problems associated with transport.

<u>Area Control Site</u>

This control site is in the same area (e.g. city or county) as the pollutant source but not adjacent to it. The factors to be considered in site selection are similar to those for local control sites. All possible effort should be made the sites identical except for the presence of the pollutant at the site under investigation.

VOL 12

1 6354

Sampling equipment used for various types of natural waters (lake, reservoir, municipal wastes, surface waters, groundwater, stormwater, etc.) usually have common features. The sampling equipment can be divided into two major groups: surface and sub-surface sampling. Surface sampling equipment include (Krajca, 1989) :

- samplers and sampling containers (including pressure vessels) for samples collection and transportation,
- sampling accessories such as scoops on long poles, grips, and forceps and for handling samplers,
- equipment for closed pipe sampling,
- suction probes for pore water sampling,
- precipitation samplers,
- automatic sampling equipment with basic components such as automatic control blocks water distribution systems and sets of samplers or collecting vessels).

For the sub-surface sampling, the sampling equipment includes depth samplers and other equipment which parts designed to operate under water, in places that are inaccessible to the operator.

For the selection of appropriate sampling equipment, factors such as appropriate materials for sampling equipment and sample containers, type of sampling equipment (manual or automatic), cleaning of sampling equipment (Krajca, 1989). The following section discusses these criteria and the description of the commonly used water sampling equipment also included.

4.1 MATERIAL USED FOR SAMPLING EQUIPMENT AND CONTAINERS

Selection of the material for sampling equipment and sample containers should consider (Krajca, 1989):

- the material must be inert to the sample or more particularly those of its constituents which are to be analyzed,
- no biological activity occurs,
- able to withstand any sterilization, cleansing or preservation procedures.

VOL 12

16355

Materials commonly used for sample containers include glass and plastics (e.g., polyethylene). Selection of the type of sample containers will be discussed in Chapter 5. In addition to glass and plastics, metals are also commonly used, especially for the sampling equipment. Stainless steel sampling equipment is usually made of chrome-nickel steel with alloying additions of tungsten and molybdenum (both non-magnetic). These alloys are corrosion resistant and able to withstand strong acidic or alkaline samples for a long period of time. Compatibility of metals with various types of water samples was discussed by Krajca (1989) (see Appendix B). However, non-metallic material (e.g. plastic) should be used for metal analysis in order to avoid leaching problems. Blank tests should always be carried out to confirm that the sample is not affected by the material of the sampling equipment or sample containers (e.g., equipment blank).

4.2 WATER SAMPLING EQUIPMENT - MANUAL

As mentioned above, there are two types of water sampling equipment: surface and subsurface sampling. Surface water samples are usually taken directly into the sample container, which is also used for transport. If it is not possible to collect the sample by submerging the container by hand, laboratory forceps or a holder with a sliding sleeve can be used. If the sample is to be taken from the mainstream by reaching out from the bank then it may be best to attach the container to a segmented rod made up to appropriate length (e.g. dip sampler). Such sampling device is usually made of stainless steel.

Subsurface sampling is generally for depth sampling. Samplers can be categorized into three general types: free-flushing samplers, non-flushing samplers and combined samplers. Free-flushing samplers consist of a tubular body which is open at both ends. This allows the sampling chamber to pass through the water on its way down to the sampling point with only a minimum disturbance or mixing. Simple flushed samplers usually can be used in the horizontal mode, e.g. for sampling open streams, provided that suspension and controls have been suitably adapted. Flushing occurs with the sampler at rest. The degree of flushing depends upon the water velocity at the sampling point. Flushed samplers are primarily suitable for homogeneous, single phase liquid samples. Their main advantage is simple design and reliable operation, even at high pressures and temperature. When sampling heterogeneous liquids, attempts to flush the sampler by repeatedly raising and lowering, can result in partial separation of the mixture because the hydraulic resistance inside the sampler may cause more the mobile phase to flow around the sampler.

Unlike free-flushing samplers, non-flushed samplers make use of reduced pressure to effect sampling in which flushing of water samples through the sampling chamber is avoided. This is achieved through a difference in pressure between the inside of the sample chamber and the water at the sampling level. Examples of non-flushed samplers include bottle samplers, bag samplers, telescopic samplers and piston samplers. The third kind subsurface samplers is the combined sampler that combines the features of two or more basic types of sampler.

4.2.1 Kemmerer Bottles (Figure 4-1)

Kemmerer bottles may be used in most situations where access to the sampling sites is from a boat or structure such as bridge or pier, and where samples at depth are required. Kemmerer bottles are a messenger-activated water sampling devices. Water flows easily through the bottle in the open position. Once it is lowered to the desired depth, a messenger is dropped down to the sample line, tripping the release mechanism which

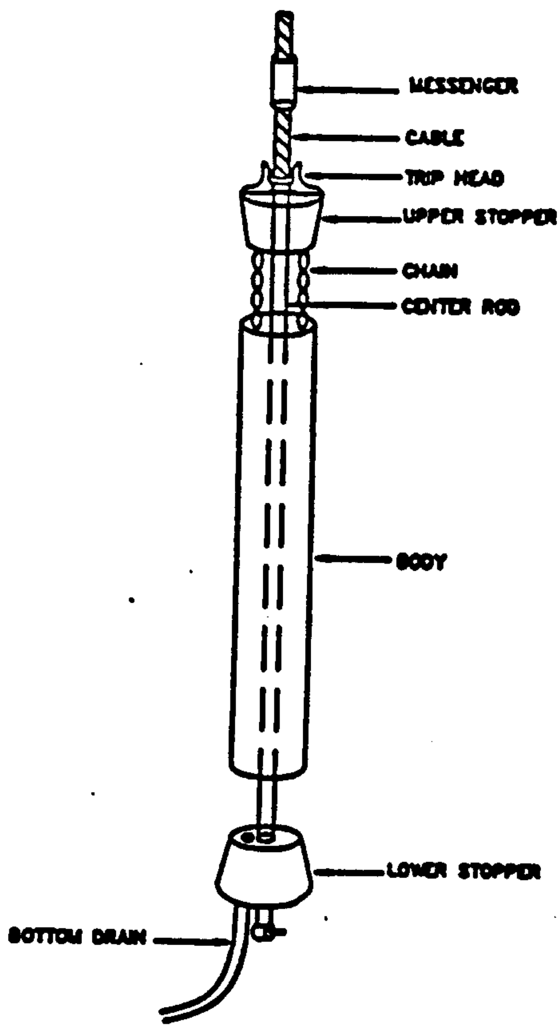

Figure 4-1 Kemmerer Bottles (US EPA, 1991)

causes the bottle to close. Both top and bottom are sealed to prevent further contact with the water column. Commercially available Kemmerer bottles are made of different types of material such as brass, plastic, stainless steel or acrylic. They can collect sample at specific depths between 3 - 600 feet.

4.2.2 Dip Samplers (Figure 4-2)

When the direct access to a sampling site is limited, such as an outfall or lagoon bank, a dip sampler is very useful for such sampling situations. The long handle on the dip sampler allows access from a discrete location. Dip sampler can be constructed of inert material such as stainless steel or Teflon.

4.2.3 Pond Samplers (Figure 4-3)

A pond sampler consists of an adjustable clamp attached to the end of a two- or three-pieces telescoping aluminum tube that serves as the handle. The clamp is used to secure a sampling beaker/container. A pond sampler is easily and inexpensively fabricated and usually not available commercially. It is commonly used to collect water samples from disposal ponds, pits, lagoons, and similar reservoirs. Grab samples can be obtained at distances as far as 3.5 m from the edge of the ponds.

4.2.4 Van Dorn Samplers

Van Dorn samplers, also known as alpha water samplers by others, are made of inert plastic tubing (generally PVC) closed with hemispherical rubber (urethane) end caps connected by a length of rubber passing through the sample chamber (available in 2,3, or 6 L capacities). When the sampler is being lowered the end caps are held open by a pair of chains attached to a 'lock' on the outside of the chamber. A messenger weight is released when the sampler is at the desired sampling depth. This will cause the end caps to snap sharply over the ends of the chamber to close it. There are two types of Van Dorn water samplers, i.e. Van Dorn-Vertical (Figure 4-4) and Van Dorn-Horizontal (Figure 4-5). The Van Dorn-Vertical is good for general water sampling. The Van Dorn-Horizontal is useful for collecting water at the sediment-water interface or sampling a thin layer of the water column. Van Dorn samplers generally are not recommended for sampling trace organics as they rely on an organic elastic closing mechanisms that can contaminate the samples.

Similar sampling mechanism as Van Dorn Samplers include Ruttner and Theiler-Friedinger water samplers. These two samplers are commonly used in Europe (Krajca, 1989). Ruttner's water samplers (Figure 4-6) are generally constructed of Perpex (plexiglass) and its open lids are in the horizontal position. Theiler-Friedinger's samplers, on the other hand, have the open lids in the vertical position and are constructed of light-metal or PVC (Figure 4-7). Both Ruttner and Theiler-Friedinger samplers have 1 - 3 L volume capacities.

4.2.5 Peristaltic Pumps

Peristaltic pumps can be used to draw in water sample through a Teflon tubing and pumped directly into the sampling containers (Figure 4-8). A medical grade silicone or C-Flex tubing is generally used as the pumping tubing. This system is highly versatile and portable. A timer can be used to provide constant sampling intervals and can also provide

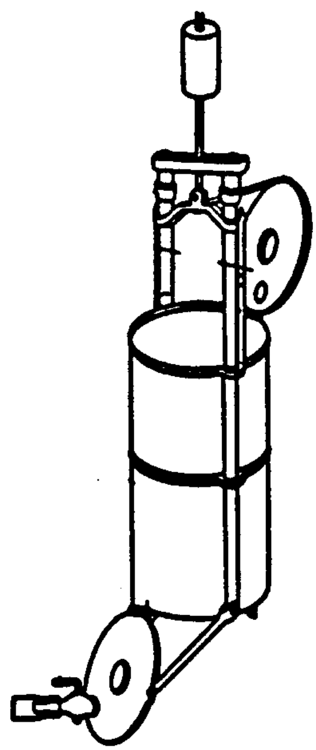

Figure 4-7 Theiler-Friedinger Sampler (Krajca, 1989)

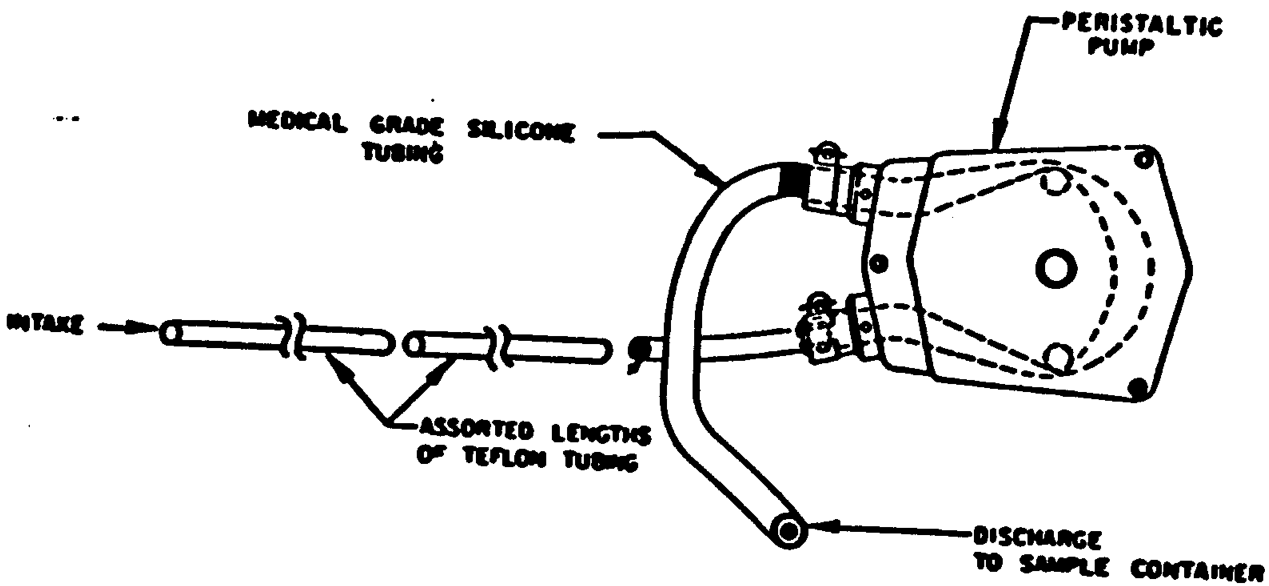

Figure 4-8 Peristaltic Pump Sampler (US EPA, 1984)

composite samples. This system allows sample collection at depths to 30 feet. The water sample contacts only tubing and stainless steel fittings. This method is not recommended for sampling volatile organics due to reduced pressure in the suction tubing, or for oil and grease due to coating of the tubing.

The system as shown in Figure 4-8 can also be altered so that the water sample is collected in a vacuum flask and does not enter the pump (Figure 4-9). The integrity of the collection system can be maintained with only the most non-reactive material (Teflon) contacting with the sample.

The main disadvantage of this method is the limited lift capacity of the pump, i.e. at ~30 feet. This lift capacity decreases with higher density fluids and with increase wear on the silicone pump tubing. Increased altitude decreases the pump's ability to lift. When sampling a liquid stream with a considerable flow rate, it may be necessary to weight the bottom of the suction line.

4.2.6 Knudsen Bottles

A Knudsen bottle is generally used for collection of water samples and water temperature data using up to three reversing thermometers. The sampler is constructed of nickel-plated metal with an average length and capacity of 0.5 m and 1.2 L, respectively.

4.2.7 Nansen Bottles

A Nansen bottle is similar to the Knudsen bottle, but it is designed to sample depths of ~3000 feet or more. The end valves is made of bronze, and the cylinder is made of brass. It is also available with either a tin-plated or Teflon-lined cylinder. A Nansen bottle has a capacity of 1.3 L and an overall length of ~2 feet. Several Nansen bottles can also be used in series for water sampling.

4.2.8 Simple Bottle Samplers

A simple bottle sampler is essentially a glass or polyethylene bottle and is generally used for surface sampling. The sample container is filled by displacement when the open bottle is put beneath the surface. Its advantage of this bottle sampler is its simplicity of operation mode, inexpensive, small size and weight in relation to the sample volume. However, there is no depth control using simple bottle sampler. In addition, the water sample is partially aerated which may be unsuitable for sampling dissolved oxygen (DO), carbon dioxide or other gases.

4.2.9 Niskin's Bag Samplers (Figure 4-10)

A Niskin's sampler is made of two ribbed aluminum plates connected by spring loaded hinges. It is kept in the closed position by a messenger operated mechanism. The sampling bag is fitted with pockets on each side to hold the plates, and is filled through a tube protected by a plastic casing. When the sampler is at the sampling depth, the messenger is released and activates a guillotine to cut off the cover of the inlet tube, which hangs away from the sampler body. At the same time, the two plates spring apart and the sample is sucked into the bag through the inlet. After the bag is filled, the end of the tube is automatically closed with a clamp, and the sampler can be pulled up to the surface. The

VOL 12

1

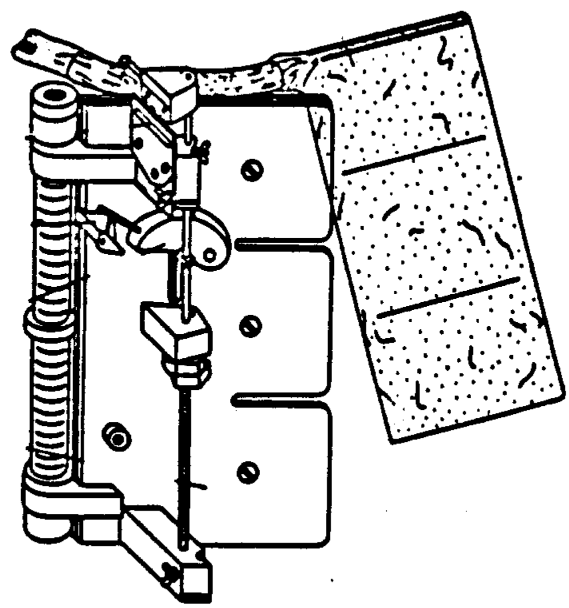

Figure 4-10 Niskin's Bag Sampler (Krajca, 1989)

bag can be used for transportation and storage, or emptied into another container. Sample contamination by this sampler is virtually eliminated, and groups of bags can be submerged as a series, on a single suspension cable either one above the other or side by side. Niskin's bag samplers are available in PVC and Teflon-lined for organics sampling. The sample volume capacity is 1.2 - 30 L.

4.3 AUTOMATIC SAMPLERS

Automatic samplers are being used increasingly in most of the monitoring programs to meet the requirements of NPDES permits. The advantages of automatic samplers include their consistency in samples collection, capability of collecting multiple bottle samples, minimal labor requirements, unattended operation, and the decrease in variability of samples caused by sample handling. However, no single automatic sampler is ideally suited for all situations. General criteria needed to be considered in selection of an automatic sampler include:

- ease of operation and repair,
- simple design with minimum operating parts and maximum long-term reliability,
- minimum number of parts in contact with water,
- resistance to corrosion, dust and sand, and low susceptibility to clogging,
- ability to use battery or main power,
- ability to tolerate varying climatic conditions,
- ability to operate a sampling schedule based on time or flow volume through the sampling chamber,
- ability to preserve samples at specified temperature for at least 24 hours.

Detailed information on the theoretical design considerations and actual field performance data for automatic samplers can be found in references such as Lauch (1976) and Shelley and Kirkpatrick (1975). The basic components of automatic samplers are a pump and a system for transporting the water sample to the collecting center (a tank or sample containers). Medical-grade silicone tubing must be used in peristaltic pumps to avoid contamination of the sample by organic peroxides used in the manufacturing of conventional grades of silicone tubing. Additionally, when sampling for toxic pollutants, the suction line must be made of Teflon (Newburn, 1988). The sample collection chamber sometimes is also connected to an autoanalyzer (e.g. flowmeter, pH and DO meter). Examples of automatic samplers used previously for stormwater sampling include ISCO models 3700 and 2900, Sigma Model 800SL, NB Model WS-1000, TN Technologies Priority Contaminant Samplers (PCS), etc. A full detailed list of automatic samplers is also given in *Addendum to Handbook for Sampling and Sample Preservation* (US EPA, 1983).

Automatic samplers are constantly being developed and improved. Recent innovations include flow and rainfall measuring equipment, and remote telemetry capability. In order to obtain the most current and correct information, manufacturers must be contacted to obtain specifications.

Automatic samplers are capable of collecting either grab or composite samples. Current automatic samplers mostly contain at least 24 sample bottles for grab sampling in which each individual sample is collected into separate sample bottle. For composite samples, small aliquots are taken at frequent intervals, usually over a 24-hours period, and collected in a single container. Most automatic samplers are also capable of gathering either timed-interval samples or samples collected proportional to flow. Timed-interval samplers have a fixed interval of time between each aliquot or sample. Flow-proportioned or flow-weighted samples are based generally on equal increments of flow as measured by the built-in flowmeter. A flow-weighted composite sample can be obtained by collecting small aliquots in a single container over small increments of flow (Newburn, 1988). However, dry weather conditions can create problems in collecting flow-weighted composite samples due to the absence of flow in the stormdrains. In such situation, only time-interval grab or composite samples can be collected.

Although automatic samplers are considered versatile and reliable in collecting samples, considerable maintenance is required for proper operation. Other disadvantages of automatic samplers include susceptibility to fouling by solids, inflexibility (fixed maximum sample volume), and possible sample contamination. Furthermore, automatically samplers cannot properly sample certain contaminants, such as oil and grease. Oil and grease can be stratified in the sample stream which makes collecting a representative sample from a single point impossible. The tubing required in the sampler's pumping system may contaminate samples (carry over from one sample to another) or may alter the sample concentration (adsorption of the contaminants to the tubing walls). Another major disadvantage of automatic samplers is their cost and susceptibility to vandalism. The sampler itself may cost as little as $1,000, but the infrastructure associated with the sampler, including telemetry, construction and flow measuring equipment may cost as much as $30,000 or more per station.

Most of the new stormwater monitoring programs are based upon automatic samplers. The cost and difficulty of manually collecting flow-weighted composite samples are prohibitive. Chapter 9 of this report includes several case studies, all of which used automatic samplers. It should be consulted for further information.

VOL 12

1

6370

Some properties of the samples can change, either quantitatively or qualitatively, during the interval between their collection and analyses. These changes may be spontaneous or due to the sampling handling procedures. If possible, field analysis, or *in situ* analysis, is recommended in order to avoid any possible changes. When *in situ* analysis can not be carried out, the samples should be appropriately stored and preserved to maintain parameter stability during the delays in transport and storage. The following sections will discuss the samples storage, sample preservation, recommended holding time and sample volume prior to any analysis in the laboratory.

5.1 FIELD ANALYSIS

Field analysis, or *In situ* analysis, refers to all measurements made at the sampling site. Field analysis is generally used when the parameters are known to change with time and cannot be preserved. In addition, field analysis can also be used to check the reliability and reproducibility of the sample. The parameters measured in the sampling site include temperature, pH, conductivity, buffering capacity, ferrous iron, E° (effectively oxidation and reduction potential), some organoleptic properties (e.g., taste, odor, color and turbidity), concentrations of carbon dioxide, hydrogen sulfide and other soluble gases. Some of these parameters, such as conductivity, pH, and ferrous iron, should be determined first in the field and then in the laboratory using preserved samples. In this way, the degree of change that occurred during transport and storage can be determined (Krajca, 1989).

5.2 SAMPLE STORAGE

It is important to take proper precautions for samples storage during sample transportation from the sampling site to the laboratory. Sample containers used in storing the sample prior to analysis are very important. Selection of sample container depends on factors such as resistance to breakage, size, weight, interference with constituents, cost and availability (US EPA, 1982). The following sections discuss factors that need to be considered prior to sample storage.

5.2.1 Container Material

There are two major types of material used for sample container, i.e., plastic and glass (Hellwig, 1964):

1. Glass
   - Kimax or Pyrex brand - borosilicate
   - Vycor - generally lab ware
   - Ray-Sorbor Low - Actinic - generally lab ware
   - Corex - generally lab ware

VOL 12

1637/

2. Plastic:
   - Conventional polyethylene
   - Linear polyethylene
   - Polypropylene
   - Polycarbonate
   - Rigid polyvinyl chloride
   - Teflon

The above glass and plastic materials have their advantages and disadvantages (Table 5-1). For example, borosilicate glass bottles have the advantages that their internal surface is readily apparent and that they can be more vigorously cleaned. In addition, they are inert to most materials. However, glass bottles are more liable to breakage.

In general, three main considerations involve in choosing container materials (Suess, 1982):

1. the material of the containers may cause contamination of samples (e.g., sodium and silica can leached from glass, organic substances can be leached from plastics),

2. determinands may be sorbed on the walls of containers (e.g., trace metals by ion-exchange processes on glass surfaces, adsorption of benzene by plastics),

3. constituents of the sample may react with the containers (e.g., fluoride may react with glass).

The above mentioned processes generally become more important as the concentrations of determinands become smaller (e.g., less than 1 mg/L). Thus type of container used for storing samples can be critical. However, if large concentrations of constituents such as chloride, sulfate, hardness, nitrate, etc., the type of container is usually unimportant.

As a general rule, glass bottles should be used when organic compounds (e.g., pesticides, oil and grease) are to be determined. Plastic or polyethylene bottles should be used for determinands that are major constituents of glass, e.g., sodium, potassium, boron, silica (Suess, 1982; US EPA, 1982). For most bacteriological samples, bottles that can withstand sterilization temperatures should be used (ASTM, 1989).

5.2.2 Container Caps

The types of container caps used with the sample containers is also important. There are two major types of plastic used in container caps: polyethylene and bakelit with liners. Polyethylene caps are recommended for ease of cleaning unless oil and grease are to be analyzed. There are three types of liners available and their advantages and disadvantages are listed in Table 5-2. Generally caps with Teflon liners should be used for pesticides and oil and grease samples. Silicone rubber material should be avoided for trace metals due to possible zinc contamination (Gibbs, 1975; ASTM, 1989).

5.2.3 Container Structure

Wide mouth containers are mostly used. This structure permits easy filling and sample removal. It is also easily cleaned, quickly dried, and can be stored inverted. A narrow

Table 5.1 Glass and Plastic Advantages and Disadvantages (EPA, 1982).

	Borosilicate Glass	Conventional Polyethylene
Interference with sample	Inert to all constituents except strong alkali	Good for most constituents except organics and oil and grease
Weight	Heavy	Light
Resistance to breakage	Very fragile	Durable
Cleaning	Easy to clean	Some difficulty in removing adsorbed components
Sterilizable	Yes	In some instances
Space	Takes up considerable space	Cubitainers - substantial space savings during extended field studies

VOL 12

1 6373

R0049678

Table 5.2 Bottle Cap Liner Advantages and Disadvantages (EPA, 1982).

Liner Type	Advantages	Disadvantages
Wax coated paper	Generally applicable to most samples, inexpensive	Must be inspected prior to each because of deterioration. Cannot use with organics
Neoprene	Same as wax coated paper	Same as wax coated paper
Teflon	Applicable for all analyses Minimizes container/sample interaction	High cost

VOL 12

1 6374

neck bottle is recommended when the interaction with the cap liner or outside environment is to be minimized. For pesticide sample collection, a solvent cleaned glass container should be used (Hellwig, 1976).

5.2.4 Disposable Containers

When the cost of cleaning is high, disposable containers generally are recommended. These containers should be precleaned and sterile. The most commonly used disposable container is the molded polyethylene container which is shipped nested and sterile to the buyer (US EPA, 1982).

5.2.5 Container Cleaning

Cleaning of sample containers prior to sampling is another important step in order to avoid any unnecessary contamination. Chromic acid is often suitable for glass, and hydrochloric acid (approximately 1 mole/L) can be used to clean polyethylene. The use of concentrated nitric acid should be avoided for cleaning plastic bottles as it may cause the formation in the plastic of chemical groups with ion-exchange properties (Suess, 1982). Non-phosphate or biodegradable detergent can also be used. Glass bottles that have contained samples with chromate or heavy metals should be rinsed with dilute nitric acid before final thorough rinsing with water. After the final rinse the pH should be checked to assure that toxic acids or chromate are not present (ASTM, 1989).

5.2.6 Container Preparation

In addition to the above mentioned cleaning procedure, special precaution should be taken to avoid adsorption and contamination due to interaction with container walls. Special procedures to prepare the sample containers for metals, organics and microbiological samples are outlined below (US EPA, 1982) :

1. <u>Metals</u> : A solution of one part nitric acid to four parts water should be used to rinse the container, and then followed with a rinse using distilled water. If phosphorous is to be analyzed, a solution of one part hydrochloric acid to one part water is used instead. The container caps are treated in similar way.

2. <u>Organics</u> : When oil and grease or pesticides are to be analyzed, methylene chloride should be used to rinse the containers, followed by acetone. For pesticide analysis, pesticide grade acetone or hexane should be used. The containers should have been previously treated with chromic acid solution. The caps are also treated similarly.

3. <u>Microbiological</u> : For microbiological analyses, the containers and its cap/stoppers should be sterilized by autoclaving at 121°C for 15 minutes or by dry heat at 180°C for 2 hours. The bottles should also be wrapped in Kraft paper or covered with aluminum foil before sterilization so contamination can be avoided.

5.3 HOLDING TIME

Holding time is defined as the time interval between collection and analysis. More reliable analytical results will be obtained with shorter holding time. It is, however, difficult to determine the maximum time that is allowed to elapsed between sample collection and analysis before any deterioration of sample occurs. The characteristics of the samples, analysis that are to be performed, and the conditions of the storage are among the factors that need to be considered in determining the holding time. There is some variability among various authors on the maximum allowable holding times for various analytes. Recommended maximum holding times for various analytical parameters, which have been compiled by the US EPA (1974), are listed in Appendix C.

5.4 SAMPLE VOLUME

The volume of sample collected generally is not important as long as it is sufficient for all the required analyses and there is enough leftover in case some analyses need to be repeated. In general, approximately 8 liters (about 2 gallons) are required for a fairly complete analysis. The volume of sample required for specific types of pollutants analyses, which has also been compiled by the US EPA (1974), are shown in the Appendix C.

However, certain points need to be considered while collecting the samples (Suess, 1982):

- the sample containers should be completely filled for determining dissolved gases, purgeable/volatile organics, pH and conductivity in weakly buffered waters,
- the sample containers should not be completely filled when samples require vigorous shaking before portions for analysis (e.g., for bacteria or undissolved materials),
- when small concentrations of determinands are present as discrete particles (e.g., dissolved materials, algae, bacteria), a minimum volume of sample may be needed to control errors arising from the statistical variations in the number of particles in a given volume of sample. The required sample volume usually will be given in the analytical method.

5.5 SAMPLE PRESERVATION

Changes of the physical (e.g., volatilization, adsorption, diffusion, and precipitation) and chemical (e.g., photochemical and microbiological degradation) conditions of the samples may occur during the time interval between sample collection and analyses. These changes can be minimize by using proper preservation techniques.

Preservation techniques are selected on the basis of their ability to minimize changes in order to preserve the integrity of the sample after collection. Preservation guidelines for certain types of sample and analyses have been compiled by the US EPA (1974). The recommended preservation methods are listed in the Appendix C. Preservation of samples has also been discussed in a number of literature such as US EPA (1982), Keith (1988), Suess (1982) and ASTM (1989). Preservation methods are generally limited to addition of preserving reagent, pH control, refrigeration and freezing. Combination of these methods are often used for the preservation of sample. The following section discusses some of the preservative methods commonly used.

5.5.1 Addition of Preserving Reagent

Stability of sample conditions can be achieved by adding a chemical reagent (or a preservative) to an empty sample container before collection. When the sample is added, the preservative disperses immediately, stabilizing the parameter(s) of concern for a certain period of time. However, when the added preservative interferes with other parameters being measured, additional samples for those parameters must be collected. For example, concentrated nitric acid added for preserving the metals would interfere with BOD, so an additional sample must be collected for BOD.

As a general guideline, acidification (usually with nitric or hydrochloric acid) of samples is carried out for trace metals analyses. Different acids and acidities can be use for different metals. The minimum acidity required for stability depends on the metal. In general, sufficient amount of nitric or hydrochloric acids should be added to give a final concentrations in the range of 0.05 - 0.1 mole/L in the sample after collection (Suess, 1982).

When the samples are subject to biological changes, addition of mercuric chloride or acidification are more frequently used. In general, mercuric chloride (20 - 40 mg/L) can be used for preserving nitrogen compounds, while sulfuric acid (1 - 2 ml/L) is used for determinands such as COD, fats, and greases (Suess, 1982).

5.5.2 pH Control

This type of preservation method usually involves acidification (or chemical addition) of the sample. For example, concentrated nitric acid is added to lower the pH to less than 2 in order to keep metal ions in a dissolved state.

5.5.3 Refrigeration

Refrigeration of samples is another common preservation method. It is commonly used for biological examination in which the samples is refrigerated immediately after collection and held at a temperature less than 4°C.

5.5.4 Special Sample Containers

Samples with photosensitive constituents (e.g., polynuclear aromatic hydrocarbons and bromo- or iodo-compounds) should be collected and stored in amber glass containers to protect them from light (Parr et al., 1988) and stored in dark areas prior to analysis. It is also possible to use collapsible containers which facilitate collecting samples with no gas space in the container.

VOL 12

1637

6.0
FLOW MEASUREMENT

Flow measurement is one of the most important monitoring parameters in any sampling program. Care must be taken in selecting a site suitable for flow measurement as well as the flow measurement method. The ideal site allows flow measurements to meet program objectives, provides ease of operation and accessibility, personnel and equipment safety, and freedom from vandalism. Flow measurement is so important that site selection may be dominated by the ability to measure flow rate.

