Vehicle Inspection Programs Smog inspection programs are largely ineffective for certain problem vehicles, which have high mass emissions and whose owners avoid the intent of the inspection by finding dishonest inspectors or defeating controls after an inspection. The gaseous emissions from vehicles contribute to urban runoff pollution as they settle on land or are rained out. It is estimated that the majority of pollutants from automobiles in Los Angeles are produced by older vehicles and it is very likely that automobiles are one of the greatest contributors to urban runoff pollution. Smog inspection programs have no requirements at present to control dripping or leaking vehicles.

It may be economically impractical to require leaks to be fixed, especially for older cars. Never the less, smog inspection programs can be improved; for example, there is a proposal to change the existing program of static inspections to moving vehicle inspections, or requiring independent inspectors who do not also perform repairs. Recent programs to remove old vehicles by allowing industries to purchase them to obtain air pollution credits should be encouraged since reduced hydrocarbon emissions in urban runoff will undoubtedly occur.

Stormdrain Water Disinfection Two recent studies (Green, 1992; Gold et al., 1993) have shown the presence of fecal contamination in stormdrains. An inspection program that can target illegal connections and leaks will help eliminate this problem. Indicator water quality parameters are required.

Detention Basins Detention basins are now a well-developed technology for stormwater pollution control. One or more demonstration projects are required to convince agencies and the public of their value in Los Angeles.

Stormwater Infiltration Dry weather flow constitutes the vast majority of urban runoff pollution during the April to September periods. Dry weather flow can be reduced by using infiltration zones in regions near stormdrains. For example, Ballona Creek could be equipped with a porous low flow channel to allow infiltration. Further study to determine the feasibility, amount and impacts of the infiltration are required.

<u>Diversion of Dry Weather Flow to Sanitary Sewers</u> Dry weather flow in particularly sensitive areas or areas without proper stormdrain termination (e.g., Pico-Kenter) could be diverted to sanitary sewers. This option has several advantages. Sanitary facilities usually have lower flow rates in the summer than in the winter, when sanitary sewer infiltration occurs. The reduced summer sanitary flow may provide capacity to allow several stormdrains to be diverted. In wet weather the diversion can be terminated by automatic monitoring equipment. The demonstration project at Pico-Kenter is a good example of this practice and should be further investigated and developed to allow its more widespread use. Spill detection technology, to prevent the introduction into the sanitary sewer of a spill, such as gasoline, may be required.

ASSESSMENT OF STORM DRAIN SOURCES OF CONTAMINANTS TO SANTA MONICA BAY

VOLUME V
TOXICITY OF DRY WEATHER URBAN RUNOFF

University of California, Los Angeles

June 14, 1994

This report represents Volume V from a series of reports which form the basis of a pollution assessment and monitoring plan for Santa Monica Bay. Volume I describes land use statistics, catchment areas, existing water quality monitoring data, rainfall data, NPDES permit information for existing permits to storm drains, and contaminant mass emission estimates, based upon land use modeling. Volume II reviews sampling techniques, including sampling equipment, and other aspects associated with sampling such as a quality assurance plan. Volume III presents the proposed monitoring plan. Volume IV addresses best management practices as they apply to the Santa Monica Bay area. This volume describes dry weather flow water quality and chronic toxicity.

The contract was performed by UCLA under the direction of Professor Michael K. Stenstrom of the Civil and Environmental Engineering Department, and Professor I.H.(Mel) Suffet of the Environmental Health Sciences Department. There were several key individuals from both UCLA departments who assisted with the project; they include Kenneth Wong, Linda Schweitzer, Mario Capangpangan and Ed Ruth.

The project was conducted in parallel with a project sponsored by the American Oceans Campaign. Samples were collected, analyzed and toxicity testing was performed by the funding provided through this project. Special organic analysis were funded by the American Ocean Campaign.

The contractors are grateful for the assistance of many individuals. The Santa Monica Bay Project and LA Regional Water Quality Control Board staffs were most helpful. We extend our special thanks to Dr. Guang-yu Wang, Ms. Catherine Tyrrell, Dr. Rainer Hoeinke and Mr. Xavier Swamikannu. The Los Angeles County Department of Public Works and the City of Santa Monica were helpful in permitting the sampling. We are also indebted to the members of the Technical Advisory Committee of the Santa Monica Bay Project and others who reviewed and commented on our draft reports.

ABSTRACT

Five storm drains representing different types of land use and hydraulics were sampled over an extended dry weather season. Samples were taken for routine water quality analysis as well as short-term, chronic toxicity analysis. The five drains had water quality approximating secondary treated wastewater effluents for many parameters, and were somewhat higher for other parameters, such as COD, TSS and turbidity.

Four drains were tested with three marine species for toxicity and varying amounts were found in all four drains. The most toxic drain had the least flow rate, and it is suspected that the higher toxicities are associated with stagnant drain water and lack of dilution from flushing which occurred with the other drains.

One storm drain was analyzed in depth to ascertain the source of the toxicity. Inconclusive results were obtained in that different most likely causes were found from three different samplings. In one case the cause was consistent with the presence of organic chemicals. On another occasion the cause was consistent with the presence of toxic metals. On another occasion the toxicity disappeared after 24 hours, which is consistent with the presence of an oxidizing agent, such as residual chlorine from disinfection.

The toxicity was generally present in samples that contained more than 10% and less than 50% storm drain effluent. This suggests that a 10 fold dilution would reduce the toxicity below the detection limits used in this analysis. A brief review of the literature to determine ways of estimating the initial dilution of a storm drain found no reliable, proven methods for low flow conditions. For high flow conditions, jet nozzle methods might be applicable, but must be verified.

1.0 INTRODUCTION

This report presents the results of a one-year investigation of the toxicity of dry weather urban runoff to Santa Monica Bay. It is one of many projects sponsored by the Santa Monica Bay Restoration Project to ascertain the status of contaminant inputs to the Bay, with the eventual goal of developing a comprehensive action plan to restore and maintain the quality of Santa Monica Bay.

Dry weather runoff is a potential problem to Santa Monica Bay. Dry weather runoff is a somewhat confusing term, since "dry weather" suggests no rainfall and therefore no stormwater runoff. Storm drains in Los Angeles, with perhaps very minor exceptions, are separated from sanitary drains. The sanitary flow is conveyed to the various treatment plants through separate drains and sewers. One wonders why storm drains have flow when there is no rain and no wastewater discharge.

The answer is that certain wastewaters are discharged to the storm drains. There are also other inputs such as runoff from landscape irrigation, natural seeps and springs, uncontrolled and/or unregulated discharges, including illegal discharges, and treated secondary effluents. The discharges are sometimes referred to as "nuisance waters," although the magnitude of the discharges to the various storm drains in the Los Angeles Basin are much greater in magnitude than the traditional concept of nuisance waters.

Discharges entering storm drains include legal, NPDES permitted discharges. These might be cooling tower blow down, such as occurs with air conditioning systems, land dewatering, which is sometimes necessary when constructing new buildings, and discharges from facilities that use water without contaminating it, such as cooling towers. Cooling tower discharges should be free of most contaminants. They may be elevated in salt concentrations but should have a total organic carbon (TOC) concentration of 5 mg/L or less, and have no residual chlorine or corrosive inhibitors.

These permitted, normally harmless waters and wastewaters comprise the dry weather flow into Santa Monica Bay. Potential problems exist with these discharges. One potential problem is that the dry weather flow may hide or disguise an unpermitted, illegal, discharge. Several examples of sanitary sewer breaks have been documented in the course of the projects sponsored by Santa Monica Bay. Another problem is that the dry weather flow may scour pollutants from surfaces as they flow to the Bay. Emissions from vehicles maybe scoured and transported to the Bay through this mechanism. Also trash and other debris maybe washed into the Bay by dry weather flow.

The purpose of this investigation was to ascertain the potential aquatic toxicity and water quality of the dry weather flows just prior to their entering the Bay. Five storm drains were monitored for many water quality parameters, including conventional contaminants and analysis for a broad range of organics using gas chromatography/mass spectrometry (GC/MS). The drains were Pico-Kenter, Ashland Avenue, Ballona Creek (at the Inglewood overpass), Centinela Creek (at the Inglewood over pass), and the Sepulveda Channel as it enters Ballona Creek, just east of the Inglewood over pass.

Marine aquatic toxicity was assessed for four storm drains using three species (the Centinela Drain was not tested for toxicity). A screening assay was first performed to determine which drains had the highest toxicity. An in-depth analysis was later performed to attempt to determine the type of contaminants causing the toxicity in the runoff.

The toxicity analysis were performed at the Southern California Coastal Water Research Project (SCCWRP) in their Long Beach laboratory. The other analysis were performed at UCLA, principally in the Department of Civil and Environmental Engineering and the Department of Environmental Health Sciences.

The bulk of the results are contained in appendices. Appendix B contains all the water quality data. Appendix D contains the toxicity data and the interpretation of the results. Appendix E contains the GC/MS data.

A parallel study was performed under partial sponsorship of the American Oceans Campaign (Suffet *et al*, 1993). This parallel study provided funding to perform the GC/MS analysis.

VOL 12

2.1 Sampling Location

The selection of storm drains as sampling locations of this project were based on the types of land-use, location and ease of sampling. Five storm drains in the Santa Monica Watershed were selected for sampling: Pico-Kenter; Ashland Avenue; Ballona Creek at Inglewood; Sepulveda Channel at Ballona Creek, and Centinela Creek at Inglewood (the first two storm drains were named with reference to their neighboring streets). Figure 1 shows the location of these five storm drains.

Originally only three storm drains were required in the request for proposals. A fourth storm drain was added in order to make a more complete evaluation of different land uses. Later, a cooperative sampling program was started with a project funded by the American Oceans Campaign (Suffet *et al.*, 1993), which required the addition of a fifth storm drain. Centinela Creek was selected as the fifth storm drain. Toxicity testing was never performed at this drain.

2.2 Sampling Procedures

Samples were bailed from the storm drains using a stainless steel bucket. Morning and afternoon grab samples were collected into a 2- or 4-L glass bottles, composited, and stored in ice chests with blue-ice packs while being transported to the laboratory. Samples were collected from the middle of the open channel from Ballona Creek, Centinela Creek (low flow channel) and the Sepulveda Channel. At Pico-Kenter, they were collected from the wet well installed to divert low flow to the sanitary sewer. At Ashland Avenue samples were withdrawn from an open access hole on Neilson Avenue in Santa Monica. All samples were stored in a refrigerator at 4°C until the time of analysis. The time between sample collection and analysis was within the holding times recommended by the US EPA (1983).

2.3 Materials

Chemicals. Analytical or better grade chemicals and HPLC grade solvents (e.g., methanol and methylene chloride) were used for the chemical analyses and solid phase extraction. All these materials were obtained from Fisher Scientific (Tustin, CA).
SPE columns. The 1000 mg C18 columns used were obtained from Burdick and Jackson (Muskegon, MI).

2.4 Conventional Chemical Analysis

Conventional water quality analyses were performed on the collected storm drains samples. The analyzed water quality parameters are listed in Table 1. All the parameters, except for UV absorbance, were analyzed according to the *Standard Methods* (1989) procedures. The

1654

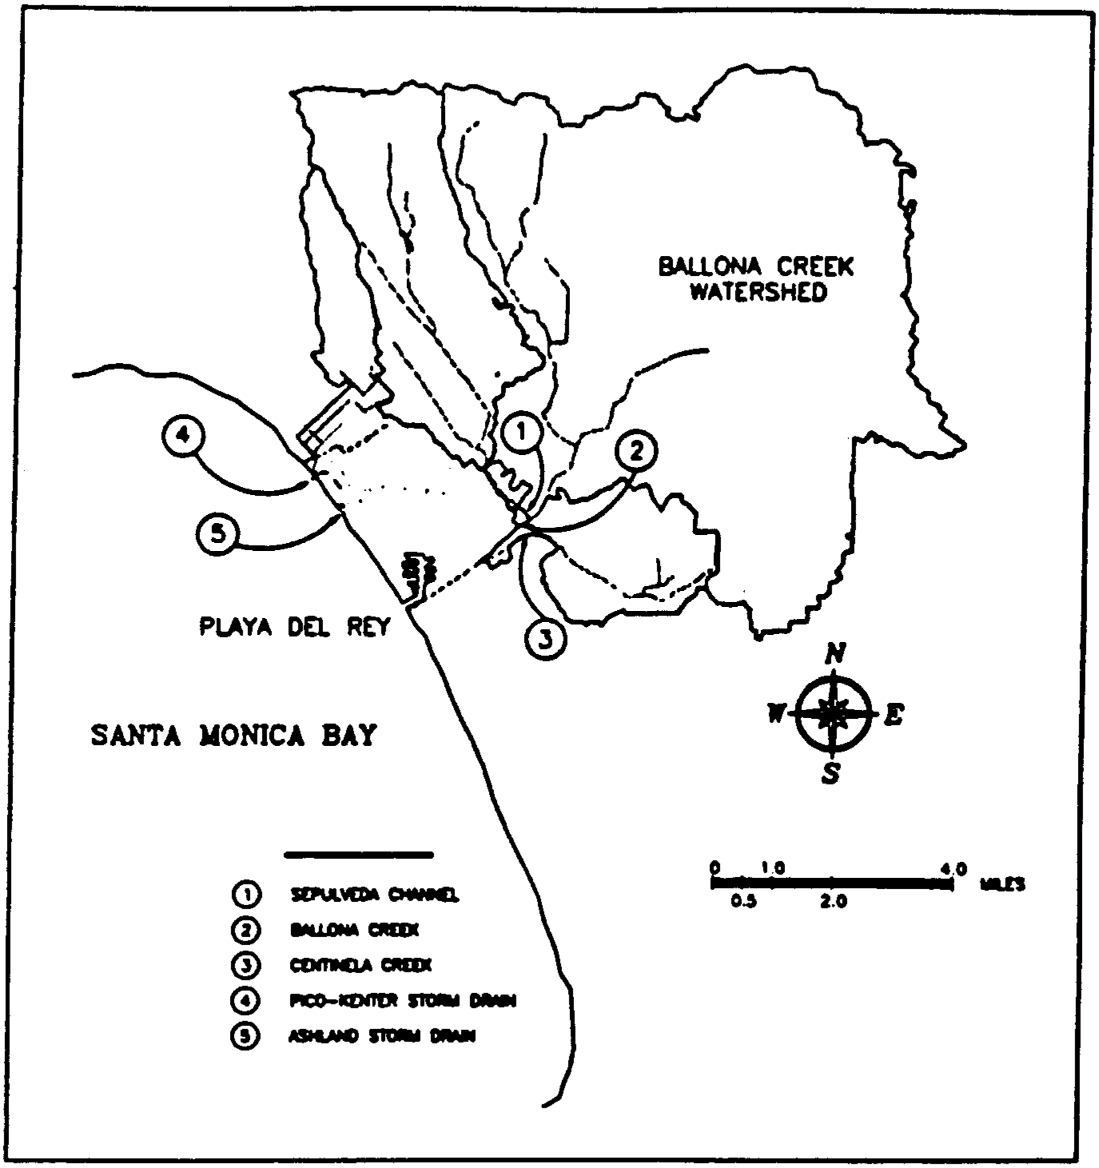

Figure 1. Sampling location of the five selected storm drains.

UV-absorbance of the collected storm drain samples (filtered) was measured at a wavelength of 254 nm, using Hewlett-Packard HP 8452A Diode Array Spectrophotometer. The measured UV-absorbance is a qualitative measure of the amount of organic carbon in the samples.

2.5 Velocity Measurement

The velocities of the flow across Ballona Creek, Sepulveda Channel and Centinela Creek were measured during each sampling period. The velocity at Ballona Creek and Sepulveda Channel were measured using a Marsh McBurney velocity meter at approximately five foot intervals across the channel. The water depth was also recorded at the same time and location. The velocity at the Centinela Creek was determined differently. Several small floating objects (bits of Styrofoam cup, etc.) were timed and the results were averaged. The depth of flow, which was too shallow to permit the use of the velocity meter, was also measured. The obtained data were used to calculate the average flow rate through the channel.

2.6 Solid Phase Extraction

The C18 SPE method described by Mount and Carnahan (1989) was the basis of our fractionation procedures to isolate non polar organic compounds from the collected storm drain samples. However, instead of using the proposed elution solvent system of methanol-water mixtures, a modified elution solvent system which involved mixtures of methanol-water and methanol-methylene chloride was used. A detailed description of the development of this modified elution system is given in the Appendix A and also described by Lau and Stenstrom (1993). The modified procedure was required because of the poor recoveries observed by the Mount and Carnahan procedure. The following procedures were used to fractionate non- polar organic compounds from the collected samples.

Filter blank. A 1 µm glass fiber filter (Whatman GF/B) was prepared by first acid washing with 10% HNO_3 and then rinsing thoroughly with deionized water. Next, approximately 200 ml of deionized water was passed through the filter, and the last 30-50 mls of filtrate were collected for the filter toxicity blank. The storm drain sample was then filtered.

Column blank. The 1000 mg C18 SPE columns were conditioned by pumping through 25 mls of HPLC grade methanol through the column at a flow rate of 5 mls/min. Before the sorbent dried, approximately 50 mls of deionized water were pumped through the column. The last 25-30 mls deionized water were collected for a column blank toxicity test. Pumping continued until no water emerged from the column.

Elution blank. Three elution blanks were collected from the prepared column by pumping 2 x 1.0 ml of each of the following solvents: 50% (v/v) methanol in water, 100% methanol, and 50% (v/v) methylene chloride in methanol, through the column and the eluates were collected in a clean glass vial as the SPE elution blanks. The column was allowed to dry between each elution.

SPE fractionation. The same C18 SPE column was again conditioned with 25 mls of methanol and 25 mls of deionized water. Before the sorbent dried, 1000 mls of filtered storm drain sample were pumped through the column at a rate of 5 mls/min. A 30 ml sample of the post C18 column effluent was collected after 500 mls of the sample passed through the column. The sorbent was dried by continuing the pumping after the entire 1000 mls sample passed through the column. Then 2 x 1.0 ml of 50% (v/v) methanol in water, 100% methanol, and 50% (v/v) methylene chloride in methanol were added sequentially into the column. Each fraction was collected into clean glass vials. The column was allowed to dry prior addition of each elution solvent mixture.

1 6557

Toxicity testing was performed on the filtered sample, post C18 sample, the SPE eluates and all blanks (e.g., filter blank, column blank and elution blank).

2.7 Toxicity Procedures

Three marine test methods described in the California Ocean Plan (SWRCB, 1990) were used in this study: the echinoderm fertilization test, red abalone embryo development test, and giant kelp germination/germ tube growth test. Storm drain samples were stored under refrigeration in sealed 4-L glass bottles until the day of testing. Samples were thoroughly mixed before a 2.5-L subsample was removed and filtered through 1 µm glass fiber filter (Whatman GF/B).

The toxicity tests were conducted in two phases: Phase I - Relative Toxicity of Storm Drains and Phase II - Examination of Toxic Components. Toxicity testing was performed at the Southern California Coastal Water Research Project's (SCCWRP) laboratory in Long Beach. Seawater dilutions of each sample were prepared by adding appropriate amounts of seawater and brine solutions to create the desired dilutions and maintain a salinity of 32 - 35 mg/g. The dilution of the collected storm drain sample produced the required concentrations of storm drain sample for the toxicity tests, and test organisms were added to each sample within three hours of dilution. The concentrations of storm drain sample used in the toxicity testing were expressed in percentage of storm drain sample water used in the dilutions. For example, a concentration of 56% corresponds to a diluted sample consisting of 56% storm drain sample and 44% dilution water. The number of concentrations (expressed in % of storm drain sample (v/v)) and replicates of the samples used in the toxicity tests are shown in Table 2.

Table 2. Number of dilutions and replicates of each toxicity test.

Phase (1)	No. locations (2)	No. dilutions (3)	Concentration (% v/v) (4)	No. replicates (5)
I	4	5	5.6, 10, 18, 32, 56	3
	3	4	5.6, 12, 25, 56	3
II	1	3 for blanks	12, 25, 56	2
		2 for SPE eluates	0.1, 0.2	2

Echinoderm fertilization test. The echinoderm fertilization test was conducted according to methods described by Dinnel *et al.* (1987). Purple sea urchins *Strongylocentrotus purpuratus* were collected from the intertidal in northern Santa Monica Bay and held at SCCWRP until used in the tests. Ten mls of each sample dilution were added to replicate glass test tubes and equilibrated to 15°C in a water bath. Sea urchins were then induced to spawn through injection of potassium chloride. The gametes were collected and diluted with seawater to produce stock solutions of the density recommended by the protocol. The test was conducted by adding sperm to each test tube. After 60 minutes of sperm

VOL 12

1 6558

R0049863

exposure, eggs were added to each tube for a 20 minute fertilization period. The sample was then preserved for microscopic examination. Toxic effects were indicated by a reduction in the percentage of fertilized eggs from that observed in a control sample (seawater).

Abalone development test. The abalone development test, using embryos of the red abalone *Haliotus rufescens*, was conducted according to methods described by Anderson *et al.* (1990). Sexually mature abalone were obtained from a commercial aquaculture facility and held at SCCWRP until used in the tests. Two hundred mls of each sample dilution were added to replicate 250 ml glass beakers and placed in a 15°C water bath. Abalone were induced to spawn by exposure to a hydrogen peroxide solution. The eggs were then fertilized, adjusted in density, and added to the exposure beakers. The developing embryos were exposed for 48 hours and preserved for microscopic examination. Toxic effects were indicated by an increased incidence of larvae with abnormally developed shells.

Giant kelp test. Tests with giant kelp were also conducted according to the procedures described by Anderson *et al.* (1990). Kelp blades containing reproductive spores (sporophyll) were obtained from offshore, uncontaminated kelp beds located near Santa Barbara and used within 24 hours. The toxicity test was conducted in 250 ml beakers containing 200 ml of the sample dilution. A glass microscope slide was placed on the bottom of each beaker to provide a surface for settlement of the kelp spores. Zoospore release from the sporophyll blades was induced by desiccation followed by immersion in seawater. The density of the released spores was adjusted and the appropriate number of spores was added to each beaker. The spores were exposed to the sample dilutions for 48 hours at 15°C and a controlled light level ($50 \mu Em^{-2} sec^{-1}$). During this period of 48 hours, the spores germinated and formed gamethphyte plants. The slides were then removed from each beaker and preserved for microscopic examination. Two endpoints were assessed: percentage spore germination and gametophyte length. Toxic effects were indicated by reductions in germination and gametophyte length, relative to a control group.

2.8 EDTA and Sodium Thiosulfate Addition Tests

EDTA and sodium thiosulfate addition tests described by Norberg-King *et al.* (1992) were conducted during the second phase of the toxicity test. The unfiltered storm drain samples with EDTA or sodium thiosulfate were analyzed for toxicity using the echinoderm fertilization test.

EDTA addition test. A stock solution of EDTA was prepared and added into 30 ml unfiltered storm drain samples. The final concentrations of EDTA in the samples were 3, 8, and 30 mg/L. Three different concentrations, 12%, 25% and 56% (v/v) of storm drain sample, were prepared from these EDTA-added samples and used for the toxicity test.

Sodium thiosulfate addition test. A stock solution of sodium thiosulfate was prepared and added into 30 mls of unfiltered storm drain samples. The final concentrations of sodium thiosulfate in the samples were 10 and 25 mg/L. Similar to the EDTA addition test, three concentrations, 12%, 25% and 56% (v/v) of storm drain sample, were prepared and used for the toxicity test.

2.9 GC and GC-MS

GC. The three SPE fractions were first analyzed using a Varian Vista 6000 gas chromatograph equipped with a splitless injector and flame ionization detector (FID). A 30 m x 0.25 mm i.d. DB5.625 capillary column (J & W Scientific) was used to analyzed the non polar organic compounds (e.g., polyaromatic hydrocarbons) in the fractions. The GC temperature program was 40°C for 2 min., 40° - 140°C at 25°C/min., 140° - 290°C at 10°C/min., and 290°C for 20 min. The splitless injector and FID temperatures were 275°C and 300°C, respectively.

GC-MS. The SPE fraction(s) which show toxicity were analyzed by GC-MS to identify possible organic compounds present in that fraction. The GC-MS system used was a Finnigan 4000 Quadrapole mass-spectrometer with a Finnigan 9610 gas chromatograph. A Grob type splitless injector (at 290°C) was used for sample injection onto a 30 m x 0.25 mm i.d. DB-5MS capillary column (J & W Scientific). The GC temperature program was 30°C for 4 min., 40° - 300°C at 6°C/min. and 300°C for 30 min. Mass spectral data were collected by using a scan range of 35 - 500 amu and a scan rate of 1 scan/s.

3.1 Summary of Water Quality Data

Samplings were conducted from April 1992 to January 1993. The number of samples collected from each storm drain during this period are given in Table 3. The number of samples collected varied from location to location due to several factors. For example, no sample was collected from the storm drain at Ashland Avenue on several occasions due to seawater intrusion into the storm drain. More samples were taken from the Ballona Creek since it was the selected storm drain for the second phase of the toxicity testing.

As mentioned in the previous experimental sections, conventional water quality parameters (Table 1) of the collected samples were analyzed according to the *Standard Methods*. All the data collected between April 1992 and January 1993 for these five storm drains are tabulated in Appendix B. The mean and standard deviation of each analyzed water quality parameter are given in Table 3. From Table 3, it is observed that the water quality of the storm drain at Ashland Avenue is usually worse than the other four storm drains. Most of the analyzed water quality parameter concentrations from the Ashland Avenue storm drain are greater than the other storm drains. This poor water quality may be due to the storm drain condition. The Ashland Avenue storm drain is stagnant during low flow periods, due perhaps because of sand plugging its mouth (The Ashland Avenue drain, unlike the Pico-Kenter Drain, terminates at the surf line). During high tides, sea water may enter the drain, which was detected by high conductivity and total dissolved solids (TDS) concentration. Ashland Avenue is the only drain that has a tidal interaction (the sampling station on Ballona Creek is above the point of tidal interaction).

Table 3 also shows that samples from the Sepulveda Channel have high total dissolved solids (TDS) and hardness. The high TDS concentration results from ion exchange regeneration waters released by NPDES permit to this storm drain. The dissolved oxygen (DO) concentrations in Ballona Creek, Sepulveda Channel and Centinela Creek were often greater than the saturation concentration because of photosynthesis; both drains are open channels and had abundant algae during the sampling.

At various sampling times, the water quality of some of the storm drains was comparable or worse than typical secondary effluents. Table 4 shows the selected water quality comparison between the storm drain samples and typical secondary effluent. The secondary effluent parameters are typical of those plants which discharge into the storm drains in Los Angeles County. These discharges are regulated more strictly than other plants, due to the possibility of human contact in the open drain channels and infiltration into ground water basins. The results show that the chemical oxygen demand (COD) of water samples from Ashland Avenue is much greater than the value of typical secondary effluents prior discharge to the receiving waters. A similar observation was made on the total suspended solids (TSS) of the analyzed storm drain samples.

3.2 Hardness Interference

According to the *Standard Methods* (1989), the presence of certain metallic ions such as aluminum, cadmium, copper and lead may interfere the hardness test. Indistinct end-point

Table 3. Summary of water quality data (average and standard deviation) for the selected storm drains.

Parameters (1)	Pico-Kenter (2)	Ashland Avenue (3)	Ballona Creek (4)	Sepulveda Channel (5)	Centinela Creek (6)

or stochiometric consumption of EDTA may occur. False, high indications of total hardness may be obtained. This type of interference can be eliminated by adding certain inhibitors (i.e., sodium sulfide nonahydrate or sodium cyanide) as suggested by *Standard Methods*. It was observed that the total hardness of some samples from the Ashland Avenue, Ballona Creek and Sepulveda Channel were lower after addition of sodium sulfide nonahydrate. For example, the afternoon grab sample from Ballona Creek which was collected on December 14, 1992 had a total hardness of 1750 mg/L as $CaCO_3$ without addition of sodium sulfite nonahydrate. The total hardness of the same sample decreased to 1180 mg/L as $CaCO_3$ (~ 33% decrease) after adding the inhibitor. This indicates the presence of interfering ions such as aluminum, cadmium, copper or lead in those samples. Appendix C describes the effect of these interfering ions on the total hardness of some samples.

3.3 Mass Emissions

The velocity and depth of water in the Ballona Creek, Sepulveda Channel and Centinela Creek were measured during sampling. Figure 2 shows the cross-section of the Ballona Creek, Sepulveda Channel and Centinela Creek. The velocity and water depth measurements were used to calculate the flow rate of the water passed through the storm drain, using the following equation (1):

$$\textit{Flow rate}\ (\frac{ft^3}{s}) = \text{Area}\ (ft^2)\ \times\ \text{Velocity}\ (\frac{ft}{s}) \qquad (1)$$

The area of Sepulveda Channel and Ballona Creek (except the first and last 5 ft of Ballona Creek) was determined as follows:

$$\textit{Area}\ (ft^2) = \text{width}\ (ft)\ \times\ \text{depth}\ (ft) \qquad (2)$$

For the Ballona Creek, the areas of the first and last 5 ft sections were determined as follows:

$$\textit{Area}\ (ft^2) = \frac{1}{2}\ \times\ \text{width}\ (ft)\ \times\ \text{depth}\ (ft) \qquad (3)$$

The flow rate at the Centinela Creek was measured differently than the above two storm drains. Unlike Ballona Creek and the Sepulveda Channel which were divided into several small areas, there was only one area determined in the Centinela Creek in which Eq. (2) was used. The width across the low-flow channel in Centinela Creek at the point of measurement is 85 in.

Table 5 shows the flow rate of the Ballona Creek, Sepulveda Channel and Centinela Creek. It is observed that Ballona Creek has greater flow rate than Sepulveda Channel and Centinela Creek. The average flow rate during the sampling of Ballona Creek, Sepulveda

Channel and Centinela Creek are 3.37 ft^3/s, 0.85 ft^3/s and 1.18 ft^3/s, respectively (see Table 5). The calculated flow rate at Ballona Creek, Sepulveda Channel and Centinela Creek were then used to determine the annual mass emission of pollutants from dry weather flow into the Santa Monica Bay using the following equation:

$$\textit{Mass emission}\ (\frac{kg}{yr}) = \text{Concentration}\ (\frac{kg}{m^3}) \times \text{Flow rate}\ (\frac{m^3}{yr}) \qquad (4)$$

VOL 12
1
6566

The calculated average dry weather mass emission of pollutants (i.e., TDS, TSS, COD, NH_3-N and NO_2-N) from Ballona Creek, Sepulveda Channel and Centinela Creek are given in Table 6. The obtained results show that the mass emission of those selected pollutants from Ballona Creek are greater than those from Sepulveda Channel and Centinela Creek. No estimates are given for Pico-Kenter and Ashland Avenue storm drains as the flow rates were not determined in these two drains. The flow at Ashland Avenue was mostly stagnant during the dry season, suggesting that few pollutants from this storm drain were discharged into the Bay on a routine basis. It is assumed that the stagnant water was "blown out" from the drain from time to time due to release of the sand plug at the surf line; however no blow outs were observed during testing. The dry weather flow from the Pico-Kenter storm drain during the period of the study was discharged to the Hyperion treatment plant.

The flow rates reported in Table 6 vary from those indicated by the gauging stations on Ballona Creek. A review of the procedure and the gauging station data found no error in reporting or calculating flow rates. One possible source of error is a difference in calibration - the gauging station might be calibrated for wet weather flow.

The appearance of the drain water varied from drain-to-drain. The open channel drains (Ballona, Sepulveda, and Centinela) were usually clear in appearance except for algae. Strings and rafts of algae were routinely observed in these drains. The color was usually green but occasionally they were "sandy" colored. Pico-Kenter frequently appeared highly colored from high turbidity. The color was often light orange or tan, which suggest the presence of clays in the suspended solids. Ashland Avenue always appeared black or dark gray and frequently had an odor.

3.4 Toxicity

The following section summarizes the toxicity results of four storm drains, i.e., Pico-Kenter, Ashland Avenue, Ballona Creek and Sepulveda Channel. The detailed reports and raw data of the toxicity tests are included in Appendix D.

3.4.1 Phase I - Relative Toxicity of Storm Drains

The objective of this phase of toxicity testing was to determine the most toxic storm drain among these four storm drains (Centinela Creek was excluded from toxicity analysis), and also to determine the most sensitive test organism among the three test species. Four sampling periods were performed in this phase, i.e., August 24, September 8, September 29 and October 12, 1992. Sampling was performed on two locations on the August 24 (i.e., Pico-Kenter and Ashland Avenue) and September 8, 1992 (i.e., Ballona Creek and Sepulveda Channel). It was necessary to sample drains in pairs because only two sets of storm drains could be analyzed by SCCWRP at a time. The storm drain with the least toxicity from this first sampling was excluded from the next following toxicity tests.

Samples collected from the selected storm drains were tested for toxicity according to the previously described procedures. For each toxicity test, except the kelp germ tube test, the percentage response of the organisms at each tested dilution/concentration of the collected storm drain samples was calculated; for the kelp germ tube test, the mean length of the kelp germ tube was measured instead. These dose-response results were then plotted versus the various concentration of the samples {expressed in % of storm drain sample (v/v)} used in the toxicity tests. Figures 3 - 6 show examples of dose-response plots for abalone, sea

Table 7. NOEC and EC50 values for storm drains samples (Phase I).

Location	Sampling Date	NOEC				EC50			
		Abalone Development	Kelp Germ.	Kelp Length	Urchin Fertilization	Abalone Development	Kelp Germ.	Kelp Length	Urchin Fertilization
(1)	(2)	(3)	(4)	(5)	(6)	(7)	(8)	(9)	(10)
Pico-Kenter	Aug. 24 '92	18	>56	>56	>56	42	> 56	> 56	> 56
	Sept. 29 '92	nd	nd	nd	≥56	nd	nd	nd	> 56
	Oct. 12 '92	12	≥56	25	25	21	> 56	> 56	41
Ashland Avenue	Aug. 24 '92	<5.6	18	18	10	6.8	32	> 56	17
	Sept. 29 '92	nd	nd	nd	5.6	nd	nd	nd	14
	Oct. 12 '92	5.6	5.6	5.6	<5.6	10	22	50	< 5.6
Ballona Creek	Sept. 8 '92	>56	>56	>56	<5.6	> 56	> 56	> 56	14
	Sept. 29 '92	nd	nd	nd	12*	nd	nd	nd	> 56
	Oct. 12 '92	≥56	≥56	≥56	≥56	> 56	> 56	> 56	> 56
Sepulveda Channel	Sept. 8 '92	>56	>56	>56	10	> 56	> 56	> 56	nt

Note: All values are in % (v/v) of the storm drain samples. NOEC = the highest concentration not statistically different from controls; EC = effective concentration to cause 50% toxic effect; nd = not determined as technical difficulties prevented measurement of toxicity; nt = toxicity found but data not amenable to testing for EC50 (see Figure 2a); * = NOEC can also be stated as ≥56 since 56% concentration was not significantly different from respective brine control. A NOEC of 12 is felt to be more appropriate since 25% concentration was significantly toxic and 56% brine control was toxic, making accuracy Of 56% effluent results questionable.

VOL 12

1 6571

urchin, giant kelp germination and germ tube length tests (for samples collected on August 24, 1992).

From the dose-response data, EC50 values, i.e., the effective concentrations that caused 50% toxic effect on the test organisms, were calculated. The obtained EC50 values are used as the indicator of relative toxicity; lower EC50 values indicate greater toxicity. Table 7 shows the EC50 values obtained from the first toxicity testing for the collected samples of the four selected storm drains. The Ashland sample showed significant toxicity in three toxicity tests, except the kelp germ tube test. Both Pico-Kenter and Ballona Creek samples showed toxicity in one toxicity tests, i.e., abalone and urchin tests, respectively. The EC50 value of both abalone and germ growth tests for Ashland sample were lower than Pico-Kenter and Ballona Creek samples (EC50 values of greater than 56% indicate that no or very little toxicity present for the conditions tested).

In addition to EC50, another parameter was also obtained from the toxicity data, i.e., NOEC - the highest concentration not statistically different from controls. When both NOEC and EC50 values of a sample are 56%, they indicate that no toxicity is present in the sample. Little toxicity is said to be present in the sample when its NOEC value is <56%, and the EC50 of the sample is >56%. Table 7 shows an example of such observation. For the Ashland sample collected at August 24, the EC50 value of kelp germ tube test is >56%; however, the NOEC value of the same test is 18%. This result indicates that toxicity was present in the Ashland sample even though the EC50 value could not be determined.

The Sepulveda Channel sample collected on the September 8 has very little toxicity. The EC50 values were greater than 56% (see Table 7) and NOEC values for all toxicity tests, except urchin test, were greater than 56%. An inconsistent pattern of toxicity was found in the urchin test and thus the EC50 value was not able to be determined (see Figure 2a). Based upon these data, Sepulveda Channel was, therefore, excluded from subsequent toxicity tests.

As mentioned above, the second and third samplings of the Phase I toxicity tests were performed on the September 29 and October 12, 1992. Similar to the first toxicity tests, the percentage response of the organisms at each tested concentration (% in v/v) of the collected storm drain samples was calculated. However, only four instead of five concentrations (% in v/v) of the storm drain samples were used, i.e., 5.6%, 12%, 25% and 56%. Three replicates of each sample were conducted for each toxicity test. The EC50 values calculated from the dose-response data of the toxicity tests are shown in Table 7.

For samples collected on September 29, the EC50 of the abalone and kelp tests was not determined due to technical difficulties which prevented the measurement of toxicity. The EC50 could only be determined on the urchin test. Table 7 shows that Ashland Avenue sample had the lowest EC50 value, e.g., 14%, among the three storm drains tested. Very little toxicity was present in the samples collected from Pico-Kenter and Ballona Creek on Sept. 29, as shown by the EC50 of >56%. However, the NOEC of Ballona Creek sample was found to be 12% in the urchin test whereas NOEC of Pico-Kenter sample was ≥ 56%. Therefore, the Ballona Creek sample collected on Sept. 29 was more toxic than Pico-Kenter sample in the urchin test.

For samples collected on October 12, toxicity was detected in all four toxicity tests for Ashland Avenue sample. The Pico-Kenter storm drain tested toxic with all toxicity tests, except the kelp germination test (where both EC50 and NOEC were >56%). There was very little toxicity detected in all the toxicity tests for Ballona Creek samples. The NOEC and EC50 values obtained from the toxicity tests for samples collected on October 12 are also shown in Table 7.

VOL 12

3.4.2 Relative Toxicity

By using the obtained EC50 values from toxicity tests, the relative toxicity of Pico-Kenter, Ashland Avenue and Ballona Creek storm drains were assigned 3 for the most toxic to 1 for the least toxic storm drain for each toxicity test. For example, for samples collected on October 12, Ashland Avenue was the most toxic to the abalone test, followed by Pico-Kenter and Ballona Creek. Therefore, 3 was assigned to Ashland, 2 to Pico-Kenter and 1 to Ballona Creek. By using the same procedures, similar numbers were also assigned to all samples for all four toxicity tests and the results are shown in Tables 8 and 9. Table 8 shows the relative site toxicity ranks by species whereas Table 9 shows the relative rank test sensitivity to storm drain samples.

The Ashland Avenue storm drain was usually the most toxic to each test organism and consistently produced the greatest toxicity in all tests conducted. No clear distinction between the relative toxicity of the Ballona Creek and Pico-Kenter storm drains was observed. The abalone test was more sensitive to Pico-Kenter samples, with kelp test being the least sensitive. Ballona Creek samples produced the greatest toxic effects on sea urchin sperm while the abalone and kelp tests were unaffected by samples from this storm drain.

3.4.3 Phase II - Examination of Toxic Components

The objective of this phase of toxicity testing was to determine the type of compounds (e.g., organics or metals) that caused the toxicity in the selected storm drain. Based on the toxicity results from Phase I, the Ballona Creek storm drain and the sea urchin test were selected for this phase. Even though the relative toxicity of this location is not as great as Ashland Avenue, the annual input of runoff from Ballona Creek to Santa Monica Bay is much greater than the other storm drains, which means the mass emission from Ballona Creek will be much larger.

Three samplings were performed during this phase, i.e., on the November 23 and December 14, 1992, and January 19, 1993. The sampling procedures were slightly different than previous samplings. Grab samples from morning and afternoon were collected separately. Preliminary toxicity tests were performed on these two grab samples in order to determine which grab sample had a higher level of toxicity. Solid phase extraction (SPE) was then performed on the grab sample which exhibited greater toxicity. Samples collected from the extraction (e.g., SPE eluates, post C18, column blanks, etc.) were tested for toxicity. These tests were performed after the first rainfall of the 1992-93 water year, which occurred in late October. In order to insure that only dry weather flow was collected during sampling, the storm drain flow was monitored to insure that it returned to dry weather flow rates prior to sampling.

3.4.3.1 SPE Eluates

Currently, most of the methods used for toxicity-based (bioassay-directed) fractionations required the extraction of the sample with an organic solvent after some preliminary clean-up, and subsequent fractionation of the extract using normal-phase chromatography. The solvent systems used are extremely toxic to aquatic organisms (Burkhard *et al.*, 1991) and when these methods are used, solvent exchange and/or evaporation procedures are required before toxicity testing can be done. Losses of volatile toxicants can occur during these steps which may bias results

1 6574

The octadecyl (C18) solid phase extraction procedure used in this project was based on the method developed by Mount and Anderson-Carnahan (1989). This toxicity-based method has been successfully used to extract and fractionate non polar toxicants from the effluents for toxicity tests using cladocerans (water fleas) and fishes. In addition, low artifactual toxicity and excellent detection limits for gas chromatography/mass spectrometry (GC/MS) for toxicants identification can be obtained from this method. However, a preliminary recovery study showed that highly hydrophobic compounds such as chrysene and benzo(a)pyrene could not be eluted from the C18 sorbent by the elution solvents used by Mount and Anderson-Carnahan. Therefore a modified elution solvent system which consists of three fractions was developed for use on Phase II samples.

The first sampling of this phase was conducted on November 23, 1992. Preliminary toxicity results on the morning and afternoon grab samples showed that the afternoon sample produced toxic effects at concentrations ≥ 25%. Therefore, solid phase extraction procedures were used to concentrate the afternoon grab sample of Ballona Creek. In addition to the overall extraction procedures which were described in the experimental section, an additional sample manipulation was conducted. The pH of the sample was adjusted to pH 3 and pH 11 using 1N HCl acid and NaOH, respectively. Then samples with initial pH (pH_o), pH 3 and pH 11 were extracted using the C18 columns. The pH of deionized water used to prepare the filter and column blanks for the pH 3 and pH 11 samples was also adjusted prior to the extraction. During the solid phase extraction, two 30 ml samples of post C18 column effluents (i.e., after 25 mls and 950 mls of the sample passed through the column) were collected from each column. After the whole sample passed through the column and the column dried, 2 x 1.0 ml volume of six solvent mixtures were used to elute the sorbed organic from the C18 column. The solvent mixtures used for the elution of sorbed organics was 50%, 80%, 90% (v/v) of methanol in water, 100% of methanol, 10%, 20% and 50% (v/v) of methylene chloride in methanol.

Initially toxicity tests using the sea urchin were conducted on the filter blanks, column blanks and post C18 column effluents. Three concentrations were used, i.e., 12%, 25% and 56% (v/v) of storm drain sample. The results show that the pH_o filter and column blanks were highly toxic. Filter blank toxicity was also found at pH 3 and less at pH 11. Post C18 column effluent at pH_o was not toxic. In addition, a repeat of the baseline toxicity test with the Ballona Creek afternoon sample stored at SCCWRP showed a reduction of toxicity. Due to these bad results, it was suspected that toxicity may be introduced into the samples during the sample manipulations and extraction process. Therefore, it was decided that no further toxicity should be performed on the other samples, such as the SPE eluates, in order to save costs.

Two additional samples from Ballona Creek were collected on December 14, 1992 and January 12, 1993. The afternoon grab sample of December 14 and morning grab sample of January 12 were selected for the toxicity evaluation. Unlike the first sampling, the pH of the samples was not adjusted to either pH 3 or pH 11. Based on the earlier experience with the acute TIEs, it was found that major pH adjustment tests were not needed to characterize the toxicity of the sample (Norberg-King *et al*, 1992).

The solid phase extraction procedures used were as described in the experimental section. The three SPE eluates were then tested for toxicity using the urchin fertilization test. Two concentrations were used for the test, i.e., 0.1% and 0.2%, which corresponds to 50% and 100% (v/v) of storm drain sample, including the 500 fold increase obtained through the SPE procedures (the concentration factor of 500 times was obtained based on a sample volume of 1000 ml and elution volume of 2 ml). Table 10 shows the percentage fertilization of the SPE eluates (which has been normalized for blank response), post C18 effluents and the filtrates (pre-C18) of the Ballona Creek samples collected during this

Table 10. Toxicity results of C18 solid phase extraction (SPE) samples.

Jan. 19 '93 AM	50	30	16	88	100	52	56	93	100	72	43	20

Note: All values are the mean % fertilization of sea urchin of two replicates.

phase. The results show that the 100% methanol fraction was the most toxic among the three eluates for both sampling periods. Little or no toxicity was present in the first and third eluate. The results suggest that most of the toxicants were present in the 100% methanol fraction for both sampling periods.

Table 10 also shows the toxicity results of pre- and post C18 samples at the concentrations tested. For the December 14 afternoon sample, a decrease in toxicity was observed after the passing the sample through the C18 column. At the concentration of 56%, the post C18 sample showed greater percentage fertilization (76%) than the untreated (pre-C18) sample (which only has 15% fertilization). This observation suggests that the C18 column removed toxicity and organic toxicants were most likely present in the sample. For the January 19 morning sample, no reduction of toxicity was observed in the post C18 sample and only moderate toxicity was observed in the 100% methanol fraction. Normally this result would suggest the presence of non-organics (e.g., metals), which are not removed by the C18 column; however, in this case it is not conclusive due to poor fertilization in the column blank. The presence of metals and other toxicants such as oxidative compounds in the samples can be confirmed by the EDTA and sodium thiosulfate addition tests.

3.4.3.2 EDTA and Sodium Thiosulfate Addition Tests

The objective of EDTA addition test is to detect toxicity caused by certain cationic metals. Non-toxic complexes will be formed after EDTA addition to the collected storm drain samples. Loss of toxicity with EDTA addition suggests that cationic metals are causing toxicity. The sodium thiosulfate addition test can detect toxicity caused by oxidative compounds (such as chlorine) and other compounds (such as copper and manganese). Toxicity from bromine, iodine, ozone, and chlorine dioxide is also reduced by the addition of sodium thiosulfate (Norberg-King *et al.*, 1992). The toxicity results of EDTA and sodium thiosulfate addition tests are shown in Table 11. For the sample collected on December 14, sodium thiosulfate reduced toxicity while EDTA only partially reduced the toxicity. This indicates that oxidative compounds may have caused toxicity in the December 14 sample. Reverse results were obtained for the sample collected on January 19, 1993. High percentage fertilization (Table 11) was observed in the samples with added EDTA while low percentage fertilization was observed in the thiosulfate addition test. These results show that EDTA completely removed the toxicity of the January 19 sample while thiosulfate had no effect on the sample toxicity. Therefore, cationic metals may be present in the January 19 sample and thus causing the toxicity.

Table 11. Toxicity results of the EDTA and sodium thiosulfate addition tests.

Sampling Date	EDTA Addition			Thiosulfate Addition	
	3 mg/L	8 mg/L	30 mg/L	10 mg/L	25 mg/L
(1)	(2)	(3)	(4)	(5)	(6)
Dec. 14 '92	44	12	-	99	98
Jan. 19 '93	92	96	92	10	12

Note: All values are the mean value of % fertilization of sea urchin at a concentration of 56% (v/v) storm drain sample.

The toxicity results obtained from this phase were variable and not conclusive due to the small number of samples tested. For example, for December 14 sample, toxicity was found in the raw sample (pre-C18 sample), the 100% methanol eluate and EDTA addition test, whereas no toxicity was found in the thiosulfate addition test and post C18 sample. It is not clear what might cause this type of toxicity, but an organic oxidant is possible; it would be reduced by the thiosulfate and through adsorption onto the C18 column. Other possibilities also exist. More toxicity tests should be performed in order to determine these variabilities.

3.5 GC/MS Results

Tables 12 and 13 show the GC/MS results averaged over the period of the study. The results show many compounds that are potentially toxic to the marine organisms tested. Appendix E contains the GC/MS data for the separate samplings based on the parellel study performed by Suffet *et al* (1993). The absence of compounds does not assume that they were not present, but only that they were below detection limits.

No correlations were observed between the measured compounds and the observed toxicity.

4.0 DILUTION

The toxicity analyses presented earlier in this report show that dilution of the dry weather urban runoff with uncontaminated seawater can reduce toxicity to below detection limits. It was also observed that in some cases the toxicity in the storm drain sample disappeared after 2 or 3 days. This disappearance could be due to a chemical or biochemical detoxification reaction. For example, if free or combined chlorine were present in the urban runoff, it would decompose after a finite period of time, perhaps hours to one or two days, depending upon the concentration and type of chlorine residual. It is therefore reasonable to consider mixing and dilution as a best management practice. The initial dilution would protect aquatic species near the mouth of the storm drain and allow the toxicity-producing contaminants to decompose. For long lasting toxicity-producing contaminants, or for contaminants that might bioaccumulate, dilution might mitigate the immediate impact but would probably not prevent longer term impacts. For biodegradable contaminants, dilution could have a large beneficial effect.

A literature review was conduced to determine if previous research had been performed to determine dilution and initial mixing of a low flow rate, buoyant plume of fresh water entering sea water at surface level. No previous experimentally based research was found. Previous researchers (Stenstrom *et al.*, 1982), have suggested dilution as a best management practice, and a low flow diffuser has been installed at Pico-Kenter storm drain; however no quantitative experimental validation of the amount of dilution or anticipated benefits has been made.

A large body of research exists on deeper water diffuser systems, such as those used for the City of Los Angeles Hyperion treatment plant in El Segundo, the Los Angeles County Joint Water Pollution Control Plant in Carson and the Orange County Treatment Plant. These studies however are not directly applicable to storm drains discharging across beaches or small creeks flowing into coastal waters. One of the authors of this report has submitted a proposal to the USC Sea Grant program in order to study the initial dilution that occurs at the mount of a storm drain during wet and dry weather conditions. The results of this study, if funded, should provide experimental evidence of initial dilution of storm drains.

Woodward Clyde Consultants performed a "scoping" estimate of initial dilution of Ballona Creek as part of the Playa Vista Project. No experimental verification was performed, and they qualified their estimate for planning purposes only; however, their results and methodology provide the best estimate for dilution available at this time. They calculated a dilution based upon a dimensional analysis of the "near field" mixing and solved the diffusion equation to estimate "far field" dilution.

The near field effect is caused by the energy of the discharge (a jet or plume of fresh water entering saline water). They used a non-dimensional analysis using the Froude number, subject to the following assumptions:

- Steady-state conditions exist for the Bay as well as for the storm drain;
- The water depth of the Bay at the point of discharge is much deeper than the thickness of the plume of storm drain water;

- The shoreline is straight and storm drain and plume are perpendicular to the shoreline;
- The maximum concentration (minimum concentration) occurs along the shoreline;
- Mixing processes can be adequately characterized by a bulk dilution factor.

These assumptions are stringent and not fully applicable to the various storm drains that enter the Bay. For example, the Bay and the drains are in a constant state of flux. Tides and wind-induced currents are time-varying. The straight shoreline is not applicable to a situation where pockets or local stagnant zones are created by coastal structures or geometry of the shoreline.

WCC estimated the initial dilution factor from as follows:

$$S_s = F_o (b/h)^{0.25}$$

where,

S_s	=	Bulk dilution defined as the ratio of the local flow rate to the initial flow rate,
F_o	=	Froude number,
b	=	discharge half-width,
h	=	discharge depth.

Using this equation for Ballona Creek at a flow rate of 5,000 ft^3/sec, which is significantly more than its flow rate during dry weather conditions, they estimated a initial near field dilution of 1.2 to 1.9, and concluded that 1.5 was a reasonable estimate.

The far field dilution was estimated by assuming steady state conditions and modeling the flows and currents as a two-dimensional diffusion problem. In this approach, tides and wind-induced waves are treated as diffusion or dispersion, which are random in direction. They solved the two dimensional equations and performed a sensitivity study over a range of dispersion coefficients (D) from 0.01 to 0.00001 ft/sec. Over this range the far field dilution was estimated as 1 at D=0.00001 to 3 with D=0.01 at a distance of 5,000 feet from the Creek mouth. At 25,000 feet with D=0.01 the dilution increased to 9, but remained between 1 and 2 with D=0.00001.

The total dilution for a Ballona Creek, over the range of assumptions provided, ranges from 1 to perhaps as much as 20. These dilutions are far less than normally considered by the California Ocean Plan (e.g., 100 to 200), and far less than can be obtained with ocean outfall diffusers, such as those used at the large coastal wastewater treatment plants.

The dilution of dry weather flow, which is much less than the 5,000 ft^3/sec. flow rate used in the above analysis, should be significantly less for the near field, since there is very little energy contained in discharge (the discharge is not like a "jet" entering the shoreline), but perhaps greater for the far field, since there is much less volume entering the Bay.

It is concluded that no reliable quantitative estimates of low flow dilution of storm drain discharges can be made. Best available information suggests that 1 to 10 is the probable dilution. Undoubtedly dilution of storm drains like Pico-Kenter can be enhanced by devices such as a low-flow diversion that conveys dry weather flow across the beach and well into the surf. Further research is needed to adequately characterized initial dilution and its potential benefits.

5.0 CONCLUSIONS

Water quality of five storm drains and relative toxicity of four storm drains in Santa Monica Bay Watershed were analyzed during low flow (dry weather) conditions. The water quality of the selected storm drains varied during the sampling periods, and was often comparable or worse than typical secondary effluents. This indicates that it is just as important to control dry weather urban runoff as it is to control secondary effluents.

Short-term chronic toxicity tests also show that significant toxicity was present in the selected storm drains. Probable sources of the toxicity ranged from non-organic (e.g., metals and oxidizing compounds) to organic contaminants. More samplings are needed to determine the variability of the toxicity. Toxicity testing should also be included in monitoring programs of urban runoff. Further work to identify the toxic components through quantitative chemical analysis (such as gas chromatography/mass spectrometry for organics) are also needed. Dilution of 10 fold or more was usually sufficient to reduce toxicity to below detection limits. A survey of the literature to determine dilution of storm drains that enter coastal waters found very little information. For Ballona Creek, during wet weather flow, the dilution might be as much as 10 fold. Further research is needed to determine the likely dilution at the mouth of storm drains.

A large amount of dry weather water quality data was collected. This data set is larger and more complete than any available previously for a single Santa Monica Bay storm drain at a single location. The new data have been added to the combined data set assembled from agency monitoring data in an earlier report (Stenstrom and Strecker, 1993).

INTRODUCTION

Currently, most of the methods used for toxicity-based (bioassay-directed) fractionations require the sample extraction with an organic solvent after some preliminary clean-up, and subsequent fractionation of the extract using normal-phase chromatography. The solvent systems used are extremely toxic to aquatic organisms (Burkhard *et al.*, 1991) and solvent exchange and/or evaporation procedures are required before toxicity testing can be done. Losses of volatile toxicants can occur during these steps which may bias results.

After completing the development of the improved procedures, US EPA (Durhan *et al.*, 1993a, b) published an improved procedures which were nearly identical to the procedures we developed.

C18 SOLID PHASE EXTRACTION

The toxicity-directed method for fractionating non-polar organic toxicants using solid-phase extraction (SPE) described in phase II of EPA's "Methods for Aquatic Toxicity Identification Evaluations" (TIE) were used in this project. The proposed SPE method used octadecylsiloxane (C18) columns and an elution scheme with decreasing polarity. Prior to the extraction of actual storm drain samples, recovery studies using standard solutions of a combination of eight common polyaromatic hydrocarbons (PAHs) were performed. Modifications of the SPE procedures have been made based on the results of the recovery study in order to obtain good percentage recovery of PAHs from the C18 SPE columns. The following section described the rationale of the SPE procedures development which will be used for the actual storm drain samples.

EXPERIMENTAL PROCEDURES

Materials

SPE column. The 500 mg and 1000 mg octadecyl C18 columns used were obtained from Burdick and Jackson (Muskegon, MI)

Chemicals. Polyaromatic hydrocarbons (PAHs) mixed in the standard solutions, i.e., napthalene, 2-methylnapthalene, acenpathene, fluorene, anthracene, pyrene, chrysene and benzo(a)pyrene were obtained from Aldrich (Milwaukee, WI). The PAHs mixture in methanol was spiked into one liter deionized water.

Solvents. HPLC grade methanol, methylene chloride, hexane, carbon tetrachloride and isopropanol from Fisher Scientific (Tustin, CA) were used for SPE.

SPE procedures

The 1000 nmg C18 SPE column was conditioned with 25 ml of methanol and 25 ml of deionized water. Before the sorbent dried, 1000 ml standard water solution containing PAHs was then pumped through the column at a rate of 5 ml/min. The sorbent was dried by continuing the pumping for ~ 15 minutes after the whole 1000 ml sample passed through. Then 2 successive 1.0 ml volume of methanol/water, methanol and

VOL 12

1 6586

R0049891

methylene chloride/methanol were added sequentially into the column. Each fraction was collected separately into clean glass vials. The column was allowed to dry prior addition of each elution solvent mixture. The concentration of PAHs in each eluates were then analyzed using GC/FID. With the known initial concentration of each PAHs in the standard solution, the percentage recovery of each PAH was determined as follows:

$$\% \text{ Recovery} = \frac{\text{Concentration of PAH in eluate (GC determined)}}{\text{Expected concentration}} \times 100$$

Gas Chromatography Analysis

The SPE fractions were analyzed using a Varian Vista 6000 gas chromatograph equipped with a splitless injector and flame ionization detector (FID). A 30 m x 0.25 mm i.d. DB5.625 capillary column (J & W Scientific) was used to analyzed the PAHs in the fractions. The GC temperature program was 40°C for 2 min, 40° - 140°C at 25°C/min, 140° - 290°C at 10°C/min, and 290°C for 20 min. The splitless injector and FID temperatures were 275°C and 300°C, respectively.

The above procedure is a general description of C18 SPE procedures used in our recovery study. Changes on the elution volume and elution solvents were made when the effect of these parameter on the percentage recovery of PAHs were studied.

RESULTS AND DISCUSSION

Methanol as the Elution Solvent

Our first recovery studies used only one fraction of 2 x 1.5 ml of methanol to elute the sorbed PAHs from the 500 mg C18 column. The final concentrations of PAHs in the eluates collected from the 100 mg size columns were used to determine the recovery of the each PAHs. Low recoveries were obtained for most of the PAHs (Table A-1). Anthracene, acenapthene, fluorene and 2-methylnpathalene were recovered the most, greater than 40%. Both napthalene and benzo(a)pyrene have low recovery, less than 10%. It is suspected that the low recoveries might be caused by insufficient elution volume. Therefore, additional three successive 1.5 ml of methanol was used to elute the sorbed PAHs from the 500 mg and 1000 mg C18 columns. The obtained results only show slight improvement of the recoveries of PAHs (Table A-1). Therefore, it was suspected that maybe methanol might be too polar to be able to elute the strongly hydrophobic PAHs. Low recovery of napthalene may also due to it's loss through volatilization as napthalene is considered semi-volatile ($H_c = 0.018$).

To determine the suitability of methanol as the elution solvent for PAHs, an addition of 200 µL of methylene chloride was used to elute the sorbed PAHs from the 100 mg C18 columns after the first 300 µL methanol. The results show that PAHs were only partially desorbed from the C18 sorbent by 100% methanol. Subsequent addition of methylene chloride helped to further elute some of the PAHs. The overall recovery (combination of methanol and methylene chloride eluates) of PAHs improved for most of the PAHs. However, the percentage recovery of chrysene and benzo(a)pyrene was still not good (Table A-1).

The improvement of the percentage recovery of most of PAHs helps to reconfirm our suspicions of the weakness of methanol as the elution solvent for PAHs. Therefore, the effect of other solvents, i.e., hexane, carbon tetrachloride, methylene chloride and 2-propanol, as the elution solvent for PAHs was studied. However, only 1000 mg size columns were used as hexane, methylene chloride and carbon tetrachloride were not miscible in water. The percentage recovery of most of the PAHs approached 100% in the hexane, carbon tetrachloride and methylene chloride cases (Table A-2). The percentage recovery of benzo(a)pyrene has improved from about 20% to almost 50%. No improvement of the recovery was obtained by using 2-propanol as the elution solvent.

Even though strong non-polar solvents such as hexane, carbon tetrachloride and methylene chloride improved the recovery of the PAHs, these solvents are not desirable as the elution solvent as (1) they are not miscible in water, and (2) they are toxic to the marine organisms used in the toxicity tests. A solvent exchange procedure is usually required before they can be used in toxicity assays. An alternative elution solvent system which meet these two criteria is needed as preliminary results had shown that the proposed elution solvent system by Mount and Carnahan cannot elute PAHs from the C18 sorbent efficiently. The modified elution solvent include methanol-methylene chloride mixtures so that those strongly sorbed PAHs such as chrysene and benzo(a)pyrene can be eluted from the C18 sorbent.

Composition Methanol-Water and Methanol-Methylene Chloride

Preliminary tolerance tests for marine organisms showed that methanol-water, methanol, and methanol-methylene chloride were acceptable elution mixtures. However, it was very desirable to limit the quantity of methylene chloride to less than 0.1% in the toxicity assay. Therefore, different composition of methanol-water and methanol-methylene chloride as elution solvents were studied.

A total of six fractions were used to fractionate the PAHs from the C18 columns. Two different compositions of methanol-water and methanol-methylene chloride were studied, i.e., a 10% and 25% gap between each fraction. The 10% gap in the first proposed elution solvent system consisted of 80% and 90% of methanol (v/v) in water, 100% methanol, 10%, 20% and 50% methylene chloride (v/v) in methanol. The second proposed solvent system, which has a 25% gap between each fraction, consisted of 50% and 75% of methanol (v/v) in water, 100% methanol, 25%, 50% and 75% of methylene chloride (v/v) in methanol. The percentage recovery of the eight PAHs were determined in each fractions and compared. The results of the first and second proposed elution solvent systems are shown in Tables A-3 and A-4.

Table A-3 shows that more fractionation occurs in the 10% gap solvent system than the 25% gap system. It is observed that at least 3 distinct fractions could be collected in the 10% gap system (Table A-3). For example, both napthalene and 2-methylnapthalene were fractionated into the 2nd fractions (i.e., 90% methanol), while most of the acenapthene, fluorene, anthracene and pyrene were found in the 3rd fraction (i.e., 100% methanol). Both chrysene and benzo(a)pyrene were fractionated into the 4th fraction (i.e., 10% methylene chloride).

For the 25% gap elution solvent system, less fractionation of PAHs was observed (Table A-4). There were only two distinct fractions collected in this system. Most of napthalene, 2-methynapthalene, acenpathene, fluorene and anthracene were fractionated in the 3rd fraction (i.e., 100% methanol). Pyrene, chrysene and benzo(a)pyrene were found in the

4th fraction (i.e., 25% methylene chloride). There was no or insignificant PAHs found in the first and last two fractions.

Tables A-3 and A-4 also show that the overall percentage recovery of PAHs were greater in the 25% gap solvent system. However, as better fractionation of PAHs was obtained in the 10% gap system, it was decided that the composition of methanol-water and methylene chloride-methanol in the 2nd proposed elution solvent system will be used instead.

Elution Volume

The fractionation of PAHs caused by the volume of the elution solvent used was also studied. Two different elution volumes were compared, i.e., 2 x 1.0 ml and 2 x 1.5 ml of 80% and 90% of methanol (v/v) in water, 100% methanol, 10%, 20% and 50% of methylene chloride (v/v) in methanol. The results of the percentage recovery of PAHs using 2 x 1.0 ml and 2 x 1.5 ml of elution volume are shown in Tables A-3 and A-5. The total percentage of both volumes each PAH are quite similar, except for 2-methylnapthalene in which a total of 76% was recovered when 2 x 1.5 ml elution volume was used and only 46% was recovered when 2 x 1.0 ml of elution volume was used.

Tables A-3 shows that for the 2 x 1.0 ml elution volume, greater recovery was observed with 100% methanol fraction than 90% methanol. For the 2 x 1.5 ml elution volume (Table A-5), the opposite was observed. Few PAHs were recovered in the 80% methanol and 50% methylene chloride fractions (for both 2 x 1.0 ml and 2 x 1.5 ml cases). No conclusion can be made here regarding which volume is better, except the volume of solvent and solvent make up can interact to effect recovery.

Based on the results of the above mentioned recoveries, it was decided to use the following elution scheme for the fractionation of PAHs from the C18 columns: 2 x 1.0 ml of 80% and 90% of methanol (v/v) in water, 100% methanol, 10%, 20% and 50% of methylene chloride (v/v) in methanol. The following section discussed the repeatability of this modified system based on a total of eight similar extractions.