There are many flow measurement methods. The objective of this section is to present a brief overview of the current flow measurement methods and equipment appropriate for the storm drain monitoring programs and to list advantages/disadvantages. Detailed information of methods of flow measurements can be found in references such as *Flow Measurement Engineering Handbook* (Miller, 1983), *Water Measurement Manual* (USDI, 1974) and *Fluid Meters* (ASME, 1971).

The measured flow rate is generally used to determined the mass emission of contaminants (mass emission = flow rate x concentration). If the concentration of contaminants and flow rate vary with time, a flow weighted average must be determined to quantify mass emission. In addition, the number of discrete samples that make up the composite sample depends upon the variability of contaminant concentration and flow. Examples of manual compositing samples based on flow rate are given by the US EPA (1982). Inaccurate flow measurements will lead to inaccurate flow proportional composite samples.

Most of the flow measuring devices, however, have disadvantages such as:

- devices (e.g. weir) can reduce flow in the storm drain
- increase the risk of flooding,
- debris and trash can hang up on the device.

General criteria for an ideal flow measuring device include:

- no or insignificant restriction of storm drain flow,
- ability to use the device over a wide range of flows,
- no tendency to be fouled by debris.

6.1 OVERVIEW OF TRADITIONAL FLOW MEASURING DEVICES

The traditional flow measuring devices commonly used include weirs, flumes, venturis, orifices, positive displacement meters, flow nozzles, etc. These devices are generally not suited for stormwater flow measurements primarily because they restrict flow too much and require too much pressure drop for accurate measurement. In addition, they are also susceptible to clogging or fouling by the debris or suspended solids. More detailed information of these flow measuring devices can be found in the literature, but a brief overview is provided here.

6.1.1. Weirs

A weir is an overflow structure built across an open channel to measure the rate of flow. Weirs may be termed rectangular, triangular or trapezoidal, depending on the shape of the opening. The relationship between head and discharge are different for different weirs. More detailed information can be found in references such as *Water Measurement Manual* (USDI, 1974) and *Fluid Meters* (ASME, 1971). One of the parameters that affects weir flow measurements is the weir coefficient (C_w), i.e. a coefficient characteristic of flow conditions over the weir. The coefficient differs from one type of weir to another. Corrosion of the weir crest or damage caused by floating debris may alter the C_w value. Weirs also have the tendency to settle suspended particles or debris near their upstream side. This build-up will further restrict the flow in the sewer, increase the risk of flooding and bias water quality samples. In addition, the use of a weir usually results in a relatively large head loss. Therefore, permanently installed weirs are generally not suited for flow measurements in storm drains, unless they have been previously installed for other purposes and their head loss has already been accounted for in providing for flood protection. Temporary weirs are sometimes useful. The downstream side of a weir can be used a place to obtain representative samples from stratified streams, since the entire flow is mixed as it passed over the weir. In areas like Southern California, with seasonal rainfall, and dry weather runoff, low flow channels may be equipped with weirs without loss of flood protection.

6.1.2 Flumes

Flumes consist of three sections: a converging upstream section, a throat or contracted section, and diverging downstream section. The flume size is given by the width of the throat section. Flumes are considered better than weirs as most flumes have a self-cleansing feature in which build-up of particulate matters onto their upstream side can be avoided. In addition, the head loss resulted from flumes is relatively less than weirs. Commonly used flumes as flow measurement devices include Parshall flumes, Palmer Bowlus flumes and cut-throat flumes. Flumes create head loss and reduce maximum flow rate. Additionally they are expensive to construct, especially if they need to be retrofitted into existing facilities.

6.1.3 Positive-Displacement Meters

Positive-displacement (PD) meters separate the flow into discrete volumes and then sum to total volume by counting unit volume that passes through the meter. As fluid enters a chamber, an impeller, a piston, a diaphragm, or a disk rotates or moves to accommodate the entering fluid, and a known volume is discharged. Seals are required to separate the volumes, and the pressure loss across the meter provides the energy to drive the moving parts. The fluid temperature and viscosity affect the range and accuracy. Manufacturers should be consulted on temperature, pressure and viscosity limitations. Positive-displacement meters have no time basis. Therefore, they are seldom used to indicate instantaneous flow rate. They are unsuitable for storm drain monitoring because of their head loss and tendency to foul.

6.1.4 Differential Head Meters

Examples of differential head meters include venturi meters, flow nozzles, orifice plates, elbow flowmeter and pitot tubes. The measured the flow rate is proportional to the differential pressure between the undisturbed flow and the constriction section of the pipe caused by the meters. The difference of pressure may be measured with a differential manometer or pressure gauge. A straight length of pipe at least 10 diameters long is usually installed upstream of the meter. The main disadvantage of these differential head meters is the large permanent pressure loss that occurs across the section. Among these differential head metes, venturi meters have the lowest pressure loss whereas orifice meters cause the largest permanent pressure loss. Another disadvantage of these differential head meters is their susceptibility to clogging in waters with high suspended solids concentration. The head differences are also difficult to measure at low flow conditions.

6.2 ALTERNATIVE FLOW MEASURING DEVICE

Most of the traditional flow measuring devices mentioned above are considered poor in obtaining accurate results because they restrict flow too much. Alternative flow measuring devices include magnetic flowmeters, ultrasonic flowmeters and flow gauges (in which the flow is estimated using equations such as Manning, Chezy and Hazen-William's equations). These alternative devices are superior to those mentioned above due their low or negligible pressure loss.

6.2.1 Magnetic Flowmeter

The operation of magnetic flowmeter is based on Faraday's Law of Induction which essentially averages velocity over the pipe area. The voltage induced by a conductor (which is the liquid stream to be measured) moving perpendicular to flow direction and magnetic field (which is produced by a set of electromagnetic coils). The induced voltage is then detected by two flushed-mounted electrodes on a diameter of a non-conducting pipe wall. The low level millivolt signal is proportional to the average pipeline velocity. Thus magnetic flowmeters are considered ideal for all conductive fluids that operate in both laminar and turbulent flow regimes. Fluids to be measured must be a conductivity of at least 2 μmho/cm to be measurable (Miller, 1983).

Magnetic flowmeters generally are used in pipes flowing full. In addition to their ability to operate in a wide flow measurement range (laminar and turbulent flow regimes), their advantages also include accuracy of ± 0.5 - 1 %, negligible pressure loss, no moving parts, and rapid response time. However, the cost of magnetic flowmeters is high. Build-up of grease deposits or pitting by abrasive wastewaters can also foul the electrodes. Installation of magnetic flowmeters also require straight sections along the pipes with minimum length. Thus, regular inspection and cleaning of the electrodes are necessary. Built-in ultrasonic cleaning devices are the most commonly used (Hayward, 1979).

6.2.2 Ultrasonic Flowmeters

There are two types of ultrasonic flowmeters: time-of-flight and Doppler effect (Miller ,1983).

VOL 12

1 6380

- Time-of-flight meter: In time-of-flight ultrasonic flowmeters, a high-frequency (~ 1 MHz) pressure wave is beamed at an acute angle across the pipe. The time required for the wave to reach the opposite wall depends on liquid velocity, whether it is moving with or against the flow and on the speed of sound through the liquid. Flow rate information is obtained from the measured time of travel. There are many varieties of time-of-flight meters. The main differences are usually in the number of beam paths across the pipe. A single beam instrument averages along the beam and not across the pipe area. This make the single-path measurement dependent on velocity profile. Multipath meters average along several paths, reducing profile dependency. Both single-path and multipath ultrasonic flowmeters are sensitive to swirl. They are generally used in clean fluid applications, where the ultrasonic beam is not continuously interrupted by fluid particles. Their accuracy is between ± 1 to 4 %, depending on design and applications.

- Doppler flowmeters: In Doppler flowmeters, the sound pressure front does not pass through the pipe. It is reflected back to a detector by particulate matter moving with the flow. The difference between reflected frequency and fixed transmitted frequency is used to calculate the flow rate (Miller, 1983). Doppler flowmeters depend on small particles or impurities in the flow. Therefore, its accuracy depends on particles concentration and distribution. Accuracy is also influenced by the relative velocity between fluid and particles.

The advantages of ultrasonic flowmeters are low maintenance (including cleaning), wide flow range, low headloss and relative high accuracy of measurement. However, their disadvantages include high initial cost and errors from heavy turbulence and foam (US EPA, 1982). New types of ultrasonic flowmeters can be inserted into pipes using a metal bar which holds the meter against the pipe wall. This type of installation produces the least pressure drop and tendency to catch fouling materials.

6.3 ESTIMATED FLOW MEASUREMENT METHODS

In the absence of a flow measuring device, channel or sewer bottom slope, depth of flow and flow velocity measurements can also be used to estimate the flow. Among the commonly used estimation methods are the Manning, Chezy and Hanzen-William's equations.

6.3.1 Manning Equation

$$V = \frac{1}{n}(R)^{\frac{2}{3}}(S)^{\frac{1}{2}} \qquad (1)$$

where

V = average velocity of flow (ms^{-1})
R = hydraulic radius (cross-sectional area divided by wetted perimeter, m)
S = slope of the energy grade line
n = roughness coefficient

The Manning equation can be used to estimate flow in channels or pipes.

6.3.2 Chezy Equation

$$V = C(RS)^{\frac{1}{2}} \qquad (2)$$

where

C = Chezy coefficient

Chezy coefficient is most frequently expressed as

$$C = \frac{1}{n}(R)^{\frac{1}{6}}$$

The Chezy equation generally applies to open channel only.

6.3.3 Hanzen-William's Equation

$$V = 0.85\ C_H R^{0.63} S^{0.54} \qquad (3)$$

where

C_H = Hanzen-William's coefficient

The Hazen-William's equation is generally used for pipes flowing full.

The usefulness of the above equations for flow measurement is limited due to the difficulties of assigning an appropriate value to the roughness coefficient which varies with the channel or sewer material (concrete or brick), and the surface of the channel or sewer. For sewers, it varies also with the ratio of depth of flow to the depth when flowing full. In addition, the slope of energy grade line (which is taken as the slope of the channel or sewer) may also cause the inaccuracy in flow measurement. For example, the Manning equation is only applicable when the channel slope is less than about 0.10. Various tables, nomographs, slide rules, and charts have been prepared to simplify calculation and facilitate solution of these problems (Linsley and Franzini, 1979).

6.4 FLOW MEASUREMENT CONCLUSIONS

There is no ideal flow measuring device that is suited for all sampling locations. The flow measuring devices should provide "real-time" indication of flow rate in order for automatic samplers to obtain flow weighted composites. Total flow, provided by integrators or totalizers is also very important, especially to determine the accuracy of rainfall/runoff models, which were used extensively in the design of the Santa Monica Bay monitoring plan developed as a part of this study. The flow measurement cost per sampling points may be as high as $25,000 - 30,000 (in 1991 dollars). Site-specific information on previously used monitoring equipment is presented in Chapter 9.

Implementation of correct sampling procedures is very important so that accurate results can be obtained. However, problems still occur in sampling, even in the hand of an experience sampling personnel. The most commonly encountered sampling problems include sample contamination (caused by sampling devices or sample containers), interaction between samples and sampler material (e.g. sorption), and problems due to stratified contaminants such as suspended solids and oil and grease.

7.1 SAMPLE CONTAMINATION

Water sample contamination is the most common sampling problem. The usual sources of contamination are the sampling devices and sample containers. Carryover between samples from the sampling devices will occur if the device is not cleaned thoroughly prior to sampling. Sampling devices are generally cleaned with detergent (non-phosphate) and hot water. Sometimes manufacturers also provide guidelines for cleaning the sampling devices and these guidelines should always be followed. The devices also should be rinsed at least three times with water to be sampled; this procedure flushes out any remaining cleaning solutions that may dilute the sample. Special cleaning procedures are often required for specific contaminants. Consult the analytical protocol for further information.

In addition to sampling devices, sample containers must also be cleaned according to appropriate cleaning procedure (e.g. the Standard Operating Procedure (SOP), and ASTM's cleaning procedures). Solvents used for cleaning sample containers include 10% nitric acid (for trace metals analyses), pesticide grade hexane or acetone (for organics analyses) and methanol. Concentrated chromate acid (typically 20 g potassium dichromate in a liter of concentrated sulfuric acid) is also commonly use to clean glass sample containers. Detailed information on the cleaning procedures of sample containers can be found in references such as ASTM and Standard Methods.

Blanks are used to assess contamination. Blank samples usually include an equipment blank and transport blank (see Chapter 3). Selections of blanks should be made by considering all likely sources of contamination for the specific situation.

7.2 SORPTION

Analyte sorption is another common sampling problem. Materials used for sampling devices or sample containers should be inert to the collected water samples (see Chapter 5). For example, PVC and plastics other than Teflon tend to sorb organics and leach plasticizers and other chemicals used in their manufacture. In addition, some pesticides and halogenated compounds strongly sorb to glass (Keith, 1991).

Tubing material used in the automatic samplers is very important. Thermoplastic materials, such as polypropylene, have the tendency of sorbing many organics. Therefore they should be avoided. Teflon tubing is recommended as the suction tubing in the automatic samplers as Teflon materials are inert to almost all constituents. Selection of an appropriate tubing material should be made based on the manufacturer's guidelines, in which compatibility of the tubing materials with certain analytes is provided.

7.3 OTHER SAMPLING PROBLEMS

Oil and grease and suspended solids usually require special techniques to avoid problems. Sampling problems caused by oil and grease include the following:

a. Adsorption of oil and grease onto the tubing wall
   - common problem in automatic samplers.
   - suitable tubing material has to be chosen in which adsorption onto the tubing wall can be avoided.
   - tubing suitable for sample may not be compatible with peristaltic pumps.

b. Sample stratification
   - free oil and grease tends to float on water surface whereas the fraction that attached to the particulates tends to deposit on the bottom.
   - at the chosen sampling location (or sampling depth) one should be able to collect samples which include the free-floating and heavy fractions of oil and grease in the water. Automatic samplers are not capable of doing that as the samples is generally collected from a specific sampling depth.
   - manual water samplers (such as Kemmerer bottles, Von Dorn Vertical bottles) are suitable to collect a sample from the water column.

Suspended solids in water may cause the following sampling problems:

a. Clogging/fouling problems in the automatic samplers
   - constant cleaning/flushing of the automatic sampler intake position is needed.

b. Fouling of flow measuring devices
   - especially in weirs in where the suspended solids are deposited onto their upstream section and restrict flow.

c. Sample stratification
   - the effects similar to those of oil and grease.
   - It is difficult to collect representation samples using automatic equipment, for the same reasons as for oil and grease. Manual water samplers such as Van Dorn and Kemmerer bottles are recommended to collect water samples with high concentration of suspended solids.

8.0
QUALITY ASSURANCE IN SAMPLING

All sampling programs should have a Quality Assurance (QA) plan. The objectives of QA plan are to make sure the generated data are precise, accurate, representative, comparable and complete. Data falling outside the acceptable levels for these criteria will results in the potential sources of error being investigated, corrected, and recorded with a repeated analysis of questionable samples. Examples of quality assurance elements include the collection of sample blanks, duplicates and spike samples (US EPA, 1984). A QA Coordinator within the organization should be assigned so that he/she can undertake activities such as quality planning, auditing and other programs to insure reliability and complete integration of the QA plan.

A quality assurance plan for a sampling program generally include the following steps:

1. The sampling program should describe details on sampling locations, sample type, sample frequency, number of samples, duration of sampling, sample volume, sample collection methods and holding times, equipment to be used for the sample collection, sample containers, pretreatment of containers, type and amount of preservative to be used, blanks, duplicates/triplicates, spiked samples, replicates, and chain of custody procedures.

2. Procedures for routine testing, maintenance and calibration of sampling equipment should be developed. Manufacturers' instructions are appropriate guides for these procedures. Information on quality assurance guidelines for field analysis, equipment calibration and documentation is given by US EPA (1977).

3. Random control checks should be performed to make sure that appropriate sampling guidelines on sample collection, handling and chain of custody are followed by the field personnel. If deviation occurs, appropriate corrective action should be taken. In addition, analytical quality control as an aid to quality assurance must be performed through duplicate, split, and spike samples. Sample preservative blanks, and known standard solutions, and accuracy may be evaluated using control chart.

The above mentioned steps are just a general descriptions of a QA plan for a sampling program. More detailed information on implementation of QA plan is given by US EPA (1980). In general, a QA project plan should address the following:

1. Title page, with provision for approval signatures
2. Table of contents
3. Project descriptions
4. Project organization(s) and responsibilities
5. QA objectives for measurement data (precision, accuracy, completeness, representativeness, and comparability)
6. Sampling procedures
7. Sample custody
8. Calibration procedures, references and frequency

VOL 12 1 6385

9. Analytical procedures
10. Data reduction, validation, and reporting
11. Internal QC checks and frequency
12. QA performance audits, system audits, and frequency
13. QA reports to management
14. Preventive maintenance procedures and schedule
15. Specific procedures to be used to routinely assess data precision, representativeness, comparability, accuracy and completeness of the specific measurement parameters involved.
16. Corrective action

Successful implementation of a QA plan depends on the competence of the monitoring personnel. All personnel involved in any function that may affect data quality (e.g. sample collection, analysis, data reduction and quality assurance) should have sufficient training in their appointed jobs to contribute to the reporting of complete and high quality data.

REVIEW OF EXISTING MONITORING PROGRAMS

In order to facilitate the development of a comprehensive monitoring program for the Santa Monica Bay Project, existing nonpoint source storm water projects that are similar to the Santa Monica Bay Project were reviewed to provide important information on the following monitoring elements for both dry and wet weather periods:

- number of monitoring stations
- types of constituents monitored
- frequency of sampling

The following nonpoint source projects were reviewed:

1) Santa Clara Nonpoint Source Control Program
2) Alameda County Urban Runoff Clean Water Program
3) Orange County NPDES Stormwater Permit Program
4) Bellevue Urban Runoff Program

The following discussion will provide a review of each project. For each project reviewed, a brief background of the project is discussed. Next, the discussion is organized according to 1) number of monitoring stations, 2) types of constituents monitored, and 3) frequency of sampling. Lastly, a brief summary is provided. The description include the rationale for some aspects of the plan which may be repetitive with other parts of this report, but is included for emphasis.

9.1 SANTA CLARA NONPOINT SOURCE CONTROL PROGRAM

9.1.1 Background: Initial Characterization Phase

The Santa Clara Nonpoint Source Control Program (Program) was initiated in 1987 to address concerns on nonpoint source discharges from storm water into the South San Francisco Bay Region or commonly known as the Lower South Bay. The Lower South Bay is classified by US EPA and the California State Water Quality Control Board as a water quality limited segment under section 304(L) of the Clean Water Act. Because of the water quality concerns of the Lower South Bay, the San Francisco Bay Regional Water Quality Control Board (Regional Board) has pursued an active regulatory role in controlling point and nonpoint discharges into the Lower South Bay. In the 1986 Basin Plan, the Regional Board directed Santa Clara County to develop and implement an Action Plan to conduct dry and wet weather water quality monitoring "for the evaluation of both concentrations of pollutants as well as total pollutant loadings and comparison with waste loads from point source discharges".

An action plan was developed in the summer of 1987 (CH2M-Hill and EOA, Inc. 1987) and implemented by WCC in the fall of 1987, and completed by WCC in the summer of 1989. The results of the hydrologic and water quality monitoring program, and the loads estimates were presented in Volume I of the Loads Assessment report (WCC, 1991a). This report constitutes the initial characterization phase of the Program. It should be

1 6387

emphasized that the major objective of this phase was to evaluate dry and wet weather pollutant concentrations and loads to the Lower South Bay.

9.1.1.1 Monitoring Stations

The Study Area is approximately 690 square miles and is divided into 11 watersheds. Given the size of the Study Area, and the need to project loads from the entire area, it was not feasible to monitor the entire Study Area and thereby estimate loads based on monitoring data alone. Instead, the study was designed to develop sufficient monitoring data to calibrate and verify a watershed load prediction model, which then could be applied to estimate loads from both gauged and ungauged watersheds.

There were a total of 16 stations representing three types of stations. Figure 9-1 shows the locations of these stations, and the 11 watersheds of the Santa Clara County.

9.1.1.1.1 Land use Stations

A total of seven stations representing small, relatively homogeneous land use catchments found in the area. Two stations (L1 and L2) represented industrial land use, and three stations represented low-density single-family residential (L4 and L5), and multi-family residential (L6) land uses. One station each is represented for commercial (L3) and open (L7) land uses. Table 9-1 provides a brief description of each station. Most of these stations are manhole or open channel stations except for the open land use station (L7), which is a natural creek. Data generated from these land use stations were used to characterize water quality from specific land uses, and also used as input to the loading model.

9.1.1.1.2 Stream Stations

Four stream stations were located in the lower portions of the watersheds and had relatively large, multiple land use catchments. These stations are located near the Bay, but above the zone of tidal influence in order to eliminate the effect of backwater on flow monitoring. Two stations (S3 and S4) drain the largest watersheds located in the eastern and central regions representing about 50 % of the total area. These two stations representing two of the largest watersheds also receive substantially more rainfall than the other smaller western watersheds. The other two stations (S1 and S2) represents smaller watersheds occupying the western region of the study area. WCC evaluated the adequacy of these four stream stations in representing the 11 watersheds (WCC 1991b). WCC found that the land use distribution of all four stations not only represented their respective watersheds that they reside, but also adequately represents the overall land use composition of the Study Area.

The important distinction between the stream and the land use stations is that the stream stations support aquatic habitat and therefore water quality must meet aquatic life criteria. Both dry (from base flow) and wet weather sampling were conducted at the stream stations.

9.1.1.1.3 Reservoir Stations

Six reservoir stations were located below the upland reservoirs and were used to estimate loads associated with reservoir (spillway) releases during wet years.

R3	Open	3800
R4	Open	7670
R5	Open	4600
R6	Open	125000

In comparisons with the requirements of Part II of the Federal NPDES storm water regulations, the regulations require monitoring of five to ten stations.

9.1.1.2 Constituents Monitored

The suite of constituents that were selected for chemical analyses on water and sediment samples were focused on potentially toxic contaminants, including heavy metals, organics (volatiles, semi-volatiles, pesticides and herbicides), nutrients, bacteria, and some conventional pollutants. This list of constituents were developed based on results of a Nationwide Urban Runoff Program, NURP (US EPA 1983), and also water quality excedances of specific pollutants in the South Bay. Table 9-2 summarizes the full list of constituents analyzed. This is a relatively comprehensive list when compared with the requirements specified in the Federal NPDES Part II regulations.

Metals analysis are commonly measured based on the total extractable fraction, i.e., metals that in solution as well as those associated with the suspended solids. The total fraction is used in estimating the total loads and comparisons with water quality criteria. However, the dissolved fraction, i.e., sample that is filtered through a 0.45μm filter, is the fraction that is directly available for organism uptake and therefore is more relevant for use in comparisons with water quality criteria. For two storm events, the dissolved fraction for metals was also analyzed.

This full suite of constituents was only conducted during the first storm, and sometimes in a few stations for the second storm only. Based on the results of the initial sampling a more limited suite (reduced) of analyses were performed for subsequent sampling rounds. The reduced suite of analyses is also presented in Table 9-2. The constituents that were dropped included volatile and semi-volatile organics, chlorinated herbicides, organophosphorus pesticides, and hexavalent chromium. These constituents that were dropped were mostly not detected in the storm water.

Constituents such as volatile organics have high potential to volatilize in turbulent storm waters. Unless the monitoring station is very close to the source (such as adjacent to an industrial facility that is illegally discharging volatiles), the presence of volatile organics in storm water is rarely found. For semi-volatiles, only the polynuclear aromatic hydrocarbons (PAHs) were retained for subsequent sampling analyses because PAHs are relatively toxic and some are known carcinogens. Additionally, PAHs are commonly found in petroleum by-products, and in combustion of wood and petroleum fuels. Rather than analyzing for 80 compounds in the semi-volatiles analysis, a specific PAH method using EPA 610 was used in subsequent sampling. In the EPA 610 method, a total of 16 specific PAH compounds are analyzed.

Another important secondary objective of the characterization phase was to evaluate the effects of storm water on toxicity in streams in Santa Clara County. While chemical monitoring has traditionally played an important role in evaluating water quality, toxicity monitoring using surrogate organisms is increasingly becoming a vital tool to evaluate potential impairment of receiving water bodies. Short-term chronic bioassay tests using three freshwater organisms were used to evaluate potential toxicity effects of both dry and wet weather samples. These tests are developed by US EPA (1986) and are routinely used in compliance monitoring of potential toxic effluent from industrial-treated as well as publicly-owned treatment works (POTW) wastewaters. The three surrogate organisms used in these tests are *Ceriodaphnia dubia* (an aquatic invertebrate), *Selenastrum capricornutum* (a freshwater alga), and *Pimephales promelas* (a fathead minnow fish).

These tests evaluate the effects of storm water on three key organism indicators: mortality, reproduction, and growth.

9.1.1.3 Frequency of Sampling

9.1.1.3.1 Wet Weather

Figure 9-2 summarizes the types and frequency of sampling during both dry and wet weather periods. The goal of the study was to conduct sampling over two wet weather seasons (1987-1988 and 1988-1989). However, because of the extensive time required to select stations, install and test automated sampling equipment, only one storm was captured for the first wet weather season (1987-1988). A total of six storms were captured for the second wet weather season (1988-1989). Samples were collected as flow-weighted composites by automatic samplers. These samples represent average pollutant concentrations that were used to estimate total pollutant loads. Additionally, grab samples were taken during the early part of the storm for selected pollutants (such as oil and grease, volatile organics, bacteria) because of short holding times, special container requirements, or volatility. The following paragraphs discuss the rational for selecting the sampling frequency.

The wet weather season for California is about six months, starting in October and ending in April. Based on the national weather service rainfall gage at San Jose, the average storm volume for the 1948-1989 period is 0.7 inches, with most of the rain occurring during the months of November through March.

To adequately characterize storms during the wet weather season, a total of six storms collected about once every month were considered sufficient to cover the range of hydrological conditions. Of the six storms, the first storm of the wet weather season must be collected. This is because the first storm of the wet weather season is thought to have the largest pollutant concentrations. The high concentrations are attributable to the opportunity for dry deposition of pollutants on ground surfaces during the extended dry summer period, which are scoured by the first rainfall.

It is important to note that continued monitoring of the stream stations and specific industrial stations have to date generated about 15 to 20 data points per station. These data will be used as initial baseline conditions to be compared with additional monitoring (in future monitoring years) to evaluate potential improvements in water quality due to implementation of storm water pollution control measures across the County.

To provide a comparison with the requirements for Part II of the Federal storm water regulations, a minimum of three storm events separated by at least one month are required.

9.1.1.3.2 Dry Weather

Dry weather sampling was conducted during the summer of 1988, as well as dry weather flows during the wet weather season (i.e., in between storms). Both water and sediment samples were collected. The main objective of dry weather water sampling is to evaluate pollutant concentrations and loads during base flow from stream stations. A total of seven samples were collected; two during the summer, and five in between storms. Sediment sampling was conducted four times to evaluate sediment concentrations which serve as both sources and sinks for pollutants. All dry weather samples were collected as manual grabs.

9.1.2 Background: NPDES Permit Phase

Following the characterization phase, the Program applied for and obtained an NPDES storm water permit in June of 1990. From 1990 to date, WCC has continued to conduct monitoring for the Program. However, the monitoring objectives in this Permit period have expanded to include additional objectives. It must be emphasized here that the objectives of a monitoring program clearly drives the requirements for the type and frequency of monitoring.

The objectives of the monitoring program for the Permit Phase include the following:

- evaluate long-term trends in water quality
- identification of storm water pollutant sources
- comply with water quality objectives
- water quality improvements
- evaluate control measure effectiveness monitoring

Additional monitoring elements of this phase that are relevant to this discussion are summarized in section 9.1.2.1

9.1.2.1 Monitoring Stations

Table 9-3 shows the types of stations in the Permit phase. The total number of stations is ten. Five stations were retained from the characterization phase. These include four stream stations (S1 through S4), and one industrial station (L2). It was important to continue to monitor these stations because the stream stations can be considered as receiving water bodies supporting aquatic habitat, and as such can represent long-term monitoring stations. The industrial station was kept because of high concentrations of pollutants (especially chromium, cadmium, copper, lead and zinc) detected in the storm water. Continued monitoring of this industrial station will help in monitoring effectiveness of various source control measures that will be implemented in this industrial sub-catchment.

Five new stations were added. These include two stations for monitoring the effectiveness of pollutant removal of a detention basin, and another two for monitoring two major highways. The fifth station was selected to represent another industrial land use area.

9.1.2.2 Constituents Monitored

A set of constituents similar to the reduced suite was used in the permit phase, with the exception of PAHs. This reduced suite of analyses is shown in Table 9-4. Results of PAH analyses using EPA method 610 showed that most of the concentrations were less than the detection limit. Frequently, detection limits were elevated to 5 to 10 times the acceptable detection limits. A combination of high matrix interferences from salts and other natural humic organics found in the storm water, and low detection resolution by the High Performance Liquid Chromatography (HPLC) method, are likely responsible for the poor results.

A more superior method developed by Texas A&M's Geochemical and Environmental Research Group (GERG) was used for subsequent analysis of PAHs. The GERG method eliminates the matrix interference by various cleanup techniques, and uses Gas Chromatography / Mass Spectrometry (GC/MS) - Selected Ion Monitoring Mode (SIM) instrumentation to optimize detection of the specific PAHs. The number of PAHs include

(a) Methods for Chemical Analysis of Water and Wastes (1983) EPA-600/ 4-79-020 the 16 EPA method 610 methods, and 14 additional methylated PAHs. Detection limits range from 0.003 to 0.100 µg/L, which is about more than 100 times lower than the detection limits for EPA method 610.

More sophisticated techniques to evaluate the groups of pollutants responsible for toxicity were used for toxicity testing. The 7-day short-term chronic bioassays used in the characterization phase showed that storm water from urbanized land uses were mostly toxic, especially to Ceriodaphnia. The tests, however, do not show what pollutants are responsible for toxicity.

Phase I Toxicity Identification Evaluation (TIE) tests (Mount and Carnahan, 1988, 1989a, 1989b) were used on storm water samples in the Permit Phase. If samples show toxicity (i.e., mortality), these Phase I TIE tests, using a combination of chemical and physical manipulations, are able to distinguish what broad groups of pollutants are responsible for causing toxicity. These groups tested include metals, non-polar organics, volatiles, ammonia, and strongly oxidizing agents.

9.1.2.3 Frequency of Sampling

All stations sampled for five storms for the wet weather season. Samples were collected as flow-weighted composites by automatic samplers. No dry weather water or sediment samples were conducted because of the fact that dry weather concentrations and loads were believed to be small and insignificant when compared with wet weather loads.

9.2 ALAMEDA COUNTY URBAN RUNOFF CLEAN WATER PROGRAM

9.2.1 Background: Initial Characterization Phase

In the San Francisco Bay Region, the Alameda County Urban Runoff Clean Water Program also addresses the impact of nonpoint source pollution from storm water runoff on the South Bay . The objectives of this Program is similar to the Santa Clara Valley Nonpoint Source Control Program. The Alameda Program was initiated in September 1988, and monitoring was conducted for two wet weather periods and one dry weather period between October 1989 and April 1991 (WCC 1991c).

9.2.1.1 Monitoring Stations

The Study Area is 345 square miles and 15 watersheds drain the area. There were a total of 16 stations. Figure 9-3 shows the locations of these stations. Out of these 16 stations, 10 were land use stations (L1 through L10) draining homogeneous land uses such as commercial, industrial, and residential. Another six stations were major stream or creek stations draining large mixed land uses. Table 9-5 summarizes the land uses types and drainage areas for each of the station.

9.2.1.2 Constituents Monitored

The suite of chemical analyses are similar to the Santa Clara Valley Nonpoint Source Control Program. A full suite of analyses were conducted for the first storm and a reduced suite was conducted for subsequent storms. A similar procedure was also followed for dry

weather samples. For metals, both the total and dissolved fractions were analyzed on all samples.

9.2.1.3 Frequency of Sampling

Figure 9-4 summarizes the types and frequency of monitoring. A total of 11 storm events were conducted for the two wet weather periods. For each station, anywhere from five to nine storms were sampled.

Eight sampling events were conducted for the dry weather period at the six stream stations that had base flow. Two events were conducted during the summer (April to August 1990), and six events in between storms; three during the first wet weather, and another three during the second wet weather.

Four sediment sampling events were conducted at the six stream stations.

9.2.2 Background: NPDES Permit Phase

Subsequent to the initial characterization phase, the Program obtained a NPDES storm water permit in July 1990. The results of the characterization phase were used to direct the monitoring program for the permit phase.

9.2.2.1 Monitoring Stations

The number of stations were reduced from 16 to seven. Out of these seven stations, five of them were from the initial phase. These five stations are four stream stations (S1, S2, S3, and S5), and one industrial station (L3). The four stream stations drain the most important watersheds of the Alameda County, and also support aquatic habitat and riparian vegetation. The industrial station was retained because of the presence of elevated concentrations of metals and acute toxicity to biological organisms. Two new stations were initiated in a marsh environment to evaluate storm water pollutant removal effectiveness of the marsh.

9.2.2.2 Constituents Monitored

A reduced suite of analyses was conducted as shown in Table 9-4. Additionally, to aid in better understanding the issue of how much of the sorbed metals (attached to suspended solids) is bioavailable for organism uptake, a weak-acid extraction method, to supplement the traditional total and dissolved methods, was included. This weak-acid extraction was conducted on storm samples from one stream station for selected metals (cadmium, chromium, copper, lead, and zinc).

9.2.2.3 Frequency of Sampling

For each wet weather season, five storm events per station were conducted. Storm samples were collected as flow-weighted composites by automatic samplers.

9.3 ORANGE COUNTY NPDES STORMWATER PERMIT PROGRAM

In July 1990, the San Diego and Santa Ana Regional Water Quality Control Boards issued NPDES Storm Water and Urban Runoff permits to the Orange County Storm Water Permit Program. The Program is comprised of the Orange County Flood Control District, the County of Orange, and its 29 incorporated cities. The objectives of the monitoring program are the following:

- to define the type, magnitude and sources of pollutants in the storm water system discharges within each permittees respective jurisdiction so that appropriate pollution prevention and correction measures can be identified;
- to evaluate the effectiveness of pollution prevention and correction measures; and
- to evaluate the compliance with water quality objectives established for the storm water system or its components.

The monitoring program to meet these objectives include extensive dry and wet weather sampling in four major watersheds of the County. Monitoring was initiated in January 1991. The following sections summarizes the scope of the monitoring program.

9.3.1 Monitoring Stations

There are a total of 54 stations spread over four major watersheds. These four watersheds are:

- Huntington Harbor / Anaheim, Sunset, Bolsa Bay
- Upper Newport Bay
- South County
- Santa Ana River

The types of stations are basically divided into storm channels (upstream of tidally-influenced areas) and receiving waters in the Bay. There are 34 storm channel stations and 20 Bay monitoring stations. Table 9-6 shows the list of storm channel and Bay monitoring stations in their respective watersheds. About half of these stations are located in the Newport Bay watershed. Most of these stations have been previously monitored by the Orange County Flood Control District. The bulk of the monitoring prior to the permit period was conducted during non-storm periods. Only limited data were collected during storm periods.

Out of the 34 storm channel stations, 23 are considered to be "waters of the State" and are therefore receiving waters. The other storm channel stations drains into stream tributaries that are receiving waters. Water from all these 34 storm channels ultimately drain into the Bay. Monitoring in the Bay include 20 stations.

9.3.2 Constituents Monitored

The selection of monitoring constituents was based on the analyses of past data conducted by the Orange County Environmental Management Agency, the RWQCB Toxic Substances Monitoring Program for Huntington Beach Channels and the State Mussel Watch Program. The list of constituents including nutrients, metals and organics are shown in Table 9-6.

M = Monthly Dry Weather Water Samples
ST = Storm Samples (4 for Storm Channels and 2 for Bay Stations)
PS = Post Storm Samples
SEMI = Semi-Annual Dry Weather Water and Sediment Samples
NUTRIENTS = Nitrate + Nitrite, Ammonia, Total Kjeldahl Nitrogen (TKN), Total Phosphate, Total Suspended Solids, Volatile Suspended Solids, pH, Dissolved Oxygen, Specific Conductance, Turbidity.
PAHs = Polynuclear Aromatic Hydrocarbons
PHP = Organochlorine Pesticides and Polychlorinated biphenyls, Chlorinated Herbicides and Selected Organophosphorus Pesticides
METALS = Copper, Chromium, Lead, Cadmium, Silver, Nickel, Zinc
S = Sediment
W= Water

The constituents that will be routinely analyzed for both dry and wet weather include the nutrients and metals. Nutrients, metals and organic constituents will only be analyzed on sediment samples collected during the dry weather periods. The decision to monitor only organic constituents during the dry weather is likely due to non-detectable concentrations of these organics during the wet weather.

9.3.3 Frequency of Sampling

Table 9-6 shows the frequency of monitoring for both storm channel and Bay stations. For the storm channel stations, two storms per station are proposed to be monitored for the first wet weather season for all stations. In subsequent years, three to five storms will be sampled. Two post-storm samples will be conducted to evaluate potential chronic effects of storm water for selected stations. During dry weather, water samples will be collected monthly for analysis. Sediment samples will also be collected two times during the dry weather period for selected stations.

Sampling storm water in the Bay is difficult because of tidal influence, and significant amounts of rainfall to produce a freshwater lens. An estimated rainfall of more than 0.5 inch is required for the receiving waters to exhibit a freshwater influence. The number of storms sampled per station will vary depending the weather and the amount of manpower and equipment available. Two post-storm samples (48 and 96 hours after the storm event) will be conducted for selected stations. Monthly water samples, and semi-annual sediment samples will be collected during the dry weather period for selected stations.

Water samples will be collected as discrete hourly samples for a 24 hour period by automatic samplers during storms and flow composited in the laboratory. The post storm sampling will be conducted 12 hours after the initial 24 hour sampling period. Samples will be taken once every three hours for a 72 hour period. Dry weather samples will be collected by a combination of grabs and automatic samplers, depending on the availability of the automatic samplers. Post-storm sampling and sediment samples will be collected by manual grab methods.

9.4 BELLEVU URBAN RUNOFF PROGRAM

Many aspects of urban runoff have been studied in Bellevue, Washington by the Environmental Protection Agency under the NURP study, with cooperation from the University of Washington, the US Geological Survey (USGS), the Municipality of Metropolitan Seattle (METRO), and the City of Bellevue Storm and Surface Water Utility. This section will describe briefly some of those studies and will focus on the sampling performed by the USGS.

9.4.1 University of Washington Projects

The University of Washington's Civil Engineering Department and Fisheries Research Institute performed studies of two receiving water bodies, one which had contributions from urban runoff and one that did not, to identify the impacts associated with urban development on receiving waters. Biological, chemical and physical parameters were analyzed. The main objectives of the project were:

- Document the variations (spatial and temporal) in distribution and abundance of aquatic organisms in urban streams
- Compare the condition of an urban and rural stream in the same general area
- Evaluate the biological, chemical and physical effects of urbanization on streams

9.4.2 Seattle METRO Project

The purpose of this project was to identify priority pollutants and other toxic pollutants in storm water as part of METRO's "Toxic Pollutant Inventory." The projects in Bellevue supplied samples to the Metro program for analysis. The results of this study were used to assess potential problems and evaluate best management practices. Besides identifying the toxic substances, the project also focused on identifying their sources through sampling and a literature review.

9.4.3 US Geological Survey Project

The USGS performed monitoring from 1979 to 1982 as part of the NURP study. The USGS reported the four main objective of the study were:

- Establish a consistent and accessible data base for typical watersheds
- Determine the magnitude and frequency of storm runoff loads of water quality constituents from three catchments in the city
- Develop methods for estimating storm and annual loads of water quality constituents from unsampled catchments in the study area
- Test the effectiveness of storm water quality management alternatives for the attenuation of constituent loads carried in storm water.

9.4.4 Monitoring Stations

There were a total of 8 stations within three catchments. These catchments were:

- Surrey Downs
- Lake Hills
- 148th Avenue S.E.

Five of these stations were used to monitor storm water quality and three of them were used to monitor wet and dry atmospheric deposition quality, only the storm water quality stations will be considered in this report. Table 9-7 shows the list of monitoring stations, their respective catchment, and land use breakdown. The Surrey Downs and Lake Hills catchments were predominately single family residential areas and are both approximately 100 acres. These two catchments were used to evaluate the effectiveness of street sweeping.

The 148th Avenue S.E. catchment has three main land uses: open park land, high density residential (9 dwellings per acre), and commercial. The total size of the catchment is 24 acres, however, one fourth of the catchment is occupied by 148th Avenue S.E. This catchment was used to investigate the effects of detention basins on storm water quality.

Table 9.7 Description of Stations for the USGS Monitoring in Bellevue, Washington.

Catchment	Station ID	Land Use of Catchment	Drainage Area (acres)
Surrey Downs	Catchment Outfall	91% R, 6% C, 3% O	95
Lake Hills	Catchment Outfall	90% R, 7% C, 3% O	102
148th Ave S.E.	Storm sewer below Lake Hills Boulevard	16% R, 24% C, 60% O	24
	Outlet from Detention Basin No. 3		
	Outlet from Detention Basin No. 5		

Three stations were located in this catchment. One captured storm water at the outlet of the catchment, one captured storm water at the outlet of control structure No. 3, and one at the outlet of detention basin No. 5. The samples from the outlet of control structure No. 3 were considered to be representative of the inflow into detention basin No. 5.

Water from all the catchments eventually drained into Lake Washington. The Surrey Downs catchment drains into an artificial pond, then into Mercer Slough and into Lake Washington. Lake Hills drains into Kelsey Creek, then into Mercer Slough and into Lake Washington. The 148th Avenue S.E. catchment drains into Larson Lake, then into Kelsey Creek and Lake Washington.

9.4.5 Constituents Monitored

The selection of monitoring constituents was specified by the Advisory Technical Planning Committee for the USGS and the US EPA. The list of constituents including nutrients, metals and organics is shown in Table 9-8. Also some samples were analyzed for major anions and cations, trace elements, ultimate carbonaceous biochemical oxygen demand, insecticides, herbicides, oil and grease, and total volatile residue.

9.4.6 Frequency of Sampling

Figure 9-5 shows the frequency of water quality monitoring in the three catchments. A total of 31 storm events were monitored at the Surrey Downs station and 37 storm events at the Lake Hills station. The 148th Avenue S.E. catchment was monitored for 23 storm events at the sampling station below Lake Hills Boulevard and 7 storm events at the other two stations.

Most catchment outlet water samples were collected by automatic samplers preset at 5 to 50 minute sampling intervals during storms. Each sampler filled 24 two-liter bottles in approximately 10 seconds. Samples collected at control structure No. 3 and detention basin No. 5 were collected manually using a depth integrated sampler. Depth integrated samplers were used at the outlets to collect samples for insecticide, herbicide, oil and grease, and sediment particle size analysis.

9.5 EQUIPMENT SUMMARY

Table 9-9 shows equipment used in two of the reviewed monitoring programs and three other programs known to the authors. It is included to show the types of equipment being used and specified. The inclusion is in no way an endorsement of the indicated products (some of the products are no longer available). The table indicates that automatic samplers are being used in all monitoring programs.

10.0 CONCLUSIONS

This report has reviewed sampling methods for water and wastewater with particular regard for stormwater. Chapters 2 through 5 discussed statistical methods, sample types, sampling equipment and sample storage and preparation. Chapter 6 reviewed flow measuring techniques. Chapter 7 discussed specific sampling problems while Chapter 8 reviewed quality assurance plans. Chapter 9 reviewed four case studies to illustrate the application of the materials presented in the earlier chapters. From this information, several conclusions are made:

1. Stormwater sampling programs may have many common procedures but many if not most of the elements are based upon site-specific considerations.

2. Stormwater monitoring programs are new and have been implemented in a development at fashion within tiered programs. The first parts of such programs usually sample a large number of stations, storm events and water quality parameters with the objective of determining the best monitoring strategy. Such programs anticipate a reduced suite of analysis and storm samples in subsequent years of the sampling program.

3. The most popular way to monitor is through automatic samplers which are set-up and programmed to sample specific storm events. Flow measuring equipment is usually provided with the automatic samplers and is usually comprised of Doppler-type flowmeters which can be installed without reducing the storm drain capacity. Traditional flow measuring equipment has little applications for stormwater monitoring.

4. Monitoring programs are created to both estimate pollutant loads as well as to better define aspects of the monitored watershed, such as land-use/pollutant concentration characteristics.

PREFACE AND ACKNOWLEDGEMENTS

This report represents Volume III from a series of four volumes of reports which form the basis of a pollution assessment and monitoring plan for Santa Monica Bay. Volume I describes storm drainage system land use statistics, catchment areas, existing water quality monitoring data, rainfall data, NPDES permit information for existing permits to storm drains, and contaminant mass emission estimates, based upon land use modeling. Volume II reviews sampling techniques, including sampling equipment, and other aspects associated with sampling such as a quality assurance plan. Volume III presents the proposed monitoring plan. Volume IV addresses best management practices as they apply to the Santa Monica Bay area. The first draft of this volume was issued in October, 1992.

The contract was performed by UCLA and Woodward-Clyde Consultants (WCC). Professor Michael K. Stenstrom of the Civil and Environmental Engineering Department, UCLA and Eric Strecker from WCC's Portland office were the project managers. There were several key individuals from both UCLA and WCC who assisted with the project; they include Sim-Lin Lau and Kenneth Wong (UCLA) and Lou Armstrong, Gail Boyd, Carol Forrest, and Joan Kersnar (WCC).

The contractors are grateful for the assistance of many individuals. The Santa Monica Bay Project and LA Regional Water Quality Control Board staffs were most helpful. We extend our special thanks to Dr. Guang-yu Wang, Ms. Catherine Tyrrell, Dr. Rainer Hoeinke and Mr. Xavier Swamikannu. Several public agencies were very helpful in providing data and information to us. The Los Angeles County Department of Public Works and the Southern California Association of Governments (SCAG) provided catchment area and land use data, respectively. We are also indebted to the members of the Technical Advisory Committee of the Santa Monica Bay Project and others who reviewed and commented on our draft reports.

The monitoring plan includes two primary goals: 1) assessing mass emissions of contaminants to Santa Monica Bay, and 2) developing more data in order to provide a better understanding of the relationship between land use and pollutant runoff. These two goals were developed in a workshop conducted in June, 1992 which was attended by representatives from the agencies responsible for implementing the monitoring plan, citizens groups and regulatory agencies. The plan addresses these goals by proposing 16 sampling stations

To determine the mass emissions 4 candidate sampling stations, located on Ballona Creek, Malibu Creek, Pico-Kenter and Topanga Creek, are proposed. These stations would sample runoff from about 75 percent of the Bay's watershed. To better understand the relationship between land-use and pollutant runoff characteristics, 12 additional candidate stations are proposed to monitor 6 different types of land uses, including single-family residential, multi-family residential, commercial, industrial, open, and highway.

Final sampling station locations are not proposed because the exact location will depend upon many site specific concerns, which are beyond the scope of this project. It is felt that the exact monitoring locations should be determined by the monitoring agency, who will be able to address such issues as proximity to electric power, freedom from vandalism, site hydraulics, and safety.

In addition to the candidate locations of the monitoring stations, additional information is provided on sampling techniques, analytical procedures, quality assurance procedures, data reporting, field crew training and methods for estimating pollutant loads. This information complements the sampling review presented in Volume II.

LIST OF FIGURES

1.0 INTRODUCTION

This monitoring plan describes the objectives and approach for collecting data on the quality of storm drain discharges to Santa Monica Bay. The plan presents the methods used for selecting monitoring sites, specifies types of equipment required, discusses storm selection and runoff estimation procedures, and presents sampling event management and field sampling methods. Quality assurance and control, data reporting, monitoring schedule and training requirements are also presented. A more detailed review of sampling procedures and techniques is presented in Volume II of these reports (Stenstrom, et al., 1993) and should be consulted for more information on sampling. Included in the plan is a discussion of methods for pollutant load estimation.

1.1 MONITORING PLAN OBJECTIVES

The objective of this monitoring program is to provide accurate data for assessing the extent of pollutant loadings to Santa Monica Bay from storm drains and streams, from both dry and wet weather flows. The data should provide information that allows the determination of the need for and the prioritization of best management practices (BMPs). It should identify areas with potential water quality problems and provide for accurate and defensible detection of constituents. It should also provide information for assessing long-term trends in the quality of storm drain discharges to Santa Monica Bay. The monitoring program provides for an assessment of pollutant mass emissions to the Bay in an economical fashion. The plan includes installation of continuous flow monitoring stations, which will allow for collection of hydrologic data from all events, and in addition could be used to identify illicit dumping or illegal connections.

It is recommended that this program be integrated with other monitoring programs including those that are not part of the early NPDES permit, such as the comprehensive Bay monitoring Bay plan. If possible, collecting information on receiving waters (e.g., surf zone, coastal lagoons, and Malibu Estuary) during monitored storm events would also be appropriate, at least initially. Receiving water quality information can be used to determine the impact of storm water discharges on the health of the Bay, during and just after runoff events.

Finally, the proposed plan has been designed to assist the co-permittees in meeting the intent of both the Federal regulatory program for municipalities as well as Los Angeles County's "early permit" requirements specific to Santa Monica Bay.

1.2 MONITORING APPROACH

To meet the monitoring plan objectives noted above, a combination of two sampling approaches have been formulated. One approach is to collect samples at locations that monitor runoff from the largest possible areas of the watershed. Mass emissions can be estimated directly from these data. The second approach is to monitor runoff from locations having a single predominant land use. Data from these monitoring stations can be used with a pollutant loadings model to determine loadings to the Bay from unmonitored areas. These data can also be used to prioritize drains and to facilitate the process of selecting appropriate and effective BMPs.

The combination of these two approaches provides some redundancy in how loadings can be estimated as well as improve our information and understanding of pollutant/land use relationships for the Santa Monica Bay watershed. Having both types of stations allows the use of the data from the mass emission stations with the data from a variety of land use stations to calibrate and validate with existing and future land-use-based pollutant loadings models.

The mass emission stations will likely be permanent and used for quite sometime. Data from these stations will also establish a baseline for future comparisons. The permanence of these stations helps justify their costs, including the cost for data telemetry. The permanency of the land use stations will depend upon future efforts to model the Santa Monica Bay watershed. Data from these stations, and the ability to exactly repeat the sampling protocol, will be vitally important for future modeling efforts.

The plan includes a detailed Quality Assurance/Quality Control element to help assess the accuracy of the field and analytical program. Station equipment was recommended to provide accuracy of measured flows, and ease and accuracy in sample collection. The plan also includes a description of the storm selection process, sampling methods, and data reporting.

Water quality data should be obtained during dry weather as well as wet weather. Flow measurements should be made continuously at all stations, and samples will be collected for laboratory analyses in both wet and dry weather. Dry weather monitoring should provide information on the quantity and quality of base flows and may indicate the presence of illicit discharges or illegal dumpings. However, it is highly recommended that a separate illicit connection detection program be developed and implemented to find and eliminate these sources of pollutants. Monitoring of storm events would provide information on rainfall-runoff relationships and pollutant loadings from specific catchments and land uses.

1.3 MONITORING PLAN SUMMARY

In designing the monitoring plan, the climate and rainfall patterns of the Los Angeles area were considered. The number of storms that can be sampled during a given year may be quite limited; a total of eight storms will be targeted over the two-year monitoring period. Monitoring during dry weather is also proposed. The monitoring program proposed in this plan is summarized as follows:

- Monitoring of drainage areas with single land uses (i.e., residential, commercial, and light industrial), as well as drainage areas with mixed land uses (i.e., mass emissions stations).
- Continuous flow and rainfall measurement for all stations.
- Collection of grab samples and flow-composited samples for eight storm events over a period of 2 years.
- Collection of grab samples and 24-hour flow-composited samples during dry weather 4 to 6 times per year over a period of 2 years at the mass emissions stations; collection of grab samples during dry weather at the single land use sites if flow measurements indicate a possible problem (if a

VOL 12

permitted discharge to the selected stormdrain is found, it must be accounted for it the plan, or a different single land use site must be selected.

- Analysis of the samples for:
  - conventional pollutants
  - nutrients
  - bacteria
  - total and dissolved metals
  - volatile and semi-volatile organic compounds
  - pesticides/herbicides

In addition to the full suite of parameters listed above, a reduced suite of parameters has been recommended. Final locations of the monitoring stations have not been provided at this time, since this will require consideration of detailed site-specific information such as hydraulic conditions, general site access, and health and safety of the sampling crew.

1

6441

This section of the monitoring plan describes the criteria that were used to select candidate sites for flow and water quality monitoring in Santa Monica Bay.

2.1 SITE SELECTION CRITERIA

To accurately determine storm water characteristics in a large, diverse study area, a strategic monitoring program can use some stations that sample runoff from relatively small and homogenous land use catchments (so called "single land use" or "upland" stations) and some stations that sample runoff from relatively large catchments representing a composite of land uses (so called "mass emissions" stations). The mass emissions stations are sometimes located in streams toward the lower ends of watersheds and are sometimes referred to as "stream" stations.

The study design requires a station mix that is representative of the land use distribution in the Santa Monica Bay Watershed. Table 2-1 shows the land use distribution within Santa Monica Bay Watershed. The table shows that the principal land uses within the watershed are single-family residential (26 percent) and undeveloped or open lands (57 percent). Other land uses include multiple-family residential (7 percent), commercial (3 percent), light industrial (2 percent), and public (2 percent) areas. Other urban areas constitute the remaining 3 percent of the total area.

Single-family residential areas and open spaces should be targeted in the monitoring program because these land use categories overwhelmingly form the largest types of land uses. Commercial and industrial areas are candidates for direct sampling, because previous studies have shown that these land use types contribute a significant percentage of pollutants to urban storm water runoff despite their relatively small contributing area (EPA, 1983). These previous studies also indicated that the quality of runoff from these types of land uses are widely variable from site to site, so that large parcels with various properties and uses are desirable to characterize the overall pollutant loadings from these types of land uses. Although not included in the land use breakdown, traffic corridors can also be significant contributors of runoff pollutants (Driscoll, et al., 1989). One traffic corridor site previously monitored by Cal Trans should be included with the single land use sites.

Other urban and public land uses not targeted by the single land use sites should be sampled at the designated mass emissions stations. The single land use stations should also monitor other land use types in those instances where the other land uses form a small percentage of the catchment to the monitoring station.

The following criteria were used as guidelines in selecting the single land use sites:

- The total catchment area is large enough (greater than about 50 acres) to generate significant runoff and not be affected by possible localized irregularities.
- The catchment consists primarily of one of the targeted land use types.

TABLE 2-1

LAND USE IN SANTA MONICA BAY WATERSHED

LAND USE	ACREAGE	PERCENT OF TOTAL
Single-Family Residential	70,200	26
Multi-Family Residential	18,500	7
Commercial	8,500	3
Light Industrial	4,000	2
Public	5,200	2
Other Urban	8,200	3
Open	150,200	57
Unknown	400	<1
TOTAL	265,200	100

VOL 12

16443

- A single outfall or discharge point for the catchment has been identified or is likely to exist.

In determining the single land use stations, the land use data generated by the WCC geographical information system (GIS) was heavily relied upon. The subbasins having more than 50 acres were ranked by the percentage of each land use type. Maps of the subbasin drainage systems were then reviewed to select potential candidates from the subbasins with the highest percentage of each land use type. Drainage system maps for subbasins in the Hollywood Quadrangle were not available for review. Further evaluation of the potential sites is required before final selection.

Monitoring sites on basins that discharge directly to the sea (via outfalls) would need to be located upstream to avoid tidal influences and/or backwater effects that could affect sampling results.

Preliminary storm water monitoring stations were selected from examination of County of Los Angeles Department of Public Works drainage maps, based on the above criteria and are presented in the next section. Additional information from field reconnaissance would be required for each site to confirm the preliminary monitoring site selections reported herein. The following technical and operational requirements should be used during the final site selection and verification process:

Catchment Area Characteristics

- The drainage system and boundaries are known
- Land uses are known
- Contamination from or interaction with the sanitary system is unlikely to occur (this may be challenging for some catchments, such as Ballona Creek, where spills from sanitary sewers are frequent)

Hydraulic Suitability

- Uniform flow conditions exist
  - upstream sections are straight and uniform for (at least approximately six channel widths or 12 pipe diameters)
  - backwater conditions do not exist (i.e., receiving waters do not back up to the monitoring site)
  - pressure flow or pipe surcharging does not occur within normal precipitation ranges for sampling and never occurs at levels that could endanger equipment
  - tidal flows do not affect the sampling location
- A rating curve can be reliably determined or other flow measuring technique developed (channel bottom must be stable and not subject to cutting and filling during periods of high and low flows).
- The channel or storm drain is soundly constructed and stable
- Well mixed conditions exist (i.e., the sampling site is located sufficiently downstream from any major upstream storm water inflows)
- The access point (e.g., manhole, bridge) is not excessively deep

VOL 12

1644

- The sampling equipment should not impede flow and reduce flood protection

Crew Safety

- The site has good access during all weather conditions
- The crew should be easily visible
- Minimal traffic or other hazards exist
- The station is relatively secure from vandalism
- Confined space entry can be performed safely and in compliance with regulations during wet and dry weather conditions

Use of the above criteria would help ensure that the storm water samples are representative, as well as meeting safety requirements.

2.2 PRELIMINARY SINGLE LAND USE STATION SITES

Preliminary monitoring sites were selected to represent the following land use types: single-family residential, multi-family residential, commercial, light industrial, and traffic corridor. For each of these sites, the basin number, subbasin name, and component land use type areas, by acreage or percentage, is presented in Table 2-2a and 2-2b. Following the subbasin name, a paragraph is included which describes the catchment composition. The site identification codes, or subbasin names, are based upon the County of Los Angeles Public Works maps. Each code represents the name of a subbasin from the map and the name of the outfall draining the subbasin.

2.2.1 Single-Family Residential

The screening process identified six preliminary station sites (outfalls or manholes draining a particular subbasin) for single-family residential land use. Two of these sites would be selected for monitoring.

BI9815 is in basin #24 of the Venice Quadrangle located near Hermosa Beach in the City of Manhattan Beach. BI9815 is approximately 225 acres with land use breakdowns of 93 percent single-family residential, 4 percent multi-family residential, 2 percent commercial, and 1 percent open. BI9815 is a piped system draining to Santa Monica Bay. The outfall is located near Hermosa Beach in Manhattan Beach.

BI5238 is in basin #21 of the Inglewood Quadrangle located north of UCLA in Bel Air. The 248-acre basin drains a steep canyon with land uses of 95 percent single-family residential, 4 percent public, and 1 percent open space. BI5238 has only one pipe outlet.

SMB62 is in basin #8 of the Point Dume Quadrangle on Point Dume. SMB62 contains 181 acres of 95 percent single-family residential, 4 percent public, and 1 percent open land use. The open channel system drains into Santa Monica Bay possibly requiring the sampling station to be moved upstream from the outfall to avoid tidal influences.

BI9817 is in basin #26 of the Redondo Beach Quadrangle near Palos Verdes Point. The 231 acre subbasin is 91 percent single-family residential, 6 percent multi-family residential, and 3 percent commercial land use. The system is piped with a direct outfall into Lunada Bay.

BI81 is in basin #21 of the Venice Beach/Inglewood Quadrangles east of Hughes Airport and north of Los Angeles Airport. The 785-acre piped system runs from Manchester Avenue to 83rd Avenue and is 91 percent single-family residential, 1 percent multi-family residential, and 8 percent light commercial land uses.

BI4881 is in basin #21 of the northern Inglewood Quadrangle located near Pepperdine University. The 450-acre piped system drains an area from the 66th Street to Manchester Avenue into a larger subbasin, BI4883. The land uses include 91 percent single-family residential and 9 percent public. Because of BI4881's proximity to BI81, only one of these two stations should be selected.

2.2.2 Multi-Family Residential

The screening process identified one preliminary station site and 10 potential sites that require further review of drainage system maps for multi-family residential land use. Two sites are suggested for monitoring.

BI249C is in basin #20 of the southwest Beverly Hills Quadrangle. The basin contains 505 acres with 59 percent multi-family residential, 19 percent open, 12 percent public, 5 percent commercial, 3 percent other urban, and 2 percent single-family residential land use. The basin is located in Santa Monica along Pico Boulevard. The piped system drains into the Kenter Canyon Storm Drain System. A station could be put on the upper reach of the basin near 14th Street to increase the multi-family land use percentage.

BI5212 is in basin #21 of the east Hollywood Quadrangle and is located in Los Angeles north of Wilshire Boulevard and south of Sunset Boulevard. The 634 acre channel and piped system contains 63 percent multi-family residential, 17 percent single-family residential, 11 percent commercial, 7 percent public, 1 percent light industrial, and 1 percent open land uses. BI5212 eventually forms a piped system which drains to the Grant Boundary Piped System.

2.2.3 Combined Residential

The screening process identified three preliminary station sites and nine potential sites that require further review of drainage system maps for combined residential land use. These sites could be substituted for one or more of the single or multi-family sites mentioned above.

BI504 is in basin #21 of the central Beverly Hills/Venice Beach Quadrangles and is located in Ballona. The land uses are 74 percent single-family residential, 25 percent multi-family residential, 3 percent commercial, and 3 percent public. BI504 drains an area of 462 acres from Charnoch Road to Ballona Creek between Bentivela Avenue and Alla Road. BI504 is most likely a piped system.

BI503 is in basin #21 of the central Beverly Hills/Venice Beach Quadrangle located east of BI504. The land uses are 70 percent single and 25 percent multi-family. It drains an 198 acre area from Venice Avenue and Sepulveda Channel into Ballona Creek. Sample station #12 is located at the outfall of the piped system to Ballona Creek.

VOL 12

1 6452

BI736 is in basin #20 of the southwest Beverly Hills Quadrangle located in Santa Monica, south of Pico Boulevard and north of Rose Avenue. BI736 drains 195 acres of 73 percent multi-family residential, 20 percent single-family residential, 4 percent open, and 3 percent commercial land uses. BI736 drains directly into Santa Monica Bay through a piped system. Two sample stations are located at the outfall, #30 and #22.

BI5213 is basin #21 of the east Hollywood Quadrangle and is located in Los Angeles north of the Hollywood Freeway and south of Silver Lake Reservoir. The 809 acre piped system contains 77 percent single-family residential, 16 percent multi-family residential, 4 percent open, 2 percent light industrial, 1 percent commercial, and 1 percent public land uses. BI5213 drains into the Grant Boundary Piped System.

BI648A is in basin #21 of the central Hollywood Quadrangle and is located in Las Cienegas between Venice Boulevard and Washington Boulevard. The 322 acre piped system drains to the upper reach of Ballona Creek. the land uses include 62 percent multi-family residential, 28 percent single-family residential, 8 percent commercial, and 2 percent open. BI648A also is a possible multi-family residential land use site candidate.