Repeatability of the Modified Elution Solvent System

As mentioned in the above sections, the modified elution solvent system consists a total of 6 fractions, i.e., 2 x 1.0 ml volume of the following solvents: 80% and 90% methanol (v/v) in water, 100% methanol, 10%, 20% and 50% methylene chloride (v/v) in methanol. A total of 8 extractions were conducted to determine the variability SPE procedures using the modified elution solvent system. The extraction procedures of these extractions were identical except for the concentration of PAHs. For each extraction, the concentration of all PAHs, except benzo(a)pyrene were equal; the range of concentrations of each PAH (in the water solution) was varied from 10 µg/L to 40 µg/L. The concentration of benzo(a)pyrene ranged from 20 µg/L to 80 µg/L. The average percentage and standard deviation of each PAH recovery in each SPE fraction obtained from 8 extractions are shown in Table A-6. Repeatability of the extraction procedures, as measured by the standard deviation of the recovery, was generally within 5% for fluorene as the most repeatable, and 21% for 2-methylnapthalene as the least repeatable.

From Table A-6 it is observed that the 80% methanol-water fraction (1st fraction) eluted no PAHs. Most of the napthalene was recovered in the 90% methanol fraction (2nd fraction). Anthracene, fluorene and acenapthene were eluted almost entirely in the 100% methanol fraction (3rd). 2-methynapthalene, pyrene, chrysene and benzo(a)pyrene were not well separated. Table A-6 also shows that elution with methylene chloride (4th and 5th fractions) is required to recover those PAHs with high log K_{ow} value (such as chrysene and benzo(a)pyrene). Most were recovered with a maximum of 20% methylene chloride. The sequence of PAHs elution from the C18 column is also shown in Figure 1.

CONCLUSIONS

Based on the results of the recovery studies using eight commonly detected PAHs, a modified elution solvent system consists of six fractions of methanol-water, methanol and methylene chloride mixtures was developed, i.e., 2 x 1.0 ml of 80% and 90% of methanol (v/v) in water, 100% methanol, 10%, 20% and 50% of methylene chloride (v/v) in methanol. Three distinct groups of PAHs were obtained from the C18 column when this elution solvent system was used: napthalene in the 90% methanol fraction; acenapthene, fluorene and anthracene in the 100% methanol fraction, and chrysene and benzo(a)pyrene in either 10% or 20% methylene chloride fraction. The repeatability of the extraction was within the range of 5-21%.

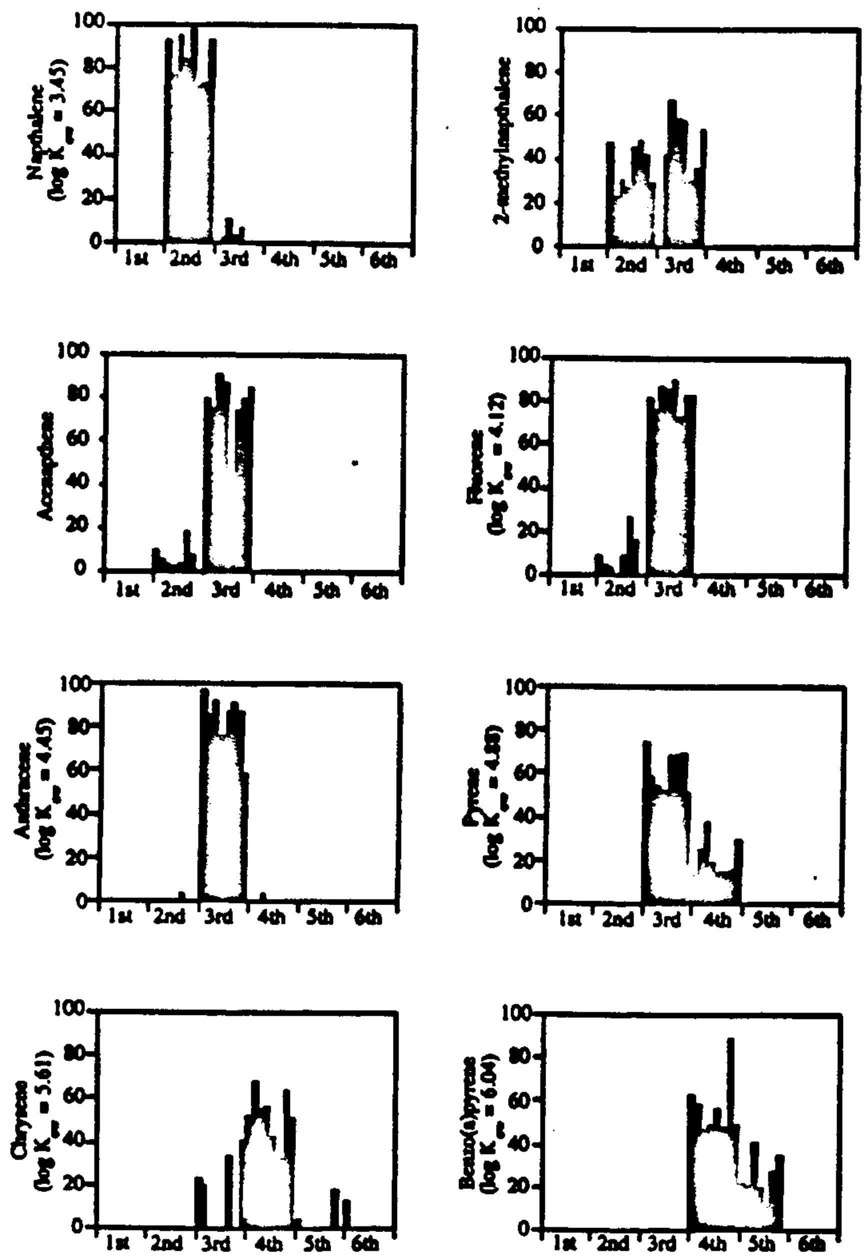

Figure A-1. C18 SPE modified elution scheme. The vertical axis represents the percent recovery of each PAH in each fraction. 1st: 80% methanol in water; 2nd: 90% methanol in water; 3rd: 100% methanol; 4th: 10% methylene chloride in methanol; 5th: 20% methylene chloride in methanol; 6th: 50% methylene chloride in methanol.

Table A-1. Total percentage recovery of PAHs from initial SPE recovery studies.

PAHs compounds (1)	1st Recovery 500 mg C18 (2)	2nd Recovery 500 mg C18 (3)	2nd Recovery 1000 mg C18 (4)	3rd Recovery* 1000 mg C18 (5)

INTRODUCTION

According to *Standard Methods*, the presence of some metal ions such as Al, Cd, Cu, and Pb can cause interference in the hardness analysis. Indistinct end-point or stochiometric consumption of EDTA may happen. These interferences may be reduced by adding certain inhibitors. There are three types of Inhibitors suggested by *Standard Methods*, i.e.,

1. Inhibitor I: Sodium cyanide
2. Inhibitor II: Sodium sulfide nonahydrate ($Na_2S.9H_2O$) or $Na_2S.5H_2O$
3. Magnesium salt of 1,2-cyclohexanediaminetetraacetic acid (MgCDTA)

Due to the unavailability of MgCDTA, it was decided to test the effect of Inhibitors I and II on the hardness test.

EXPERIMENT I

Sample: Ballona Creek @ Inglewood (sampled on 12/14/92)

Inhibitor: Inhibitors I and II

Hardness Results:

Table C-1. Total hardness results from Experiment 1.

Sample (1)	Without Inhibitors (2)	Inhibitor I (3)	Inhibitor II (4)
Morning	860	832	619
Afternoon	1750	1700	1180

Note: All values are in mg/L as $CaCO_3$

Discussion

From Table C-1, total hardness of Ballona Creek samples collected in the morning and afternoon, without addition of either inhibitor, was 860 and 1750 mg/L as $CaCO_3$, respectively. When Inhibitor I (250 mg/ 50 ml diluted sample) was added into these samples, a slight decrease of the total hardness was observed (~ 3%). With Inhibitor I, the total hardness of the morning sample was 832 mg/L as $CaCO_3$ whereas the afternoon sample has total hardness of 1700 mg/L as $CaCO_3$. Different observations were made in the samples with the addition of Inhibitor II. When 1 ml of Inhibitor II solution was added into 50 ml of the diluted samples, a decrease of total hardness to 619 and 1180 mg/L as $CaCO_3$ was observed for morning and afternoon samples, respectively (~ 28 - 33% decrease). Therefore, it is concluded that significant interfering metal ions (such as Al, Pb, Cu, Cd and Zn) were presence in the Ballona Creek samples, causing false high value of total hardness.

VOL 12

1 6604

EXPERIMENT 2

Sample: Standard solution of Ca and Mg (mixture) (Concentration: 108 mg Ca/L and 82 mg Mg/L with a theoretical hardness of 606 mg/L as $CaCO_3$; 1000 ppm Ca and Mg reference solutions were used to prepare this standard solution)

Inhibitor: None

Hardness results:

Table C-2. Total hardness results from Experiments 2 and 3.

	Ca and Mg standard solution		
	Without interfering ions (1)	With interfering ions (2)	With interfering ions + Inhibitor II (3)
Total hardness (mg/L as $CaCO_3$)	625	895	650

EXPERIMENT 3

Sample: Same concentrations of Ca and Mg except with addition of the following ions:

Al ~10 mg/L
Cd ~13 mg/L
Cu ~10 mg/L
Pb ~13 mg/L
Zn ~111 mg/L

Inhibitor: Inhibitor II

Hardness results: See Table C-2

Discussion

Table C-2 shows that total hardness of the standard solution with added interfering ions, without adding Inhibitor II, was 895 mg/L as $CaCO_3$. By comparing these total hardness results with those obtained from Experiment 2, we can conclude that the presence of these ions increased the consumption of EDTA and gave false high results of total hardness measurement. Another observation was noted during the titration. The sharp end-point of the indicator was absent. The presence of these interfering ions may also cause an indistinct end-point. By adding Inhibitor II before titration these interferences were reduced. Table C-2 shows that total hardness of the standard solution after addition of Inhibitor II decreased from 895 mg/L to 650 mg/L as $CaCO_3$. Thus it can be concluded that Inhibitor II reduces the interferences caused by the above mentioned metal ions.

Due to the above observation, analysis of total hardness of previous samples from Sepulveda Channel, Ballona Creek and Ashland (with suspected high content of total hardness) were repeated. The total hardness results without the addition of Inhibitor II were compared with total hardness of those samples analyzed with Inhibitor II. The purpose of this comparison was to determine the presence of the any interfering metal ions (such as Al, Cu, Cd, Zn, Pb, etc.). It is important to note that some of these samples may deteriorated due to the long storage period (~ 1-2 months).

EXPERIMENT 4

Sample: Ca and Mg standard solution (no interfering ions)

Inhibitor: Inhibitor II

Results:

Table C-3. Comparison of total Hardness of Ca and Mg standard solution with and without using Inhibitor II.

	Ca and Mg standard solution	
	Without Inhibitor II (1)	With Inhibitor II (2)
Total hardness (mg/L as $CaCO_3$)	620	620

Discussion

Table C-3 shows that Inhibitor II does not affect the total hardness results if none of the interfering ions are present in the sample. The total hardness of Ca and Mg standard solution without addition of Inhibitor II is the same as the total hardness of standard solution which has added Inhibitor II.

EXPERIMENT 5

Sample: Previous samples from Sepulveda Channel @ Ballona Creek, Ballona Creek @ Inglewood and Ashland
Note: Almost all of the Sepulveda Channel samples were re-analyzed, except sample taken on 11/2/92 which was unavailable. Only a subset of the Ballona Creek samples (which had total hardness of > 500 mg/L as $CaCO_3$) were analyzed. Previous results show that three Ashland samples have a total hardness of > 1000 mg/L as $CaCO_3$. However, only two Ashland samples were analyzed as the sample from 11/2/92 was not stored.

Inhibitor: Inhibitor II

Results: See Tables C-4 (Sepulveda Channel), C-5 (Ballona Creek) and C-6 (Ashland)

VOL 12

1 5607

Discussion

Tables C-4, C-5 and C-6 show that the total hardness of the stored samples (which were stored for more than 1-2 months) of Ballona Creek and Sepulveda Channel, without addition of the Inhibitor II, are quite similar to those results obtained previously. After addition of Inhibitor II, the total hardness of some samples was reduced, which indicates that some interfering metal ions were present. Almost all the Sepulveda Channel samples (except sample which was taken on 6/12/92) have reduced total hardness (about 20-30% reduction) (Table C-4). For Ballona Creek samples, only half of the samples analyzed were found to have reduced total hardness results with the addition of Inhibitor II (Table C-5). The percentage reduction of these samples is less than those in the Sepulveda Channel samples, i.e., about 10-15% only. This shows that the amount of interfering ions present in the Ballona Creek samples is less than those in the Sepulveda Channel samples.

Unlike Ballona Creek and Sepulveda Channel samples, the total hardness results for stored Ashland samples, without the addition of Inhibitor II, were quite different from those obtained previously. For example, the total hardness of Ashland sample dated 9/29/92 increased from 1286 mg/L to 1670 mg/L as $CaCO_3$ after the sample was stored for nearly 3 months. This dissimilarity may be due to deterioration of Ashland samples. However, the purpose of this experiment was to determine the presence of interfering ions in the sample that may cause the false results of total hardness test. The results show that interfering ions are present in two Ashland samples as the total hardness was reduced after addition of Inhibitor II (Table C-6).

Table C-4. Total hardness of Sepulveda Channel @ Ballona Creek samples.

Sampling date (1)	Previous analysis (2)	Total hardness ($CaCO_3$) Repeated analysis: Without Inhibitor II (3)	Total hardness ($CaCO_3$) Repeated analysis: With Inhibitor II (4)
6/12/92	1364	1370	1350
7/7/92	1570	1440	1090
7/27/92	750	780	690
8/24/92	2100	2080	1390
9/8/92	1434	1340	1015
9/29/92	818	870	795
10/12/92	1524	1490	1150
11/2/92	3113	-	-
12/10/92	1444	1330	1085

Table C-5. Total hardness of Ballona Creek @ Inglewood samples.

Sampling date (1)	Previous analysis (2)	Total hardness (mg/L as $CaCO_3$) Repeated analysis: Without Inhibitor II (3)	Total hardness (mg/L as $CaCO_3$) Repeated analysis: With Inhibitor II (4)
8/24/92	628	600	600
9/8/92	594	650	580
9/29/92	1082	1000	870
11/2/92	720	560	560
12/10/92	808	920	800

Table C-6. Total hardness of Ashland Avenue samples.

Sampling date (1)	Previous analysis (2)	Total hardness (mg/L as $CaCO_3$) Repeated analysis: Without Inhibitor II (3)	Total hardness (mg/L as $CaCO_3$) Repeated analysis: With Inhibitor II (4)
9/29/92	1286	1670	1280
12/10/92	1680	1810	1215

CONCLUSION

It is suspected that interfering ions such as aluminum, cadmium, copper and lead were present in some of the samples collected from Ashland, Ballona Creek and Sepulveda Channel. The total hardness results obtained from samples in the absence of inhibitor sodium sulfide nonahydrate was found to be higher than those samples that had added the inhibitor.

VOL 12

APPENDIX D1
TOXICITY ANALYSIS OF
STORM DRAIN DRY WEATHER FLOW
SAMPLES COLLECTED 8/24 AND 9/28/92

INTRODUCTION

This report summarizes the results of marine toxicity tests conducted on samples of dry weather flow collected from four storm drains in Los Angeles (Ashland, Ballona Creek, Pico-Kenter, and Sepulveda). The intent of these experiments was to determine the concentration of effluent (diluted with seawater) that caused a 50% response in the test organisms (EC50) and also the highest concentration that did not cause a statistically significant level of toxicity (NOEC).

METHODS

Three species were used for toxicity testing. These were giant kelp (*Macrocystis pyrifera*), red abalone (*Haliotis rufescens*), and purple sea urchins (*Strongylocentrotus purpuratus*). Toxicity tests were conducted in accordance with the methods described in the State of California's Ocean Plan wherever possible. The prinicpal deviation from these methods was the degree of replication used. Three instead of the recommended five replicates were tested for each effluent concentration. Replication was reduced in response to the EPA's (Region IX) request to increase the number of concentrations tested.

Storm drain samples were stored under refrigeration in sealed 4 L glass bottles until the day of testing. Tests were initiated within 48 hours of sample collection. Samples were thoroughly mixed before a 2.5 L subsample was removed and filtered through Whatman GF/B glass fiber filters. Samples from two locations (Ashland and Pico-Kenter) were centrifuged (3,200 x g for 10 min) prior to filtration to remove large particulates.

Seawater dilutions of each sample were prepared by adding appropriate amounts of seawater and brine solutions to create the desired concentrations and maintain a salinity of 32-35 mg/g. Concentrations containing 5.6, 10, 18, 32, and 56% storm drain effluent were prepared for each location. Toxicity test organisms were added to each sample within three hours of dilution. The pH of some dilutions of the Ballona and Sepulveda effluents was adjusted by addition of 0.2 N HCl in order to maintain a pH range of 7.9-8.3.

Several dilutions of unfiltered samples were also prepared to examine potential changes in toxicity related to filtration. Only one replicate was prepared for each of these samples. Brine controls (containing the same volumes of brine added to the three highest concentrations of storm drain effluent) were prepared to identify test effects related to the salinity adjustment method.

The dissolved oxygen, pH, and total ammonia content of a subsample of each effluent dilution was measured at the start of the toxicity tests. Measurements were made using electrodes that were calibrated daily. Oxygen and pH measurements were also made at the termination of each 48 hour test. Separate measurements were made on solutions obtained from kelp and abalone test beakers. Temperature within selected test chambers was measured daily with a mercury thermometer during the 48 hour tests. Water temperature

1 6609

during the sea urchin fertilization test was measured in a test tube placed alongside the rack containing the test samples.

A concurrent reference toxicant test was run for each of the different toxicity tests. Seawater dilutions of copper chloride were used in the sea urchin and kelp reference toxicant tests. Zinc sulfate was the reference toxicant for the abalone test.

RESULTS AND DISCUSSION

Water Quality

Initial water quality measurements indicated that the undiluted samples were of low salinity (Table D1-1). Seawater brine was added during dilution preparation so that most of the diluted samples had a salinity of 34 mg/g (Appendix Tables D1.a-1 and a-4). Insufficient brine was available to fully adjust the Ashland 56% dilution to normal seawater salinity. The final salinity of this sample was 32 mg/l, a level still within the tolerance range of the test organisms.

Initial pH was elevated in the Ballona Creek and Sepulveda samples (Table D1-1). The 32 and 56% dilutions of these samples had unacceptably high pH values as a result. A small amount of HCl was added to these dilutions to reduce the pH and thus minimize toxicity artifacts during the tests.

Dissolved oxygen and ammonia concentrations were also measured on the sample dilutions (Tables D1.a-1 - a-6). Oxygen was within an acceptable range for all dilutions. Ammonia was elevated in dilutions of Ashland effluent only. These ammonia concentrations may have contributed to the toxicity of Ashland effluent to abalone. The measured concentrations of ammonia are not likely to have produced toxic effects on sea urchin sperm or kelp spores.

Kelp and abalone test chamber temperatures were generally within the desired range of 14-16°C (Tables D1.a-2, a-3, a-5, and a-6). Excessive temperatures were measured during the first day of the August 26-28 kelp test. Heat generated from the increased illumination required for this test was responsible for this situation. Temperatures were successfully reduced and stabilized after this situation was discovered. The control and reference toxicant results for this test are within the expected ranges, indicating that the temperature deviation did not seriously affect the test. Temperatures during the August and September sea urchin tests were 15.5 and 14.6°C, respectively.

Sea Urchin Toxicity

Results of sea urchin fertilization toxicity tests are summarized in Tables D1-2 and D1-3. Control fertilization was 89-98%, well within the desired range of 50-100%. Effluent from Ashland, Ballona, and Sepulveda storm drains were toxic to sea urchin sperm. Examination of the NOEC and EC50 statistics (Table D1-4) indicates the relative toxicity of each site. Fertilization was inhibited at concentrations ≥ 5.6% for Ballona and > 10% for Ashland and Sepulveda.

The EC50 (when available) is the best indicator of relative toxicity; lower EC50 values indicate greater toxicity. Ballona was the most toxic station, with an EC50 of 14%.

Ashland was slightly less toxic and Sepulveda had the lowest toxicity of the three stations producing an effect on sea urchin fertilization. An unusual dose-response pattern was found for the Sepulveda sample (Figure D1-1), an increase in fertilization relative to the value at 18% (instead of a decrease) was measured for the 32% concentration. Consequently, an EC50 could not be calculated for Sepulveda.

Additional treatments (brine controls, unfiltered samples, and egg controls) were tested to determine the impact of various aspects of the testing procedure. Brine controls at the 56% water concentration were toxic to sea urchin sperm.. This result was not unexpected, as the sea urchin fertilization tests is very sensitive to most salinity adjustment procedures. Brine toxicity did not influence the results of the tests, however, since storm drain effluent toxicity was found at concentrations much lower than those containing toxic concentrations of brine.

Several dilutions of unfiltered effluent were tested to determined if the filtration step had a substantial effect on toxicity. The Ashland sample caused greater effects on fertilization in the unfiltered state. Results for the filtered and unfiltered samples from the other locations were similar.

Egg controls (no sperm added during test) were incorporated at EPA's request. Results for the egg controls indicate that there was no false fertilization caused by the storm drain samples or the handling of the egg solution.

<u>Abalone Toxicity</u>

Toxicity to red abalone embryos was caused by exposure to effluent from the Ashland and Pico-Kenter locations (Table D1-5). Effluent from Ballona Creek and the Sepulveda Channel did not produce toxicity at the concentrations tested (Table D1-6). Ashland effluent was more toxic than Pico-Kenter effluent, as can be seen from examination of the dose-response plots (Figure D1-1) and NOEC and EC50 statistics (Table D1-4). The lowest concentration of Ashland effluent tested (5.6%) caused significant toxicity to the abalone.

There was no toxicity associated with the use of brine in the abalone toxicity tests. Unfiltered effluent from Pico-Kenter appeared to produce greater toxicity than did similar concentrations of filtrate (Table D1-5). Toxicity results for unfiltered samples from the other locations were similar to those obtained for filtrates.

<u>Kelp Toxicity</u>

Two endpoints were assessed during the kelp spore toxicity tests. Both spore germination percentage and length of the germ tube were significantly reduced by exposure to Ashland effluent (Tables D1-7 and D1-8). The kelp test was the least sensitive of the three toxicity tests, as shown by the relatively high Ashland NOEC and EC50 values.

Exposure of kelp spores to effluent from Pico-Kenter, Ballona, and Sepulveda did not produce any toxicity at the dilutions tested Tables D1-7 -10). Many of the test concentrations produced germ tube lengths greater than the corresponding reference groups (Figure D1-2). This situation is occasionally encountered in tests where growth is measured. Increased growth in a toxicity test is usually regarded as an overcompensation to a small stress. Another possibility is that germ tube growth was influenced by nutrients present in the storm drain effluents.

The brine control results indicated an inhibitory effect on germination at the 18% concentration during the September 9, 1992 experiment (Table D1-9). Higher concentrations of brine did not produce similar effects, indicating toxicity was caused by something other than the brine. The brine results did not affect the interpretation of the data since the effluent samples did not cause toxicity. Brine effects were not indicated for the other test time or endpoint.

The effect of filtration on Ashland toxicity to kelp spores could not be assessed. The high concentration of particulates in the dilutions tested prevented settlement of the spores on the glass slides used for measurement of germination and germ tube length.

Table D1-1. Summary of initial water quality data for undiluted storm drain effluent samples. Measurements were made on the day of toxicity test initiation. Values are expressed in percent effluent. Salinity is expressed as mg/g.

INTRODUCTION

This report summarizes the results of marine toxicity tests conducted on two samples of dry weather flow collected from three storm drains in Los Angeles (Ashland, Ballona Creek, and Pico-Kenter). These tests were a continuation of work initiated in August, 1992. The objective of the tests described in this report was to collect additional toxicity data for use in determining the most toxic location and relative sensitivity of the test species used. Reference toxicant results for all tests conducted to date are also summarized in this report.

METHODS

Storm drain dry weather flow samples were collected on September 29 and October 12, 1992. Basic test methods were essentially the same as described in the previous report dated September 29, 1992. The number of dilutions tested was reduced to four (instead of five) and the concentrations used previously (5.6, 10, 18, 32, and 56%) were changed. Concentrations containing 5.6, 12, 25, and 56% storm drain effluent were prepared for each location.

Toxicity tests of samples collected September 29, 1992 were initiated on two successive days. Filtrate prepared on the first day (abalone and kelp tests) was stored at 5°C and used to prepare fresh effluent dilutions for the second day's work (sea urchin test). All three toxicity tests of the October 12, 1992 samples were initiated on the same day. Toxicity tests were initiated within 48 hours of sample collection in all cases.

Abalone and kelp toxicity tests of the September 29 sample were judged unacceptable because of poor control performance. Consequently, only limited water quality and microscopic analyses of these tests were performed. NOEC and EC50 values were not calculated for these data. An additional set of kelp and abalone toxicity tests was conducted on the October 12 sample in order to complete the initial phase of the project.

RESULTS AND DISCUSSION

Water Quality

The initial pH of undiluted Ballona Creek effluent was high (Table D2-1) and similar in value to the first sample tested. The pH values for the 56% Ballona test concentrations were unacceptably high (> 8.3) and were adjusted with dilute HCl before use (Appendix Tables D2.a-1 and a-2). The pH of samples from Ashland and Pico-Kenter were lower (Table 1) and did not produce unacceptable values once diluted with seawater.

Salinity of Ballona and Pico-Kenter effluents were low (Table D2-1) and similar to the values measured previously. The salinity of Ashland effluent was elevated on both sampling occasions, probably because of tidal seawater intrusion. Adjustments made during the preparation of effluent dilutions eliminated salinity variations in the test solutions Tables D2.a-1 and a-2).

All experiments except the October 1 sea urchin fertilization test were conducted at temperatures of 14-15°C. The exposure temperature for the October 1 sea urchin test was 11.8°C. Temperature during the October 13 sea urchin experiment was 14.5°C. Fluctuations in temperature were well within the tolerance range of the test species and were not likely to cause undesirable levels of stress. Concurrent reference toxicant test data indicate that the test sensitivity did not vary greatly as a result of this temperature difference. Other water quality measurements of test solutions at the beginning and end of the toxicity tests indicated that acceptable conditions were present during all of the tests (Tables D2.a-1 - a-4).

Relative Toxicity

Effluent from the Ashland storm drain had the greatest relative toxicity on both sampling occasions (Table D2-2). EC50s for this location ranged from 10% (abalone) to 22% (kelp). Ballona Creek effluent was least toxic of the three sites. No toxicity was found in the October sample and relatively minor toxicity was measured in the September 29 Ballona Creek sample. Pico-Kenter effluent from September 29 was not toxic to sea urchins (only test completed). The October sample produced intermediate toxic responses in all three test species, with EC50s ranging from 21% (abalone) to >56% (kelp).

Sea urchin toxicity

The sea urchin test was the only test conducted on the 9/29 sample that had acceptable control performance. A small reduction in fertilization was measured in one of the brine controls (56%, Table D2-3). Effluent from the Ashland drain was most toxic, producing reduced fertilization at concentrations of 12% and above. No toxicity was produced by exposure to Pico-Kenter effluent. An unusual dose-response pattern was obtained for the Ballona Creek sample. Significant toxicity was measured at a concentration of 25%, but not at 56%. The reason for this occurrence is not known, although it may be the result of an interaction between the effluent and the brine solution used to adjust salinity.

Fertilization test results for the 10/12 samples indicated toxicity for Ashland and Pico-Kenter only (Figure D2-1). Seawater and brine control results were within the desired range (Table D2-4). No fertilization was observed in any of the test samples exposed to Ashland effluent. Consequently, there was no need to conduct statistical tests on these data.

Abalone toxicity

Poor quality gametes were used in the abalone toxicity test of the 9/29 samples, resulting in poor control embryo development (Table D2-5). A few samples from this experiment were examined in order to estimate the relative toxicity of the samples. These data indicated that Ashland was toxic at 12%, some toxicity was present at Pico-Kenter, and no toxicity was evident at Ballona Creek (Figure D2-1). These accuracy of these results is uncertain because of the poor control results and limited number of samples examined.

Much better control results were obtained in the toxicity test of the 10/12 samples (Table D2-6). Control survival (68%) was still below the acceptable limit of 85% used for compliance monitoring purposes. Poor embryo development was also observed in the brine control for the 56% concentration. It was not felt that the low control survival would eliminate the usefulness of this test and all samples were therefore examined. This decision was supported by the reference toxicant test results, which indicated that the sensitivity of this test was within acceptable limits. Abalone embryo toxicity was produced by the Ashland and Pico-Kenter samples, but not Ballona Creek. This is similar to the pattern suggested by the aborted test of the 9/29 samples. Ashland was most toxic, with significant embryo deformities caused by exposure to 12% effluent.

Kelp toxicity

Spore germination in controls for the toxicity test of the 9/29 samples was very low and indicated that the test results could be unreliable. Control germ tube length measurements were within normal limits, however, and a limited number of samples were measured to estimate the relative toxicity of each site (Table D2-7). No indication of substantial toxic effects on germ tube length was found for any of the storm drain sites. Even Ashland, typically the most toxic site, produced only a slight reduction in length (Figure D2-2).

Control germination and tube length during the test of the 10/12 samples were higher and within acceptable limits. Germination was only reduced by Ashland effluent concentrations of 12% and above (Table D2-8). Reductions in germ tube length were produced by the brine, 12% and greater concentrations of Ashland effluent, and 56% Pico-Kenter effluent (Table D2-9). The dose response plots for these samples were typical in appearance (Figure D2-3).

Reference toxicant results

An important part of the QA/QC effort for this project was the testing of a concurrent reference toxicant dilution series for each species and sample investigated. The reference toxicant results are intended to document the relative sensitivity of the test species between experiments. Results for all of the reference toxicant tests are summarized in this report (raw data is available upon request). Corresponding storm drain effluent toxicity test data for the first sampling period (8/24 & 9/8) are described in the previous report dated 9/29/92.

Zinc was the reference toxicant used for the abalone toxicity tests. Reference toxicant results (NOEC) for experiments conducted on 8/26, 9/9, and 10/13 were all within limits stated in the test procedure.

Copper was used as the reference toxicant in the kelp toxicity tests. Experiments conducted on 9/9 and 10/13 were within the desired range, but the NOEC for the 8/26 test was above the acceptable limit. These results indicate that the 8/26 kelp test of Ashland and Pico-Kenter samples may have been less sensitive than subsequent experiments. It should be emphasized that there is no guarantee that the reference toxicant results bear any relation to variations in the actual sensitivity of kelp spores to storm drain effluents. The measured toxicity to kelp of Ashland and Pico-Kenter samples tested on 8/26 and 10/13 was very similar, suggesting that the 8/26 data are of acceptable accuracy.

Sea urchin fertilization reference toxicant tests also used copper. Results for this group of tests are presented as the EC50 and compared to SCCWRP data for the previous two years.

An acceptable range of response for the sea urchin test has not yet been developed. As a substitute, the data are plotted as quality control charts using ± 2 standard deviations of the cumulative mean as control limits. This approach is recommended by the EPA for toxicity data. All of the storm drain reference test data fell within control limits and were similar to prior results obtained at SCCWRP. The conclusion is that the sea urchin fertilization tests conducted during this project were of typical sensitivity.

CONCLUSIONS

The phase 1 toxicity test objectives for this project have been successfully completed. Tests with three marine species were conducted and have provided data that can be used to rank the relative toxicity of the sites and describe variability in toxicity.

The Ashland site was found to be most toxic to each of the three species of test organisms (Table D2-10). This location consistently produced the greatest toxicity in all tests conducted. No clear distinction between the relative toxicity of the Ballona Creek and Pico-Kenter sites can be made. Comparison of the EC50 values for the different samples shows that the test species responded differently to these sites, as shown in Table D2-11. The abalone test was more sensitive to Pico-Kenter effluent, with the kelp test being least sensitive. Ballona Creek effluent produced the greatest toxic effects on sea urchin sperm, however, while the abalone and kelp tests were unaffected by effluent from this site.

The differential sensitivity to each site shown by the tests also makes it difficult to generalize about which species is the most sensitive. The kelp test was always the least sensitive to each of the effluent types, however.

A moderate degree of temporal variability in effluent toxicity was found in this study. The magnitude of toxic effects produced by Ashland effluent was similar between sampling times. Pico-Kenter effluent was consistently toxic to abalone embryos, but produced toxic effects on sea urchin sperm in only one of three tests. Ballona Creek effluent produced a different level of toxicity to sea urchin sperm in each of the three tests conducted; toxic effects ranged from strong (EC50 = 14%) in the first sample to nontoxic in the last sample tested.

The temporal variability found in this study is not surprising, considering that each effluent represents a mixture of many separate inputs. It is interesting to note that the Ballona and Pico-Kenter samples having the greatest initial pH usually produced the greatest toxic effects. While pH itself was controlled during the test and not likely to produce toxicity directly, these pH changes may be related to variations in other effluent characteristics having an impact on relative toxicity.

Table D2-1. Summary of initial water quality data for undiluted storm drain effluent samples. Measurements were made on the day of toxicity test initiation. Salinity units are mg/g.

Location (1)	Collection Date (2)	pH (3)	Salinity (4)
Ashland	9-29-92	8.13	8
	10-12-92	8.03	9
Ballona	9-29-92	9.40	2
	10-12-92	9.16	3
Pico-Kenter	9-29-92	8.32	2
	10-12-92	8.58	2

Table D2-2. Storm drain effluent NOEC and EC50 values for storm drain samples collected September 29 and October 12, 1992. Values are expressed in percent effluent.

Location (1)	Sampling Date (2)	NOEC: Abalone Develop. (3)	NOEC: Kelp Germ. (4)	NOEC: Kelp Length (5)	NOEC: Urchin Fert. (6)	EC50: Abalone Develop (7)	EC50: Kelp Germ. (8)	EC50: Kelp Length (9)	EC50: Urchin Fert. (10)
Ashland	9-29-92	nt[a]	nt	nt	5.6	nt	nt	nt	14
	10-12-92	5.6	5.6	5.6	<5.6	10	22	50	< 5.6
Ballona	9-29-92	nt	nt	nt	12[b]	nt	nt	nt	> 56
	10-12-92	≥56	≥56	≥56	≥56	> 56	> 56	> 56	> 56
Pico-Kenter	9-29-92	nt	nt	nt	≥56	nt	nt	nt	> 56
	10-12-92	12	≥56	25	25	21	> 56	> 56	41

[a]Insufficient data to calculate value.

[b]NOEC could also be stated as ≥56% since 56% concentration was not significantly different from respective brine control. A NOEC of 12 is felt to be more appropriate since 25% concentration was significantly toxic and 56% brine control was toxic, making accuracy of 56% effluent results questionable.

Table D2-3. Summary of Purple sea urchin fertilization test; conducted October 1, 1992. Abbreviation: % Ref = mean response expressed as a percentage of the appropriate reference group(s); NS = not significantly difference relative to reference; S = statistically significant difference; NT = not tested (no need or data not sufficient).

APPENDIX D3
TOXICITY RESULTS OF BALLONA CREEK SAMPLE COLLECTED 12/10/92

The following are data reports for the two toxicity tests conducted on samples of Ballona Creek dry weather flow collected December 14, 1992.

Experiment 194

The first experiment was conducted on December 14, immediately after sample collection to characterize the initial toxicity of the samples. Samples were tested at concentrations of 12, 25, and 56%. Control fertilization was 68% which is within the range considered acceptable for this test. Samples containing 56% runoff were not examined for fertilization because the 56% brine control was strongly toxic (Table D3-1). Results for the 12 and 25% concentrations indicated that the afternoon sample was about twice as toxic as the sample collected in the morning.

The pH of the runoff samples ranged from 8.45 (a.m.) to 8.26 (p.m.) which is considerably lower than the pH of samples collected previously.

Samples of deionized water from UCLA and filter blanks prepared with either UCLA or SCCWRP water were also tested for toxicity in the first experiment. No toxicity was detected in a sample of 25% UCLA water. Egg fertilization in the filter blank prepared from UCLA water was 79% of the unfiltered sample, indicating that some toxicity was introduced by the filtration process. The filter blank using SCCWRP water was more toxic; fertilization in these samples was only 38% of the unfiltered water (25% brine control).

Experiment 195

The second experiment was conducted on December 16, following laboratory manipulation of the Ballona p.m. sample to characterize toxicity. Control fertilization and brine control results were satisfactory for this test (Table D3-2). A baseline toxicity test was conducted on a sample of effluent that had been stored at SCCWRP (unfiltered, 5°C). Baseline toxicity was substantially less than measured on December 14, but still sufficient to permit evaluation of the TIE samples.

Strong toxicity was found in the 56% filter blank solution. Filter blank results (corrected for control response) at 25% were similar for the 12/14 and 12/16 experiments, indicating the same level of toxicity was probably present in both blanks. Toxicity was also found in the column blank samples, reflecting the toxicity of the filter blank solution passed through the column.

Toxicity was reduced by the C18, EDTA, and thiosulfate treatments. Examination of the results for the 56% samples indicate that toxicity was partially removed by the C18 column and completely removed by thiosulfate treatment. Toxicity was found in the thiosulfate blank, as was the case in the previous TIE experiment.

The EDTA treatment results had an unusual pattern. Fertilization at 25% sample concentration was high (no toxicity) for both the 3 and 8 mg/l EDTA solutions. Reduced fertilization was measured at the 56% sample concentrations, with the lowest fertilization occurring in the 8 mg/l solution. There are two interpretations of this pattern. First it could be an indication of partial toxicity removal, as was found for C18 column treatment. An alternate explanation would be toxicity produced by the EDTA treatment. Toxicity due to the EDTA compound is unlikely since the results of previous experiments indicate that solutions of 250 mg/l EDTA were nontoxic. One possibility is that the 56% EDTA solutions may have had an altered pH which adversely affected fertilization rate (pH of the EDTA solutions was not checked or adjusted in this experiment, but was adjusted in the previous TIE experiment). We are investigating this situation and should have more information in a few days.

Analysis of the column elutriate blanks indicated no toxicity for methanol solutions and slight toxicity for the 50% methylene chloride/50% methanol blank. Elution of the C18 column with 100% methanol was successful in recovering a portion of the toxicity in the aqueous sample.

Solvent extracts of two different Ballona Creek samples (11/23 and 12/14 collections) were also tested for toxicity. Strong toxicity was found in solutions containing 0.1% of the extract while 0.01% solutions were nontoxic. It is questionable whether the extract toxicity corresponds to the whole effluent toxicity since the toxic reconstituted solutions were much more concentrated than the original aqueous sample. Even the nontoxic 0.01% extract solutions were more concentrated (equivalent to 80% undiluted effluent) than the highest concentration of aqueous sample tested (56%).

VOL 12

The following are data reports for the two toxicity tests conducted on samples of Ballona Creek effluent collected January 19, 1993.

Experiment 196

The first experiment was conducted on January 19, immediately after sample collection to characterize the initial toxicity of the samples. Samples were tested at concentrations of 12, 25, and 56%. The initial pH values of the two effluent samples were 8.26 and 8.33, similar to the pH of the December 14 samples.

Control fertilization was 100% (Table D4-1), indicating the test organisms were of acceptable health. No toxicity was present in the brine controls. Both the morning and afternoon samples were toxic, with less than 10% fertilization at a concentration of 56% effluent. The results for the 25% concentration indicated that the morning (a.m.) sample was slightly more toxic; this sample was selected for the TIE procedure.

Experiment 197

The second experiment was conducted on January 21, following laboratory manipulation of the Ballona a.m. sample to characterize toxicity. The pH of the effluent sample declined slightly to 7.87 after two days of storage. The pH of the EDTA- and Thiosulfate-treated effluent samples was 7.40-7.93 after dilution with laboratory seawater which had a pH of 7.99. A small amount of HCl was added to samples having a pH less than 7.9 to adjust them to pH 7.93-8.09.

Control fertilization and brine control results were satisfactory for this test (Table D4-2). A baseline toxicity test was conducted on a sample of effluent that had been stored at SCCWRP (unfiltered, 5°C). Baseline toxicity was similar to that measured two days earlier. Slightly greater toxicity was measured at 12 and 25%, which is a pattern not seen in previous tests of stored Ballona Creek samples.

Some toxicity was found in the filter blank samples, although it was much less than measured in previous experiments. This result may indicate a beneficial effect of using distilled water from SCCWRP. Increased toxicity (relative to the filter blank) was measured in the column blank samples. This is an indication of toxic materials being leached from the column. Evidence of column toxicity could not be detected in previous experiments because of the high toxicity of the filter blanks.

Only a slight reduction in toxicity was measured following treatment of the Ballona Creek sample with the C18 column.

Toxicity was completely removed by a 3 mg/L EDTA addition. The additional EDTA treatments were also nontoxic, indicating that no adverse effects were produced by this chemical.

1656

Toxicity was absent in the thiosulfate blank. This result was somewhat unexpected, as strong blank toxicity was measured in both previous TIE experiments. Thiosulfate treatment had no effect on Ballona Creek effluent toxicity.

The solvent elution fractions of the C18 column were tested for toxicity even though column treatment was relatively ineffective. The solvent blank results were generally acceptable; only the 50% $MeCl_2$ blank showed moderate toxicity at a concentration of 0.2%. A small amount of toxicity was recovered from the column by elution with 100% methanol. The amount of toxicity recovered was too small to significantly contribute to the baseline toxicity of the effluent sample. Elutions with 50% methanol or methylene chloride were ineffective.

December 1993

Dear Reader:

The State Coastal Conservancy is pleased to present its Los Angeles River Park and Recreation Area Study. This study was prepared in response to a request from the State Legislature to help explore beneficial uses of the river, including an assessment of the river's potential for public access, recreation and wildlife enhancement. Its specific purpose is to provide, for the first time, a comprehensive set of information on potential improvement projects that could contribute to overall river corridor planning, and to cooperative efforts of communities along the river to improve their river frontage.

Sincerely,

Peter Grenell
Executive Officer

I. INTRODUCTION

In recent years, interest in the Los Angeles River has been growing among state and local legislators, local governments, and a host of environmental groups and community organizations. Long managed primarily as a flood control channel and considered by many to be nothing more than a blight on the urban landscape, there is an increasing awareness of the tremendous potential of the Los Angeles River to become a recreational and environmental amenity for the greater Los Angeles area. Despite substantial community interest in the "greening" of the Los Angeles River, until recently no public agency has planned comprehensively for such a multiple-benefits vision. Local jurisdiction for the river corridor is fragmented among 12 cities, Los Angeles County, and the U.S. Army Corps of Engineers, making comprehensive planning for the entire watershed a difficult and complicated undertaking.

Then, in the spring of 1990, Los Angeles Mayor Tom Bradley established a Los Angeles River Task Force. Composed of representatives of the city council, commissioners, and city staff, the mission of the task force was to "articulate a vision for the future of the river." The task force established a broad set of goals for the river and proposed three demonstration projects that would express these goals.

Not long after the formation of the Los Angeles River Task Force, the Los Angeles County Board of Supervisors initiated the Los Angeles River Master Plan. The master plan is being prepared by the Los Angeles County Department of Public Works with input from 13 cities, as well as citizens' groups and representatives from state and federal agencies. The purpose of the master plan is to explore the potential of the river to become a recreational amenity while maintaining its function of flood protection.

It is in this context that the State Coastal Conservancy has conducted its study. The Conservancy was requested by the State Legislature in 1990 to assist in the mounting efforts to examine the potential beneficial uses of the Los Angeles River. Senate Bill 1920 authorized the Coastal Conservancy to prepare a plan for this area that included an assessment of the river's potential for enhancement for public recreation and wildlife habitat uses.

The Conservancy's response was to initiate two complimentary studies. The first, to be carried out through the American Institute of Architects, is to be an analysis of the major issues, opportunities, and constraints involved in a large-scale restoration of the river corridor. This study is still in progress. The second study, carried out directly by Conservancy staff, is an identification of improvement projects that could be carried out in the near-term along the river corridor. This document represents the results of this second study.

This study was carried out in consultation with the Los Angeles County Department of Public Works, with other local agencies having jurisdiction over various portions of the study area, and other interested groups. This study built in particular upon the ongoing work of the Department of Public Works and the Army Corps of Engineers and upon the work of the city of Los Angeles' Los Angeles River Task Force. The Department of Public Works, in conjunction with other county departments and the National Park Service, has begun to develop a multi-purpose master plan for the Los Angeles River and Tujunga Wash.

The study area was the approximately 50 miles of river corridor from the confluence of Bell Creek and Arroyo Calabasas in Canoga Park to Long Beach Harbor. It includes 12 cities as well as portions of unincorporated Los Angeles County. Contacts were initiated with all of the local jurisdictions contained in the study area, including the city and county of Los Angeles, Burbank, Glendale, Vernon, Bell, Maywood, South Gate, Cudahy, Lynwood, Paramount, Compton, and Long Beach. Efforts were made to identify the recreation and enhancement priorities of these jurisdictions. Projects identified range from those that require no changes in existing river conditions or management practices, to those that would demand dramatic changes in current land uses and priorities. Recommendations are also made regarding areas and issues requiring future study.

Los Angeles County covers an area of over 4,000 square miles and has a population that is rapidly approaching 9 million people. According to a 1989 *Los Angeles Times* survey, the quality of the human environment is generally perceived by residents to have declined in recent years. The entire region is heavily urbanized and is plagued with many of the environmental quality problems associated with such an area: significant air pollution, water quality problems, crowding, urban blight, noise, toxic waste disposal problems, including groundwater contamination, and very heavy traffic. Air pollution in the basin exceeds federal clean air standards 30-50% of the year. Recent plans by environmental regulatory agencies in the basin suggest that improving environmental quality would require significant government action; plans provide for significant restrictions on development, transportation, land use, and energy use.

Along with the population, the density of development in Los Angeles is increasing, and as a result, noise and traffic are increasing. Recent studies of the major transportation corridors indicate that on some freeways "rush hour" conditions exist for extended periods (as long as six hours in the morning and five hours in the afternoon). Adjacent surface streets are also crowded with traffic. These conditions adversely affect commercial activity as well as the general social environment.

The Los Angeles metropolitan area has less per capita park acreage than any other large metropolitan area in the United States. In most communities, parks and open space are in short supply and high demand. Clearly, there is an urgent need for more open space and additional recreational facilities in the Los Angeles area, as well as a need to ameliorate the problems of air pollution and traffic congestion. The enhancement of the Los Angeles River as a recreational and environmental resource could serve in large part to meet these needs.

II. BACKGROUND

Figure 1
Location Map

II. BACKGROUND

The Los Angeles River flows for more than 50 miles from the Santa Monica Mountains at the western end of the San Fernando Valley to the Pacific Ocean at Long Beach. From its start at the junction of Calabasas and Bell creeks in the Santa Monica Mountains, the river flows eastward through the San Fernando Valley. It bends around the Hollywood Hills and flows south onto the broad coastal plain of the Los Angeles Basin, eventually discharging into San Pedro Bay at Long Beach Harbor. The river is joined by several tributaries, notably the Tujunga Wash, Arroyo Seco, Rio Hondo, and Compton Creek, and drains an area of 824 square miles.

The river has been channelized for its entire length. The river bottom and banks are lined with either concrete or grouted rock except for two areas, one in the vicinity of Glendale, and the other a stretch of river from Willow Street to the Pacific Ocean in Long Beach. The river channel in both areas is soft-bottomed with riprap or concrete along the banks.

Since the flood control system was completed, development has been permitted to directly abut the channel right of way. The river is bordered by a dense mixture of residential, commercial, and industrial development for much of its length. Through the San Fernando Valley, the river flows past heavily developed residential and commercial areas. From the Arroyo Seco, north of downtown Los Angeles to the confluence with the Rio Hondo, the river passes through industrial and commercial areas and is bordered by rail yards, freeways, and major commercial and government buildings. From the Rio Hondo to the Pacific Ocean, the river flows through industrial, residential, and commercial areas, including major refineries and petroleum products storage facilities, several major freeways, rail lines and rail yards serving the ports of Los Angeles and Long Beach, large industrial complexes, and extensive residential and commercial developments.

Los Angeles River
Park and Recreation Area Study

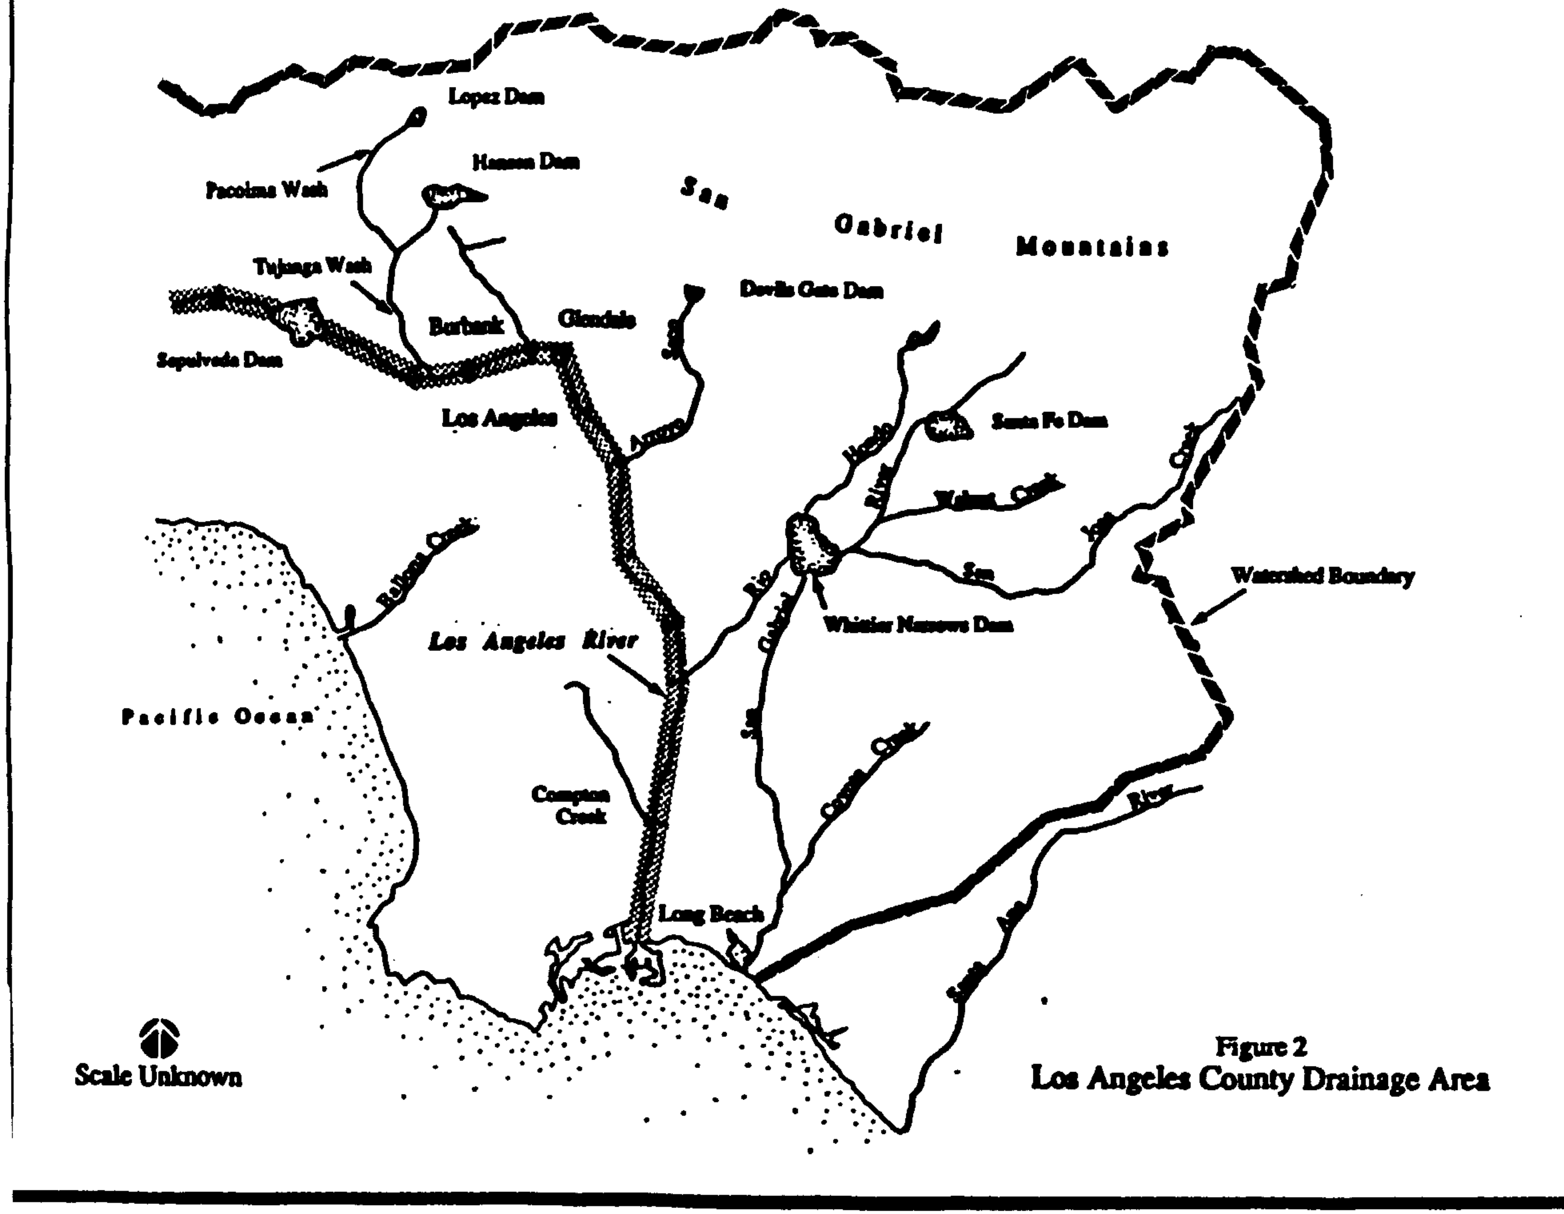

Figure 2
Los Angeles County Drainage Area

HYDROLOGY

The Los Angeles River and the San Gabriel River are the two principal streams that drain the entire Los Angeles Basin south of the San Gabriel Mountains. This area comprises the Los Angeles County Drainage Area (LACDA). The Los Angeles River is fed by several tributaries that start in the mountain ranges that rim the Los Angeles Basin.

The Los Angeles River channel was constructed between the late 1930s and the 1950s. The river channel consists of a concrete paved invert and sides from Willow Street to Interstate 5, near the Pasadena Freeway, and from the Riverside Drive bridge to Tujunga Wash. The area between Interstate 5 and Riverside Drive is a stone or earth and stone channel bottom with concrete-paved or stone sides. The river south of Willow Street to the mouth consists of a natural earth invert with concrete-paved or stone side slopes. The reach of the river above the confluence of the Tujunga Wash consists of concrete channel sections, except for an earthen channel and berm stretch within the Sepulveda Basin.

Most of the Los Angeles River has a trapezoidal channel section with some reaches consisting of a rectangular channel section. The bottom width of the trapezoidal channel ranges from 160 feet to 510 feet. Rectangular sections of the river range from 50 feet to 220 feet in width. The channel depths vary; deeper sections are generally located in the downstream reaches. The Los Angeles River channel has depths varying from 13 to 34 feet, measured from the top of the berm (or top of channel if there is no berm) to the invert.

Earthen levees with concrete facing typically parallel each side of the river channel. The levees act as access roadways, and many areas have been paved. Equestrian and bicycle trails are also located on or next to the levees south of the Rio Hondo. Chain-link fencing has typically been used to separate the river channel from the berms in order to keep maintenance workers and others using the levees from falling into the river channel.

Beyond the berms on one or both sides of the river are parallel overhead electric transmission lines. These lines parallel portions of the river.

Low-flow water in the river channel is from residential runoff through storm drains and from two city of Los Angeles wastewater treatment plants — Tillman and Glendale. The water from the treatment plants makes up nearly all the low-flow in the channel during the dry months.

The Los Angeles River channel is operated and maintained by two agencies — the U.S. Army Corps of Engineers (the Corps) and the Los Angeles County Department of Public Works (LACDPW). The Corps operates the reach of the river between the Rio Hondo and the Tujunga Wash. The remaining portions of the river are operated and maintained by the LACDPW.

The Corps has determined that the LACDA system does not at present provide the desired urban area base standard of 100-year flood protection for all parts of the drainage area. In the lower portion of the river, the current system has the capacity to withstand only a 25- to 40-year storm event. The Corps has proposed increasing the flood control capacity of the existing system by building parapet walls on top of existing levees along the Rio Hondo channel and along the Los Angeles River channel south of the confluence with the Rio Hondo. The project will require modifications to existing bridges on both rivers, modifications to existing channels at the confluence, and reinforcement of the levees.

ECONOMICS AND DEMOGRAPHICS

The Los Angeles metropolitan area is the center of the manufacturing, trade, financial, and service industries in the western United States, with a gross product exceeding $100 billion annually. The economy, although dominated by manufacturing and trade, is quite diversified and has sustained long-term growth for almost 70 years. The Los Angeles/Long Beach harbors form the largest harbor complex on the west coast of the United States, handling almost as much cargo as the three other major port complexes combined (San Francisco-Oakland, Seattle-Tacoma, and Portland). The region is a major transshipment point for Pacific Rim trade.

Throughout the 1980s the economy of the Los Angeles area remained strong relative to other parts of the state and the nation, and although unemployment has increased over the last two years, 15 of California's 27 largest employers are located in the Los Angeles area. The principal employment sectors in the region are trade, manufacturing, services, and government. Per capita income in Los Angeles county in 1990 was $15,368. As of 1990, the average price of a house in Los Angeles County was $226,400, and average rent for a two-bedroom apartment was $570. Housing units are almost evenly divided between owner-occupied and rented.

With a population approaching 9 million people over an area of over 4,000 square miles, Los Angeles County has the largest population of any county in the United States. From 1980 to 1990 the population of Los Angeles County increased by more than 18% (from 7,477,400 to 8,863,164), the largest population increase of any county in the nation. The population density in Los Angeles County is extremely high, with 2,183 people per square mile. The Southern California Association of Governments (SCAG) predicts a county population of over 10 million by the year 2010. The population is evenly divided between male and female.

The Los Angeles area has always been multi-ethnic and multi-cultural. In recent years, the area has experienced a large immigration of peoples from Mexico and Central America and Asia, as well as from other areas of the United States. According to U.S. Census data, the years between 1980 and 1990 saw dramatic shifts in ethnic demographics. Although still the single largest racial group in Los Angeles County, the population of non-Hispanic whites decreased from 52.9% of the total population to 40.8%. Hispanics represent the second-largest ethnic group (after non-Hispanic whites) in Los Angeles County. People of Hispanic origin increased as a percentage of population from 27.6% to 37.8% between 1980 and 1990, with Mexican-Americans constituting the largest segment of this group. It is predicted that Hispanics will become the majority ethnic group in Los Angeles County in the very near future. The percentage of African-Americans in the population decreased from 12.6% to 11.2% (although total numbers increased slightly). The most dramatic change was the increase in the Asian population in Los Angeles County. The percentage of Asian-Americans in the total population almost doubled between 1980 and 1990, increasing from 6.1% to 10.8%, with Chinese- and Filipino-Americans representing the largest segments of this group.

The ethnic distribution within the county has also shifted over the last ten years, with non-Hispanic whites and African-Americans moving out of the central and southern portions of the city of Los Angeles and the small cities south of Los Angeles and Hispanics moving in. Downtown and

East Los Angeles, as well as many "eastside" cities, are now predominantly Hispanic. Asians are settling primarily in the San Gabriel and San Fernando valleys and the northern-central portions of the city of Los Angeles.

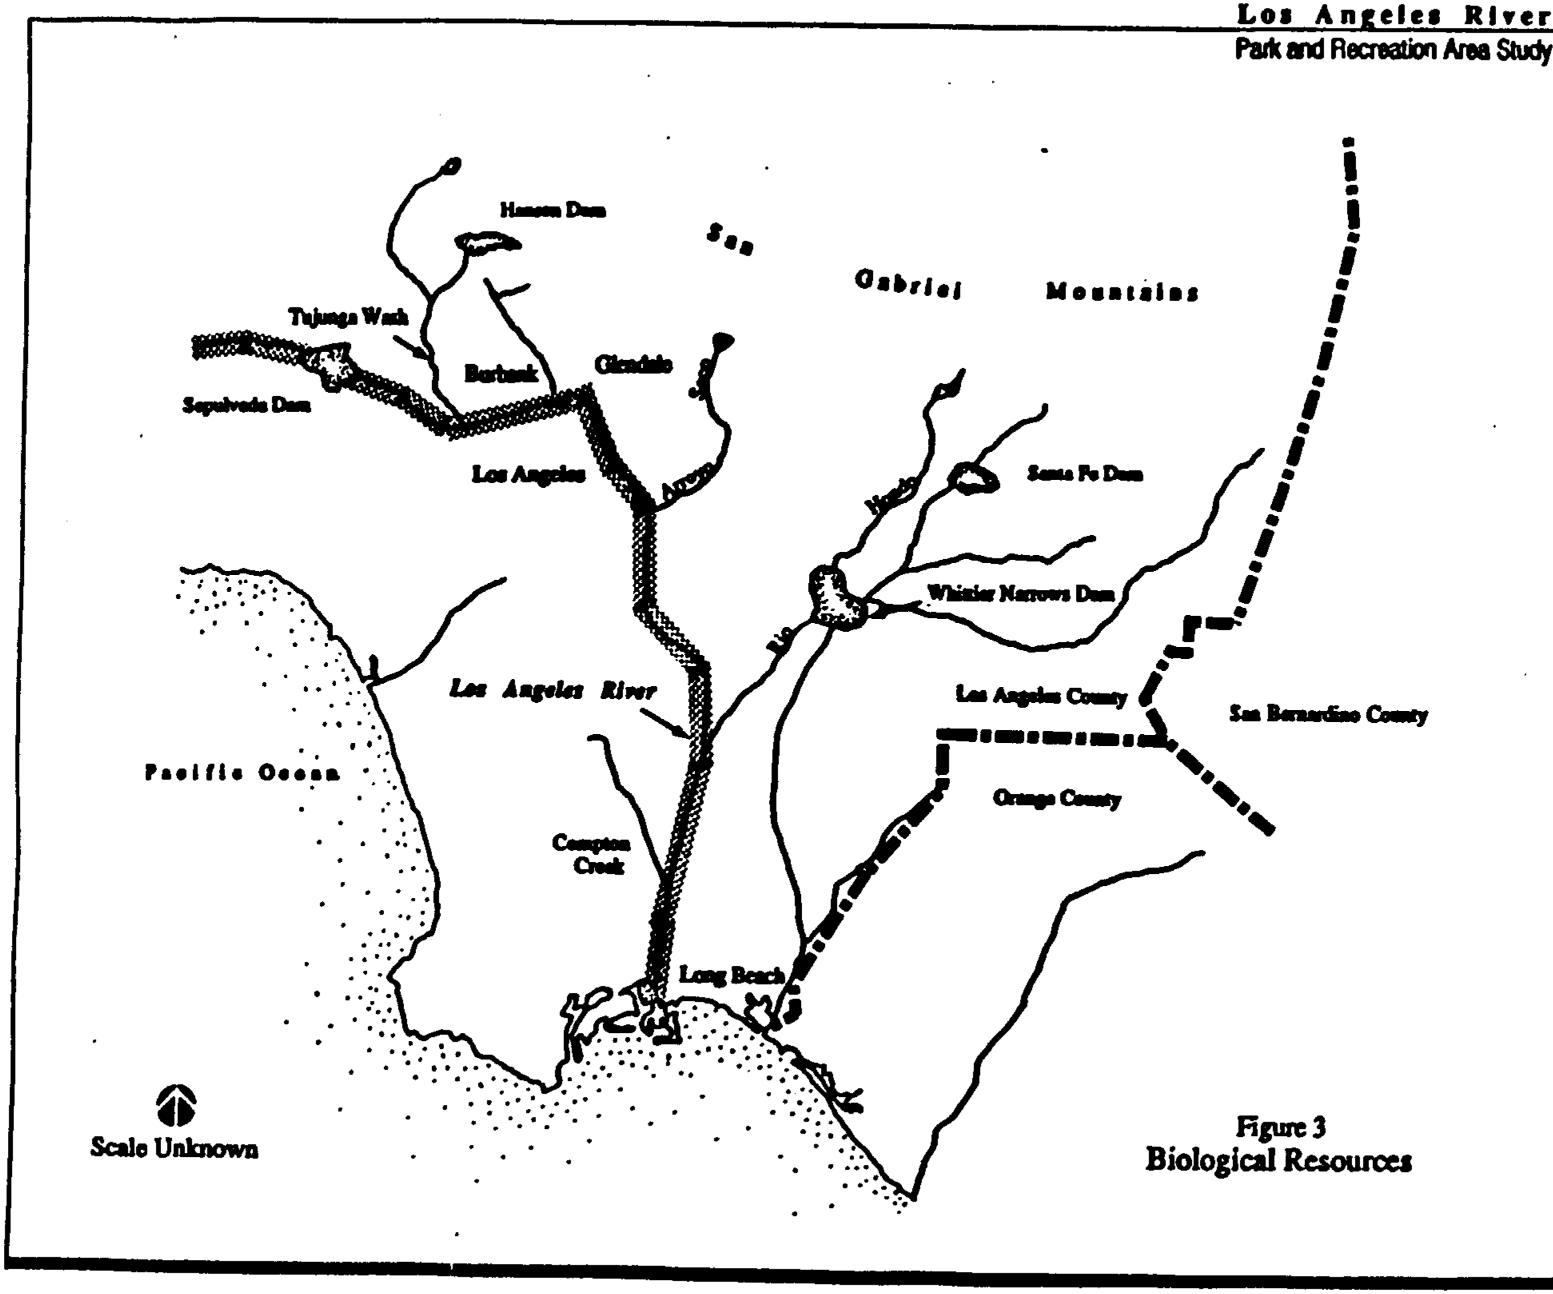

Figure 3
Biological Resources

BIOLOGICAL RESOURCES

The Los Angeles River has been modified from its natural condition to such an extent that little remains of the formerly rich riparian and related habitats that made up the river system. Most of the river below the Sepulveda Basin is contained within a concrete-lined channel surrounded by urbanized areas. A recently completed study of the biota of the river by the Los Angeles County Museum of Natural History concluded, however, that:

> Despite the severe fragmentation of natural habitat associations, the loss of numerous native taxa, and the establishment of many exotic plant and animal species, the Los Angeles River and its tributaries continue to harbor a rich biota in certain soft-bottomed channel areas, flood control basins, and unchannelized foothill and montane reaches. The potential for restoration of wetland and riparian habitats and other heavily impacted upland habitats bears investigation. (NHMLACF, March 1993, pp i-ii)

Vegetation

Three areas of the Los Angeles River that were not paved when the river was channelized are the area upstream of Sepulveda Dam within the Sepulveda Basin, the Glendale Narrows, a 6-mile stretch of the river near Glendale between the Burbank Western Channel and the Arroyo Seco, and a 2.6-mile section in Long Beach.

The Glendale Narrows has a cobblestone bottom and a large, stabilized gravel bank with dense vegetation consisting mainly of willows (*Salix* spp.), giant reeds (*Arundo donax*), Bermuda grass (*Cynodon dactylon*), fennel (*Foeniculum vulgare*), and castor bean (*Ricinus communis*). Scattered sycamore (*Platanus racemosa*), ash (*Fraxinus uhdei*), mulberry (*Morus alba*), and pepper trees (*Schinus molle*) are also found on the bank. Bulrush (*Scirpus americana*), ludwigia (*Ludwigia peploides*), speedwell (*Veronica anagalis-aquatica*), and knotweed (*Polygonum* spp.) occur along the edges of the bank.

In Long Beach, the section of the river below Willow Street is soft-bottomed. The buildup of silt on both sides of the river in this area has allowed for the growth of a 10- to 15-foot-wide riparian corridor, containing rushes (*Scirpus* spp.), cattails (*Typha* spp.), willows (*Salix* spp.), mulefat (*Baccharis glutinosa*), and several ruderal species. This area is influenced by tidal waters from the mouth of the river and, at high tides, sea water extends almost up to Willow Street.

Other areas within the watershed that contain habitat areas include Hansen Dam, Sepulveda Dam, Santa Fe Dam, Whittier Narrows Dam, and Compton Creek. Hansen Dam and Whittier Narrows Dam, in particular, have good riparian habitat and support a variety of animal species. The Santa Fe Dam basin has a small riparian area and a unique assemblage of alluvial scrub. Compton Creek is a tributary of the lower Los Angeles River and has a soft-bottomed section upstream of its confluence with the river. This section of the creek is characterized by riparian habitat dominated by such species as bulrush (*Scirpus americana*) and arroyo willow (*Salix lasiolepis*).

Small patches of freshwater marsh still exist in some areas of the river, notably the soft-bottomed area near Glendale and in the Sepulveda Basin.

Flood plain (willow/cottonwood) forest remnants occur in the Sepulveda and Hansen basins. Big Tujunga Wash has areas of unaltered streambed with riparian woodlands consisting of willow (*Salix bonplandiana*), white alder

(*Alnus rhombifolia*), and western cottonwood (*Populus fremontii*).

Other habitats associated with the Los Angeles River and its watershed, such as valley oak savanna, live oak woodland, chaparral, alluvial scrub, douglas fir/canyon oak woodland, and mixed coniferous forest, continue to exist, generally in the outlying areas of the watershed. The Los Angeles County Natural History Museum noted in its study of the biota of the river that:

> It is important to recognize the value of the vegetation of the Los Angeles River as habitat for other biotic resources. It may represent a highly altered state from native vegetation but studies might show it to function similarly on some levels. (NHMLACF, 1993: B-9)

Wildlife

Populations of mollusks, fish, reptiles, amphibians, and mammals also live in and around the river:

Mollusks: The number of mollusks found in the river has declined precipitously since the river was channelized (NHMLACF, 1993: C-1- C-8) but a few snail species and other mollusks still occur in the river system. Decline of mollusk populations is attributed to loss of habitat due to channelization and water pollution.

Fish: Of the seven endemic species of fish once found in the river only three are still found in the river system. Of these three (arroyo chub, Santa Ana sucker, Santa Ana speckled dace) only one species, the arroyo chub, still exists in large numbers in the river. Four introduced species (fathead minnow, goldfish, mosquito fish, and tilapia) are also present in the river. Poor water quality and the lack of refuge areas during high flows (a result of channelization) are the major reasons for the decline of the native fish species.

Amphibians & Reptiles: Of the 33 species of amphibians and reptiles known to have inhabited the Los Angeles River drainage historically, 19 species are thought to still occur in or along the river channel. These include four species of salamanders, three species of frogs, six species of lizards and six species of snakes. The western toad (*Bufo boreas*), Pacific treefrog (*Hyla regilla*), bullfrog (*Rana catesbeiana*), and two-striped garter snake (*Thamnophis hammondii*) are found in the river channel. The other species occur in the riparian zone or in the foothills of the Santa Monica Mountains near the river channel.

Birds: The Los Angeles River drainage supports a great diversity of bird species in spite of the channelization of much of the river. The river channel in Long Beach has both concrete and soft-bottom stretches. In summer and fall, algal growth on areas of the concrete-lined channel attract large numbers of shorebirds and other birds that feed on invertebrates in the algae.

The soft-bottomed channel in Long Beach supports areas of willows and other vegetation that may provide habitat for some bird species. This vegetation is removed occasionally by the Los Angeles County Department of Public Works (with the approval of the California Department of Fish and Game). Large numbers of migrating shorebirds feed in this area of the river from July through October. Species found in the area include western sandpiper, American avocet, black-necked stilt, long-billed dowitcher, and least sandpiper. Black-necked stilts and American avocets nest on small islands in the river south of Willow Street.

The vegetated, soft-bottomed portion of Compton Creek, the spreading basins along the Rio Hondo channel, and the soft-bottomed Glendale Narrows section provide habitat for a number of different species. Great egrets, snowy egrets, black-crowned night-herons, and loggerhead shrikes occur along Compton Creek. Northern shovelers, American wigeons, American coots, and several species of shorebirds use the Rio Hondo spreading basins as overwintering grounds. Pied-billed grebe, cinnamon teal, killdeer, black phoebe, and red-winged blackbirds nest in the Glendale Narrows section of the river.

Sepulveda Basin, Hansen Dam, and Big Tujunga Wash also support significant numbers of birds. Canada geese overwinter at the Sepulveda Basin. Waterfowl and shorebirds are commonly seen in the basin. Hansen Dam Basin supports a large number of waterbirds and shorebirds, including five species of grebes and nine species of herons. Riparian species nesting in the basin include green heron, belted kingfisher, and blue grosbeak. Alluvial wash and scrub areas of Big Tujunga Wash provide habitat for greater roadrunner, lesser nighthawk, cactus wren, rock wren, and Costa's hummingbird

Mammals: Rats (*Rattus*), house mice (*Mus*), and feral cats and dogs constitute the majority of the mammal population of the channelized portions of the river. The channelized river section has little remaining habitat suitable for native species. Raccoon, coyote, striped skunk, and opossum, which can adapt to urban environments, are generally found throughout the watershed. Open fields adjacent to the river often provide habitat for such species as rabbits, gophers, voles, moles, and shrews. Much of the upper watershed, however, still supports many, if not all, of the historic number of mammal species native to the area. The Tujunga Wash area supports a number of different species, including native mice, kangaroo rats, bats, and jack rabbits.

Los Angeles River
Park and Recreation Area Study

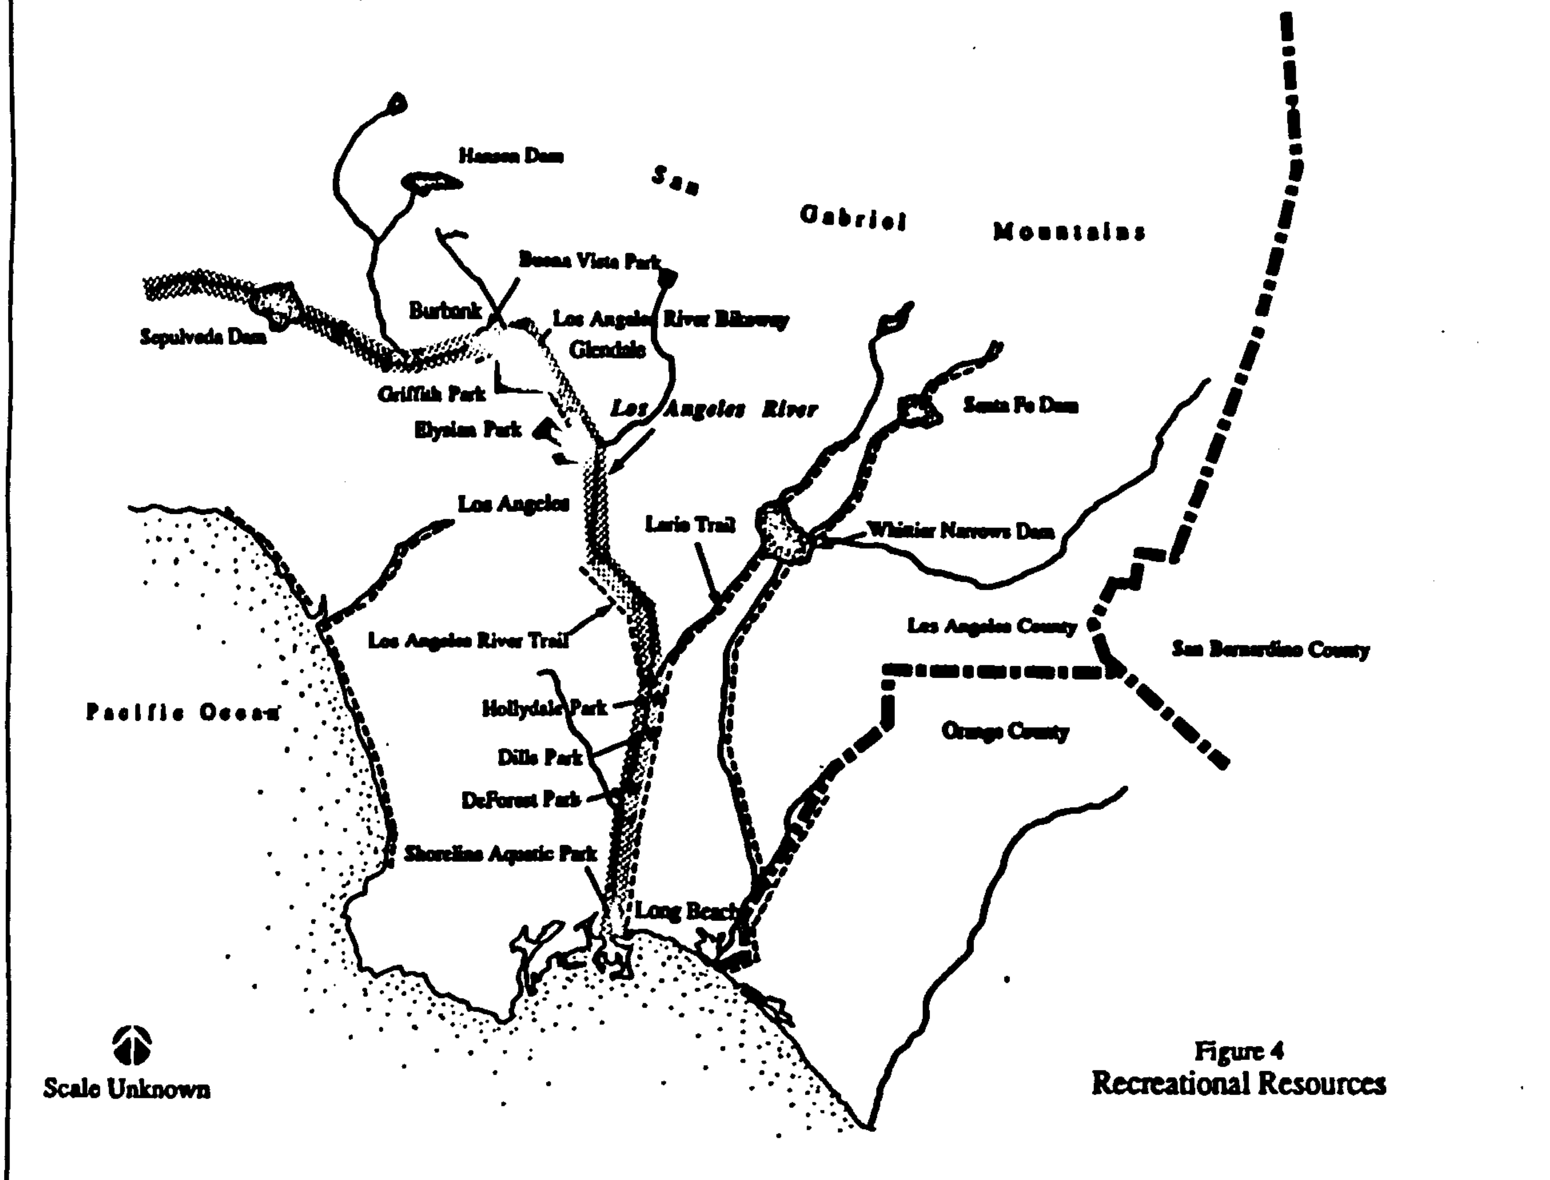

Figure 4
Recreational Resources

RECREATIONAL RESOURCES

The Los Angeles River and the flood control system of which it is a part currently provide several different types of recreational facilities. These facilities, which are concentrated at the four flood control basins (Sepulveda Basin, Hansen Dam, Whittier Narrows, Santa Fe Dam), include recreation lakes, picnic grounds, hiking and riding trails, and playing fields. All four basins have been designated as recreation areas by Los Angeles County.

Recreation facilities associated with the river channel itself are limited to the Lario (Los Angeles River-Rio Hondo Channel) Trail, the Los Angeles River Trail, and associated equestrian trails. The channel provides several miles of hiking and bicycle trails. The trail along the Los Angeles River begins at the Pacific Ocean and connects with the Rio Hondo and San Gabriel trail systems, which provide access into the San Gabriel Mountains. The bike path uses the service roads on top of the channel levees. Equestrian trails are often separate from the bike path and are either a fenced paved trail or an unpaved strip next to the bike path. The trails along the river are not landscaped and do not include rest stops or other facilities that would make them more attractive to trail users.

Access to the bike trails is often from major streets, and access to equestrian trails is from parks adjacent to the river. A gate in the fencing at these river crossings provides access to the trails. These access points are generally between one and two miles apart.

The city of Los Angeles is currently in the process of constructing Phase I of the new Los Angeles River Bikeway. Phase I will consist of a seven-mile trail beginning at the confluence of the Arroyo Seco and the Los Angeles River at Figueroa Street (adjacent to Elysian Park) and extending along the west bank of the river to the intersection of Riverside and Zoo drives in Griffith Park. Phase I is expected to be completed by 1995. The city intends to begin planning next year for the Phase II extension of the trail, from Griffith Park along the Los Angeles River and the Tujunga Wash to Strathern Park in the San Fernando Valley.

The Los Angeles River channel adjoins several community parks, including Griffith Park and Elysian Park in Los Angeles, Buena Vista Park in Burbank, Hollydale Park in South Gate, Dills Park in Paramount, and DeForest Park and Shoreline Aquatic Park in Long Beach.

The Juan Bautista de Anza National Historic Trail, which is presently in the planning stage, will follow the Los Angeles River from Glendale to the San Fernando Valley. The trail follows the route of the de Anza Expedition of 1775-76 from Mexico to San Francisco. The National Park Service has begun preparation of a comprehensive plan for the trail route. National historic trails combine recreation and historic interpretation.

III. PREVIOUS STUDIES

III. PREVIOUS STUDIES

Numerous studies of the Los Angeles River have been conducted over the past several years by public agencies, nonprofit organizations, and community groups. These studies vary widely, from conceptual sketches to detailed plans for specific areas. Content ranges from bird inventories to proposals for freeway development. Since the emphasis of this study is parks and recreation development, those studies that focus on these uses of the river are briefly summarized below. These studies include two conducted by the city of Los Angeles and two completed by the U.S. Army Corps of Engineers.

The LACDA System Recreation Study: Los Angeles County Drainage Area (U.S. Army Corps of Engineers, Los Angeles District, March 1980)

This report presents the results of a study conducted by the Los Angeles District of the Army Corps of Engineers that analyzed the recreational potential of the land within the Los Angeles County Drainage Area (LACDA). The LACDA includes all of Los Angeles County south of the San Gabriel Mountains. This drainage area has been developed over the past 50 years by the Corps and the Los Angeles County Flood Control District into a complex system of rivers, channels, and flood control basins that collect the urban runoff from the entire greater Los Angeles area, as well as runoff from the mountain ranges that surround the area, and carry it to the ocean or to spreading basins. The primary purpose of the system was to prevent flooding in developed areas within the flood plain.

This study was the first comprehensive effort on the part of the Corps to assess the recreational potential of the land within the LACDA system. The methodology consisted of data gathering from literature searches, meetings with local agencies and community groups, and physical inspection of the entire system. The data were analyzed to determine those recreation uses that were possible in the system and to assess the recreational needs of the Los Angeles area. This analysis included an assessment of existing trail systems and recreational facilities and a determination of where new trails and recreational facilities were most needed. The study includes in the appendices a set of detailed, annotated maps of each section of the LACDA system showing existing conditions and facilities and proposed projects.

The primary emphasis of the study is a proposal for the development of a regional trail network along the channel system. The study includes a detailed survey of existing conditions throughout the channel system, an analysis of the suitability of different channel segments for trail development, and a system for prioritizing the development of new trails. The study does not include an analysis of the recreational uses of the many flood control basins and reservoirs in the system. All other parts of the system are included in the study with the exception of Ballona Creek, the San Gabriel River, the Rio Hondo River, and the Los Angeles River south of the Rio Hondo confluence. These areas were excluded from the study because trail systems were already in place or under construction (the Lario and San Gabriel river trails).

The Regional Trail System: The LACDA report proposes the creation of a network of trails linking the major parts of the Los Angeles region through the use of the LACDA flood control channels. The backbone of the system would be formed by the Lario and San Gabriel trails, together with extensions from both these trail systems west through the San Fernando Valley and east through the San Gabriel Valley. Secondary connector trails would provide access to the backbone trail from nearby residential areas.

Non-Trail Projects: Although the main emphasis of the LACDA Recreation Study is on the development of a trail system, the report also discusses the potential for the development of other, non-trail recreational facilities within the LACDA system. The discussion does not attempt to identify all of the possible locations for such facilities but rather to identify the types of non-trail uses that would be desirable and to suggest some of the most feasible potential locations for these types of projects.

The study proposes the following kinds of non-trail projects:

- Linear parks and green spaces for urban neighborhoods
- Non-linear parks
- Transportation projects
- Nature study and wildlife conservation areas.

Los Angeles County Drainage Area (LACDA) Review; Final Feasibility Report (U.S. Army Corps of Engineers, Los Angeles District, December 1991)

The Corps' December 1991 LACDA Review summarizes the findings of a feasibility study that examined the potential problems and inadequacies of the existing LACDA mainstem flood control system. Extensive new development in the Los Angeles Basin over the past 50 years has resulted in increased runoff, particularly in the lower portion of the basin. The report concluded that the current system has the capacity to withstand only a 25- to 40-year storm event and outlines several measures that could be taken to prepare the system for a 100-year storm.
The Corps proposes to increase the flood control capacity of the existing system by building parapet walls ranging from one to eight feet in height on top of existing levees along the entire Rio Hondo channel south of Whittier Narrows Dam and along the Los Angeles River channel south of the confluence of the Rio Hondo, a total distance of 21 miles. Construction of the parapet walls would require raising or modifying several street, railroad and utility bridges to accommodate the added height and would cost an estimated $280 million.

The Corps concluded that increasing the channel height in the lower reach of the system was the "optimum" means of increasing flood control capacity in the system based on its National Economic Development (NED) criteria. These criteria attempt to balance the cost of any proposed system improvements against the benefits that would be derived from their implementation. According to the Corps' analysis, other alternative methods for increasing the system's capacity would not be cost-effective.

Other alternatives examined included measures taken in the upper watershed that might reduce the inflow of flood waters to the existing system, alterations to existing flood control reservoirs, and modifications to the mainstem channel areas other than the construction of parapet walls. It was determined by the Corps that none of the alternative approaches analyzed was cost-effective according to NED criteria. This finding led the Corps to conclude that raising the channel walls was the only method feasible for increasing the system's flood control capacity.

The raising of parapet walls along the Rio Hondo and the lower reach of the Los Angeles River channel would have serious impacts on both public use of the river and the aesthetics of the river generally. Walls along the riverside of the public access trails could obstruct or eliminate visual contact with the river, thereby diminishing the attraction of the trail. The Corps and the County Department of Public Works have decided to address this concern by raising the height of the access road adjacent to the parapet walls. The road will be raised depending on the height of the walls such that the wall height is never more than four feet above the grade of the access road.

Los Angeles River Greenbelt Corridor Feasibility Study (City of Los Angeles Planning Department - Recreation & Parks Department, December 1990)

This report outlines several recommendations that the city of Los Angeles should follow toward the goal of creating a Los Angeles River Greenbelt Corridor.

Recommendations include: development of a specific plan around a linear park concept; construction of a bikeway along the river; initiation of landscaping of the river corridor; provision of incentives to owners of land adjacent to the river to provide open space when developing their property; work with the U.S. Army Corps to improve its properties; development of a demonstration project for adaptive reuse of flood control right-of-way for recreational and aesthetic purposes.

The report also includes the following points:

- Most of the right-of-way of the river within the city of Los Angeles is already designated as open space in various plans.
- Opportunities for multiple use of public lands, including flood control, recreation, open space, transportation, and public utilities, should be considered in all planning efforts.
- Creation of a continuous uninterrupted bikeway system along the entire length of the river will be difficult because of the narrowness of the right-of-way and/or obstructions in many areas.
- The greenbelt corridor could serve to connect parks and open spaces throughout the region and in this way act as a wildlife corridor.
- A prototype greenbelt corridor has been established in Long Beach at DeForest Park.
- Planning for the greenbelt corridor should be coordinated among all the affected cities and agencies along the river.

Report of the City of Los Angeles - Los Angeles River Task Force (Office of the Mayor, City of Los Angeles and National Park Service Rivers, Trails and Conservation Assistance Program, January 1992)

This report summarizes the activities of the Los Angeles River Task Force, outlines broad goals for the river and identifies three demonstration projects.

The goals developed by the task force are the following:

- Meet flood control needs within the context of multiple use of the Los Angeles River.
- Restore the river's natural ecosystem wherever possible.
- Improve quality and maximize use of river water.
- Enhance the inherent beauty of the river and its environs.

- Maximize appropriate public uses and recreation opportunities of the river.
- Develop alternative transportation uses.
- Encourage land uses that enhance the environment of the river.
- Enhance public awareness and build support for the Los Angeles River.
- Develop coordinated governance of the river corridor.
- Produce and adopt a master plan for the river.
- Develop strategies for implementation of the plan.

The task force recommended the following demonstration projects:

- *River/Recreation Link in Sepulveda Basin* (San Fernando Valley)
  This project would incorporate the river into the adjacent Balboa Park environment by creating visual and physical linkages between the two. Project components include: river cleanup, vegetation rehabilitation, development of a nature trail, nature study program, river and boating safety program, and water quality monitoring.

- *Los Angeles River Greenway* (Griffith Park)
  This project consists of the development of the first segment of a greenway along the route of the proposed Los Angeles River bike path. Project components include: landscape planting, signage, and a bicycle safety program.

- *Downtown Historic Site and Bridge Event* (Downtown)
  Development of an historical site and a native plant demonstration garden at the Broadway Bridge near Elysian Park. The garden will replicate as closely as possible the landscape encountered by Spanish explorers de Portola and de Anza in 1769 as they prepared to ford the Los Angeles River. Other project components include a cultural festival, an annual bridge celebration, an arts festival, a native plant garden dedication, and a river regatta.

The Los Angeles River Watercourse Improvement Draft Reconnaissance Report; Environmental Restoration/Recreation
(U.S. Army Corps of Engineers, November 1992)

This reconnaissance study was initiated at the behest of the city of Los Angeles to determine what opportunities exist in or near the river corridor for environmental restoration, public recreation, non-motorized (bicycle, equestrian, and pedestrian) transportation, and water conservation. The study was limited to the approximately 19 miles of river corridor that run between Sepulveda Reservoir and the Arroyo Seco confluence (the San Fernando Valley to Downtown Los Angeles). It is a preliminary investigation only and will be used by the Corps to determine whether to actually develop a project plan. The Corps conducted a series of workshops in the project area to solicit public input. The draft Reconnaissance Report recommends that a feasibility analysis be conducted for the following four projects:

- A detention basin at the Taylor Yard, an old railroad switch yard owned by Southern-Pacific
- A riparian habitat area on a 12-acre parcel of undeveloped land at Crystal Springs in Glendale
- A spreading grounds on a 48-acre site on the south bank of the river in Griffith Park
- A 19.2-mile recreation and commuter bikeway along the west and south bank of the river channel from the confluence of the Arroyo Seco to the San Diego

Freeway (The bikeway has not been approved for further study and will not be included in the final report).

The draft report was released in November 1992 and it is anticipated that the final report will be completed by July 1993. If a local sponsor, such as the city of Los Angeles, is identified, the Corps will proceed to a feasibility study.

The Biota of the Los Angeles River: An Overview of the Historical and Present Plant and Animal Life of the Los Angeles River (State Department of Fish and Game and the Los Angeles County Museum of Natural History, March 1993)

This 300-page report was prepared by the Natural History Museum of Los Angeles County with a grant from the California Department of Fish and Game. The report consists primarily of a series of comprehensive inventories of the plant and animal species currently found in or around the Los Angeles River. These inventories were conducted for algae, vascular plants, freshwater mollusks, fish, amphibians and reptiles, birds, and mammals. The report also documents historical changes in composition of the plant and animal communities of the Los Angeles River. The boundaries of the study areas used for the species inventories varied with the type of organisms being sampled. Birds, for example, were surveyed on a drainage-wide basis, whereas algae and fish were sampled only in major channels.

Report on the Taylor Yard Planning and Urban Design Workshop (American Institute of Architects, American Planning Association, American Society of Landscape Architects, Urban Design Advisory Coalition, Los Angeles Forum for Architecture and Urban Design, and the Architectural Foundation of Los Angeles, December 1992)

The workshop was initiated at the request of Los Angeles City Councilman Mike Hernandez and the Friends of the Los Angeles River (FOLAR) in order to study alternative uses for the Taylor Yard, a 241-acre railroad maintenance facility that is currently being offered for sale by the owner, Southern Pacific Railroad. Taylor Yard represents the largest undeveloped parcel near downtown Los Angeles. The site's proximity to downtown, Elysian Park, several significant neighborhoods, and the junction of the Glendale, Pasadena, and Golden State freeways, as well as its frontage on the Los Angeles River, makes it of particular interest to planners, developers, and elected officials.

This report represents the results of a planning workshop, conducted in two, two-and-one-half day sessions, that was intended to gather information, generate involvement from the members of the surrounding communities, and develop a set of recommendations for future uses of the Taylor Yard site. The articulated goals of the workshop were: to generate viable concepts for mixed-use development of the Taylor Yard and its surrounding area; identify and involve the stakeholders in the area; address the major constraints, issues and opportunities of the Taylor Yard site; present recommendations for the refinement and implementation of the alternative use concepts generated.

The report presents a set of basic development principles for the area, as well as some alternative scenarios for land use, urban design, and transportation.

The basic development principles for the Taylor Yard site presented in this report were the following:

- Require that development contributes job opportunities to the community

- Preserve and reinforce local-serving commercial uses
- Facilitate local business development and ownership
- Facilitate the development of housing that provides for the needs of the community
- Use development of Taylor Yard to stimulate capital formation that benefits the community.

The report outlines two general scenarios for land use and development. The first of these scenarios emphasizes the development of a mixed-use community-serving area or "town center," which would extend from Division Street into the Taylor Yard. This town center would be flanked by light-industrial and community-serving recreation areas. The other scenario emphasizes job creation and revenue generation through the development of "big box" discount retail commercial and large-scale industrial uses.

The report recommends the development of the Los Angeles River frontage as an intensive recreation-oriented corridor, containing bike, pedestrian, and/or equestrian paths, nature-study areas, and other amenities, as well as extensive landscaping.

IV. ONGOING STUDIES

IV. ONGOING STUDIES

Concurrent with the Coastal Conservancy's efforts, a number of other studies of the Los Angeles River have been undertaken by other organizations. These studies are still in progress but when completed should add substantially to the general knowledge about the Los Angeles River and contribute to ongoing planning efforts.

The Los Angeles River Master Plan **(Los Angeles County Department of Public Works)**

In July 1991, the Los Angeles County Board of Supervisors directed the Department of Public Works (the Department), which along with the U.S. Army Corps of Engineers oversees the LACDA Flood Control System, to undertake a comprehensive study of possible public uses of the Los Angeles River and Tujunga Wash corridors.

This effort is being managed by the Department of Public Works in coordination with the Los Angeles County Department of Parks and Recreation, the Los Angeles County Department of Regional Planning, and the National Park Service Rivers, Trails, and Conservation Assistance Program. The primary focus of the master plan will be the river's potential for open space, environmental enhancement, recreation, and education. Other ancillary uses will be explored as well, including housing, commercial development, and transit. The study will look at the entire length of the Los Angeles River from its origin in the San Fernando Valley to its mouth in Long Beach and the length of Tujunga Wash from its confluence with the Los Angeles River to Hansen Dam.

Its purpose is to identify optimal uses of the channel system compatible with the overriding purpose of flood control. This study will not be looking at any proposals that could interfere with the flood control function of the system.

A major component is public outreach and community participation. The Department will be initiating a series of public workshops intended to solicit input from the residents of all of the cities in the river corridor. Regular advisory committee meetings began in September 1992. The advisory committee consists of representatives of cities along the river and other interested agencies. The Department is projecting a two- to three-year time frame for the entire effort.

Taylor Yard Flood-Detention Study **(California Department of Water Resources, Los Angeles County Department of Public Works and the Friends of the Los Angeles River)**

This study is being conducted with a $77,000 grant from the Urban Streams Restoration Program of the California Department of Water Resources. It will take a multi-objective approach to flood control on the Los Angeles River by exploring the feasibility of developing a flood water detention basin in the Taylor Yard just north of downtown Los Angeles. This use of the Taylor Yard could potentially provide flood protection for downtown Los Angeles, as well as providing parkland and riparian habitat. It is anticipated that a plan will be completed by September 1993.

V. TRANSIT STUDIES

VOL 12 15--5

R0050020

V. TRANSIT STUDIES

Over the years, various proposals have been made regarding the possible use of the Los Angeles River as a transportation corridor. The Los Angeles area suffers from chronic and severe traffic congestion and solutions to this problem are continually being sought. The construction of new transportation corridors in the Los Angeles area, where most of the likely sites are already fully developed, would be very costly and disruptive. This has led to the consideration of the river course as a possible location of a new transportation corridor. The two most recent studies to examine this potential use of the river corridor are briefly described below.

Los Angeles River and Tujunga Wash Channels Conceptual Engineering Analysis of Potential Transportation Uses **(Los Angeles County Transportation Commission, February 1991)**

This study examines the possibility of using the channel bottoms themselves for vehicular traffic. Specifically, the study examined using the Tujunga Wash channel as a two-lane reversible High Occupancy Vehicle facility. The Los Angeles River channel was proposed for use by truck and other commercial traffic. Such a use may relieve traffic congestion, at least temporarily, but would have some very serious drawbacks. Most importantly, the channel could not be used to carry traffic at all during periods of flood runoff, or when flooding is expected. Also, the year-round low flows in the channel are expected to increase in the next few years, due to increased urban runoff, and these increased flows could interfere with use of the channel by vehicles at all times of the year. Finally, the use of the channel bottoms by traffic would seriously interfere with the use of the bicycle and equestrian paths on the channel banks. The proposal was strongly rejected by several public agencies and by local citizens and is no longer being actively promoted.

Advanced Implementation Proposal **(Los Angeles River Transit Committee, March 1992)**

The Los Angeles River Transit Committee proposal calls for the development of a Los Angeles River rapid transit system. The proposal envisions a system of electric-powered elevated trains along the entire length of the river as well as the development of "River Center Plazas" that would consist of retail stores, restaurants, community centers, and other facilities. The proposal also suggests that a series of parks, recreation areas, and wildlife areas be created along the river banks as part of the project. The project would also include redevelopment programs for surrounding communities.

Los Angeles River
Park and Recreation Area Study

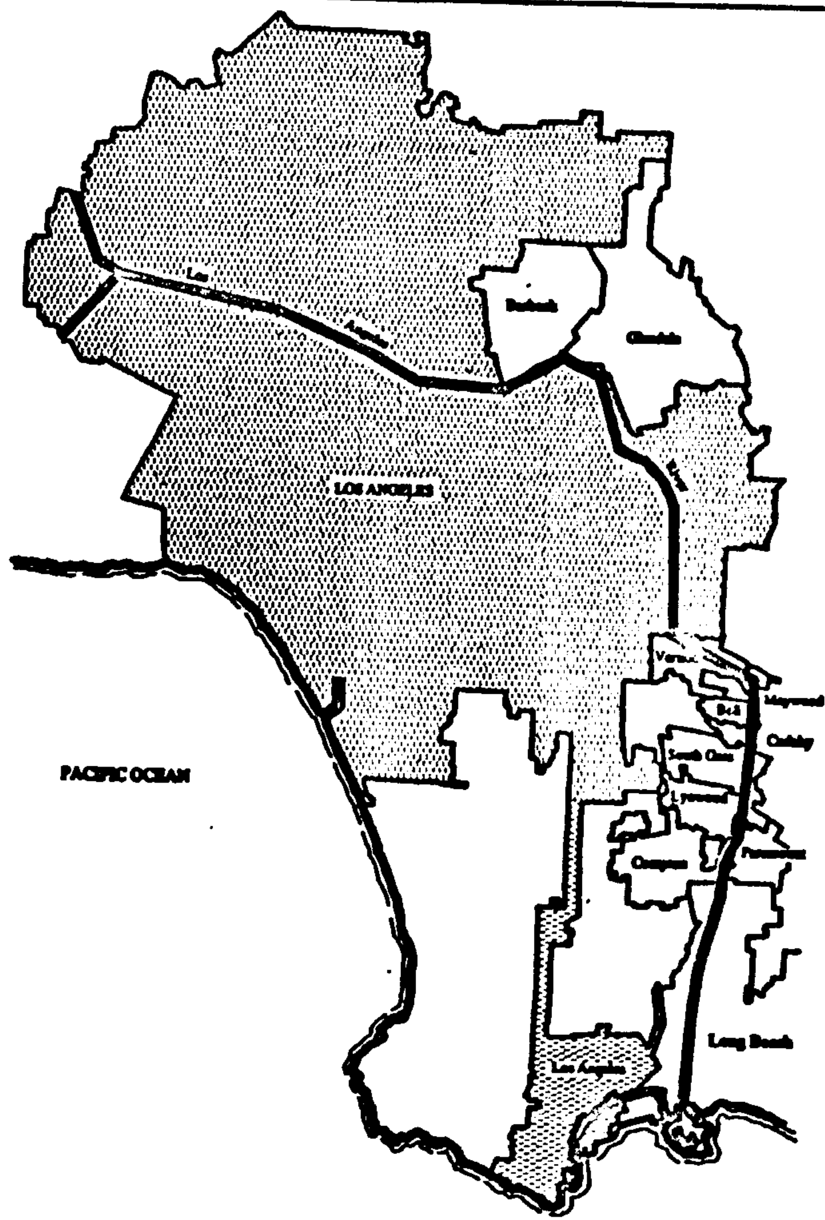

Figure 5
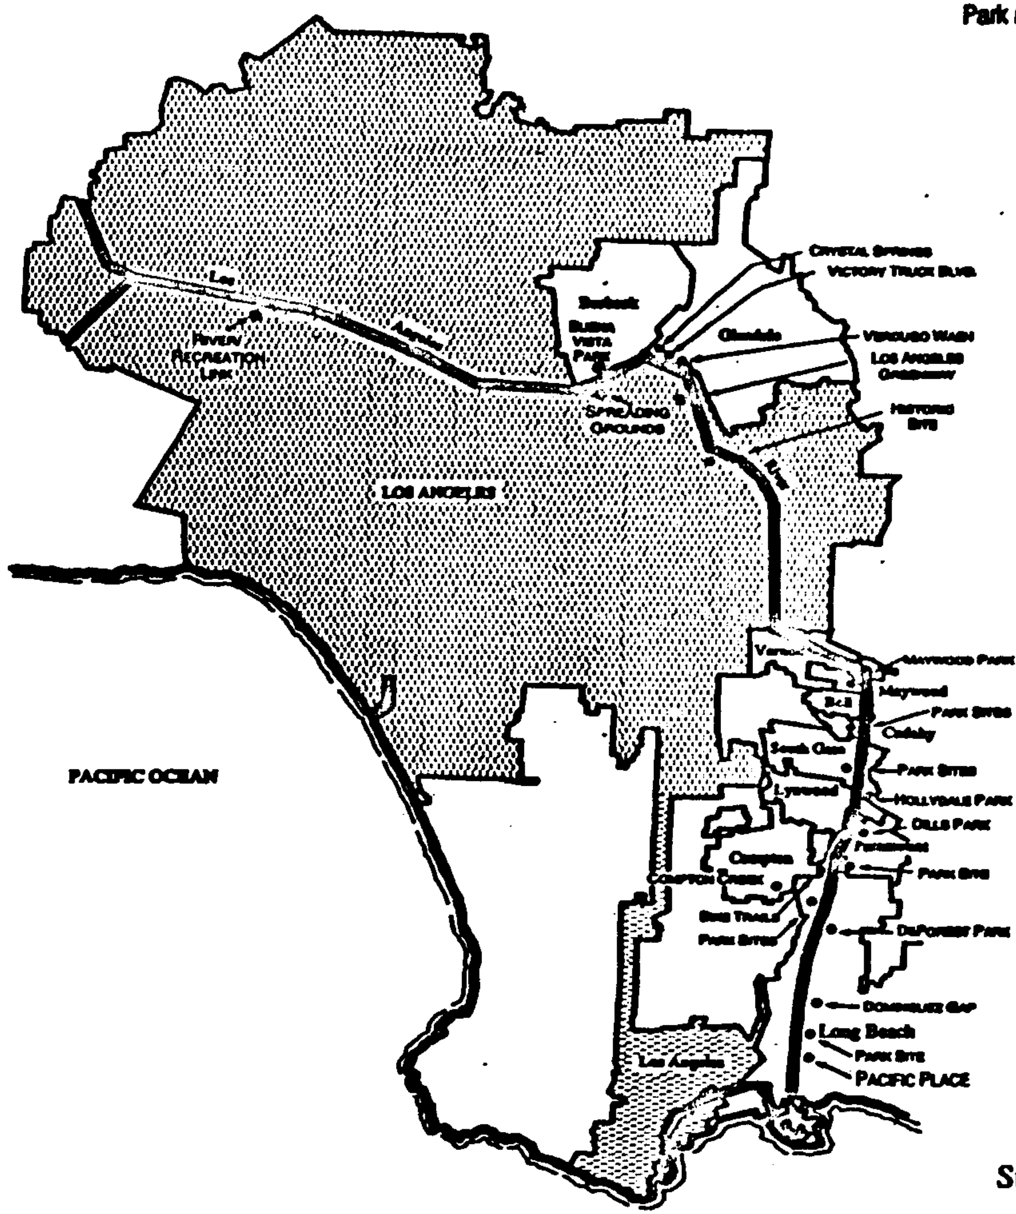
Los Angeles River Cities

Scale Unknown

VI. COMMUNITY PROJECT INVENTORY



Scale Unknown

Figure 6
Summary of Projects

VI. COMMUNITY PROJECT INVENTORY

Coastal Conservancy staff made site visits to most of the communities along the Los Angeles River, meeting with city and county officials in order to directly observe the state of existing park and recreation facilities and assess the potential for enhancement. These site visits were carried out in cooperation with staff from the Los Angeles County Department of Public Works.

The results of the Conservancy's observations are summarized below. An effort has been made to include examples of effective uses of the river corridor as well as to point out areas in need of improvement.

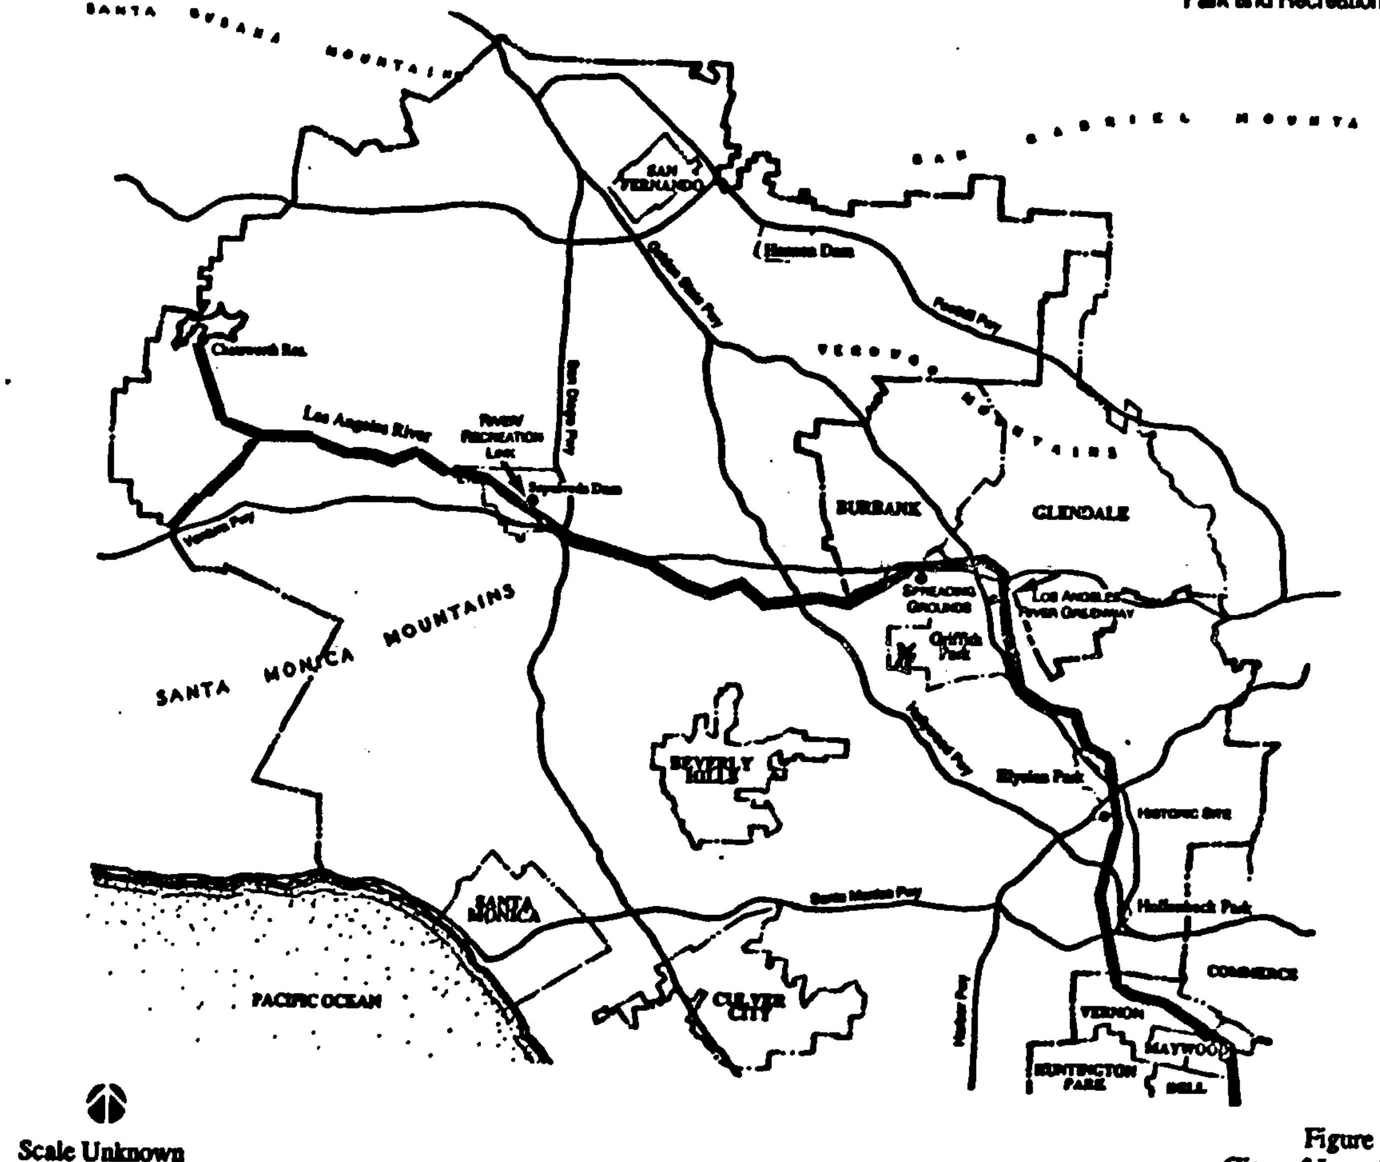


Figure 7
City of Los Angeles

LOS ANGELES

Community Profile
Area: 468.7 square miles *Population: 3,422,600*
Los Angeles is the largest city on the West Coast and the second largest city in the nation. It is the home of numerous cultural institutions, including two major universities, several art museums, and an internationally acclaimed symphony.

Los Angeles is perhaps best known as the capital of the country's multi-billion dollar motion picture industry, but the economy is in fact quite diversified, providing over 1 million jobs in 1990, primarily in the manufacturing and service industries. Both per capita income and household income in Los Angeles are slightly higher than statewide averages.

The strong economy of the Los Angeles region has attracted newcomers from all over the world, and the city of Los Angeles hosts a population of remarkable ethnic diversity. This diversity contributes greatly to the richness of Los Angeles' cultural mix.

The ethnic composition has changed somewhat in recent years, with Hispanic and Asian-American populations increasing most rapidly. African-Americans, who are leaving central and south-central Los Angeles, are gradually being replaced by a recent wave of immigrants from southeast Asia, Mexico, and Central America

Los Angeles has not escaped the problems typical of all large cities, however. As of 1989, nearly 19% of Los Angeles residents, primarily people of color, live below the poverty line. The city of Los Angeles, as well as most of the smaller surrounding cities, is plagued with gang activity, drug trade, and violent crime. Like most cities, Los Angeles has too few resources to devote to the social problems that result from poverty.

Los Angeles has 8,593 total acres of park space, more per capita acreage than many other cities along the river. The major open space areas within the city are Griffith and Elysian parks, and the Sepulveda Basin and Hansen Dam recreation areas. These parks are heavily used, attracting over 30 million visitors per year from throughout the region.

River Profile
With the exception of the stretches through Griffith Park and Sepulveda Basin, the banks of the Los Angeles River as it flows through the city of Los Angeles are entirely developed. This development is composed of a variety of land uses, ranging from dense, low-income housing, to industrial, municipal, and commercial. Much of the river is inaccessible to the public in Los Angeles. The main public open spaces within the city limits are the Sepulveda Basin and Hansen Dam recreational areas, Griffith Park, and Elysian Park, with a combined area of 8,292 acres.

<u>Sepulveda Basin Recreation Area</u>
Sepulveda Basin is a 2,150-acre flood control reservoir located in the San Fernando Valley. It serves as a good example of how flood control uses can be combined with recreation. Designed primarily as a basin to collect and hold

storm water runoff, the basin is dry outside of flood conditions and contains land in natural or semi-natural conditions suitable for wildlife habitat and low-intensity recreational uses. The entire basin is owned by the Corps of Engineers and the majority of the developable land is leased to the city of Los Angeles Department of Recreation and Parks. The city has developed the basin into a multi-use recreational area that includes three public golf courses, various baseball fields, a sports center, a landscaped park, cricket fields, picnic areas, a recreational lake, a bike path and several hiking and jogging trails. The river is used by park visitors in the Sepulveda Basin, and the city of Los Angeles has recently attempted to obtain permits from the county and the Corps to operate a recreational canoeing program on the river.

Griffith Park

Griffith Park is a 4,217-acre park located at the border of Los Angeles and Burbank. It is the largest park in the city of Los Angeles. Griffith Park is one of the three locations where the Los Angeles River seems most like a natural river. The high water table made it impossible to pave the channel bottom in this area and so the river through Griffith Park remains soft-bottomed and supports a riparian ecosystem. The river is flanked by stands of willows, sycamores, and cottonwoods, and bird and animal life abounds in and around it. The river is spring-fed in this area and so contains water year-round. The trails and paths along the river in this area, both formal and informal, are heavily used by the public for hiking, horseback riding, and bird watching. The Juan Bautista de Anza National Historic Trail, which is currently in the planning stage, will cross the river in Griffith Park. (It is thought that de Anza's 1775-76 expedition camped along the river in what is now Griffith Park.) The river corridor through Griffith Park provides city residents with a tremendous recreational amenity, while continuing to function as a flood control channel during winter storms.

Griffith Park can serve as an example of the benefit of incorporating green areas into the urban landscape. The water and plant life serves to lower temperatures and improve air quality considerably. In addition, although it is surrounded by dense development, Griffith Park provides an atmosphere of natural serenity that can provide a much-needed antidote to the rigors of urban life. In a city as densely populated as Los Angeles, more of these oases are sorely needed.

Potential Projects

Much of the industrial corridor along the river in Los Angeles is in economic transition. The largest landowners on the river, the three large transcontinental railroad companies, are selling off rights-of-way and old terminal and equipment yard facilities. Many of these facilities are being acquired by the Metropolitan Transit Authority, or MTA, (formerly the Los Angeles County Transportation Commission, or LACTC) for incorporation into the new county-wide public transit system. In addition to railroad land, many of the large industrial tracts near downtown are obsolete and are in demand for conversion to commercial and residential uses. The coming years may represent a unique historic opportunity to incorporate the river as an environmental and recreational resource into a changing downtown. Careful, proactive planning on the part of city and regional decision makers will be required. The river could be enhanced to provide the recreation facilities and green space so desperately needed within the city.

A good start has been made toward a comprehensive planning effort for the river corridor by Mayor Tom Bradley's Los Angeles River Task Force. In January 1992, this group of planners, city and county officials, administrators, and design professionals released a report that developed a set of goals for enhancing the river corridor and proposed three demonstration projects that would incorporate the stated goals. The demonstration projects are: the development of a river/recreation link in the Sepulveda Basin; the creation of a greenbelt along a segment of proposed bike path near Griffith Park; and the development of an historical site interpretive center and native plant garden in the downtown area. The mayor's staff is currently pursuing funding to implement the model projects.

The city of Los Angeles is also currently developing Phase I of the new Los Angeles River Bikeway, a Class I bikeway that will run along the west bank of the river from Elysian Park to Strathern Park in the San Fernando Valley. Phase I of the project consists of the first 7.3 miles, beginning at the confluence of the Arroyo Seco and the Los Angeles River and ending at the intersection of Riverside and Zoo drives in Griffith Park. This section of the bikeway is expected to be completed in 1995.

The development of a bikeway along the Los Angeles River is also proposed in the Army Corps of Engineers' Environmental Restoration/Recreation Reconnaissance Study. The Corps' bike path proposal includes plans for a 19.2-mile Class I bicycle path running from the confluence of the Los Angeles River and the Arroyo Seco near downtown, to the Sepulveda Dam Recreation Area. The trail would run along the west bank of the river (becoming the south bank where the river bends to run east-west) from the Arroyo Seco, crossing over the river at Hazeltine Avenue at the Ventura Freeway, and from there would continue on the north bank of the river to the Sepulveda Dam Recreation Area. The Corps proposes the development of a parallel bike trail on the north bank of the river between Fulton Avenue and Colfax Avenue in the San Fernando Valley. The Corps' proposal also includes plans for open space amenities such as small parks along the bike path and a golf course on the north bank in the San Fernando Valley. The bikeway proposal, though approved, has not been recommended for further study. Implementation of the project is, therefore, uncertain.

Another proposal included in the Army Corps of Engineers' Environmental Restoration/Recreation Reconnaissance Study is the construction of a spreading grounds for groundwater recharge on a 48-acre parcel (owned by the Los Angeles City Department of Water and Power) on the south bank of the river in Griffith Park. This proposal includes plans for the construction of an artificial streambed that would run along the perimeter of the spreading grounds and would be flanked on both sides by riparian vegetation. The center of the spreading grounds would remain bare or would be paved with a permeable material that would allow water percolation but prevent the growth of volunteer plants. The existing equestrian staging area adjacent to the 48-acre site could also be used as a spreading grounds with the existing equestrian trail running along the perimeter. Lawns and rest areas could be placed adjacent to the spreading grounds along the existing trails.

Some additional proposals for the river area downtown may grow out of the Downtown Strategic Plan, currently under development by the Los Angeles Community Redevelopment Agency. The draft Downtown Strategic Plan contains a major open space element that recognizes the opportunity to create additional park space on the east side the river.

One very ambitious scenario proposes that the entire area from the river east to Hollenbeck Park, between the 1st Street Bridge and the Olympic Boulevard Bridge, be developed into one large park. Smaller-scale scenarios include proposals for a 100-foot-wide river-front esplanade linking a series of smaller parks. All of the proposals include the assumption that a river-front park should also function as a flood detention basin during the rainy season. The river area is not currently included in the downtown redevelopment district, however, and so such plans are still only conceptual.

A new redevelopment district may soon be forming to include much of the area east of the Los Angeles River. Steps should be taken to include the river in either this new redevelopment district or in the downtown redevelopment district for the express purpose of formulating a comprehensive open space plan for the area near the river.

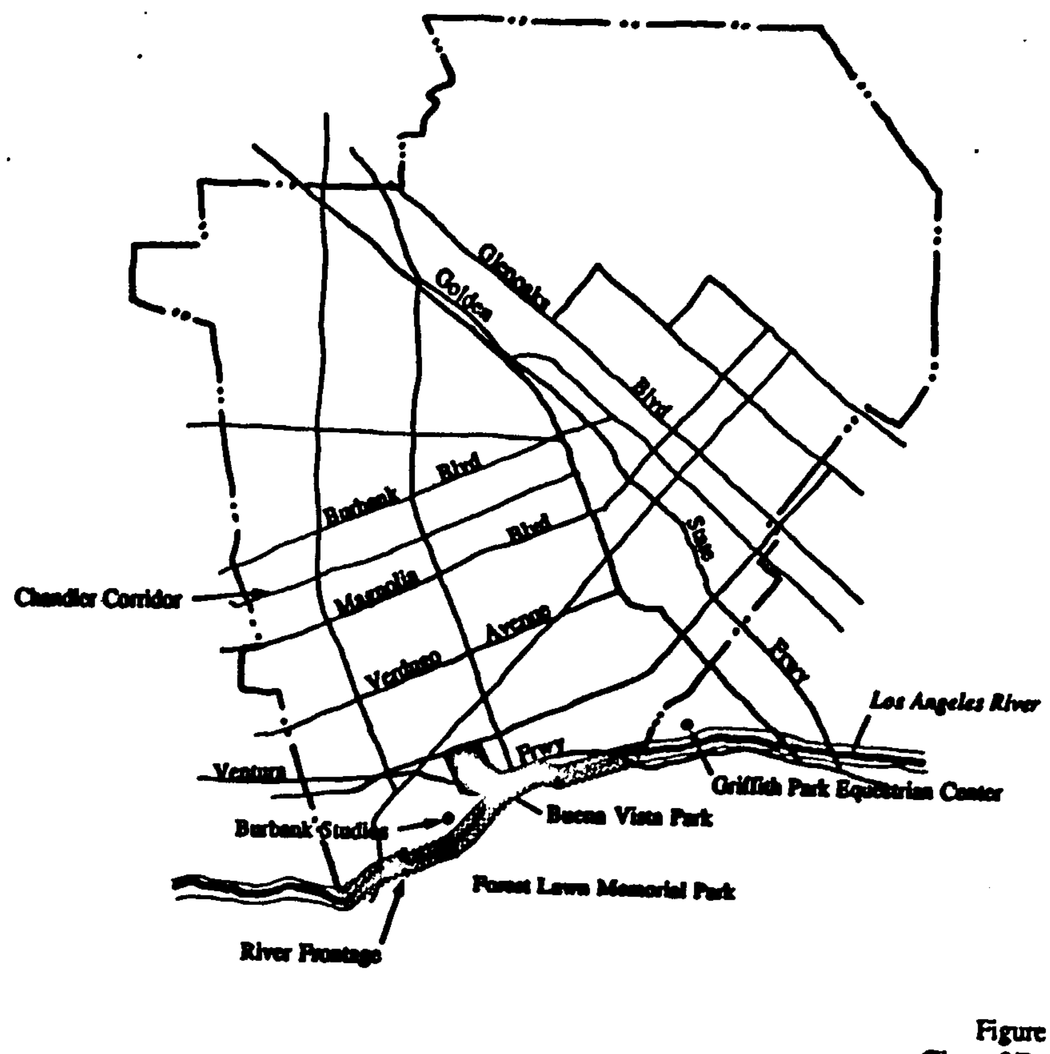

Figure 8
City of Burbank

BURBANK

Community Profile

Area: 17 square miles *Population: 93,643*

Burbank is the fourth-largest city in the study area. Its population is primarily non-Hispanic white, with Hispanics comprising the second-largest ethnic group.

Burbank was incorporated in 1917 and by the mid-1920s had become a center for the burgeoning motion picture and aviation industries; a trend that exists to this day. Warner Brothers and Walt Disney studios and the Lockheed Corporation are still among the city's ten largest employers. Burbank is economically healthier than many other cities in the Los Angeles area. As of 1992, Burbank's unemployment rate was 5.9%, substantially lower than state and county-wide averages. With an almost 1:1 ratio of employment to population, Burbank has been classified by the federal government as a job-rich "Central City."

The city is actively undertaking the revitalization of its downtown business district through the planned development of several projects, including a sports arena, a new retail center, a new branch of the Los Angeles County Natural History Museum, and a transit center to accommodate the county public transit system that is currently under construction. City officials are interested in encouraging non-motorized transportation as a part of redevelopment plans through the development of bicycle trails that would connect with transportation nodes. The river corridor in Burbank could undoubtedly play a role in the development of such facilities.

The city of Burbank contains 830.7 acres of parks and open space, including the 113-acre DeBell Golf Course. The largest parks in Burbank are Stough Park, Wildwood Canyon Park, and Brace Canyon Park. Stough Park and Wildwood Canyon Park are largely undeveloped open space.

River Profile

Burbank contains approximately two miles of river frontage. Through Burbank, the Los Angeles River is contained in a below-grade concrete channel. The river approximately delineates the boundary between the city of Burbank (on the north) and the city of Los Angeles (on the south). Through Burbank, land use on the north bank of the river is residential (upper middle class homes on 1/3- to 1/2- acre lots), with fenced and landscaped back yards facing the river. Many of these homes are zoned to allow horse ownership, and a dirt equestrian trail, beginning at the Griffith Park Equestrian Center, continues through Burbank past these homes, ending at the Burbank Studios. Across the river from Burbank lies Forest Lawn Memorial Park, and an undeveloped portion of the Hollywood Hills. Because of the open space on the south bank and the landscaped back yards facing onto the north bank, this portion of the river is lined on both sides with trees that produce a pleasant and inviting atmosphere for the equestrian trail. It is a good example of the dramatic improvement that can be made simply by landscaping the river banks. Trees growing alongside the channel can make a great deal of difference in the appearance and overall feeling without altering the actual channel at all.

Buena Vista Park is the primary public open space near the river in Burbank. The park is centered around a tributary flood channel that flows into the Los Angeles River. The flood channel was formerly a typical concrete-lined culvert that was replaced with an artificial streambed that carries the creek's normal flows. The artificial stream has a winding, rocky bed similar in appearance to a natural streambed. The main channel meanders and has been embellished with rocks and plants. It is flanked by grassy terraces about four feet high on either side that have been landscaped and contain concrete benches and picnic tables. These terraces are about three feet lower than the rest of the park and carry high waters when the main channel overflows. The terraces are bounded by artificial rock ledges, which act as the walls of the high-flow channel. The artificial streambed is a vast improvement aesthetically over the old concrete culvert and is a major attraction of Buena Vista Park. The project won a design award from the American Society of Landscape Architects for park and recreational planning. The park is very well used; it is adjacent to three major television studios and a large medical center, and close to a residential area.

Potential Projects

Buena Vista Park continues across Riverside Drive down to the river where it connects with the equestrian trail that runs along the top of the Los Angeles River channel. This equestrian trail is at present the only recreational facility actually located on the river in Burbank. City officials have expressed interest in expanding uses of its river frontage for bicyclists and pedestrians, and in expanding Buena Vista Park to the east to connect with Griffith Park. This expansion is proposed for some land adjacent to the river that is owned by the city of Los Angeles but is physically accessible only from Burbank. Such an expansion would create a continuous greenbelt from Griffith Park to Buena Vista Park that could be incorporated into the existing river trail system.

Burbank contains two flood hazard areas and control of flood waters is a high priority for the city, but the development of bikeways and pedestrian paths is also a high priority. Burbank will soon begin developing a comprehensive bikeway plan for the entire city that will include plans for a river bikeway. An off-street bikeway along Interstate 5 has already been developed and the mayor is expected to appoint a task force to develop the bikeway plan. One of the main objectives is to create a link with bike trails from other cities and to actually make it feasible to commute by bicycle.

One area under discussion is the Chandler Corridor, an old Southern Pacific railroad line that is now owned jointly by the Metropolitan Transit Authority (MTA) and the city of Burbank. Plans for this corridor include a light rail mass transit line and a bicycle trail that will connect with the Multi-Modal Transit Center (for the Red Line) planned for downtown Burbank. The city has already purchased land for the transit center from Southern Pacific Railroad.

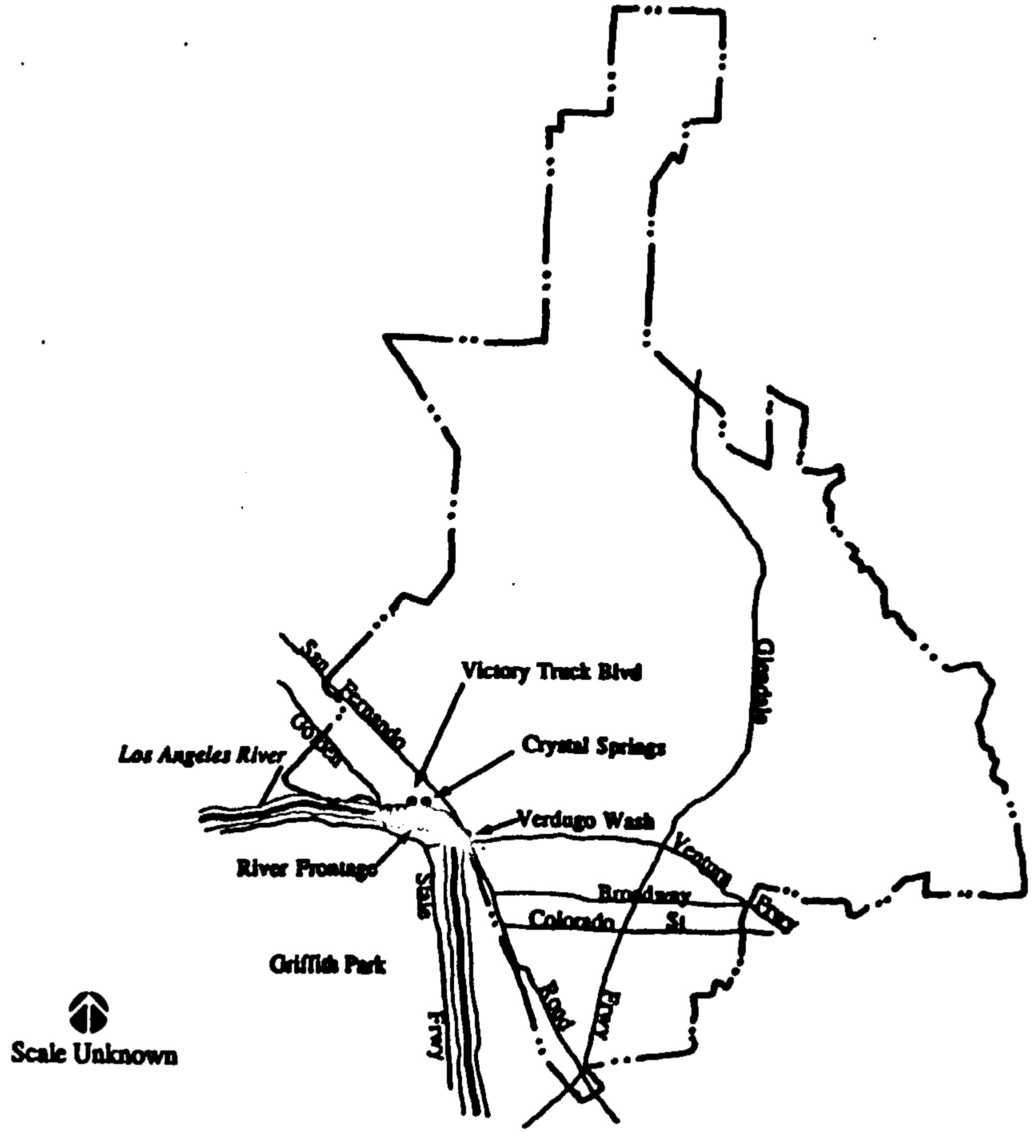

Figure 9
City of Glendale

GLENDALE

Community Profile

Area: 30.48 square miles *Population: 185,000*

Glendale is the third-largest city in Los Angeles County after Los Angeles and Long Beach. The city has experienced significant population growth in the last ten years. The 1990 Census found that the population of Glendale increased by 29.5% between 1980 and 1990. Glendale's annual growth rate had been declining since the 1960s to a low of 0.5% between 1970 and 1980. A building boom in the 1980s, however, reversed the trend and resulted in a growth rate of 2.6%, which was higher even than the 2.2% rate between 1950 and 1960.