BI11021 is in basin #21 of the northeast Hollywood Quadrangle. The basin contains 1,299 acres with 64 percent single-family residential, 22 percent multi-family residential, 6 percent commercial, 4 percent public, 2 percent light industrial, and 1 percent other urban land uses. The basin is located in east Hollywood between Olive Hill and the Silver Lake Reservoir, north of the Hollywood Freeway and south of Los Feliz Boulevard. The piped system drains to the Grant Boundary piped system. The BI11021 monitoring site would need to be moved upstream near the intersection of Hillhurst Avenue and Romaine Street to avoid possible dual outlets.

BI572 is in basin #21 of the east Hollywood Quadrangle and is located in Hollywood between 4th Street and the Santa Monica Mountains. The 1,068 acre piped system eventually drains to Ballona Creek. Land uses include 56 percent multi-family residential, 32 percent single-family residential, 6 percent commercial, 4 percent public, 1 percent open, and 1 percent other urban.

2.2.4 Commercial

The screening process identified two preliminary station sites and two potential sites that require further review of drainage system maps for commercial land use. Two commercial sites would be recommended.

BI249D is in basin #20 of the southwest Beverly Hills Quadrangle located between w Boulevard and Colorado Avenue in Santa Monica. The basin is 76 acres with 91 percent commercial and 9 percent open land use. The piped system discharges into Santa Monica Bay. It appears to have two possible outlets and actual drainage must be further investigated.

RXFRD1 is in basin #21 of the central Beverly Hills Quadrangle located between Santa Monica Boulevard and Wilshire Boulevard in Beverly Hills. The upper reach of storm drain #412 can be isolated for approximately 80 acres of commercial property. RXFRD1 is 59 percent single-family residential, 24 percent commercial, 10 percent multi-family residential, 5 percent light industrial, and 2 percent public land uses.

VOL 12

1 6543

2.2.5 Light Industrial

The screening process identified four preliminary station sites and two potential sites that require further review of drainage system maps for light industrial land use. Two stations would be recommended for sampling.

BLLNA9 is in basin #21 of the Beverly Hills Quadrangle located northwest of Santa Monica High School on Wilshire Boulevard. The 78-acre piped system appears to drain to two possible outlets but remains a good candidate due to its high concentration of light industrial land use. The land uses are 75 percent light industrial and 25 percent single-family residential.

BLLNA6 is in basin #21 in the southeastern Beverly Hills Quadrangle located in Culver City near the Santa Monica Freeway. BLLNA6 is a 108-acre piped system draining to Ballona Creek with two pipe/channel storm drains, #424 and MTD 613. Storm drain #424 is predominantly light industrial and appears to be easily isolated, thus increasing the light industrial land use percentage.

CULVER1 is in basin #21 of the southeastern Beverly Hills Quadrangle located just northwest of DESILU Studios in Culver City. The piped section along Washington Boulevard could be isolated, as it appears to drain a light industrial area of approximately 60 acres. The land use percentages are 48 percent single-family residential, 29 percent light industrial, 12 percent multi-family residential, 6 percent public, 3 percent other urban, and 2 percent commercial.

2.2.6 Commercial and Light Industrial

The screening process identified two preliminary station sites and four potential sites that require further review of drainage system maps for combined commercial and light industrial land use. These sites could be substituted for one or more of the commercial and/or light industrial sites.

BI5242 is in basin #21 of the Venice Quadrangle located in Ballona north of Marina Del Ray. The 681-acre piped system drains 170 acres of commercial and light industrial land (25 percent of the total). Approximately 80 acres of light industrial and commercial land could be isolated on storm drain 3872 at the intersection of Thatcher and Oxford Avenues. The reach drains from Redwood Avenue to Thatcher Avenue. Additional confirmation of actual area drainage patterns will be needed.

BI3402 is in basin #23 of the Venice Quadrangle located in El Segundo just south of the Los Angeles International Airport (LAX). The 443-acre basin drains 149 acres of commercial and light industrial land (34 percent of the total). BI3402 drains from Mariposa Avenue to El Segundo Boulevard. Reach 3401 on the eastern portion could be isolated at Penn Street and El Segundo Boulevard, providing approximately 100 acres of light industrial and commercial land use.

BI52041 is in basin #21 of the southeast Hollywood Quadrangle and is located in Los Angeles between 12th Street and Jefferson Boulevard. The 1,082 acre piped system drains into storm line #5204. The land use percentages include 47 percent commercial, 35 percent light industrial, 17 percent unknown, and 1 percent public.

BI52042 is in basin #21 of the southeast Hollywood Quadrangle adjacent to BI52041. BI52042 is located in Los Angeles between 12th Street and the University of Southern California. The 442 acre piped system drains to storm line #5204. The land use percentages include 70 percent light industrial, 23 percent public, and 7 percent commercial. Sample station #3 is located in BI52042.

BI52043 is in basin #21 of the southeast Hollywood Quadrangle and is located in Los Angeles adjacent to BI52041 and BI52042. The 2,934 acre system drains to storm line #5402. The land use percentages include 33 percent multi-family residential, 24 percent single-family residential, 21 percent commercial, 10 percent public, 7 percent light industrial, 3 percent other urban, and 2 percent open. BI52043 should be isolated on the upper reach to produce a much higher commercial and light residential land use percentage.

2.2.7 Open Space

The screening process identified ten preliminary station sites for open space land use. Two stations would be recommended.

ARSEQ1, ARSEQ2 and ARSEQ3 are in basin #1 of the Trifuno Pass Quadrangle. The 8000 acres of combined area drain portions of the Santa Monica Mountains into the Arroyo Sequint and discharges into the Pacific Ocean near Sequint Point and Leo Carrillow State Beach, east of Solromar. The Roosevelt Highway appears to provide good access to the channel. The drainage system is well defined with approximately 99 percent open land use.

LATIG1 is in basin #10 of the Point Dume Quadrangle located east of Malibu Riviera and Point Dume. LATIG1 drains 697 acres of 100 percent open space in Latigo Canyon to Santa Monica Bay.

LACHU1 is in basin #4 of the Trifuno Pass Quadrangle located east of Sequint Point and north of the Roosevelt Highway, allowing good access. The basin drains 826 acres of open space in Lachusa Canyon to the Pacific Ocean. Rain gage #4867 is located in the northern end of LACHU1 allowing access to local rainfall information.

PENA1 is in basin #15 of the Topanga Quadrangle located west of Topanga Beach in Pena Canyon. The 483 acres of 100 percent open space drains directly to Santa Monica Bay via a channel system.

TUNA1 is in basin #15 of the Topanga Quadrangle located in Tuna Canyon west of Topanga Beach and Pacific Palisades and directly east of PENA1. The 935 acres drains the 97 percent open and 3 percent single-family residential land uses through a channelized system.

RAMRZ1 is located in basin #8 of the Point Dume Quadrangle east of Malibu. The 1675-acre basin contains 99 percent open space and 1 percent single-family residential land uses. The basin drains most of the steep terrain of Ramiriz Canyon.

LALIS1 is in basin #3 of the Trifuno Pass Quadrangle located east of Sequint Point and north of the Roosevelt Highway, allowing good access. The basin drains 943 acres of open space in Los Alisos Canyon to the Pacific Ocean. LALIS1 is located west of LACHU1.

TEMES1 is in basin #18 of the central Topanga Quadrangle located north of Pacific Palisades. The 1548-acre area drains Temescal Canyon which is 87 percent open space and 13 percent single-family residential land use. The 1300 acres of the upper basin could be isolated, providing a possible monitoring site.

TRANC1, TRANC2, and TRANC3 are adjacent to one another in basin #6 of the Point Dume Quadrangle located in Trancas Canyon west of Point Dume. The three basins drain 5217 acres in the Santa Monica Mountains National Recreation Area and discharge to the Pacific Ocean through an open channel near Trancas. The land uses are 98 percent open, 1 percent single-family residential, and 1 percent public land uses. Sampling Station #34 is also located just south in TRANC4 providing additional monitoring information.

SNICH is in basin #6 of the Trifuno Pass Quadrangle located east of Sequint Point and north of the Roosevelt Highway, allowing good access. The basin drains 847 acres of open space to the Pacific Ocean. SNICH is located directly west of LACHU1 and LALIS1.

2.2.8 Transportation

The land use breakdowns that were obtained from Southern California Association of Governments (SCAG) and incorporated into the Project GIS system did not include a category for highways or other major transportation corridors. However, one site in the watershed was previously monitored by Cal Trans (Racin et al., 1982) and is proposed as a transportation land use station site for this monitoring program. The station site is located in Los Angeles on Interstate 405 at a 36-inch reinforced concrete pipe culvert. The station receives runoff from 3.2 acres of paved highway. At this location, Interstate 405 has 4 lanes in each direction and had an average daily traffic load of 200,000 vehicles in 1980.

The second candidate transportation site is in basin #21 of the east Hollywood Quadrangle and is located in Los Angeles. Over 6,500 linear feet of the Hollywood Freeway Corridor drain to the B15213 system including 4,000 feet from basin B15212. This represents a preliminary site selection and will require further review of specific highway drainage maps, which is beyond the scope of this plan.

2.3 PRELIMINARY MASS EMISSIONS STATION SITES

Stations were selected for mass emissions station sites which comprise large percentages of Santa Monica Bay Watershed land use mix or have been estimated to contribute significant portions of storm water runoff pollutants. The land use composition of the catchments of each of the mass emission monitoring sites is summarized in Table 2-3. Descriptions of the mass emissions station sites are presented below. The stations listed below are preliminary. The actual location of the station would depend on field reconnaissance of the storm drainage system. Together, these stations would measure runoff from a 4-basin total of 169,376 acres or approximately 75 percent of the 225,474 acre Santa Monica Bay Watershed.

2.3.1 Ballona Channel

Ballona Channel drains 82,287 acres of basin #21 and a total of 36.5 percent of the Santa Monica Bay Watershed. Land use in the basin includes 46 percent single-family residential, 18 percent multi-family residential, 8 percent commercial, 4 percent light industrial, 4 percent public, 3 percent other urban, 17 percent open space, and less than 1 percent unknown.

TABLE 2-3a
PRELIMINARY MASS EMISSIONS SAMPLING STATION SITES

LAND USE (Acres)

SUBBASIN NAME	BASIN #	Single-Family Residential	Multi-Family Residential	Commercial	Light Industrial	Public	Other Urban	Open	Unknown	Subbasin Total Acreage

2.3.2 Malibu Creek

Malibu Creek drains 70,292 acres of basin #12 and a total of 31.2 percent of the Santa Monica Bay Watershed. Land use in the basin includes 8 percent single-family residential, 1 percent multi-family residential, 1 percent commercial, 1 percent light industrial, less than 1 percent public, 2 percent other urban, and 87 percent open space.

2.3.3 Pico-Kenter Storm Drain

Pico-Kenter Storm Drain drains 3,191 acres in basin #20 and a total of 1.4% of the Santa Monica Bay Watershed. Land use in the basin includes 49 percent single-family residential, 12 percent multi-family residential, 2 percent commercial, 3 percent public, 1 percent other urban, and 33 percent open space.

2.3.4 Topanga Creek

Topanga Creek drains 12,606 acres of basin #16 and a total of 5.6 percent of the Santa Monica Bay Watershed. Land use in the basin includes 12 percent single-family residential, 18 percent multi-family residential and 88 percent open space. Topanga Creek was selected because flows were previously measured at this creek, and records of stream flow are available from USGS and the Los Angeles County Department of Public Works. Since selecting this site we have learned that the flow monitoring station was removed; restoration of this station will be necessary for this creek to be used.

This section describes the types of equipment needed to implement the monitoring plan. Overviews of equipment installation, calibration, verification, and operation are also presented.

3.1 EQUIPMENT SELECTION

Equipment should be selected to perform flow monitoring and water quality sampling to meet the monitoring plan objectives. Various types and models of rain gages, water quality samplers, and flow monitoring systems are available. Minimum technical specifications should be developed for requesting bids from vendors. In general, the specifications should include that the stations be: automated with various programming and sampling options; capable of being linked by telemetry for remote operation and data transfer (recommended for long-term monitoring because it will reduce staff maintenance time and allows for continuous monitoring of the stations); installed as permanent but easily moveable stations; and supported by a sophisticated station and flow data management program.

3.1.1 Rain Gages

Rain gages are located throughout the watershed as shown in Figure 3-1. These gages are operated by the Los Angeles County Department of Public Works who should consider making them available for use in the monitoring program. The system should be set up so that at least some of the data (based upon final monitoring station selection) collected by these gages can be immediately available for inspection via a telemetry system and can be downloaded to a computer for graphical or tabular display.

3.1.2 Flow Monitoring Hardware/Software and Equipment Control

It is recommended that when possible monitoring stations (closed conduit stations), both water depth and velocity, be independently monitored because a variety of parameters (slope, roughness...) are necessary to ensure the accuracy of Manning's equation. The cross-sectional area of water can be obtained from the measured water depth and the shape of the given pipe. The flow can then be computed as the cross-sectional area multiplied by the average velocity.

Flow estimates for open channel stations should be obtained using rating curves established for each station. Rating curves correlate flow with depth using a limited set of velocity and flow depth measurements. This would require measurement of velocities over a variety of flow depths during several storm events.

Alternative methods for estimating flow without velocity measurements exist and may be utilized prior to establishing a rating curve to estimate flow rates. Depth measurements can be used in conjunction with channel characteristics and empirical flow equations to calculate flows (Manning's equation).

FIGURE 3-1

RAINFALL STATIONS LOCATION MAP 1988-89

VOL 12

Other equipment that should be installed at the monitoring stations include a system microprocessor; water quality sampler control unit; equipment housing (open channel stations only); computer site-specific software for hardware control; telemetry equipment; and power source (batteries or other electrical power). Decisions regarding specific equipment types or makes should be made by the implementing agency.

A typical station configuration is presented in Figure 3-2, which shows the major components of a monitoring station located in a manhole. A monitoring station located in an open channel would have a separate enclosure for the flow monitor and sampler. Open channel stations would use an overhead structure (a bridge) to mount the non-intrusive ultrasonic depth sensors or stream bottom-mounted pressure transducer. A rain gage is not shown in the figure. Finally a separate structure can be located adjacent to the sampling location and the equipment can be located inside, with appropriate connection to the liquid surface.

The exact type of installation will depend upon site-specific conditions; in some cases several alternative installations can provide adequate sampling. In such cases the preference of the agency performing the sampling will determine the sampling station design.

Station operation is depicted in Figure 3-3. Software on a personal computer would enable communication with the rain gage and flow monitor over a phone line. The flow estimated from the depth and velocity data would be used to update the cumulative volume. When a pre-defined cumulative volume is exceeded, the flow monitor would send a signal to activate the water quality sampler. The sampler collects a sample through the intake line. Signals from the rain gage can also be used to activate the water quality sampler for individual samples, but this method is not recommended in this plan.

3.1.3 Water Quality Samplers

Each station should be equipped with an automatic water quality sampler that can be configured for either discrete or composite sampling. For storm water monitoring, the samplers can be configured to fill sample bottles for composite sampling by collecting samples per calculated flow volumes. For parameters that need to be tested on-site or in discrete samples, grab samples can be collected manually. For some parameters, such as oil and grease, in some cases it is necessary to use a hand sampler to collect a representative sample (see Volume II of these reports). Water quality samplers are available in refrigerated units which require a source of electrical power. If no power source is readily available, samples can be kept cool using ice, and the equipment can be powered using batteries. This decision should be made by the implementing agency.

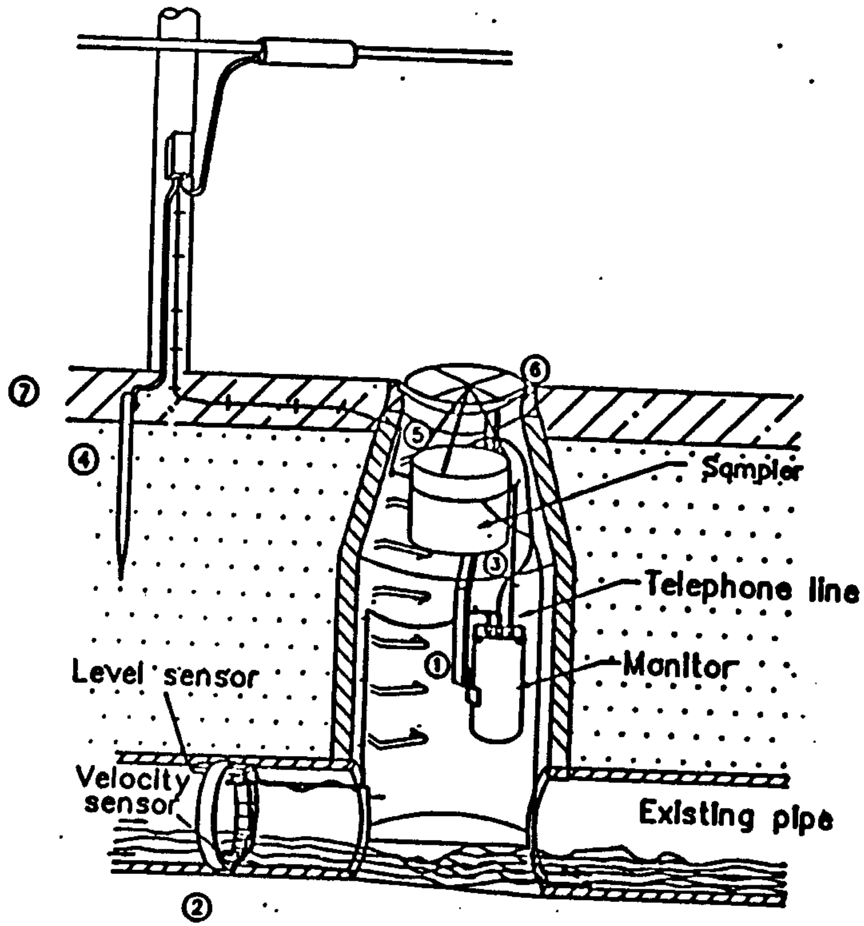
3.2 EQUIPMENT INSTALLATION

The monitoring stations would be located in manholes, closed conduits, or in open channels. The following text provides a generalized overview of equipment installation procedures at these stations.

3.2.1 Closed Conduit and Manhole Stations

At manhole stations, sensor equipment should be installed in locations which provide the most stable hydraulic conditions. Typically these conditions occur just upstream from the location of the manhole, because construction of the manhole may have altered the original

1 5451



Mounting Details

1. Mounting flange consists of marine grade aluminum bar stock. Width is 3" — length is determinate upon the individual site condition.
2. Sensor mounting plates consist of marine grade aluminum bar stock that are attached with 1/4" anchor bolts (316SS). Embedment depth approx. 1".
3. Cables are anchored with 1/4" anchor bolts (316SS). Approximate embedment depth is 1".
4. Grounding rod is provided by phone company and is installed by them as per their specifications.
5. Cable penetration through corbel is made with rotary hammer drill and is then sealed with a urethane or epoxy compound.
6. Manhole rim is drilled and tapped. Aluminum mounting flange is attached with 3/8" threaded stud (316SS).
7. Roadcut depth varies between 6" and 12" depending on local regulations. Cut is then sealed with PRECO road sealant.

FIGURE 3-2 MONITOR AND SAMPLER INSTALLATION SPECIFICATIONS

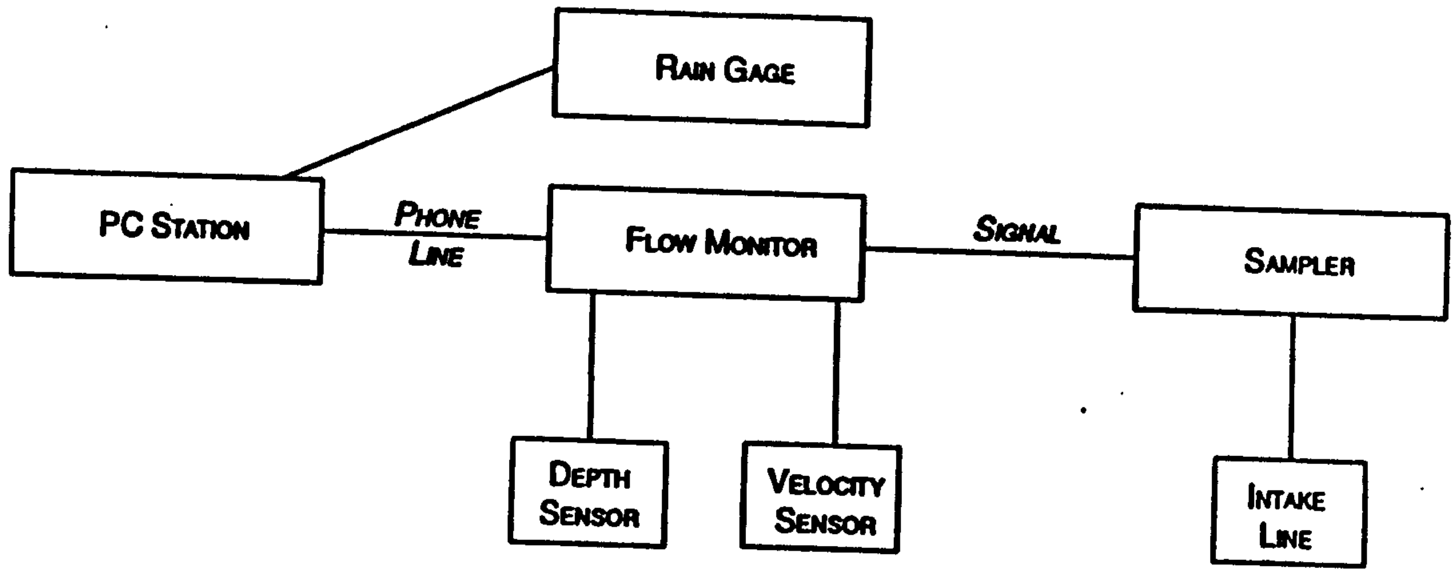


FIGURE 3-3 STATION COMMUNICATION

shape of the pipe at this point, thus changing the hydraulic characteristics of the channel. Actual sensor installation consists of mounting the depth and velocity sensors to expansion rings sized for an individual pipe and then expanding the ring for a tight fit. The expansion rings facilitate easy removal of the sensors for maintenance or replacement or movement to another site. The water sampler intake tubing and strainer are to be mounted at the invert of the pipe just downstream of the sensing equipment ring.

The sampling equipment can be mounted in the manhole so that it does not interfere with activities on the surface. Alternatively, it may be more desirable to mount the equipment in a protective enclosure at the surface. The choice will depend upon site-specific conditions.

3.2.2 Open Channel Stations

For an open channel station at a bridge or culvert, non-intrusive ultrasonic depth sensors can be mounted to the underside of these structures at or near mid-channel. Velocity sensors and pressure transducers should be mounted on the bottom at the center of these channels. The water quality sampler intake tubing and strainer are to be located just downstream at mid-channel. The intake is to be located so that water samples would be collected at the same width cross section location where depth measurements are made. The flow monitor microprocessor and water quality sampler units should be mounted in weather proof enclosures. For channels with low flow sections, the pressure transducer and intake screen will need to be located to sense the lowest point of the invert. If both wet and dry weather flows are to be measured, two sensors with different ranges may be required.

3.3 EQUIPMENT CALIBRATION

Calculation of flow in the closed conduits can be based either on the depth of flow, or the depth and the velocity of flow. Both depth and velocity of flow should be measured upon installation by means independent of the flow sensor to verify sensor readings. Depth measurements can be verified with a scaled wading rod or similar device. In order to verify and adjust the velocity sensors, concurrent measurements should be taken with hand-held electromagnetic velocity meters.

In cases were pressure flows exists alternative procedures may be required.

3.4 VERIFICATION AND OPERATION OF STATION EQUIPMENT

Station equipment and telemetry should be verified prior to storm sampling events. Equipment diagnostics should be performed to check the equipment. In addition, operation of each of the water quality samplers should be verified through operation of the samplers. Station preparation, event initiation, event operation, event shut down, and data transfer procedures will be fully described in the Standard Operations Procedures (SOPs). These are outlined in Chapter 7.

VOL 12 1 6464

4.0 STORM SELECTION AND RUNOFF ESTIMATION PROCEDURES

This section describes procedures used to estimate and measure rainfall and storm water runoff volumes. Also included are the criteria used for the selection of storms to be sampled.

4.1 BACKGROUND

One objective of the storm water sampling program is to estimate the relationship between rainfall amounts and runoff volumes for use in pollutant load estimation models. The runoff coefficient is defined as the fraction of the total rainfall volume (i.e., the amount of rainfall over the watershed area) that becomes storm water runoff. Runoff volume estimates (calculated by multiplying the runoff coefficient and the predicted rainfall volume) are used to program the sampling equipment to collect representative flow-weighted composite samples. Runoff volumes are also used in conjunction with calculated site median concentrations (SMC) of pollutants as input to storm water runoff models that generate (basin wide) pollutant loads.

Eight storm events are to be sampled over the course of two years (an average of 4 sampling events per year). These events should be selected to represent the various typical seasonal storms for the Santa Monica Bay area with the realization that storms available for sampling may be few. Storm selection criteria are designed to determine which storms will be sampled. These criteria will be used to ensure that sampled storms represent the storm characteristics (e.g., volume, intensity, antecedent dry period) that are typical for Santa Monica Bay and meet Federal regulatory requirements.

4.2 STORM SELECTION CRITERIA

Storm characteristics were determined for selected rain gages operated by the Los Angeles County Department of Public Works (LACDPW) with records available through the National Weather Service. Details are presented in Stenstrom and Strecker (1993). The rain gage records were analyzed for storms that were defined as having more than 0.10 inches of precipitation with a six-hour inter-event time. Characteristics of storms occurring during the wet season (i.e., November through April) were computed separate from the dry season. The results of the analyses are compiled by station and for the entire watershed in Table 4-1. Santa Monica Bay has an average of approximately 16 storm events per wet season.

The NPDES permit application requires storm water data from three storm events occurring at least one month apart, with an "event" defined as a minimum of 0.1 inches of rain occurring at least 72 hours from the previously measurable (greater than 0.1 inch of rainfall) storm event. At least three storms should be sampled where the duration and total volume are within about 50 percent of the average storm to meet the NPDES permit application requirements. Based upon analysis of data from the LACDPW rain gages, these storms should be between 6 to 25 hours in duration and about 0.4 to 1.7 inches in volume. These criteria can be relaxed if needed to make sure that enough storms are available for sampling.

TABLE 4-1
WET SEASON STORM STATISTICS (a)

STATION	PERIOD OF ANALYSIS (water years)	STORM VOLUME (inches/storm)		STORM INTENSITY (inches/hour)		STORM DURATION (hours/storm)		TIME BETWEEN STORMS (hours)	
		Average	Coef of Var	Average	Coef of Var	Average	Coef of Var	Average	Coef of Var
0619	1948-1980	1.06	1.22	0.084	0.66	12.5	0.85	209	1.32

8230	1948-1989	0.69	1.07	0.074	0.73	10.5	0.88	219	1.36
Minimum		0.67		0.061		10.5		198	
Maximum		1.09		0.101		14.2		258	
Average		0.87		0.072		12.5		225	

(a) For storms having more than 0.10 inches of precipitation with a 6-hour inter-event time during November through April.

Storms can be sampled during both the wet and dry seasons. As defined in Table 4-1, the wet season is defined as lasting from the beginning of November through the end of April. This wet season is associated with more frequent storms and shorter dry weather intervals between storms. Conversely, the dry season is associated with less frequent storms of greater intensity and longer dry weather intervals between storms. It is likely that almost all of the representative storm events will occur during the wet season.

4.3 RUNOFF ESTIMATION PROCEDURES

The predicted rainfall amounts, watershed area, and runoff coefficients (the product of all three parameters) can used to estimate runoff volumes for each of the selected catchments. Runoff coefficients by land use were developed for the loadings model based upon information from Los Angeles County.

Water depth and resulting flow data should be continually collected from each sampling station at a uniform time interval (5 minutes is typical during a storm event). The data would be retrieved using a portable computer (directly or by modem through telemetry equipment) and would ultimately be downloaded to a database. Runoff coefficients specific to each sampled catchment should be based upon an estimate of the impervious area percent in previous estimates for each of the land uses in the catchment.

Each storm event monitored by the flow and rainfall monitors provides additional information for calculating runoff coefficients. These coefficients can be calculated by dividing the total measured runoff for the event by the total rainfall volume over the contributing catchment. As those data are developed, the expected result coefficient for each watershed can be refined. It will also be a function of total rainfall and as well as condition of the watershed (e.g., the presence of residual moisture from a previous rainfall). Finally, flows from permitted discharges (if any) must be subtracted from the measured flow rates.

Once the total runoff volume is estimated, the water quality samplers should be programmed to collect a sample each time after approximately five percent of the runoff volume has flowed past the sensors. Therefore, the water quality sampler is programmed to collect about 20 samples over the entire storm. Each time the sampler is triggered to collect a sample a pre-specified volume of storm water would be deposited into one of the bottles. The total volume of storm water collected should be greater than or equal to the volume of sample needed by the laboratory to conduct all of the specified analyses. If a storm happens to be larger than expected, the sampler's bottles may be filled prior to the end of the storm. In this case it will be necessary to replace the full bottles with empty bottles.

For dry weather sampling, the water quality samplers should be programmed to collect a sample once each hour for 24 hours. The samples collected would be flow-weighted for laboratory analysis. Grab samples can be collected at the beginning of the sampling period and/or at the end of the sampling period. Dry weather sampling at the mass emission stations is proposed for 4 to 6 times per year during the 2-year sampling period. Unlike the mass emission stations, the single land use sites may not have base flows. Any flows that do occur during dry weather at the single land use stations may be due to illicit connections. It is proposed that one grab sample would be collected at the single land use stations if the continuous flow measurements indicate a potential problem (i.e., unaccounted for flow).

VOL 12

6467

5.0 SAMPLING EVENT MANAGEMENT AND WATER QUALITY FIELD SAMPLING METHODS

The objective of this section is to describe the field sampling methods for obtaining water samples. Automatic flow-weighted composite samples and manual grab samples should be collected. Automatic samplers would be used to collect flow-weighted composite water samples throughout the duration of a storm event or the duration of the dry-weather monitoring period, whereas grab samples would represent instantaneous samples.

Storm sampling would primarily be performed by automatic samplers because of their ability to automatically trigger sampling when a storm starts and their ability to composite storm water samples, based on flow volumes. Automatic samplers would also be used to collect the 24-hour flow composited sample during dry weather at the mass emission stations (by reprogramming the samplers). Grab samples would be collected for instantaneous field measurements at each initial station visit during a storm event and at the beginning and/or end of the dry-weather monitoring period. At the time of grab sample collection, chemical/bacteriological constituents that have short holding times (such as fecal streptococci) and those that are highly volatile in nature (such as volatile organic compounds) would be collected.

Figure 5-1 provides an overview of the storm event decision/action tree. The main elements of the tree are discussed below. Dry-weather monitoring would occur as described in Section 4.3.