Glendale's population is predominantly non-Hispanic white (64%) and 68% of the population is older than 25. The city has the highest average household income ($44,936) of any of the Los Angeles River cities. Retail trade, finance, insurance, and real estate are the city's major employers.

Along with population growth has come a large demand for recreational and open space facilities. Existing parks and athletic fields are always in use. There is an especially great need for parks on the west side of the city.

The city has formed a redevelopment agency for the San Fernando Road corridor adjacent to the river. The redevelopment agency is interested in public improvements along the river and has proposed that $1.5 million be allocated for planning such improvements.

The Juan Bautista de Anza National Historic Trail, presently in the planning stage, will cross Glendale in the vicinity of the Los Angeles River.

River Profile

The portion of the Los Angeles River within the city of Glendale is approximately one mile long and includes the area where the river curves south heading toward the sea. The river area is a mix of residential, office park, and industrial uses. There is some vacant land immediately adjacent to the river, eight acres owned by the city of Los Angeles, identified as Crystal Springs, and four acres of land owned by the city of Glendale along Victory Truck Boulevard. Griffith Park is located across the river from Glendale.

The river channel in Glendale is part of one of the three unpaved sections of the Los Angeles River. The river channel has near vertical concrete walls and a cobblestone bottom. A significant amount of mixed native riparian and exotic vegetation has grown in the channel on the Griffith Park side of the river. The Glendale Narrows area provides habitat for a number of different bird species, including pied-billed grebe, cinnamon teal, black phoebe, and red-winged blackbirds.

The mouth of the Verdugo Wash, near where the 134 Freeway crosses the river, has a soft-bottomed channel. The wash supports a dense growth of mixed native riparian and exotic vegetation, including willows. The area may now be functioning as riparian habitat for several plant and animal species.

Potential Projects

Crystal Springs: This is an eight-acre site along the river owned by the city of Los Angeles and managed by the Department of Water and Power. It is currently vacant and used for monitoring well sites and storage of materials.

The city of Glendale is interested in developing the site (in conjunction with a parcel of land owned by Glendale along Victory Truck Boulevard) with athletic fields. The park could have a bike trail and bridge across the river to Griffith Park.

The city has also considered establishing an environmental education program, possibly including an interpretive center, at this site as part of the proposed park. Interpretation of the river at this site would make sense as the Glendale Narrows section is one of the three remaining soft-bottomed sections of the river, contains a significant amount of vegetation in the channel, and supports high bird use.

The U.S. Army Corps of Engineers has prepared a draft environmental restoration/recreation reconnaissance study for the Los Angeles River (November 1992). The study identifies this site for potential restoration. The proposal calls for the creation of a two-acre seasonal wetland, plantings of riparian and wetland vegetation, and construction of a trail on one side of the wetland.

Victory Truck Boulevard: This four-acre parcel is owned by the city of Glendale. The property could be connected with Crystal Springs to be developed as a large active recreation park, including athletic fields and a bike trail, or it could be included in the Army Corps' proposed wetland restoration project.

Environmental education: The city is interested in the idea of developing an environmental education program for the Los Angeles River similar to one now being developed at the Governor Deukmejian Wilderness Park in the San Gabriel Mountains. An interpretive center could be established as part of the development of a river park at the Crystal Springs site. An environmental education program would likely focus on: the plant and animal habitats of the Glendale Narrows section of the river; Native American history of the area; the Juan Bautista de Anza expedition, etc.

Verdugo Wash: The habitat value of this channel should be assessed and recommendations made for its improvement for plants and animals.

Los Angeles River
Park and Recreation Area Study

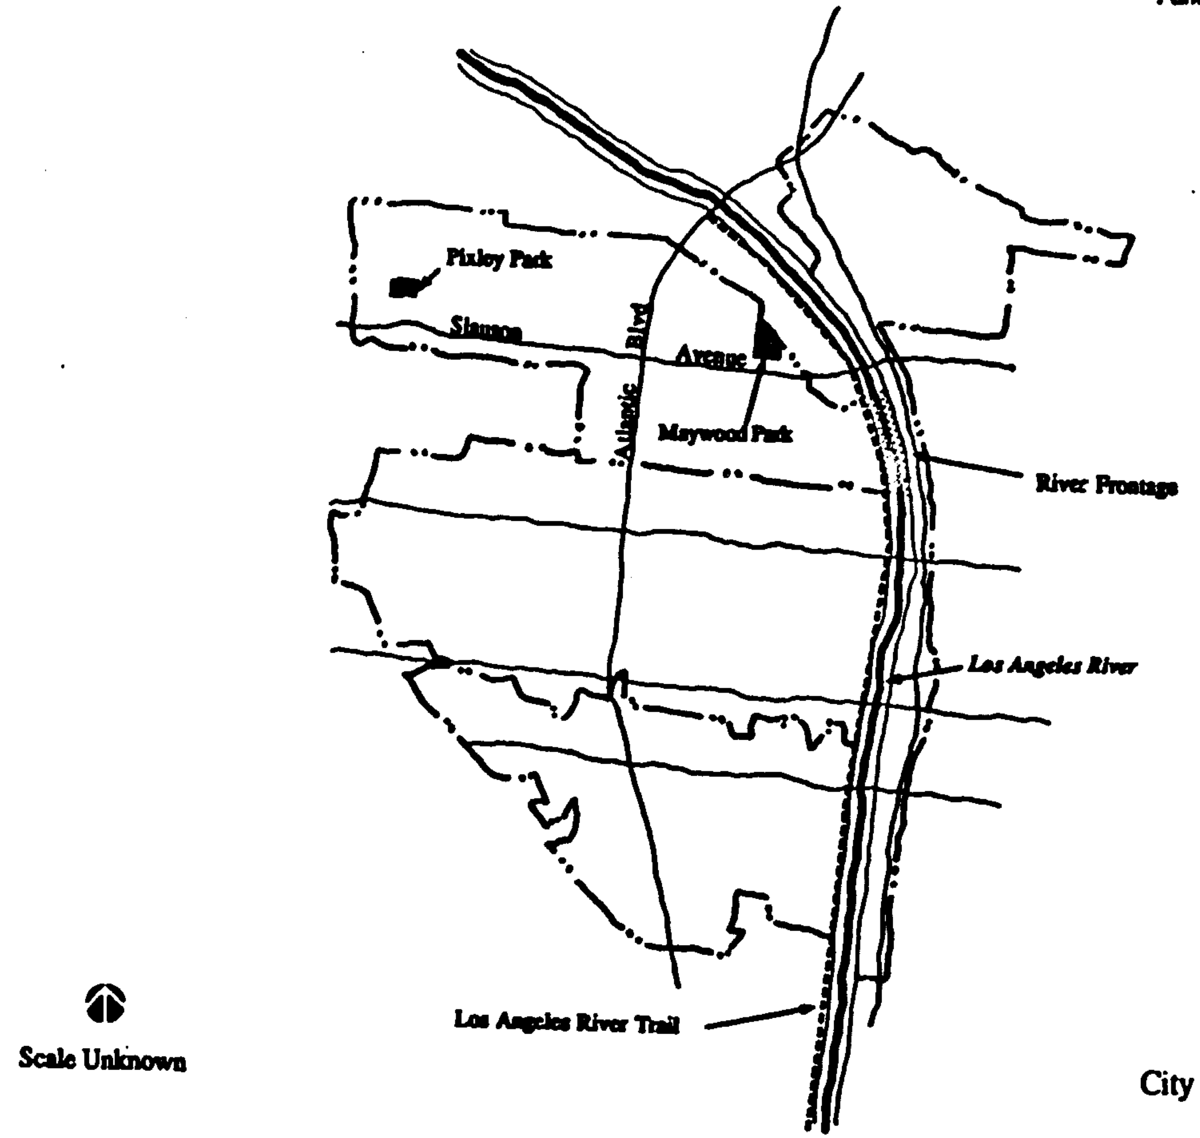

Figure 10
City of Maywood

MAYWOOD

Community Profile

Area: 1.41 square miles *Population: 28,552*

Maywood is a small residential community located southeast of Los Angeles. The city is primarily residential with two main commercial streets, Atlantic Boulevard and Slauson Avenue, and some light industry on the city's periphery. Maywood's population is predominantly Hispanic (93%) and the city's population density (23,900 persons/square mile) is the highest of any of the cities along the Los Angeles River. Manufacturing and retail trade are the largest employers in the city.

Maywood has two parks, Maywood Park (five acres) and Pixley Park (half acre). Existing recreation facilities are in heavy demand and the city needs to develop more, especially soccer fields and baseball fields.

River Profile

Maywood's river frontage extends for approximately one-half mile between Slauson Avenue and Randolph Street on the west bank of the river. The river in Maywood is characterized by steep rock-gunite banks and a concrete bottom. The Los Angeles River Trail runs along the top of the levee. Access to the trail is possible from Randolph Street and Slauson Avenue.

The land uses along the river consist of several light industrial activities in the first block immediately adjacent to the river channel and residential development behind the industrial area.

Potential Projects

There are no park, recreation or habitat improvements possible along the river channel in Maywood at this time. The river bank and levee are completely paved. The area adjacent to the river is zoned industrial and consists of a paved street and a developed industrial strip.

The city would like to make some improvements to Maywood Park, located three blocks from the river channel. This heavily used park is in need of new landscaping and walkways.

The city would also like to develop some new soccer fields to address the increasing demand on the limited existing facilities. These new facilities would likely not be constructed near the river.

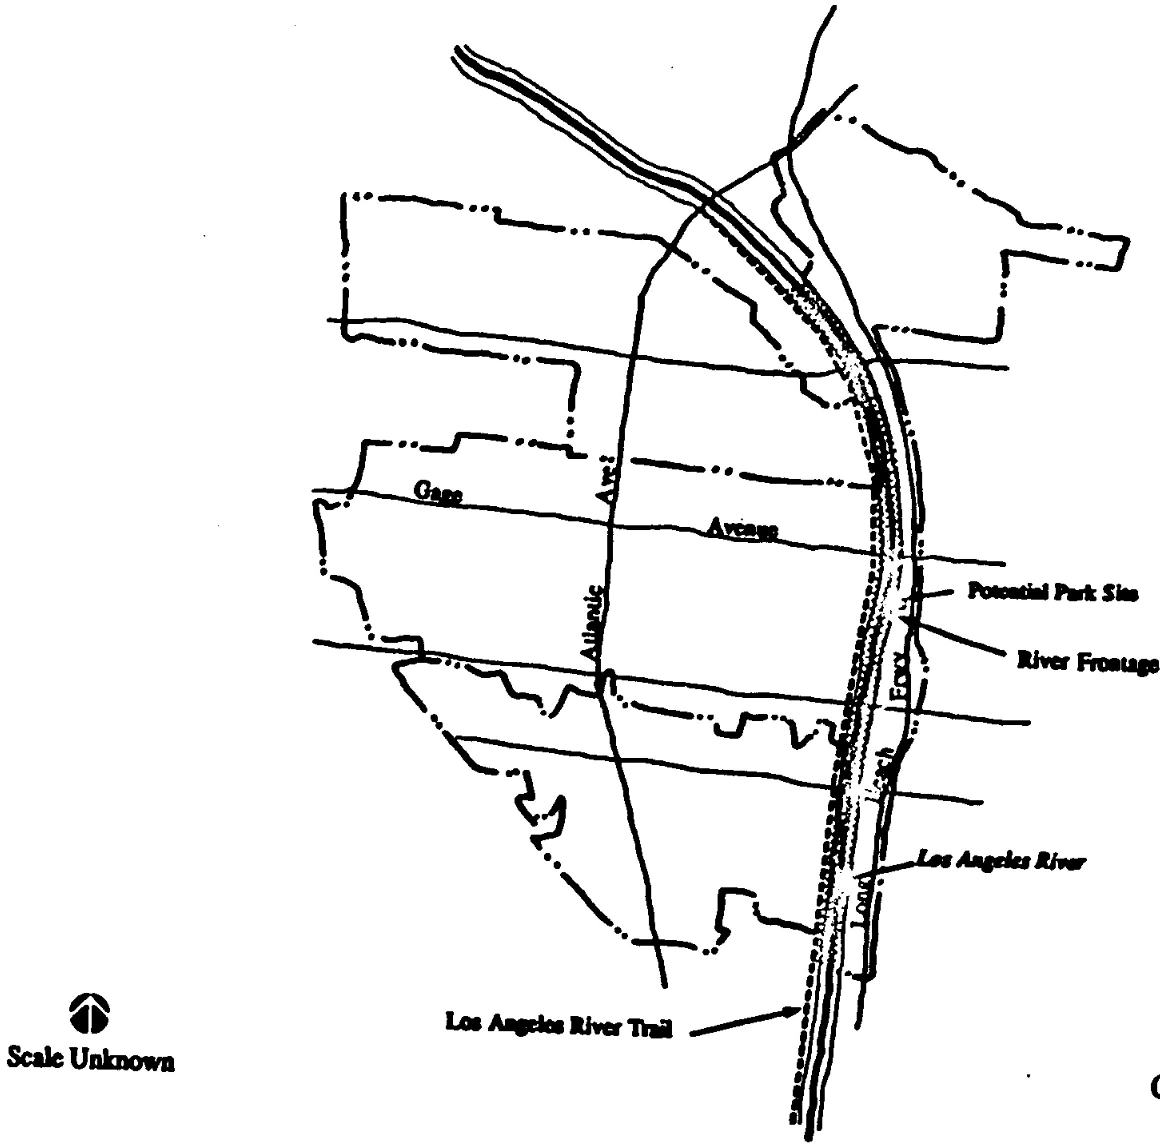

Figure 11
City of Bell

BELL

Community Profile

Area: 2.81 square miles *Population: 34,365*

The population of Bell is predominantly Hispanic (86%) with an average household size of 3.8 and an average household income of $31,569. Bell is a densely developed city but has very little park space. There are only five parks within the city limits, all less than three acres in size. With less than 12 acres of total park space and more than one-third of its population below the age of 18, the demand for parks and recreation facilities in Bell clearly exceeds demand.

River Description

The city of Bell straddles the river over a distance of approximately three miles. As it runs through Bell, the river is contained within levees that stand approximately ten feet above street level. The city's entire residential area and most of its commercial development is west of the river. This portion of Bell is entirely developed with no vacant land whatsoever. Residential development extends all the way to the county right-of-way at the edge of the levee. The area adjacent to the river contains some of Bell's lowest-cost housing. The Los Angeles River Trail runs along the top of the west levee through Bell.

The portion of the city lying east of the river is also very densely developed, almost entirely with industrial uses, but does contain the few undeveloped parcels remaining in Bell. Ownership of the vacant parcels is not certain, as this land lies between the Long Beach Freeway and the river's edge.

Potential Projects

Parks and recreational facilities are sorely lacking in Bell and the development of additional recreational facilities is a high priority for the city. Unfortunately, Bell has very little money available for the acquisition and development of additional park space. City Parks and Recreation staff are currently pursuing funding options for parks development.

Bell's redevelopment district includes some river frontage on the east side of the river, and the creation of additional park space on any vacant land near the river could be included in any redevelopment proposals. In addition, some of the large industrial tracts immediately adjacent to the river, west of the Long Beach Freeway, could potentially be converted to park use. Such a park should be made accessible to users of the Los Angeles River Trail by providing crossover points at Florence or Gage Street. It should include landscaping with native and/or drought-tolerant species, restrooms, drinking fountains, benches, and shaded areas. The adjacent city of Bell Gardens is currently preparing a parks master plan. It may be advantageous for both cities to establish a park on river-front property in Bell and adjacent to Bell Gardens to be administered jointly by the two cities.

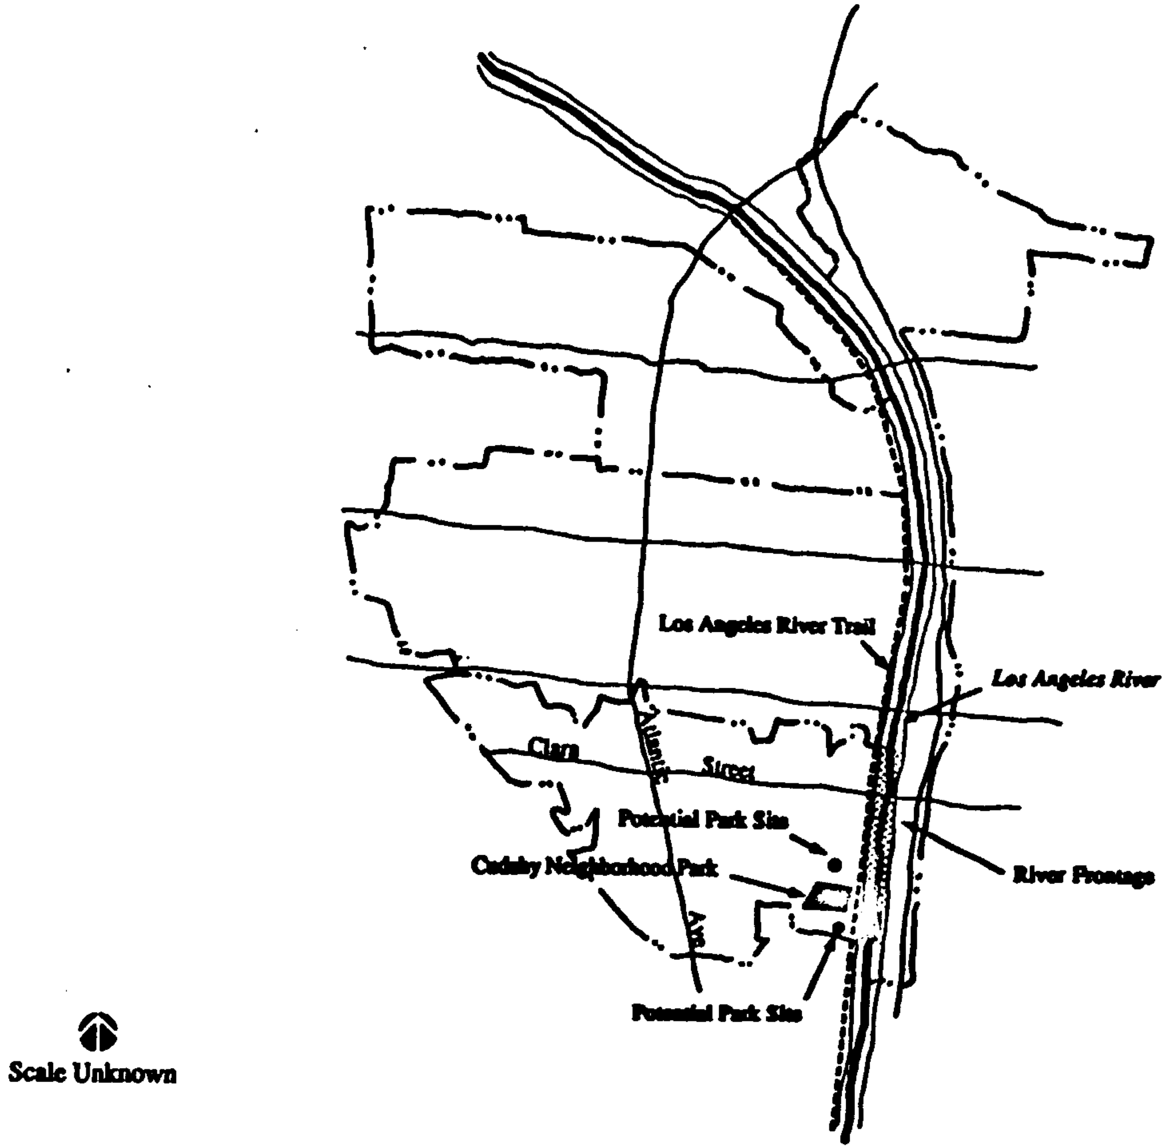

Figure 12
City of Cudahy

CUDAHY

Community Profile

Area: 1.07 square miles *Population: 20,400*

Cudahy is a small city with one of the lowest per capita incomes in the state. Its population is predominantly Hispanic (88%) and extremely young: over 38% of the population is under the age of 18. Average household size is 4.3 persons and the average household income is $30,336. Cudahy has one of the highest population densities in Los Angeles County. The city has approximately 5,416 housing units, and another 200 are expected to be constructed by 1995. Once these units are built, the city will be very near its projected maximum housing build-out level. The current population density and the expected near-term growth point to the need for additional park space and supervised recreation programs.

Besides the Cudahy Neighborhood Park, there are only two other, much smaller, parks in Cudahy for a total of 19 acres of park area. The city's particularly low median age imposes a great demand on municipal recreation programs; participation in youth recreation programs has more than doubled in the last three years. Currently, more than 1,000 youngsters are enrolled in the city's recreation programs. The need for playing fields and ballparks is particularly great, but more space is also needed to provide passive recreation opportunities for senior citizens, and picnic facilities and play areas for young families.

River Profile

The Los Angeles River is contained behind levees approximately 15 feet above grade as it runs through Cudahy for approximately one mile. The land adjacent to the river in Cudahy is a high-density, low-income residential area developed in the 1950s. The 13-acre Cudahy Neighborhood Park and Civic Center, as well as the public elementary school, are located next to the river. Development extends all the way up to the county right-of-way at the foot of the levee. The area below the levees is extremely low ground that floods routinely during even minor storms. The Los Angeles River Trail runs along the west levee.

Potential Projects

The demand for recreational facilities in Cudahy is very high and the existing facilities are inadequate to meet this demand. City staff have identified two vacant parcels near the river as suitable for these uses: a small one-acre parcel at Park and Elizabeth streets, and a large 40-acre parcel at Fostoria Street and River Road. Both of these sites are in close proximity to the river and to Cudahy Neighborhood Park. The overriding recreational need in Cudahy is for playing fields of all kinds, baseball and/or softball parks in particular. Were these parcels to be acquired by the city, their primary use would undoubtedly be as playing fields given the high demand, but these parcels could also serve as staging areas for the Los Angeles River Trail. Restrooms, drinking fountains, benches, and bike racks should be provided, as well as a striped and signed bicycle route over city streets connecting both of these areas with Cudahy Neighborhood Park and with the Los Angeles River Trail. The city of Cudahy lacks the funds to acquire or develop additional park space, but city staff are working with state and local agencies to identify funding sources for the acquisition of these parcels.

VOL 12

6738

R0050043

Los Angeles River
Park and Recreation Area Study

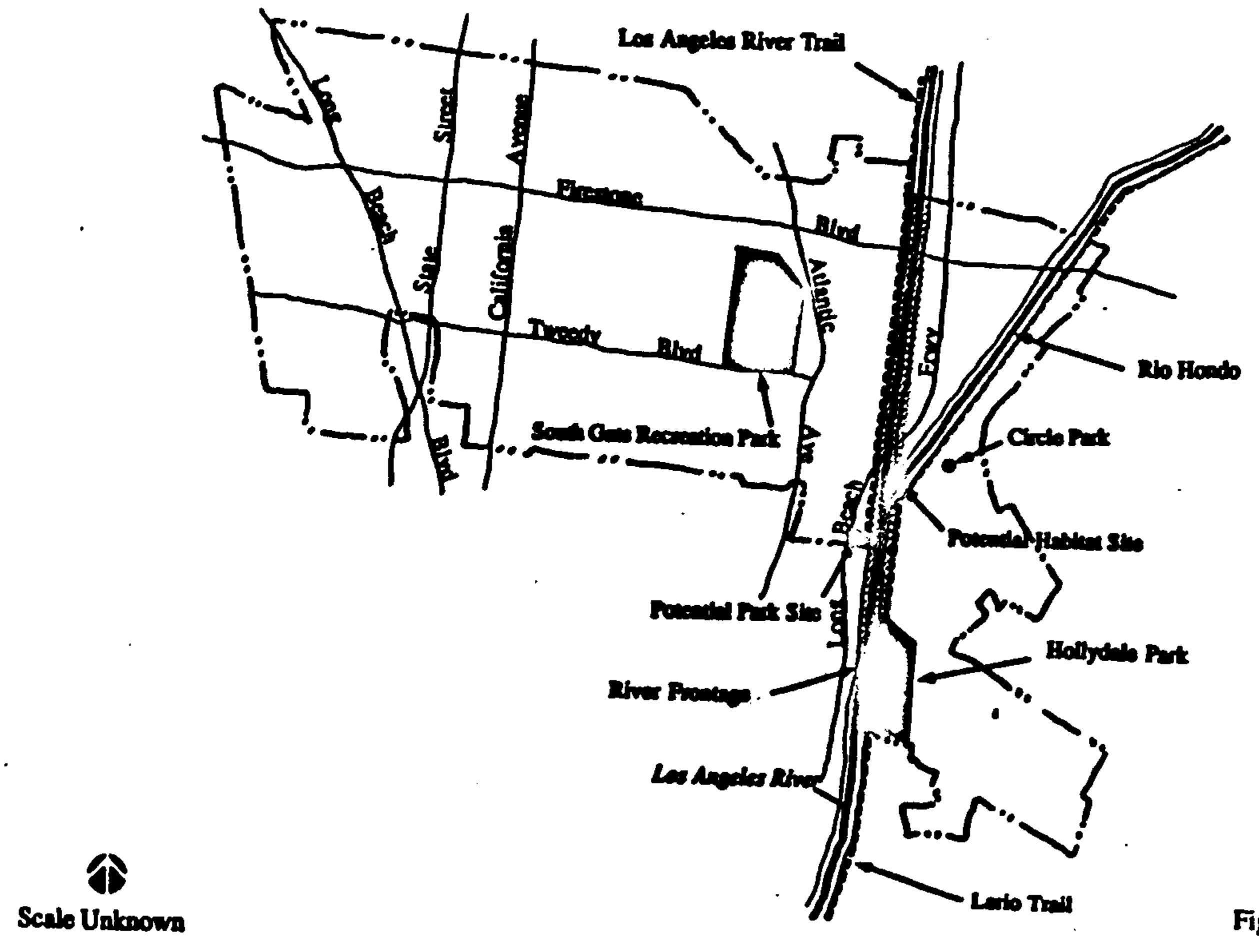

Figure 13
City of South Gate

SOUTH GATE

Community Profile

Area: 7.32 square miles *Population: 86,284*

South Gate is a small industrial city located ten miles south of downtown Los Angeles. The city has a young (68% under age 35) and predominantly Hispanic population (83%).

Manufacturing and retail trade are the largest employment sectors in the city. In recent years, however, several of the large industrial employers have closed their plants in South Gate. Many of these plant closings have occurred in the industrial area along the Los Angeles River. The city has created a redevelopment agency to address redevelopment of much of the area adjacent to the river.

The city has eight park facilities, ranging from 97-acre South Gate Recreation Park and 56-acre Hollydale Park on the east side of the city to three small playgrounds on the west side. Hollydale Park is the only park located adjacent to the Los Angeles River.

The city's major need is for park/open space on its west side. Its major park and recreation facilities are all located on the east side of the city. Hollydale Park, the city's second-largest park, is isolated from most of the city by virtue of its location on the east side of the Los Angeles River. Residents of the west side of the city are poorly served by the existing facilities.

River Profile

South Gate has an approximately 2.5-mile stretch of the Los Angeles River within its city limits and occupies both banks of the river for much of that stretch. The Rio Hondo meets the Los Angeles River in South Gate. The river in South Gate is characterized by steep rock-gunite banks and a concrete bottom. The Lario Trail follows the east bank of the river until it reaches the mouth of the Rio Hondo, from which point it travels along the Rio Hondo. The paved trail is paralleled by an equestrian trail. The Los Angeles River Trail runs along the levee on the west bank of the river north from Imperial Highway.

The river is lined by a mixture of industrial and residential land uses. Much of the industrial area is now derelict. The city has one large park located adjacent to the river, Hollydale Park. The city's major park, 97-acre South Gate Recreation Park is located approximately one-half mile west of the river. Circle Park, a four-acre neighborhood park, adjoins the Rio Hondo north of the confluence of the Rio Hondo and Los Angeles River.

Hollydale Park has a playground, basketball, volleyball, handball and tennis courts, several athletic fields, and an equestrian center. The park is located on the east bank of the river in the Hollydale neighborhood, which is isolated by its location on the opposite bank of the river, south of the rest of the city.

A narrow strip of undeveloped county right-of-way lies along the residential areas adjoining the river. A large undeveloped property lies along the west bank of the river immediately north of Imperial Highway. A triangular parcel at the confluence of the Los Angeles River and the Rio Hondo is also undeveloped.

Potential Projects

South Gate is in great need of active and passive parks and open space. The city needs new athletic fields, playgrounds, community recreation rooms, and picnic areas. Although the need for new facilities is on the west side of the city, vacant land along the Los Angeles River developed as a park or recreational facility would still benefit the community.

The possibility of developing the vacant rights-of-way and easements described above should be pursued. Narrow, vacant stretches of right-of-way on both sides of the river should be landscaped, preferably with native and/or drought tolerant species.

The triangular parcel at the confluence of the Los Angeles River and the Rio Hondo is not easily accessible as it is surrounded by water on two sides and the Long Beach (710) Freeway and the Union Pacific Railroad tracks block access from the north. The isolation of this parcel, though not conducive to a park site, would be beneficial for habitat. The introduction of shallow ponds and riparian vegetation may attract birds to this relatively isolated and, therefore, relatively "safe" site.

The large vacant parcel on the west bank of the river north of Imperial Highway between the Long Beach Freeway and the river is a continuation of a vacant parcel south of Imperial Highway in Lynwood. The parcel is accessible from the Imperial Highway; the Los Angeles River Bike Trail begins adjacent to the parcel at Imperial Highway. Use of the site could be addressed in a number of ways: landscaping with native and/or drought tolerant trees and shrubs, development of a passive park or staging area for the Los Angeles River Trail, or development of a small-scale recreational facility.

The park or staging area should be landscaped and provide some or all of the following: parking, bike racks/lockers, restrooms, water fountains, benches, and trash receptacles. The staging area could serve both the Los Angeles River Trail and the Lario Trail on the east bank of the river.

Development of a recreational facility, i.e., playground or athletic field, could be problematic at this site due to the small size of the parcel in relation to the amount of space needed for a soccer field, parking lot, restrooms, etc. In addition, access to and from the site from Imperial Highway would be more of an issue for a facility such as a soccer field, which would likely attract more car traffic than would a small passive park or staging area.

The city would like to make several improvements to Hollydale Park, including new tennis courts, new fencing for the equestrian center, and upgrading of the existing playground.

VOL 12

1

6742

R0050047

Los Angeles River
Park and Recreation Area Study

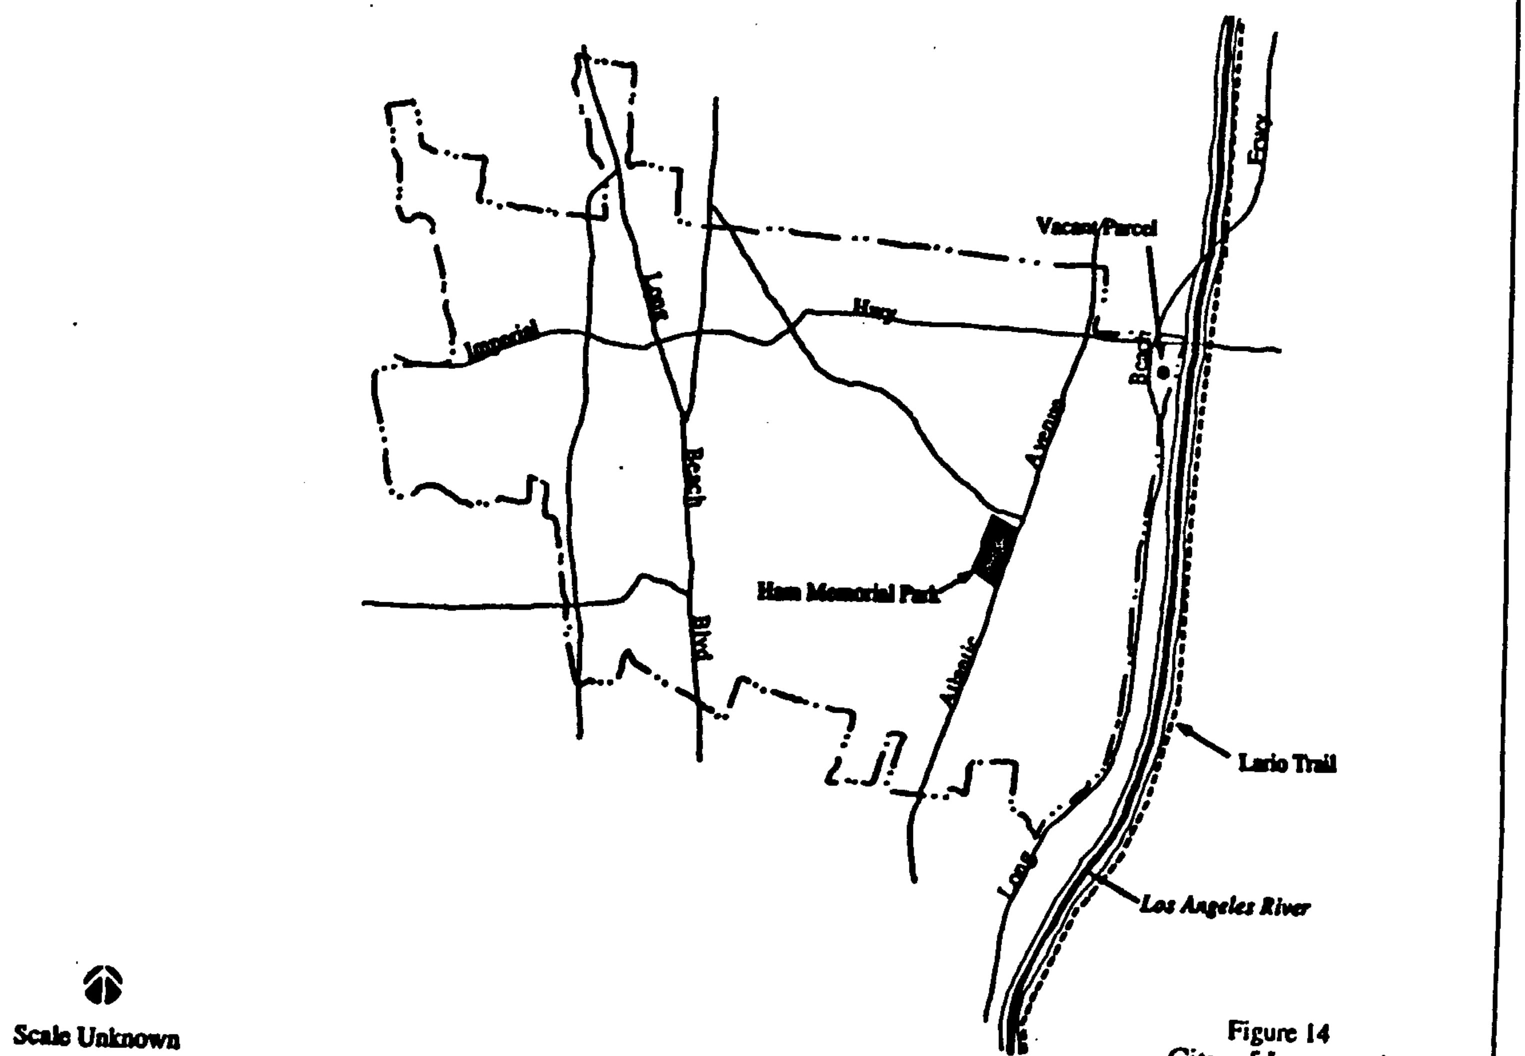

Figure 14
City of Lynwood

LYNWOOD

Community Profile

Area: 5 square miles *Population: 54,400*

Lynwood is extremely densely developed with very little vacant land. Affordable housing is in very short supply and the construction of additional housing is a high priority for the city. Only three parks serve Lynwood: Mervyn Dymally Park, Ham Memorial Park, and Los Amigos Park. Dymally Park is the largest at 32 acres. Ham and Los Amigos parks are substantially smaller, 11 acres and three acres, respectively. With 46 acres of park space for over 66,000 people, the existing park facilities in Lynwood are inadequate to serve the recreational needs of the community.

River Profile

The land adjacent to the river in Lynwood is almost entirely developed, and the Long Beach Freeway obstructs any direct access to the river from Lynwood. The only undeveloped areas of river frontage are small patches of vacant land between freeway on-ramps. The Lario Trail runs along the east levee of the river in this location, across the river from Lynwood, and there is no access to the trail from Lynwood.

The largest tracts of land in single ownership directly adjacent to the river are industrial tracts that are currently in use.

Potential Projects

Lynwood would appear to have very little potential for parks development. City staff have stated that the construction of additional housing on the remaining vacant land is a higher priority than parks development. Lynwood has few resources to devote to parks and recreation, and even were it to receive money from outside sources, very few sites are suitable for new parks development. The only possibilities for additional recreational facilities in Lynwood would appear to be through the conversion of existing uses.

However, residents of Lynwood could gain better access to the parks on the east side of the river in South Gate and Paramount if connections were provided from Lynwood across the freeway and the river to the Lario Trail. It may be possible to provide such a connection from Imperial Highway. A striped bike and pedestrian lane would be one way to provide this connection, but it may be safer and more feasible to shuttle bicyclists and pedestrians from Lynwood to the east side of the river via the existing shoppers' shuttle bus service. Buses could be equipped with bike racks and expand their current route to include a destination on the east side of the river at or near an access point to the Lario Trail.

Some small vacant parcels between the freeway on-ramps and the river could possibly be improved with landscaping or enhanced for wildlife habitat. In particular, the vacant parcel between the river and the Long Beach Freeway that connects with a vacant parcel in South Gate could potentially be landscaped or enhanced in such a way. In South Gate, this parcel connects to the Los Angeles River Trail, but no such connection exists in Lynwood. This area is not safely accessible to the public for recreational use.

Figure 15
City of Paramount

PARAMOUNT

Community Profile

Area: 4.8 square miles *Population: 45,700*

Paramount is a small industrial city located north of Long Beach. Hispanics are the largest segment of the population (60%), with non-Hispanic whites and African-Americans representing the next largest ethnic groups, 20% and 10%, respectively. Average household size is 3.8 and average household income is $32,466. The manufacturing and wholesale trade industries are the largest employers.

Paramount has approximately 40 acres of total park space. The largest park in Paramount is Senator Ralph C. Dills Park, better known as Banana Park, a ten-acre park next to the east levee of the Los Angeles River.

River Profile

Paramount has slightly more than two miles of river frontage. The river frontage north of Rosecrans Avenue is entirely developed with residential and industrial uses. Dills Park, the largest of Paramount's ten parks, runs next to the river right-of-way for approximately one-half mile between Rosecrans Avenue and Somerset Boulevard. Dills Park is a long narrow strip-park immediately adjacent to the county right-of-way below the east levee. It is bordered by the Compton Golf Course on the south. The park has a bike trail, picnic facilities, handball courts, and some play equipment and is heavily used by Paramount residents. There is a connection to the Lario Trail in Dills Park but the park is below the levee, and has no visual or physical connection to the river.

Immediately south of Dills Park are the Compton Golf Course and Dominguez High School, both lying within a small pocket of Compton on the east side of the river. The Lario Trail runs along the top of the levee embankment through Paramount. Except for the portion running past Dills Park and the Compton Golf Course, this stretch of the river is entirely devoid of landscaping. Trail users overlook the high cinder block walls and chain-link fences that separate the back yards of homes, industrial sites, and municipal and county equipment yards from the river right-of-way. Some vacant land adjacent to the river right-of-way is located south of the Compton Golf Course.

Potential Projects

Additional recreational facilities are needed in Paramount. The city staff are interested in acquiring more lands for parks and linking these with the Lario Trail. The area near the river is densely developed, however, and the only property adjacent to the river with any potential for park development is an eight-acre parcel between Atlantic Place and Hunsaker Avenue south of Alondra Boulevard. This parcel is currently in use as a truck yard but has been included in Paramount's redevelopment district. The redevelopment plan for the site proposes retail uses. Due to its proximity to the river and Dills Park, it would be highly desirable for at least part of the site to be devoted to park space. This property is large enough to accommodate at least modest recreation and park facilities in addition to the proposed retail uses. The strip along Alondra and along the river could be landscaped and developed with benches, restrooms, drinking fountains, small playgrounds, and possibly handball and/or basketball courts. Such facilities would undoubtedly be heavily used since Paramount currently has only 40 acres of park space to serve its more than 45,000 residents. Development of this strip as a park would also further extend the greenbelt created by Dills Park and the Compton Golf Course and could provide another connection with the Lario Trail.

City staff are also interested in improving the appearance of the space between Dills Park and the levee embankment with landscaping. This levee wall is currently bare and unattractive and screening it with vegetation would greatly enhance the appearance of the park. This area could be planted with small trees and shrubs, preferably drought-tolerant natives. Because of the densely populated area immediately adjacent to the river, any landscaping done here must not interfere with the integrity of levee. The levee wall itself is maintained by the Los Angeles County Department of Public Works (LACDPW) and is fenced off.

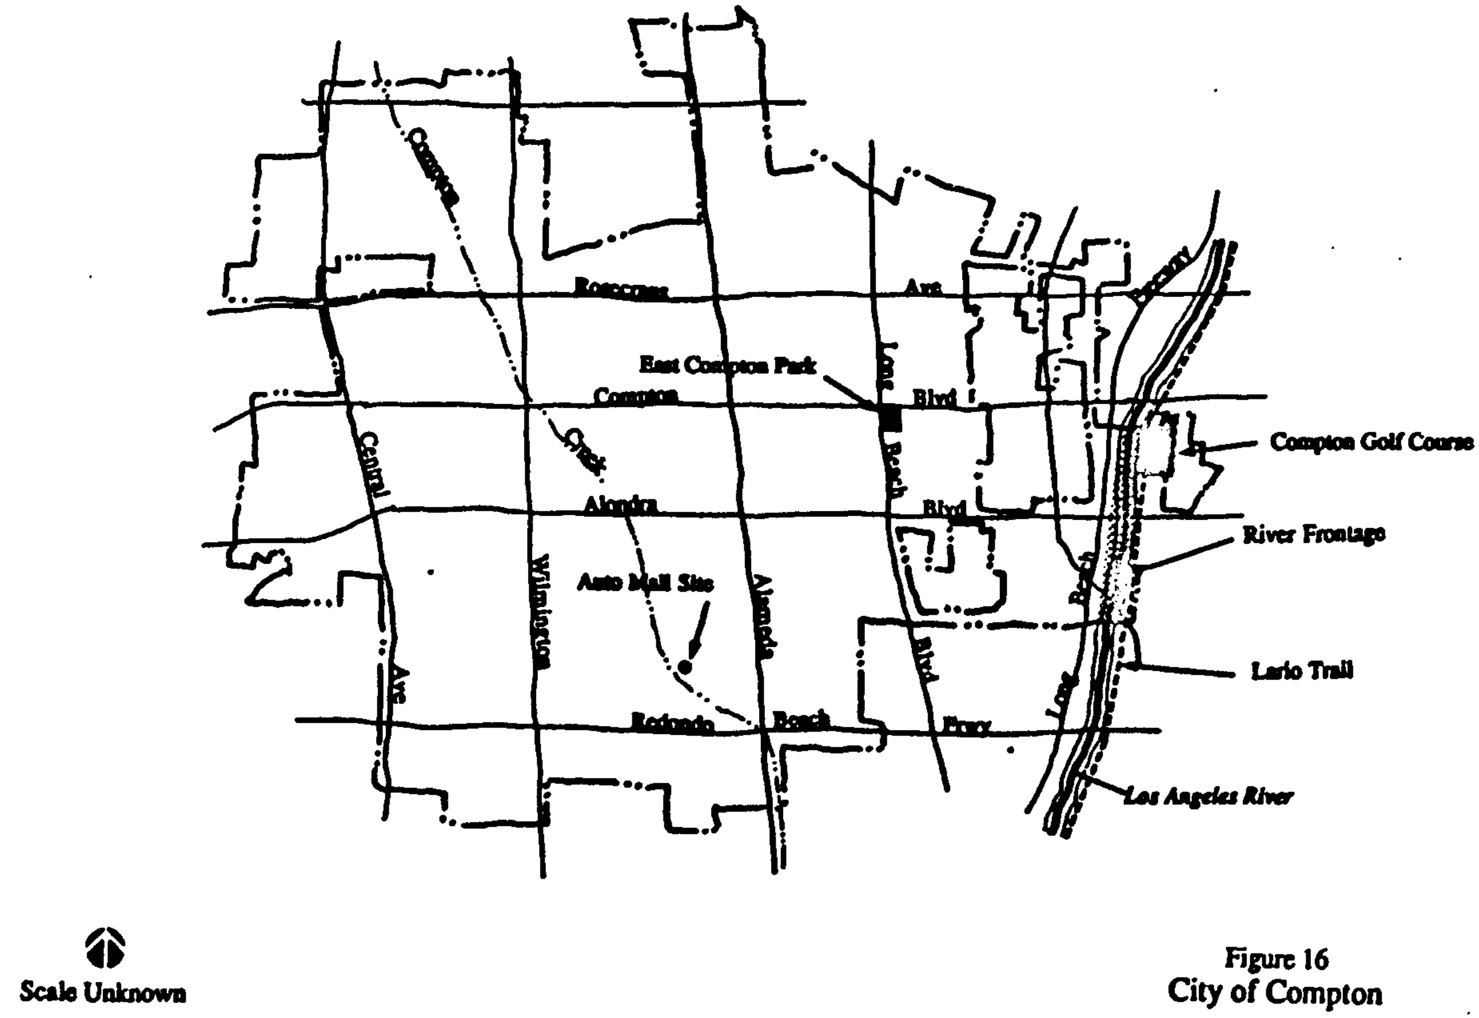

Figure 16
City of Compton

COMPTON

Community Profile

Area: 10.1 square miles *Population: 90,454*

The population of Compton is approximately 55% African-American and 43% Hispanic. Average household income is $37,066 and average household size is 4.0 persons. The median home value is $108,000 and the median rent is $477 per month. The primary industries are manufacturing and wholesale trade.

There are 13 parks in the city of Compton, plus the Compton Golf Course, a par three golf course heavily used by Compton residents. Total park area in Compton, not including the golf course, is 58 acres. The largest park in Compton is Gonzales Park, which is 14 acres in size. All the other parks in the city are less than six acres in size.

River Profile

The Los Angeles River is contained in levees as it flows through Compton. Land uses near the river include low-income residential, industrial, and municipal. Many of the industrial sites near the river in Compton are becoming obsolete and may be converted into other uses in the future. The largest open space area near the river in Compton is the Compton Golf Course, which is located next to the river on the east side. Immediately adjacent to the golf course is Dominguez High School, one of Compton's public high schools. The Lario Trail runs along the east levee in Compton, but the trail is in a severe state of disrepair and is impassable in many locations.

Compton Creek is a major tributary of the Los Angeles River. Although culverted over approximately half of its length, it runs above ground through Compton. Compton Creek, although channelized, supports surprisingly dense riparian vegetation in this area. Directly adjacent to Compton Creek is the site of a 33-acre auto mall, now deserted. New uses for the site are currently under development, and city planners envision using the site for another commercial use that would generate revenue for the city.

Potential Projects

Like all other cities in the south watershed, Compton has too little park space and too few recreational facilities to serve its citizens. Recreational facilities for young people are particularly needed. Because most of the city of Compton lies on the west side of the river, City Parks and Recreation staff are interested in developing a bike path on the west levee to make it more accessible to Compton residents. Were a path to be developed on the west levee, it would be necessary to provide a crossing of some kind near the Compton Golf Course so the path could rejoin the Lario Trail on the east levee in Paramount. City staff have also expressed interest in developing a bike route that would connect East Compton Park, a county regional park that lies 0.3 miles from the river, with the Lario Trail. This could be established either through the construction of a separate bike path, or more simply by creating a striped bicycle lane over city streets. In any case, a way should be found to connect the Lario Trail on the east side of the river with the rest of Compton on the west side. The Lario Trail through Compton is badly in need of rehabilitation and repair. Such repair work should also include landscaping with native shrubs and the addition of benches and rest areas for trail users.

Another potential site for the development of recreational facilities is the old auto mall site on Compton Creek. The vacant land directly alongside the creek here has the potential to be developed into a creekside park for passive recreation. The creek is readily accessible from here and would be a good candidate for an urban creek restoration project that could combine wildlife habitat enhancement with environmental education opportunities. It may also be possible to develop a pedestrian/bike path along one of the banks of Compton Creek. Any development plans for the auto mall site should incorporate Compton Creek into the design and include provisions for park development along the creek. Such a park could prove to be a tremendous amenity to Compton residents. The 1991 LACDA Review proposes the construction of three-foot high parapet walls and armoring the outside of the levees along one mile of Compton Creek, including the reach through the auto mall site. The construction of these walls would in all likelihood preclude the enhancement of Compton Creek in this location, but may possibly still accommodate the development of recreational features.

VOL 12

6751

Los Angeles River
Park and Recreation Area Study

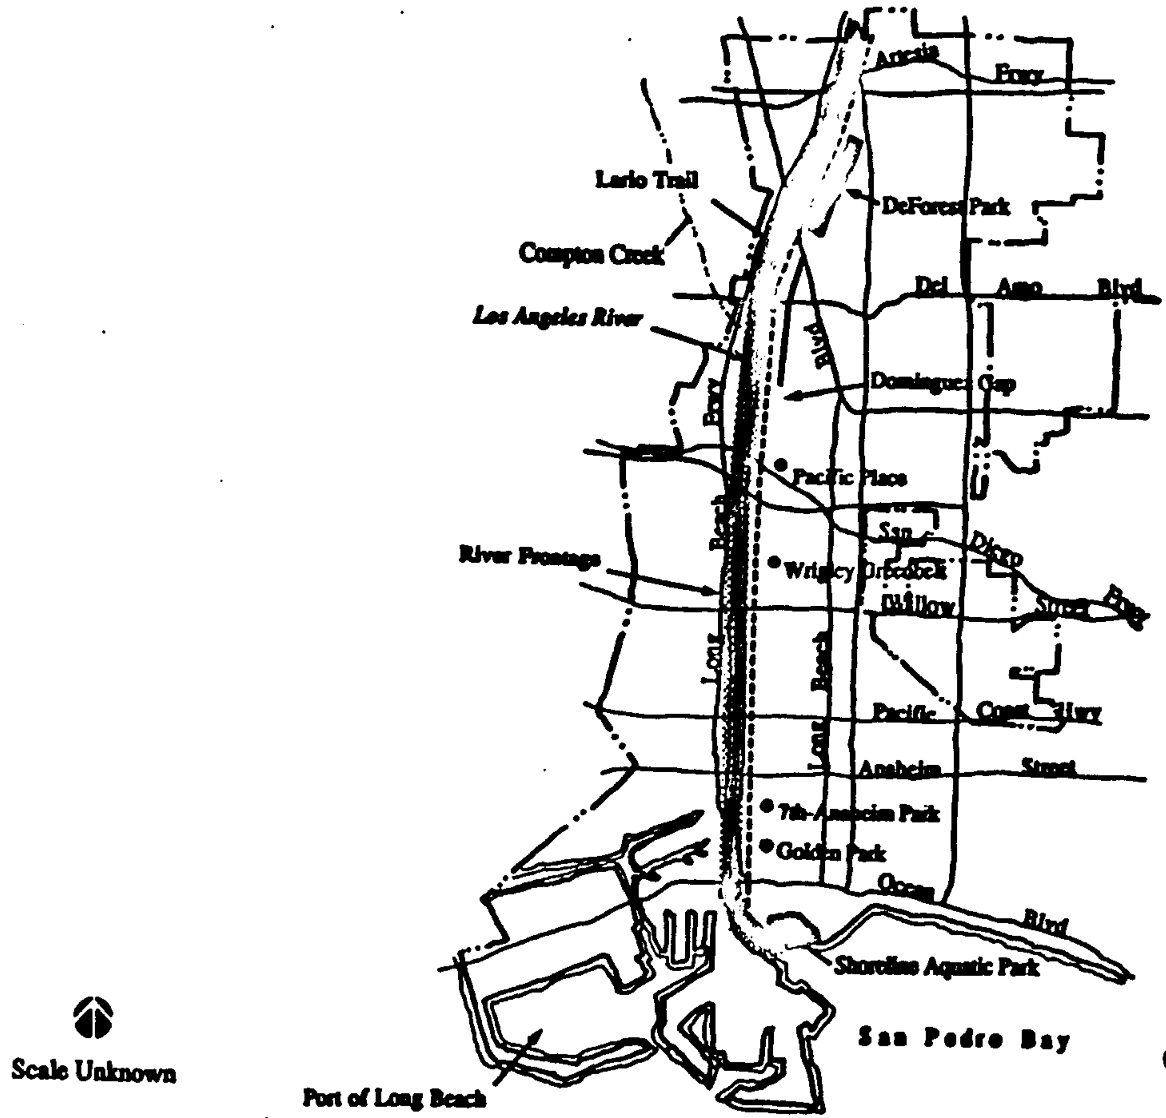

Figure 17
City of Long Beach

LONG BEACH

Community Profile

Area: 49.71 square miles *Population: 439,300*

Long Beach is the second-largest city in Los Angeles County and the fifth-largest city in California. The city is located 22 miles south of downtown Los Angeles. The Port of Long Beach handles the most cargo tonnage of any West Coast port.

The 1990 Census indicated that the population of Long Beach is getting younger and more ethnically diverse. The median age of the population declined from 31.1 in 1980 to 30.0 in 1990. The Hispanic and Asian/Pacific Islander populations of the city have increased significantly since 1980: the Hispanic population was 100% larger in 1990 than it was in 1980; the Asian/Pacific Islander population was 197% larger in 1990 than it was in 1980.

Long Beach has a number of park and recreation facilities. These range from the 726-acre El Dorado Park and 239-acre Recreation Park to many small neighborhood parks. As the population of the city has grown younger in the last ten years, the demand for more active recreation facilities has also increased. Much of the population increase is occurring on the city's west side in districts adjoining the river. The city is presently attempting to address the increased demand for both active and passive parks by developing such parks on vacant lands along the river (see discussion of specific projects below).

River Profile

Long Beach has approximately nine miles of river frontage, from the Artesia Freeway (91) to the mouth of the river at San Pedro Bay. The Long Beach Freeway (710) and an almost continuous band of undeveloped city and county rights-of-way and utility easements take up much of the west bank of the river for most of its course through Long Beach. Surrounding land uses are predominantly residential for most of the river's extent in Long Beach. The city has two parks on the east bank of the river, DeForest Park, between 59th and 63rd streets, and Shoreline Aquatic Park, located at the river mouth. The Lario Trail and an adjoining equestrian trail run along the east bank of the river

A stretch of the river from Willow Street south to the ocean is one of three areas along the river with soft bottoms. The buildup of silt on both sides of the river has allowed for the growth of a 10- to 15-foot-wide riparian corridor, containing rushes, cattails, willows, mulefat, and several exotic species. This vegetation likely provides habitat for some animal species, including mollusks, amphibians, reptiles, birds, and small mammals. The area is cleared of vegetation periodically by the Los Angeles County Department of Public Works.

This lower stretch of the river provides feeding grounds for a variety of sea birds, including the brown pelican and the California least tern, nesting habitat for such species as red-winged blackbirds, and roosting areas for several types of shorebirds. Large numbers of migrating shorebirds feed here from July through October.

Compton Creek, a tributary of the Los Angeles River, has a soft-bottomed section upstream of its confluence with the Los Angeles River south of Del Amo Boulevard. The native riparian and exotic vegetation of the soft-bottomed creek area attracts egrets, black-crowned night herons, and loggerhead shrikes.

The Dominguez Gap spreading grounds and channel extend north for approximately two miles from Del Mar Avenue to DeForest Park immediately adjacent to the river levee on the east bank of the river. The spreading grounds and channel contain water at times during the winter and spring and attract some bird use. Riparian vegetation occurs in some areas of the spreading grounds/channel.

Water quality, siltation, and debris from upstream are issues of concern to the city. Debris originating upstream of Long Beach travels downstream, is trapped by the breakwaters in Long Beach Harbor, and ends up on the city beaches. Poor water quality in the river is a problem, especially when it rains and the rising coliform levels result in the closure of the city's beaches.

The city is presently in the process of developing three park projects along the river. Long Beach has secured a permit from the Los Angeles County Department of Public Works to develop a passive neighborhood park on a county-owned strip of land between Willow and 34th Street. The park, the Wrigley Greenbelt, will include a meandering path and landscaping. It will be developed by the city and the neighborhood and maintained with the help of the neighborhood. The neighborhood to the south of the proposed park has expressed an interest in extending the park to their area.

The city is developing an active recreation park, Golden Park, to the east of the river channel at Golden Avenue between 6th Street and Broadway. The seven-acre park will contain baseball fields, soccer fields, basketball and tennis courts, and picnic areas. It is intended to serve residents of the downtown area. The city would like to add an additional seven acres to the park by moving an existing highway off-ramp west of its present location. It has applied for grant funds to relocate the off-ramp.

The third park development is proposed as part of the city's plan for redesign of the Queensway Bay area at the mouth of the river. The plan calls for the creation of a landscaped park strip, including a "shallow water habitat" on the south side of the river. The park strip would include a new amphitheater and the existing Spruce Goose Dome.

Potential Projects

The major potential projects for the Long Beach stretch of the river involve developing the large county flood control rights-of-way, vacant city-owned parcels, and utility easements that line the river into passive and active parks and, where feasible, habitat areas. The large utility easements on the west side of the river and the smaller city- and Los Angeles County Department of Public Works-owned parcels on the east side are very significant resources for the city of Long Beach. Multiple use of these parcels (e.g. passive park and flood control) on both sides of the river should be investigated.

A less intensive use of these areas would be large-scale tree planting that would reduce both urban heat island effect and poor air quality, aesthetically improve the river corridor and possibly provide habitat for bird species if appropriate native riparian species (willows, cottonwoods) are used. Small depressions could be filled with water and planted with cattails and bulrushes to provide freshwater marsh habitat. Another potential use is as community gardens. Some areas have already been leased to commercial nurseries.

Neighborhood Parks: Development of a string of neighborhood parks, such as DeForest Park and the Wrigley Greenbelt would "green" the river through Long Beach, providing an amenity for the adjoining neighborhoods and potentially, if consideration is given to plant selection and potential habitat creation, for birds and other wildlife.

Dominguez Gap: Use of the Dominguez Gap spreading basin as a multi-function facility should be investigated. Can the facility's function as a spreading ground be compatible with creation of wetland/riparian habitat of some kind? Any study should examine whether creation of both open water areas and riparian zones, by maintaining some water in the basin throughout the year and planting native riparian vegetation (willows, cottonwoods, etc.) in some parts of the basin/channel, would interfere with the function of the spreading basin. Willow and cottonwood trees could be planted around the immediate perimeter of the basin but not in the basin bottom itself in order to maintain percolation rates.

Other Projects: The city has long-range plans for two future park sites along the east bank of the river. Neither project has developed very far

- *Pacific Place site* — This 21-acre site located between the San Diego (405) Freeway and Del Mar Avenue is a high-priority park acquisition site for the city. The site is an abandoned oil field/water separation facility. The city would like to expand an existing neighborhood park, Los Cerritos Park, which adjoins the site, into a community park with active recreation facilities, such as baseball and soccer fields.

- *7th Street to Anaheim Street Park* — The city would also like to develop a park along the river between 7th Street and Anaheim Street in a narrow band of land west of DeForest Avenue. The park has not been planned at this time but would likely consist of a landscaped strip with a jogging/walking trail paralleling the river.

The city would like funding assistance for two other park projects:

- *A redesign of DeForest Park* to regrade the site, remove vegetation, and mosquito abatement.

- *Development of an irrigation system* for the Wrigley Greenbelt.

- *Access connections* from the neighborhoods to the Lario Trail need to be improved. More frequent access points and/or better directional signage are necessary. The trail is heavily used but access to it is not convenient or easy from most neighborhoods.

Environmental education: An environmental education program, potentially including an interpretive center, would focus on the rich bird life of the Long Beach section of the river and the hydrologic function and habitat value of the river mouth.

VII. CONSTRAINTS TO ALTERNATIVE USES OF THE LOS ANGELES RIVER

VII. CONSTRAINTS TO ALTERNATIVE USES OF THE LOS ANGELES RIVER

Introduction

The LACDA study prepared by the U.S. Army Corps of Engineers, discussed above, outlined several areas of potential conflict with plans for non-flood control uses of the flood control system. Any or all of these issues could be significant constraints to proposals for the development of parks, recreation facilities, etc., within the boundaries of the flood control system. Every change of use proposed for the Los Angeles River channel must address these issues.

The LACDA study identified seven issues that could potentially block proposed new uses within the flood control system:

Regulatory Constraints

Secondary uses of the flood control system must not interfere with the flood control function of the system. No changes can occur that would alter the channel's ability to hold or carry water. Any obstructions such as dams, landscaping, etc., must be removable or must not impede the movement of flood waters. Both the Army Corps of Engineers and the Los Angeles County Department of Public Works (LACDPW) must review and approve proposed secondary uses.

Physical Constraints

The flood control channels are crossed by numerous bridges for streets and railroads that are physical obstacles to public access.

Ownership

Not all land within flood channel corridors is owned by the Corps of Engineers or by the LACDPW. Many areas are easements with provisions that only allow use for flood control purposes. Secondary uses are generally not allowed under the terms of the leases. Purchase or acquisition through condemnation may be required to gain the legal rights to use land for non-flood control purposes.

Jurisdictional Coordination

It is extremely difficult to coordinate the multitude of local governments and state and federal agencies that have jurisdiction over the Los Angeles River corridor to carry out projects of a regional nature.

Safety

Safety is a major concern when considering increasing public access to the flood control channels. Safety hazards can result from user conflicts, such as encounters between bicyclists and equestrians, or bicyclists and pedestrians. In some areas, recreational users are in danger of falling into the channel, or being assaulted or robbed.

Conflicts with Channel Neighbors

Some owners of property adjacent to flood control channels object to increased public access along the channels because of concerns of loss of privacy, vandalism, and use of the public trails by criminals to gain access to homes and businesses.

Funding

Funding to carry out any park and recreation projects is quite limited. Many of the cities along the river corridor do not have local revenues available to fund such improvements.

In spite of these constraints, improvements to the river corridor are possible, both in the near term and over a longer period of the next ten to 50 years. What is needed is careful planning, close coordination among the participating jurisdictions, and an overriding commitment to opening up the river for the use and enjoyment of future generations of Los Angeles County residents.

VIII. RECOMMENDATIONS

VIII. RECOMMENDATIONS

GENERAL RECOMMENDATIONS

As the population density in the Los Angeles area increases, it is becoming apparent that the need for additional park and open space has reached a critical state. The greater Los Angeles area has the lowest amount of per capita park acreage of any major metropolitan area in the nation. The "discovery" of the Los Angeles River as a possible source of new park space and recreational facilities creates a unique opportunity to look at the river in a new way. The Los Angeles River has the potential to become one of the region's greatest recreational resources, forming a 50-mile open space/recreational "green corridor" through the center of the region.

Attention has also been focused on the river corridor as a potential site for redevelopment and economic revitalization. Several scenarios have been proposed for commercial, light industrial, and public transit facilities development on parcels adjoining the river. More proposals of this kind can be expected in the future as efforts are made by local governments to generate public and private sector interest in revitalizing the river corridor.

In general, the State Coastal Conservancy recommends that parks and recreation become a high-priority land use for the entire river corridor. Development of this use should be linked to improved flood control, economic, and transportation development along the corridor. Other uses in the river corridor that should be part of a multi-objective river management strategy include non-motorized transportation, local economic development, expanded native riparian habitat, detention basins, and spreading grounds.

Specifically, policies should be adopted by local governments and state and federal agencies with jurisdiction over the river that have as an ultimate goal the creation of a continuous system of parks and recreational trails along the river's banks from the Sepulveda Basin to Long Beach, consistent with flood control and economic development needs.

- Undeveloped utility, flood control, and other easements and rights-of-way along the river channel should be developed into parks, trail corridors, and/or plant and animal habitat wherever feasible and without sacrificing flood control needs. River-fronting parks and trails should be incorporated into commercial, residential, and industrial development along the river. Those easements or lots adjacent to the river that are not large enough or otherwise cannot accommodate park development should be landscaped along the river to provide air quality benefits, animal habitat and aesthetic improvement of the river corridor.

- New land uses should not obstruct public access to the river corridor, or prevent the extension and improvement of the regional trail system. New land uses should accommodate the placement of landscaping materials on lands directly adjacent to the river.

- Alternative methods for flood control should be explored, with a goal of providing protection against a 100-year flood, removing the Federal Emergency Management Agency (FEMA) floodplain designation from surrounding areas, creating a wider and more permeable channel, increasing flood water retention, reducing peak flood flows, restoring the upper watershed, increasing groundwater recharge capacity, and restoring riparian and tidal wetlands. Flood control needs of downstream communities must be considered of primary importance in the development of any alternative methods.
- Any proposals for public transit along the river corridor should include environmental enhancement and public access as integral parts of their schemes.
- Coordination of planning activities, funding for river corridor improvements, and formulation of strategies for assuring equity of benefits and costs among river corridor communities should be carried out on a regional basis by representatives of local governments and community groups with assistance from state and federal agencies.

ALTERNATIVE FLOOD CONTROL

There is a growing recognition that the benefits of channelization have been overestimated on many flood control projects in the United States and elsewhere in the world. The problems of channelization include: underestimation of the costs of channel maintenance, unrealistic expectations of the smoothness of concrete channels, underestimation of the effects of sediment and debris in major floods, problems with maintaining supercritical flows, loss or significant reduction in groundwater recharge, worsened water quality, disruption of wildlife corridors, loss of plant and animal habitat, and replacement of a natural river corridor by a concrete channel. Recognition of these problems has resulted in a major reexamination of the way rivers are managed.

Protection of lives and property must be the first priority of any river management plan, but as existing flood control systems need to be redesigned to address ever increasing runoff and water flows, alternative flood control methods should be considered as part of a multi-objective approach to river management.

Examples of such techniques include soft-bottomed channels that allow for scour, a series of flood water detention basins, enlarged spreading basins, alternative channel bank stabilization, increased percolation in the watershed (e.g., porous parking lots and driveways), diversion of peak flood flows, onsite storage of runoff, restoration of the upper watershed (e.g., revegetation of the slopes, upstream reservoirs), and creation of a "riverway." [1]

(Note: The U.S. Army Corps of Engineers in the 1991 Los Angeles County Drainage Area (LACDA) Review studied several alternative flood control methods, including diversion alternatives, non-structural measures, new reservoirs and upper basin modifications, and concluded that these methods were either too expensive or ineffective in reducing peak flows in the lower basin.)

A benefit of such alternative methods could be the restoration of such natural river features as wetlands, which would act

[1] A "riverway" is the river corridor between the flood protection levees or walls and may include the main river channel, adjacent flood plain, seasonal and permanent wetlands, and detention or retention ponds.

as water retention basins. Restoration of former wetland areas along channelized rivers would provide flood control, groundwater recharge, habitat, and aesthetic benefits.

The function of the Los Angeles River is first and foremost as a flood control channel serving much of the Los Angeles Basin. Any proposed alteration of the existing channel must clearly be found not to interfere with or lessen the flood control function of the river. The intent of this section is to present alternative flood control methods that could be incorporated into the management of the Los Angeles River.

These alternative flood control methods offer several advantages over traditional channelization in terms of plant and animal habitat creation, groundwater recharge, and other natural river functions that concrete-lined channels do not provide while also addressing the flood control needs of the region. We recommend that the use of such methods be incorporated into a multi-objective approach to river management.

USE-SPECIFIC RECOMMENDATIONS

Recreation/Public Access

- Extend the regional trail system along the river through downtown and into the San Fernando Valley, thus creating a trail system for the entire length of the Los Angeles River from the western San Fernando Valley to the ocean at Long Beach. The Lario Trail follows the Los Angeles River up to its confluence with the Rio Hondo, from which point it follows the Rio Hondo into the San Gabriel Valley. The existing Los Angeles River Trail runs along the levee on the west bank of the river for approximately four miles from Maywood to South Gate, connecting with the Lario Trail in South Gate. This trail should be extended north into downtown Los Angeles where it could connect with the new Los Angeles River Bikeway that begins at Elysian Park.

- Many of the project proposals described in the U.S. Army Corps of Engineers' 1980 LACDA System Recreation Study would be valuable additions to the regional trail system. The 1980 LACDA Study should be reexamined, updated where necessary, and a concerted effort made to begin implementation of the regional trail concept proposed in the study.

- Improve access connections to the existing trail network. These should include improvements to existing access points, development of new access points, and better directional signage.

- Implement the "Los Angeles River Greenway" demonstration project proposed by the Los Angeles River Task Force. This project proposes the incorporation of landscaping into the various bicycle paths that are being planned along the Los Angeles River north of downtown. The purpose would be not only to improve the bike paths aesthetically, but to enhance air quality and reduce the urban heat island effect, providing a more enjoyable and healthier environment for bicyclists and pedestrians. Reclaimed water from the river channel itself would be used for irrigation as it is already being used at an adjacent city recreation facility. Landscaping should incorporate appropriate native plants.

- Linear parks, like those proposed in the 1980 LACDA Recreation Study, should be developed on vacant lands adjacent to the river. These parks need not be large, and could be nothing more than small landscaped areas with trees, benches, and drinking fountains. The emphasis should be on interspersing segments of the regional trail with green areas that can be used for rest and quiet enjoyment.

- Development and implementation of the following specific projects: Burbank (Buena Vista Park expansion); Glendale (Crystal Springs Park); Cudahy (land acquisition); South Gate (development of flood control rights of way); Paramount (land acquisition); Long Beach (development of flood control rights-of-way/utility easements).

Habitat Enhancement

- Preserve and enhance those few areas that still contain riparian plant communities to improve the quality of these areas for wildlife habitat. Where possible, additional habitat areas should be created.

- Redesign of the river channel where feasible to create a wide, permeable channel and flood plain system that would better integrate flood control with groundwater recharge, habitat, and open space uses. Further feasibility studies are needed to determine locations where the removal of concrete channel bottoms and banks and the creation of a wider, permeable channel might be possible. The new design should not result in induced flooding upstream or downstream or increase the potential for channel erosion or structural failure.

- Landscape flood control rights-of-way and public and utility easements with appropriate native vegetation to provide plant and animal habitat.

- Implement the "Sepulveda Basin River Recreation Link" demonstration project proposed by the Los Angeles River Task Force to improve the visual and physical linkages between the Los Angeles River and adjacent Balboa Park. Project components include the ongoing cleanup of trash and debris from the river channel, and the restoration and enhancement of native riparian vegetation in and along the channel. The project also proposes the development of a nature trail and interpretive signage.

- Develop and implement the following projects: Los Angeles (DWP Spreading Basin); Glendale (DWP Site - Crystal Springs); Long Beach (Dominguez Gap).

Environmental Education

- Those parts of the river corridor that contain natural or semi-natural riparian habitat can be used for environmental education of adults as well as schoolchildren. In highly urbanized settings, even very small reaches of semi-natural habitat areas can provide important educational opportunities. Efforts should be made to enhance these degraded areas for the enjoyment and education of local residents.

- Develop specific regional and local environmental education programs focused on the Los Angeles River as a functioning natural habitat in a developed urban area — curriculum programs for local schools and a series of interpretive centers/museums along the river.

- The Sepulveda Basin River/Recreation Link demonstration project cited above includes a proposed nature trail and interpretive signs for the river where it connects with

Balboa Park. The development of these facilities would be a valuable educational asset.

- Develop and implement the following project: Glendale (environmental education program and/or interpretive center for the Los Angeles River).

Aesthetic Improvements

- Over the entire course of the river, recreational facilities (parks and trails) should be enhanced with native and/or drought tolerant landscaping, attractive signs, inviting rest and entry areas, and murals. A unified design scheme, including directional and interpretive signage for such features, should be used to give a sense of connection to these facilities throughout the various communities along the river.

- Flood control rights-of-way and public and utility easements along the river corridor should be landscaped with native and/or drought tolerant vegetation. Use of native species should be emphasized.

- Implement the first phase of the Los Angeles River Task Force "Los Angeles River Greenway" project. This project proposes the development of coordinated landscaping, including trees, shrubs, and ground cover, along the bike paths that line the river. The location for the first phase of this project is the unpaved land adjacent to the flood control maintenance road near the Zoo Drive overpass of I-5 in the city of Los Angeles.

Alternative Flood Control Methods

- Hydrological studies should be conducted that explore the potential for alternative methods of flood control for the Los Angeles River that do not sacrifice or undermine 100-year or other flood protection standards and needs. These studies will utilize computer models and relevant experiences elsewhere in the United States to determine whether a multi-objective restoration plan is feasible. These studies should include the following elements:

1. Establishment of clear objectives for the Los Angeles River.
2. Compilation of all hydrologic data relating to the Los Angeles River that may affect flood control, groundwater recharge, etc.
3. Identification of opportunities and constraints, including flood protection, groundwater recharge, surface water levels, recreation, biological resources, and economic impacts.
4. Establishment of a technical working group comprising agencies, public interest groups, and all local governments/cities adjacent to the Los Angeles River (The Los Angeles County Department of Public Works has done this as part of its master plan effort).
5. Development of a computer model of the entire Los Angeles River system to investigate the possibilities of alternative flood control measures and ascertain the upstream and downstream impacts of implementing these alternative flood control measures in a staged fashion. This is important to ensure that a restoration plan for one area does not create induced flooding upstream or downstream.

The model could be used as a design and management tool for the watershed. The computer model would complement the results obtained from the U.S. Army Corps of Engineers physical model of the river. The physical model simulates the flows in the Rio Hondo and lower reaches of the Los Angeles River.

6. Conceptual designs for specific reaches of the Los Angeles River.

Recent developments in flood plain management and flood alleviation methods that should be considered (and their economic impacts analyzed) include:

- Soft-bottomed channels
- Series of flood water detention basins
- Enlarged spreading basins
- Increased percolation in the watershed
- Restoration of the upper watershed
- Diversion of peak flows
- Onsite storage of runoff
- Creation of a "riverway"

Any recommendations resulting from these studies should provide protection against floods up to the 100-year event and should be designed to remove the FEMA 100-year flood plain designation from surrounding areas.

(Note: The U.S. Army Corps of Engineers in the 1991 Los Angeles County Drainage Area (LACDA) Review studied several alternative flood control methods, including diversion alternatives, non-structural measures, new reservoirs and upper basin modifications, and concluded that these methods were either too expensive or ineffective in reducing peak flows in the lower basin.)

Air Quality

- Landscaping along the river corridor, most importantly the planting of double rows of trees should be undertaken wherever feasible. Such planting will improve the air quality of the area around the river and will help to counteract the pollution created by millions of cars that travel daily along the streets and freeways adjacent to the river. Tree planting can also counteract the heat island effect by helping to lower temperatures near the river. The landscaping should consist of appropriate native species.

Institutional

- Create a mechanism for coordination among the many agencies and governments that have jurisdiction along the river.

- Establish an intergovernmental association or agreement to coordinate planning activities and channel funds for river improvement projects. The association should be made up of representatives of local governments, local, state and federal agencies, and community groups.

- Prepare a master plan for the river that promotes the concept of the Los Angeles River as a regional resource. (The Los Angeles County Department of Public Works began such a planning effort in 1991.)

DATE: July 31, 1991

TO: Tenants

FROM: Geraldine Knatz, Director of Planning

SUBJECT: Non-Point Source Permits for Stormwater Discharges

In November, 1990, the U.S. Environmental Protection Agency published its final rule on non-point source stormwater discharges. These rules require operators of industrial facilities (which includes most of the Port's tenants) to apply for National Pollutant Discharge Elimination Systems (NPDES) permits for their stormwater discharges by November, 1991.

There are two ways by which we can comply with these new regulations. The first is for each tenant to apply for an individual permit, independently gathering the information and filling out the forms. The second is for the Port to apply for a "master" permit on behalf of our tenants. Clearly, the second option will be more efficient and will considerably lessen the burden on each of you, since the effort and expense of gathering, organizing, and presenting the necessary information will be substantial.

The Port intends to submit a joint application on behalf of our tenants. To be included in the joint application, each of you must give us your help and cooperation. We cannot include you in the application if you do not do your part. The application requires us to provide information on the storm drain system and on each facility's operational characteristics and current permit status. Enclosed is a questionnaire that requests the necessary information. It is essential that each of you assign someone from your organization to fill out this questionnaire and to act as a point of contact for the Port on this matter.

We ask that you immediately fill out the questionnaire completely and with accurate information. A Port representative will be contacting you after August 15, 1991 to collect the questionnaire and, if necessary, to help complete it. We will, of course, arrange in advance a mutually convenient time for that visit. In the meantime, if you have any questions, please contact Dr. Robert Kanter, Manager of Environmental Planning at (213) 590-4156.

t. Petroleum/Coke/Coal				
u. Salt				
v. Other (Please list below)				

1. Units: gallons, barrels, pounds, cubic feet, etc.

VOL 12

16777

R0050082

22. Are any control measures, such as a berm, used to prevent drainage from entering the storm drains from the location(s) of any outside activities, identified by questions 17 through 21?
Yes_______ No_______

If Yes, describe:

23. Does this facility discharge any process wastewater, such as cooling tower or wash water, or any other materials to the storm drains?
Yes_______ No_______

If Yes, describe:

23b. To the municipal sewer system? Yes_______ No_______

If Yes, describe discharge:

D. <u>Other Discharges</u>

24. Is the Site Map attached: Yes_______ No_______

25. Do you have any knowledge of the discharge or dumping of used oil, toxic chemicals, or/any other materials into the storm drains at this business?
Yes_______ No_______

If Yes, describe:

26. Do you have an emergency spill cleanup plan? Yes_______ No_______

VOL 12

1 6778

R0050083

27. Do you have any knowledge of previous leaks or spills of any materials listed on Attachment 1 or Attachment 2? Yes______ No______

If Yes, include the approximate date, amount and type of material released.

Table 1 Industries Affected By Stormwater Regulation

Mandatory Industries
(Require a permit in any case)

Lumber & Wood Products, Except Furniture
2411 Logging Camps & Logging Contractors
2421 Sawmills & Planing Mills, General
2426 Hardwood Dimension & Flooring
2429 Sawmills, Special Product, N.E.C.
2431 Millwork
2435 Hardwood Veneer & Plywood
2436 Softwood Veneer & Plywood
2439 Structural Wood Members, N.E.C.
2441 Boxes, Nailed Wood & Shook
2448 Pallets & Skids, Wood
2449 Containers, Wood, N.E.C.
2451 Mobile Homes, Wood
2452 Buildings, Prefabricated Wood
2491 Wood Preserving
2493 Reconstituted Wood Products
2499 Wood Products, N.E.C.

Paper & Allied Products
2611 Pulp Mills
2621 Paper Mills
2631 Paperboard Mills

Chemicals & Allied Products
2812 Alkalies & Chlorine
2813 Gases, Industrial
2816 Pigments, Inorganic
2819 Chemicals, Industrial Inorganic, N.E.C.
2821 Plastics Materials & Resins
2822 Rubber, Synthetic
2823 Cellulosic Man-Made Fibers
2824 Organic Fibers, Noncellulosic
2841 Soap & Other Detergents
2842 Polishes & Sanitation Goods
2843 Surface Active Agents
2844 Toilet Preparations
2861 Gum & Wood Chemicals
2865 Cyclic Crudes & Intermediates
2869 Chemicals, Industrial Organic, N.E.C.
2873 Fertilizers, Nitrogenous
2874 Phosphatic Fertilizers
2875 Fertilizers, Mixing Only
2879 Chemicals, Agricultural, N.E.C.
2891 Adhesives & Sealants
2892 Explosives
2893 Printing Ink
2895 Carbon Black
2899 Chemical Preparations, N.E.C.

Petroleum Refining & Related Industries
2911 Petroleum Refining
2951 Paving Mixtures & Blocks
2952 Asphalt Felts & Coatings
2992 Lubricating Oils & Greases

Petroleum Refining & Related Industries (cont'd)
2999 Petroleum & Coal Products, N.E.C.

Leather & Leather Products
3111 Leather Tanning & Finishing

Stone, Clay, Glass, & Concrete Products
3211 Glass, Flat
3221 Glass Containers
3229 Glass, Pressed & Blown, N.E.C.
3241 Cement, Hydraulic

Date: December 4, 1991

To: Tenants and Non-Tenants of the Long Beach Harbor District Included Under the Port's Stormwater Runoff Permit

From: Geraldine Knatz, Director of Planning

Subject: Guidelines for Preparation of a Stormwater Pollution Prevention Plan

As you are aware, the Port is preparing an application for a Stormwater Runoff Permit required by Federal and State Law. Inclusion is free to Port tenants and at a nominal charge to non-tenants. Our previous letter described in some detail the complex requirements of this new permit and the unique requirements within the Harbor District.

Because the permit requirements are new we are finding the enforcement agency, the Regional Water Quality Control Board (RWQCB), cannot answer all of our questions regarding implementation of the law. Nevertheless certain requirements are clear and the Port is moving ahead with its application.

The Port is currently providing the following services to you during this initial phase of permit application:

1. Meeting with the RWQCB to clarify issues related to individual industrial facilities in the Harbor District and how these facilities should be addressed in the National Pollution Discharge Elimination System (NPDES) permit.

2. Conducting a complete engineering/hydrology study in the Harbor District to define stormwater infrastructure and drainage patterns.

3. Obtaining physical and operational data on each facility and entering that data into a computer database.

4. Designing a monitoring plan for the Harbor District to meet the program's requirements.

5. Conducting "Year One" of the water quality monitoring and reporting program required under this permit.

These elements comprise approximately 90% of the permit requirements. The final permit element is a "Stormwater Pollution Prevention Plan" (plan) for each facility. This is a requirement that only the facility operator/owner can prepare. We are providing you with guidelines for the preparation of a plan for your facility (Enclosure). The State Water Quality Control Board has issued these guidelines which attempt to cover all types of industrial facilities. We have reviewed these guidelines and feel that some items may not be relevant to all facilities. We recommend that you develop a plan that addresses as many of the categories as possible. The Port will be happy to answer as many of your questions as we can. As we have indicated on the guidelines we can supply, at your request, a copy of the drainage pattern maps surrounding your facility.

A copy of your final "Stormwater Pollution Prevention Plan" must be submitted to ths Port no later than May 1, 1992. You will also be required to keep a copy on site so RWQCB representatives can review it upon request. If you have any questions at all please contact Dr. Robert Kanter at (213) 590-4156.

Cordially,

Geraldine Knatz

Geraldine Knatz, Ph.D.
Director of Planning

VOL 12

1 6789

GUIDELINES FOR PREPARING A STORMWATER POLLUTION PREVENTION PLAN

A Stormwater Pollution Prevention Plan *(plan)* must be prepared by each facility covered by the Port's Non-Point Source (NPS) National Pollution Discharge Elimination System (NPDES) permit. The *plan* is required to include the Best Available Technology/Best Control Technology (BAT/BCT) to prevent contaminants from entering State waters.

The *plan* must be submitted to the Port and a copy must be retained on site. Plans kept on site may be inspected by representatives of the Regional Water Quality Control Board (RWQCB) and/or local agencies with jurisdiction over storm drains or water courses which receive stormwater discharge from the facility.

This *plan* may reflect requirements for Spill Prevention Control and Countermeasure of the Clean Water Act or Best Management Practices Programs and may incorporate any part of such plans into the Stormwater Pollution Prevention Plan. The RWQCB and/or local agencies may notify the facility operator if the minimum requirements for the *plan* are not met. After making the required changes the operator shall send *plan* modifications to RWQCB.

The facility operator must also amend the *plan* whenever there is a change in design, construction, operation, or maintenance which has a significant effect on the potential for the discharge of pollutants to surface waters or the local agency's storm drain system. The *plan* may also have to be amended if the facility has not attained compliance with current water quality control standards.

The *plan* shall include, at a minimum, the following items:

** a. A topographic map (or other map if a topographic map is unavailable), extending one-quarter mile beyond the property boundaries of the facility, showing the facility, springs, other surface water bodies, and drinking water wells listed in public records or otherwise known to the discharger.

b. A site map showing:

** (1) All drainage and discharge structures;

** (2) An outline of the tributary drainage areas for each discharge point;

(3) Paved areas and buildings;

(4) Past and present areas of potential pollutant contact;

(5) Existing pollutant controls;

(6) Surface water locations;

(7) Areas of existing or potential soil erosion.

c. Description of significant potential sources of pollutants in stormwater discharges and identification of any dry-weather pollutant discharge locations including:

(1) Loading/unloading liquids or dry bulk materials;

(2) Any outdoor storage of raw materials, intermediate products, or finished products;

(3) Outdoor process activities, and any activities which generate dust or particulates;

(4) Illicit connections or management practices; and

(5) Waste disposal practices.

d. A listing of all chemicals which may contact stormwater and estimates of concentrations in the stormwater runoff;

e. An estimate of the area of impervious surfaces (including paved area and building roofs) within each drainage area;

f. Source controls, such as covering of pollutant areas, sweeping of paved areas, containment of potential pollutants, etc.;

g. Isolation/separation of industrial from non-industrial pollutant sources so that runoff from these areas do not mix;

h. Treatment/conveyance structures such as drop inlets, channels, retention/detention basins, treatment vaults, infiltration galleries, filters, oil/water separators, etc., and the effect of any of these on groundwater quality;

i. Design criteria for the structures/conveyances;

j. Maintenance schedules including inspection and testing for failure;

VOL 12 1 6791

k. Spill prevention and response procedures, staff training and responsibilities;

l. Ercsion control measures such as riprap, revegetation, slope stabilization, etc.;

m. An estimate of pollutant reduction levels expected from implementing the controls and how the discharge will meet effluent limits (if any) and water quality objectives;

n. Creation of a Stormwater Pollution Prevention Committee. Name the specific individuals within the organization who are responsible for developing the *Plan* and assisting the Plan Manager in its implementation, maintenance and revision;

o. Creation of employee training programs to inform personnel at all levels of responsibility of the components and goals of the *Plan*. Training should address topics such as spill response, good housekeeping and material management practices. The *Plan* shall identify periodic dates for such training.

p. Identification and training of qualified plant personnel to inspect equipment and plant areas, including any stormwater control facilities. Material handling areas shall be inspected for evidence of or the potential for pollutants entering the waters of the State. A tracking and follow-up procedure shall be described to ensure that adequate response and corrective actions have been taken in response to the inspection. Records of inspections shall be maintained.

q. Establishment of internal record keeping and internal reporting procedures;

r. Provision for inspections of sufficient frequency to ensure continued compliance with this Order.

** Items the Port can supply to you upon request.

The Port of Long Beach

VOL 12

DATE: April 29, 1992

TO: Tenants and Non-Tenants Preparing Storm Water Pollution Prevention Plans

FROM: Geraldine Knatz, Director of Planning

SUBJECT: Drainage Maps

Enclosed please find copies of your facility's Storm Water Pollution Prevention Plan drainage maps. They fulfill the drainage and area boundary requirements (part a. and parts b. 1 & 2) listed in the guidelines that we sent to help you prepare your plan. We have done our best to select maps for your site that meet guideline requirements that the area covered should extend, where possible, one-quarter mile from your facility's boundaries. If you see from the legend that other maps are available that would improve your plan, please contact our office to request them.

The Port of Long Beach submitted its Notice of Intent (NOI) to the Regional Water Quality Control Board (RWQCB) on March 30, 1992. Board staff is now in the process of reviewing that information. Unless we receive further instructions from the RWQCB, the only remaining obligations of the Port's tenants and non-tenants included in the NOI are to complete a comprehensive Storm Water Pollution Prevention Plan (SWPPP) and follow that plan in daily facility operations.

At the end of the program's first year we will send you a reminder to update your SWPPP, including any changes in chemicals used, storage facilities, facility layout, or staff training procedures. The Port will be investigating, and passing on to you, Best Management Practices (BMP) for preventing storm water pollution. If you develop any interesting pollution reduction ideas we would like to hear about them. By sharing innovations we can promote cleaner, safer coastal waters.

If you would like to suggest control techniques, need to request additional maps, or have any questions regarding your plan, please contact Darcelle Pruitt at (310) 590-4160.

Sincerely,

Geraldine Knatz

Geraldine Knatz, Ph.D.
Director of Planning

VOL 12

Date: May 20, 1992

To: Storm Water Program Participants

From: Geraldine Knatz, Director of Port Planning

Subject: Storm Water Pollution Prevention Plan

The Port's May 1st target date for the completion of your facility's Storm Water Pollution Prevention Plan has come and gone, but we have not received any documentation from you that fulfills the State of California's Storm Water Pollution Prevention Plan (SWPPP) requirements.

The Port has already accepted much of the responsibility necessary for successfully completing the State's mandated program. However, the things we have asked you to prepare require site-specific information about operations of your facility, that only you can provide. Accordingly, you need to proceed with the preparation of the SWPPP. The Port has provided the Regional Water Quality Control Board (RWQCB) with a list of facilities included under our storm water permit. We will also provide them with a list of Pollution Prevention Plans on file with us which correspond to the named facilities. Those facilities which have not provided the Port with an SWPPP will be listed separately. The Port, because of its size, fully expects an audit by the RWQCB. We want all facilities in compliance before such an audit occurs.

1 6796

Since enforcement is likely to include fines for non-compliance, we wish to emphasize that you must complete a Storm Water Pollution Prevention Plan as soon as possible, and submit it to the Port no later than June 15, 1992. If you need additional help in completing your plan, please call Darcelle Pruitt at (310) 590-4160.

Sincerely,

Geraldine Knatz

VOL 12

Date: August 27, 1992

To: Storm Water Program Participants

From: Geraldine Knatz, Director of Planning

Subject: Storm Water Pollution Prevention Plan

Thank you for your interest in the Port's Storm Water Pollution Prevention Program. We are approaching the State's October 1, 1992 Storm Water Pollution Prevention Plan (SWPPP) implementation date. After that date, facilities without a SWPPP in place can be inspected and fined by the State Water Resources Control Board (SWRCB) or the Regional Water Quality Control Board (RWQCB).

As you know, the Port has been offering assistance to program participants to help them comply with the State's storm water requirements. Thus far, response to the Port's program has been very good, but we are still concerned that not all participants have an adequate SWPPP at the facility and on file with the Port. Our records show that your facility:

0 needs to submit SWPPP

0 needs to make substantial revisions to its SWPPP (please revise per attached guidelines)

0 needs to make suggested revisions to its SWPPP

0 needs to submit final SWPPP for Port files

Please submit the necessary material by September 5, 1992. The Port will then integrate your SWPPP into our files for the SWRCB and RWQCB should they decide to visit the Port after October 1, 1992.

At the end of the program's first year the Port will be providing you with an update of recent developments in Best Management Practices (BMP) for preventing storm water pollution and we will conduct a site visit to review adherence to your SWPPP. We will also discuss updates to your SWPPP, including any changes in personnel responsibilities, chemicals used, storage facilities, facility layout, or staff training procedures. If you develop any interesting pollution reduction ideas we would like to hear about them so we can share them with others.

If you have any questions, please contact Darcelle Pruitt at (310) 590-4160.

Sincerely,

Geraldine Knatz

Subject: Storm Water Pollution Prevention Plan

Thank you for submitting your facility's Storm Water Pollution Prevention Plan (SWPPP). We have reviewed your document and believe it meets the Regional Water Quality Control Board's SWPPP requirements. We are very pleased with the results of your efforts. Now that you have a complete document you should begin implementing your best management practices for controlling storm water pollution.

At the end of the program's first year the Port will be providing you with an update of recent developments in Best Management Practices (BMP) for preventing storm water pollution and we will conduct a site visit to review adherence to your SWPPP. We will also discuss updates to your SWPPP, including any changes in personnel responsibilities, chemicals used, storage facilities, facility layout, or staff training procedures. If you develop any interesting pollution reduction ideas we would like to hear about them so we can share them with others.

FROM: Geraldine Knatz, Director of Planning

SUBJECT: Request for Proposal to Conduct Non Point Source Run-off Water Quality Monitoring

INTRODUCTION

The Port of Long Beach in compliance with the California National Pollutant Discharge Elimination System (NPDES) General Permit for Storm Water Discharges Associated with Industrial Activities will be conducting water quality monitoring for non point source discharges throughout the Harbor District.

A. SCOPE OF SERVICES

Qualified firms are invited to submit proposals to provide water quality monitoring services.

The monitoring program will include two years of field observations, field sampling, laboratory analyses, and reporting. The analytical techniques utilized will be identical at each station (Figure 1). However, the variables analyzed at each station differ, because the industrial activities which may contribute to the input differ from one area of the Harbor to another.

1. Establish Station Coordinates

On or prior to the first storm water monitoring event establish station locations with suitable navigation equipment so that the visits will be repeatable and accurate to within 5 meters (~15 feet). Pre and Post calibration logs for all field equipment shall be maintained during the contract period by the contractor. These logs shall be made available upon request to the Port or their designated representative for review.

2. Sampling Frequency

Wet Season Sampling - Collection and analysis of grab water samples of storm water discharges within 30 minutes of one significant storm event for the first year and two significant (continuous discharge of storm water for approximately one hour or more) storm events for the second year that are preceded by at least three working days of dry weather. If collection of the sample during the first 30 minutes is impracticable, the sample will be taken as soon as practicable thereafter, and documentation must be provided explaining why the sample could not be taken in the first 30 minutes.

Dry Season Sampling - Collection and analysis of water samples will take place once during the dry season. All stations and variables monitored during the wet season will be repeated during the dry season. Results will be compared with those obtained during the wet season.

3. <u>Field Sampling and Observations</u>

a. During each sampling event and at each station the following observations will be recorded:

- Measure or estimate of storm water discharged from surface runoff and storm drains;
- Observed flows or discharges from storm drains or paved surfaces;
- Presence or discharge of floating material;
- Presence or discharge of oil and grease on water surface; and
- Presence of any odors adjacent to the sampling station.

b. Two water samples will be collected at each station, resulting in a total of 40 samples (plus 10% QA/QC) for the entire sampling area during each sampling episode. Each sample will consist of a "Grab Sample" collected within one meter of the surface. All sampling and sample preservation will be in accordance with the current edition of "Standard Methods for the Examination of Water and Wastewater" (American Public Health Association), including the use of appropriate non-contaminating sampling apparatus and sample holding glassware which is compatible with the subsequent chemical analyses to be performed. Table 1 shows specific analyses required at each station. All analyses will be conducted in a laboratory certified for such analyses by the State Department of Health Services. Analytical techniques will follow those listed in 40 CFR Part 136. Analytical results will be reported in appropriate units along with detection limits as appropriate.

4. <u>Laboratory Analyses and Quality Assurance</u>

a. A minimum of 10% of all samples will be re-analyzed and compared with the original analytical results for Quality Control. In addition, a minimum of two "blind spiked" synthetic seawater samples with known contaminant levels will be analyzed to ensure instrument accuracy.

5. <u>Accessory Data</u>

Collect historic and current data from facilities that have NPDES permits with or without storm water requirements. Compare historic data with data collected during this program. These facilities include Dow Chemical U.S.A., Atlantic Richfield Corporation, County of Los Angeles Department of Public Works, the Southern California Edison Company, and others (names to be provided by the Port).

6. <u>Reporting</u>

Storm water monitoring reports will be submitted to the Planning Division in draft form by tha prime contractor within 21 days following the sampling period. The following information will be reported for each sampling period:

a. The date, exact location, and time of sampling, observations, and/or measurements;

b. The individual(s) who performed the sampling, observations, and/or measurements;

c. Flow measurements or estimates based on calculations tied to the storm event;

d. The date(s) and times the laboratory analyses were performed;

e. The individual(s) who performed the analyses;

f. The analytical techniques or methods used and the results of such analyses;

g. Quality assurance/quality control results;

h. Non-storm water discharge records; and

i. All calibration and maintenance records of instruments used.

j. Brief narrative comparing point source data from No. 5 above with data from comparable water areas in the Port.

VOL 12

1 5801

B. GENERAL PROPOSAL INFORMATION AND CONTENT

1. Proposal Content

- A summary of the firm's and any subcontractor's experience in conducting water quality monitoring surveys.
- A description of the technical approach to conducting the monitoring surveys including a project schedule.
- Resumes and qualifications of all technical personnel who would be assigned to the conduct the surveys, perform laboratory analyses, and evaluate the results.
- A summary of the firm's project management system. The proposed Project Manager and Project Principal should be clearly designated, and the organization of a typical project team, including lines of communication and responsibility, should be described.
- A detailed cost breakdown for each task including staff costs by labor category, equipment and other direct costs, and a schedule of overhead, indirect, general and administrative costs and fees.

2. Insurance Requirements

Firms are advised that the selected consultant will be required to provide and maintain insurance coverage with limits no less than:

a. General Liability: $1,000,000 per occurrence for bodily injury, personal injury, and property damage. If Commercial General Liability Insurance or other form with a general aggregate limit is used, either the general aggregate limit shall apply separately to this project/location or the general aggregate limit shall be twice the required occurrence limit.

b. Automobile Liability: $1,000,000 per accident for bodily injury and property damage.

c. Ocean Marine Liability with Protection and Indemnity: $1,000,000 per accident for bodily injury and property damage.

d. Employer's Liability: $1,000,000 per accident for bodily injury.

e. Professional Liability: $1,000,000 per claim.

Proof of insurance coverage must be provided by insurance endorsement forms or a certified copy of policy which names the Port of Long Beach as coinsured.

VOL 12 1 6802

C. EVALUATION FACTORS

Proposals shall be a maximum of 15 pages in length and will be evaluated on a 100-point basis as follows:

1. <u>Criteria</u>

Criteria	Points
Corporate Experience (including subcontractors)	20
Staff Qualifications (including subcontractors)	30
Technical Approach/Understanding of the Program	30
Management Approach/System	10
Cost	10

To be eligible for consideration, cost proposal must be clear, accurate, and complete as regards to the requirements set forth above. Proposal will be evaluated to determine the bidder's understanding of the program and ability to respond realistically to this request.

D. SUBMISSION OF PROPOSALS

Five copies of the proposal are due no later than 4:30 p.m. on December 15, 1992. Proposals may be mailed or hand delivered to:

Planning Division
Port of Long Beach
925 Harbor Plaza
Long Beach, CA 90802

Hand-carried proposals must be delivered to the offices of the Planning Division on the 4th floor.

If you have any questions concerning this solicitation, please contact Ms. Stacey Crouch, at (310) 590-4160.

Sincerely,

Geraldine Knatz

SUBJECT: Annual Site Inspection/Best Management Practice Guidelines

Last year the Port, with your help, embarked on a very progressive program to comply with the Environmental Protection Agency's Storm Water Pollution Control requirement, which is part of the nation's Clean Water Act. When my staff met with you during the preparation of your Storm Water Pollution Prevention Plan (SWPPP), we indicated that yearly updates and compliance checks would be necessary. The law requires us, as the permit holder, to self monitor and to report our findings yearly. In addition, the law requires everyone in the program to adopt Best Management Practices (BMPs) to control storm water pollution.

This spring, in accordance with those permit requirements, we will conduct the first annual site inspection of our Storm Water Program participant's facilities. The purpose of the inspection is to verify that your facility is following its SWPPP and to suggest modifications to the SWPPP if necessary. We plan to conduct the inspections in April and May. A Port staff member will contact you soon to schedule the site visit.

In addition, as a service to facility participants, the Port is currently preparing a compendium of storm water BMPs. A copy of those BMPs will be distributed to you when it becomes available. The guidelines will provide you with an array of source controls and treatment technologies that may help your facility meet the Storm Water Pollution Control objectives. These guidelines should also be used to evaluate the effectiveness of the BMPs that you have already identified in your SWPPP.

If you have any questions, please contact Stacey Crouch, Project Manager, at (310) 590-4160.

Sincerely,

Geraldine Knatz

1 68007

VOL 12

1-5808

BEST MANAGEMENT PRACTICES GUIDELINES

The techniques described below provide guidance in developing and implementing best management practices (BMPs) for storm water pollution control at industrial sites and commercial facilities. The techniques in these guidelines will provide you with several alternatives for addressing the requirements of the Clean Water Act and helping you comply with state water quality requirements.

WHAT ARE BMPs?

Federal law requires that industrial storm water discharges meet all provisions of Sections 301 and 402 of the Clean Water Act (CWA) in order to control pollutant discharges. These provisions require the use of best available technology (BAT) economically available and best conventional pollution control technology (BCT) to reduce pollutants to meet water quality standards.

The State of California has interpreted Federal regulations to include both the use of BMPs (to control or eliminate sources of pollutants in storm water) and limitations on the discharge of polluted non-storm water. The State defines BMPs as schedules of activities, prohibitions of practices, maintenance procedures, and other management practices to prevent or reduce the pollution of waters of the United States.

SELECTING BMPs

From a water quality standpoint there are generally two reasons to implement Best Management Practices. The first is to protect existing water quality from future degradation, the second is to correct existing water quality problems.

Source control BMPs are the best solution for protecting existing water quality. Source control BMPs are operational practices that prevent pollution by reducing potential pollutants at the source. Treatment control BMPs, on the other hand, are methods of treatment to remove pollutants from storm water. In general, treatment control BMPs do not need to be introduced unless source control BMPs fail to reduce or eliminate pollutants. On the other hand, if an owner/operator is considering improvements to a facility, all appropriate and feasible alternatives should be incorporated into the facility's design and operation.

Your choice of BMPs for your facility will be most effective if you employ a step-wise decision-making process:

Step 1: Identify Activities and Existing BMP Controls

You should first identify the activities at your facility that could cause water pollution, and note their locations. You probably already use BMPs, but some may need "tightening up" to achieve their full effectiveness.

Step 2: Identify Potential Remedies for Non-Storm Discharges

Resolving non-storm water discharges has first priority. Non-storm water discharges to storm water collection systems must be either eliminated or permitted under a separate NPDES permit.

Step 3: Identify Readily Applicable Source Control BMPs

Low and modest cost BMPs, many of which are probably already in place at your facility, will usually satisfy permit requirements. For example, proper housekeeping practices are often all that is needed to provide effective source control.

Step 4: If Necessary, Consider More Substantial Control BMPs

If the BMPs identified in Step 3 still leave areas of significant pollution, or if you are required to meet numeric effluent limits, then you should consider more substantial source control BMPs. For example, you might cover a large exposed activity area to eliminate runoff.

You should also consider whether treatment control BMPs may be less expensive than elaborate source control BMPs.

Step 5: Prepare BMP List and Set Priorities

List the BMPs you have identified as necessary to achieve compliance. Make sure the BMP list meets the minimum requirements specified in the general permit. Then, decide which BMPs to implement first, and include them in your SWPPP.

SOURCE CONTROL OR TREATMENT TECHNOLOGIES?

Source control BMPs are preferred because (1) they are generally 100% effective if implemented properly; and (2) they are generally less expensive than treatment control BMPs. Treatment technology BMPs, on the other hand, are rarely 100% effective, even if maintained and operated properly.

The following two sections present analyses, compiled for the Storm Water Quality Task Force, of source control measures and treatment technologies. This material may help you to formulate appropriate measures for your facility. For source control, each BMP is keyed

VOL 12

1

6809

to a specific industrial activity, and describes recommended management practices to control waste from that activity. The second section presents several treatment technologies appropriate for reducing pollutants in storm water.

SOURCE CONTROL BMPs

Excerpts from
California Storm Water Best Management Handbook
March 1993

VOL 12

INTRODUCTION

This chapter describes specific source control Best Management Practices (BMPs) for common industrial activities that may pollute storm water. Chapter 2 led you through the steps of identifying activities at your facility that can pollute storm water while Chapter 3 provided guidance on selection of BMPs. This chapter provides you with the BMPs that best fill your facility's need. Best management practices for each of the activities shown below are provided in the following fact sheets.

Each fact sheet contains a cover sheet with:

- A description of the BMP
- Approach
- Requirements
  - Cost, including capital costs, and Operation and Maintenance (O&M)
  - Maintenance (including administrative and staffing)
- Limitations

The side bar presents information on where this BMP applies, targeted constituents, and an indication of the level of effort and cost to implement.

Further information is also provided in additional sheets. This information includes a more detailed description of the BMP, requirements to implement, examples of effective programs, and references.

BMPs are provided for each of the following industrial activities consistent with Worksheet 4 in Chapter 2.

Industrial Activities Requiring BMPs

- **SC1** Non-Storm Water Discharges to Drains
- **SC2** Vehicle and Equipment Fueling
- **SC3** Vehicle and Equipment Washing and Steam Cleaning
- **SC4** Vehicle and Equipment Maintenance and Repair
- **SC5** Outdoor Loading/Unloading of Materials
- **SC6** Outdoor Container Storage of Liquids
- **SC7** Outdoor Process Equipment Operations and Maintenance
- **SC8** Outdoor Storage of Raw Materials, Products, and By-Products
- **SC9** Waste Handling and Disposal
- **SC10** Contaminated or Erodible Surface Areas
- **SC11** Building and Grounds Maintenance
- **SC12** Building Repair, Remodeling, and Construction
- **SC13** Over-Water Activities
- **SC14** Employee Training

Fact sheet SC14, Employee Training, is a compilation of the training aspects of the individual source control fact sheets. Its purpose is to facilitate the integration and development of a comprehensive training program for all industrial activities at a facility.

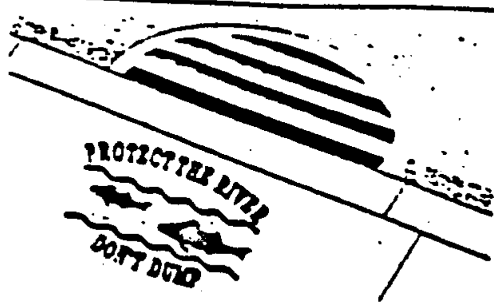
VOL 12

ACTIVITY: NON-STORM WATER DISCHARGES TO DRAINS



Applications

- Manufacturing
- Material Handling
- Vehicle Maintenance
- Construction
- Commercial Activities
- Roadways
- Waste Containment
- Housekeeping Practices

DESCRIPTION

Eliminate non-storm water discharges to the storm water collection system. Non-storm water discharges may include: process wastewaters, cooling waters, wash waters, and sanitary wastewater.

APPROACH

The following approaches may be used to identify non-storm water discharges:

- Visual Inspection
  - The easiest method is to inspect each discharge point during dry weather.
  - Keep in mind that drainage from a storm event can continue for three days or more and groundwater may infiltrate the underground storm water collection system.
- Piping Schematic Review
  - The piping schematic is a map of pipes and drainage systems used to carry wastewater, cooling water, sanitary wastes, etc.
  - A review of the "as-built" piping schematic is a way to determine if there are any connections to the storm water collection system.
  - Inspect the path of floor drains in older buildings.
- Smoke Testing
  - Smoke testing of wastewater and storm water collection systems is used to detect connections between the two systems.
  - During dry weather the storm water collection system is filled with smoke and then traced to sources. The appearance of smoke at the base of a toilet indicates that there may be a connection between the sanitary and the storm water system.
- Dye Testing
  - A dye test can be performed by simply releasing a dye into either your sanitary or process wastewater system and examining the discharge points from the storm water collection system for discoloration.

REQUIREMENTS

Costs (Capital, O&M)

- Can be difficult to locate illicit connections especially if there is groundwater infiltration.

LIMITATIONS

- Many facilities do not have accurate, up-to-date schematic drawings.
- TV and visual inspections can identify illicit connections to the storm sewer, but further testing is sometimes required (e.g. dye, smoke) to identify sources.

Targeted Constituents

- ○ Sediment
- ● Nutrients
- ● Heavy Metals
- ● Toxic Materials
- ◐ Floatable Materials
- ● Oxygen Demanding Substances
- ● Oil & Grease
- ● Bacteria & Viruses

● Likely to Have Significant Impact
○ Probable Low or Unknown Impact

Implementation Requirements

- ◐ Capital Costs
- ○ O&M Costs
- ○ Maintenance
- ◐ Training

● High ○ Low

R0050118

Additional Information — Non-Storm Water Discharges to Drains

Facilities subject to storm water permit requirements must include a certification that the storm water collection system has been tested or evaluated for the presence of non-storm water discharges. The State's General Industrial Storm Water Permit requires that non-storm water discharges be eliminated prior to implementation of the facility's SWPPP.

Non-storm water discharges to the storm water collection system may include any water used directly in the manufacturing process (process wastewater), air conditioning condensate and coolant, non-contact cooling water, cooling equipment condensate, outdoor secondary containment water, vehicle and equipment wash water, sink and drinking fountain wastewater, sanitary wastes, or other wastewaters. Table 4.1 presents disposal option information for specific types of wastewaters.

To ensure that the storm water system discharge contains only storm water, industry should:

- Locate discharges to the municipal storm sewer system or waters of the United States from the industrial storm sewer system from:
  - "as-built" pipeline schematics, and
  - visual observation (walk boundary of plant site).
- Locate and evaluate all discharges to the industrial storm sewer system (including wet weather flows) from:
  - "as-built" pipeline schematics,
  - visual observation,
  - dye tests,
  - TV camera,
  - chemical field test kits, and
  - smoke tests.
- Develop plan to eliminate illicit connections:
  - replumb sewer lines,
  - isolate problem areas, and
  - plug illicit discharge points.
- Develop disposal options.
- Document that non-storm water discharges have been eliminated by recording tests performed, methods used, dates of testing, and any on-site drainage points observed.

TABLE 4.1 QUICK REFERENCE - DISPOSAL ALTERNATIVES

(Adopted from Santa Clara County Nonpoint Source Pollution Control Program - December 1992)

All of the waste products on this chart are prohibited from discharge to the storm drain system. Use this matrix to decide which alternative disposal strategies to use. **ALTERNATIVES ARE LISTED IN PRIORITY ORDER.**

Key:
- HHW — Household hazardous waste (Government-sponsored drop-off events)
- POTW — Publically Owned Treatment Plant
- Reg.Bd. — Regional Water Quality Control Board (Oakland)

"Dispose to sanitary sewer" means dispose into sink, toilet, or sanitary sewer clean-out connection.
"Dispose as trash" means dispose in dumpsters or trash containers for pickup and/or eventual disposal in landfill.
"Dispose as hazardous waste" for business/commercial means contract with a hazardous waste hauler to remove and dispose.

DISCHARGE/ACTIVITY	BUSINESS/COMMERCIAL Disposal Priorities	BUSINESS/COMMERCIAL Approval	RESIDENTIAL Disposal Priorities
General Construction and Painting; Street and Utility Maintenance			
Excess paint (oil-based)	1. Recycle/reuse. 2. Dispose as hazardous waste.		1. Recycle/reuse. 2. Take to HHW drop off
Excess paint (water-based)	1. Recycle/reuse. 2. Dry residue in cans, dispose as trash. 3. If volume is too much to dry, dispose as hazardous waste.		1. Recycle/reuse. 2. Dry residue in cans, dispose as trash 3. If volume is too much to dry, take to HHW drop off
Paint cleanup (oil-based)	Wipe paint out of brushes, then: 1. Filter & reuse thinners, solvents. 2. Dispose as hazardous waste.		Wipe paint out of brushes, then: 1. Filter & reuse thinners, solvents 2. Take to HHW drop off
Paint cleanup (water-based)	Wipe paint out of brushes, then: 1. Rinse to sanitary sewer.		Wipe paint out of brushes, then: 1. Rinse to sanitary sewer.
Empty paint cans (dry)	1. Remove lids, dispose as trash.		1. Remove lids, dispose as trash
Paint stripping (with solvent)	1. Dispose as hazardous waste.		1. Take to HHW drop off.
Building exterior cleaning (high-pressure water)	1. Prevent entry into storm drain and remove offsite 2. Wash onto dirt area, spade in 3. Collect (e.g. mop up) and discharge to sanitary sewer	POTW	
Cleaning of building exteriors which have **HAZARDOUS MATERIALS** (e.g. mercury, lead) in paints	1. Use dry cleaning methods *** 2. Contain and dispose washwater as hazardous waste (Suggestion: dry material first to reduce volume)		

DISCHARGE/ACTIVITY	BUSINESS/COMMERCIAL Disposal Priorities	Approval	RESIDENTIAL Disposal Priorities
General Construction and Painting; Street and Utility Maintenance (cont'd)			
Non-hazardous paint scraping/ sand blasting	1. Dry sweep, dispose as trash		1. Dry sweep, dispose as trash
HAZARDOUS paint scraping/sand blasting (e.g. marine paints or paints containing lead or tributyl tin)	1. Dry sweep, dispose as hazardous waste		1. Dry sweep, take to HHW drop-off
Soil from excavations during periods when storms are forecast	1. Should not be placed in street or on paved areas 2. Remove from site or backfill by end of day 3. Cover with tarpaulin or surround with hay bales, or use other runoff controls 4. Place filter mat over storm drain Note: Thoroughly sweep following removal of dirt in all four alternatives.		
Soil from excavations placed on paved surfaces during periods when storms are not forecast	1. Keep material out of storm conveyance systems and thoroughly remove via sweeping following removal of dirt		
Cleaning streets in construction areas	1. Dry sweep and minimize tracking of mud 2. Use silt ponds and/or similar pollutant reduction techniques when flushing pavement		
Soil erosion, sediments	1. Cover disturbed soils, use erosion controls, block entry to storm drain. 2. Seed or plant immediately.		
Fresh cement, grout, mortar	1. Use/reuse excess 2. Dispose to trash		1. Use/reuse excess 2. Dispose as trash
Washwater from concrete/mortar (etc.) cleanup	1. Wash onto dirt area, spade in 2. Pump and remove to appropriate disposal facility 3. Settle, pump water to sanitary sewer	POTW	1. Wash onto dirt area, spade in 2. Pump and remove to appropriate disposal facility 3. Settle, pump water to sanitary sewer
Aggregate wash from driveway/patio construction	1. Wash onto dirt area, spade in 2. Pump and remove to appropriate disposal facility 3. Settle, pump water to sanitary sewer	POTW	1. Wash onto dirt area, spade in 2. Pump and remove to appropriate disposal facility 3. Settle, pump water to sanitary sewer

DISCHARGE/ACTIVITY	BUSINESS/COMMERCIAL Disposal Priorities	Approval	RESIDENTIAL Disposal Priorities
General Construction and Painting; Street and Utility Maintenance (cont'd)			
Rinsewater from concrete mixing trucks	1. Return truck to yard for rinsing into pond or dirt area 2. At construction site, wash into pond or dirt area		
Non-hazardous construction and demolition debris	1. Recycle/reuse (concrete, wood, etc.) 2. Dispose as trash		1. Recycle/reuse (concrete, wood, etc. 2. Dispose as trash
Hazardous demolition and construction debris (e.g. asbestos)	1. Dispose as hazardous waste		1. Do not attempt to remove yourself. Contact asbestos removal service for safe removal and disposal 2. Very small amounts (less than 5 lbs) may be double wrapped in plastic and taken to HHW drop off
Saw cut slurry	1. Use dry cutting technique and sweep up residue 2. Vacuum slurry and dispose off-site. 3. Block storm drain or berm with low weir as necessary to allow most solids to settle. Shovel out gutters; dispose residue to dirt area, construction yard or landfill		
Construction dewatering (Nonturbid, uncontaminated groundwater)	1. Recycle/Reuse 2. Discharge to storm drain		
Construction dewatering (Other than nonturbid, uncontaminated groundwater)	1. Recycle/reuse 2. Discharge to sanitary sewer 3. As appropriate, treat prior to discharge to storm drain	POTW Reg. Bd.	
Portable toilet waste	1. Leasing company shall dispose to sanitary sewer at POTW	POTW	
Leaks from garbage dumpsters	1. Collect, contain leaking material. Eliminate leak, keep covered, return to leasing company for immediate repair 2. If dumpster is used for liquid waste, use plastic liner		

VOL 12

1698-7

DISCHARGE/ACTIVITY	BUSINESS/COMMERCIAL Disposal Priorities	Approval	RESIDENTIAL Disposal Priorities
General Construction and Painting; Street and Utility Maintenance (cont'd)			
Leaks from construction debris bins	1. Insure that bins are used for dry nonhazardous materials only (Suggestion: Fencing, covering help prevent misuse)		
Dumpster cleaning water	1. Clean at dumpster owner's facility and discharge waste through grease interceptor to sanitary sewer 2. Clean on site and discharge through grease interceptor to sanitary sewer	POTW POTW	
Cleaning driveways, paved areas * (Special Focus = Restaurant alleys Grocery dumpster areas) * Note: Local drought ordinances may contain additional restrictions	1. Sweep and dispose as trash (Dry cleaning only). 2. For vehicle leaks, restaurant/grocery alleys, follow this 3-step process: a. Clean up leaks with rags or absorbents. b. Sweep, using granular absorbent material (cat litter). c. Mop and dispose of mopwater to sanitary sewer (or collect rinsewater and pump to the sanitary sewer). 3. Same as 2 above, but with rinsewater (2c)(no soap) discharged to storm drain.		1. Sweep and dispose as trash (Dry cleaning only) 2. For vehicle leaks, follow this 3-step process: a. Clean up leaks with rags or absorbents; dispose as hazardous waste. b. Sweep, using granular absorbent material (cat litter) c. Mop and dispose of mopwater to sanitary sewer.
Steam cleaning of sidewalks, plazas * * Note: Local drought ordinances may contain additional restrictions	1. Collect all water and pump to sanitary sewer. 2. Follow this 3-step process: a. Clean oil leaks with rags or adsorbents b. Sweep (Use dry absorbent as needed) c. Use no soap, discharge to storm drain		
Potable water/line flushing Hydrant testing	1. Deactivate chlorine by maximizing time water will travel before reaching creeks		
Super chlorinated (above 1 ppm) water from line flushing	1. Discharge to sanitary sewer 2. Complete dechlorination required before discharge to storm drain

Best Management Practices

DESCRIPTION

Prevent fuel spills and leaks, and reduce their impacts to storm water.

APPROACH

- Design the fueling area to prevent the runon of storm water and the runoff of spills:
  - Cover fueling area if possible.
  - Use a perimeter drain or slope pavement inward with drainage to sump.
  - Pave fueling area with concrete rather than asphalt.
- Where covering is infeasible and the fuel island is surrounded by pavement, apply a suitable sealant that protects the asphalt from spilled fuels.
- If dead-end sump is not used to collect spills, install an oil/water separator.
- Install vapor recovery nozzles to help control drips as well as air pollution.
- Discourage "topping-off" of fuel tanks.
- Use secondary containment when transferring fuel from the tank truck to the fuel tank.
- Use adsorbent materials on small spills and general cleaning rather than hosing down the area. Remove the adsorbent materials promptly.
- Carry out all Federal and State requirements regarding underground storage tanks, or install above ground tanks.
- Do not use mobile fueling of mobile industrial equipment around the facility; rather, transport the equipment to designated fueling areas.
- Keep your Spill Prevention Control and Countermeasure (SPCC) Plan up-to-date.
- Train employees in proper fueling and cleanup procedures.
- For a quick reference on disposal alternatives for specific wastes see Table 4.1, SC1.

REQUIREMENTS

- Costs (Capital, O&M)
  - The retrofitting of existing fueling areas to minimize storm water exposure or spill runoff can be expensive. Good design must occur during the initial installation. Extruded curb along the "upstream" side of the fueling area to prevent storm water runon is of modest cost.
- Maintenance
  - Clean oil/water separators at the appropriate intervals.
  - Keep ample supplies of spill cleanup materials on-site.
  - Inspect fueling areas and storage tanks on a regular schedule.

LIMITATIONS

- Oil/water separators are only as effective as their maintenance program.

5822

R0050127

Additional Information — Vehicle and Equipment Fueling

Spills from fueling or from the transfer of fuels to the storage tank can be a significant source of pollution. Fuels carry contaminants of particular concern to humans and wildlife, such as heavy metals, toxic materials, and oil and grease, which are not easily removed by storm water treatment devices. Consequently, control at the source is particularly important. Adequate control can be achieved with careful design of the initial installation, retrofitting of existing installations, and proper spill control and cleanup procedures, as described below.

Design

With new installations, design the fueling area to prevent the runon of storm water and the runoff of spills. This can be achieved by contouring the site in the appropriate fashion. Covering the site is the best approach but may not be feasible if very large mobile equipment is being fueled. Storm water runon can be diverted around the fueling area by an extruded curb or with a "speed bump", if vehicle access is needed from this direction. Spills can be contained within the fueling area either by using a perimeter drain or by sloping the pavement inward with drainage to a sump. In both cases the drain can be connected to the storm drain with a valve that is only closed during fueling operations and left open at all other times. Pave the fueling area with Portland cement concrete rather than asphalt, since the latter will gradually disintegrate and be washed from the site.

Spill Control

The following spill control measures will reduce spilling or reduce the loss of spilled fuels from the site:

- Install vapor recovery nozzles.
- Do not "top off" tanks.
- Place secondary containment around the fuel truck when it is transferring fuel to the storage tank. The truck operator should remain with the truck while the transfer is in progress.
- Place a stockpile of spill cleanup materials where it will be readily accessible.
- Use dry methods to clean the fueling area whenever possible. If you periodically clean by pressure washing, place a temporary plug in the downstream drain and pump out the accumulated water. Properly dispose the water.
- Train employees on proper fueling and cleanup procedures.

Designated Area

If your facility has large numbers of mobile equipment working throughout the site and you currently fuel them with a mobile fuel truck, consider establishing a designated area for fueling. With the exception of tracked equipment such as bulldozers and perhaps small forklifts, most vehicles should be able to travel to a designated area with little lost time. Place temporary "caps" over nearby catch basins or manhole covers so that if a spill occurs it is prevented from entering the storm drain.

Examples of Effective Programs

- The Spill Prevention Control and Countermeasure (SPCC) Plan, which is required by law for some facilities, is an effective program to reduce the number of accidental spills.
- The City of Palo Alto has an effective program for commercial vehicle service facilities. Many of the program's elements, including specific BMP guidance and lists of equipment suppliers, are also applicable to industrial facilities.

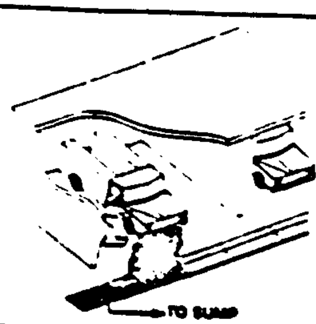
ACTIVITY: VEHICLE AND EQUIPMENT WASHING & STEAM CLEANING



DESCRIPTION

Prevent or reduce the discharge of pollutants to storm water from vehicle and equipment washing and steam cleaning.

APPROACH

- Consider off-site commercial washing and steam cleaning businesses.
- Use designated wash areas, preferably covered to prevent contact with storm water and bermed to contain wash water.
- Discharge wash water to sanitary sewer, after contacting local sewer authority to find out if pretreatment is required.
- Educate employees on pollution prevention measures.
- Consider filtering and recycling wash water.
- Do not permit steam cleaning wash water to enter the storm drain.
- For a quick reference on disposal alternatives for specific wastes see Table 4.1, SC1.

REQUIREMENTS

- Capital costs vary depending on measures implemented.
  - Low cost ($500-1,000) for berm construction.
  - Medium cost ($5,000-20,000) for plumbing modifications (including re-routing discharge to sanitary sewer and installing simple sump).
  - High cost ($30,000-150,000) for on-site treatment and recycling.
- O&M costs increase with increasing capital investment.
- Maintenance
  - Berm repair and patching.
  - Inspection and maintenance of sumps, oil/water separators, and on-site treatment/recycling units.

LIMITATIONS

- Some municipalities may require pretreatment and monitoring of wash water discharges to the sanitary sewer.
- Steam cleaning can generate significant pollutant concentrations requiring permitting, monitoring, pretreatment, and inspections. The measures outlined in this fact sheet are insufficient to address all the environmental impacts and compliance issues related to steam cleaning.

VOL 12

Additional Information — Vehicle and Equipment Washing and Steam Cleaning

Washing vehicles and equipment outdoors or in areas where wash water flows onto the ground can pollute storm water. If your facility washes or steam cleans a large number of vehicles or pieces of equipment, consider contracting out this work to a commercial business. These businesses are better equipped to handle and dispose of the wash waters properly. Contracting out this work can also be economical by eliminating the need for a separate washing/cleaning operation at your facility.

If washing/cleaning must occur on-site, consider washing vehicles inside the building to control the targeted constituents by directing them to the sanitary sewer where they can be pretreated or sent directly to the sanitary treatment facility. Washing operations outside should be conducted in a designated wash area having the following characteristics:

- Paved with Portland cement concrete,
- Covered or bermed to prevent contact with storm water,
- Sloped for wash water collection,
- Discharges wash water to the sanitary or process waste sewer, or to a dead-end sump. Discharge pipe should have a positive control valve that allows switching between the storm drain and sanitary or process sewer,
- Clearly designated, and
- Equipped with an oil/water separator (see Chapter 5, TC7, Oil/Water Separators and Water Quality Inlets).

Examples of Effective Programs

The City of Palo Alto has an effective program for commercial vehicle service facilities. Many of the program's elements, including specific BMP guidance and lists of equipment suppliers, are applicable to industrial vehicle service facilities.

The U.S. Postal Service in West Sacramento has a new vehicle wash system that collects, filters, and recycles the wash water.

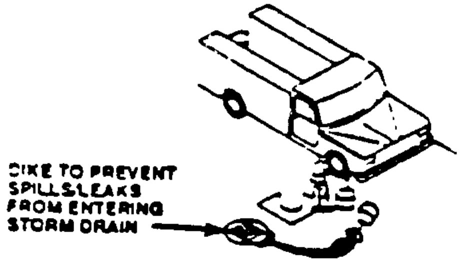
ACTIVITY: VEHICLE AND EQUIPMENT MAINTENANCE AND REPAIR



Applications

Manufacturing
Material Handling
Vehicle Maintenance
Construction
Commercial Activities
Roadways
Waste Containment
Housekeeping Practices

DESCRIPTION

Prevent or reduce the discharge of pollutants to storm water from vehicle and equipment maintenance and repair by running a dry shop.

APPROACH

- Keep equipment clean, don't allow excessive build-up of oil and grease.
- Keep drip pans or containers under the areas that might drip.
- Do not change motor oil or perform equipment maintenance in non-appropriate areas. Use a vehicle maintenance area designed to prevent storm water pollution.
- Inspect equipment for leaks on a regular basis.
- Segregate wastes.
- Make sure oil filters are completely drained and crushed before recycling or disposal.
- Make sure incoming vehicles are checked for leaking oil and fluids.
- Clean yard storm drain inlets(s) regularly and especially after large storms.
- Do not pour materials down drains or hose down work areas; use dry sweeping.
- Store idle equipment under cover.
- Drain all fluids from wrecked vehicles.
- Recycle greases, used oil or oil filters, antifreeze, cleaning solutions, automotive batteries, hydraulic, and transmission fluids.
- Switch to non-toxic chemicals for maintenance when possible.
- Clean small spills with rags, general clean-up with damp mops and larger spills with absorbent material.
- Paint signs on storm drain inlets to indicate that they are not to receive liquid or solid wastes.
- Train employees.
- Minimize use of solvents.
- For a quick reference on disposal alternatives for specific wastes see Table 4.1, SC1.

REQUIREMENTS

- Costs (Capital, O&M) - Should be low, but will vary depending on the size of the facility.
- Maintenance - Should be low if procedures for the approach are followed.

LIMITATIONS

- Space and time limitations may preclude all work being conducted indoors.
- It may not be possible to contain and clean up spills from vehicles/equipment brought on-site after working hours.
- Drain pans (usually 1 ft. x 1 ft.) are generally too small to contain antifreeze, which may gush from some vehicles, so drip pans (3 ft. x 3 ft.) may have to be purchased or fabricated.
- Dry floor cleaning methods may not be sufficient for some spills. Use three-step method instead.
- Identification of engine leaks may require some use of solvents.

Additional Information — Vehicle and Equipment Maintenance and Repair

Vehicle or equipment maintenance is a potentially significant source of storm water pollution. Activities that can contaminate storm water include engine repair and service (parts cleaning, spilled fuel, oil, etc.), replacement of fluids, and outdoor equipment storage and parking (dripping engines). For further information on vehicle or equipment servicing, see SC2, Vehicle and Equipment Fueling, and SC3, Vehicle and Equipment Washing and Steam Cleaning.

Waste Reduction

Parts are often cleaned using solvents such as trichloroethylene, 1,1,1-trichloroethane or methylene chloride. Many of these cleaners are harmful and must be disposed of as a hazardous waste. Cleaning without using liquid cleaners (e.g. wire brush) whenever possible reduces waste. Prevent spills and drips of solvents and cleansers to the shop floor. Do all liquid cleaning at a centralized station so the solvents and residues stay in one area. Locate drip pans, drain boards, and drying racks to direct drips back into a solvent sink or fluid holding tank for re-use.