5.1 PRE-STORM PREPARATION STRATEGY

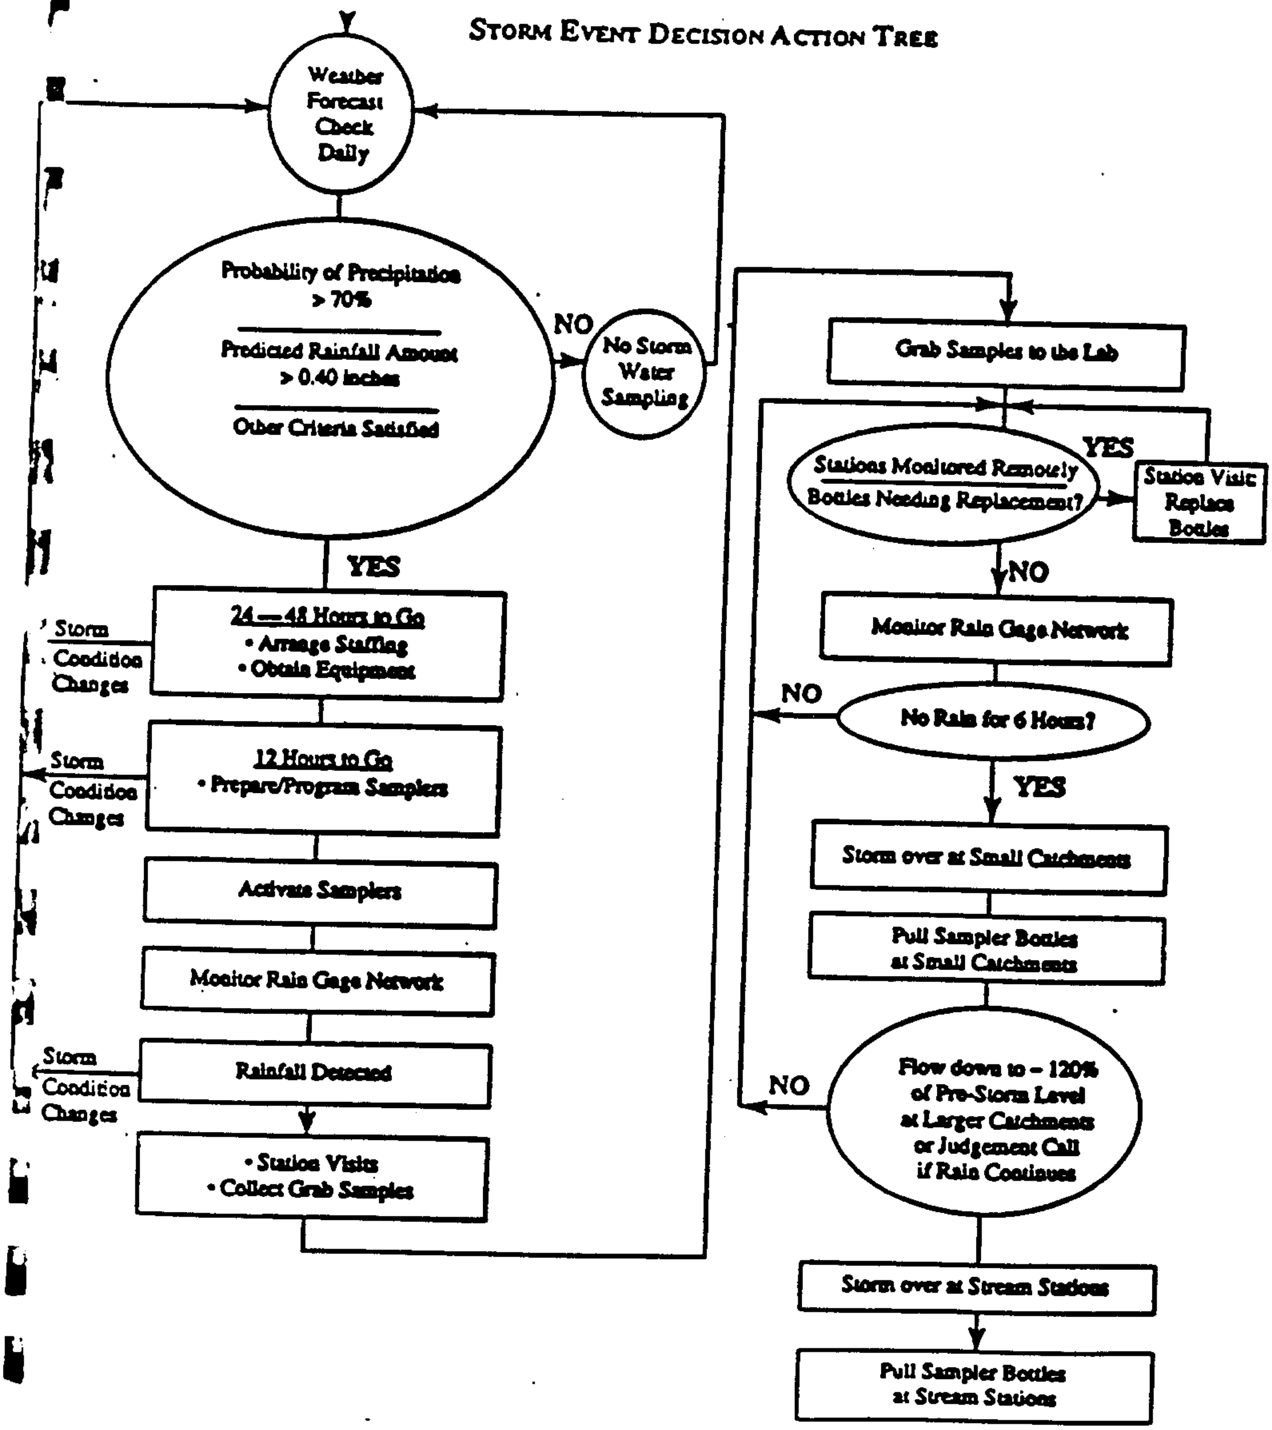
For wet-weather monitoring, preparation for storm water sampling would include weather forecasting, storm selection, mobilization strategies, and determination of appropriate automatic sampler settings. Proper coordination and management of these tasks would set the stage for effective storm sampling.

Weather forecasting will be an important aspect of storm water collection. It will be necessary to obtain the most reliable and up-to-date information on each storm's physical characteristics. The Sampling Event Coordinator (for discussion of sampling event staffing and roles, see Section 9), in consultation with the Program Manager would decide to mobilize and prepare for a given sampling event based on the probability of rainfall and, the expected rainfall amount, coverage, duration, and intensity.

The Sampling Event Coordinator would discuss upcoming storms with the Program Manager to ensure consistency with the storm selection criteria previously outlined. Preparation for a storm sampling event would be initiated when the probability of precipitation is about 70 percent or greater and the predicted rainfall amount is approximately 0.40 inches or greater, provided that the required conditions for the antecedent dry period are met (i.e., at least 72 hours with less than 0.1 inches of rain) and the target number of storms to be sampled in the season has not been reached. Additional criteria may be applied, including longer antecedent dry periods. Criteria could also be relaxed to make sure that enough storms are sampled.

Figure 5-1

Storm Event Decision Action Tree



VOL 12

1 6469

R0049774

Weather forecasts are available each day from the National Weather Service and from private consultants. These forecasts include probability of precipitation, precipitation start and end times, and precipitation amount. If the forecast suggests that the storm satisfies the selection criteria, mobilization activities should begin 48 hours before the storm. Specific crew personnel would be identified, sampler batteries would be recharged, and sample bottles would be checked and made available. Within 12 hours of a given storm's arrival, if the updated forecast shows that the storm still satisfies the selection criteria, field crews would prepare the samplers (e.g., load and ice bottles, load the batteries, check the sampler program, and start the samplers).

5.2 SAMPLING EVENT MANAGEMENT

At least two to three field teams of two people each would be used during the initial stages of monitoring to visit each site, collect grab samples, and check the performance of the automatic samplers. As the sampling event progresses and grab sampling is completed only one to two field teams would be needed to check the samplers, change bottles, and deliver samples to the analytical laboratory.

All in-field water sampling activities would be coordinated from a centralized location. The Sampling Event Coordinator would coordinate all field crews during the sampling event. Communication is best maintained with each crew in the field via cellular phones or radios.

If any problems with the sampling equipment occur during the sampling event, it is the Sampling Event Coordinator who would decide the solution. For wet weather monitoring, the Coordinator would also decide when the storm is "over" based on previously-specified criteria. These criteria may be based on the number of hours since the last recorded rainfall or the number of hours since the start of the storm and/or a return to or near to pre-storm base flow conditions.

5.3 FLOW COMPOSITE SAMPLES

Once the decision is made to sample, estimates of the runoff volume expected at each station would be made, based on the predicted rainfall amount and the runoff coefficients corresponding to land use and soil type for the catchment of each sampling station. Monitoring stations are required that have flow measuring equipment as well as one or more automatic samplers that can communicate with the flow measuring equipment (some manufacturers make combine units). Once a runoff volume is projected, the data logger/controller for each station would be programmed to trigger the water quality sampler to collect a sample after each 1/20 of the total projected storm event volume has flowed past the flow monitor.

Borosilicate glass bottles would be placed in each automatic sampler. The bottles would be solvent-rinsed to remove trace organic contaminants and acid-cleaned to remove trace metal contaminants. If the water quality sampling units are not refrigerated, a sufficient amount of ice or "blue ice" would also be placed around the bottles in order to keep the storm water samples cool. Once activated, the automatic samplers would collect equal volumes of runoff water at flow-paced intervals for wet-weather monitoring and unequal volumes of runoff water at equal time intervals for dry-weather monitoring. All samples would be combined in the laboratory to create a single flow-weighted composite sample for analysis.

The goal is for the automatic sampler to collect the volume of sample that is adequate for the specified suite of chemical analyses. The required sample volumes are shown in Table 5-1. If insufficient volumes are collected, the runoff samples would be analyzed for fewer chemical constituents, as prioritized in Table 5-1. An excess amount of sample collected would require additional time and effort for sample bottle handling in the field, and compositing of samples in the laboratory, and could result in incomplete sampling event due to full bottles. When the forecasted runoff is different from the actual runoff volume, the sampling volume can be adjusted during the event. This may be important to assure complete sample capture, as the automatic units will not continue to collect samples when the sample bottles are full. If the programmed sampling volume is altered during the event, the sample bottles would be changed and the laboratory would recomposite the bottles proportionate to the sampling volume setting for each bottle.

During wet-weather monitoring, the criteria for when to stop sampling at a given station would depend on the amount of flow occurring at that station, rather than the amount of rainfall. The automatic samplers are triggered by flow, so if the flow monitoring equipment detects no flow, the sampler would not try to collect a sample. For the stations which have base flow, the criterion for halting sampling can be based on the return of flow to about 120 percent above the pre-storm base flow. This criterion is a compromise between the time needed to capture the falling limb of the stream hydrograph and the deadlines imposed by constituents with short holding times. As the overall monitoring program progresses, more specific criteria for halting the samplers at each station can be developed as more hydrographs are obtained.

If another storm front arrives unexpectedly within a six-hour period from when rainfall and sampling was halted, the two fronts could be considered one storm event, sampling could resume, and the sample bottles from both fronts could be composited in the lab. Weather forecasting should be utilized to minimize the likelihood of halting sampling prematurely.

For the dry-weather sampling, a procedure similar to that described above should be used to collect the composite samples. The primary difference between the dry-weather and wet-weather procedures is that in dry-weather sampling, initiation and completion of sampling would be set to correspond to convenient working hours rather than flow conditions.

Once sampling is terminated, the sample bottles will be removed and transferred directly to the laboratory under strict chain-of-custody procedures. If an excess amount of water is collected, these samples will be manually composited in the laboratory. In this case, the sample water must be thoroughly mixed by using a pump to transfer the water back and forth between a bottle from each set. Mixing will be considered adequate when the turbidity (as determined by EPA Method 180.1) of the samples in the bottles is the same.

5.4 GRAB SAMPLES

Grab samples would be collected for bacteria (due to the short 24-hour holding time required), volatile organic compounds, TPH, oil and grease, total phenols, cyanide, acrolein, acrylonitrite, and field measurements including pH, temperature, conductivity and turbidity. For manhole stations that are deeper than 10 feet below ground surface elevation, grab samples could be collected using the automatic samplers. The program on the automatic sampler could be halted temporarily. The pump tube would then be disconnected from the sampler in order to fill the grab sample bottles using the manual pump actuating feature of the automatic sampler. Grab samples from depths of less than 10 feet can usually be taken using manual grab sampling equipment. Alternatively, other types of pumps can be provided for deep locations.

TABLE 5-1
PRIORITIZED COMPOSITE ANALYSIS LIST AND VOLUME REQUIREMENTS WATER QUALITY SAMPLES

Composite Sample Priority Level	Priority Analyte	Volume Required	Volume Required	Volume Required	Volume Required	Volume Required
1	TOTAL METALS Antimony, Arsenic, Beryllium, Cadmium, Chromium, Copper, Lead, Mercury, Nickel, Selenium, Silver, Thallium, Zinc	250 mL	250 mL	250 mL	250 mL	250 mL
2	DISSOLVED METALS Antimony, Arsenic, Beryllium, Cadmium, Chromium, Copper, Lead, Mercury, Nickel, Selenium, Silver, Thallium, Zinc	250 mL	250 mL	250 mL	250 mL	250 mL
3	TSS/TDS/ HARDNESS/BOD5/ COD	1L	1L	1L	1L	1L
4	NH3/TKN/TOTAL P/ NO3/ORTHO-P	1L	1L	1L	1L	1L
5	SEMI-VOLATILE ORGANICS	1L	1L	1L	1L	
6	POLYNUCLEAR AROMATIC HYDROCARBONS (PAH)	2L	2L	2L		
7	ORGANOPHOSPHORUS PESTICIDES/ ORGANOCHLORINE PESTICIDES	2L	2L			
8	CHLORINATED HERBICIDES	1L				
	TOTAL VOLUME REQUIRED	8.5 L	7.5 L	5.5 L	3.5 L	2.5 L

Grab Samples:

1. Bacteria - a) Fecal Coliform (1 - 125 ml container)
   b) Fecal Streptococci (1 - 125 ml container)
   c) Enterococci (1 - 125 ml container)
2. Total Oil and Grease/TPH (1 - 1L Glass Bottle)
3. Volatile Organics (2 - 40 ml VOA vials)
4. Acrylonitrile and Acrolein (2 - 40 ml VOA vials)
5. Total Phenols (1 - 1L Glass Bottle)
6. Cyanide (1 - 1L Glass Bottle)

For wet-weather monitoring, grab samples should be collected during the beginning of the storm on the rising limb of the hydrograph. This may provide concentrations reflecting the higher levels of pollutants which are sometimes observed in the first part of an event, as compared with those observed during the remainder of the event. If the total mass emissons are to be estimated, a representative number of samples must be collected from both legs of the hydrograph.

5.5 SAMPLE TRANSFER AND CHAIN-OF-CUSTODY

The transfer of samples from the field to the laboratory should proceed through the proper chain of custody. Once grab samples are collected in the field, they should be taken to a centralized location for transfer to the laboratory. The centralized location should be accessible to all field personnel and laboratory couriers. Samples should be iced, labeled, and readied for pick-up or delivered to the laboratory. Chain-of-custody forms similar to the example shown in Figure 5-2 will be completed. The field sampling team leader would coordinate sample transferrals and courier pick-ups, as appropriate. A similar procedure should be used when composite samples have been collected.

This section of the monitoring plan describes the selection of sample analysis methods and the analysis suites.

6.1 BACKGROUND

The main purpose of the monitoring plan is to improve the quantification of pollutant loadings to Santa Monica Bay from separate storm sewer systems and to facilitate efforts to identify "problem" land use areas for prioritizing the implementation of a storm water management program. The sample analysis methods are EPA-approved methods which have low detection limits in order to generate reliable data at the typically low analyte concentrations present in storm water samples. The general strategy for selection of constituents for analysis is to begin with a broad analysis list (i.e., full analytical suite) (Table 6-1) and, based on the results from the first three storm events, focus the program on those constituents which are present in storm drains to Santa Monica Bay at concentrations which may be of concern (i.e., the proposed reduced analytical suite). The analysis suite required for the Federal NPDES Permit Part 2 discharge characterization application for separate storm sewer systems is shown for the readers' information.

6.2 CONSTITUENTS AND ANALYSIS METHODS

For the Santa Monica Bay Storm Water Monitoring Program, the suggested list of chemical constituents that should be analyzed in storm water runoff contains all of the parameters required for the Part 2 NPDES permit application plus several additional constituents which are of local interest. The analyses should be performed by a certified laboratory.

6.2.1 Federal Permit Requirement Sampling Suite

The Federal requirements do not include analyses for some chemical parameters which may be important components of storm water discharge (e.g., pesticides, herbicides, total petroleum hydrocarbons). Therefore, storm water analysis for Santa Monica Bay should include these parameters during the first three storm events (Table 6-1). Selection of these additional constituents was based on two major considerations: 1) analytes expected to be present in separate storm sewer systems based on results of the Nationwide Urban Runoff Program (NURP); and 2) parameters which are necessary to interpret data for other pollutant chemicals. For example, total hardness is necessary to determine the aquatic toxicity of some metals and, total petroleum hydrocarbons have been shown to be present at significant concentrations in other urban storm water studies. The reduced analysis list may be used for subsequent sampling events, based on results from the first three events.

6.2.2 Reduced Analysis Suite

The reduced analysis suite should be finalized after the results from several full analysis storms are available. Due to the anticipated turn-around-time for laboratory analysis, an

VOL 12
1 6475

R0049780

additional storm event may be sampled before all of the data have been obtained from the previous storm. An anticipated reduced suite that is based on the results of NURP and storm water monitoring in other municipalities has been developed for interim storm water analysis (Table 6-1).

7.0 QUALITY ASSURANCE AND CONTROL PLAN

This section presents the Quality Assurance and Quality Control Plan for the monitoring program.

7.1 BACKGROUND

The measurement of chemical constituents at the trace level is often difficult due to inherent properties of environmental samples, field sampling techniques, and analysis techniques. In order to assess and maximize data quality, a strict Quality Assurance and Quality Control (QA/QC) Plan should be implemented as an integral part of the monitoring program.

The objective of a QA/QC Plan is to provide a mechanism for on-going control and evaluation of the sampling and analysis procedures throughout the course of the project, and to quantify data precision and accuracy for use in future data interpretation processes.

A strict system of quality assurance and quality control should be followed in all phases of the monitoring program, including sampling, laboratory analysis, and data reporting/validation. This plan includes elements to address both sampling and analysis concerns, including sample contamination, variability, and analytical accuracy and precision.

7.2 STANDARD OPERATING PROCEDURES

A field manual of Standard Operating Procedures (SOPs) should be prepared for crews. This section contains information that should be incorporated into the SOPs.

7.2.1 General Field Procedures

Field crews would be responsible for setting up the stations, collecting grab samples, ensuring that composite sampling is occurring properly, replacing bottles, recording information from the samplers, and documenting activities taking place, transferring and labeling bottles properly. The following Standard Operating Procedures should be followed by field crews to ensure acquisition of reliable and accurate data.

7.2.2 Pre-Sampling Mobilization

Station Assignments

Field personnel should be divided into a number of two-person crews (Field Teams) depending on the duration of the sampling event, and local safety rules. One member of each Field Team would be designated as the Team Leader. Multiple Field Teams would be used to ensure the timely collection of grab samples during the beginning of a sampling event, especially in short storms, which require very rapid collection of grab samples. The Field Manager should assign each Field Team to a set of monitoring stations, based on the geographical location of the monitoring stations. A single Field Team should assist during the later stages of a sampling event.

Sample Bottle Check

Pre-Storm Bottle Delivery - The Field Manager would make arrangements for clean bottles, ice chests, and blue-ice packs with laboratory personnel for all deliveries and pickups.

Bottle Inventory - Each Field Team would perform a bottle inventory check before leaving for the field. Individual inventories would depend on the number of sampling stations a Field Team has been assigned. Tables 7-1 and 7-2 contains the number, size, and types of bottles required for a single station.

Equipment Check

Each Team Leader should perform an equipment check-out on all field equipment. The check should confirm that all equipment is available and in proper working order. Check lists for vehicles, water quality, safety, personnel, and miscellaneous equipment would be provided.

Water Quality Sampler Preparation

All automatic water quality samplers should be inspected and made operational before each sampling event. This process would consist of the following procedures:

- Inspection of the sampler, hoses, and electrical connections
- Checking of the sampler program
- Installation of charged batteries (if applicable)
- Inspection of pump tube and replacement as needed
- Loading of cleaned sample bottles
- Icing of cleaned sample bottles (if temperatures are above 40°F)
- Setting of sampler to "run" mode

7.2.3 Sample Collection

Sampler Access Procedures

Sampler Access (Manhole Sites) - Water quality samplers at manhole sites could besuspended below the manhole covers using three suspension cables and clips, or located at the surface in a structure, as indicated previously. Removal of the manhole cover would be preceded by setting up the traffic control system and checking the manhole with a four-gas meter (used to test for indications of oxygen, methane, carbon monoxide, and hydrogen sulfide). If the meter indicates a problem, the manhole cover would not be opened, and the station would not be sampled until the meter indicates there is no problem.

Sampler Access (Stream Stations) - Stream stations would have samplers contained in locked enclosures. Access would be gained by unlocking a padlock and lifting the top of the enclosure. The lid would be supported by a brace located inside the enclosure. The

1

6481

sampler should not need to be removed from the enclosure for any of the sampling activities.

Grab Sampling Procedures

Type of samples to be collected at each station - Grab samples would be collected for six analyses. Each analysis has specific volume and bottle material requirements which must be met. In addition, some constituents require preservatives or other special attention. Table 7-2 summarizes specific grab sampling requirements. Note that grab sample QA/QC would require the collection of additional volumes for each of the parameters at a location designated by the Field Manager. The sample bottles for the volatile organic compounds and acrolein and acrylonitrile must be completely filled with no trapped air.

Getting sample into bottles - At stations deeper than 10 feet, grab samples should be obtained by pumping samples with the water quality sampler. The flow composite program would be interrupted, and the sample would be pumped using the sampler's manual mode. In order to avoid interfering with the normal flow compositing process, Field Teams would need to consult with the Sampling Event Coordinator before interrupting and restarting any sampler program. At stations less than 10 feet deep, manual sampling equipment would be utilized.

Field QA/QC Procedures

Water Sampling QA/QC - Several tests would be conducted to help identify potential sources of introduced error in the water sampling process. These tests include: travel, grab sample, and equipment blanks; grab and composite duplicates; and matrix spike and matrix spike duplicates. Potential laboratory and/or field contamination would be assessed through analysis of blind equipment blanks and sample duplicates at a frequency of one duplicate and one equipment blank per sampling event. The degree to which collected samples reflect actual field samples would be assessed through the analysis of duplicate field samples at a frequency of one field duplicate per sampling event. The Field Manager would assign QA/QC responsibilities during sampling mobilization. The specific field procedures for conducting these tests are presented below.

Travel Blanks - The travel blanks should be supplied by the contract laboratory. Travel blanks would be placed in one of the fields outgoing ice chests and transported through the entire sampling event. These blanks would then be returned to the lab for analysis. Travel blanks would not be opened by any person(s) other than laboratory personnel.

Grab Sample Blanks - Grab sample blanks would be obtained by completing the normal grab sampling process, but instead of pumping sample water, clean deionized water should be used. One set of blanks will be collected for each sampling event.

Equipment Blanks - Equipment blanks would be obtained by letting the sampler fill a complete set of bottles with clean deionized water. One set of blanks would be collected from a single station for each sampling event. Equipment blanks should be collected at the end of a sampling event to minimize program interruptions.

Flow Composite Matrix Spike and Matrix Spike Duplicates - One automatic water quality sampler should be set to collect twice the normal sample volume per sampling event in order to provide for the matrix spike and matrix spike duplicate analysis. Water quality samplers would be instructed to take twice the normal sample volume by doubling the number of triggers generated by the flow monitor. The process would be controlled by the

Sampling Event Coordinator. This would require collection of two sets of sample bottles and compositing in the laboratory.

Sample Labeling and Chain of Custody Procedures

Team Leaders would bear responsibility for the care and proper transfer of samples. Care of the samples would be the responsibility of the Team Leaders until official transfer (using proper chain-of-custody records) of the samples to the assigned Sample Custodian. As part of this responsibility, the Team Leader must be sure samples are labeled correctly and meet critical holding times. Samples with short holding times must be transferred in a timely manner.

Sample Labeling - Sample labels must be filled out completely. At a minimum, the following information should be entered on every label:

1. Date and time (24-hour clock). Storm composites should include the time when sampling was initiated.
2. Site code (station identification)
3. Type of analysis required
4. Total number of containers for each analysis and the number of each contained (e.g., 1 of 3, 2 of 3, and 3 of 3)
5. Signature or initials of Team Leader

Chain-of-Custody - The following organizational scheme has been developed to minimize confusion during the sample chain-of-custody process:

1. Each Team Leader should check bottle labeling, assemble all samples in an orderly manner, and fill out chain-of-custody forms.
2. Each Team Leader should surrender samples to the Sample Custodian (designated by the Sampling Event Coordinator) using chain-of-custody forms.
3. The Sample Custodian should then transfer the samples to laboratory personnel. The Sample Custodian would be fully responsible for the care of the sample and meeting critical holding time limitations until the samples are officially transferred to the contract laboratory.

7.2.4 Post-Sampling Procedures

When the Sampling Event Coordinator makes the final determination that the sampling is complete, crew(s) will:

1. Remove and label the remaining sample bottles.
2. Record the number and timing of samples taken by the sampler. This will be accomplished by halting the Water Quality Sampler Program and reviewing the sampler history log.
3. Turn off the samplers.

VOL 12

1

6483

4. Remove the batteries.

After sampling is complete and the sampling event is officially over (as determined by the Sampling Event Coordinator), field crews would unload equipment. Crews should check in with the Sampling Event Coordinator to make sure all staff are safely accounted for.

7.3 LABORATORY PROCEDURE QA/QC

A list of laboratory analysis methods are described in Section 7.0. A certified contract laboratory would be contracted to perform all chemical analyses (unless a certified public agency laboratory is utilized). The suite of chemical analysis for all water samples is shown in Table 6-1. In addition to performing the analysis, the laboratory must make every effort to meet target detection limits for each analytical method. Other QA/QC objectives that the laboratories must meet include holding times and sample preservation techniques, as shown in Table 7-3.

7.3.1 Precision

Laboratory precision should be assessed through the analysis of laboratory duplicates and matrix spike duplicates at the frequency of 10 percent of the total samples for the lab duplicates and five percent for the matrix spike duplicates. Combined field and laboratory precision should be evaluated through the analysis of field duplicate samples at the frequency of one duplicate sample per sampling event, as described above. Specific field duplicate precision objectives are presented in Table 7-3. Due to the inherent variation in environmental samples, these objectives may be viewed as goals and not requirements.

7.3.2 Accuracy

Laboratory accuracy should be assessed through the analysis of "blind" standard reference samples and through the analysis of laboratory-prepared matrix spike samples. A goal of five percent of the samples would be analyzed as matrix spikes by spiking the sample with standard and measuring the analytical recovery. Blind reference samples would be analyzed once every quarter in which samples are analyzed.

7.3.3 Laboratory Blank

Sample contamination resulting from laboratory analysis procedures or sample storage methods should be assessed through the analysis of laboratory blanks and equipment blanks. Laboratory blanks (reagent and/or method) should be reported for each day samples are analyzed.

7.3.4 Completeness

All reported analyses should be evaluated against the requested analyses to evaluate the completeness of the analytical characterization of the water samples. Any missing data will be accounted for by the laboratory or field programs with an overall goal of 95 percent completeness.

7.4 LABORATORY COMPOSITING

Compositing of the samples would be performed at contract laboratory. Unless the trigger volumes have been changed with the second set, the mixing is done directly. A 19 liter glass bottle should be cleaned using non-phosphate liquid detergent and triple-rinsed with deionized water. The bottle should be placed on a stir plate with a magnetic stir bar. The minimum volume in the bottles should be determined, and this quantity should be taken from each sample bottle and added to the 19 liter glass bottle. The final mixed sample should be distributed into the appropriate glass, amber, or plastic bottles prior to the analytical testing. If the volume for triggering a particular sample was changed during the course of a sampling event, the Sample Custodian would work with the contract laboratory to composite properly the sample.

7.5 DATA REDUCTION, VALIDATION, AND REPORTING

Overall data quality would be assessed based on sampling and analytical conditions, adherence to internal QC procedures, and results of accuracy and precision checks.

Actual detection limits would be reported in the final report summary along with the results of the external QA samples, field replicates, laboratory duplicates, matrix spike, matrix spike duplicates, and equipment and reagent blanks.

7.6 CORRECTIVE ACTION

In the event the data quality objectives are not met, the contract laboratory should notify the Quality Assurance Task Leader who would evaluate the severity of the problem and recommend a solution to the monitoring task leader.

7.7 QA/QC REPORT

Summary results of the QA/QC program would be provided as brief memorandums detailing any analysis or sampling problems and the potential effects on the analysis results for each event.

8.0
DATA REPORTING

Data collected as part of this monitoring program should be stored in electronic format to enable easy retrieval, data interpretation, and graphing.

Data collected would fall under the following categories:

- Rainfall
- Runoff
- Field Chemical Data
- Laboratory Chemical Data
- Quality Assurance/Quality Control Data

Hydrological data (rainfall and runoff) collected at the monitoring stations should be transferred to a centralized file. These data should be checked for errors and arranged to show rainfall and runoff volumes and hydrographs during each sampled storm event. Following each event, a storm report should be prepared which summarizes the results of sampling, except laboratory results.

Chemical data generated by the contract laboratory would be input into a database by the laboratory. In addition to the laboratory electronic data, raw laboratory data reports would also be received from the laboratory. Once the data are received by the Project Manager, errors in transcription and reporting and compliance to QA/QC contract objectives would be checked and resolved. The final chemical data would be reported in a manner that is easy to read and understand. After laboratory results are received from the laboratory, a brief memorandum would be prepared which summarizes the chemistry results for each event.

At the end of the program, a monitoring data report would be prepared which summarizes results of the program. The report would be based upon the storm reports and a laboratory results memorandum.

9.0 MONITORING PLAN MANAGEMENT, ADMINISTRATION AND COORDINATION

An example organizational chart for the Monitoring Program is provided in Figure 9-1. Implementation and overall coordination of the Monitoring Program is the responsibility of the Program Manager. The Program Manager would be assisted by the Sampling Event Coordinator and the Quality Assurance Task Leader.

The Sampling Event Coordinator would be responsible for evaluating the weather forecasts as provided by the storm forecasting service and, in consultation with the Program Manager, deciding on which storms warrant mobilization for the sampling efforts. The Sampling Event Coordinator would also be responsible for the Field Manager.

The Field Manager would be in charge of the field sampling program, which includes; 1) assignment and supervision of Field Teams and Team Leaders, 2) field equipment maintenance and operation, 3) proper sampling collection and handling, and 4) field QA/QC and laboratory analysis.