Safer Alternatives

If possible, eliminate or reduce the amount of hazardous materials and waste by substituting non-hazardous or less hazardous materials. For example:

- Use non-caustic detergents instead of caustic cleaning agents for parts cleaning (ask your supplier about alternative cleaning agents).
- Use detergent-based or water-based cleaning systems in place of organic solvent degreasers. Wash water may require treatment before it can be discharged to the sewer. Contact your local sewer authority for more information.
- Replace chlorinated organic solvents (1,1,1-trichloroethane, methylene chloride, etc.) with non-chlorinated solvents. Non-chlorinated solvents like kerosene or mineral spirits are less toxic and less expensive to dispose of properly. Check list of active ingredients to see whether it contains chlorinated solvents. The "chlor" term indicates that the solvent is chlorinated.
- Choose cleaning agents that can be recycled.
- Contact your supplier or refer to trade journals for more waste minimization ideas.

Reducing the number of solvents makes recycling easier and reduces hazardous waste management costs. Often, one solvent can perform a job as well as two different solvents.

Recycling

Separating wastes allows for easier recycling and may reduce treatment costs. Keep hazardous and non-hazardous wastes separate, do not mix used oil and solvents, and keep chlorinated solvents (like 1,1,1-trichloroethane) separate from non-chlorinated solvents (like kerosene and mineral spirits).

Many products made of recycled (i.e., refined or purified) materials are available. Engine oil, transmission fluid, antifreeze, and hydraulic fluid are available in recycled form. Buying recycled products supports the market for recycled materials.

Spill Leak Clean Up

Clean leaks, drips, and other spills with as little water as possible. Use rags for small spills, a damp mop for general cleanup, and dry absorbent material for larger spills. Use the following three-step method for cleaning floors:

1. Clean spills with rags or other absorbent materials.
2. Sweep floor using dry absorbent material.
3. Mop floor. Mop water may be discharged to the sanitary sewer via a toilet or sink.

SC4

Best Management Practices

R0050132

Additional Information — Vehicle and Equipment Maintenance and Repair

Good Housekeeping

Also consider the following measures:

- Avoid hosing down your work areas. If work areas are washed, direct wash water to sanitary sewer.
- Collect leaking or dripping fluids in drip pans or containers. Fluids are easier to recycle if kept separate.
- Keep a drip pan under the vehicle while you unclip hoses, unscrew filters, or remove other parts. Use a drip pan under any vehicle that might leak while you work on it to keep splatters or drips off the shop floor.
- Promptly transfer used fluids to the proper waste or recycling drums. Don't leave full drip pans or other open containers lying around.

Do not pour liquid waste to floor drains, sinks, outdoor storm drain inlets, or other storm drains or sewer connections. Used or leftover cleaning solutions, solvents, and automotive fluids and oil are toxic and should not be put in the sanitary sewer. Post signs at sinks to remind employees, and paint stencils at outdoor drains to tell customer and others not to pour wastes down drains.

Oil filters disposed of in trash cans or dumpsters can leak oil and contaminate storm water. Most municipalities prohibit or discourage disposal of these items in solid waste facilities. Place the oil filter in a funnel over the waste oil recycling or disposal collection tank to drain excess oil before disposal. Oil filters can be crushed and recycled. Ask your oil supplier or recycler about recycling oil filters.

Put pans under leaks to collect fluids for proper recycling or disposal. Keeping leaks off the ground reduces the potential for storm water contamination and reduces cleanup time and costs. If the vehicle or equipment is to be stored outdoors, oil and other fluids should be drained first.

Designate a special area to drain and replace motor oil, coolant, and other fluids, where there are no connections to the storm drain or the sanitary sewer and drips and spills can be easily cleaned up.

Be especially careful with wrecked vehicles, whether you keep them indoors or out, as well as vehicles kept on-site for scrap or salvage. Wrecked or damaged vehicles often drip oil and other fluids for several days.

- As the vehicles arrive, place drip pans under them immediately, even if you believe that the fluids have leaked out before the car reaches your shop.
- Build a shed or temporary roof over areas where you park cars awaiting repair or salvage, especially if you handle wrecked vehicles. Build a roof over vehicles you keep for parts.
- Drain all fluids, including air conditioner coolant, from wrecked vehicles and "part" cars. Also drain engines, transmission, and other used parts.
- Store cracked batteries in a non-leaking secondary container. Do this with all cracked batteries, even if you think all the acid has drained out. If you drop a battery, treat it as if it is cracked. Put it into the containment area until you are sure it is not leaking.

Examples of Effective Programs

The City of Palo Alto has an effective program for commercial vehicle service facilities. Many of the program's elements, including specific BMP guidance and lists of equipment suppliers, are also applicable to industrial vehicle service facilities.

Pick N Pull Auto Dismantlers in Rancho Cordova drains all fluids from automobiles before they enter the yard.

Ecology Auto Wrecking in Rialto is surrounded by a steel plate/concrete fence and has a completely paved lot that is graded to a central low point. Collected storm water is channeled through an underground drainage system of clarifiers

SC4

VOL 12 1 6828

R0050133

and then stored in a 60,000 gallon UST before being processed through a filter system. In addition, the work area is covered, ventilated and has an additional sump. Vehicle fluids are drained in this area and segregated for recycling.

All Auto Parts, Fontana, has a complete water recycling system in a 10,000 square foot concrete slab surrounded by a curb that contains all the runoff and sends it to the recycling system. All receiving, dismantling, and shipping occurs on the slab.

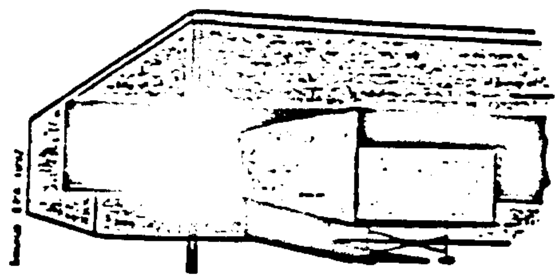
ACTIVITY: OUTDOOR LOADING/UNLOADING OF MATERIALS



Applications

Manufacturing

Material Handling

Vehicle Maintenance

Construction

Commercial Activities

Roadways

Waste Containment

Housekeeping Practices

DESCRIPTION

Prevent or reduce the discharge of pollutants to storm water from outdoor loading/unloading of materials.

APPROACH

- Park tank trucks or delivery vehicles so that spills or leaks can be contained.
- Cover the loading/unloading docks to reduce exposure of materials to rain.
- Seal or door skirt between trailer and building can also prevent exposure to rain.
- Design loading/unloading area to prevent storm water runon:
  - grading or berming, and
  - position roof downspouts to direct storm water away from loading/unloading areas.
- Contain leaks during transfer.
- Use drip pans under hoses.
- Make sure fork lift operators are properly trained.
- Employee training for spill containment and cleanup.

REQUIREMENTS

- Costs (Capital, O&M) - Should be low except when covering a large loading/unloading area.
- Maintenance
  - Conduct regular inspections and make repairs as necessary. The frequency of repairs will depend on the age of the facility.
  - Check loading and unloading equipment regularly for leaks:
    - valves,
    - pumps,
    - flanges, and
    - connections.

LIMITATIONS

- Space and time limitations may preclude all transfers from being performed indoors or under cover.
- It may not be possible to conduct transfers only during dry weather.

Targeted Constituents

Best Management Practices

R0050135

VOL 12

Additional Information — Outdoor Loading/Unloading of Materials

The loading/unloading of materials usually takes place outside. Loading or unloading of materials occurs in two ways: materials in containers or direct liquid transfer. Materials spilled, leaked or lost during loading/unloading may collect in the soil or on other surfaces and be carried away by runoff or when the area is cleaned. Rainfall may wash pollutants from machinery used to unload or move materials. The loading or unloading may involve rail or truck transfer.

The most important factors in preventing these constituents from entering storm water is:
- Limit exposure of material to rainfall.
- Prevent storm water runon.
- Check equipment regularly for leaks.
- Contain spills during transfer operations.

Loading or unloading of liquids should occur in the manufacturing building so that any spills that are not completely retained can be discharged to the sanitary sewer, treatment plant, or treated in a manner consistent with local sewer authorities and permit requirements. Best management practices include:
- Use overhangs or door skirts that enclose the trailer.
- Park tank trucks during delivery so that spills or leaks can be contained.
- Design loading/unloading area to prevent storm water runon which would include grading or berming the area, and positioning roof downspouts so they direct storm water away from the loading/unloading areas.
- Check loading and unloading equipment regularly for leaks, including valves, pumps, flanges and connections.
- Look for dust or fumes during loading or unloading operations.
- Use a written operations plan that describes procedures for loading and/or unloading.
- Have an emergency spill cleanup plan readily available.
- Employees trained in spill containment and cleanup should be present during the loading/unloading.
- Establish depots of cleanup materials next to or near each loading/unloading area, and train employees in their use.
- For loading and unloading tank trucks to above and below ground storage tanks, the following procedures should be used.
  - The area where the transfer takes place should be paved. If the liquid is reactive with the asphalt, Portland cement should be used to pave the area.
  - Transfer area should be designed to prevent runon of storm water from adjacent areas. Sloping the pad and using a curb, like a speed bump, around the uphill side of the transfer area should reduce runon.
  - Transfer area should be designed to prevent runoff of spilled liquids from the area. Sloping the area to a drain should prevent runoff. The drain should be connected to a dead-end sump or to the sanitary sewer. A positive control valve should be installed on the drain.
- For transfer from rail cars to storage tanks that must occur outside, use the following procedures:
  - Drip pans should be placed at locations where spillage may occur, such as hose connections, hose reels, and filler nozzles. Use drip pans when making and breaking connections.
  - Drip pan systems should be installed between the rails to collect spillage from tank cars.

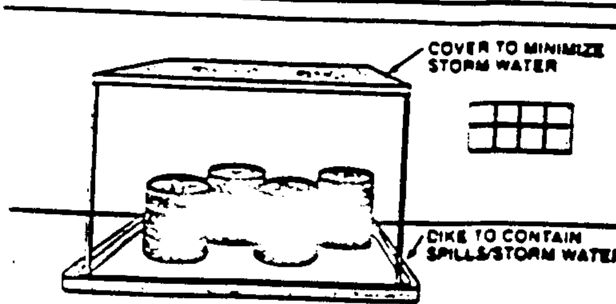
ACTIVITY: OUTDOOR CONTAINER STORAGE OF LIQUIDS



Applications

- *Manufacturing*
- *Material Handling* (circled)
- *Vehicle Maintenance*
- *Construction* (circled)
- *Commercial Activities* (circled)
- *Roadways*
- *Waste Containment*
- *Housekeeping Practices* (circled)

DESCRIPTION

Prevent or reduce the discharge of pollutants to storm water from outdoor container storage areas by installing safeguards against accidental releases, installing secondary containment, conducting regular inspections, and training employees in standard operating procedures and spill cleanup techniques.

APPROACH

- Protect materials from rainfall, runon, runoff, and wind dispersal:
  - Store materials indoors.
  - Cover the storage area with a roof.
  - Minize storm water runon by enclosing the area or building a berm around it.
  - Use "doghouse" for storage of liquid containers.
  - Use covered dumpsters for waste product containers.
- Storage of oil and hazardous materials must meet specific Federal and State standards including:
  - Spill Prevention Control and Countermeasure Plan (SPCC) Plan,
  - secondary containment,
  - integrity and leak detection monitoring, and
  - emergency preparedness plans.
- Train operator on proper storage.
- Safeguards against accidental releases:
  - overflow protection devices to warn operator or automatic shut down transfer pumps,
  - protection guards (bollards) around tanks and piping to prevent vehicle or forklift damage, and
  - clear tagging or labeling, and restricting access to valves to reduce human error.
- Berm or surround tank or container with secondary containment system:
  - dikes, liners, vaults, or double walled tanks.
- Some municipalities require that secondary containment areas be connected to the sanitary sewer, prohibiting any hard connections to the storm drain.
- Facilities with "spill ponds" designed to intercept, treat, and/or divert spills should contact the appropriate regulatory agency regarding environmental compliance.

REQUIREMENTS

- Cost (Capital, O&M)
  - Will vary depending on the size of the facility and the necessary controls.
- Maintenance: Conduct routine weekly inspections.

LIMITATIONS

- Storage sheds often must meet building and fire code requirements.

VOL 12

Additional Information — Outdoor Container Storage of Liquids

Accidental releases of materials from aboveground liquid storage tanks, drums, and dumpsters present the potential for contaminating storm waters with many different pollutants. Materials spilled, leaked or lost from storage containers and dumpsters may accumulate in soils or on the surfaces and be carried away by storm water runoff. These source controls apply to containers located outside of a building used to temporarily store liquid materials. It should be noted that the storage of reactive, ignitable, or flammable liquids must comply with fire codes.

Container Management

To limit the possibility of storm water pollution, containers used to store dangerous waste or other liquids should be kept inside the building unless this is impractical due to site constraints. If the containers are placed outside, the following procedures should be employed:

- Dumpsters used to store items awaiting transfer to a landfill should be placed in a lean-to structure or otherwise covered, dumpsters shall be kept in good condition without corrosion or leaky seams.
- Garbage dumpsters shall be replaced if they are deteriorating to the point where leakage is occurring. It should be kept undercover to prevent the entry of storm water. Employees should be made aware of the importance of keeping the dumpsters covered and free from leaks.
- A fillet should be placed on both sides of the curb to facilitate moving the dumpster.
- Waste container drums should be kept in an area such as a service bay. If drums are kept outside, they must be stored in a lean-to type structure, shed or walk-in container to keep rainfall from reaching the drums.

Storage of reactive, ignitable, or flammable liquids must comply with the fire codes of your area. Practices listed below should be employed to enhance the fire code requirements.

- Containers should be placed in a designated area.
- Designated areas should be paved, free of cracks and gaps, and impervious in order to contain leaks and spills.
- Liquid waste should be surrounded by a curb or dike to provide the volume to contain 10 percent of the volume of all of the containers or 110 percent of the volume of the largest container, whichever is greater.
- The area inside the curb should slope to a drain.
    - For used oil or dangerous waste, a dead-end sump should be installed in the drain.
    - All other liquids should be drained to the sanitary sewer if available. The drain must have a positive control such as a lock, valve, or plug to prevent release of contaminated liquids.
- The designated storage area should be covered.
- Containers used for liquid removal by an employees must be placed in a containment area.
    - A drip pan should be used at all times.
- Drums stored in an area where unauthorized persons may gain access must be secured to prevent accidental spillage, pilferage, or any unauthorized use.
- Employees trained in emergency spill cleanup procedures should be present when dangerous waste, liquid chemicals, or other wastes are loaded or unloaded.

The most common causes of unintentional releases:

- External corrosion and structural failure,
- Installation problems,
- Spills and overfills due to operator error,
- Failure of piping systems (pipes, pumps, flanges, couplings, hoses, and valves), and
- Leaks during pumping of liquids or gases from truck or railcar to a storage facility or vice versa.

Operator Training/Safeguards

Well-trained employees can reduce human errors that lead to accidental releases or spills. Employees should be familiar with the Spill Prevention Control and Countermeasure Plan. The employee should have the tools and knowledge to

SC6

Best Management Practices

1 6833

R0050138

immediately begin cleaning up a spill if one should occur. Operator errors can be prevented by using engineering safe guards and thus reducing accidental releases of pollutant. Safeguards include:

- Overflow protection devices on tank systems to warn the operator to automatically shutdown transfer pumps when the tank reaches full capacity,
- Protective guards (bollards) around tanks and piping to prevent vehicle or forklift damage, and
- Clearly tagging or labeling all valves to reduce human error.

Tank systems should be inspected and tank integrity tested regularly. Problem areas can often be detected by visually inspecting the tanks frequently. Problems or potential problems should be corrected as soon as possible. Registered and specifically trained professional engineers can identify and correct potential problems such as loose fittings, poor welding, and improper or poorly fitted gaskets for newly installed tank systems. The tank foundations, connections, coatings, and tank walls and piping systems also should be inspected. Inspection for corrosion, leaks, cracks, scratches in protective coatings, or other physical damage that may weaken the tank system should be a part of regular integrity testing.

<u>Secondary Containment</u>

Tanks should be bermed or surrounded by a secondary containment system. Leaks can be detected more easily and spills can be contained when a secondary containment systems are installed. Berms, dikes, liners, vaults, and double-wall tanks are examples of secondary containment systems.

One of the best protective measures against contamination of storm water is diking. Containment dikes are berms or retaining walls that are designed to hold spills. Diking is an effective pollution prevention measure for above ground storage tanks and railcar or tank truck loading and unloading areas. The dike surrounds the area of concern and holds the spill, keeping spill materials separated from the storm water side of the dike area. Diking can be used in any industrial facility, but it is most commonly used for controlling large spills or releases from liquid storage areas and liquid transfer areas.

For single-wall tanks, containment dikes should be large enough to hold the contents of the storage tank for the facility plus rain water. For trucks, diked areas should be capable of holding an amount equal to the volume of the tank truck compartment. Diked construction material should be strong enough to safely hold spilled materials. Dike materials can consist of earth, concrete, synthetic materials, metal, or other impervious materials. Strong acids or bases may react with metal containers, concrete, and some plastics. Where strong acids or bases or stored, alternative dike materials should be considered. More active organic chemicals may need certain special liners for dikes. Dikes may also be designed with impermeable materials to increase containment capabilities. Dikes should be inspected during or after significant storms or spills to check for washouts or overflows. Regular checks of containment dikes to insure the dikes are capable of holding spills should be conducted. Inability of a structure to retain storm water, dike erosion, soggy areas, or changes in vegetation indicate problems with dike structures. Damaged areas should be patched and stabilized immediately. Earthen dikes may require special maintenance of vegetation such as mulching and irrigation.

Curbing is a barrier that surrounds an area of concern. Curbing is similar to containment diking in the way that it prevents spills and leaks from being released into the environment. The curbing is usually small scaled and does not contain large spills like diking. Curbing is common at many facilities in small areas where handling and transfer liquid materials occur. Curbing can redirect contaminated storm water away from the storage area. It is useful in areas where liquid materials are transferred from one container to another. Asphalt is a common material used for curbing; however, curbing materials include earth, concrete, synthetic materials, metal, or other impenetrable materials. Spilled materials should be removed immediately from curbed areas to allow space for future spills. Curbs should have manually-controlled pump systems rather than common drainage systems for collection of spilled materials. The curbed area should be inspected regularly to clear clogging debris. Maintenance should also be conducted frequently to prevent overflow of any spilled materials as curbed areas are designed only for smaller spills. Curbing has the following advantages:

- Excellent runon control,
- Inexpensive,
- Ease of installment,
- Provides option to recycle materials spilled in curb areas, and
- Common industry practice.

SC6

VOL 12

1 6834

VOL 12

Additional Information — Outdoor Container Storage of Liquids

Maintenance

- Weekly inspection should be considered and include:
  - Check for external corrosion and structural failure.
  - Check for spills and overfills due to operator error.
  - Check for failure of piping system (pipes, pumps, flanges, coupling, hoses, and valves).
  - Check for leaks or spills during pumping of liquids or gases from truck or rail car to a storage facility or vice versa.
  - Visually inspect new tank or container installation loose fittings, poor welding, and improper or poorly fitted gaskets, and
  - Inspect tank foundations, connections, coatings, and tank walls and piping system. Look for corrosion, leaks, cracks, scratches, and other physical damage that may weaken the tank or container system.

Examples of Effective Programs

The "doghouse" design has been used to store small liquid containers. The roof and flooring design prevent contact with direct rain or runoff. The doghouse has two solid structural walls and two canvas covered walls. The flooring is wire mesh about secondary containment. The unit has been used successfully at Lockheed Missile and Space Company in Sunnyvale.

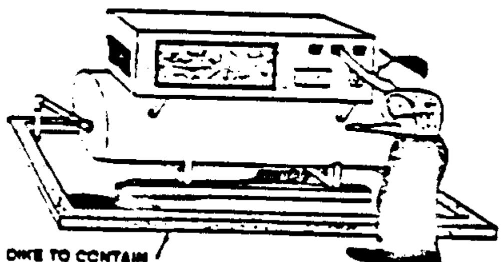
ACTIVITY: OUTDOOR PROCESS EQUIPMENT OPERATIONS AND MAINTENANCE



Applications

- Manufacturing (circled)
- Material Handling
- Vehicle Maintenance
- Construction (circled)
- Commercial Activities (circled)
- Roadways
- Waste Containment
- Housekeeping Practices (circled)

DESCRIPTION

Prevent or reduce the discharge of pollutants to storm water from outdoor process equipment operations and maintenance by reducing the amount of waste created, enclosing or covering all or some of the equipment, installing secondary containment, and training employees.

APPROACH

- Alter the activity to prevent exposure of pollutants to storm water.
- Move activity indoors.
- Cover the area with a permanent roof.
- Minimize contact of storm water with outside manufacturing operations through berming and drainage routing (run on prevention).
- Connect process equipment area to pubic sewer or facility wastewater treatment system.
- Clean regularly the storm drainage system.
- Use catch basin filtration inserts (Chapter 5, TC6, Media Filtration) as a means to capture particulate pollutants.
- Some municipalities require that secondary containment areas (regardless of size) be connected to the sanitary sewer, prohibiting any hard connections to the storm drain.

REQUIREMENTS

- Costs (Capital, O&M)
  - Variable depending on the complexity of the operation and the amount of control necessary for storm water pollution control.
- Maintenance
  - Routine preventive maintenance, including checking process equipment for leaks.

LIMITATIONS

- Providing cover may be expensive.
- Space limitations may preclude enclosing some equipment.
- Storage sheds often must meet building and fire code requirements.

Additional Information — Outdoor Process Equipment Operations and Maintenance

Outside process equipment operations can contaminate storm water runoff. Activities, such as rock grinding or crushing, painting or coating, grinding or sanding, degreasing or parts cleaning, landfills, waste piles, wastewater and solid waste treatment and disposal, and land application are process operations that use hazardous materials and that can lead to contamination of storm water runoff. Pollutants from the wastewater and solid waste treatment and disposal areas result from waste pumping, additions of treatment chemicals, mixing, aeration, clarification, and solids dewatering.

Possible storm water contaminants include heavy metals, toxic materials, and oil and grease. Waste spilled, leaked, or lost from outdoor process equipment operations may build up in soils or on other surfaces and be carried away by storm water runoff. There is also a potential for liquid waste from lagoons or surface impoundments, associated with outdoor equipment operations, to overflow to surface waters or soak the soil, which can be picked up by storm water runoff.

The preferred (and possibly the most economical) action to reduce storm water pollution is to alter the nature of activity such that pollutants are not exposed to storm water. This may mean performing the activity during dry periods only or substituting benign materials for more toxic ones. Actions other than altering the activity include enclosing the activity in a building and connecting the floor drains to the sanitary sewer. The area used by the activity may be so great as to make enclosure prohibitively expensive. Building cost can be reduced by not covering the sides, and thus eliminating the need for ventilating and lighting systems. When certain parts of the activity are the worst source of pollutants, those parts can be segregated and enclosed or covered.

Curbs can be placed around the immediate boundaries of the process equipment. The storm drains from these interior areas can be connected to the facility's process wastewater system.

Reducing the amount of waste that is created and consequently the amount that must be stored or treated is another way to reduce the potential for storm water contamination from outside manufacturing activities. Waste reduction BMPs are available for a wide range of industries and are designed to provide ideas and ways to reduce waste (see References).

Hydraulic/Treatment Modifications

If storm water becomes polluted, it should be captured and treated. If you do not have your own process wastewater treatment system, consider discharging to the public sewer system. Use of the public sewer might be allowed under the following conditions:

- If the activity area is very small (less than a few hundred square feet), the local sewer authority may be willing to allow the area to remain uncovered with the drain connected to the public sewer.
- It may be possible under unusual circumstances to connect a much larger area to the public sewer, as long as the rate of storm water discharges do not exceed the capacity of the wastewater treatment plant. The storm water could be stored during the storm and then transferred to the public sewer when the normal flow is low, such as at night.

The majority of the pollutants in storm water are discharged over time by the small, high frequency storms. Less polluted runoff from the infrequent large storms can be bypassed to the storm drain. To implement this BMP, a hydraulic evaluation of the downstream sewer system should occur in consultation with the local sewer authority.

Industries that generate large volumes of process wastewater typically have their own treatment system that discharges directly to the nearest receiving water. These industries have the discretion to use their wastewater treatment system to treat storm water within the constraints of their permit requirements for process treatment. It may also be possible for the industry to discharge the storm water directly to its effluent outfall without treatment as long as the total loading of the discharged process water and storm water does not exceed the loading had a storm water treatment device been used. This could be achieved by reducing the loading from the process wastewater treatment system. Check with your Regional Water Quality Control Board, as this option would be subject to permit constraints and potentially regular monitoring.

Best Management Practices

DESCRIPTION

Prevent or reduce the discharge of pollutants to storm water from outdoor material and product storage areas by enclosing or covering materials, installing secondary containment, and preventing storm water runon.

APPROACH

- Protect materials from rainfall, runon, runoff and wind dispersal:
  - Store material indoors.
  - Cover the storage area with a roof.
  - Cover the material with a temporary covering made of polyethylene, polypropylene, or hypalon.
  - Minimize storm water runon by enclosing the area or building a berm around the area.
  - Use "doghouse" for storage of liquid containers.
- Parking lots or other surfaces near bulk materials storage areas should be swept periodically to remove debris blown or washed from storage area.
- Install pellet traps at storm water discharge points where plastic pellets are loaded and unloaded.
- Keep liquids in a designated area on a paved impervious surface within a secondary containment.
- Keep outdoor storage containers in good condition.
- Use berms and curbing.
- Use catch basin filtration inserts (Chapter 5, TC6, Media Filtration)

REQUIREMENTS

- Costs (Capital, O&M)
  - Costs should be low except where large areas may have to be covered.
- Maintenance
  - Berm and curbing repair and patching.

LIMITATIONS

- Space limitations may preclude storing some materials indoors.
- Some municipalities require that secondary containment areas (regardless of size) be connected to the sanitary sewer, prohibiting any hard connections to the storm drain.
- Storage sheds often must meet building and fire code requirements.

R0050144

Additional Information — Outdoor Storage of Raw Materials, Products, and By-Products

Raw materials, by-products, finished products, containers, and material storage areas exposed to rain and/or runoff can pollute storm water. Storm water can become contaminated by a wide range of contaminants when materials wash off or dissolve into water or are added to runoff by spills and leaks.

Paved areas should be sloped in a manner that minimize the pooling of water on the site, particularly with materials that may leach pollutants into storm water and/or groundwater, such as compost, logs, and wood chips. A minimum slope of 1.5 percent is recommended.

Curbing should be placed along the perimeter of the area to prevent the runon of uncontaminated storm water from adjacent areas as well as runoff of storm water from the stockpile areas. The storm drainage system should be designed to minimize the use of catch basins in the interior of the area as they tend to rapidly fill with manufacturing material. In these cases, consider the use of the catch basin insert filter described in Chapter 5, TC6 (Media Filtration). The area should be sloped to drain storm water to the perimeter where it can be collected or to internal drainage alleyways where material is not stockpiled. If the raw material, by-product, or product is a liquid, more information for outside storage of liquids can be found under SC6, Outdoor Container Storage of Liquids.

Examples

The "doghouse" design has been used to store small liquid containers. The roof and flooring design prevent contact with direct rain or runoff. The doghouse has two solid structural walls and two canvas covered walls. The flooring is wire mesh about secondary containment. The unit has been used successively at Lockheed Missile and Space Company in Sunnyvale.

ACTIVITY: WASTE HANDLING AND DISPOSAL

DESCRIPTION

Prevent or reduce the discharge of pollutants to storm water from waste handling and disposal by tracking waste generation, storage, and disposal; reducing waste generation and disposal through source reduction, re-use, and recycling; and preventing runon and runoff from waste management areas.

APPROACH

- Maintain usage inventory to limit waste generation.
- Raw material substitution or elimination.
- Process or equipment modification.
- Production planning and sequencing.
- SARA Title III, Section 313 requires reporting for over 300 listed chemicals and chemical compounds. This requirement should be used to track these chemicals although this is not as accurate a means of tracking as other approaches.
- Track waste generated.
  - Characterize waste stream.
  - Evaluate the process generating the waste.
  - Prioritize waste streams using: manifests, biennial reports, permits, environmental audits, SARA Title III reports, emission reports, NPDES monitoring reports.
  - Inventory reports.
  - Data on chemical spills.
  - Emissions.
  - Shelf life expiration.
- Use design data and review: process flow diagram, materials and applications diagram, piping and instructions, equipment list, plot plan.
- Use raw material and production data and review: composition sheets, materials safety data sheets (MSDS), batch sheets, product or raw material inventory records, production schedule, operator data log.
- Use economic data and review:
  - Waste treatment and disposal cost.
  - Product utility and economic cost.
  - Operation and maintenance labor cost.
- Recycle materials whenever possible.
- Maintain list of and the amounts of materials disposed.
- Waste segregation and separation.
- Check industrial waste management areas for spills and leaks.
- Cover, enclose, or berm industrial wastewater management areas whenever possible to prevent contact with runon or runoff.
- Equip waste transport vehicles with anti-spill equipment.

Applications

R0050146

ACTIVITY: WASTE HANDLING AND DISPOSAL (Continue)

- Minimize spills and fugitive losses such as dust or mist from loading systems.
- Ensure that sediments or wastes are prevented from being tracked off-site.
- Training and supervision.
- Stencil storm drains on the facility's property with prohibitive message regarding waste disposal.
- For a quick reference on disposal alternatives for specific wastes see Table 4.1, SC1.
- Consider ordering industry-specific or waste stream-specific guidance from PPIC (see Appendix G).

REQUIREMENTS

- Costs (Capital, O&M)
  - Capital and O&M costs for these programs will vary substantially depending on the size of the facility and the types of waste handled. Costs should be low if there is an inventory program in place.
- Maintenance
  - None except for maintaining equipment for material tracking program.

LIMITATIONS

- Hazardous waste that cannot be re-used or recycled must be disposed of by a licensed hazardous waste hauler.

VOL 12

1 6842

R0050147

SC9

Additional Information — Waste Handling and Disposal

Industrial waste management activities occur in areas that can contaminate storm water and include landfills, waste piles, wastewater and solid waste treatment and disposal, and land application. Typical operations which affect storm water pollution may include waste pumping, treatment chemicals storage, mixing, aeration, clarification, and solids dewatering.

Waste Reduction

Waste spilled, leaked, or lost from waste management areas or outside manufacturing activities may build up in soils or on other surfaces and be carried away by storm water runoff. There is also a potential for liquid waste from lagoons or surface impoundments to overflow to surface waters or soak the soil where pollutants may be picked up by storm water runoff.

Waste reduction for manufacturing activities is the best way to reduce the potential of storm water contamination from waste management areas. Reduction in the amount of industrial waste generated can be accomplished using many different types of source controls such as:

- Production planning and sequencing.
- Process or equipment modification.
- Raw material substitution or elimination.
- Loss prevention and housekeeping.
- Waste segregation and separation.
- Close loop recycling.

An approach to reduce storm water pollution from waste handling and disposal is to assess process activities at the facility and reduce waste generation. The assessment is designed to find situations where waste can be eliminated or reduced and emissions and environmental damage can be minimized. The assessment involves collecting process specific information, setting pollution prevention targets, and developing, screening and selecting waste reduction options for further study. Starting a waste reduction program is economically beneficial because of reduced raw material purchases and lower waste disposal fees. In addition, material tracking systems to increase awareness about material usage can reduce spills and minimize contamination, thus reducing the amount of waste produced.

Spill/Leak Control

Waste can be prevented from contaminating storm water by checking waste management areas for leaking containers or spills. Corroded or damaged containers can begin to leak at any time. Transfer waste from these damaged containers into safe containers. Dumpsters should be covered to prevent rain from washing waste out of holes or cracks in the bottom of the dumpster. Leaking equipment including valves, lines, seals, or pumps should be repaired promptly.

Vehicles transporting waste should have spill prevention equipment that can prevent spills during transport. The spill prevention equipment includes:

- Vehicles equipped with baffles for liquid waste.
- Trucks with sealed gates and spill guards for solid waste.

Loading or unloading wastes can contaminate storm water when the wastes are lost from the transfer. Loading systems can also be used to minimize spills and fugitive emission losses such as dust or mist. Vacuum transfer systems can minimize waste loss.

Runon/Runoff Prevention

Storm water runon should be prevented from entering the waste management area. Storm water pollution from runon can be prevented by enclosing the area or building a berm around the area. Other alternatives for reducing storm water pollution include:

- Preventing the waste materials from directly contacting rain.

SC9

VOL 12

16843

Additional Information — Waste Handling and Disposal

- Moving the activity indoor after ensuring that all safety concerns such as fire hazard and ventilation are addressed.
- Covering the area with a permanent roof.
- Covering waste piles with temporary covering material such as reinforced tarpaulin, polyethylene, polyurethane, polypropylene or hypalon.

To avoid tracking materials off-site, the waste management area should be kept clean at all times by sweeping and cleaning up spills immediately. Vehicles should never drive through spills. If necessary, wash vehicles in designated areas before they leave the site, and control the wash water.

Minimizing the runoff of polluted storm water from land application of industrial waste on-site can be accomplished by:

- Choosing a site where:
  - slopes are under 6 percent
  - the soil is permeable
  - there is a low water table
  - it is located away from wetlands or marshes
  - there is a closed drainage system
- Avoiding applying waste to the site:
  - when it is raining
  - when the ground is frozen
  - when the ground is saturated with water
- Growing vegetation on land disposal areas to stabilize soils and reduce the volume of surface water runoff from the site.
- Maintaining adequate barriers between the land application site and the receiving waters. Planted strips are particularly good.
- Using erosion control techniques
  - mulching and matting,
  - filter fences,
  - straw bales,
  - diversion terracing,
  - sediment basins.
- Performing routine maintenance to ensure the erosion control or site stabilization measures are working.

Examples of Effective Programs

The port of Long Beach has a state-of-the-art database for identifying potential pollutant sources, documenting facility management practices, and tracking pollutants.

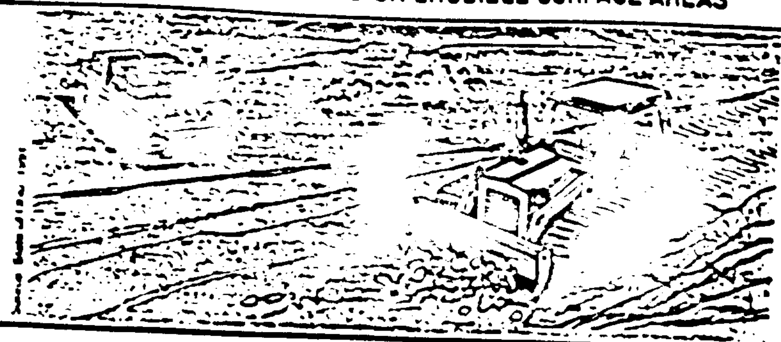
VOL 12

ACTIVITY: CONTAMINATED OR ERODIBLE SURFACE AREAS



Applications

Manufacturing
Material Handling
Vehicle Maintenance
Construction
Commercial Activities
Roadways
Waste Containment
Housekeeping Practices

DESCRIPTION
Prevent or reduce the discharge of pollutants to storm water from contaminated or erodible surface areas by leaving as much vegetation on-site as possible, minimizing soil exposure time, stabilizing exposed soils, and preventing storm water runon and runoff.

APPROACH
This BMP addresses soils which are not so contaminated as to exceed criteria (see Title 22 California Code of Regulations for Hazardous Waste Criteria), but the soil is eroding and carrying pollutants off in the storm water.

Contaminated or erodible surface areas can be controlled by:
- Preservation of natural vegetation,
- Re-vegetation,
- Chemical stabilization,
- Removal of contaminated soils, or
- Geosynthetics.
- For a quick reference on disposal alternatives for specific wastes see Table 4.1, SC1.

REQUIREMENTS
- Cost (Capital, O&M)
  - Except for preservation of natural vegetation, each of the above solutions can be quite expensive depending upon the size of the area.
- Maintenance
  - Maintenance should be minimal, except possibly if irrigation of vegetation is necessary.

LIMITATIONS
Disadvantages of preserving natural vegetation or re-vegetating include:
- Requires substantial planning to preserve and maintain the existing vegetation.
- May not be cost-effective with high land costs.
- Lack of rainfall and/or poor soils may limit the success of re-vegetated areas.

Disadvantages of chemical stabilization include:
- Creation of impervious surfaces.
- May cause harmful effects on water quality.
- Is usually more expensive than vegetative cover.

Additional Information — Contaminated or Erodible Surface Areas

Of interest here are areas within the industrial site that are bare of vegetation and therefore subject to erosion. They may or may not be contaminated from past or current activities. Activity may or may not be occurring in the area of interest. According to the State's General Industrial Activity Storm Water Permit, the SWPPP must include BMPs that deal with these situations. If the area is temporarily bare because of construction, see SC12, Building Repair, Remodeling, and Construction.

Contaminated or erodible surfaces can result from the human activities such as vegetation removal, compacting or disturbing soil, and changing natural drainage patterns. Industries must identify the areas of contaminated or erodible surfaces. The areas may include:

- Heavy activity where plants cannot grow.
- Soil stockpiles.
- Steep slopes.
- Construction areas.
- Demolition areas.
- Any area where soil is disturbed.

The most effective way to control erosion is to preserve existing vegetation. Preservation of natural vegetation provides a natural buffer zone and an opportunity for infiltration of storm water and capture of pollutants in the soil matrix. By preserving stabilized areas, it minimizes erosion potential, protects water quality, and provides aesthetic benefits. This practice is used as a permanent control measure. Vegetation preservation on-site should be planned before disturbing the site. Preservation requires good site management to minimize the impact of construction when construction is underway. Proper maintenance is important to ensure healthy vegetation that can control erosion. Different species, soil types, and climatic conditions will require different maintenance activities such as mulching, fertilizing, liming, irrigation, pruning and weed and pest control. Maintenance should be performed regularly especially during construction phases.

Advantages of preservation of natural vegetation are:

- Can handle higher quantities of storm water runoff than newly seeded areas.
- Increases the filtering capacity because vegetation and root systems are usually dense in preserved natural vegetation.
- Enhances aesthetics.
- Provides areas for infiltration, thus reducing the quantity and velocity of storm water runoff.
- Allows areas where wildlife can remain undisturbed.
- Provides noise buffers and screens for on-site operation.
- Usually requires less maintenance than planting new vegetation.

The measure of choice is to leave as much native vegetation on-site as possible, thereby reducing or eliminating the problem. However, assuming the site already has contaminated or erodible surface areas, there are three possible courses of action:

1. Re-vegetate the area if it is not in use and therefore not subject to damage from site activities. In as much as the area is already devoid of vegetation, special measures are likely necessary. Lack of vegetation may be due to the lack of water and/or poor soils. The later can perhaps be solved with fertilization. Or the ground may simply be too compacted from prior use. Improving soil conditions may be sufficient to support vegetation. If available process wastewater can be used for irrigation, see Construction Best Management Practice Handbook for procedures to establish vegetation.

SC10

Best Management Practices

2. Chemical stabilization (for example ligno sulfate) can be used as an alternate in areas where temporary seeding practices cannot be used because of season or climate. It can provide immediate, effective, and inexpensive erosion control. Application rates and procedures recommended by the manufacturer should be followed as closely as possible to prevent the product from forming ponds and creating large areas where moisture cannot penetrate the soil. The advantages of chemical stabilization include:
   - Easily applied to the surface.
   - Effective in stabilizing areas.
   - Provides immediate protection to soils that are in danger of erosion.

3. Removal of contaminated soils is a last resort and quite expensive. The level and extent of the contamination must be determined. This determination and removal must comply with State and Federal regulations. permits must be acquired, and fees paid.

4. Geosynthetics include those materials that are designed as an impermeable barrier to contain or control large amounts of liquid or solid matter. Geosynthetics have been developed primarily for use in landfills and surface impoundments, and the technology is well established. There are two general types of geosynthetics: geomembranes(impermeable) and geotextiles(permeable).
   - Geomembranes are composed of one of three types of impermeable materials: elastomers(rubbers), thermoplastics(plastics), or a combination of these two types of materials. The advantages of these materials include: 1) the variety of compounds available, 2) sheeting is produced in a factory environment, 3) polymeric membranes are flexible, and 4) simple installation. The disadvantages include: 1) chemical resistance must be determined for each application, 2) seaming systems may be a weak link in the system, and 3) many materials are subject to attack from biotic, mechanical, or environmental sources.
   - Geotextiles are uncoated synthetic textile products that are not water tight. They are composed of a variety of materials, most commonly polypropylene and polyester. Geotextiles serve five basic functions: 1) filtration, 2) drainage, 3) separation, 4) reinforcement, and 5) armoring.

For more information on geosynthetics, see the reference below.

SC11

Best Management Practices

DESCRIPTION

Prevent or reduce the discharge of pollutants to storm water from buildings and grounds maintenance by washing and cleaning up with as little water as possible, preventing and cleaning up spills immediately, keeping debris from entering the storm drains, and maintaining the storm water collection system.

APPROACH

- Leaving or planting native vegetation to reduce water, fertilizer, and pesticide needs.
- Careful use of pesticides and fertilizers in landscaping.
- Integrated pest management where appropriate.
- Sweeping of paved surfaces.
- Cleaning of the storm drainage system at appropriate intervals.
- Proper disposal of wash water, sweepings, and sediments.
- For a quick reference on disposal alternatives for specific wastes see Table 4.1, SC1.

REQUIRMENTS

- Costs (Capital, O&M)
  - Cost will vary depending on the type and size of facility.
  - Overall costs should be low in comparison to other BMPs.
- Maintenance
  - The BMPs themselves relate to maintenance and do not require maintenance as they do not involve structures.

LIMITATIONS

- Alternative pest/weed controls may not be available, suitable, or effective in every case.

1 6848

R0050153

VOL 12

Additional Information — Building and Grounds Maintenance

Buildings and grounds maintenance includes taking care of landscaped areas around the facility, cleaning of parking lots and pavement other than in the area of industrial activity, and the cleaning of the storm drainage system. Painting and other minor or major repairs of buildings is covered in SC12 (Building Repair, Remodeling, and Construction). Certain normal maintenance activities can generate materials that must be properly disposed. Other maintenance activities can enhance water quality if they are carried out more frequently and/or in a more deliberate fashion.

<u>Pesticide/Fertilizer Management</u>

Landscape maintenance involves the use of pesticides and fertilizers. Proper use of these materials will reduce the risk of loss to storm water. In particular, do not apply these materials during the wet season as they may be carried from the site by the next storm. When irrigating the landscaped areas, avoid over-watering not only to conserve water but to avoid the discharge of water which may have become contaminated with nutrients and pesticides.

It is important to properly store pesticides and application equipment, and to dispose the used containers in a responsible manner, consistent with state regulations. Personnel who use pesticides should be trained in their use. The California Department of Pesticide Regulation and county agricultural commissioners license pesticide dealers, certify pesticide applicators, and conduct on-site inspections.

Written procedures for the use of pesticides and fertilizers relevant to your facility would help maintenance staff understand the "do's" and "don'ts". If you have large vegetated areas, consider the use of integrated pest management (IPM) techniques to reduce the use of pesticides.

<u>Parking/Storm Sewer Maintenance</u>

A parking area that drains to the same storm drainage system as the industrial activity that is to be permitted must also be evaluated for suitable BMPs. Storm water from parking lots may contain undesirable concentrations of oil, grease, suspended particulates, and metals such as copper, lead, cadmium, and zinc, as well as the petroleum byproducts of engine combustion. Deposition of air particulates, generated by the facility or by adjacent industries, may contribute significant amounts of pollutants.

The two most appropriate maintenance BMPs are periodic sweeping and cleaning catch basins if they are part of the drainage system. A vacuum sweeper is the best method of sweeping, rather than mechanical brush sweeping which is not as effective at removing the fine particulates.

Catch basins in parking lots generally need to be cleaned every 6 to 12 months, or whenever the sump is half full. A sump that is more than half full is not effective at removing additional particulate pollutants from the storm water. If the storm drain lines have a low gradient, less than about 0.5 feet in elevation drop per 100 feet of line, it is likely that material is settling in the lines during the small, frequent storms. If you have not cleaned the storm drain system for some time, check the lines as well. If they are not cleaned, the catch basins will likely be filled during the next significant storm by material that is washed from the lines. Also, install "turn-down" elbows or similar devices on the outlets of the catch basins; they serve to retain floatables, oil and grease.

Clearly mark the storm drain inlets, either with a color code (to distinguish from process water inlets if you have them) or with the painted stencil of "DO NOT DUMP WASTE". This will minimize inadvertent dumping of liquid wastes.

Sweepings and sediments from these maintenance activities are generally low in metals and other pollutants and therefore can be disposed on-site or to a construction debris landfill. Test the material if there is a reasonable doubt whether metals or other pollutants are present. If concentrations of contaminants are high, it indicates that other BMPs may be needed to eliminate or reduce emissions from the source. If a vactor truck is used to clean the storm drainage system,

SC11

Best Management Practices

R0050154

1 6849

dirty water will be generated. This water should not be discharged to the storm drainage system as it is silt laden and contains much of the pollutants that were removed by the catch basins. The water should be disposed to the process wastewater system, if you have one, or to the public sewer if permission is granted by the local sewer authority. Alternatively, the water can be placed somewhere on the site where it can evaporate.

The cleaning of the paved surfaces and catch basins in the areas of industrial activity has been discussed previously in SC5 (Loading and Unloading of Materials), SC7 (Outdoor Process Equipment Operations and Maintenance), and SC8 (Outdoor Storage of Raw Materials, Products, and Byproducts).

If some employees have cars that are leaking abnormal amounts of engine fluids, encourage them to have the problem corrected.

<u>Examples of Effective Programs</u>

Information on integrated pest management may be obtained from the Bio-Integral Resource Center, P.O. Box 7414, Berkeley, CA 94707, 510-524-2467.

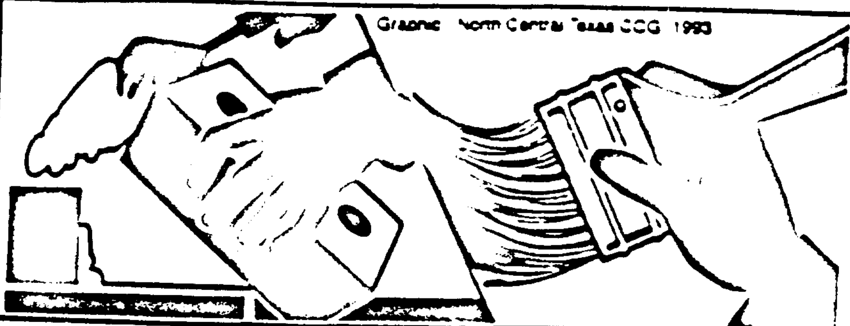
R0050155

ACTIVITY: BUILDING REPAIR, REMODELING AND CONSTRUCTION



DESCRIPTION

Prevent or reduce the discharge of pollutants to storm water from building repair, remodeling, and construction by using soil erosion controls, enclosing or covering building material storage areas, using good housekeeping practices, using safer alternative products, and training employees.

APPROACH

- Use soil erosion control techniques if bare ground is temporarily exposed. See the Construction Activity Best Management Practice Handbook.
- Use permanent soil erosion control techniques if the remodeling clears buildings from an area that are not to be replaced. See SC10 (Contaminated or Erodible Surface Areas).
- Enclose painting operations, consistent with local air quality regulations and OSHA.
- Properly store materials that are normally used in repair and remodeling such as paints and solvents.
- Properly store and dispose waste materials generated from the activity. See CA20, Solid Waste Management, Construction Handbook.
- Maintain good housekeeping practices while work is underway.

REQUIREMENTS

- Costs (Capital, O&M)
  - These BMPs are generally of low to modest in cost.

LIMITATIONS

- This BMP is for minor construction only. The State's General Construction Activity Storm Water Permit has more requirements for larger projects. The companion "Construction Activity Best Management Practice Handbook" contains specific guidance and best management practices for larger-scale projects.
- Hazardous waste that cannot be re-used or recycled must be disposed of by a licensed hazardous waste hauler.
- Safer alternative products may not be available, suitable, or effective in every case.
- Be certain that actions to help storm water quality are consistent with Cal- and Fed-OSHA and air quality regulations.

Modifications are a common occurrence particularly at large industrial sites. The activity

VOL 12

Additional Information — Building Repair, Remodeling, and Construction

may vary from minor and normal building repair to major remodeling, or the installation of new facilities on currently open space. These activities can generate pollutants that can reach storm water if proper care is not taken. The sources of these contaminants may be solvents, paints, paint and varnish removers, finishing residues, spent thinners, soap cleaners, kerosene, asphalt and concrete materials, adhesive residues, and old asbestos installation.

Good Housekeeping

Proper care involves a variety of mostly common sense, housekeeping actions such as:

- Keep the work site clean and orderly. Removing debris in a timely fashion. Sweep the area.
- Cover materials of particular concern that must be left out, particularly during the rainy season.
- Educate employees who are doing the work.
- Inform on-site contractors of company policy on these matters and include appropriate provisions in their contract to make certain proper housekeeping and disposal practices are implemented.
- Make sure that nearby storm drains are well marked to minimize the chance of inadvertent disposal of residual paints and other liquids.
- Do not dump waste liquids down the storm drain.
- Advise concrete truck drivers to not wash their truck over the storm drain. Have a designated area that does not drain to the storm drain.
- Clean the storm drain system in the immediate vicinity of the construction activity after it is completed.

Proper education of off-site contractors is often overlooked. The conscientious efforts of well trained employees can be lost by unknowing off-site contractors, so make sure they are well informed about what they are expected to do.

Painting operations should be properly enclosed or covered to avoid drift. Use temporary scaffolding to hang drop cloths or draperies to prevent drift. Application equipment that minimizes overspray also helps. Local air pollution regulations may, in many areas of the state, specify painting procedures which if properly carried out are usually sufficient to protect water quality. If painting requires scraping or sand blasting of the existing surface, use a ground cloth to collect the chips. Dispose the residue properly. If the paint contains lead or tributyl tin, it is considered a hazardous waste.

Mix paint indoors before using so that any spill will not be exposed to rain. Do so even during dry weather because cleanup of a spill will never be 100% effective. Dried paint will erode from a surface and be washed away by storms. If using water based paints, clean the application equipment in a sink that is connected to the sanitary sewer. Properly store leftover paints if they are to be kept for the next job, or dispose properly.

When using sealants on wood, pavement, roofs, etc. quickly clean up spills. Remove excess liquid with absorbent material or rags. If when repairing roofs, small particles have accumulated in the gutter, either sweep out the gutter or wash the gutter and trap the particles at the outlet of the downspout. A sock or geofabric placed over the outlet may effectively trap the materials. If the downspout is tight lined, place a temporary plug at the first convenient point in the storm drain and pump out the water with a vactor truck, and clean the catch basin sump where you placed the plug.

Soil/Erosion Control

If the work involves exposing large areas of soil employ the appropriate soil erosion and control techniques. See the Construction Best Management Practice Handbook. If old buildings are being torn down and not replaced in the near future, stabilize the site using measures described in SC10, Contaminated or Erodible Surface Areas.

If a building is to be placed over an open area with a storm drainage system, make sure the storm inlets within the

1 6852

SC12

Best Management Practices

building are covered or removed, or the storm line is connected to the sanitary sewer. If because of the remodeling a new drainage system is to be installed or the existing system is to be modified, consider installing catch basins as they serve as effective "in-line" treatment devices. See TC2 (Wet Ponds) in Chapter 5 regarding design criteria. Include in the catch basin a "turn-down" elbow or similar device to trap floatables.

Recycle residual paints, solvents, lumber, and other materials to the maximum extent practical. Buy recycled products to the maximum extent practical.

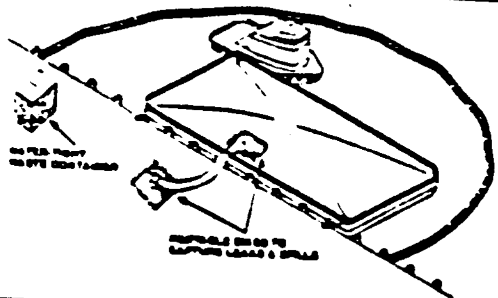
Best Management Practices for Industrial Storm Water Pollution Control, Santa Clara Valley Nonpoint Source Pollution Control Program, 1992.

ACTIVITY: OVER-WATER ACTIVITIES



DESCRIPTION
Prevent or reduce the discharge of pollutants to storm water and receiving waters from over-water activities by minimizing over-water maintenance, keeping wastes out of the water, cleaning up spills and wastes immediately, and educating tenants and employees.

APPROACH
- Properly dispose of domestic wastewater and ballast water.
- Limit over-water hull surface maintenance to sanding and minor painting.
- Use phosphate-free and biodegradable detergents for hull washing.
- Use secondary containment on paint cans.
- Have available spill containment and cleanup materials.
- Use ground cloths when painting boats on land.
- Use tarps, plastic sheeting, etc. to contain spray paint and blasting sand.
- Properly dispose of surface chips, used blasting sand, residual paints, and other materials. Use temporary storage containment that is not exposed to rain.
- Immediately clean up spills on docks or boats.
- Sweep drydocks before flooding.
- Clean catch basins and the storm drains at regular intervals.
- Post signs to indicate proper use and disposal of residual paints, rags, used oil, and other engine fluids.
- Educate tenants and employees on spill prevention and cleanup.
- Include appropriate language in tenant contracts indicating their responsibilities.
- Marinas should provide wastewater disposal facilities.

REQUIREMENTS
- Cost (Capital, O&M)
  - Most of the BMPs are of low and modest cost. Exceptions are stations for temporary storage of residual paints and engine fluids, and wastewater pumpout facilities.
- Maintenance
  - Keep ample supply of spill cleanup materials.

LIMITATIONS
Private tenants at marinas may resist restrictions on shipboard painting and maintenance. Existing contracts with tenants may not allow the owner to require that tenants abide by new rules that benefit water quality. Even biodegradable cleaning agents have been found to be toxic to fish.

Additional Information — Over-Water Activities

Over-water activities occur at boat and ship repair yards, marinas, and yacht clubs, although the later are not required to obtain a permit. Activities of concern include chipping and painting of hulls, on board maintenance of engines, and the disposal of domestic wastewater and ballast water. With few exceptions, BMPs to protect water quality are common sense, low cost changes to normal day-to-day procedures.

Over-water Activity Minimization
Work on boats in the water should be kept to a minimum. Major hull resurfacing should occur on land. Surface preparation over water should be limited to sanding. Painting should be limited to spot work. In marinas, tenant maintenance over water should be such as to not require opening more than a pint size paint can. Paint mixing should not occur on the dock.

Good Housekeeping
When conducting on board maintenance, used antifreeze should be stored in a separate, labeled drum and recycled. Fuel tank vents should have valves to prevent fuel overflows or spills. Boats with inboard engines should have oil absorption pads in bilge areas and they should be changed when no longer useful or at least once a year.

Marina owners should provide temporary storage stations for used engine fluids, paint cans, and other maintenance materials. Signs should be posted at the head of each dock indicating maintenance rules. Marina owners should install a wastewater disposal system, either dockside lines or a pumpout station. Tenant contracts should include language indicating their responsibilities.

When painting on shore, place paint cans in a tray or comparable device that collects spills and drips. Use groundcloths when painting. Use spray guns that minimize overspray; also enclose the area with plastic tarps. Identify a designated area for washing boats. Vacuum sweep work areas frequently. When doing repairs or painting on a tidal grid or similar open "dry dock", use ground cloths to retain chips and spilled paint. The repair yard owner should install signs so that boat owners who are doing their own work know their responsibilities.

Large boat repair yards can implement the above BMPs. There are several additional measures. With regard to dry dock operations: sweep the accessible areas of the dry dock before flooding; and pick up other debris that appears after the ship is floated. Remove floatable debris such as wood. Shipboard cooling and process water discharges should be directed to minimize contact with spent abrasives, paints, and other debris. Look for and repair leaking valves, pipes, hoses, or soil chutes carrying either water or wastewater. Plastic sheeting or other suitable materials should be installed when sandblasting and spray painting.

Use drip pans or comparable devices when transferring oils, solvents, and paints. Regularly clean the shoreside work areas of debris, sandblasting material, etc. Clean catch basins or other parts of the storm drainage system that might accumulate these materials.

Fish Waste
Fish wastes must also be managed properly. Recycling fish wastes back to the water is encouraged when disposal will not result in water quality or public nuisance problems, such as wastes washing up onshore or causing odors or bacteria problems. Fish wastes should not be recycled in any dead end lagoons or other poorly flushed areas. Marina owners should provide fish cleaning stations where waste recycling can occur without adversely affecting water quality.
Note: San Francisco Bay Area boat repair and maintenance facilities. The San Francisco Bay Regional Water Quality Control Board has issued a General Storm Water NPDES Permit to boat yards which work primarily on pleasure vessels less than 65 feet in length. The General Permit requires maintenance of pressure wash containment and recycle or pretreatment system implementation of a Storm Water Pollution Control Plan (SPCP) and a Monitoring Program.

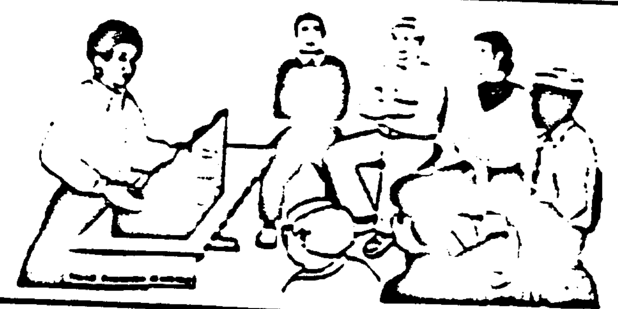
ACTIVITY: EMPLOYEE TRAINING



Applications

- Manufacturing
- Material Handling
- Vehicle Maintenance
- Construction
- Commercial Activities
- Roadways
- Waste Containment
- Housekeeping Practices

DESCRIPTION

Employee training, like equipment maintenance, is not so much a best management practice as it is a method by which to implement BMPs. This fact sheet highlights the importance of training and of integrating the elements of employee training from the individual source controls into a comprehensive training program as part of a facility's Storm Water Pollution Prevention Plan (SWPPP).

The specific employee training aspects of each of the source controls are highlighted in the individual fact sheets. The focus of this fact sheet is more general, and includes the overall objectives and approach for assuring employee training in storm water pollution prevention. Accordingly, the organization of this fact sheet differs somewhat from the other fact sheets in this chapter.

OBJECTIVES

Employee training should be based on four objectives:

- Promote a clear identification and understanding of the problem, including activities with the potential to pollute storm water;
- Identify solutions (BMPs);
- Promote employee ownership of the problems and the solutions; and
- Integrate employee feedback into training and BMP implementation.

APPROACH

- Integrate training regarding storm water quality management with existing training programs that may be required for your business by other regulations such as: the Illness and Injury Prevention Program (IIPP) (SB 198) (California Code of Regulations Title 8, Section 3203), the Hazardous Waste Operations and Emergency Response (HAZWOPER) standard (29 CFR 1910.120), the Spill Prevention Control and Countermeasure (SPCC) Plan (40 CFR 112), and the Hazardous Materials Management Plan (Business Plan) (California Health and Safety Code, Section 6.95).
- Businesses, particularly smaller ones that are not regulated by Federal, State, or local regulations, may use the information in this Handbook to develop a training program to reduce their potential to pollute storm water.

LISTING OF INDUSTRIAL ACTIVITIES

Employee training is a vital component of many of the individual source control BMPs included in this chapter. Following is a compilation of the training aspects of the source control fact sheets.

SC14

Best Management Practices

R0050162

ACTIVITY — EMPLOYEE TRAINING (Continue)

SC1 Non-Storm Water Discharges to Drains
- Use the quick reference on disposal alternatives (Table 4.1) to train employees in proper and consistent methods for disposal.
- Consider posting the quick reference table near storm drains to reinforce training.

SC2 Vehicle and Equipment Fueling
- Train employees in proper fueling and cleanup procedures.
- The SPCC Plan may be an effective program to reduce the number of accidental spills from fueling.

SC3 Vehicle and Equipment Washing and Steam Cleaning
- Train employees in standard operating procedures and spill cleanup techniques described in the fact sheet.

SC4 Vehicle and Equipment Maintenance and Repair
- Train employees in standard operating procedures and spill cleanup techniques described in the fact sheet.
- Paint stencils to remind employees not to pour waste down storm drains.

SC5 Outdoor Loading/Unloading of Materials
- Use a written operations plan that describes procedures for loading and/or unloading.
- Have an emergency spill cleanup plan readily available.
- Employees trained in spill containment and cleanup should be present during loading/unloading.
- Make sure fork lift operators are also properly trained.

SC6 Outdoor Container Storage of Liquids
- Registered and specifically trained professional engineers can identify and correct potential problems such as loose fittings, poor welding, and improper or poorly fitted gaskets for newly installed tank systems.
- Employees trained in emergency spill cleanup procedures should be present when dangerous waste, liquid chemicals, or other wastes are handled.

SC7 Outdoor Process Equipment Operations and Maintenance
- The preferred and possibly most economical action to reduce storm water pollution is to alter the activity. This may mean training employees to perform the activity during dry periods only or substituting benign materials for more toxic ones.

SC8 Outdoor Storage of Raw Materials, Products, and By-Products
- Train employees in standard operating procedures and spill cleanup techniques described in the fact sheet.

SC9 Waste Handling and Disposal
- Train employees in standard operating procedures and spill cleanup techniques described in the fact sheet.
- Paint stencils to remind employees not to pour waste down storm drains.

SC10 Contaminated or Erodible Surface Areas
- Training is not a significant element of this best management practice.

SC14

Best Management Practices

VOL 12 1 6858

R0050163

ACTIVITY — EMPLOYEE TRAINING (Continue)

SC11 Building and Grounds Maintenance

- Personnel who use pesticides should be trained in their use. The California Department of Pesticide Regulation and county agricultural commissioners license pesticide dealers, certify pesticide applicators, and conduct on-site inspections.
- Written procedures for the use of pesticides and fertilizers relevant to your facility would help maintenance staff understand the "do's" and "don'ts". If you have large vegetated areas, consider the use of integrated pest management (IPM) techniques to reduce the use of pesticides.

SC12 Building Repair, Remodeling, and Construction

- Proper education of off-site contractors is often overlooked. The conscientious efforts of well trained employees can be lost by unknowing off-site contractors, so make sure they are well informed about what they are expected to do.

SC13 Over-Water Activities

- Post signs to indicate proper use and disposal of residual paints, rags, used oil, and other engine fluids.
- Educate tenants and employees on spill prevention and cleanup.
- Include appropriate language in tenant contracts indicating their responsibilities.

SC14

R0050164

VOL 12

16859

TREATMENT CONTROL BMPs

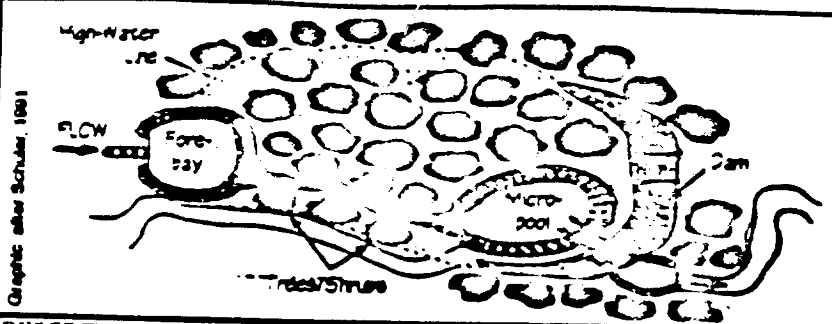
VOL 12

1

6860

R0050165

BMP: EXTENDED DETENTION BASINS



DESCRIPTION

Extended detention basins are dry between storms. During a storm the basin fills. A bottom outlet releases the storm water slowly to provide time for sediments to settle.

EXPERIENCE IN CALIFORNIA

There are no known basins in California. Hydraulic detention basins may function like extended detention basins if the former has been sized to control the pre-development 2-year event. More liberal standards do not provide sufficient detention time.

SELECTION CRITERIA

- Objective is to remove only particulate pollutants.
- Use where lack of water prevents the use of wet ponds, wetlands or biofilters.
- Use where wet ponds or wetlands would cause unacceptable mosquito conditions.

LIMITATIONS

- May be less reliable than other treatment control BMPs.
- Inability to vegetate banks and bottom may result in erosion and resuspension.
- Limitation of the orifice diameter may preclude use in small watersheds.
- Requires differential elevation between inlet and outlet.
- Pending their volume and depth basin designs may require approval from State Division of Safety of Dams.

DESIGN AND SIZING CONSIDERATIONS

- Basin volume is sized to capture a particular fraction of the runoff.
- Drawdown time of 24 to 40 hours.
- Shallow basin with large surface area performs better than deep basin with same volume.
- Place energy dissipators at the entrance to minimize bottom erosion and resuspension.
- Vegetate side slopes and bottom to the maximum extent practical.
- If side erosion is particularly severe, consider paving or soil stabilization.
- If floatables are a problem, protect outlet with trash rack or other device.
- Provide bypass or pass through capabilities for 100 year storm.

CONSTRUCTION/INSPECTION CONSIDERATIONS

- Make sure the outlet is installed as designed.

BMP: EXTENDED DETENTION BASINS (Continue)

MAINTENANCE REQUIREMENTS

- Check outlet regularly for clogging.
- Check banks and bottom of surface basin for erosion and correct as necessary.
- Remove sediment when accumulation reaches 6-inches, or if resuspension is observed.

COST CONSIDERATIONS

- Generally less expensive than wet ponds and wetlands, but more expensive than biofilters.

TC5

Additional Information — Extended Detention Basins

General

Extended detention ponds and vaults may be particularly appropriate to California where dry weather base flow cannot be used to maintain water levels, as is required for wet ponds and constructed wetlands. These systems are suitable for essentially any size tributary area from an individual commercial development to a large residential area. Surface ponds are less expensive to construct, but underground vaults may be appropriate in commercial developments. Use of concrete retaining walls will reduce the space required by a pond. The basic elements of an extended detention basin are illustrated in Figure 5A. The configuration shown in Figure 5A is most appropriate for large sites.

Extended detention provides a lower removal efficiency than wet ponds and constructed wetlands: the facilities are smaller thereby reducing their effectiveness with particulate pollutants, and they do not have the ability to remove dissolved contaminants. Also, extended detention facilities may be less reliable than constructed wetlands or wet ponds because of the lack of a permanent water pool (See Figure 5A). But if desired, a shallow pool of 1 to 3 feet could be included in the design but this is more of an aesthetic consideration. If irrigation water is available, a thick grass turf on the bottom of the facility may provide some removal of dissolved contaminants, like a vegetated biofilter. See TC4 Biofilters for recommendations on turf grass and groundcover species.

Where irrigation water is not available, there may be concerns about erosion and resuspension of particulate pollutants in surface ponds. This, however, has not been a significant problem in Austin, Texas where sand filters are preceded by dry settling ponds (Hartigan, pers. comm.). However, the design must incorporate several features to minimize the potential for this problem. Drought tolerant vegetation may work but has not been evaluated. Nonvegetative materials may help such as concrete or plastic grids, small riprap, erosion matting, or paving. A paved forebay may facilitate maintenance thereby reducing the material available for resuspension.

The recommended drawdown time of 24 to 40 hours for a full pond is based on very limited laboratory data. A few extended detention ponds have been monitored and generally provide a removal efficiency of 60 to 80% with a drawdown time of about 24 hours. Forty hours is recommended in order to settle out the finer clay particles in California sediment that typically adsorb toxic pollutants.

Design

Determine the volume of the basin using the appropriate figure from Appendix D. The procedure is as follows: (1) select the appropriate figure for your area; (2) determine for the catchment the percentage of impervious area directly connected to the storm drain system; (3) choose a capture goal, and read the required unit volume required for the basin; and (4) multiply this unit volume times the total acreage of the catchment and convert to cubic feet. This volume is also referred to as water quality capture volume shown in Figure 5A. Total impervious acres may be used in lieu of directly connected impervious acres if it is easier to determine the former, although this will result in a larger facility. Although these variations are not equivalent, they are reasonable given the uncertainty of the methodology and expected basin performance.

What should be the capture goal? To achieve an equivalent pollutant capture percentage as a wet pond, 85 to 95 percent of the runoff must be captured and detained. But capture volumes over 85 percent are not cost effective as the capture cases in Appendix D show. Therefore it is recommended that a capture volume of 85 percent be used for determining the detention basin size required. Because of the possibility of resuspension of materials during extreme storms consideration should be given to placing the basin off line, that is, it should have a bypass for the extreme events. Bypassing larger events will also allow the bedload carried by the storm and is necessary for beach replenishment to move downstream.

A drawdown time of 40 hours is recommended in order to settle out the finer clay particles as stated above; however, 24 hours can be used if it can be demonstrated that this rate will remove 80% of the solids. The analysis of runoff using

TC5

VOL 12

1 5863

R0050168

the hydrologic model STORM and California precipitation data found that increasing the drawdown time from 24 to 40 hours increased the size of the basin by only about 10% to 20% depending on the location (see Appendix D).

Proper hydraulic design of the outlet is critical to achieving good performance of the detention basin. The two most common outlet problems that occur are: 1) the capacity of the outlet is too great resulting in partial filling of the basin and less than designed for drawdown time and 2) the outlet clogs because it is not adequately protected against trash and debris. To avoid these problems, two alternative outlet types are recommended for use: 1) V-notch weir, and 2) perforated riser. The V-notch weir will not clog, but it is also difficult to maintain small release rates at low heads. The perforated riser if properly designed and gravel packed gives much better control and is recommended over the V-notch weir.

Two different approaches can be used to control the outflow. One is to use a single orifice outlet with or without the protection of a riser pipe. The other is to use the perforated riser itself for discharge control. Both approaches are presented below.

<u>Flow Control Using a Single Orifice</u>
The outlet control orifice should be sized using the following equation (GKY, 1989).

$$a = \frac{2A(H-H_o)^{0.5}}{3600CT(2g)^{0.5}} = \frac{(7x10^{-5})A(H-H_o)^{0.5}}{CT} \qquad (1)$$

where:
- a = area of orifice (ft^2)
- A = average surface area of the pond (ft^2)
- c = orifice coefficient
- T = drawdown time of full pond (hrs.)
- g = gravity (32.2 $ft./sec^2$)
- H = elevation when the pond is full (ft)
- H_o = final elevation when pond is empty (ft)

With a drawdown time of 40 hours the equation becomes:

$$a = \frac{(1.75X10^{-6})A(H-H_o)^{0.5}}{C} \qquad (2)$$

Assuming an average release rate at one half the pond depth, a common approach in several design manuals, leads to considerable error. If the pond has a significant variation of surface area with depth, do not use Equation (2); consult GKY (1989).

Care must be taken in the selection of "c": 0.60 is most often recommended and used. However, based on actual tests GKY (1989) recommends the following:

c = 0.66 for thin materials, that is, the thickness is equal to or less than orifice diameter

c = 0.80 when the material is thicker than the orifice diameter

Drilling the orifice into an outlet structure that is made of concrete can result in considerable impact on the coefficient, as does the beveling of the edge. The experiments by GKY (1989) were with sharp edged orifices.

TC5

Additional Information — Extended Detention Basins

Equation (1) defines the orifice area where a single orifice outlet is used to regulate the detention basin outflow. However, a recent survey of extended detention facilities (Galli, pers. comm.) found the drawdown time of small storms that do not fill the facility to be too short to provide effective treatment. The facilities surveyed were designed for a drawdown time of 24 hours. A 40 hour drawdown may provide sufficient time for the smaller storms. But it may be prudent to take additional steps to be certain that the small storms, which represent the majority of pollution, are effectively treated. One approach would be to check the design analysis to determine if the facility takes at least 24 hours to drain when half full. If not, either modify the design to achieve this objective, or install a two orifice outlet. The lower outlet is sized to drain a half-full facility in 24 hours. The second orifice is placed at the mid-water elevation and is sized in combination with the lower orifice to drain the entire facility in 40 hours. Another approach is to install the outlet about one foot above the bottom of the pond (essentially enlarging the micropool area). This lower area will dry up between storms and will capture much of the volume of small storms and improving pollutant removal.

Three alternative outlet structures are suggested (Figure 5B). The concrete block structure is appropriate for large ponds. The riser pipe is suggested for small to large ponds. Placing the outlet control in the berm or in a manhole located downstream of the facility is most suitable for small ponds.

Recommendations regarding the design of a riser pipe are shown in Table 5A for Austin (1988). Table 5A provides guidance on the location of holes. To prevent clogging of this orifice and the bottom orifices of the riser pipe, wrap the bottom three rows of orifices with geotextile fabric and a cone of one to three inch rock. The holes in the riser pipe should not be modified to achieve a 40 hour drawdown time. Rather, <u>the control orifice should be placed downstream.</u> For small facilities, place the control orifice in a manhole between the pond and the filter as shown in Figure 5B. Use a "T-pipe" (Figure 5B) to submerge the orifice.

TABLE 5A PERFORATED OUTLET RISER PIPE ORIFICES (Austin, 1988)

RISER PIPE DIAMETER	VERTICAL SPACING BETWEEN ROWS (center to center)	NUMBER OF PERFORMATIONS	PERFORATION DIAMETER
6 in.	2.5 in.	9 per row	1 in.
8 in.	2.5 in.	12	1 in.
10 in.	2.5 in.	16	1 in.

Clogging of the bottom holes has been observed in riser pipes in the mid-Atlantic states (MWCOG, 1992) suggesting that the diameter of the riser holes should not be less than 3/4 to 1" (MWCOG, 1992) although a minimum diameter of 2" is now being considered (Galli, pers comm.). However, most of the facilities surveyed had risers <u>without</u> the gravel cone and the outlet holes were modified to provide drawdown control. Modifying the holes in the riser to control the outlet rate reduces the diameter of the holes and increases the risk of clogging. However, gravel packing the riser pipe as shown in Figure 5B.2 and 5C.1 will minimize this risk. Submerging the control orifice as shown in Figure 5B.3 will allow the use of a smaller orifice diameter. One orifice with a diameter of 1/2 inch, or 1 inch to be conservative, allows the use of extended detention for very small catchments. Detention facilities in western Washington use this concept and have not experienced clogging problems.

<u>Flow Control Using the Perforated Riser</u>

For outlet control using the perforated riser as the outflow control, it is recommended that the procedure developed by the Denver Urban Drainage and Flood Control District be used (UDFCD, 1992) as illustrated in Figures 5C and 5D. Figure 5D uses a valve for C_e of 0.65. This design incorporates flow control for the small storms in the perforated riser but also provides an overflow outlet for large storms. If properly designed, the facility can be used for both water quality and

TCS

VOL 12 1 5856

Additional Information — Extended Detention Basins

drainage control by: 1) sizing the perforated riser as indicated for water quality control; 2) sizing the outlet pipe to control peak outflow rate from the 2 year storm; and 3) using a spillway in the pond berm to control the discharge from larger storms up to the 100 year storm.

Other Design Considerations

- Do not locate on fill sites or on or near steep slopes if it is expected that much of the water will exit through the bottom, or modify the bottom to prevent excessive infiltration.
- Energy dissipation at the inlet to minimize erosion
- Vegetate the slopes and bottom for the same reason
- Freeboard of 1 foot
- Side slopes of at least 2:1 unless vertical retaining walls are used
- Incorporate bypass or overflow for large events
- Provide dedicated access to the basin bottom (minimum 4:1) for maintenance vehicles
- With a riser structure, include an anti-vortex device and a debris barrier.

Maintenance

Conduct inspections semiannually and after each significant storm. Remove floatables and correct erosion problems in the pond slopes and bottom. Pay particular attention to the outlet control orifice(s) for signs of clogging. If the orifice is located in a Type 2 catch basin, remove sediments if they are within 18 in. of the orifice plate. Often extended detention basins serve multiple uses, e.g. baseball field, resulting in higher maintenance costs.

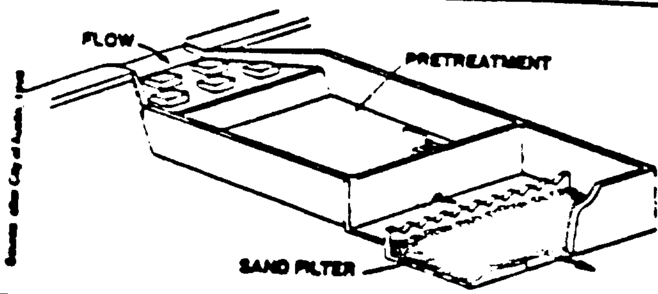
BMP: MEDIA FILTRATION



Considerations

- Soils
- Area Required
- Slope
- Water Availability
- Aesthetics
- Hydraulic Head
- Environmental Side Effects

DESCRIPTION

Consists of a settling basin followed by a filter. The most common filter media is sand; some use peat/sand mixture.

EXPERIENCE IN CALIFORNIA

- A tenant at the Port of Long Beach recently installed a sand filter. The City of Los Angeles will soon install several experimental filters.

SELECTION CRITERIA

- Objective is to remove only sediment (particulate pollutants).
- Use where unavailability of water prevents the use of wet ponds, wetlands, or biofilters.
- Can be placed underground.
- Suitable for individual developments and small tributary areas up to about 100 acres.
- May require less space than other treatment control BMPs.

LIMITATIONS

- Filter may require more frequent maintenance than most of the other BMPs.
- Head loss.
- Dissolved pollutants are not captured by sand.
- Severe clogging potential if exposed soil surfaces exist upstream.

DESIGN AND SIZING CONSIDERATIONS

- Settling basin smaller than wet or extended detention basin.
- Spread flow across filter.
- Place filter offline to protect from extreme events.
- Minimize erosion in settling basin.

CONSTRUCTION/INSPECTION CONSIDERATIONS

- Be certain filter sand is clean and the outlet device from the basin to the filter is level.

MAINTENANCE REQUIREMENTS

- Clean filter surface about twice annually; or more often if watershed is excessively erosive.

COST CONSIDERATIONS

- Filtration system may use less space than other systems.
- Smaller media improves performance but increases maintenance costs.

VOL 12

Additional Information — Media Filtration

Sand filters may be particularly suitable for industrial sites because the settling basin can be located underground. A sand filter consists of two units: settling basin and the filter. Pretreatment is essential to avoid rapid clogging of the filter. Peat/sand mixture has been used: peat having the ability to remove dissolved contaminants. However, there have been clogging problems (Tomasak, et al., 1987) but this may be due to using the wrong type of peat (Galli, 1990). Limited research indicates that compost made from leaves is very effective at removing dissolved phosphorus and metals, and oil and grease (Stewart, 1989). A new concept is placement of a filter device in a catch basin insert (McPherson, 1992) which may be very well suited for industrial sites.

Field research in the City of Austin, Texas (Austin, 1990) indicates the sand filter has a removal efficiency of suspended solids that is similar to wet ponds and extended detention: 70 to 90%. The observed removal of metals was 20 to 80%, depending on the metal, 20 to 30% for nitrogen, and 50 to 60% for phosphorus. These rates are also similar to wet ponds, which is not expected as a filter does not remove dissolved contaminants. Sand with a diameter smaller than used in Austin would likely improve performance but has not been tried.

The sand filter should be an ideal system for the Central Valley and Southern California. It does not rely on vegetation, and has proven itself in the City of Austin. The sand filter is suitable for tributary areas of a less than an acre to about 50 acres.

Make certain that any soil erosion problems in the site have been corrected (Chapter 4). Experience in Austin indicates that exposed soils during construction "upstream" from the filter can result in penetration of fines into the filter media, resulting in a need to replace the entire filter bed. The system should have a bypass for extreme events.

Alternative configurations

The most experience to date is with surface facilities shown conceptually in Figure 6A. It can be used on catchments up to perhaps 50 acres. Its origin is Austin, Texas where there are now several hundred facilities. The "Austin" filter uses an extended detention basin with a drawdown time of 24 hours. Two other systems are most suitable for small catchments of a few acres. An underground "linear" filter (Figure 6B) is used in Delaware (Shaver, 1991). The filter accepts sheet flow from adjacent pavement. It, therefore, may be ideal for industrial applications. Another underground design (Figure 6C) developed in Washington D.C. (Truong, 1989) is also ideal for developments. It accepts concentrated flow. Both of these underground systems use a wet vault (or water quality inlet, see TC7) as the pretreatment device. The fourth concept is (Figure 6D) is an insert placed in existing catch basins. It should only be used where maintenance staff are available to check the filter frequently and where local flooding will not occur if the filter clogs.

Determining the volume of the pretreatment unit

To size the pretreatment basin refer to the sizing methods for extended detention (TC5). With the sand filter the pretreatment basin need not be as efficient as a full size system. The pretreatment system, however, should be large enough to provide a removal efficiency that avoids rapid clogging of the filter. As yet, there is no clear answer on this question. For now it is suggested that the volume of a wet vault be such as to achieve a removal efficiency of 50 to 60%.

The volume of an pretreatment unit can be decreased by reducing the drawdown time, which results in a lower but acceptable removal efficiency. The facility volume can be determined from TC5 Extended Detention using a drawdown time of 24 hours.

TC6

Best Management Practices

1 6872

R0050177

Additional Information — Media Filtration

<u>Determining the surface area of the filter</u>

The following equation is derived from Austin (1988) for a maximum (full pretreatment basin) filtration time of 24 hours:

$$\text{Filter area (ft}^2\text{)} = 3630 S_u AH/K(D+H) \quad (1)$$

where:
- S_u = unit storage (inches-acre) from Appendix D
- A = area in acres draining to facility
- H = depth (ft) of the sand filter
- D = average water depth (ft) over the filter taken to be one-half the difference between the top of the filter and the maximum water surface elevation
- K = filter coefficient recommended as 3.5 (Austin)

Equation (1) is appropriate for the filter media size recommended by the City of Austin, diameter of 0.02 to 0.04 inches. The filter area must be increased if a smaller media is used (see Austin, Texas (1988)).

Configuring a surface sand filter (City of Austin concept)

Additional design criteria for the settling basin (Austin, 1988):

- For the outlet use a perforated riser pipe, as described in TC5, Extended Detention
- Size the outlet orifice for a 24 hour drawdown
- Energy dissipator at the inlet to the settling basin
- Trash rack at outlets to the filter
- Vegetate slopes to the extent possible (see Vegetated Biofilters)
- Access ramp (4:1 or less) for maintenance vehicles
- One foot of freeboard
- Length to width ratio of at least 3:1 and preferably 5:1
- Sediment trap at inlet to reduce resuspension. One concept is shown in Figure 6E.

Additional design criteria for the filter:

- Use a flow spreader (Figure 6A).
- Use either of two alternative sand bed designs (Figure 6F).
- Use clean sand 0.02 to 0.04 inch diameter.
- Some have placed geofabric on sand surface to facilitate maintenance.
- Underdrains (Figure 6A).
  - Schedule 40 PVC.
  - 4 inch diameter.
  - 3/8 inch perforations placed around the pipe, with 6 inch space between each perforation cluster.
  - maximum 10 foot spacing between laterals.
  - minimum grade of 1/8" per foot.

<u>Configuring the linear filter</u>

Take the volume for the pretreatment unit and the filter area identified above and configure into a structure similar to that shown in Figure 6B. The structural design in Figure 6B assumes traffic loads over the filter. The structure can be less robust if it is located along the edge of the pavement, away from traffic. Other recommendations (Shaver, 1991):

TC6

Best Management Practices

VOL 12

1 5873

VOL 12

Additional Information — Media Filtration

- Depth of sand 18"
- Diameter of the outlet pipe should be 6" or less: use multiple outlets if necessary

The filter must be positioned relative to the pavement in a manner that evenly distributes the flow as it enters the sedimentation chamber. Pavement design and construction is therefore critical.

Configuring the wet vault filter
Similarly the volume of the wet vault and filter area are configured into a rectangular unit similar to that shown in Figure 6C. Other considerations for the wet vault include:

- A length to width ratio of at least 3:1 to minimize short-circuiting
- Baffles to reduce entrance velocities and to retain floatables
- Access ports to facilitate maintenance
- Depth of the wet pool of at least 3 feet but not more than 10 feet

Catch basin insert
The catch basin insert filter may be ideal for industrial sites as it can be placed in existing catch basins, and therefore may avoid the need for an "end-of-pipe" facility. The system is illustrated in Figure 6D. It consists of a series of trays. The top tray is a sediment trap. Filter material is placed in the lower trays. Of several materials examined, the most suitable appears to be household fiberglass insulation. Limited tests indicate over 90% removal of metals and oil (McPherson, 1992). As the insert requires frequent attention it should only be used where a maintenance person is located on-site. The insert has a bypass along one side should the filter material clog and is hydraulically designed so as to not compromise the primary purpose of a catch basin, to get storm water into the drain system. The concept shown in Figure 6D is proprietary (Enviro-drain, 1992).

Maintenance
Inspect semiannually, and after major storms. Sediment should be removed from the settling basin when 4 inches accumulates and from the filter when 1/2 inch accumulates, or when there is still water in the basin or over the filter 40 hours after the storm. Remove floatables. Experience in Austin indicates the filter surface must be cleaned about twice each year by raking off the dried sediment. Failure to clean the filter regularly may result in the need to replace the entire media because of penetration of fines into the filter. It is more cost effective over the long term to clean the filter regularly as recommended. If there are open space areas in the tributary that are erosive or if construction is occurring, more frequent cleaning will be necessary. It may be necessary to replace the filter media after construction activity has ceased and the soils are stabilized.

Consult Austin (1988), Truong (1989), and Shaver (1991) for additional design and maintenance criteria.

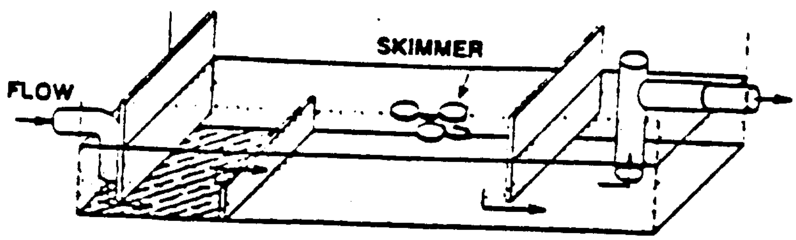
BMP: OIL/WATER SEPARATORS AND WATER QUALITY INLETS



DESCRIPTION

Oil/water separators are designed to remove one specific group of contaminants: petroleum compounds and grease. However, separators will also remove floatable debris and settleable solids. Two general types of oil/water separators are used: conventional gravity separator and the coalescing plate interceptor (CPI).

EXPERIENCE IN CALIFORNIA

Oil/water separators are in use throughout California at industrial sites. Oil/water separators are used at all bulk petroleum storage and refinery facilities. A few jurisdictions require new commercial developments to install separators under certain situations that are environmentally sensitive.

SELECTION CRITERIA

Applicable to situations where the concentration of oil and grease related compounds will be abnormally high and source control cannot provide effective control. The general types of businesses where this situation is likely are truck, car, and equipment maintenance and washing businesses, as well as a business that performs maintenance on its own equipment and vehicles. Public facilities where separators may be required include marine ports, airfields, fleet vehicle maintenance and washing, facilities, and mass transit park-and-ride lots. Conventional separators are capable of removing oil droplets with diameters equal to or greater than 150 microns. A CPI separator should be used if smaller droplets must be removed.

LIMITATIONS

- Little data on oil characteristics in storm water leads to considerable uncertainty about performance.
- Air quality permit (conditional authorization) permit-by-rule from DTSC may be required.

DESIGN AND SIZING CONSIDERATIONS

- Sizing related to anticipated influent oil concentration, water temperature and velocity, and the effluent goal. To maintain reasonable separator size, it should be designed to bypass flows in excess of first flush.

CONSTRUCTION/INSPECTION CONSIDERATIONS

- None identified.

MAINTENANCE REQUIREMENTS

- Clean frequently of accumulated oil, grease, and floating debris.

COST CONSIDERATIONS

- Coalescing plate material is costly but requires less space than the conventional separator.

Additional Information — Oil/Water Separators and Water Quality Inlets

General Information

Oil/water separators will be needed for a few types of industrial sites where activities result in abnormal amounts of petroleum products lost to exposed pavement, either by accidental small spills or normal dripping from the vehicle undercarriage. This will most likely be related to vehicle and mobile equipment maintenance activities. Separators may also be advisable where an area is heavily used by mobile equipment such as loading wharfs at marine ports. Limited data indicates oil/water separators can reduce the oil/grease concentration below 10 mg/l (Lettenmaier, et al. 1985).

Wet ponds, constructed wetlands, and biofilters will remove petroleum products but their reliability is uncertain where high concentrations of petroleum products may occur frequently. Also, BMPs that rely on vegetation may be damaged or become unsightly if high concentrations of oil and grease occur frequently.

The sizing of separators is based upon the rise rate velocity of oil droplet and rate of runoff. However, with the exception of storm water from oil refineries there are no data describing the characteristics of petroleum products in urban storm water that are relevant to design: either oil density and droplet size to calculate rise rate or direct measurement of rise rates. Further, it is known (Silverman, 1982) that a significant percentage of the petroleum products are attached to the fine suspended solids and therefore are removed by settling not flotation. Consequently, the performance of oil/water separators is uncertain.

The basic configurations of the two types of separators are illustrated in Figure 7A. With small installations, a conventional gravity separator has the general appearance of a septic tank, but is much longer in relationship to its width. Larger facilities have the appearance of a municipal wastewater primary sedimentation tank. The CPI separator contains closely spaced plates which enhances the removal efficiency. In effect, to obtain the same effluent quality a CPI separator requires considerably less space than a conventional separator. The angle of the plates to the horizontal ranges from 0° (horizontal) to 60°, although 45° to 60° is the most common. The perpendicular distance between the plates typically ranges from 0.75 to 1 inch. The storm water will either flow across or down through the plates, depending on the plate configuration.

A related system is the water quality inlet illustrated in Figure 7B. It is essentially a conventional gravity separator but without the appropriate geometric configuration (see Design discussion below). Another name for this systems is a wet vault. Water quality inlets have been found to be generally ineffective (Shepp, et al., 1992) because the recommended size (200 to 400 ft^3/acre of tributary) is too small. To be effective, a water quality inlet must have the surface area and volume that is similar to that of conventional separators. They may exhibit odor problems during the summer because of the lack of bacterial degradation of accumulated organic matter and the lack of reaeration of the wet pool. Facilities in Washington D.C. have been observed to have odor but, it has been noticeable only when the system is opened for inspection.

Design of Conventional Separators

The sizing of a separator is based upon the calculation of the rise rate of the oil droplets using the following equation (modified from API, 1990):

$$V_p = 1.79\,(d_p - d_c)\,d^2 \times 10^{-8}/a \qquad (1)$$

where:
- V_p = rise rate (ft/second)
- a = absolute viscosity of the water (poises)
- d_p = density of the oil (gm/cc)
- d_c = density of the water (gm/cc)
- d = diameter of the droplet to be removed (microns)

Additional Information — Oil/Water Separators and Water Quality Inlets

A water temperature must be assumed to select the appropriate values for water density and viscosity from Table 7A. The engineer should use the expected temperature of the storm water during the December-January period. There are no data on the density of petroleum products in urban storm water but it can be expected to be between 0.85 and 0.95. To select the droplet diameter the engineer must identify an efficiency goal based on an understanding of the distribution of droplet sizes in storm water. However, there is no information on the size distribution of oil droplets in urban storm water. Figure 7C is a size and volume distribution for storm water from a petroleum products storage facility (Brown et al., undated). The engineer must also select a design influent concentration, which carries considerable uncertainty because it will vary widely within and between storms.

To illustrate Equation 1: if the effluent goal is 10 mg/l and the design influent concentration is 50 mg/l, a removal efficiency of 80% is required. From Figure 7C: this efficiency can be achieved by removing all droplets with diameters 90 microns or larger. Using a water temperature of 10°C gives a water density of 0.998. Using an oil density of 0.898, the rise rate for a 90 micron droplet is 0.0011 feet per second.

It is generally believed that conventional separators are not effective at removing droplets smaller than of 150 microns (API, 1990). Theoretically, a conventional separator can be sized to remove a smaller droplet but the facility may be so large as to make the CPI separator more cost-effective.

Sizing conventional separator (modified from API, 1990).

$$D = (Q/2V)^{1/2} \qquad (2)$$

where: D = depth, which should be between 3 and 8 feet
Q = design flow rate (cfs)
V = allowable horizontal velocity which is equal to 15 times the design oil rise rate but not greater than 0.05 feet per second

If the depth exceeds 8 feet, design parallel units dividing the design flow rate by the number of units needed to reach the maximum recommended depth of 8 feet. Equation (2) is simplified from equations in API (1990) based on a recommended width to depth ratio of 2. The constant in Equation (2) can be changed accordingly if a different ratio is assumed. Some engineers may wish to increase the facility size to account for flow turbulence. See API (1990) for the design procedure.

Then:

- Calculate length, $L = VD/V_p$
- Compute width, $W = Q/(VD)$. This should be 2 to 3 times the depth, but not to exceed 20 feet
- Baffle height to depth ratio of 0.85 for top baffles and 0.15 for bottom baffles
- Locate the distribution baffle at 0.10L from the entrance
- Add one foot for freeboard
- Install a bypass for flows in excess of the design flow

Determining the design flow, Q, requires identification of the design storm. The separator is expected to operate effectively at all flow rates equal to or less than the peak runoff rate of the design storm. The design storm need not be an extreme event, as is typically used in the sizing of flood control facilities. If sized to handle a storm frequency between the 3-month to 1-year event, the facility will effectively treat the vast majority of storm water that occurs over time. All events equal to or less than the 6-month event represents about 90% of the precipitation over time; designing for a 2-year

TC7

VOL 12 1 5883

R0050188

event only increases the amount of runoff treated by about 5% (increase from 90% to 95% of rainfall treated). For the design storm selected, calculate the peak runoff rate using the rational method.

Application of the Conventional Oil/Water Separator
Assume that a conventional oil/water separator is to be used to treat runoff from a 1/2 acre parking lot. Assume further it is to be sized to treat runoff from a rainfall rate of 0.50 inches/hr (which translates to a runoff rate of 0.50 cfs/acre when the area is 100 percent impervious.

Using the example above, the computed Vp is 0.0011 ft/sec. Using Equation 2, V =15 x 0.0011= 0.0165 ft/sec which is less than 0.05 ft/sec; thus,

D = (Q/2V)0.05 = (1/2 x 0.05/(2 x 0.0165)) x 0.05
D = 3.8 ft.

L = VD/Vp = 0.0165 x 3.8/0.0011
L = 57 ft.

W = Q/(VD) = 0.25/(0.0165 x 3.8)
W = 4.0 ft, since W is less than 2 x D, increase width to W = 3.8 x 2 = 7.6 ft.

Thus, a conventional oil/water separator sized to capture runoff from a 0.5 in/hr rainfall on a 1/2 acre parking lot would be:

D = 3.8 ft
W = 7.6 ft
L = 57 ft

Sizing CPI separator
Manufacturers can provide packaged separator units for flows up to several cubic feet per second. For larger flows, the engineer must size the plate pack and design the vault. Given the great variability of separator technology among manufacturers with respect to plate size, spacing, and inclination, it is recommended that the design engineer consult vendors for a plate package that will meet the engineer's criteria. Manufacturer's typically identify the capacity of various standard units. However, the engineer's design criteria must be comparable to that used by the manufacturer in rating its units.

The engineer can size the facility using the following procedure. First identify the expected plate angle, H (as degrees), and calculate the total plate area required, A(ft^2).

$$A = Q/V_p \text{Cosine} H \qquad (3)$$

CPI separators are not 100% hydraulically efficient, ranging from 0.35 to 0.95 depending on the plate design (Aquatreod, undated). If the engineer wishes to incorporate this factor, divide the result from Equation 3 by the selected efficiency.

- Select spacing, S, between the plates, usually 0.75 to 1.5 inch.
- Identify reasonable plate width, W, and length, L.
- Number of plates, N = A/WL.
- Calculate plate volume, P_v(ft^3).

TC7

Best Management Practices

VOL 12 1 5884

R0050189

P_V = (SS/12 + LCosineH)(WLSineH)   (4)

- Add a foot beneath the plates for sediment storage.
- Add 6" to 12" above the plates for water clearance so that the oil accumulates above the plates.
- Add one foot for freeboard.
- Add a forebay for floatables and distribution of flow if more than one plate unit is needed.
- Add after bay for collection of the effluent from the plate pack area.
- For larger units include device to remove and store oil from the water surface.

Horizontal plates require the least plate volume to achieve a particular removal efficiency. However, settleable solids will accumulate on the plates complicating maintenance procedures. The plates may be damaged by the weight when removed for cleaning. The plates should be placed at an angle of 45° to 60° so that settleable solids slide to the facility bottom. Experience shows that even with slanted plates some solids will "stick" to the plates because of the oil and grease. Placing the plates closer together reduces the plate volume. However, if debris is expected such as twigs, plastics, and paper, select a larger plate separation distance. Or install ahead of the plates a trash rack and/or screens with a diameter somewhat smaller than the plate spacing.

Recognizing that an oil/water separator also removes settleable solids, it can also be considered a wet vault (TC2). The engineer can use Figure 2B (See TC2) to estimate the efficiency of both the conventional and CPI separators. As Figure 2B does not include the effect of plate technology, a CPI separator should perform considerably better than indicated in Figure 2B for the same V_b/V_r ratio.

See API (1990) for further design concepts for both the conventional and CPI separators.

<u>Maintenance</u>

Check monthly during the wet season and clean several times a year. Always clean in October before the start of the wet season. Properly dispose the oil.

Subject: Deletion of Coast GM Salvage from the Port of Long Beach Non-Point Source Program

Reference: NOI #4B10S003628

Dear Mr. Swamikannu:

As you know, the Port of Long Beach elected to hold the Storm Water NPDES Permit to cover its tenants under the NPDES Program. In order to be covered under the program, tenants must cooperate with Port requirements, most importantly by preparing, submitting, and updating a Storm Water Pollution Prevention Plan. Tenant cooperation is essential to ensure that the Port's program complies with the EPA's NPDES requirements for participating in the NPDES Program.

Coast GM Salvage, however, has not complied with the Port's requirements. Accordingly, please update your files to reflect that Coast GM Salvage has not elected to be included under the Port of Long Beach Storm Water NPDES Permit Program.

If you have any further questions regarding this matter, please contact Stacey Crouch at (310) 590-4160.

Sincerely,

Geraldine Knatz, Ph.D.
Director of Planning

SUBJECT: Annual Site Inspections

Thank you for participating in the Non-Point Source Pollution Control Program and doing your part to comply with the Federal and State's Clean Water Act. As in the past year, the Port of Long Beach will continue to coordinate facility compliance with EPA Non-Point Source Storm Water Pollution Prevention Plan (SWPPP) requirements. Your continued cooperation is essential to the success of this very important program.

This spring, Planning Division staff will conduct its 1994 Storm Water Pollution Prevention Plan site inspections of the participating facilities. As in the past year, Planning staff encourages continued adherence to your approved facility SWPPP and the use of Best Management Practices (BMP's). In addition, we urge you to review and implement additional BMP's as appropriate. If there are modifications to your facility, please incorporate those changes into your facility's SWPPP and submit the revised SWPPP to the Planning Division for approval.

Planning staff will be in contact with your facility to arrange a date to conduct its 1994 site inspection. If you have any further questions, please contact Stacey Crouch at (310) 590-4160. Thank you for your continued participation in the SWPPP program.

Sincerely,

Geraldine Knatz

SUBJECT: Annual Site Inspections

As a participant in the EPA's Non-Point Source Program, it is a vital concern of the Port of Long Beach to be continually striving to improve pollution control measures within the Harbor District. The recent lawsuits over alleged violations of the Non-Point Source Program's regulations make it more important than ever that the Port of Long Beach enforce both strict adherence by its tenants to their approved SWPPPs and the use of Best Management Practices.

Starting in June, 1994, Planning Division staff will begin to conduct the 1994 site inspections required by our Storm Water Pollution Prevention Plan. Accordingly, in the next few weeks Planning staff will contact you to arrange a date for the 1994 site inspection.

If you have any further questions, please contact Stacey Crouch at (310) 590-4160. Thank you for your continued participation in the SWPPP program.

Sincerely,

Robert Kanter

Dear Mr. Wyant:

On June 30, 1994, the Planning Division of the Port of Long Beach conducted its annual site inspection of your facility. Since there have not been any significant changes to your facility, the current SWPPP is still in effect.

Please be advised that if there are changes to your facility in the future, a revised SWPPP must be submitted to the Planning Division of the Port of Long Beach for approval. In the meantime, please remember that facility cleaning and good housekeeping practices are effective tools in keeping contaminants from reaching the storm drain system.

If you have any further comments or questions, please contact Stacey Crouch at (310) 590-4160.

Sincerely,

LOS ANGELES COUNTY DRAINAGE AREA
REVIEW FEASIBILITY STUDY

SECTION ONE: EXECUTIVE SUMMARY

This is an interim report for the Los Angeles County Drainage Area (LACDA) Review studies conducted under authorization provided in the House Resolution dated 11 June 1969. It summarizes the findings of an extensive feasibility investigation of problems and opportunities related to flood control, water conservation, recreation, transportation, and environmental enhancement in the LACDA Mainstem System (the Los Angeles and San Gabriel Rivers, the Rio Hondo, and the Tujunga Wash) as depicted in Figure 1. The major findings of this investigation are:

1) While the LACDA Mainstem System of flood control reservoirs and channel improvements has provided effective protection to the urban communities of the basin for over 40 years, there are inadequacies in the system. Some reaches of the mainstem system provide only 25- to 50-year protection. In the lower Rio Hondo and Los Angeles River reaches protected by levees, there is a threat that floods exceeding the 25- to 40-year event could overtop the existing levees and cause these levees to fail with catastrophic results. The 500-year flood plain covers approximately 200 square miles (320,000 structures), mostly in the lower reaches of the basin; damages in this flood plain would total approximately $5.4 billion. The 100-year flood plain covers approximately 82 square miles; damages from the 100-year flood would be $2.3 billion.

2) The system inadequacies are the result of different factors. The various design storms formulated for the individual sections of the system over 50 years ago were based on a short period of record; based on a longer period of record, it now appears that the overall system was only designed to control a flood resulting from a storm with a 50-year recurrence interval.

Also, extensive urban development in the basin, combined with a comprehensive system of storm drains to carry local runoff into the mainstem system, has greatly accelerated runoff, particularly in the lower river basin areas. Thus peak flows have increased dramatically compared to those originally predicted for these reaches of the system.

3) Based on a thorough analysis of measures to correct the system inadequacies, it was concluded that only improvements to the lower basin channels themselves would be cost-beneficial solutions to the flooding problems identified. Other alternatives were found to be either excessive in cost (new channels, diversion alternatives, new reservoirs, modifying existing reservoirs) or ineffective in reducing peak flows through the critical project reaches in the lower basin (new reservoirs, non-structural measures, modifying existing reservoirs, modifying channel bridges, re-regulation of reservoirs). Modifications in upper basin reaches were found to have very low benefit-to-cost ratios, in part because the channels in most reaches of the upper basin provide nearly 100-year levels of protection; in areas with lower levels of protection, the overflow areas are limited and damages are not extensive. No economically justified alternatives were identified for increasing the level of protection in upper basin reaches.

   Transfer of Whittier Narrows Dam releases from the Rio Hondo to the San Gabriel River was determined to be unjustified because this would require modifications to the San Gabriel River channel greater in cost than those contemplated for the Los Angeles River and Rio Hondo channels while having larger environmental impacts and still requiring improvements to the Los Angeles River. Modifying flood control releases to involve two distinct channels was not economically justified.

4) Given the nature and extent of the flooding problem identified in this study, it was determined that the focus of study should be on flood control improvements. Water conservation, recreation, transportation, and/or environmental enhancement opportunities would be studied within the

framework of the flood control improvements being investigated. This decision was made following an initial review of potential opportunities to pursue these objectives; this review indicated that opportunities were limited or constrained by the flood control solution and were therefore dependent on the nature of the flood control solution identified.

5) The plan selected to improve available flood protection in the lower Los Angeles Basin requires modification of the Rio Hondo from Whittier Narrows Dam to the Los Angeles River and continuing down the Los Angeles River to the Pacific Ocean. The modifications are as follows: (a) Raising the effective channel height by building parapet walls on 21 miles of existing levees; (b) raising or modifying 27 bridges to accommodate the parapet walls; (c) widening and converting to rectangular cross-section 1.5 miles of channel below the confluence with the Rio Hondo; (d) armoring the land side of the levees in four locations and (e) applying a concrete overlay in reaches with an existing rough grouted stone channel surface.

6) The optimum level of protection for the proposed plan was established based on National Economic Development (NED) criteria. The need to avoid raising the Artesia/Long Beach Freeway overcrossing was also considered in defining the NED level of protection. Modifications of channel walls may be made to convey the 133-year design flows for the lower reach of the Los Angeles River without requiring this overcrossing to be altered, thereby avoiding the expense and social impacts of freeway bridge modification. The ability of flood flow breakouts to spread over large areas makes the minimum level of protection provided in the proposed plan also the overall level of protection. The NED Plan provides between 100 and 133-year level of protection for the lower LACDA basin.

7) Cost and benefit estimates indicate the NED Plan would provide $60.2 million in annual flood damage reduction benefits at an annualized cost of $46.5 million. Net annual NED benefits from the plan are $13.7 million, and the project benefit-to-cost ratio is 1.3 to 1. The Federal share of the $337.4 million first costs would be $168.7 million (50 percent of total first costs); the local sponsor, the Los Angeles County Flood Control District, would bear the remaining cost of $168.7 million (50 percent of total first costs).

Based on these findings, the District Engineer recommends that improvements to the Los Angeles River and Rio Hondo channels in the lower reaches of the LACDA basin be constructed substantially in accordance with the plan outlined in this report.

LOS ANGELES COUNTY DRAINAGE AREA
REVIEW FEASIBILITY STUDY

SECTION TWO: THE STUDY AND FEASIBILITY REPORT

A. STUDY AUTHORITY

This study was conducted in response to local concerns regarding the completeness and adequacy of flood control within the Los Angeles County Drainage Area (LACDA) and in response to local interest in the potential to increase water conservation, transportation, and recreation resources within LACDA. These interests led to the following congressional resolution:

House of Representatives Resolution, approved 11 June 1969, reading in part:

"Resolved by the Committee on Public Works of the House of Representatives, United States, that in accordance with Public Law 639, Eighty-seventh Congress, the Secretary of the Army and the Secretary of Agriculture are directed to make a joint investigation and survey in accordance with their existing authorities of the San Gabriel River Basin, California, and to prepare a joint report on such investigation and survey setting forth their recommendations for the installation of the works of improvement needed for utilization, and disposal of water, and for flood control and allied purposes."

B. PURPOSE AND SCOPE OF STUDY

This combined Feasibility Report and Environmental Impact Statement presents the study findings associated with the Los Angeles County Drainage Area (LACDA) Review Study, Los Angeles County, California. Its intent is to review the adequacy of flood control along the mainstem systems of the Los Angeles and San Gabriel rivers, the Rio Hondo, and Tujunga Wash.

The focus of this study was originally quite broad, including investigations throughout the LACDA basin for flood control, water conservation, recreation, transportation, and environmental problems and opportunities. During the feasibility study phase, the magnitude of the flooding problem was recognized, and a greater effort was devoted to developing a solution to this problem. The other study purposes had shown only limited opportunities, and their implementation may have conflicted with potential flood control solutions. In order to accomplish this study, it was decided that other study purposes would be incorporated within the framework of the flood control solution if at all possible. The flood control solution ultimately focused on the three mainstem river systems for the following reasons:

1. **Previous Interim Reports addressed major issues.** Two previous interim reports have addressed problems and opportunities considered critical in areas outside of the mainstem system (Baldwin Hills and Ballona Creek). An additional study of Hansen Dam was also completed. Thus, the primary focus of this interim is appropriately on the mainstem. The previously completed interims are as follows.

   Interim 1: Ballona Creek and Tributaries. This study investigated possible inadequacies in flood protection on Ballona Creek and tributaries due to increases in runoff brought about by urbanization and storm drain installation. No economically justified plan for Federal implementation could be found. However, two bridges were identified on Ballona Creek that constricted flow and caused flooding.

   Interim 2: Baldwin Hills Landslide Study. This study addressed landslide, mudslide and related problems caused by the storms of 1978 and 1980 in the Baldwin Hills area of Los Angeles. No economically justified plan of improvement could be found.

Interim 3: Hansen Dam. This study investigated sedimentation problems and incidental water conservation and recreation opportunities. The study found that the ongoing excavation of reservoir material by sand and gravel contractors continues to maintain project capacity and provides an ongoing solution to sedimentation problems at this facility. Additional recreation was not found to be economically justified at this site. Because Hansen Dam is an integral part of the LACDA system, the report deferred analysis of flood control and water conservation to this mainstem report.

2. **Levels of protection on many tributaries were adequate.** A general analysis of numerous tributaries to the mainstem system concluded that levels of protection on these tributaries were adequate (100-year or higher). This conclusion was based on detailed analysis of data from stream gauges in the watershed. Compton Creek was found to provide slightly less than 100-year protection. While no analysis for Compton Creek was proposed, any relief the mainstem study could provide would be evaluated, and certainly, any impacts involved in a mainstem solution would be mitigated as part of the overall solution. Further study of Compton Creek may be undertaken at a later date. The effect of this analysis of tributaries was to reduce the scope of this study interim.

   In 1985, the Sierra Madre channel in eastern Los Angeles County was evaluated, but no improvements were recommended because the city council and local residents were generally opposed to alterations which would affect structures built up to the existing channel wall system. Los Angeles County subsequently requested that further analysis of the channel be suspended.

3. **Work on smaller, non-tributary drainages was not justified.** A post-1969 flood review of many small streams draining directly into the Pacific indicated that flood control improvements would be inappropriate for one or more of the following reasons: (a) the level of development within the flood plain was too sparse to justify a project; (b) local residents were opposed to alteration of the channel; (c) development was planned for the future, but existing levels were inadequate to support a project; (d) justification of a project would depend on

VOL 12 1 6923

land enhancement benefits; (e) the overflow was contained within a well-entrenched channel; and/or (f) the scope of the problem was limited and its solution was appropriate for local action. Of 39 local streams surveyed, including some in the upper watershed areas for the LACDA mainstem system, only two were identified for which further study would be necessary to determine whether there was potential for a justifiable project: Topanga Canyon and Trifuno Creek.

In the absence of significant new development of the 100-year flood plain in many of these small watersheds, no project appeared to be feasible in 1969; the advent of flood plain management regulations several years later placed restrictions on flood plain development, which limited flood-prone development in many of these small streams. Increased public opposition to flood control measures such as channel improvements and dams also contributed to the conclusion that these smaller streams would not be appropriate for Federal action. Topanga Canyon and Trifuno Creek were eliminated from this study on the basis of these considerations.

4. **Problems identified by the local sponsor were studied and issues resolved.** In 1975, the Los Angeles County Flood Control District (LACFCD) identified six county priorities in addition to mainstem rivers and related facilities. Ballona Creek was one of these six potential projects. The other five (Arroyo Seco near Pasadena, Stone Canyon in West Los Angeles, Laguna Dominguez Channel near Dominguez Hills, Los Cerritos Channel near Long Beach, and Bee Canyon in the Santa Susana Mountains above the San Fernando Valley) were evaluated for flooding problems. Arroyo Seco was found to provide protection above the 100-year level. Devil's Gate Dam on this arroyo was found to be unsuitable for modification for system-wide flood control purposes. The Stone Canyon channel was found to provide 100-year protection. Laguna Dominguez Channel was subsequently studied by the Los Angeles County Department of Public Works and found to be adequate in all but the uppermost reach. The uppermost reach has been improved as a result of the Century Freeway construction project. Los Cerritos channel was found to provide near 100-year protection and thus became

a low priority. Outflow from the Bee Canyon watershed flows past the upper Van Norman Reservoir. Although there was concern that flood flows could contaminate the water supply system, this watershed was found to have an insignificant local flooding impact or impact within the overall system and, therefore, is a low study priority.

5. **The flood threat is greatest on the mainstem system.** Finally, the study was focused on the mainstem because subsequent to the floods of 1969, it was believed that the existing mainstem system might have insufficient capacity in some reaches. The February 16, 1980 flood, about a 40-year event, caused near-capacity channel flows in the lower Los Angeles River that deposited debris on the top of levees (see Figure 2) which had previously been thought to have 100+ year protection. The mainstem system carries substantially greater flows than the tributary system and crosses the areas of greatest urban density. Review of the mainstem system thus became a high priority for the entire basin.

The review of mainstem problems and opportunities included an analysis of the entire mainstem system from the upstream flood control reservoirs of the mainstem rivers to the mouth of the two river systems (Los Angeles-Rio Hondo and San Gabriel). Therefore, this report considers the following watercourses (Figure 1):

a) The Los Angeles River, from Sepulveda Dam to the Pacific Ocean;
b) The San Gabriel River, from Santa Fe Dam to the Pacific Ocean;
c) Tujunga Wash, from Hansen Dam to the Los Angeles River; and
d) Rio Hondo, from Whittier Narrows Dam to the Los Angeles River.

The report considers alternative solutions to the water and related land use problems on these watercourses and recommends a feasible solution to the problems for implementation. Consideration was given to economic, environmental, and social needs of the area.

1 6926

C. STUDY PARTICIPATION AND COORDINATION

The Corps of Engineers, Los Angeles District - which will be referred to in this document as the Corps - has been responsible for managing the LACDA Review Study; for plan formulation and evaluation; for coordinating the flood control planning process with other local, state, and Federal agencies and the public; and for report preparation.

The Los Angeles County Flood Control District (LACFCD), an element of the Los Angeles County Department of Public Works (LACDPW), is the local sponsor of the study. The County Department of Public Works consists of the former County Flood Control District, the former County Engineer, and the former County Department of Roads. The unification of these functions occurred in 1985. For purposes of this report, the local sponsor will be referred to as Los Angeles County, or simply the County. Throughout the study, and especially during problem analysis and plan formulation, Los Angeles County assisted the Corps in identifying areas which should receive priority in the study during plan formulation and in evaluating the acceptability of flood control measures.

There has been ongoing coordination with the U.S. Fish and Wildlife Service, who also cooperated in the investigation. They provided the Corps with a Planning Aid Letter and prepared the Coordination Act Report. Because no reservoir re-regulation was proposed, there was no need for a Habitat-Based Evaluation of the proposed improvements. Nearly all of the viable habitat in the flood control system is in the reservoir area behind the dams, since a majority of the channels in the LA River system are concrete lined from dam outlet to the ocean. No improvements are proposed for areas in which significant habitat for wildlife exists.

The general public has also been kept informed of the study, and public participation has been an important goal throughout this study. Public dissemination of information has been achieved through press releases, direct-mail brochures and newsletters, and public workshops and meetings. At these meetings, the public has had an opportunity to participate in study scoping, problem identification, plan formulation, and alternative evaluation phases of the study.

A complete list of agencies and representatives with which coordination has taken place may be found in Section 8 of the Environmental Impact Statement (EIS).

E. THE STUDY PROCESS AND THE CONTENT OF THIS REPORT

The Study Process

This feasibility study has been conducted in accordance with Corps Planning Regulations and Guidance (summarized in the Planning Guidance Notebook). It has been an iterative process; that is, there have been several phases of problem analysis/plan formulation and plan evaluation. The purpose of this iterative process has been to ensure that all problems have been given full consideration and all alternatives have been identified and evaluated.

The general flow of a feasibility study is to begin with the broadest possible scope within the constraints imposed by the authorization and Corps regulations and slowly narrow the scope by eliminating alternatives, using data developed during the study. Thus, an initial step is to formulate a very broad range of alternative measures which can be considered for solving problems. The general feasibility of these measures is evaluated, and those measures that are clearly infeasible or ineffective are eliminated after an initial review. A smaller number of measures are then evaluated in more detail. After the remaining measures have been evaluated, the scope of study shifts to evaluation of combinations of these measures (alternatives). Alternatives are evaluated in detail in terms of their completeness, acceptability, efficiency (cost-effectiveness), and environmental and socio-economic impacts. As the number of alternatives is narrowed, the level of detail of study increases. This iterative process is reflected in the plan formulation section of this report.

Feasibility Report Contents

This report can be viewed as containing two parts. Part I is the main report and the environmental impact statement (EIS). Part II consists of the technical documentation reports, as listed below. Note that only Part I is being circulated for public comment. The technical reports are too voluminous and generally too technical to justify their general circulation. They are available for review at the Los Angeles District Office of the Corps of Engineers, 300 N. Los Angeles Street, Los Angeles, California, 90053. The appropriate telephone number is (213) 894-5461. For reference, the technical reports are:

A) **Hydrology**: This is a detailed discussion of storm history, predicted storm frequency and intensity, rainfall-runoff analysis combined with reservoir operations, and downstream floodrouting to define the resulting flood flow frequencies in the LACDA basin.

B) **Hydraulics**: This technical report provides an analysis of the projected overflows resulting from various-sized floods. It also provides an analysis of the existing channel capacities and the design analysis of the various alternatives.

C) **Design**: This technical report describes the various elements of the recommended design, and provides detailed materials and construction costs.

D) **Recreation**: This technical report identifies all existing recreation on the mainstem.

E) **Geotechnical**: This technical report describes the general site conditions and provides design and construction material considerations.

F) **Real Estate**: This technical report identifies real estate requirements and associated costs.

G) **Economics**: This technical report analyzes damages associated with the existing (baseline) condition and compares the costs and benefits of the alternatives. Support for the selection of the NED Plan is documented.

The main report summarizes the results of the feasibility study in a nontechnical manner, and presents the material on the NED Plan somewhat more technically. Following the Commander's recommendations at the end of the main report, the environmental impact statement describes the nature and scope of the environmental impacts of the NED Plan and evaluates the other alternative given consideration during the study process.

F. STUDY AREA DESCRIPTION

Location and Extent of Study Area

Los Angeles County, located in the South Coastal Basin of the Pacific slope, has varied terrain consisting of precipitous mountains, low-lying foothills, valleys, and coastal plains. A vast majority of urban development is found on flat alluvial plains and uplifted terraces which are surrounded by various mountain ranges. The area bounded by the Santa Susana and San Gabriel Mountains on the north, and on the east and southeast by the Chino, San Jose, and Puente Hills, is the area under study that is usually referred to as the Los Angeles County Drainage Area (LACDA) basin. See Figure 1 for a map of the LACDA basin.

Drainage Basin Description

The LACDA basin feeding the mainstem system covers 1,459 square miles, a large percentage of which is urbanized flatlands and valleys crossed by three major rivers: the Los Angeles, Rio Hondo, and San Gabriel. The remaining watersheds of the LACDA basin cover approximately 300 square miles.

The Los Angeles River is formed by the junction of the Calabasas and Bell Creeks in the Santa Monica Mountains. From the junction of these two creeks, the river flows into the Sepulveda Reservoir, a Corps flood control facility with a design capacity of 22,493 acre-feet. Tujunga Wash (flowing out of Hansen Dam, capacity 25,446 acre-feet), Pacoima Wash (flowing out of Lopez Dam, capacity 441 acre-feet), Burbank-Western, and smaller creeks draining the western San Gabriel Mountains join the river as it flows easterly along the San Fernando Valley. The river bends south around the Hollywood Hills, is joined by Verdugo Wash, and then flows south through the Los Angeles Narrows and onto the broad coastal plain. The river is joined by a number of tributaries, including Sycamore Canyon, Arroyo Seco, and the Rio Hondo. The Rio Hondo carries runoff from its own watershed and also runoff from the San Gabriel Basin, as transferred through Whittier Narrows Reservoir (capacity 34,947 acre-feet). From the Rio Hondo confluence, the Los Angeles River continues south another 12 miles and discharges into San Pedro Bay at the Long Beach Harbor. The Los Angeles River drains an area of 824 square miles, which includes 132 square miles of the Rio Hondo basin.

The San Gabriel River drains the eastern San Gabriel Mountains and portions of the Chino, San Jose, and Puente Hills. The river's upstream tributaries merge above Santa Fe Dam (capacity 32,109 acre-feet). Two major tributaries, Walnut and San Jose creeks, join the river before it reaches Whittier Narrows Reservoir. The San Gabriel and Rio Hondo combine flows at this reservoir. Flood control releases from Whittier Narrows Dam are made to the Rio Hondo (also referred to as the Rio Hondo Diversion Channel), which travels southwest and connects with the Los Angeles River. On the east side of Whittier Narrows Dam, the San Gabriel River exits in a southerly direction, is joined by Coyote Creek downstream, and finally discharges into Alamitos Bay, six miles east of the mouth of the Los Angeles River. The San Gabriel River drains an area of 635 square miles.

Whittier Narrows Reservoir receives flows from both the Rio Hondo and the San Gabriel River. Under normal operating conditions, primary flood control releases are made to the Rio Hondo, which has a capacity of 36,500 ft^3/s, and only 5,000 ft^3/s is released into the San Gabriel River. The San Gabriel River is intended to receive spillway overflow from Whittier Narrows in large flood events. There are no uncontrolled spillway flows to the San Gabriel River for flood events of less than 100-year magnitude.

Study Reaches

Table 1 indicates the channel reach designations used throughout this study (see Figure 3). The reach designations are generally based on clearly definable geographic boundaries. Reaches generally begin at a reservoir or at the confluence of a major tributary; thus, a new reach may have significantly different hydraulic characteristics from the reach immediately upstream. For example, the upper Los Angeles River reach from Sepulveda Dam to Arroyo Seco confluence is an entrenched channel with an initial channel capacity of 16,900 ft^3/s. This capacity increases to 83,000 ft^3/s as tributaries join the river. At Arroyo Seco, the capacity increases to 104,000 ft^3/s to accommodate inflows from this major tributary. On the San Gabriel River, study Reach 7 begins at Imperial Highway, a major bridge crossing and a general transition point in topography for the watershed.

Climate, Precipitation, Topography, Land Use, and Runoff

It is critical to understand the climate in Southern California in order to gain an appreciation of the nature of the flood threat facing Los Angeles. Flooding is caused by the interaction of climate, topography, and development.

In general, the Los Angeles area has a mild climate characterized by warm, dry summers and cool, wet winters. Both temperature and precipitation vary considerably with elevation, topography, and distance from the Pacific Ocean: a storm producing moderate rainfall on the coast (1" during a 24-hour period) may produce very heavy rainfall in the mountains (up to 10-20" during the same 24-hour period). Precipitation characteristically occurs in the form of localized cloudbursts and general heavy rains, although snow occurs in the higher elevations. In general, the quantity of precipitation increases with elevation. Flood flows, which normally occur during the period of November through March, are characterized by high peak flows and short durations.

The physical characteristics of the drainage area serve to intensify precipitation. As storm clouds cross the basin and are forced over the mountains to the east, they lose a vast majority of their moisture content in the mountain areas. High rainfall rates, combined with the steep slopes in the upper reaches, can cause violent, debris-laden flows from local canyons. Once mountain soils are saturated, runoff is very rapid from the steep mountain slopes, creating a very fast rise in the level of rivers and streams. As these peak flows reach the flat developed plain, their velocity is reduced and sediment begins to settle out into the river bed. This can reduce channel capacity, and therefore a number of upper watershed debris basins have been constructed as a part of the LACDA system to control debris.

Rapid runoff and erosion of upper basin watershed areas is unimpeded by the sparse vegetative cover found in these areas of coarse, porous, and rocky soils. At very high altitude, well-developed forests of evergreens and oaks provide some stability to soils, and there are riparian bands along many stream courses. The remainder of the upper watershed is in chaparral and coastal sage vegetation which is susceptible to burning, particularly during dry periods in the late summer and early fall. In burned out areas, which may not have an opportunity to regrow before storms begin in late fall, high intensity rainfall runs off rapidly and causes massive erosion of the watershed, carrying mud and debris into the basin below.

Local rainfall in developed areas also runs off quickly; the greater the development, the less opportunity there is for rainfall to soak into the ground. Runoff from roofs, parking lots, and streets builds rapidly, contributing to peak flows as it runs through local drainage systems to the main streams and rivers. Combined peak flows from the mountains and from local runoff may exceed channel capacity for a period of only six hours, but in this time they can cover a substantial area with debris-laden flow.

VOL 12

Flood History

The Los Angeles River has altered its point of discharge to the ocean numerous times in the distant past. This is consistent with the alluvial nature of the L.A. basin. The most recent relocation occurred in the mammoth flood of 1862 when the mouth of the LA River moved from Ballona Creek to its present location in Long Beach Harbor. Since 1900, significantly damaging flood flows occurred in 1914, 1934, 1938, 1952, 1969, 1980 and 1983. It can clearly be seen that large floods occur only infrequently in Los Angeles, but the magnitude of their destruction is enormous. Although a flood with a 100-year or greater frequency has not occurred in the 20th century, floods of near this magnitude have occurred in the past and caused extensive damages throughout the basin.

1

The February 1938 flood is the most damaging flood of record. It caused an estimated $40 million in damages ($795 million in 1990 dollars) throughout Los Angeles County and the loss of 49 lives. A large volume of floodwater, predominately originating in the San Gabriel Mountains, caused significant flooding in the cities of Glendale and Burbank. Extreme flood flows eroded the banks of the Tujunga Wash, damaging residential and commercial structures and washing out bridges and roads.

5938

With the construction of the LACDA system, especially reservoirs and channel modifications, the magnitude and frequency of flooding in the area has been reduced. The floods of January and February 1969 were the most devastating to occur since 1938; and in some areas of the County, rainfall actually surpassed that experienced during the 1938 storm. Most notable was the channel flow on the lower half of the Los Angeles River which represented over 80% of the design capacity. However, the LACDA flood control system, which was 99% complete, protected the Los Angeles metropolitan area from what otherwise would have been unprecedented damage. Most of the damages which did occur were caused by mudflows in the foothill areas or by local storm drain inadequacies. In the entire Los Angeles County, seventy-three lives were lost, and damages amounted to $31 million; $12 million in damages were sustained in the LACDA basin ($45 million in 1990 dollars).

The LACDA system was severely tested during the flood of 1980. Channel capacities were exceeded in the upper reaches of the Los Angeles River and the levee near the City of Long Beach was very nearly overtopped. If the levee had been overtopped and actually failed due to erosion of the back side of the levee, the resultant flooding could have caused a catastrophic loss of life in addition to the economic damages to the residential, commercial, and industrial properties in the City of Long Beach.

While the existing system has prevented a total of nearly $3.6 billion in flood damages since construction, there have, nevertheless, been flood damages experienced in recent years. Estimates of damages throughout the LACDA basin from floods of January-February 1969 totaled over $12 million ($45 million in 1990 dollars). Flooding in recent years has generated damages in localized areas, and the mainstem system has been seriously tested, but it has not failed catastrophically.

History of Flood Control Improvements in Los Angeles County

Prior to 1914, little attention had been directed to the problem of flood control within the basin. The principal land use was for agriculture, and farmers more or less accepted the occasional floods. The 1914 flood caused over $10 million worth of structural damages (approximately $470 million in 1990 dollars) and captured the attention of area residents. Flood control improvements were then recognized as necessary to protect the widespread developments in the foothills and flood plain. On June 12, 1915, the Los Angeles County Flood Control District was created by an Act of the California Legislature and was given the responsibility for flood control and water conservation in the Los Angeles County area. The original flood control plan called for the construction of reservoirs within the surrounding mountains. Between 1917 and

1939, the Flood Control District constructed 14 dams in the San Gabriel Mountains, numerous debris basins at canyon mouths, and some unrelated channel improvements.

By 1930 it became apparent that the construction program was barely keeping pace with the increase of storm water runoff resulting from the rapid urbanization of Los Angeles County. The Flood Control District began to prepare a comprehensive flood control plan which would protect the urban areas. However, extensive damages and loss of life caused by the 1934 flood mandated immediate construction of additional flood control improvements. In order to meet this urgent need, Congress appropriated nearly $14 million under the Emergency Relief Act of 1935 for construction of storm drains, permanent channel improvements, and debris basins.

The Flood Control Act of June 22, 1936, redefined the mission of the Army Corps of Engineers from that of providing emergency relief to the permanent supervision of future flood control plans. This Act authorized the construction of flood control facilities on the Los Angeles and San Gabriel Rivers at a Federal cost not to exceed $70 million. Under this authorization, the Corps of Engineers submitted a project plan for control of the Los Angeles River in 1936 and a general plan for the Rio Hondo and San Gabriel River in 1938. The Corps plan outlined the construction of debris basins at the base of the foothills, permanent channel improvements, and the construction of three additional flood control basins. These reservoirs were to be placed at strategic locations where the various streams merged and their flows could be controlled and regulated. Sepulveda and Hansen Dams were planned for the San Fernando Valley, and Santa Fe Dam for the San Gabriel River.

The 1938 flood demonstrated the need for additional flood control measures. It left 49 dead and $40 million in damaged property (1938 dollars, which is equivalent to approximately $795 million 1990 dollars). The previously constructed flood control works proved beneficial by preventing the tragedy from being worse. At the same time it was recognized that the tributaries of the Los Angeles and San Gabriel Rivers would have to be included in the overall plan. Under the Flood Control Act of June 28, 1938, the Corps of Engineers prepared a revised plan calling for over $230 million of construction for the entire Los Angeles County Drainage Area. Additional works

VOL 12

1 5940

included construction of Lopez Dam on Pacoima Wash and Whittier Narrows Dam on the San Gabriel River.

The plan was approved by Congress in the Flood Control Act of August 8, 1941. It authorized construction of a comprehensive system consisting of the five major flood control basins previously mentioned; debris basins at the mouth of 31 tributary canyons; improvement of 93 miles of main channel and 147 miles of tributary channels; and reconstruction of 316 bridges on the Rio Hondo, Los Angeles, and San Gabriel Rivers.

Work on Hansen and Sepulveda basins, which began under the authorization of the three previous Flood Control Acts, was completed in 1941. Lopez Dam was completed in 1954 and regulates debris and streamflow from Pacoima Wash, a tributary of Tujunga Wash.

World War II temporarily brought a halt to the work on Santa Fe Dam, and it was finally completed in 1949. Whittier Narrows, the last of the five basins to be constructed, was completed in 1957. Construction of debris basins and permanent channel modifications, which had been progressing since 1935, was finally completed in 1970.