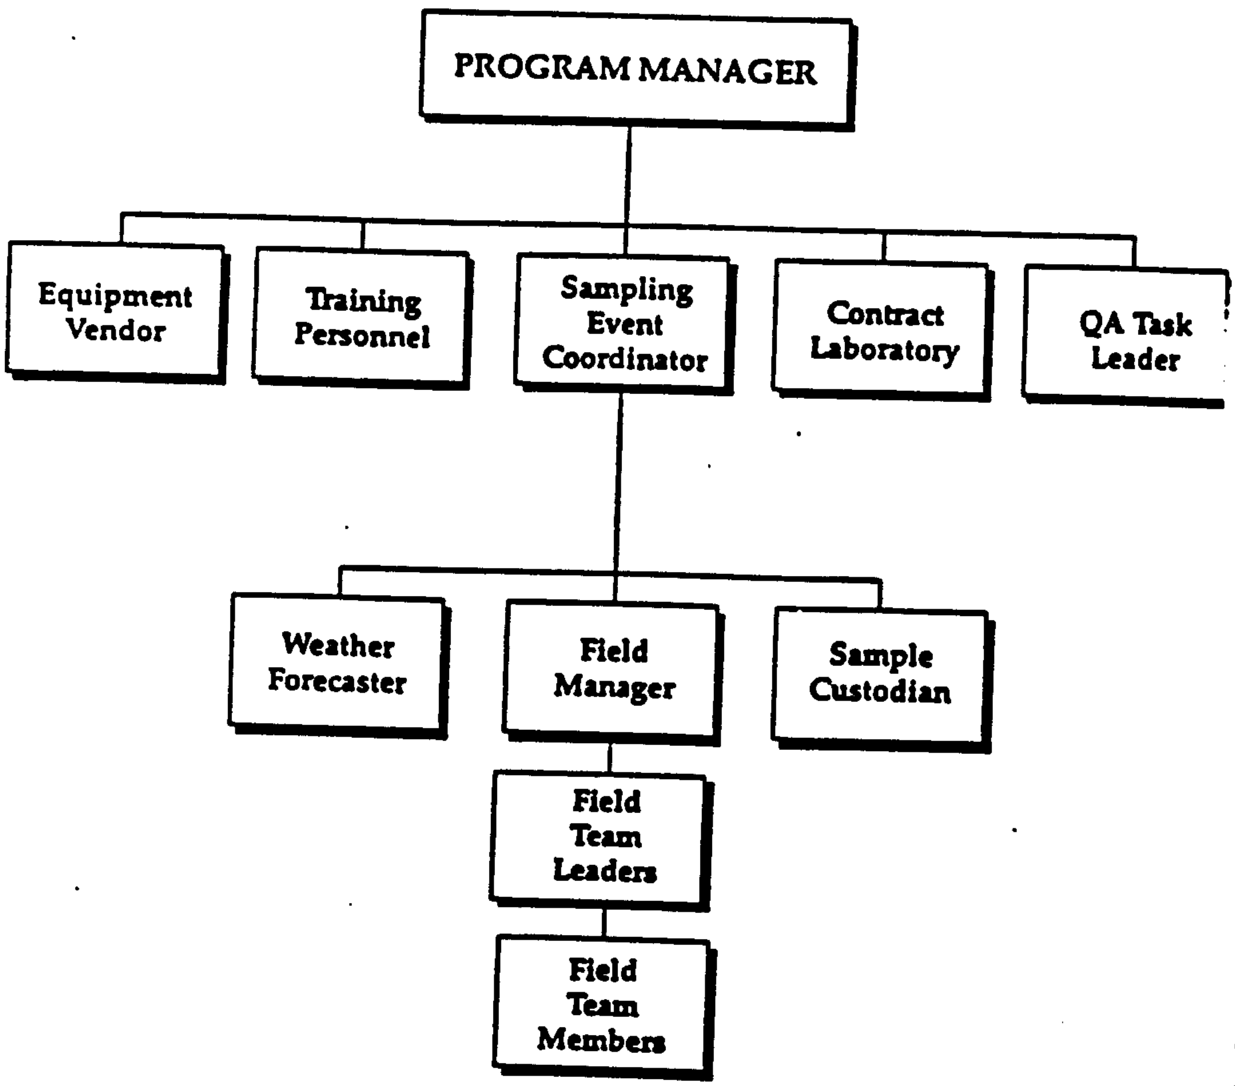
The Quality Assurance Task Leader would be responsible for on-going review, auditing, and evaluation of the overall QA program related to sampling and laboratory procedures.

The Project Manager would also be responsible for the contract laboratory. Prior to selection, the contract laboratory should be audited to 1) evaluate the laboratory's ability to perform the work, 2) ensure proper QA/QC programs are in place, and 3) initiate education of specific personnel at the laboratory on protocols involved in the analysis of water samples.

VOL 12

16489

FIGURE 9-1 MONITORING PROGRAM ORGANIZATION AND COORDINATION



VOL 12

1
6490

10.0
MONITORING PLAN SCHEDULE

The schedule for implementation of a plan like this should be developed based upon the implementing agencies time and budgetary constraints and desired timing of data needs for water quality management planning.

Sufficient time must be allowed for:

1. Final station selection, 1-2 months
2. Equipment selection, ordering, and receiving, 1-2 months
3. Equipment installation, 1 month
4. Equipment testing, weather dependent

Personnel to be involved with the field operations of the Monitoring Program would be trained in the water sampling and flow monitoring protocols set forth in this plan. The training sessions would include instruction in the set-up and operation of monitoring equipment and software used to operate the sampling equipment. Operating procedures and sampling criteria would be developed for field personnel as part of the training task. Descriptions of the training sessions are presented in this section.

11.1 MONITORING EQUIPMENT OPERATION AND MAINTENANCE

Two training sessions would be conducted on monitoring equipment operation and maintenance. The first training session would be a "dry" session to teach personnel the standard procedures necessary for successful monitoring. The second session would be a "wet" session conducted in the field during a "practice" sampling event. Field crews would be trained as they assist training personnel in all of the field procedures during an actual sampling event.

During the two training sessions, the training personnel would provide standard operating procedure summaries (SOPs) and familiarize field crews in the operation and maintenance of sampling equipment and software. The equipment for each station would consist of an automatic type composite sampler, a compatible data logger and modem, a control module, depth monitoring equipment, and possibly velocity-flow monitoring equipment.

11.2 SAMPLE COLLECTION TRAINING

Field personnel should be trained for in-field water quality sampling and measurements and data recording procedures. This training would include procedures for grab sampling to obtain certain field measurements such as temperature, pH, and dissolved oxygen content. Also, field personnel would learn techniques for field sampling consisting of composite sampler operation and grab sampling for constituents which cannot be reliably measured in composite samples. Personnel would learn the procedures for getting samples from the monitoring site to the laboratory. This would include proper sample handling, storage, and chain-of-custody procedures for both grab samples and samples taken with the automatic composite sampling equipment.

11.3 HEALTH AND SAFETY

A health and safety manual should be developed for the sampling program. All personnel should review the manual and should receive a health and safety briefing during training.

12.0 METHODS FOR ESTIMATING POLLUTANT LOADS

As noted in the introductory section, one objective of the monitoring program is to assess pollutant mass emissions to Santa Monica Bay. This section presents methods for estimating pollutant mass loads using the data to be collected in the monitoring program.

12.1 OVERVIEW OF STORM WATER POLLUTANT LOADING MODELS

The median land use concentrations by land use computed by Nationwide Urban Runoff Program (NURP) have been used in subsequent studies to estimate pollutant load from urban areas. This is commonly used for preliminary planning studies where little or no local sampling was conducted. Eugene, Oregon, for example, used NURP's mean estimate total pollutant load (WCC, 1991) as did the Piper's Creek Nonpoint Source Action Plan Study in Seattle, Washington. For both studies, runoff volumes were computed from the long-term average rainfall times the area times the runoff coefficient of each land use. Runoff coefficients were computed based on the percent impervious area typical of each land use, using a relationship developed by the Federal Highway Administration (FHWA 1990; Driscoll, et al., 1990). The relationship is expressed as follows:

$$R_V = 0.007*IMP+0.10$$

Where:

R_V = runoff coefficient
IMP = impervious fraction of the drainage area (as a percentage)

This method of computing pollutant load is the simplest of all those reviewed. It is probably sufficient for a preliminary planning study and has the advantage of minimal data requirements. However, this method assumes that the water quality of the area being modeled can be sufficiently represented by the NURP data.

Several other studies have used land-use-specific EMCs, using either NURP data or locally collected data, to compute pollutant load from a region. Woodward-Clyde Consultants estimated pollutant loads from Santa Clara Valley, California, using data from local sampling stations (WCC, 1991). Sampling stations were selected to represent uniform land use. A representative concentration for each respective land use category was computed by averaging the site mean concentrations from stations with similar land use. Runoff volumes were computed using the runoff block of the EPA's Storm Water Management Model (SWMM). Volumes of runoff from each land use type were multiplied by the representative concentration to compute loads. Mixed land use stations were used to verify the load estimates. A bias correction factor was calculated as the ratio of the predicted loads and the measured loads for the mixed land use stations. This factor was used to correct the estimate of loads from each land use. The main difference between this method and the NURP method is that SWMM is used to estimate runoff and the water quality data was collected exclusively in the study area. The advantage of this method is that by using the SWMM model the benefits of large control structures or other storm water retention best management practices can be investigated. However, a disadvantage of this method is that large amounts of data are required by SWMM for simulation. Another

16493

disadvantage is the error associated with using data from a small set of homogeneous land use stations to represent all the land use areas in the study area.

The Aquatic Habitat Institute (AHI) used data from WCC's Santa Clara Valley study and several other studies to compute pollutant loads to the entire San Francisco Bay (Gunther, 1991). AHI used runoff coefficients to compute runoff volume, in a manner similar to the Eugene study. Constituent concentrations were computed similarly to the Santa Clara study, but with a data set which included stations throughout the Bay area. This method is similar to the NURP method but uses water quality data from a specific region instead of the whole country.

Silverman, et al. (1988) developed an approach to concentration and load computation using regression analysis. They computed the load of oil and grease to San Francisco Bay using data collected at 15 stations within the region. They used runoff coefficients to compute flow volumes, which were computed from the measured flow volume at five of the sampling stations. Land uses extracted from census tract data were used to determine the percent of land tributary to each station identified as residential, commercial/industrial or undeveloped. A total of 34 samples were taken at these stations. Using land use as the independent variables and the oil and grease concentration as the dependent variable, a regression model relating land use to oil and grease loading was derived using 34 equations and three variables or unknowns. Using the coefficients from the regression model, the pollutant concentrations in storm water were calculated from all watersheds tributary to San Francisco Bay from the known areas of each land use.

Woodward-Clyde Consultants developed a regression model for computing pollutant loads in Alameda County, California, using the proportion of runoff from each land use tributary to sampling stations (WCC, 1991). This method used the assumption that the measured concentration at a sampling station is the flow weighted average of the concentration in runoff from each tributary land use. Samples were taken at 15 stations during a total of 11 storms. The land uses were divided into four categories (open, residential, commercial, and industrial). Runoff volumes, by land use, were computed using the runoff block of SWMM. Using runoff volume by land use as the independent variables and concentration at each station as the dependent variables, a multiple linear regression was performed to determine the best estimate of the concentration by land use. These concentrations by land use were then multiplied by the runoff volume by land use for the entire study area to determine the total load. The advantage of using this method is that it allows data from nonhomogeneous land use stations to be included when computing the water quality associated with each land use.

The USGS published a report (Driver and Tasker, 1990) which describes methods developed for estimating storm runoff loads and concentrations. These methods were developed by applying step-wise linear regression to the data collected from the National Urban Runoff Program (EPA, 1983). The nation was divided into three general climatic regions. For each region, a regression model was developed relating storm-runoff volumes and storm-runoff loads for 11 constituents to physical, land-use, and climatic characteristics.

The USGS selected a group of response variables according to the frequency of the variable in the database and according to the importance of the variable in urban planning. Specific response variables for each regression model were then selected using the step-wise regression procedure. This procedure sequentially selects response variables for inclusion to the model by testing the contribution the variable makes to improving the model. The variables most often selected were:

Total contributing drainage area

VOL 12 1 6494

Total storm rainfall
Percent impervious area
Percent industrial land use

The variables included in each regression model varied by region and constituent. However, there is some question of the validity of using rainfall as a variable in the regression analysis since it is directly related to runoff quantity.

These regression models provide a convenient, planning-level tool for estimating storm runoff loads. Mean annual loads can be estimated by multiplying the estimated storm load by the average number of storms per year. The chief advantage of the USGS's methodology is that it can be performed using data commonly available to planners, before any sampling is conducted. The primary disadvantage is that it does not provide any means of identifying any unusual conditions within the region of interest.

The methods previously used to model pollutant loads from storm water runoff represent a range of approaches, from fairly simple to rather complex. All of the methods, with the exception of the USGS regression analysis provide a methodology for computing the runoff and a methodology for estimating water quality; each exclusive of the other. As with any modeling effort, the method chosen for a particular study depends on the resources available, the availability of data, and the purpose of the study.

12.2 RECOMMENDATIONS

The NURP method was used as an initial estimate of storm water pollutant loads to Santa Monica Bay (Stenstrom and Strecker, 1993). However, the NURP 90th percentile values of the EMCs were used in place of the median (50th percentile) values of the EMCs because existing water quality data indicated that pollutant concentrations in the watershed are higher than the NURP median values.

Water quality data collected during the monitoring program should be used to calibrate and validate the NURP model for Santa Monica Bay. Regression techniques used in other studies could be applied to the data to determine the best estimate of pollutant concentrations for each land use type. The results of the model will provide a quick estimate of mass emissions to the Bay by subbasins and land use for use in water quality management and planning.

More detailed assessment of pollutant loadings could be developed using more complex physically-based computer models such as SWMM. Physical models have several advantages over the lump parameter models such as those using the NURP data. Storm water variations that occur between and during storms and in wet and dry seasons could be captured by physical models. Also, the effectiveness of storm water management controls could be better evaluated with physical models. The drawbacks to physical models are that more data are required and greater analytical resources including modeling expertise, computing power, and time are needed.

The data to be collected in the monitoring program will provide the data required for physical modeling. Rainfall and runoff quantities will be measured throughout the two-year monitoring period. Water quality data collected during both wet weather and dry weather will also be available. The extent to which these data can be used in a physical model will depend on the amount of data collected and the quality of the data. In addition to the data, the success of the modeling effort will depend on the expertise of the modeler and the resources allocated to the task.

PREFACE AND ACKNOWLEDGEMENTS

This report represents Volume IV from a series of four volumes of reports which form the basis of a pollution assessment and monitoring plan for Santa Monica Bay. Volume I describes land use statistics, catchment areas, existing water quality monitoring data, rainfall data, NPDES permit information for existing permits to storm drains, and contaminant mass emission estimates, based upon land use modeling. Volume II reviews sampling techniques, including sampling equipment, and other aspects associated with sampling such as a quality assurance plan. Volume III presents the proposed monitoring plan. Volume IV addresses best management practices as they apply to the Santa Monica Bay area. The first draft of Volume IV was issued on November 9, 1992.

The contract was performed by UCLA and Woodward-Clyde Consultants (WCC). Professor Michael K. Stenstrom of the Civil and Environmental Engineering Department, UCLA and Eric Strecker from WCC's Portland office were the project managers. There were several key individuals from both UCLA and WCC who assisted with the project; they include Sim-Lin Lau and Kenneth Wong (UCLA) and Lou Armstrong, Gail Boyd, Carol Forrest, and Joan Kersnar (WCC).

The contractors are grateful for the assistance of many individuals. The Santa Monica Bay Project and LA Regional Water Quality Control Board staffs were most helpful. We extend our special thanks to Dr. Guang-yu Wang, Ms. Catherine Tyrrell, Dr. Rainer Hoeinke and Mr. Xavier Swamikannu. Several public agencies were very helpful in providing data and information to us. The Los Angeles County Department of Public Works and the Southern California Association of Governments (SCAG) provided catchment area and land use data, respectively. We are also indebted to the members of the Technical Advisory Committee of the Santa Monica Bay Project and others who reviewed and commented on our draft reports.

ABSTRACT

This report presents a procedure for developing a suite of best management practices (BMPs) to control or reduce pollutants from nonpoint sourcs to Santa Monica Bay. Provisions are made for stormwater as well as dry weather flow. The procedure provide a methodology for operators of municipal storm water drainage system in Santa Monica Bay to select appropriate BMPs based upon available knowledge and resources. The procedure includes a "menu" concept where three menus of BMPs are provided. The first menu (Menu A) represents very important BMPs which might be considered mandatory. Menus B and C list BMPs that are complementry to Menu A but are more difficult to implement or produce less certain benefits. These BMPs are optinal and a technique is presented for screening the various BMPs in order to identify those most applicable to the Santa Monica Bay watershed.

During the course of this project a variety of BMPs were discussed or researched at various times by contract personnel or by others participating or reviewing the project. In order to perserve this information, the various BMPs are listed in an Appendix. Most of these BMPs are similar to one or more items covered in a menu but are more specific to the Santa Monica Bay watershed. The Appendix provides additional information which should be helpful in deciding to implement or implementing the BMP.

1.0
INTRODUCTION

The purpose of this report is to provide operators of municipal storm water systems with the information needed to evaluate a series of candidate Best Management Practices (BMPs), formally select BMPs that would be most effective in dealing with local conditions, and begin the process of developing effective implementation plans. It is difficult to develop an entirely successful plan, and more than one iteration may be required. The BMPs presented here as candidates have been "pre-screened" and "pre-qualified" by the consulting team--i.e., they are known to be worthy of consideration for addressing the problems and conditions that exist in the watersheds that contribute storm water runoff to Santa Monica Bay. In this report, we have recommended a set of BMPs that we feel should be implemented, along with those that we feel should be carefully considered for inclusion in a Santa Monica Bay Watershed Management Plan.

The formal selection process described herein is recommended because local opportunities, constraints, priorities, and other factors need to be taken into account by local decision makers before specific BMPs are selected and implemented. Furthermore, use of a formal, well-documented evaluation and selection process is prudent in circumstances where program decisions and resource commitments may come under scrutiny or challenge.

This report covers information that was presented in abbreviated form during a workshop that was held in Santa Monica on June 14, 1992. The workshop and this report were developed and presented to the municipal storm water co-permittees by personnel from Woodward-Clyde Consultants (WCC) and University of California at Los Angeles (UCLA) on behalf of the Santa Monica Bay Restoration Project.

1.1 BACKGROUND

After many years of conducting technical studies to assess the importance of urban storm water discharges as a source of water pollution, the US. Environmental Protection Agency (EPA) issued a set of draft regulations in December 1988. These draft regulations were intended to initiate and guide municipal programs for identifying and controlling pollutants that are carried through and discharged from municipal separate storm sewer systems. The regulations were issued in draft form to provide interested parties (e.g., municipal storm water dischargers, commercial and industrial interests, state and regional water quality control agencies, public interest groups, and the general public) the opportunity to review the requirements and provide comments that would guide the final rule-making process. The final rule, which is a part of EPA's National Pollutant Discharge Elimination System (NPDES), was issued by EPA in November 1990 and requires most sizable cities (based on population) in urbanized areas nationwide (as well as some industries) to conduct technical studies, identify and assess sources of storm-water-borne pollutants, and implement practical pollution controls in the form of BMPs.

During the period when EPA's draft regulations were being subjected to public review and comment (i.e., December 1988 to November 1990), several California cities, counties, flood control districts, the US EPA, the State and regional water quality control boards, and other public entities joined together in various regional consortia and developed strategies that would allow them more flexibility than the emerging federal regulations were thought to provide. These so-called "early permitting" strategies were worked out by eight groups of co-applicants in Northern, Central, and Southern California and were approved by EPA Region 9 and the respective Regional Water Quality Control Boards (RWQCBs). The resultant early permits were issued under then-existing NPDES permit structures (i.e., before the storm-water-specific regulations came into effect in November 1990). In most respects, the early permits issued for Southern California municipal storm water dischargers have similar requirements to the programs being pursued elsewhere in the United States,, but there are two important differences:

- For one, the co-permittees were given a longer time period to conduct most of the studies and planning efforts. Most sizable US. cities are required to complete their studies and planning before applying for permits in November 1992 or May 1993 (depending primarily on the size of the respective municipal separate storm sewer systems), whereas the Southern California early co-permittees are allowed to conduct the studies and planning efforts during the 5-year term of their NPDES permits.

- Second, the Southern California co-permittees were required to select and implement certain "early action best management practices" from the outset and then conduct studies and more definitive planning efforts to select and implement additional BMPs in accordance with schedules worked out with their respective RWQCBs.

During the past few years, representatives of many cities, county agencies, environmental organizations, other public interest groups, and many interested citizens and regulatory agency personnel have worked cooperatively and proactively to protect and restore water quality and beneficial uses in Santa Monica Bay. The efforts and accomplishments of the Santa Monica Bay Restoration Project, Heal the Bay, the LA-RWQCB, and others that have worked to address challenging water quality management issues, have been considerable. Their actions should not be seen as being driven by the NPDES storm water permitting process, because they have had other specific water quality improvement goals as their primary motivation. Nonetheless, there are numerous ways in which the programs have come together. This report and the June 15, 1992 workshop that preceded it are examples of how the Restoration Project and the so-called "early co-permittees" have worked together to plan appropriate BMPs.

1.2 REPORT ORGANIZATION

This document is organized into four sections. Section 1.0 (this section) provides the background needed to understand why this report was written and provides an overview of the regulatory framework. Section 2.0 provides insight on the ideas and concepts usually associated with BMPs and acts as a back drop for the rest of the report. Section 3.0 discusses the various BMPs, recommends BMPs that should be implemented now, and provides a mechanism for selecting future BMPs. Section 4.0 discusses what should be done in the future.

VOL 12 1,6505

2.0 PRINCIPLES FOR DEVELOPING STORM WATER MANAGEMENT PROGRAMS

As described in Section 1.1, over 80 cities and the County of Los Angeles are parties to an "early" NPDES permit that is intended to reduce the amounts of pollutants that enter storm water conveyance systems and receiving waters. The co-permittees that manage storm waters that discharge into Santa Monica Bay have identified existing Best Management Practices (BMPs) and instituted easily implementable BMPs. For the most part, these were practices that were either already in place (i.e., before the permit requirements came into effect) or are some variations of the pre-existing public works operations and maintenance programs (e.g., storm inlet inspection and cleaning, street cleaning, litter control). In 1991, the co-permittees developed and submitted reports (to the Los Angeles-Regional Water Quality Control Board), documented their existing programs, looked for ways to modify, refine, or intensify their practices to obtain greater storm water quality benefits, and planned early action storm water BMPs. The purpose of this early action phase was to assure that significant controls would be implemented as quickly as possible, but the co-permittees were aware that additional controls could also be needed. This section describes some principles that should be considered as co-permittees continue their efforts to evaluate local conditions and select among candidate supplementary controls.

Section 3.0 presents a structured process that is recommended for co-permittees' use for evaluating and selecting among candidate BMPs. Specifically, section 3.3 presents a sizable, pre-screened list of BMPs to consider as candidates and describes several factors that co-permittees should take into account in their selection process. The pre-screening was performed by Woodward Clyde Consultants with the assistance of the Santa Monica Bay Project staff and Technical Advisory Committee members. These concepts of pre-screening, evaluation factors, and the use of a formal structural process warrant some introduction, and that are the subject of Sections 2.2, 2.3, and 2.4.

2.1 PRE-SCREENING

The importance of urban storm water as a cause of water pollution has become apparent in some parts of the country earlier than others. This is largely because of the broad variety of hydrologic conditions and pronounced differences in receiving water conditions from area to area within the US. As a result, water quality programs in some areas have been working with storm water BMPs for many years. Fortunately, many of these BMPs have been studied to assess their performance, practicality, and costs; and this information is available for consideration by local decision-makers.

The BMPs presented herein have been selected (by Woodward-Clyde and UCLA) from a long list of storm water controls that have been used (or considered for use) in other urban locations nationwide. The pre-screening that led to the list of BMPs presented for consideration in the Santa Monica Bay area was performed in two steps, as follows:

- The first step involved eliminating BMPs that would have little or no application, given local climatic and land-use conditions. This step eliminated BMPs related to de-icing, snow removal, and control of agricultural practices (e.g., large-scale use of pesticides, herbicides, fungicides, erosion controls, poultry and livestock management, and agricultural waste management). BMPs targeted toward these types of practices are common in significant parts of many urban areas, but are not seen as being relevant in the Santa Monica Bay area.

- The second step involved establishing a philosophical bias in favor of pollution prevention (i.e., source control) and in favor of building upon a manageable number of existing programs. The concept of "pollution prevention" or "source control" implies that one should emphasize BMPs that keep pollutants out of storm water, rather than trying to remove pollutants that have already entered storm water or the receiving waters. Some source controls are structural (e.g., providing roofs to keep precipitation off of exposed storage piles, providing berms to keep site runoff away from storage piles), but most source controls are non-structural. They typically include the use of educational programs aimed toward changing people's awareness and behavior (especially regarding the proper use and disposal of household and automotive products), the use of local ordinances and inspection programs focused on identifying and converting illicit connections and illegal dumping, and the use of public works programs focused on improved "housekeeping" of public infrastructure (e.g., street sweeping, litter control, storm inlet and storm drain cleaning, channel maintenance, fleet maintenance).

2.2 EVALUATION FACTORS

The BMP evaluation and selection process described in Section 3.0 involves considering several "factors" which are intended to provide a means for incorporating the decision-makers' preferences, priorities and constraints. It is recognized that the co-permittees in the Santa Monica Bay area are all public agencies that must function within a context of: limited resources; multiple (often conflicting) demands; pre-existing obligations, commitments, and constraints; and political tensions. The requirement for intensified storm water control at the municipal level is only one of many requirements each co-permittee must deal with. Therefore, each co-permittee agency needs to carefully consider a variety of factors that reflect local social, political, environmental, and fiscal realities--because these combine to define what is "practicable" in their real-world setting. Section 3.3 describes 13 factors which are intended to help decision makers consider the following: environmental implications, effectiveness regarding pollutants of concern, implementing agency/department acceptability, regulatory requirements, public acceptance, risk/liability, fairness, reliability, sustainability, universality, implementation cost, flexibility for phased implementation, and ability to demonstrate compliance.

2.3 FORMAL EVALUATION AND SELECTION PROCESS

Section 3.0 presents a formal method for evaluating and selecting appropriate BMPs for several reasons, all of which are related to the concept that the decision makers within any given co-permittee agency may be pressed to explain (or even defend) the basis for their evaluations and selections. The need to explain their decision process may come from any of several sources, including:

- The selected BMPs will have some degree of impact on municipal services that public agencies can provide. Members of the public, interest groups, elected or appointed officials, and/or department heads may challenge (or at least inquire about) the rationale for committing public resources toward specific aspects of storm water quality control.

- Some of the BMPs will require certain parties (e.g., residents, commercial/industrial establishments, institutions, public agencies) to do things they do not want to do (or to stop doing things they want to do). Therefore, some people will not be pleased with the selected BMPs and may challenge the basis for their selection.

- On the other hand, there are those who would like to see additional (or at least more intensive) BMPs and may challenge the basis for limiting the co-permittees' obligations to only the selected BMPs.

It should be clear that the best defense against even an informal challenge would be to avoid as much as possible the allegation of having been arbitrary and capricious by employing the following strategies from the outset:

- involve the right people at the appropriate times in the process of evaluating and selecting BMPs.

- Employ relevant and appropriate information so the decision makers do not have to operate in a vacuum regarding key issues.

- Establish and follow a rational, formal decision process that is well-documented throughout. Section 3.3 describes a process that meets these objectives.

2.4 LAND-USE AND WATER QUALITY CONCERNS

It is important that decision makers have an understanding of the land-use and water quality considerations from which to base the evaluation of the BMPs on. This section presents a brief discussion of land-use considerations with regard to pollutant loadings to the Bay and a discussion of water quality parameters of concern.

2.4.1 Land-use Considerations for Selection and Targeting of BMPs

In development of the loadings model for Santa Monica Bay, the land-use data available from the Southern California Association of Governments was utilized. These land-uses included:

- Single Family Residential,
- Multi-family Residential,
- Commercial,
- Public (schools, government offices),
- Light industrial,
- Other urban (not included above), (parks, undeveloped land), and
- Unknown.

The NURP program developed estimates of typical runoff concentrations in urban areas for commercial, residential and open land uses. Other programs have been developing data for industrial runoff, although industrial runoff would be expected to vary considerably with the type of industry present.

The Santa Monica Bay Storm Drainage Pollutant Model was used to develop initial loading estimates based upon NURP data for runoff concentrations, which was adjusted based local data summarized in the loadings model report (Stenstrom and Strecker, 1993). Localized data for rainfall, land-use type, and percent impervious (estimated based upon land-use) was utilized to develop loading estimates.

Because of the large area of residential land-use in the watershed (33 percent), this land-use was found to be the highest contributor of pollutants to the Bay. Commercial areas constitute 3 percent and light industrial 2 percent of the total Bay watershed, as a comparison. However, because of their usually higher percent impervious areas and higher concentrations, commercial and industrial areas have a much higher unit area loading rate. Therefore, targeting of structural control measures in these areas would result in the highest pollutant removals per unit cost. Watershed-wide source control measures are warranted in existing residential land-uses.

Highway runoff is another likely large source of pollutants to the Bay. Because the data was not available, highways were not individually modeled. The FHWA studies (FHWA, 1990) found that in general, pollutant concentrations for heavy metals were 2 to 4 times higher in highway runoff than general urban runoff. Combined with their higher percent imperviousness, focusing on controlling pollutants from freeways and highways would also be warranted. In addition, automotive repair shops have been targeted by many other programs (Santa Clara, Bellevue) due to their expected higher contribution of pollutants.

New construction is a target that is specifically called out for action in the NPDES regulations. Both in terms of controlling erosion of soils, but also for designing and building best management practices to control pollutants from these areas. For example, in new construction the use of grass swales rather than piped drainage would improve water quality and lead to lower piping costs. Open land comprises a great fraction of certain watersheds, such as in the Malibu and Las Virgines areas. BMPs to mitigate the impacts of construction could be especially important in these areas.

2.4.2 Water Quality Parameters

Key water quality parameters that are of concern to urban nonpoint source runoff have been analyzed in many studies of urban runoff. Some pollutants have been identified as causing problems in receiving waters while other parameters have not routinely been detected or have been detected in concentrations which have not indicated that problems exist. The water quality parameters analyzed in many studies, including the Nationwide Urban Runoff Program (US EPA 1983), Santa Clara and Alameda Runoff Studies and the City of Portland Study include solids, nutrients, heavy metals, hydrocarbons, oil and greases, pesticides, herbicides, volatile organics, and oxygen demand.

The following briefly describes the groups of pollutants which typically have been found to be of concern and warrant attention in the development of plans to reduce pollutant loadings to receiving waters. These pollutants are based on the results of past sampling in the local area (Stenstrom and Strecker, 1993) and on the results of several major runoff water quality studies. These studies were conducted by Woodward-Clyde Consultants (WCC) for the Environmental Protection Agency (US EPA, 1983), Federal Highway Administration (FHWA, 1990), Santa Clara and Alameda Counties, and the Cities of Portland and Eugene.

Total Suspended Solids (TSS) The term "suspended solids" is descriptive of the organic and inorganic particulate matter which is of a size and type that allows the particles to stay suspended in water. The sediment load in a water body is influenced by a number of factors including but not limited to: particle size, stream flow, climate, geology, and vegetation of each drainage system. The conditions under which suspended sediments are considered a pollutant is a matter of definition. In general, suspended solids are considered a pollutant when they significantly exceed natural concentrations and have a detrimental effect on water quality and/or beneficial uses of the water body. Suspended sediments are often used as a indicator for other contaminants which bind easily with fine particulate matter, including heavy metals and phosphorus.

Sediment loads have been considered a problem in most all urban runoff studies, both due to their direct problems (siltation, aquatic life respiration inhibition, etc.) and their transport of other pollutants. On the other hand, sediments from natural areas provide sands for beaches, providing critical habitat. Therefore, in Santa Monica Bay, sediments from urban surfaces and from construction should be targeted, rather than natural unaccelerated erosion from undisturbed areas.

Nutrients. Nutrients are necessary for the growth and support of biota in natural water systems. Excessive quantities can over-stimulate biological growth and create objectionable water quality conditions. Runoff from fertilized areas and discharges of sewage or industrial wastes are frequently sources of significant quantities of nutrients. Other sources include urban storm water runoff and direct atmospheric deposition to water body surfaces. In general, the most important nutrient factors causing an acceleration in algae production are nitrogen compounds and phosphorus.

Nutrients have not been identified as a general problem in Santa Monica Bay. In fact the Bay is considered nutrient poor. However, urban runoff is a significant source of nutrients to receiving waters. Therefore, nutrient controls should be considered to control "localized" problems for identified receiving waters. These could include Malibu Lagoon and Marina del Rey.

Heavy Metals. Heavy metals such as copper, lead, and zinc are naturally released in very small quantities by the weathering of exposed soils and mineral deposits, corroding metal surfaces, decomposing paints, and certain corrosion-control compounds. Vehicles are sources of heavy metals. Lead from leaded fuels is a very important source. Tires can contain significant quantities of zinc. Catalytic converters are also potential sources. Heavy metals tend to have comparatively low solubility and are often mobilized by forming soluble complexes with humic materials or by becoming attached to suspended solids.

These metals are present in the biosphere as trace elements and are micronutrients necessary for plant and animal growth. Heavy metals are of concern because elevated concentration levels of soluble forms in natural water bodies can produce toxic effects in biota. Sources include regulated domestic and industrial point-source discharges, urban storm water runoff, and direct atmospheric deposition.

The most frequently detected pollutants in the NURP study were lead (94 percent), zinc (94 percent), and copper (91 percent). Chromium and arsenic were detected in 58 and 52 percent of the samples, respectively. Of the inorganic pollutants, lead, zinc, and copper exceeded criteria most often. In Portland, cadmium, nickel, and silver have also been identified as heavy metals of concern. However, in looking at treatment based controls the conclusions drawn from the analysis of lead, zinc and copper can be used to indicate the behavior of other heavy metals. For source controls, specific parameters may require individual analysis and planning. For instance, a likely source of silver in storm drains could be discharges from photographic laboratories. The State of the Bay report has indicated that there are elevated heavy metals in the sediments of the Bay, including elevated lead levels in sediments of Marina del Rey. In addition, the data developed and analyzed for this study of Santa Monica Bay (Stenstrom and Strecker, 1993) indicated that observed metals levels during storm events were significantly higher than NURP concentrations for lead and zinc. There was not enough data on other metals to make such comparisons, but they are likely high as well. Heavy metals are considered a potentially significant problem. The proposed monitoring program for storm water drainage in Santa Monica Bay should further identify the significance of heavy metals being discharged to Santa Monica Bay.

Oxygen Demand. Oxygen demand refers to the amount of oxygen that will be consumed by biological or chemical reactions involving organic and inorganic compounds. In general, moderately high dissolved oxygen content is necessary for the maintenance of healthy aquatic ecosystems. The relationship of oxygen-consuming discharges to the amount of dissolved oxygen in a receiving water body, therefore, is fundamental to the maintenance of environmental quality in natural water bodies.

Oxygen demand is measured in terms of Biochemical Oxygen Demand (BOD) and Chemical Oxygen Demand (COD). The BOD test provides an indirect measure of the quantity of biologically degradable organic matter in water in terms of the amount of oxygen required by microorganisms to oxidize it to carbon dioxide and water. The COD test measures the consumption of oxygen from a strongly oxidizing chemical agent.

In urban storm water COD levels are typically found to be about 8 times greater than BOD levels, indicating that much of the demand does not come from easily biodegradable materials. Stormwaters are often close to saturation DO concentration, and in some cases during low flow can be supersaturated due to photosynthesis. BOD and COD generally take several days to have impacts on receiving waters. It is likely that the Santa Monica Bay does not have significant oxygen deficits due to BOD and COD, but that localized problems could occur in smaller receiving waters such as Malibu Lagoon and possibly Marina del Rey.

Aesthetics. This category of pollution refers to litter, floatables, odor, scum, algae, bubbles, color(s), marine debris, and riparian vegetation impacts. Some of these inhibit habitat values, while others detract from human enjoyment or cause possibly safety problems. These pollutants have been identified as a problem in Santa Monica Bay.

Organic Pollutants. In the NURP program it was found that 63 of a possible 106 organics analyzed were detected in urban runoff. However, in general, organic pollutants exceeded applicable EPA water quality criteria much less frequently than inorganic pollutants. Of the pesticides analyzed, only 4 had a frequency of detection greater than 10 percent. These ranged in frequency of detection from 15 to 20 percent, and exceeded criteria from 8 to 17 percent of the time. Four polycyclic aromatic hydrocarbons (PAHs) were detected in urban runoff, but did not exceed EPA's freshwater life criteria. Only one form of PCB was detected (PCB-1260) and that was only a single detection. DDT was found in less than one percent of samples analyzed. The Portland study has found that organics are not generally a problem in storm water. There are however instances of pesticide concentrations in sediments. PAHs have also been detected in concentrations which exceeded the new Washington State standards.

Given that these constituents have not been found in quantities to warrant significant attention, they probably should receive less attention at this time. However, it is recommended that the Santa Monica Bay Monitoring Plan be implemented so that these parameters can be evaluated locally at an appropriate frequency until their presence or absence is determined. These parameters still warrant attention in the form of education and minimization of use; however, banning the use of pesticides and herbicides is not warranted.

Oil and Grease. Oil and grease is a prevalent constituent in urban runoff. In a study of oil and grease concentrations in urban runoff in Richmond, California, Stenstrom et al. (1984) found that oil and grease concentrations in runoff from commercial properties and parking lots are about three times higher than from residential and open areas. The NURP program did not address oil and grease. Accurately measuring oil and grease is very difficult, especially due to its affinity for coating sampling bottles and tubing. Furthermore, separating oil and grease from anthropogenic (man made) and biogenic (naturally occurring) sources is not easy to do, but has a major impact on its potential impact. Eganhouse and Kaplan (1981) measured oil and grease concentrations in the Los Angeles River and found that concentrations were generally lower during storm events than during dry flows. The State of the Bay report (MBC, 1988) estimated that urban runoff accounted for about 3 percent of the total input of oil and grease to the Bay. Recent data in Portland has found relatively low levels of oil and grease contamination. However, it is considered a problem by the public, and is sometimes visually apparent in Santa Monica Bay drainage channels, such as Ballona Creek. Therefore, it warrants a modest amount of attention in implementation of BMPs, including programs to avoid or prevent illegal dumping.

Pathogens. The State of the Bay report (MBC, 1988) indicates that during storm events, indicators of pathogens increase (fecal coliform, enterococcus), but it is uncertain whether these are primarily from animal or human wastes. Studies in Portland, Santa Clara, Alameda, Eugene, and Seattle have shown that these bacterial measures increase during storm events. In addition, on-going local studies sponsored by the Santa Monica Bay Restoration Project have shown storm drains to be a source of these indicator parameters as well as human viruses. Therefore, in Santa Monica Bay the concern for human health due to pathogens has become a concern. It is important to note that there have been many incidents of the direct release of sewage into Ballona Channel and other drainage facilities during failures of the sewer system and these direct releases more than nonpoint source runoff may be a contributor to pathogen problems. A program to locate sanitary sewer and stormdrain cross connections, including an aggressive field screening program to locate problem outfalls, is warranted.

Numerous storm water Best Management Practices (BMPs) have been developed, implemented, and evaluated over the last 20 years. Some of these BMPs specifically meet the requirements prescribed in EPA's NPDES regulations, and others are simply considered beneficial for controlling storm water. These BMPs have been pre-screened because not all of them are appropriate for use in the Santa Monica Bay area.

The following sections describe certain BMPs that should be implemented and provides the tools to select other BMPs that will be useful in controlling storm water pollution.

3.1 THE MENU CONCEPT

In the Santa Monica Bay area, municipal co-permittees are required to implement various BMPs to help control pollutants that would otherwise be discharged via their storm sewer systems. The program being guided by the Los Angeles Regional Water Quality Control Board is intended both to provide the co-permittees with the freedom to select BMPs that are appropriate to local conditions, and to assure that all co-permittees implement enough controls to achieve a meaningful level of pollution prevention.

The three-element "menu" system described herein provides a basis for balancing flexibility and assurance of meaningful control. The following discussion explains the menu system--first in direct terms, then by analogy, and then through a simple example.

Co-permittees are being provided with three lists of candidate BMPs for possible implementation in their respective jurisdictions. These lists (referred to herein as "menus") differ from one another in terms of the degree of obligation associated with each. As explained in detail below, the BMPs on Menu A are "mandatory," the BMPs on Menu B are "recommended," and those on Menu C are entirely "optional." During the process of developing local (i.e., city-specific) storm water management plans, the co-permittees will consider all three menus, but will only have to select BMPs from Menu A and Menu B. More specifically, they must select all BMPs on Menu A, but they need to select only the most appropriate BMPs from Menu B. Some co-permittees may decide to include additional BMPs from Menu C, but others may decide not to include any from Menu C. The hierarchy of obligation can be summarized as follows:

> Menu A - Mandatory - All co-permittees are required to select and implement all of the BMPs listed on Menu A, because there is sufficient evidence that these BMPs would be effective in controlling water pollution problems in the Santa Monica Bay watershed area.
>
> Menu B - Recommended - All co-permittees are required to consider all of the BMPs listed on Menu B, because they have a high likelihood of being effective if properly implemented. However, the co-permittees do not have to select or implement all Menu B BMPs, if the rejected BMPs would not be practicable or warranted (given local circumstances, conditions, and constraints) and that the selected BMPs are believed to be sufficient to control storm water pollution. That is, the burden of proof for not selecting a BMP from Menu B lies with the co-permittee.

VOL 12
1 65 / 3

Menu C - Optional - Co-permittees will be provided with an inventory of ideas to consider but are under no obligation to select or implement any of the BMPs from Menu C. The concepts listed on Menu C have been explored and/or implemented in other storm water pollution control programs, but they are provided here only as a resource to facilitate the planning process. It is likely that some co-permittees may decide to pursue one or more of the Menu C BMPs (perhaps because they may represent an opportunity to solve a local problem or because they may make good use of local resources or they would be more likely to be successful than a measure in Menu B for a given problem), but the co-permittees do not have any burden of proof for demonstrating why they did not select Menu C BMPs.

The concept of using a hierarchy of lists to structure a decision-making process has broad application. The most obvious application is the source of the term "menu." Patrons in a restaurant are presented with options in a way that facilitates matters for both the customers and the restaurant staff. Some would consider Menu A and Menu B to consist of items that are the "main course" on a menu, whereas Menu C contains "appetizers" or "dessert" items. Perhaps a more apt analogy would be the lists of courses in a college catalog. Menu A corresponds to the "core courses" that are mandatory curriculum requirements for graduation. Menu B corresponds to the courses that pertain to a particular major or are part of the standard curriculum for a degree from a particular department. Menu C corresponds to "elective" courses that a given student might take to round out their education or to build upon some particular talent. Continuing this analogy, credit would be given for every course the student takes (i.e., every BMP that is implemented), but only certain courses are obligatory.

The above-described menu system will be used in the Santa Monica Bay area to structure the process by which co-permittees evaluate, select, and implement BMPs. The BMPs that have been considered appropriate to designate as "mandatory" are listed on Tables 3-1, 3-2, 3-3, and 3-4. Again, these Menu A BMPs are well understood, by virtue of having been used with notable success in many areas. They are also believed to be cost-effective for dealing with the kinds of pollutants and conditions that exist in the Santa Monica Bay area. Furthermore, it is relatively easy for them to be implemented in compliance with the regulatory requirements of a Municipal Storm Water Management Program, as defined by the Environmental Protection Agency's (EPA's) current regulations.

3.2 MENU A BMPs

Several BMPs have been designated as being of high priority for implementation. These BMPs are to be considered mandatory by all participants in the Santa Monica Bay watershed. The Menu A BMPs focus mainly on education construction, industry, and illicit connections/illegal dumping controls.

Public Education

The central goal of public education is to reduce the amount of pollutants entering Santa Monica Bay through the storm drain system by informing the public about the causes of storm water pollution (i.e., pollutant sources and pathways) and by encouraging public involvement in reducing the storm water pollution. Public education can also teach the proper use and management of potential pollutants so they do not end up in the storm water conveyance systems.

VOL 12 1654

Table 3-1. Best Management Practices For Public Education.

Best Management Practices	Description	Suggested Steps for Implementation	Suggested Methods to Assess Effectiveness	Land Use
Label storm drain inlets and maintain labels on.	Coordinate volunteer efforts to label storm drain inlets with slogans like "No Dumpling, Flows into Bay" and Provide signs along the banks of drainage channels and creeks explaining the environmental impacts of dumping wastes.	1) Develop slogan to be used for labeling. 2) Develop a symbol that will be associated with the SMB Project. 3) Procedure stencils/signs. 4) Coordinate with community organizations to help paint the storm drains and install signs.	Record the number of catchbasins labeled and the number of signs placed along the channels and creeks.	All
Develop a general purpose brochure on Water Quality Protection and NPDES Program.	A "user friendly" brochure can be used to handout to people at community events and festivals. The brochure could also be mailed to people. The brochure would explain why storm water pollution is a problem and what people can do to help prevent it.	1) Develop graphic layout and text. 2) Develop distribution strategy, including number of brochures need. 3) Print brochures.	Count number of brochures distributed.	Residential and Comeercial

Table 3-2. Best Management Practices for Industrial Facilities.

Best Management Practices	Description	Suggested Steps for Implementation	Suggested Methods to Assess Effectiveness	Land Use
Assist industries to comply with general Permits.	Some industries may be unfamiliar with laws which requires SWPPP preparation at individual facilities. The appropriate agency should advise such industries of the State and Federal requirements.	1) Examine SWPPPs for completeness. 2) If SWPPPs are unavailable, advice the facility of State requirement and document advice with Regional Water Quality Board. 3) Assist facilities to prepare SWPPPs. 4) Provide facilities with sample SWPPPs.	Record number of industries that violate Storm Water Regulations and/or require assistance to prepare SWPPPs.	Industrial

Table 3-3. Best Management Practices for Illicit Discharge Elimination.

Best Management Practices	Description	Suggested Steps for Implementation	Suggested Methods to Assess Effectiveness	Land Use
Develop Enforcement Procedures	To clarify roles and responsibilities of inspectors, develop a set of follow-up enforcement procedures; these should be based on existing laws and regulations. The procedures should outline action to be taken for different degrees of violation severity. *This task should also be coordinated with the Industrial component.*	1) Collect data on pertinent existing laws and regulations (city, county, state and federal). 2) Develop new ordinance, if needed. 3) Empower inspectors to issue citations. 4) Develop a uniform and consistent procedures to keep records of all contact (personal, telephone, etc.) made with illicit dischargers. 5) Develop forms and/or a computer database to maintain consistency. 6) Review and adopt the procedure. 7) Train inspectors.	Effectiveness should be subjectively evaluated by the inspectors who implement the procedures. Inspectors should determine if procedures are too laborious, time-consuming, or ineffective.	N/A

Table 3-3. Best Management Practices for Illicit Discharges Elimination.

Best Management Practices	Description	Suggested Steps for Implementation	Suggested Methods to Assess Effectiveness	Land Use
Conduct "Below-ground" Inspections.	Look for illicit connections and evidence of illegal dumping by making observations from the storm drain system and tracing results upstream to the source.	1) Develop an implementation plan (including staffing and schedules). Identify high-priority areas based on land use and historical data. 2) Inspect the storm drain system - methodologies include: • walk the lines and use storm drain maps to trace dry-weather flows upstream to the sources, or • utilize dye studies or smoke tests as part of the industrial inspections, or • use video cameras in the storm drain lines to find illicit connections. 3) Make observations, and when deemed necessary, use test kits or take lab samples to find chemical constituents or bacteria. 4) Trace flows upstream to source: when source is identified either, • conduct "above-ground" inspections, or • implement enforcement procedures.	Catalog the number and nature of both confirmed and suspected illicit discharges. Also, determine the percentage of illicit discharges that could be tracked to the source. If tracked to source, estimate what percent would have been found if only "above-ground" inspections had been conducted.	Industrial, Commercial and Residential.

Table 3-3. Best Management Practices for Illicit Discharge Elimination.

Best Management Practices	Description	Suggested Steps for Implementation	Suggested Methods to Assess Effectiveness	Land Use
Conduct "above-ground" Inspections.	Investigate businesses that have a high potential for being illicit dischargers, and stop pollutants at the source. *Involves coordination with the industrial component.*	1) Develop procedures and an implementation plan (staffing and schedule). 2) Contact owners and/or operators of high priority facilities, and determine whether illicit discharges originate from site (or provide them with a questionnaire). 3) Provide information (e.g., BMPs for auto facilities or restaurants). Keep accurate records of observations made on site visits. 4) Implement follow-up procedures.	Catalog the number of illicit discharges identified and ceased. Estimate quantity of pollutants intercepted and determine the average number of person-hours required to cease each illicit discharge incidence and remove each unit (volume or weight) of pollutant.	Industrial and Commercial
Coordinate with building inspectors.	Required building inspectors to also check for illicit connections during physical inspections. *This should be coordinated with the industrial component.*	1) Educate building inspectors about urban runoff and familiarize them with the urban runoff program. 2) Develop/modify forms to facilitate inspections. 3) Implement and integrate with current ongoing inspections.	Record (1) number of illicit connections identified, and (2) number of facilities that will not require further independent inspection. Quantify savings.	Industrial and Commercial

Table 3-3. Best Management Practices for Illicit Discharge Elimination.

Best Management Practices	Description	Suggested Steps for Implementation	Suggested Methods to Assess Effectiveness	Land Use
Oil recycling	Provide a recycling alternative for people who need to dispose of used motor oil.	1) Develop an implementation plan and set up communication lines with recyclers. 2) Encourage service stations, part stores, and other related facilities to collect oil for recycle. 3) Provide facilities for citizens to deposit used oil.	Estimate unit cost to recycle each quart of oil. Compare these costs to other expenditures within the program.	All
Disposal of Hazardous Material	Provide an easy way to dispose of hazardous materials (e.g., paints).	1) Develop an implementation plan and set up communication lines with disposers. 2) Set-up a contract to provide for disposal of hazardous materials. 3) Provide a hazardous waste facility to accept small quantities of wastes from all users.	Estimate unit cost to dispose of each unit of hazardous material. Compare these costs to other expenditures within the program.	All
Illicit Discharge Hotline	Develop a hotline where citizens or inspectors cab report occurrences of illicit discharges.	1) Explore telephone alternatives and address staffing needs (may involve contracting an answering service). 2) Create a toll free that is on-line 24 hours/day.	Compare the cost of establishing the toll-free number to the amount of useful information gathered.	All

Table 3-4 Best Management Practices for Construction and New Development

Best Management Practices	Description	Suggested Steps for Implementation	Suggested Methods to Assess Effectiveness	Land Use
Insure that Construction SWPPP are complete	Provide an inspection program to insure that SWPPPs are complete.	1) Training Building Department on how to check Construction SWPPP. 2) Require submittal of a copy of SWPPP with application for Building Permit.	Record the number of SWPPPs checked.	All
Publicize the existence and encourage the use of a Guidance Manual for construction industry	Currently, in California, construction activity disturbing acres or more need to develop a SWPPP. A guidance document describing the process of developing a SWPPP and recommending BMPs should be developed.	1) Publicize a Guidance Manual. Conduct workshops to encourage users.	Record the number of construction industry representatives attending workshop or requesting manual.	All
Develop Guidance Manual for New Development	To prevent increased storm water pollution associated with new development, a Guidance Manual describing BMPs should be developed.	1) Collect and develop New Development BMPs. 2) Compile a Guidance Manual. Present manual at a workshop.	Record the number of developers attending workshop or requesting manual.	All

There are several educational BMPs that can be implemented to help reduce storm water pollution. Although their goals are related, they are diverse in terms of the audiences and pollutant types they address. Since Menu A BMPs are considered mandatory, only a few BMPs which would be beneficial to the whole watershed have been designated. Other educational BMPs should be considered from Menu B.

Table 3-1 lists public education BMPs.

Industry

Since most field studies have shown that industrial areas tend to be associated with high concentrations of pollutants in urban runoff, an effort should be made to help reduce the concentration of pollutants from industrial areas. However, in order to comply with federal and state regulations, certain industrial facilities are required to prepare their own site-specific Storm Water Pollution Prevention Plans (SWPPPs). These plans identify potential sources of storm water pollution at the facility and prescribe a series of control measures. It is likely that the Regional Water Quality Control Board will not soon be able to review all the industrial SWPPPs. As a result, the cities should implement a local program to periodically check SWPPP implementation at industrial facilities in their respective jurisdictions, as described in Table 3-2. By doing so, the cities would become familiar with industrial facility operations and may be able to avoid implementing redundant BMPs on an area-wide basis, and help ensure that the cities' storm water permit provisions are not violated because of improper discharges from industrial sites. These BMPs do not require official facility audits", only to assure that SWPPPs have been developed and updated. Facility audits can be considered under Menu B.

Illicit Discharges and Illegal Dumping

Elimination of illicit discharges and illegal dumping are important elements of storm water pollution control. Illicit discharges are physical connections that inappropriately convey and direct non-storm water flows (that should go to the sanitary sewer) to the storm drain system. Illicit discharges can originate from virtually anywhere. In industrial and commercial areas, illicit connections are a major concern, and industries are required by Federal and State storm water regulations to eliminate them. Older sewered areas, which originally had on-site treatment systems (e.g., septic tanks) may have illicit connections to the stormdrains.

Illegal dumping is the disposal of liquids or other debris into the streets, gutters, storm drain inlets, or other locations where they can wash into the storm drain system. Pollutants resulting from poor housekeeping practices, however, can also be a significant source of illegal dumping in industrial, commercial, and residential areas.

Table 3-3 identifies BMPs which address inspections, recycling programs, public education, and field screening. Recycling/disposal programs should be concentrated in residential and commercial areas. These areas may currently have the fewest programs for recycling hazardous materials. The inspection BMPs focus efforts in industrial and commercial areas.

The BMPs on Menu A should be the elements of a comprehensive illicit discharge detection and elimination program. Failure to include "below-ground" inspections or "above-ground" inspections would likely result in failure to meet regulatory requirements. Thus, at a minimum, it is mandatory that either the "below-ground" and/or the "above ground" inspections be implemented.

VOL 12 1 6522

Construction and New Development

To comply with federal and state regulations, construction sites larger a specific size (generally greater than 5 acres) are required to prepare a Storm Water Pollution Prevention Plan (SWPPP). This plan identifies potential sources of storm water pollution at the site and prescribes a series of BMPs to control that pollution. When identifying sources the SWPPP should contain a detailed list of materials and wastes with storage/access areas, loading and unloading plans and a site map showing proposed storm water discharge locations. The Program should develop a standardized guidance manual for the construction industry and develop guidelines for checking SWPPP for the building permit plan checkers. Similar guidance for new development control measures should be developed for plan checkers. Table 3-4 identifies the BMP that address construction and new development.

3.3 Menu B BMPs

Several excellent BMPs were not chosen as part of Menu A despite their merits. Although these BMPs were not chosen as Menu A BMPs (because their local applicability is yet to be confirmed), they may be very effective at reducing pollutants entering Santa Monica Bay. In fact, many of the Menu B BMPs, listed in table 3-5, should be part of a comprehensive plan to reduce pollutants due to storm water discharges. In some cases, BMPs were left in Menu B because a number of them could be used to address a certain pollutants or a specific problem, however only one or two might be needed. Therefore, the Menu B BMPs are recommended but should first be screened to determine their appropriateness. The recommended BMPs are listed in Table 3-5.

In order to help the various cities decide which of the Menu B BMPs should be implemented, a formal decision-making process has been developed. The process involves using a matrix to allow the cities to apply a series of evaluation factors to the candidate BMPs to assess their usefulness. The factors and scoring methodology are described below. The factors should be used to determine if a BMP is appropriate for implementation in a particular city. The BMPs are to be rated using a simple plus or minus scoring system. After rating each candidate BMP relative to all of the factors, the sum total of all the pluses can be used to assign an overall score to each BMP.

3.3.1 Possible Factors for Selecting Appropriate BMPs

Environmental Implications

This factor pertains to the potential environmental impacts or benefits which might be derived from the use of a candidate BMP. Although most BMPs have largely positive environmental implications, the development and operation of some of the larger-scale treatment-based controls and some maintenance-type controls could have adverse environmental consequences which warrant consideration.

Scoring:

\+ Implementation of the BMP will have more positive environmental impacts (i.e., enhances natural resources, wildlife and/or water quality) than negative impacts.

\- Implementation of the BMP could have more negative than positive environmental impacts. For example, installation of a BMP which

	Land-Use	Pollutants Addressed
CANDIDATE "SOURCE CONTROLS"		
1. Control the Use and Disposal of Fertilizers, Pesticides, and Herbicides		
a. Review current certification procedures/requirements for high volume users (e.g. commercial applicators, public agency personnel) and make recommendations for expanding the requirements to better address storm water quality impacts, as necessary.	C,R,T,I	nutrients, organic compounds
b. Restrict use of fertilizers, pesticides, and herbicides (e.g., regulate the sale of household pesticide/fertilizer products)	R	nutrients, organic compounds
c. Encourage the manufacturers & distributors of pesticides, herbicides, and fertilizers to educate the public about the proper use and management of the products.	R,C	nutrients, organic compounds
d. In cooperation with State Dept. of Agriculture and SCS, develop maps of appropriate fertilizer types and appropriate rates and combine with educational program.	ALL	nutrients, organic compounds
e. Establish planting/landscape requirements for various districts and for land uses which encourage use of vegetation, either indigenous or imported that are self sustainable without the need for human applications of fertilizers, pesticides or herbicides.	ALL	nutrients, organic compounds
f. Develop a program to educate architects, landscape architects and engineers about storm water friendly design practices to reduce the need for fertilizers, herbicides and pesticides.	NA	nutrients, organic compounds
g. Collect additional samples for pesticide/herbicide analyses and try to define problem better	NA	nutrients, organic compounds
h. Review current educ. programs related to how vol. use of pesticides/herbicides/fertilizers (e.g., household uses) & make recommendations for supplementing the pgms. with education re. storm water quality impacts & use of non-polluting alternate products.	R	nutrients, organic compounds
i. Evaluate existing O&M (and/or landscape mgmt.) programs for public right-of-ways and public drainage channels and ensure that these programs limit the discharge of pollutants from pesticides/herbicides/fertilizers to runoff	T	nutrients, organic compounds
2. Control Littering and Improper Waste Disposal Practices		
a. Continue to educate the public re: the storm water pollution impacts that result from littering practices.	ALL	BOD, Metals
b. Strengthen enforcement of existing regulations which provide legal authority to control littering	ALL	BOD, Metals
c. Work with citizen action programs to facilitate efforts to reduce littering (e.g. provide litter bags for use in cars).	R,C	BOD
d. Develop a comprehensive solid waste management program to reduce, recycle and control trash and yard debris.	ALL	BOD
e. Continue to provide, collect, and maintain more litter receptacles in strategic public areas, and during major public events. Expand programs as appropriate.	R,C	BOD
f. Educate owners and operators of trucks about the impacts of leaks, spills, and other releases from bulk materials during transportation (pollution effects of materials that are spilled onto roadways or other open space being washed into storm drains or waterways.	C,I	nutrients, oil & grease

Table 3-5: Menu B CANDIDATE BMPS
(organized by function)

	Land-Use	Pollutants Addressed
g. Promote public involvement in "Keep Watershed Clean" campaigns to "adopt-a-creek" programs for specific waterways.	ALL	All
h. Support public involvement on such issues as transportation, planning, recycling, packaging control, etc.	ALL	All
i. Strengthen enforcement of existing regulations and programs regarding spill prevention and response. The objective is to eliminate spills of contaminants onto roadways or open spaces, where they may be washed into storm drains or waterways.	T	nutrients, oil & grease, hydrocarbons
j. Develop and implement a program to ensure that municipal trucks hauling bulk materials do not leak, spill, or otherwise release contaminants onto roadways or open spaces, where they may be washed into storm drains or waterways. Consider educational activities as appropriate.	T	nutrients, oil & grease, hydrocarbons
k. Develop a program to encourage businesses (such as auto supply outlets and service stations) to provide collection services for used automobile fluids. Regulate to ensure appropriate disposal.	C,R	nutrients, oil & grease, hydrocarbons, metals
3. Prevent the Dumping of Pollutants into Storm Sewers and Drainage Channels		
a. Expand programs which provide convenient means for people to properly dispose of oil, antifreeze, pesticides, herbicides, paints, solvents, and other potentially harmful chemicals, and waste materials (recycle if possible).	R,C	BOD, oil & grease, hydrocarbons, nutrients, metals
b. Coordinate with EPA/DEQ to be sure that all potential water quality impacts are adequately considered in the new NPDES permits are issued for any discharges to storm sewers or drainage channels. Include monitoring of all pertinent constituents as a permit stipulation.	ALL	All
4. Control Oil and Grease		
a. Educate commercial/industrial sector re: the effective use of "housekeeping" practices, and oil/grease traps. Include the use of absorbents, cleaning compounds, oil/grease traps, and other techniques for controlling oil and grease in gas stations, automotive repair shops, parking areas, commercial/industrial facilities, and food service facilities.	C	oil & grease, hydrocarbons, metals
b. Educate the public to detect and repair vehicle fluid leaks.	C,R,T,I	oil & grease, hydrocarbons, metals
c. Research, strengthen (if necessary), and enforce regulations which give local jurisdictions the authority to require oil and grease controls in areas which are significant sources (e.g., gas stations, automotive shops, commercial/industrial facilities, parking areas, food service establishments).	C,I	oil & grease, hydrocarbons, metals
d. Develop technical guidance which will facilitate compliance with regulations requiring oil and grease controls (e.g., oil/grease traps, plate separators, synthetic absorbent media, grassy swales) for indus./commercial facilities.	C,I	oil & grease, hydrocarbons, metals
e. Develop and implement maintenance programs for oil/water separators where they do not exist. Ensure maintenance of existing separators.	C,I	oil & grease, hydrocarbons, metals

5 Control Erosion at Construction Sites		
a. Implement a comprehensive erosion control program which includes expanding erosion control requirements/policy city-wide, to incorporating new techniques/practices, increasing inspection and enforcement activities, and educating all affected groups (architects, engineers, contractors, public agency personnel)	O	TSS, nutrients
b. Take a more active role in the NEPA process to better address the topics of erosion potential, proposed erosion and sediment control plans, proposed inspection programs, related environmental impacts, and enforceable mitigation measures minimizing environmental impacts.	NA	TSS, nutrients
c. Establish incentives and/or requirements for contractors/developers to ensure that potential damages from erosion and/or sediment deposition are addressed and paid for	NA	TSS, nutrients
6 Control Erosion of Undeveloped Land, Park Land, and Agricultural Land		
a. Educate farmers, ranchers, and other managers of agricultural and/or open space lands re: the need for and practical methods for erosion control and sediment control	O	TSS, nutrients
b. Develop and implement programs to actively search for, identify, evaluate, and prioritize erosion problems on undeveloped land, park land, and agricultural land	O	TSS, nutrients
c. Develop and implement programs to work with landowners, tenants, and/or public agencies to apply practical erosion control and sediment control practices.	ALL	TSS, nutrients
d. Educate managers and users of park lands and open-space lands re: the need to restrict off-trail activities. Establish and enforce practical, site-specific regulations to control off-trail activities	O	TSS, nutrients, bacteria
e. Develop and implement practical programs for revegetating and otherwise restoring eroding areas (e.g., areas damaged by fires, overgrazing, landslides, improper tillage, and off-road vehicle use).	O	TSS, nutrients
f. Research, strengthen (if necessary), and enforce regulations to require erosion control and/or hydraulic runoff controls on privately-owned vacant or neglected land	O	TSS, nutrients
g. Coordinate with the Soil Conservation Service and local resource conservation programs to support their activities to control erosion and sedimentation problems.	O	TSS, nutrients
h. Restrict livestock from entering stream channels or damaging vulnerable stream bank areas.	O	TSS, bacteria
7 Control Airborne Particles		
a. Educate re: the relationship between air pollution and storm water quality problems. Coordinate with and obtain information from air quality agencies.	ALL	metals, hydrocarbons
b. Cooperate with programs (by others) which seek to reduce particulate atmospheric emissions of pollutants from individual, public, commercial, and industrial sources.	ALL	metals, hydrocarbons
c. Cooperate with programs (by others) which seek to reduce automobile use by various means (e.g., ride sharing, carpooling, public transportation, human-powered transportation).	ALL	metals, hydrocarbons
d. Suggest and encourage inspection and maintenance efforts to reduce automobile atmospheric emissions.	ALL	metals, hydrocarbons

	Land-Use	Pollutants Addressed
e. Cooperate with public transportation agencies, public agency motorpools, and/or public works departments to provide effective air pollution controls on publicly-owned vehicles and motorized equipment, and/or to use alternative clean-burning fuels where possible	C,R,I,T	metals, hydrocarbons
f. Coordinate with the State's program to control and minimize atmospheric emissions associated with fireplaces and wood-burning stoves, and to educate the public about the regulations	R	metals, hydrocarbons
8 Intensify the Maintenance/Repair of Storm Water Drainage Systems		
a. Develop O&M plan (or review & revise as appropriate, existing O&M plan) for all public storm water facilities (new & existing). Incorporate evaluation of effectiveness into the O&M plan. Provide a means of recording the observations of field inspection & maintenance personnel, and transferring that information to the appropriate dept./agency, so the information can be used to locate and eliminate the source(s) of pollutants	NA	All
b. Require O&M plans for storm water facilities related to new private development	C,R,I	All
c. Develop and implement an aggressive field program to search for, test, remove, and properly dispose of sediment deposits (in drainage channels, streams and storm water storage/retention basins) containing relatively high concentrations of pollutants	NA	All
d. Det. effectiveness of increasing freq of cleaning out inlets, catchbasins, storm sewers, pump stations, channels, & sw retention basins in areas where sediment &/or debris tend to accumulate. Implement improved pgms where approp. (private facilities)	NA	All
e. Research methods of economically and safely detoxifying high concentrations of pollutants at locations where they accumulate, i.e. detention basins, drainage channels, sedimentation trapping facilities, etc. Current information on bio-remediation and solar detoxification may offer some solutions to the disposal of wastes issue.	NA	All
f. Keep up to date inventories and maps of the storm sewer system	NA	All
9 Improve the Maintenance of Major Paved Areas		
a. Develop and implement intensified street sweeping programs in strategic locations (e.g., central business districts, shopping malls, major parking lots, industrial areas) and/or at strategic times (e.g., following extended periods of dry weather)	C,I	All
b. Determine the effectiveness of using street flushers to reduce pollutants in runoff	NA	All
c. Improve street sweeping on a watershed-wide basis (e.g., sweep more areas, more frequently)	ALL	All
d. Provide incentives to property owners to optimize street sweeping of private parking lot and other paved private areas (intensify as appropriate for selected locations).	C,I	All
e. Continue and expand pavement repair and maintenance on streets and parking areas (e.g., fill potholes, seal cracks, apply surface treatments) through a computerized pavement management system to reduce pollutants discharged to the storm drain system.	NA	All
f. Evaluate ways that transportation authorities can reduce pollutant discharges associated with their maintenance and road rehabilitation operations.	NA	All

Table 3-5: Menu B CANDIDATE BMPS
(organized by function)

	Land-Use	Pollutants Addressed
10 Prevent Rainfall and Runoff from Contacting Potential Contaminants		
a. Educate re: the need to keep rainfall and runoff from contacting potential contaminants. Describe typical examples of the problem and practical solutions	ALL	All
b. Develop and implement regulations which require landowners and/or tenants to provide covers (e.g., roofs, tarps) to keep run off of areas which contain contaminants (e.g., chemical storage areas, waste storage areas, contaminated industrial areas), and keep runoff from draining through areas which contain contaminants	I,C	All
c. Develop and implement an aggressive field program to search for, detect, and correct situations where rainfall and/or runoff presently contact potential contaminants	I,C	All
11 Other Source Controls for Industries/Commercial Facilities		
a. Develop and enforce requirements (e.g., structural controls, BMPs, connection requirements, development and redevelopment practices) for existing and developing industries and commercial establishments	I,C	All
CANDIDATE "HYDRAULIC CONTROLS"		
1. Reduce the Volume of Roof Runoff which Enters Storm Sewers		
a. Educate re: the need to minimize the total roof drain runoff volume contributing directly to both storm sewers and drainage channels. Describe basic principles and suggest practical alternatives to minimize their peak rate of discharge	C,I	All
b. Research, strengthen, implement, and enforce regs providing legal authority to prohibit new direct connections (roof drains to storm system) & which require retrofitting existing bldgs, where practical	C,I,R	All
c. Provide education and guidance encouraging architects, engineers, and building departments to implement systems which temporarily retain rainfall peaks on rooftops and/or in retention facilities, minimizing the peak rate of discharge to the storm sewer system or drainage channels.	C,I,R	All
d. Create incentives and make institutional changes to encourage that roof drains not be connected directly to the storm drainage system.	C,I	All
2. Enhance Surface Retention and Infiltration		
a. Educate re: the need to minimize the total volume of runoff and the peak rate of runoff from a given area. Describe basic principles and suggest practical alternative means to enhance surface retention and infiltration.	C,I,R	All
b. Research, strengthen (if necessary), implement, and enforce regulations which give jurisdictions the legal authority to require the drainage designs and systems which minimize the total volume of runoff and the peak rate of runoff from new construction, where local conditions permit.	C,I,R	All
c. Require new commercial, industrial, institutional, and major multi-family residential building complexes to have drainage facilities that incorporate on-site retention and/or infiltration, to assure that neither the total volume of runoff nor the peak rate of discharge to the storm sewer system or drainage channels are increased.	C,I,R,T	All

Table 3-5: Menu B CANDIDATE BMPS
(organized by function)

	Land-Use	Pollutants Addressed
d. Require new public- and private-sector developments to make significant use of design techniques for new buildings, landscaping, recreation areas, walkways, and parking areas to maximize infiltration (e.g., vegetation, groundcover, brick, cobblestones, paving blocks, "grasscrete", porous pavement). Use planted areas and/or grassy swales, where appropriate, to maximize retention and infiltration.	C,I,R,T	All
e. Remove (or perforate) paved bottoms of drainage channels, where practical, to maximize infiltration and reduce peak rates.	NA	All
f. Provide financial incentives to encourage reduction of peak rate and total volume (e.g., impervious area charge rebates)	C,I,R	All
3. <u>Evaluate Hydraulic Design Standards</u>		
a. Review and modify existing design standards (for flood control & water quality facilities) to improve water quality. Research methods being used in other areas and develop applicable regional criteria.	NA	All
b. Develop a program to educate engineers and others of new structural techniques that reduce negative water quality impacts to streams and the storm system.	NA	All
CANDIDATE "TREATMENT BASED CONTROLS"		
1. <u>Provide Sedimentation Facilities to Remove Pollutants</u>		
a. Determine the effectiveness of retrofitting selected storm sewers, sanitary sewers, and portions of the existing POTWs allowing the plants to receive and treat runoff from small storms and strategic portions of large storms.	NA	All
b. Develop a program to encourage owners of selected private areas (parking areas, vacant land, etc.) to route runoff through appropriate control structures: sedimentation basins, grassy swales; oil traps/separators (with periodic cleaning), or others. Provide special incentives (such as tax incentives) and technical assistance.	C,I,O,R	All
c. Provide financial incentives to encourage use of treatment based controls such as detention and retention facilities.	C,I,R	All
d. Develop a program encouraging public/private agencies to research new, more economical methods of improving storm water quality, i.e. compost filters and other existing experimental techniques.	ALL	All
e. Develop a program (possibly financial rewards/public recognition) to encourage individuals/inventors to create efficient, cost effective treatment techniques to replace some of the expensive devices and O&M practices now being employed i.e. oil/water separators, sedimentation man-holes, etc.	ALL	All
2. <u>Employ Vegetation to Remove Pollutants from Storm Runoff</u>		
a. Develop a program to provide financial incentives to property owner's who protect natural areas on their property considered to have valuable water quality characteristics.	ALL	All
3. <u>Provide Infiltration Basins to Remove Pollutants</u>		
a. Determine the effectiveness and potential negative environmental impacts of installing facilities on public property to encourage infiltration of runoff from neighborhood streets (e.g., use street circles, cul-de-sacs, and other curbside areas as infiltration basins or dry wells). Consider potential conflicts with existing policies and regulations. If feasible, install and maintain the facilities.	R	All

Table 3-5: Menu B CANDIDATE BMPS
(organized by function)

	Land-Use	Pollutants Addressed
4. Comprehensive Treatment Based Controls		
a. Determine the feasibility of retrofitting existing drainage and flood control facilities (e.g., storm drain inlets, retention basins, drainage channels) to function as water quality facilities. Retrofits could include installation of in-line sediment trap devices, detention/infiltration facilities or wetlands/riparian vegetation, or modification of retention facilities to detention facilities. If feasible, develop plan and implement.	NA	All
b. Determine the feasibility of building, establishing and maintaining water quality facilities (e.g., detention/retention/infiltration basins, man-made/natural wetlands, etc.). If feasible, develop a plan for conducting the work and implement the plan. Include evaluation methods to assess the performance of the facility.	ALL	All
c. Develop a pilot program for a selected small well-defined sub-basin (which is representative of a typical urbanized watershed) to implement every applicable aspect of the SWMP and conduct monitoring to assess effectiveness of the overall pilot program.	ALL	All

improves water quality could contribute to flooding problems (and impairment of natural resources) if not maintained properly

Effectiveness Regarding Pollutants of Concern

This factor refers to the candidate BMPs ability to afford a reasonable increment of control for the targeted pollutants (i.e., those pollutants that have been designated as being the focus of this storm water quality program - see discussion of pollutants in Section 2.5). It is recognized that each storm water BMP, taken independently, might not have much effect on the overall storm water pollutant loading problem. However, it is intended that each selected BMP should contribute enough toward the overall program to warrant its inclusion.

Scoring:

+ The BMP is expected to control the pollutants of concern identified for Santa Monica Bay.
- The BMP is not expected to control any of the pollutants of concern to a significant extent.

Implementing Agency/Department Acceptability

This factor pertains to how readily various public agencies and/or city departments (i.e., the storm water dischargers, not the regulatory agencies) would accept the measure and implement it properly. In many cases, implementing agencies/departments are more likely to accept a candidate BMP if its implementation would help them meet some other objective and/or if the BMP is an extension of some other program that is already in place or is expected to be implemented.

Scoring:

+ The various implementing agencies and departments would readily accept the BMP and could incorporate it into their existing programs and tasks to accomplish multiple objectives.

- The BMP would not be readily accepted and implemented by the various agencies and departments.

Regulatory Requirements

This factor refers to the candidate BMPs consistency with present and anticipated regulatory requirements. For example, the EPA is presently developing programs and policies which will require the implementation of certain storm water control measures. Candidate control measures that are likely to be required by these or other federal, state, and/or regional regulatory actions should probably be given higher priority (if they appear to be generally cost-effective) in both the screening and the selection process.

Scoring:

+ The BMP meets the intent of the NPDES storm water requirements for Storm Water Management Programs.

- The BMP does not meet the intent of the NPDES storm water requirements for Storm Water Management Programs.

VOL 12

1653

Public Acceptance

This factor refers to how readily the public would likely accept the BMP. Such evaluations are clearly subjective and depend heavily upon the segment of the "public" that is likely to be most affected, and that public's knowledge, understanding, and attitudes regarding the candidate BMP and its purpose. This latter factor can often be influenced by focused education and public information programs.

Scoring: + The public would readily understand and accept the BMP and participate (to the extent necessary/possible) in ensuring successful implementation.

\- The BMP would not be readily understood and accepted by the public.

Risk/Liability

This factor pertains the risks or liabilities which might accompany implementation of a candidate BMP. In some cases, the problems (e.g., legal, political, institutional, insurance) associated with risk and/or liability might well be more important than their cost or their effectiveness in controlling storm water pollution problems.

Scoring: + Implementation of the BMP includes a minimal amount of risk and liability.

\- Implementation of the BMP could generate a high level of liability for the implementing agency/individual (e.g., an unfenced detention facility in a residential area could be a hazard to small neighborhood children).

Equitability

This factor pertains to the degree to which the candidate BMPs associated costs and resultant benefits would be considered generally equitable. The issue here is one of fairness. In some cases, it may be necessary (or at least expedient) to implement a BMP which is considered to be inequitable (i.e., the party who will pay for the control is not the party who caused the problem and/or will not receive the benefit of the control). Such cases can be avoided by evaluating candidate BMPs relative to this factor.

Scoring: + The BMP is equitable in terms of costs and benefits--costs are borne by those who are responsible for the pollution problem and/or those who benefit from the BMP.

\- Those who pay for implementation of the BMP are not responsible for the problem and/or receive little or no benefit.

Reliability

This factor refers to the candidate BMPs ability to function, if properly implemented, in a predictable manner to effectively control pollutants. This is an important consideration as some controls are not very effective during sizable storm runoff events and/or are unpredictable in terms of their performance.

VOL 12

1 6532

Scoring: + It is highly likely that the BMP will control pollutants as it was designed to, or is expected to (as long as it is implemented and maintained properly).

- It is difficult to accurately predict how effective the BMP will be at controlling pollutants.

Sustainability

This factor refers to the candidate BMPs likelihood of being properly implemented over a long period of time after its initial introduction, and the likelihood that the BMP will continue to be effective over a long period of time. This is an important consideration for those BMPs whose effective performance depends on education, volunteer efforts, and/or the consciousness and cooperation of the public.

Scoring: + It is highly likely that the BMP will be effective at controlling pollutants over a long period of time.
- It is less likely that the BMP could be effective over a long period of time.

Universality

This factor refers to the degree to which implementation of the candidate BMP would be practical only if achieved on a very large geographic scale. For example, the lead content of urban runoff has diminished significantly, probably in response to a decade of concerted regulatory requirements and technical actions to reduce the lead content of gasoline, paint, and other products on a nationwide scale. Similar large-scale actions may be capable of reducing other storm water pollutants. Candidate BMPs need to be evaluated in this instance in terms of how universally they would have to be applied to achieve significant benefits. This can be an important consideration, because it can have significant cost, schedule, and legal/political/ institutional implications.

Scoring: + This BMP would be effective at controlling pollutants regardless of how extensively it is implemented in the Santa Monica Bay area.
- In order to be effective, it will be necessary to implement this BMP in every basin of the Santa Monica Bay Metro area.

Implementation Costs

This factor refers to the approximate magnitude of the various costs involved in the initial implementation of a candidate BMP. The cost elements to consider may vary significantly for each BMP. Implementation costs considered here include such one-time cost items as planning, design, land acquisition, construction, and equipment acquisition.

Scoring: + It would be relatively inexpensive to initiate implementation of the BMP.

- The initial cost of implementing the BMP is expected to be fairly expensive.

VOL 12 16533

<u>Operational Costs</u>

This factor refers to the approximate magnitude of the various costs associated with operations, maintenance, repair, support services, and periodic equipment replacement (where applicable). For some BMPs, this would include labor, electric power, fuel, replacement parts, monitoring programs, laboratory services, consulting services, legal services, and other continuing costs.

Scoring:
- \+ The continued cost of implementing/maintaining the BMP over time is expected to be inexpensive.
- \- The continued cost of implementing/maintaining the BMP over time is expected to be fairly expensive.

<u>Flexibility for Phased Implementation</u>

This factor refers to whether or not the BMP can easily be phased for implementation over the 5-year term of the NPDES permit.

Scoring:
- \+ It would be easy and possible to phase this BMP for gradual implementation over the life of the permit. For example, the BMP could be implemented in a pilot or demonstration study first, followed by full-scale implementation if the pilot test is successful.
- \- In order to be effective, the BMP would have to be implemented initially and continuously at a full-scale rate.

<u>Ability to Demonstrate Compliance</u>

It will be necessary to demonstrate the program's success and compliance with the NPDES permit by documenting tasks which have been accomplished and by evaluating the effectiveness of the BMPs when possible. In selecting BMPs, it is important to consider the ease of demonstrating compliance, either qualitatively or quantitatively.

Scoring:
- \+ It would be easy to demonstrate to the RWQCB and other regulatory agencies that the BMP is effective at meeting the goals and objectives of the NPDES requirements (i.e., improving storm water quality).
- \- It would be time consuming or expensive to demonstrate compliance and assess the effectiveness of the BMP either quantitatively or qualitatively.

3.4 MENU C BMPs

Menu C BMPs are BMPs that may help reduce storm water pollution in an indirect way or for a specific circumstance. Table 3- 6 lists the Menu C BMPs. These BMPs can be implemented if the circumstances for implementation are correct. For example, Menu C BMPs 3a, b are directed at controlling leaks from storage tanks. There are already regulatory requirements regarding tank leaks. Therefore, this BMP is only important if there is concern that the other regulations are not sufficient. Another example is Menu C

VOL 12

1 6535

TABLE 3-6: MENU C CANDIDATE BMPS (organized by function)	Land-Use	Pollutants Addressed
1 Control Littering and Improper Waste Disposal Practices		
a. Educate community residents about the advantages of composting and about proper composting techniques.	R	Bacteria, nutrients
b. Provide neighborhood compost sites, city operated or citizen operated. Post instruction signs, or organize local volunteer organizations to instruct residents and to maintain the site.	R	All
2 Control Leaks from Gasoline, Fuel Oil, and Chemical Storage Tanks		
a. Educate re: environmental impacts resulting from leaks and spills from gasoline, fuel oil, and chemical tanks (above and below ground).	I,C	oil & grease, hydrocarbons, metals
b. Coordinate with efforts (by others) to intensify the implementation of existing regulations calling for improved new tanks designs (e.g., double walls, monitoring locations), an aggressive self-monitoring program to be conducted by landowners and tenants, and implement a strategically focused spot-check program to search for, identify, test, and control leaking storage tanks.	I,C	oil & grease, hydrocarbons, metals
3 Control Human and Animal Wastes		
a. Educate the public through brochures re: the need to clean up and properly dispose of pet wastes.	R	bacteria
b. Implement and enforce leash laws and pet waste cleanup ordinances in selected public-use areas.	R	bacteria
c. Provide informational signs and dispense doggie litter bags in parks and other selected areas.	R	bacteria
d. Educate re: the need for proper management of wastes from suburban livestock (e.g., horses, chickens) and agricultural operations in the watershed.	I	bacteria
e. Implement a program to monitor septic tanks and cesspools, to identify failing systems, and to require repair or replacement of failing systems.	R,C,I	bacteria
f. Coordinate with Department of Agriculture to control discharge of wastes into the storm sewer system from confined animal feeding (CAF) operations.	I	bacteria

C - Commercial, R - Residential, T - Transportation, I - Industrial, O - Open, NA - Not Applicable

BMPs 4 a-f. These BMPs only need to be implemented if high levels of bacteria and fecal coliforms are found in storm water.

3.5 THE SCREENING PROCESS AND DEVELOPMENT OF THE BMP PLAN

The above sections present the tools necessary to conduct a BMP selection process utilizing a methodical approach. This approach takes into account factors that should be utilized to select a defensible set of BMPs for implementation. Section 2.5 presented a brief discussion of water quality parameters of concern and land-use considerations that should be consulted when evaluating the factor "Effectiveness regarding pollutants of concern." When evaluating the BMPs most agencies that we have worked with in the past have chosen to convene a number of individuals from the affected departments within the agencies and have each of them participate in workshops to set-up and define the water quality problems and define the BMP selection process.

There are a number of ways that co-permittees could proceed with an evaluation and selection of appropriate BMPs. Each co-permittee could evaluate the BMPs separately, with their own decision makers, and then come together to discuss and decide which BMPs should be implemented watershed wide. Or alternatively, the co-permittees could conduct the screening process as a group and then evaluate which BMPs they should consider for their areas. For many of the BMPs, it would probably make the most sense to implement them basin-wide by an overall program manager (i.e., Los Angeles County), while others may need to be implemented basin-wide but by each co-permittee, and still others will be implemented individually and not basin-wide.

In screening evaluations conducted in Eugene and Portland, another approach was to screen the selection factors first. The decision makers sometimes chose to combine factors (e.g. Implementation Costs and Operational Costs into just Costs) or to select the top 5 or 6 factors which they felt were the most important to selecting the BMPs. After this was completed, some also chose to weight the scores for 2 or 3 of the 5 or 6 factors which received the most votes as important selection factors. Those that were weighted higher received higher scores for each positive vote. Finally, in some of the evaluations, the factors were not just evaluated as either positive (+) or negative (-), but a neutral rating was also established. When this was done, summed negative ratings were subtracted from summed positive ratings to achieve a factor score from the group scoring the BMP. Then the weighting was applied to the factor score, before the total score was recorded and combined with other factor scores.

Once the rating and scoring procedures are decided upon and completed, co-permittees will then have a list of BMPs with overall scores. The next step is to then decide at what score should BMPs be implemented. It is our opinion and experience that co-permittees should not try to implement too many BMPs at one time. Our approach in Portland was to develop a histogram plot of the scores and to look for a break point in the histogram. This occurred at about 35 control measures. We felt that this was reasonable number of BMPs to consider implementing over a 5-year period; especially when one considers that many of the BMPs can be combined into more comprehensive BMPs, such as having one public education program which targets the individual education BMPs selected for implementation. The scores of the BMPs selected for implementation can also be used to guide the priority for implementation.

Once the BMPs are selected, detailed descriptions of the BMPs should be prepared. The descriptions should include a more detailed description of the BMP, identification of the staff that will be responsible for implementing the BMP (including getting it started and maintaining it), the funding requirements, schedule for implementation and ongoing activities (i.e., catch basin cleaning frequency), and how the implementation of the BMP will be documented and evaluated. These descriptions should be either prepared by the implementing departments within the perimeter's agency or at least circulated within that department for comments and input. Once the BMP descriptions are prepared and compiled, the co-permittee agency should seek and document approvals and commitments by the managers of the co-permittee agency to implement and/or support the implementation by others (i.e., Los Angles County for watershed-wide measures) of BMPs.

VOL 12

1 6537

This document has recommended a list of BMPs that should be implemented now, and a list of BMPs that should be carefully considered for implementation either now or during the next several years. The BMPs recommended in Section 3 are ones that are considered to be a base set of BMPs that should be completed as a part of an overall storm drainage quality management plan and be implemented basin-wide.

In this document, we have also described a method for carefully evaluating and selecting BMPs from a second list (Menu B). It is expected that a number of these measures should be implemented as a part of an overall storm drainage pollution management plan. However, each agency and City should carefully consider each of these measures in relation to their own identified problems and constraints. It is likely that some of these measures would be implemented by only some of the agencies or Cities in the watershed, while others may be implemented watershed-wide. We believe that agencies and Cities should evaluate this list and make selection of BMPs from the list (or any added BMPs) within 6 months. Implementation of the measures should be based upon prioritizing the BMPs for implementation during the screening process.

Participating agencies and Cities should carefully monitor the implementation of BMPs and monitor their effectiveness. Monitoring for effectiveness does not imply that water quality testing needs to be completed, but does imply that some measure be developed for each BMP to gage its effectiveness (i.e., public surveys for education campaign effectiveness, or keeping records on pounds of materials removed during street sweeping and catchbasin cleaning programs), and document that the BMP has been implemented. This "evidence" should be compiled in an annual report prepared by the County with regards to the County's NPDES permit with the Regional Board.

Finally, it is imperative that a carefully designed and implemented monitoring program be implemented. A suggested program was prepared as a part of this effort (Strecker and Stenstrom, 1993). The purpose of the program would be to better define the water quality characteristics of storm drainage discharges to Santa Monica Bay from various land-uses and overall loadings from large mixed drainages. This will enable Agencies and Cities to prioritize water quality problems and BMPs to address those problems in future management plans to be developed under the NPDES permit program. It will also begin to develop a base to which future water quality can be compared to.

6.0 APPENDIX BEST MANAGEMENT PRACTICES SPECIFIC FOR SANTA MONICA BAY

The first parts of this report have described a consensus building procedure for selecting best management practices (BMPs) for Santa Monica Bay. It is an adaptation of a general procedure that is applicable to almost any watershed and should be used to develop the final set of BMPs for the Bay. In spite of our recommendation to follow this procedure, there are several BMPs that have been studied or discussed during the course of this project, which have high applicability to the Santa Monica Bay Watershed. The authors would like to present these BMPs for further consideration and to provide a reference to existing or previous activity associated with the BMP. Pervious experience with the BMPs within the Bay watershed should be helpful in the consensus building. Several other BMPs are also presented which may not be specific to the Bay, but have been discussed over the course of this project and deserve further consideration. It is hoped that this appendix will preserve the work done in developing and studying them, and that this information will be used in the previously described consensus building procedure.

The following BMPs are recommended. They are divided into two categories; the first category is for BMPs which can most likely be implemented with existing knowledge and do not require pilot studies or demonstration projects prior to implementation. The second category includes BMPs that probably require a demonstration project before wide scale implementation.

6.1 BMPs SUITABLE FOR IMMEDIATE IMPLEMENTATION

The following BMPs are recommended for further consideration and implementation in the Santa Monica Bay watershed. The authors believe that they can be implemented based on existing information, which includes experience from other areas as well as knowledge within the technical staff of the Santa Monica Bay Restoration Project, its contractors and technical advisory committee.

<u>Public Education and Outreach Programs</u> Public education is the key to managing many problems associated with urban runoff pollution. Public education programs are preventive in nature and therefore tend to be less expensive. It is always less expensive to prevent an urban runoff pollution problem than to treat it after it has occurred. Active public participation is required to mitigate many problems such as illegal dumping, littering and other undesirable practices. Therefore, education programs should have very high priority. Several programs are underway already within the watershed. This list is not inclusive and is meant to complement and/or note the public education programs currently being developed and implemented by the City and County of Los Angeles, as well as other cities within the Santa Monica Bay Watershed.

- A watershed-wide brochure on water quality protection and NPDES permit information could be developed and distributed to residents (see menu A in the text of the report). An alternative is to develop a brochure that contains the basic education principles while leaving room for various cities and agencies to customize the brochure by including information about their specific programs or concerns. Masters of this alternative brochure could be distributed to cities and agencies for customization and publication.

- Construction is a large source of suspended solids that eventually become entrained in urban runoff. There are many construction techniques that can minimize suspended solids pollution. Education and training programs need to be developed to educate contractors and inspectors to insure that the appropriate building techniques are used. There are many Universities and Colleges in the Santa Monica Bay Watershed area that have extension programs and other education mechanisms that can be employed to provide this training. A local contractors organization (i.e. Association of General Contractors) could be utilized to help develop a manual or other educational materials describing proper erosion and pollution control practices at construction sites

- Automotive businesses are large potential sources of urban runoff pollution, especially for hydrocarbons and metals. Education programs including workshops, extension classes, and inclusions of new materials in existing automotive repair school curricula, are mechanism to educate businesses about practices to minimize urban runoff pollution.

- A "hot line" can be set up to allow citizen reports of urban pollution events. Its success would be directly related to the follow-up action (e.g., enforcement, clean-up) by appropriate agencies.

Public Participation Programs Programs to take advantage of volunteerism can be developed. Such programs could be used to clean up problem areas, stencil storm drains, post signs and foster other activities that reduce urban runoff pollution. Several Issues must be addressed prior to implementation, such as safety of the volunteers and liability.

Storm Channel Cleaning Late in the dry season, Ballona Creek and other stormwater channels with dry weather flow are heavily covered with debris and algae rafts. These algae rafts are dense and anaerobic. A proposed BMP is to clean the Creek and other channels by removing the debris and rafts. The debris and algae can either be removed or reduced in magnitude. In this way "shock" loading to the Bay during the first heavy rainfall will be reduced.

If the proposed Ballona Creek treatment plant is constructed, it might be used in conjunction with the proposed cleaning program. In this case algae mats and sediment could be mobilized and pushed toward the plant. The plant, probably composed of physical processes such as screening and sedimentation and located at the old stormwater diversion facility on Ballona Creek, could be designed to remove grit (silt) and debris. Through such treatment the mass emissions of potential toxics adsorbed to the surface of particulate are reduced, and that trash collection on the beaches is minimized. Reduced debris has beneficial impact on marine life (e.g., avoidance of mammals swallowing clear plastic bags, etc.).

Erosion Control The Malibu Creek watershed, due to its size and steep slopes, contributes a large fraction of the particulates entering the Bay, and is largely open or undeveloped. To control particulates, construction codes that minimize erosion need to be implemented. Such codes and practices should be enforced through an active inspection program, which is particularly important during the rainy season.

NPDES Enforcement After NPDES permits are required it will be difficult for the Water Quality Control Board to insure that all businesses required to obtain permits actually obtain them. To assist the Board, a database can be created from the tax assessor's databases, business code databases and SIC codes. This database can be compared to the Board's permit database and businesses not having permits can be reminded to obtain them. If they do not cooperate their non-compliance can be reported to the board for action.

Oil Recycling Oil recycling programs are still inadequate and more facilities that will accept used oil are needed. An ordinance requiring businesses selling more than a certain minimum amount of oil to accept used oil is one way of creating more recycling facilities. Also an ordinance restricting sales of oil at very small facilities (convenience stores) would force sales from to stores with recycling facilities.

Storm Drain Inlet Identification Stenciling storm drains to identify them and protect them from accidental contamination can be done County-wide. The experience in Santa Monica can be used as a model for the county-wide program. It should be possible to use volunteers or to use this as a public service activity.

Storm Drain Effluent Dispersion Many storm drains (e.g., Pico-Kenter) terminate upstream, far from the beach water line. These drains actually encourage human contact and should be extended to meet the surf line, or extended beyond the surf line if dilution is desired. In this way there will be less risk to beach goers. Pico-Kenter storm drain has been extended to provide this dilution and this experience can be used in the further evaluation and development of this BMP.

Street Sweeping and Disposal Practices A county-wide approach to disposal practices of could be employed to insure street sweeping and certain basin materials are disposed properly and to minimize losses of debris during transportation. Street sweeping practices can be reviewed to ensure that maximum benefits are obtained.

Improved Highway Runoff Control Runoff from highways is usually 2 to 4 times greater in contaminant concentration than runoff from other land uses. Controlling pollution from this land use is potentially much more cost effective than controlling pollutants from other land uses such as single-family residential. Programs could be developed with Cal Trans and others responsible for street and highway maintenance to insure that new construction and retrofit projects use the best techniques for minimizing urban runoff pollution.

BMP Construction Manual A BMP construction manual could be developed with a general contractors' organization to further BMP construction technology. Several similar manuals have been developed for other areas or disciplines and may be adaptable for this use.

Illegal Dumping and Illicit Stormdrain Connection Existing techniques for regulating and monitoring dumping and sewer/stormdrain connections can be reviewed to insure that maximum benefits are obtained. A model inspection/investigation manual could be developed for county-wide use by appropriate agencies. The manual could provide specific details on procedures, health and safety requirements and inspection practices. The manual would serve to facilitate the early implementation of this important BMP.

6.2 BMPs REQUIRING DEMOSTRATION PROJECTS BEFORE IMPLEMENTATION

Porous Pavements Porous pavement parking lots need to be demonstrated to public agencies and consulting firms in order to evaluate and prove their effectiveness. Currently, many agencies believe that porous pavement parking lots are unmanageable, and this perception needs to be changed, or new techniques need to be developed. There are other practices potentially useful for parking lots that can be implemented. Parking areas have very high emission rates per unit area and their management is probably one of the more cost effective techniques for minimizing urban runoff pollution. Additionally, parking lots generate income that can recover the cost of the management.

Infiltration Areas Grassy swales (green belts) have been used with success in many areas but are not considered a proven technology in Los Angeles. One or more demonstration projects quantifying pollutant removals are recommended.