Existing Improvements

The LACDA project is one of the most extensive flood control systems ever built to protect a metropolitan area. It includes facilities on the Los Angeles and San Gabriel Rivers, Rio Hondo, Ballona Creek, and related tributaries (Figure 1). The system was built as a cooperative effort between the Los Angeles County Flood Control District and the Corps of Engineers. Flood control improvements to the LACDA system fall into four general categories, as follows:

1. Flood control reservoirs are designed to control and reduce streamflow so that downstream main channel capacities are not exceeded. The Corps operates four major reservoirs with a total combined capacity of over 110,000 acre-feet, and Lopez Dam with a capacity of 441 acre-feet. In

VOL 12

1594

addition, there are two Corps dams on small tributaries of the San Gabriel River system, Brea Dam (capacity 4,020 acre-feet) and Fullerton Dam (764 acre-feet). These facilities ultimately drain into the San Gabriel River system but are located in Orange County and are covered by the Santa Ana River Basin and Orange County authority. They have no impact on the LACDA system problems and no impact on plan formulation for LACDA system improvements. Therefore they have not been discussed in this report. Locally operated facilities include 15 flood control and water supply reservoirs in the upper watershed areas of the LACDA basin. Combined, these local reservoirs have a maximum combined capacity of about 102,000 acre-feet, of which over half is reserved for flood control.

2. Debris basins, found at the mouth of canyons, are designed to trap debris carried by floodwaters, leaving relatively clean water to flow unimpeded in downstream channels. There are currently 129 debris basins in the watershed of the Los Angeles and San Gabriel river systems. Their purpose is to reduce the amount of debris (mud, rock, sand) which reaches the lower basin reservoirs and channels.

3. Tributary channels, such as the Arroyo Seco and Compton Creek, are designed to pass local runoff and floodwaters efficiently into the main channels. There are improved channels on 37 major tributaries of the two river systems in the LACDA basin. One effect of these channels is to speed passage of flood flows through the local communities and into the mainstem river system, either draining into a flood control reservoir or directly into one of the two mainstem rivers.

4. Main channel improvements pass the controlled or partially controlled flows to the ocean. The two main river systems have over 100 miles of mainstem channel, the characteristics of which are identified, by reach, in Table 2. The mainstem channels cross the generally flat, heavily developed flood plain; to effectively contain peak floodflows, they must be hydraulically efficient to overcome the natural tendency for water to slow

down as it crosses a flat plain. In the lower reaches of the basin, mainstem channels are at or near sea level and flow across very flat ground. To contain flows under such conditions, the natural channels are augmented by levee systems, which raise the maximum level of the river as much as 15 feet above the surrounding flood plain.

Each of these measures are combined in a unique manner to regulate flows on the Rio Hondo, Los Angeles, and San Gabriel Rivers. The major tributaries of the Los Angeles River are, in sequence proceeding downstream, Tujunga Wash, Burbank Western, Burbank Eastern, Verdugo Wash, Arroyo Seco, Rio Hondo, and Compton Creek. The tributaries are, for the most part, concrete-lined channels.

Flows to the main channel of the Los Angeles River are regulated by Sepulveda and Hansen Dams which are operated and maintained by the Corps of Engineers. The river is improved for its entire reach below Sepulveda Dam, and the channel has a shape that fluctuates between trapezoidal and rectangular. The sides and invert are lined with either concrete or grouted rock, except for an ungrouted stone invert reach in the vicinity of Glendale and the reach from Willow Street to the Pacific Ocean where the channel is soft bottomed and the walls have rip-rap protection. The Los Angeles River is entrenched down to Atlantic Boulevard, and it becomes leveed from that point to the ocean.

The San Gabriel River originates in the San Gabriel Mountains where the East and West forks merge. The upstream watershed is controlled by three Los Angeles County dams: Cogswell, San Gabriel, and Morris. As it leaves the mountains, the river is regulated by Santa Fe Dam, which is operated by the Corps of Engineers. The river continues to flow in a southerly direction and is joined by Walnut Creek and San Jose Creek. The County operates six water control reservoirs on these tributaries, the largest of which is Puddingstone Dam. The San Gabriel River flows through Whittier Narrows, is joined downstream by Coyote Creek, and finally discharges into the ocean. The San Gabriel River primarily has rip-rapped channel sides with a soft-bottom invert to permit groundwater recharge. Seven miles downstream of Whittier Narrows Dam the river becomes a trapezoidal concrete-lined channel and remains so until it reaches the tidal influences of the ocean.

The third major watercourse of the system is the Rio Hondo. It originates in the San Gabriel Mountains and has a number of tributaries, including Eaton, Santa Anita, and Sawpit washes. The County operates four small water conservation dams in this region. The Rio Hondo flows through Whittier Narrows Reservoir, continues in a southwesterly direction, and then joins the Los Angeles River.

In addition, Los Angeles County has constructed a comprehensive underground storm drain system totaling approximately 2,000 miles. This system is very effective in delivering local runoff to the major flood control channels. The County also operates twenty-nine groundwater recharge basins totaling approximately 2,000 acres.

In total, the LACDA system has over 100 miles of mainstem channel, over 370 miles of tributary channels, 129 debris basins, 15 flood control and water conservation dams, and 5 flood control dams. In spite of the current projected flood threat, it is important to note that the existing system has prevented over $3.6 billion in damages since construction.

VOL 12 1 6944

Table 2.
Channel characteristics of the Los Angeles and San Gabriel River Mainstem systems, existing conditions.

Reach	Level of Protection*	Lining	Leveed/Entrenched
1	70-150 year	Concrete	Entrenched
2	10-100+ year	Concrete	Entrenched
3	75-250 year	Concrete	Entrenched above Atlantic Blvd.
4	25-250 year	Concrete	Leveed and Rip-Rap
5	25 year	Concrete	Leveed
6	100+ year	Rip-rap and Concrete	Leveed
7	100+ year	Rip-rap and Concrete	Leveed and Entrenched
8	100+ year	Concrete	Entrenched
9	<100 year	Rip-Rap and Concrete	Leveed

* Levels of protection are approximate and vary, depending on the particular stretch of channel in the reach. Thus there are different potential breakout points for floods of varying magnitude.

VOL 12 1 5945

Economic and Demographic Development

The Los Angeles area is one of the largest manufacturing, trade, financial, and service economies in the nation, with a gross product exceeding $100 billion annually. The economy is diversified and has sustained long-term growth for almost 70 years. The Los Angeles/Long Beach harbors form the largest harbor complex on the west coast of the United States, handling almost as much cargo as the three other major port complexes combined (San Francisco-Oakland, Seattle-Tacoma, and Portland). The region is a major trans-shipment point for Pacific Rim trade.

The economy is generally considered recession-proof due to the steady net migration of residents and industry from other areas of the state and the nation: from 1980 to 1988, the population of the county increased from 7,477,400 to 8,407,400. The Southern California Association of Governments predicts a county population of 10,231,000 by the year 2010. An equal or greater percentage of growth in surrounding Ventura, San Bernardino, Riverside, and Orange counties is anticipated as well, and total southern California population (including San Diego) is projected to climb to over 23,000,000 by the year 2030. At the same time population has grown, unemployment has remained relatively low compared to urban areas in the east and midwest.

Demographically speaking, the area has always been multi-ethnic and multi-cultural. In recent years, the area has experienced a large immigration of peoples from central America and southeast Asia, as well as from other areas of the United States. Los Angeles is considered a stable, desirable location and is becoming an international city with numerous Pacific Rim corporations establishing major corporate headquarters in the area. This trend strengthens the economy of the region.

As a result of favorable economic conditions and this projected population increase, land use in the basin is intensive and property values are high and increasing rapidly. Within the 82 square-mile 100-year flood plain, there are 142,000 structures (123,000 residences) with a structure-contents value of $16.7 billion dollars. Within the 198-square-mile 500-year flood plain, there are 322,000 structures (278,000 residences) valued at $41 billion. About 500,000 people reside in the 100-year flood plain with 1,200,000 people residing in the 500-year flood plain.

Development adjacent to mainstem channels ranges from heavy industry (power stations, manufacturing, railroad facilities, refineries) to residential. Since the channel system was completed, development has been permitted to abut the right of way for the channels.

Recent development within the area is dominated by conversion of existing low density areas to high density residential and commercial zones. Moderately priced detached homes are, for example, replaced with high density condominiums (usually with garage facilities on the lower floor) which increase population density and the number of vehicles in the flood plain. Low value shopping areas are, likewise, converted to multi-story office and commercial complexes. The value of the property within the LACDA overflow area is thus projected to increase. Assuming that preliminary FEMA maps are used as the basis for flood plain designations in the 1990's, new construction should be designed to reduce flood damage, and the losses expected from a flood event are not expected to increase in real dollar terms as a result of development.

Total employment in the Los Angeles-Long Beach Partial Metropolitan Statistical Area (PMSA), which covers approximately the same area as Los Angeles County, was 4,000,000 as of 1983. The largest employment category is the service sector with 2,850,000 jobs, followed by manufacturing with nearly 900,000 employed.

Urban Growth and Runoff Characteristics

Development affects runoff because impervious areas such as roads, buildings, parking lots, and similar structures have a rapid runoff response, filling local storm drains with flows which, prior to development, would have been absorbed into the soil. Urban growth was anticipated and indeed had already occurred in portions of the LACDA basin during the initial project design phases in the 1930's and 1940's. However, the effects of urbanization on runoff exceeded the expectations of design engineers and city planners. Between 1940 and 1980, the population of Los Angeles County increased almost 270% to 7.5 million people.

Not only did this cause a greater amount of runoff from all of the impervious surfaces that now cover the basin, but it also necessitated the construction of an underground storm drain system to keep local runoff from building up in roads and low-lying areas of neighborhoods. This storm drain system concentrates and speeds flows directly into the main LACDA channels. The result of rapid runoff and a storm drain system which concentrates flows is a higher peak flow in the system. Thus, precipitation which would at one time have caused local flooding is now quickly carried to the mainstem channel where it contributes to an accumulation of flow that may break out and cause significant flooding in a more developed area downstream.

Current analysis of the LACDA system indicates that drainage from urban areas now results in larger contributions to the peak flow than predicted in original analyses. Especially evident are shortcomings in the Rio Hondo Diversion Channel and the lower Los Angeles River sizing for local stormwater inflow. The predicted and actual contributions of urban drainage to the mainstem flow of various reaches are compared in Table 3. As this table indicates, local drainage accounts for a substantial percentage of the increase in peak flows in the channels.

Table 3.
Increased flow on the Los Angeles River and Rio Hondo due to urbanization effects.

Location	Flow (ft^3/s)		
	Upstream	Downstream	Difference
Rio Hondo Diversion Channel			
Design Discharge	40,500	42,000	+1,500
50-year Computed	40,000	46,000	+6,000
1969 Flood*	38,800	46,900	+8,100
Lower Los Angeles River			
Design Discharge	110,000	146,000	+36,000
50-year Computed	100,000	148,000	+48,000
1969 Flood*	74,000	129,000	+55,000

* Observed by the Los Angeles County Department of Public Works.

To a lesser degree, urban growth in the drainage area above the flood control dams has also increased runoff, and peak runoff in particular. The increasingly impervious upstream drainage areas result in higher flow rates and quicker reactions to rainfall. These factors tend to reduce the size of the flood which can be controlled by the impoundment structure.

The impact of this urbanization is smaller in percentage terms than that in downstream reaches because the urbanized drainage area above the reservoirs is smaller in size than the urbanized drainage area in downstream areas. The reservoirs still provide significant peak flow reduction, but because the peak flow and the total inflow may have increased due to urbanization of the upper watershed, the level of protection afforded to downstream communities has been reduced. Two primary examples are Sepulveda Dam in the San Fernando Valley, which now provides just slightly less than 100-year protection, and Whittier Narrows Dam, which provides slightly greater than 100-year protection on the San Gabriel River. These facilities were originally designed for a significantly greater level of protection than they currently afford.

Environmental Resources

General

The Los Angeles area is heavily urbanized with many of the environmental quality problems associated with such an area: significant air pollution, water quality problems, crowding, urban blight, noise, toxic waste disposal problems including groundwater contamination, and very heavy traffic. Air pollution in the basin exceeds Federal clean air standards approximately 30-50 percent of the year. Water quality for human consumption is generally quite high because much of the water used is imported from the State Water Project, Owens Valley, or the Colorado River. Local water supplies from groundwater basins, which account for about 35% of all water used in the basin, are threatened by seawater intrusion and toxic waste spills. Recent plans by environmental regulatory agencies in the basin suggest that raising environmental quality would require significant government action; plans provide for significant restrictions on development, transportation, land use, and energy use.

Both water quality and water supply are issues of major concern to local agencies. Long-term projections of water supply and demand show a net deficiency in water supply for the entire southern California region by the period 2000-2010. Additional supplies are difficult to develop, and therefore conservation programs have a high priority in this region's long-range planning. There are also concerns that existing supplies may be lost due to contamination by toxic wastes.

The density of development in Los Angeles is increasing, and as a result, noise and traffic are increasing. Recent studies of the major transportation corridors indicate that there are some freeways where "rush hour" conditions exist for extended periods (as long as six hours in the morning and five hours in the afternoon). Adjacent surface streets are also crowded with traffic. These conditions affect commercial traffic and development as well as the general social environment. The quality of the human environment is generally perceived by residents to have declined in recent years, according to a 1989 Los Angeles Times survey.

Biological Resources

Below the major Corps flood control reservoirs, a majority of the mainstem channels have been modified to the extent that there are few environmental resources of significance in these reaches. In the upper reaches of the Los Angeles River, the channels are concrete lined with the exception of a six-mile reach of cobble-bottomed channel in the vicinity of Glendale, and at the downstream end of the river there is a 2.6-mile section of rip-rap lined channel with a natural invert. This channel section supports some aquatic vegetation and some fisheries resources which utilize its soft-bottomed reach. It provides feeding grounds for a variety of sea birds, including the brown pelican and the California least tern. This area is influenced by tidal forces, and vegetation and other resources are routinely scoured from the channel.

The San Gabriel River generally has a natural invert and concrete-lined channel walls for a stretch of seven miles downstream of Whittier Narrows Dam. This design was specified to allow incidental water conservation during late-season releases from the reservoir. Previously, during periods of low flow in the river, Los Angeles County contoured the channel invert into a series of terraced ponds to augment groundwater recharge. This activity used heavy machinery which effectively removed much of the vegetation which might otherwise grow in the unlined invert. Recently, seven rubber dams were installed in the channel, achieving the same water conservation goal without the impact to vegetation.

Development along the right-of-way of the channels is generally heavy on the Los Angeles River from Sepulveda Dam to the river mouth. On the San Gabriel system, however, there are several large linear park systems abutting the channel levees, including a park near the San Diego Freeway crossing. This park system, along with the undeveloped area on the back side of the mainstem levees, may provide a limited corridor for some wildlife in the region, particularly coyotes and other animals which adapt well to urban environments.

Environmental resources in the reservoirs themselves and in the watershed above are significantly greater than in the mainstem channels. The reservoirs have been designed

VOL 12 1 6951

to provide wildlife refuge areas as well as a wide range of recreation activities. As urbanization has surrounded these reservoir areas, they have become in some instances the largest areas of undeveloped land within the lower basins. The biological resources of the five main Corps reservoirs and upper watershed areas in the LACDA system are summarized below (see environmental documentation at the end of this report for more information):

1. Lopez Reservoir. This site has little biological value except as open space for wildlife habitat.

2. Hansen Dam. The reservoir provides diverse habitat for a wide variety of wildlife, potentially including an endangered bird species and an endangered plant species.

3. Sepulveda Dam. Outside of recreation areas, this reservoir contains some natural habitat areas. The reservoir area supports substantial numbers of wildlife year-round and migratory birds.

4. Santa Fe Dam. This reservoir has unique alluvial scrub areas with some areas of potential habitat for endangered species.

5. Whittier Narrows Dam. This large area has extensive riparian habitat in wildlife sanctuary areas with a wide variety of wildlife, including several endangered species.

6. Los Angeles River Channel. There is very little biological value as most of the channel is completely concrete lined, except in the area of Glendale and near the mouth of the river. The lower reach is where foraging habitat of value to two endangered species is found.

7. Rio Hondo Channel. Very little biological value due to the channel being completely lined with concrete.

8. San Gabriel River Channel. Below Whittier Narrows Dam there is a seven-mile stretch with extensive riparian habitat supporting a wide variety of wildlife. In the lower river, there is some emergent vegetation providing foraging area for native wildlife, including two endangered species of birds (brown pelican and the California least tern).

9. Compton Creek Channel. This reach has little habitat of value as it, like the mainstem LA River channel, flows through heavily developed urban area. There is soft-bottomed channel through this reach with minimal environmental value, although it is littered with refuse and is likely to be scoured on a regular basis during the rainy season.

The upper watershed areas of the LACDA system are rugged and relatively undeveloped in many areas, particularly in the San Gabriel mountain areas, which feed the Los Angeles and the San Gabriel rivers. In these areas, tributary streams provide a band of riparian vegetation leading into the mountains; local flood control and water conservation dams also provide water resources for wildlife. The tributary streams to the LACDA system, particularly unimproved reaches in the upper watershed, are a critically important environmental resource, being among the few remaining major areas of riparian habitat in the southern California area. A complete listing of plant and animal species in the reservoirs and upstream drainage areas is found in the EIS which follows this main report.

Cultural Resources

Within the immediate project location, the area of improved channels and existing reservoir facilities, cultural resources are limited to historic resources such as the many historic bridges across the Los Angeles River. There are a number of historic buildings near the channel rights-of-way for both rivers (most are in the LA River reaches).

Recreational Resources

The LACDA flood control system itself is a major recreational resource for the Los Angeles area. There are recreational areas at four of the five flood control reservoirs, with a total use of these facilities in 1988 estimated at over 5,000,000 visits. Recreation facilities include a velodrome (Sepulveda), recreation lakes, picnic grounds, hiking and riding trails, and playing fields of many types. These facilities are available for a majority of the year when the reservoirs are not in use for water storage.

The mainstem channels provide 49 total miles of hiking and bicycle trails. The trail on the Los Angeles River begins at the Pacific Ocean and connects with the Rio Hondo trail system, allowing passage through Whittier Narrows Reservoir into the San Gabriel Mountains. On the San Gabriel River trails, it is possible to travel by foot or bicycle from the mouth of the river, through Whittier Narrows and Santa Fe reservoirs, and into the San Gabriel Mountains. These trails are an important resource in an urban area where cycling on surface streets is dangerous and where few other cycling paths are available.

G. NATIONAL OBJECTIVES

The objective of Federal and federally assisted water and related land resources planning is to attempt to maximize national economic development. Contributions to NED are increases in the net value of the national output of goods and services, expressed in monetary units, or increases in economic efficiency. Plans are formulated to alleviate problems and take advantage of opportunities in ways that contribute to the national economic development. By definition, the "NED Plan" is the one which maximizes the net national economic development benefits, consistent with the Federal objective.

The policy of the Corps of Engineers in identifying the NED plan is specified in the Economic and Environmental Principles and Guidelines for Water and Related Land Resources Implementation Studies. This document states:

"The Federal objective of water and related land resources planning is to contribute to the national economic development consistent with protecting the Nation's environment, pursuant to national environmental statutes, applicable executive orders, and other Federal planning requirements."

"Protection of the Nation's environment is to be provided by mitigation (as defined in 40 CFR 1508.20) of the adverse effects (as defined in 40 CFR 1508.8) of each alternative plan. Accordingly, each alternative should include mitigation determined to be appropriate by the Agency decision-maker."

For this type of multi-purpose study, the primary category of NED benefits evaluated is generally flood damage reduction benefits. Other benefits which may be considered include benefits from water conservation, benefits from increasing the value of project area lands, benefits from providing recreation, and benefits from enhancing the socio-@ economic conditions of the project area. Flood damage reduction benefits are the principal source of NED benefits evaluated in this study.

H. STUDY PROCEDURE

Within the context of these national objectives, the intent of this study was to review the adequacy of the existing LACDA mainstem system to protect the heavily urban areas of Los Angeles. A secondary purpose was to determine if there were water conservation, recreation, environmental enhancement, and transportation needs which could be addressed in conjunction with any flood control needs. Specific study objectives were:

1. Re-evaluate the estimates of potential rainfall and runoff for the LACDA basin (meteorology and hydrology review) in light of (a) the experience of the last 40 years and (b) scientific advances which make possible more accurate projections of rainfall and runoff.

2. Given revised rainfall and runoff projections, re-evaluate the capacity of the existing system to safely contain and convey flood flows from headwaters to the Pacific Ocean, using modern computer modeling techniques to determine the actual capacity of existing system elements, primarily channels.

3. Define the nature and extent of any flooding problem, and identify any related problems which could be addressed in conjunction with a solution to flood control problems.

4. Formulate and evaluate alternative measures for addressing problems and opportunities.

5. Identify the National Economic Development plan for solving identified flood control problems.

VOL 12

169556

SECTION THREE: PLAN FORMULATION

A. FLOOD CONTROL PROBLEMS AND OPPORTUNITIES IN THE MAINSTEM LACDA SYSTEM

Causes of the Flooding Problem

The design of flood control channels and reservoirs is based on estimates of precipitation, runoff, and resulting flow in stream and river channels from storms of varying magnitude. It is the goal of the Corps to provide flood protection in the most cost effective manner possible. In urban areas where system failure could result in catastrophic damages and loss of life, it is often considered desirable to provide at least 100-year flood protection. A 100-year flood is an event that is likely to occur on average once in 100 years or, otherwise stated, has a 1 percent probability of occurring in any given year. The accuracy of precipitation, runoff, and channel flow frequency estimates is thus critical to the design of an effective system.

Since 1939, when the LACDA system was designed, there have been significant improvements in methods used for estimating the frequency and magnitude of potential floods. This is due in part to a longer period of record and in part to better analysis techniques. Applying more advanced analytical methods, and taking into account the significant changes in the development level within the LACDA basin, the estimated flow in most reaches of the Los Angeles, Rio Hondo, and San Gabriel rivers was determined for storms of various intensities. The conclusions of this review were that the existing mainstem system provided lower levels of protection than are appropriate for an urban area. This conclusion was based on the following findings:

1. The storms used as the basis for designing LACDA features in early (1930's) hydrologic studies, the so-called "design-storms," were found to occur more often than once in 100-years. This conclusion was based on current analysis that includes an additional 50 years of storm records since the beginning of the LACDA system construction. Using the updated rainfall frequency statistics and more modern techniques of analysis, Corps hydrologic engineers have

VOL 12

determined that the basis of design for much of the LACDA system was a storm with a 50-year recurrence interval. A 100-year storm is estimated to produce significantly more precipitation, runoff, and flow in streams and river channels. Thus, the LACDA system does not provide 100-year protection in all reaches.

2. Increasing urban development has resulted in increased runoff because rapidly draining, impervious cover replaces runoff-retarding soils that support vegetation. The studies which led to the design of the LACDA system addressed future urban growth in the southern California area, however, the designers were unable to predict the impact of urbanization and the effectiveness of the local storm drain system at carrying this increased runoff into the main flood control channels.

Since 1939, local officials have constructed a comprehensive system of storm drains to prevent local flooding. These drains collect runoff and carry it to the mainstem river channels rapidly. They thus have the effect of concentrating local runoff; the effect on the flow in the mainstem channels is: (1) very rapid build up to peak flow and (2) peak flows higher than previously calculated. The system of flood control reservoirs designed to collect flood flows from the upper watershed areas does not, for the most part, control the runoff from urban areas, which are in the lower basin.

From Figure 4 it can be seen that some flooding occurs immediately below Corps flood control dams during the 100-year event. This excess channel flow is the result of local storm drain contributions to the mainstem channel. On the 23 mile length of channel from Whittier Narrows Dam to the Pacific Ocean (Reaches 4 and 5) there are at least 64 storm drains connecting to the mainstem channel and 12 pumping plants discharging to the river (see Figure 5). The pumping plants collect local surface runoff and pump it up over the levees into the river. On average there is local runoff added to the channel every third of a mile through its entire length.

The majority of the heavily urbanized watershed lies downstream of any flood control structure. The rainfall meets impervious surfaces such as buildings, parking lots

and streets, and runs off into the local storm drain network. There are approximately 2000 miles of underground storm drains in Los Angeles County. These drains collect flows and efficiently convey it to the closest point of discharge, the mainstem flood control channels. This conveyance process responds very rapidly and provides little infiltration, storage or route down. The effectiveness of this system precludes any need to improve the storm drains on a wide scale basis.

Utilization of computer modelling techniques has allowed for a more detailed simulation and evaluation of the basin's drainage system performance than was previously possible. The numeric model used in the analysis is a complex single event simulation tool that provides insight on the magnitude and location of excess channel flow and as a result provides the basis for quantifying the overflow in the flood plain.

When the high velocity flood control channels were built in the 1930's there was little operational experience with this type of facility. Since that time the freeboard requirements for this type of channel have increased slightly due to the potential height of standing waves in the full flowing channel. This is only a minor consideration in determining how much flow will escape from the channel in a greater than design event.

Preliminary to modeling the mainstem channels in the LACDA study, the major tributaries of the system were evaluated using a generalized peak-area relationship. The levels of protection were found to be generally adequate or the extent of development in areas which might be flooded did not appear to be sufficient to justify further investigation.

The Without-Project Condition and the Flood Threat

For purposes of evaluating the need for increased flood protection, it is necessary to determine how often flooding would occur if no additional protection is provided, how widespread the flooding would be, and how much damage would be caused by the flooding. This is called the without-project condition. The without-project condition is generally projected over the entire economic life of the proposed project (100 years for a

VOL 12

16962

major reservoir or channel project); that is, an effort is made to predict the changes which would occur in development in the project area over this period of time. This projection is made so that the costs and benefits of the project can be analyzed over the life of the project, and to accommodate the probability that development levels in a project area will increase. In the Los Angeles basin, however, there is extensive existing development. The effect of potential future development in areas of the basin tributary to the mainstem system was calculated and was determined to have little impact on peak flows in the lower basin. As a result, the without-project condition does not change markedly throughout the life of the project.

Based on the review of precipitation and runoff and on re-evaluation of system capacity, it was determined that the LACDA system does not adequately protect many areas; the potential for the system to fail is particularly serious in the lower river reaches. Figure 4 shows the without-project overflow areas evaluated during this study. The Los Angeles River lacks 100-year protection through about half of its length. In the most critical reaches, such as the leveed sections along the Rio Hondo and the lower end of the Los Angeles River, the level of protection is less than the 50-year level.

The estimated 500-year overflow area is approximately 200 square miles, of which nearly all may be considered a fully developed, urban landscape. The population residing within this 500-year overflow area is estimated to be about 1,200,000. Similarly, the 100-year overflow area covers approximately 82 square miles, with a population estimated to be about 500,000.

Table 4 gives the total number of structures and expected damages within the 100-year and 500-year overflow area. The total value of structures and contents in the 500-year flood plain is $40.7 billion. Should such a flood occur, expected damages would total $5.4 billion (13 percent). Of the 322,000 structures in the 500-year flood plain, approximately 278,000 (86%) are single-family residences. Similarly, the total value of structures and contents in the 100-year flood plain is $17.5 billion, of which expected damages would total $2.3 billion (13 percent). Of the 142,000 structures in the 100-year flood plain, approximately 123,000 (87%) are single-family residences.

Measurement of structure elevation for damage estimation was test sampled. To ensure that any measurement error was minimized, an analysis of the combined effects of hydrology and topography were applied. For this analysis a random sample of 1% of the data caells was selected. Hydrologic cross-sections were site visited with stucture elevations measured and corrected with street topography maps. Flood inundation damages under this analysis were compared to those generated by the study's partitioned cell method. The result of this comparison indicates differences between the two methods were not statistically significant. Since neither the economic justification nor the NED plan is affected, no changes were made in the estimates of damages avoided.

For the existing without-project condition, the potential for flooding and damage along the mainstem system of LACDA can be summarized as follows:

1) **Reach 1.** From Hansen Dam to the Los Angeles River, the Tujunga Wash flows through suburban and commercial districts of the San Fernando Valley. The channel itself is within a greenbelt area which contains several major water recharge spreading grounds and numerous recreational areas. A flood in this reach would thus inundate some development, but the most significant overflows would be confined to a largely undeveloped area. A majority of anticipated damages would be to residential structures and their contents.

2) **Reach 2.** From Sepulveda Dam to the Arroyo Seco confluence, the Los Angeles River flows in an entrenched channel through highly developed commercial and residential property. A significant flood could break out of the channel at a number of points, but the extent of a breakout would be limited by the slope of the land towards the channel. Very high value property such as several movie and television studios would be flooded, but flood depths would not be great. A similar flooding scenario would occur as the river flows out of the San Fernando Valley into the central Los Angeles Basin. Rail yards and some heavy industrial areas would be flooded, but impacts would be limited and of short duration.

3) **Reach 3.** From Arroyo Seco to the Rio Hondo confluence, the Los Angeles River passes through very heavily developed industrial and commercial areas. A 100-year flood would break out in an area between the Pasadena Freeway and the Santa Monica Freeway, inundating rail yards, blocking major roads and freeways, and flooding major shopping, commercial, and government buildings. A vast majority of damages would be to commercial and industrial structures and their contents. A 500-year flood would break out in the same general vicinity but would spread over a much larger area, flowing across much of central Los Angeles before returning to the mainstem channel downstream. Flow depths would be moderate over a majority of this area.

4) **Reach 4.** The most serious flood threat is to this Los Angeles River reach, from the Rio Hondo to the Pacific Ocean. Flows overtopping the levees (generally upstream from bridges) would rapidly erode the unprotected levee walls and inundate the relatively flat and very heavily developed areas in this lower basin. Structures in the immediate vicinity of the breakout would suffer heavy damage from very deep and fast moving flows. Damages would also be high in several large low-lying areas where flood waters would tend to accumulate. Development in this reach includes several major freeways, rail lines and rail yards serving the Ports of Los Angeles and Long Beach, major refineries and petroleum products storage facilities, large industrial complexes, and extensive residential and commercial developments.

5) **Reach 5.** The Rio Hondo reach, from Whittier Narrows Dam to the Los Angeles River confluence is also heavily developed. Breakouts from the Rio Hondo would also involve levee failure, and flows from a flood originating in this reach would eventually co-mingle with those from the Los Angeles River, exacerbating the flooding in the lower river basin.

6) **Reaches 6 and 7.** The San Gabriel River from Whittier Narrows Dam to the Pacific Ocean flows through predominantly residential and commercial areas, although there is some industrial development near the river. This section currently provides a minimum of 100-year protection, but levee failures on the

Rio Hondo during more frequent events can result in floodwaters along the western bank of the San Gabriel River.

7) **Reach 8.** From Santa Fe Dam to Whittier Narrows Dam the San Gabriel River flows through residential and commercial areas, but no significant overflows along this reach are anticipated. The channel provides 500-year protection levels because of the controlling presence of Santa Fe Dam. Inflows to the dam greater than the 200-year event would spill into nearby gravel pits which have relatively massive capacities (on the order of 100,000 acre-feet). There would be significant damages to gravel mining operations, but adequate flood warning should permit all personnel to be removed prior to a flood. Damages in this infrequent event could be severe to the gravel pits.

8) **Reach 9.** Compton Creek is included as a reach so that the effects of a mainstem solution could be mitigated. The creek itself does not provide 100-year protection and is more appropriately studied under a separate authority. Any future improvements to Compton Creek do not affect plan formulation on the mainstem Los Angeles River.

Channel inadequacies are most serious in the lower Rio Hondo and Los Angeles River reaches for several reasons. First, in these reaches the river is contained by levees which may be 10-15 feet above the surrounding ground. Flow over the top of these levees for a period of an hour or more would very likely erode the unprotected back face and cause the levee to fail. The result would be high velocity breakout from the channel which would do significant damage in the immediate vicinity of the breakout and would then spread out over a wide area. Second, in the lower basin, there are also low lying areas where flows would accumulate to depths of 10 feet or more, causing serious damage to structures in these areas. Third, the lower mainstem is carrying the collected flow from the hundreds of square miles of drainage area. This massive accumulated flow represents a greater flood threat in the event of a system failure than exists in the upper reaches.

Table 4.
Number of structures and estimated damages, by reach,
100-year and 500-year flood plains, Los Angeles River and Rio Hondo.

Reach	500-year Flood plain No. of Structures	500-year Flood plain Damages in $mill	100-year Flood plain No. of Structures	100-year Flood plain Damages in $mill
1 Tujunga Wash	17,948	252.8	3,605	101.9
2 LAR above Arroyo Seco	9,425	310.6	1,272	19.7
3 LAR above Rio Hondo	81,703	618.7	700	67.1
4 LAR above Pacific Ocean	71,093	2,143.0	58,248	1,685.4
5 Rio Hondo	)*44,900	246.4	)*24,108	447.7
6 San Gabriel below Whittier Narrows		739.2		0
7 San Gabriel above Pacific Ocean	96,711	1,127.8	**53,575	0
Total Project	***321,780	5,438.5	141,508	2,321.8

NOTES * Combined total for Reaches 5 and 6 (overflows originating in these reaches commingle)

** Some structures in this reach may experience flooding but the source of the overflow is not Reach 7, thus the damage is not attributed to Reach 7.

*** Damages in the upper San Gabriel River reach (Reach 8) were not estimated because this portion of the LACDA system was found to provide 500-year protection, with the exception of the gravel pits that receive spillway flow from Santa Fe Dam.

Damages from overflows along Compton Creek were not calculated. Compton Creek was included as a project reach only because of the potential for channel modifications on mainstem reaches to impact levels of protection at Compton Creek.

B. RELATED PROBLEMS AND OPPORTUNITIES

While exploring flood control problems and appropriate methods for solving them, it is also appropriate to identify related problems and opportunities which may be addressed as a part of a solution to the primary flood control problem. For example, in designing a channel to solve a flood problem, it may be possible to provide a recreation area adjacent to the channel at little additional cost. The problems and related planning opportunities identified in this study are discussed below.

Sediment Management

There are 129 debris basins, generally located at the mouth of the canyons in the San Gabriel Mountains. These facilities are nearly all owned and maintained by the County. Their purpose is to retain sediment and debris while passing the clearer runoff into the flatter gradient channels of the Los Angeles basin. Channels flowing with clear water are far more effective conveyors of runoff than when they are filled with sediment laden flows. The County also owns and maintains 15 multi-purpose dams in the LACDA basin, generally upstream from the Corps' facilities. At present, more than half of the space behind these dams is reserved for flood control and the remainder is reserved for water conservation purposes. These dams intercept most of the sediment from the watershed above them, effectively limiting the sediment load reaching the major Corps flood control facilities. The County is thus faced with a significant maintenance problem, as high sediment loads tend to reduce the capacity of these facilities for water conservation as well as flood control purposes. In the past the County has occasionally sluiced this sediment downstream as a part of an operation and maintenance activity. If the sediment reached a Corps facility and settled out, it was subsequently removed by the County. There are environmental impacts associated with sedimentation of downstream streambeds, and there are also associated short-term reductions in flood storage capacity when this material settles out in a flood control facility. Addressing future management of sedimentation may require greater expense and the development of alternative methods of collection and disposal.

At present, sedimentation is not a significant problem at any of the Corps flood control facilities because the upstream County dams and the system of debris basins in tributary watersheds effectively limit sediment inflow to the facilities. The exception of high sediment inflow at Hansen Dam has been effectively addressed through a commercial sand and gravel mining lease arrangement. As a result of these efforts, no sediment allowance at any LACDA mainstem reservoir is currently filled.

While sediment is not currently considered a major problem from a flood control perspective, sediment management was considered worthy of study. This feasibility study looked at upper watershed sediment control through erosion control and check dam construction.

Water Conservation

Given the outlook for population growth (and therefore for increased water demand) and the limited supply of water available in the semi-arid southwestern United States, major flood control reservoirs represent a potential water conservation resource of some importance. At such reservoirs, conservation programs involve capturing late storm season inflows (when the danger of a major storm and flood event is low) and releasing them slowly to downstream groundwater recharge basins. This action is always limited by the need to ensure against flood damages.

It may be possible to increase the amount of water conserved in this manner. Any increase would depend on a re-evaluation of the amount and timing of inflows and of the flood control capacity of downstream reaches of the mainstem system. If it were possible to safely begin to store water for conservation purposes earlier in the spring, then water now lost to the sea could be captured.

The key to such action is the capability of the downstream mainstem channel system to contain releases from the reservoirs. The greater the capacity of downstream channels (to an extent), the less risk there is in holding supplies behind the mainstem dams for water conservation. Thus, before water conservation could be studied in detail, it was essential to evaluate the flooding problems on the mainstem system and develop solutions which would reduce the probability of significant flood damages.

This feasibility study explored the potential to increase water conservation by increasing delivery to spreading grounds, creating off-stream detention/conservation basins and trading developable flood control space for existing water conservation storage. None of these measures were supportable on a flood control basis, and, as such, this report does not specifically address alternatives for water conservation. Once the flood control capability of the mainstem system is upgraded to appropriate levels, it will be possible to formulate and evaluate these and other water conservation measures. This analysis may be undertaken as a separate study on a system-wide basis or under the general operational review authority granted to each District Commander. The District Commander is authorized to revise the storage allocations and operating schedules for Corps reservoirs within specific limits, provided that the public has an opportunity for review and comment. The Corps currently cooperates closely with the County to conserve as much runoff as possible.

Transportation

The need for transportation improvements in southern California is documented in numerous local, state, and federal reports. Basin freeways currently experience long periods of congestion, as do many city arterials.

Numerous studies by other agencies have suggested that the flood control channel rights-of-way, and indeed the channels themselves, could be used as transportation corridors. The Los Angeles River channel, for example, runs parallel to the Long Beach Freeway for much of its length and passes from Long Beach to downtown Los Angeles through major industrial areas. From downtown it then proceeds northwest into the major industrial and commercial areas of the San Fernando Valley. The San Gabriel River channel parallels the San Gabriel River Freeway (I-605), passing from south Long Beach through commercial and residential districts into the San Gabriel Valley. In all cases, these are heavily traveled routes. If the river channels could be adapted for transportation purposes, then a significant transportation benefit might be achieved.

In the late 1970's and early 1980's, the transportation problem was addressed to determine whether it should be carried forward for detailed study as a part of this report. Two studies were undertaken. First, the feasibility of using the existing Los Angeles River channel (concrete lined) as a busway was evaluated in a cooperative Corps-Southern California Rapid Transit District (SCRTD) test. The channel, without alterations, would not provide for short-haul service as there are no terminal facilities, and access to the channel is limited. However, SCRTD developed a test of the channel as a commute (express) busway. In this test, buses traveled the route from Long Beach to downtown Los Angeles both within the unobstructed channel (cleared of water and debris) and along local freeways.

The result of this SCRTD test was that local freeway routes were as efficient as use of the river channel. Although there was no traffic in the channel invert, the driving time between destination points via the channel right-of-way was equal to or greater than the driving time via existing roads.

Following this test, a conceptual study of potential roadways along the river channels was conducted. A number of busway and railway alternatives were evaluated. While several designs were found to be promising and technically feasible, two problems were identified which have a significant impact on project feasibility. First, designs involving single structures raised above channel level on piers placed in the center of the channel would raise the water level in the channel and would create significant turbulence and backwater, thereby increasing the risk of flooding. Second, all designs, including designs which provided for single-lane and double-lane corridors along each side of the channel, required numerous costly overpasses at bridge crossings along the river. The Los Angeles County Transportation Commission independently abandoned the Los Angeles River alignment of the San Fernando Valley light rail system in 1988.

The general conclusion of these studies was that effective use of the channel rights-of-way for transportation would have prohibitive costs. Furthermore, implementing transportation within the existing channel right-of-way would constrain numerous flood control solutions being studied. Because of the magnitude of the flood damage potential, this was not considered an appropriate constraint.

For these reasons, transportation problems have not been included in the detailed analysis of flood control problems and alternatives for their solution on the mainstem system. However, recent proposals for transportation use of the channel invert from Long Beach to downtown Los Angeles have some potential for implementation. Use of the channel by trucks would, according to state officials, greatly reduce traffic on the Harbor and Long Beach Freeways, which are major commercial arteries from the harbor area to industrial and commercial centers in the basin. Transportation proposals may be evaluated separately by the Corps at a later date; nothing in the planned upgrade of the LACDA system appears at this time to preclude adaptation of the channel for such uses. The expectation of utilizing this facility as a transportation corridor must be tempered with the constraint that flood control operations cannot be hindered or diminished and that public safety is paramount in operating the flood control system. The channel will continue to be used as a bus driver training ground/motorcycle policeman practice location and a favorite set for the movie industry.

Recreation

Because the study area is a densely populated urban environment, recreation opportunities are limited and opportunities to improve recreation are important. Throughout this study, it was clear that an effort should be made to identify and pursue new recreation opportunities to complement the existing recreation network. Recreation opportunities explored during this study included the potential for recreation associated with any new reservoirs or channels. In considering channel alterations, the potential to create new linear urban parks was given consideration. Where an alternative would involve changes to an existing channel or reservoir, alterations to improve the existing recreation system could also be addressed.

Aesthetic Improvement

Within the mainstem channel system, there are numerous opportunities to enhance the environment; many alterations to the channel environment have been proposed by local, state, and federal agencies, including restoring the channel invert to a natural condition, removing asphalt from the channel levee crest and creating a greenbelt. A number of suggestions were evaluated for altering the channel configuration to provide off-channel basins for recreation and to improve channel aesthetics.

The general conclusions of early study of these proposals has been that (1) they would be difficult to implement within the highly constrained rights-of-way for the existing mainstem system and (2) the cost of expanding the rights-of-way to permit such alterations to the system would be prohibitive. For example, doubling the width of the right-of-way for the Los Angeles River to permit a greenbelt area to be developed would involve removal of a major railway line and switching/cargo transfer yard, removal of numerous major manufacturing and distribution facilities, and removal of hundreds of residences and small businesses. The cost of this action for the reach from Long Beach to downtown Los Angeles would be excessive.

Early in the study process, then, it was determined that only limited aesthetic improvement enhancement would be economically feasible within the LACDA mainstem system existing rights-of-way. The problems which could be addressed were (1) the potential to add greenbelt corridors in reaches where rights-of-way were not seriously constrained, and (2) in locations where no additional rights-of-way are available, improving the existing aesthetics with vegetation.

C. PLANNING CONSTRAINTS

Planning constraints are overriding concerns that must be considered in the development of plans. The following are planning constraints identified in this study.

Environmental Values

Although the County of Los Angeles and all of its attendant cities recognize the seriousness of the flood problem within the LACDA basin, it is very important that environmental and esthetic values be respected. Any proposed program for flood control must take these values into account.

Cultural Resources

The Corps of Engineers, pursuant to regulations of the Advisory Council on Historic Preservation implementing Section 106 of the National Historic Preservation Act (36 CFR Part 800), is responsible for identifying cultural resources that may be affected by the proposed project. The Corps must also evaluate the eligibility of such resources for listing in the National Register of Historic Places. An assessment is made in consultation with the California Historic Preservation Officer of the project effects on cultural resources that are determined to be eligible for inclusion in the National Register.

Rights-of-Way Requirements

Dense residential and commercial development currently borders the rights-of-way of existing channels. In general, while limited increases in rights-of-way may be acquired for flood control purposes at a cost consistent with economic feasibility, acquisition of large blocks of land would have very significant social and economic impacts. If other cost-effective methods for providing flood protection are available, it is imprudent to consider acquiring significant new rights-of-way. Such an approach has the effect of disrupting the communities and businesses which the flood control project is intended to protect.

While it must be recognized that many alternatives involve buying rights-of-way within the community, a widening plan that displaces miles and miles of people and

VOL 12 1 6974

businesses is therefore unacceptable if an alternative can be formulated that would stay within the existing channel rights-of-way and provide similar benefits.

Displacement of People and Businesses

The Uniform Relocation Assistance and Real Property Law (Public Law 91-646, as amended) requires that any local sponsor acquiring land for a project involving the federal government must comply with provisions of this law. Specifically, this entitles people or businesses that are displaced or otherwise impacted by the project to proper compensation for their inconvenience, and to assistance in relocation if necessary. This assistance is in addition to any funds expended for actual purchase of property and improvements.

Groundwater Recharge

Recharge of the groundwater basins is extensive throughout the Los Angeles Basin, and is conducted by several Water Replenishment Districts. An overriding concern of both the local sponsor and the members of the Water Replenishment Districts is not to decrease the existing groundwater recharge. An example of an area that might be impacted is the stretch of the San Gabriel River that is currently soft bottom, in which water is frequently recharged. Accordingly, any flood control improvement along this reach of channel should not have an impervious bottom, or should make provision for the mitigation of loss of recharge area.

Bridges and Traffic

Automobile traffic in southern California currently strains the existing system of freeways, which have extended rush-hour periods. The freeways cross the Los Angeles, Rio Hondo, and San Gabriel rivers at numerous locations. Efforts to avoid impacts to these freeway overcrossings, and thus to traffic within the basin, were a significant

VOL 12 1 6975

planning constraint. Plans which would involve disrupting a major freeway interchange were considered to have severe socio-economic impacts.

D. PLANNING OBJECTIVES

General

The water and related land resources problems and opportunities identified in this study are stated as specific planning objectives to provide a focus for the formulation of alternatives. These planning objectives are as follows.

To reduce the potential for human suffering and possible loss of life due to catastrophic failure of the flood control system, wherever feasible.

To reduce flood damages from the study reaches, wherever feasible.

To provide, where feasible, project-related water conservation, recreation development, sediment management, transportation, and environmental enhancement opportunities.

Selection of the National Economic Development (NED) Plan

A project for flood control involving federal funds must satisfy general economic criteria that have been developed to protect the Nation's investments. The following three items are used when evaluating alternatives.

a) A positive benefit-to-cost ratio must exist. That is, the annual dollar value of tangible benefits must exceed the project's annualized cost. The benefit/cost ratio must be at or above 1.0 for an alternative to be considered economically feasible.

VOL 12

1 6976

b) The scale of the improvements should consider maximization of net benefits (benefits minus costs).

c) The stated result of the improvements must be accomplished with the most economic means available.

Principles and Guidelines for Federal water resources planning require that a plan be identified that produces the greatest contribution to the national economic development (NED). This plan, termed the NED plan, is defined as the plan providing the greatest net benefits as determined by subtracting annual charges from annual benefits. Further, the NED plan is to be selected as the recommended plan unless the Secretary of the Army grants an exception when there is some overriding reason for selecting another plan based on federal, state, local, or international concerns.

E. FORMULATION OF PRELIMINARY PLANS

Plans for rehabilitation and upgrade of the LACDA flood control system were formulated in accordance with the National Environmental Policy Act and the 1983 Water Resources Council Principles and Guidelines. Economic, environmental, and social impacts were considered throughout plan formulation.

Alternative Identification

Alternative solutions were identified in close cooperation with representatives of the Los Angeles County Department of Public Works and the U.S. Forest Service. County and Forest Service reports and plans were reviewed to avoid duplication of effort during the initial stages of plan formulation. Members of these agencies, as well as Corps representatives of the LACDA study team, held weekly plan formulation meetings over several months to address all possible alternatives.

The alternative analysis was a logical outgrowth of the problem identification phase of the study. It was initially obvious that a system-wide review was appropriate, as opposed to a limited review which would only address problems in specified reaches of the LACDA system. With this initial direction established, it was possible to approach plan formulation from a broad point of view, examining measures which could be taken to improve system performance throughout the basin, including the areas upstream of major reservoirs, the channel system in place throughout the urbanized basin, and the features of the local drainage system.

<u>Initial Stage of Plan Formulation: Review of Measures for Addressing Flooding and other Problems</u>

The initial stage of plan formulation was a broad, strategic review of all potential measures which could reasonably be used to address flooding problems. The procedure for identifying these measures was, first, to generate a checklist of all possible strategies for flood damage reduction; and second, to use the checklist geographically by formulating possible solutions on each segment of the LACDA system. The analysis began with the upper watershed areas and worked downstream through the system. In this way, any downstream measures would be formulated with full understanding of the potential effects that upstream modifications might have on channel flow characteristics.

The flood damage reduction measures fit into four main categories:

1) Reduce inflow to the system (detain water),
2) Convey more water in the system (increase channel capacity),
3) Damage management (floodfighting, floodproofing, etc.), and
4) Alter the reservoir's current operating regulations.

Item 4, re-regulating reservoirs on a system-wide basis to coordinate releases and thereby reduce flows within the channels, was proposed and given an initial evaluation. Studies were conducted to optimize the current mode of reservoir operations.

It was concluded that reoperating reservoirs cannot eliminate the potential flooding problems in the Los Angeles Basin. It is possible to improve the level of protection on some channel reaches but this benefit is often offset by a decrease in the level of protection elsewhere in the system. The Reservoir Regulation Section of the Los Angeles District is constantly striving to improve the methods of reservoir operation. While some improvement can be expected over time, it cannot be guaranteed or quantified at present. Thus, the existing approved operation schedules are used as the basis for comparing alternatives.

The use of a "real-time" reservoir response procedure has also been evaluated. Real-time operation involves nearly instantaneous transmission of extensive field data to the District's operational center. This information is usually processed by computer model to aid in deciding on the most efficient reservoir operation plan. The LACDA system was evaluated to determine the applicablity of this process.

A real-time network of gages currently exists in the basin. The accompanying computer model was modified in order to minimize its run time but the shortest run time acheived was approximately one hour. Decisions must be made in a shorter time frame than this so the model was eliminated as a feasible tool. As an alternative, it can be assumed that the information can be received, evaluated and acted upon within 30 minutes. The time it then takes for a dam tender to complete a gate change can be 15 minutes or longer per gate. If, for example, the system location under stress was the confluence of the Los Angeles River and the Rio Hondo, the controlling dam would be Whittier Narrows Dam. The travel time for flows from Whittier Narrows Dam to the confluence is 30 minutes. Thus, an optimal real-time operation could have an influence on flows at the confluence 1-1/4 hours after knowledge of the threatening situation was received. This assumes that all gages and system elements are fully functional.

The basin's response time is usually an hour or less, especially in the urbanized portions of the lower Los Angeles River. As a result, it appears that an optimal real-time response cannot avoid adverse impacts should the floodwaters threaten to exceed channel capacity. While future refinements to the current operating plans may be expected, they are not adequate or reliable enough to preclude the need for structural solutions to the flooding problem. These considerations led to the decision not to rely on re-regulation of the reservoirs as a solution to the downstream flooding problem. Having eliminated reservoir re-regulation as a measure under consideration, the remaining three categories of measures (Table 5) were examined for general appropriateness for each reach of the LACDA mainstem system.

Regional Applicability of Alternatives

Upper Watershed Areas

The first geographical areas to be explored were the watersheds above existing flood control reservoirs. Using previous Corps, County, and Forest Service studies, these watersheds were examined to determine which measures might reduce the inflow of floodwater to the existing LACDA system.
Measures considered included:

1) New dam construction in the upper canyons,
2) Vegetation and debris management measures, and
3) Modifications to the existing operating procedures of the County's upstream reservoirs (increase the storage space allocated for flood control).

Alterations to Existing Flood Control Reservoirs

Excavation of a reservoir to increase its flood storage potential and the capability of raising, re-gating, or otherwise altering the spillway elevation for the four major flood control reservoirs in the LACDA system was evaluated. Modifications that would increase the amount of flood control storage at existing dams by impounding water at a higher elevation are generally only possible where development around the reservoir's existing maximum storage boundary is sparse. The surrounding lands may then be available for purchase at an economically feasible price.

Mainstem Channel Areas Downstream from Major Reservoirs

During the analysis of the channels downstream from the major reservoirs, the focus of the plan formulation process shifted from retention of floodwater to quicker conveyance or short-term detention of channel flow. A wide variety of measures was considered in this evaluation, to include:

1) Deepen existing channels
2) Widen existing channels
3) Raise existing channel walls
4) Remove and replace or modify bridges constricting channel flow
5) Divert flows into tunnels for delivery to the ocean
6) Divert excess flows into new detention or groundwater recharge facilities
7) Alter the channel shape from trapezoidal to rectangular
8) Change the channel substrate and side wall material (from rock to concrete, for example)
9) Armor the back sides of earthen levees with non-eroding material to prevent catastrophic levee failure
10) Alter inlet structures and bridge piers to reduce turbulence in the channel
11) Floodproof and/or construct temporary walls on major roadways which would permit the diversion of floodwater for brief periods into these temporary channels

At the same time these measures were being considered, each reach of channel was evaluated to determine if damage management measures such as local flood walls, other flood proofing measures, or flood plain management might reduce the extent of damages. In addition, flood warning and evacuation plans were considered.

The result of this initial planning was a list of measures (Table 5) which might be appropriate for each distinct reach of the LACDA flood control system. These measures were screened to determine which measures would be carried forward for detailed feasibility analysis.

VOL 12

Table 5. Measures considered for flood damage reduction.

STRATEGY	SPECIFIC MEASURES CONSIDERED
1. Reduce Inflow to Mainstem System	
A. Integrate Flow Retarding Facilities into the System	
	Floodways
	Underground Aquifers
	Wetlands
	Vegetation/Debris Management
	New Dams
	Detention Basins
	Gravel Pits
B. Modify Existing Facilities	
	Modify Existing Dams
	Increase Height
	Excavate Material
	Change Gates/Outlets
2. Convey More Water in the Mainstem System	
A. Create New Conveyance Facilities	
	Pipelines/Diversions
	Tunnels
	New Channels/Aqueducts
B. Increase Existing Channel Efficiency	
	Alter Existing Channels
	Raise Channel Walls
	Widen
	Convert to Rectangular
	Deepen
	Increase Slope
	Armor Back Side of Levees
	Reduce Channel Roughness
	Reduce Bridge Obstructions
	Clear Span Bridges
	Modify Piers and Decks
3. Damage Management	
	Relocation
	Floodproofing
	Floodfighting
	Flood Plain Management/Insurance

1 5982

Public Involvement

A complete initial planning effort involving local and other Federal governmental agencies was critical to ensure that the public was presented a thorough list of possible solutions. No measure which could reasonably be expected to contribute to the solution of the identified problem was eliminated during the initial phase of plan formulation. Thus, when the public presentations were formulated, no measures which were viable from an engineering standpoint and which could contribute to the solution of flood control problems had been eliminated. The public was presented with a broad spectrum of measures to consider and discuss.

The effort to formulate a public involvement program was complicated by the size and population of the affected area. There are over 750,000 households and businesses in the area directly affected by projected overflows from the existing LACDA system, and the population which would be affected by any project is well over 4 million. These people must be afforded the opportunity to comment on formulated solutions and to recommend measures, in addition to those addressed during the initial plan formulation process. To make this possible in such a densely populated region, multiple approaches were used for public involvement.

Personnel from the County Department of Public Works were involved in the planning from the beginning. Local officials were relied on to help guide the initial planning, pointing out where some measures might not be locally acceptable and explaining local perspectives on the problem. To inform other local officials at the city level, open-forum workshops were held to discuss issues, concerns, and other solutions. Also, the Los Angeles County Board of Supervisors, the governing body of the local sponsor, was kept informed of study progress.

Information about the general potential flooding problem for the drainage basin was made available to people through the local media, in particular through press releases and interviews in the major newspapers in the region. An initial problem analysis was made available in mid-1985, prior to plan formulation, giving the general public an overview and an opportunity to communicate with Corps planners. There was an intensive publicity campaign that included a public mailing of informational brocures in 1987, and follow-up publicity about the project in spring of 1989.

Public presentations were made in October 1987 and again in March 1989. They were focused on the identified problem, including both overflow analysis and the economic assessment of damages and the array of formulated, corrective measures being considered. At least one such presentation was made in each affected area of the LACDA watershed. Presentations consisted of a general introduction and a detailed slide/video briefing, followed by an open question-and-answer period. An information bulletin was provided to all attendees. At the end of each briefing, response cards were handed out and a mailing list circulated to ensure that all interested in the study received future informational bulletins.

This open and active public involvement effort will be continued, to include review of this Feasibility Report and review of future design efforts.

F. EVALUATION OF PRELIMINARY ALTERNATIVES

The large number of preliminary alternatives considered were evaluated at several levels of detail. First, all alternatives were evaluated to determine if they showed promise of meeting project objectives. Numerous alternatives were eliminated on the basis of this initial analysis. Second, alternatives which showed some promise of meeting project objectives were subjected to a preliminary benefit-cost analysis. The screened alternatives are described in this section in the order they were presented in Table 5.

Strategy One: Reduce Inflow to Mainstem System

A. Integrate Flow Retarding Facilities into the System

Detention of water within the system of dams and channels is a primary strategy for reducing inflow to the mainstem system and improving flood control in urban areas. Detention can be achieved by capturing flows behind dams or by diverting flows into undeveloped areas such as gravel pits, groundwater spreading basins, floodways, wetlands, and other low-lying areas. In addition, a number of secondary options for reducing flows in the mainstem channels by increasing groundwater storage were considered, among them, injection wells and channels with holes in the invert and side slopes (perforated channels). Several detention strategies were eliminated after a cursory review. First, floodways were eliminated because there is simply no adequate undeveloped land for such floodways, and the massive amounts of water which would need to be diverted into the floodway would move with such force as to threaten to cause significant damage to any natural landform. A floodway susceptible to failure would thus merely transfer damages from one reach of the river to another, an unacceptable solution to the problem.

Second, storage in underground reservoirs, aquifers, or wetlands was eliminated because there are no undeveloped sites in the LACDA basin appropriate for these alternatives. Underground reservoirs would have to be capable of 10,000-20,000 acre-feet of storage and would cost perhaps hundreds of millions of dollars to construct. Injection of excess flow into aquifers would be too slow to affect peak flow significantly. And there are no wetland sites in the LACDA basin which could be used to store water; all wetlands remaining in the basin are near the coast. None of these options was found to have any appreciable impact on peak flows in the channels. Given only limited water conservation benefits from these options, and the potential for high costs and some impacts to flow rate in the channels (greater flow resistance and turbulence from perforated channels), they were eliminated from consideration early in planning.

Another option involves land management to reduce runoff and debris production in the upper watershed, thereby reducing peak flows. Management of vegetation is one approach, but it is generally effective only where the slope of hillsides is moderate and substantial vegetation can be established. This is not feasible in the semi-arid mountains surrounding the Los Angeles Basin. The steep slopes and long hot, dry seasons mean that vegetative communities at most elevations are limited to coastal sage scrub, grasses, and chaparral. These communities burn off in the fire season with some regularity, and there is often little chance for significant growth prior to the start of the rainy season.

A second approach is construction of debris basins and check dams. There are already 129 major debris basins in the upper watershed areas, and effective sites for additional basins or check dams have generally been utilized. In addition, these structures are generally too small to significantly reduce peak flows to downstream areas; they fill quickly in early flood stages and have no capacity remaining when peak flows occur.

Erosion control and alteration of the watershed to improve retention of rainfall are both extremely difficult to accomplish. If they could be achieved, it is doubtful that they would have a significant impact on peak flooding because peak flows occur when thin soils have been saturated and there is no additional capacity in the soil. This approach is worth pursuing in the long term for the benefit of improved land management, but cannot presently be relied on to provide significant reductions in peak flows.

Upper watershed erosion control also does not address the problem of increases in lower basin local runoff, which cause the majority of the flooding problems in the basin. Therefore, there would be only minor benefits from programs that reduced upper watershed runoff and erosion. They were not pursued as primary solutions to the flooding problem.

New Dams

New dams in the canyons above existing Corps facilities were considered at the following locations:

1) The Los Angeles River basin above Sepulveda Dam,
2) Tujunga Wash above Hansen Dam,
3) Arroyo Seco watershed above Devil's Gate Dam, a local dam owned by the city of Pasadena, and
4) The watershed above the Santa Fe Flood Control Basin.

These locations were determined to have the largest potential capacity of all those surveyed.

Small dams have little effect on peak flood flows because they fill up very early in a flood and therefore have no capacity when peak flows arrive; the runoff they do capture arrives prior to peak flows and would therefore generally pass harmlessly within the main river channel to the ocean. Since they are spilling when peak flows occur, they do not reduce the flooding problem. To be effective, an upstream dam would require at least 10,000 acre-feet of storage.

Factors that needed consideration in an analysis of new dam sites include the following:

1) The environmental impacts associated with the construction of a new dam would require substantial mitigation.

2) The Forest Service would not favor dams unless they have public access and recreation areas.

3) Small dams would require costly debris removal while providing minimal benefits.

4) Many of the dam sites considered in the initial plan formulation stage were in relatively developed areas, and construction would require relocation of recreation facilities, roads and some homes.

5) If new flood control capacity were proposed, a reoperation analysis would need to address how the existing space would be incorporated into the existing system and what potential existed for increasing available water conservation space.

In the western upper watershed, the three sites were identified - north of Pipe Canyon, near Bill Lake Camp, and on the Little Tujunga - and evaluated to determine whether they would have a significant impact on flooding; that is, whether their maximum potential capacity would be adequate to affect peak flows. An analysis indicated that these reservoirs would be at or near capacity when peak inflows were experienced and, therefore, that they would have virtually no impact on peak flow into the major downstream reservoirs (Sepulveda and Hansen Reservoirs). In addition, their estimated costs were high, and there was potential for significant environmental and recreational impacts.

None of the new dam alternatives would have allowed outflows from Hansen or Sepulveda reservoirs to be reduced enough to have an effect on downstream flooding problems. For example, even a reduction in releases from Sepulveda Dam of 20% (3300 ft^3/s) would have only minor impacts on downstream flows because local runoff increases flow in the mainstem by as much as 40,000 ft^3/s.

A new reservoir was considered in the watershed above Devil's Gate Dam on Arroyo Seco. Such a reservoir would reduce flooding to some extent in the downtown Los Angeles area, but would not have a major impact on the lower Los Angeles River where the flooding problem is greatest. Thus there would be relatively high costs and environmental impacts without offsetting flood control benefits.

In the upper San Gabriel River watershed, several sites were evaluated. In this watershed, the major dam sites have already been used, and the remaining sites would have little storage and thus little impact on downstream flooding.

In short, new dams in the upstream canyons were found to have too little storage to provide significant flood control benefits. At the same time, they would have had high costs and potentially high environmental impacts.

New dams were also briefly considered below the existing major reservoirs, for example, on Tujunga Wash below Hansen Dam and on uncontrolled tributaries such as Compton Creek. A brief survey of the potential sites, none of which held much promise as dam locations, indicated that a facility large enough to have an effect on flows downstream would require acquisition and clearing of heavily urbanized areas. The cost of this would be prohibitive given the high value of commercial property in the potential storage areas. Therefore, new dams were eliminated from further study.

Detention Basins

Where adequate land is available, peak flows may be directed over a weir or through an inlet structure to detention basins. This effectively reduces the flow moving through downstream channel reaches and thus prevents channel capacity from being exceeded.

Several detention basin sites were identified in the upper reaches of the Los Angeles River system, and these were evaluated to determine the feasibility of diverting peak flows to them (Table 6).

Table 6. Detention basin sites/gravel pits considered.

Project Reach	Detention Basin	Potential Size Acres	Potential Size Storage	Conclusions
1	Pacoima Spreading Grounds	153	2,200 af	Not cost effective
1	Tujunga Wash Spreading Grounds	188	2,000 af	Not cost effective
2	Taylor Yard	200	5,200 af	Not cost effective
8	Livingston Gravel Pits	415	29,000 af	Not cost effective
8	Conrock Gravel Pits	365	30,000 af	Not cost effective

Pacoima Spreading Grounds. The Pacoima Spreading Grounds are a 153-acre site located off the Pacoima Wash in Reach 1 of the LACDA System (see Figure 6). During initial plan formulation, a weir to direct flow to the spreading basin was investigated which would require excavation of the existing grounds to a depth of 15 feet and would entail removal of approximately 4,600,000 yds^3 and provide storage of 2,200 acre-feet at a cost of almost $24,000,000 ($5/yd^3). Greater excavation depths are not feasible or consistent with water conservation operation of these areas. Initial evaluation of this alternative indicated a benefit-to-cost ratio of greater than one-to-one, but later evaluation determined that costs would greatly exceed benefits.

The more detailed review of this alternative determined that, to accommodate the peak flow and volume necessary to significantly reduce flooding downstream, a 2-mile weir would be required. Due to the fact that the site cannot accommodate a 2-mile weir, an inlet structure would need to be designed instead to intercept floodflows on the wash and deliver them to the basin at a rate of 9600 ft^3/s. This inlet structure raised estimated project costs significantly.

A second problem was the need to drain the detention basin rapidly after each flood event. The general winter storm pattern in southern California is often characterized by a series of storms sweeping out of the north or central Pacific at one- to five-day intervals. This occurs when the Pacific High locates to the south and east of the area, permitting a regular sequence of storms to penetrate to the south. Under such conditions, it is possible for one flood event to be followed relatively rapidly by another significant storm. To retain flood control capacity in dams and detention basins, it must be possible to draw them down within several days. Thus the detention basins would have to be connected to the local storm drainage system, which would require significant upgrading of the system. This requirement also added to the preliminary costs. Impacts, both positive and negative, to the existing water spreading activities were not evaluated in detail.

Finally, a detention basin in this reach would have only very limited benefits for the downstream Los Angeles River reaches where a majority of damages occur. Detention would have to be justified on the basis of Tujunga Wash flood control benefits alone.

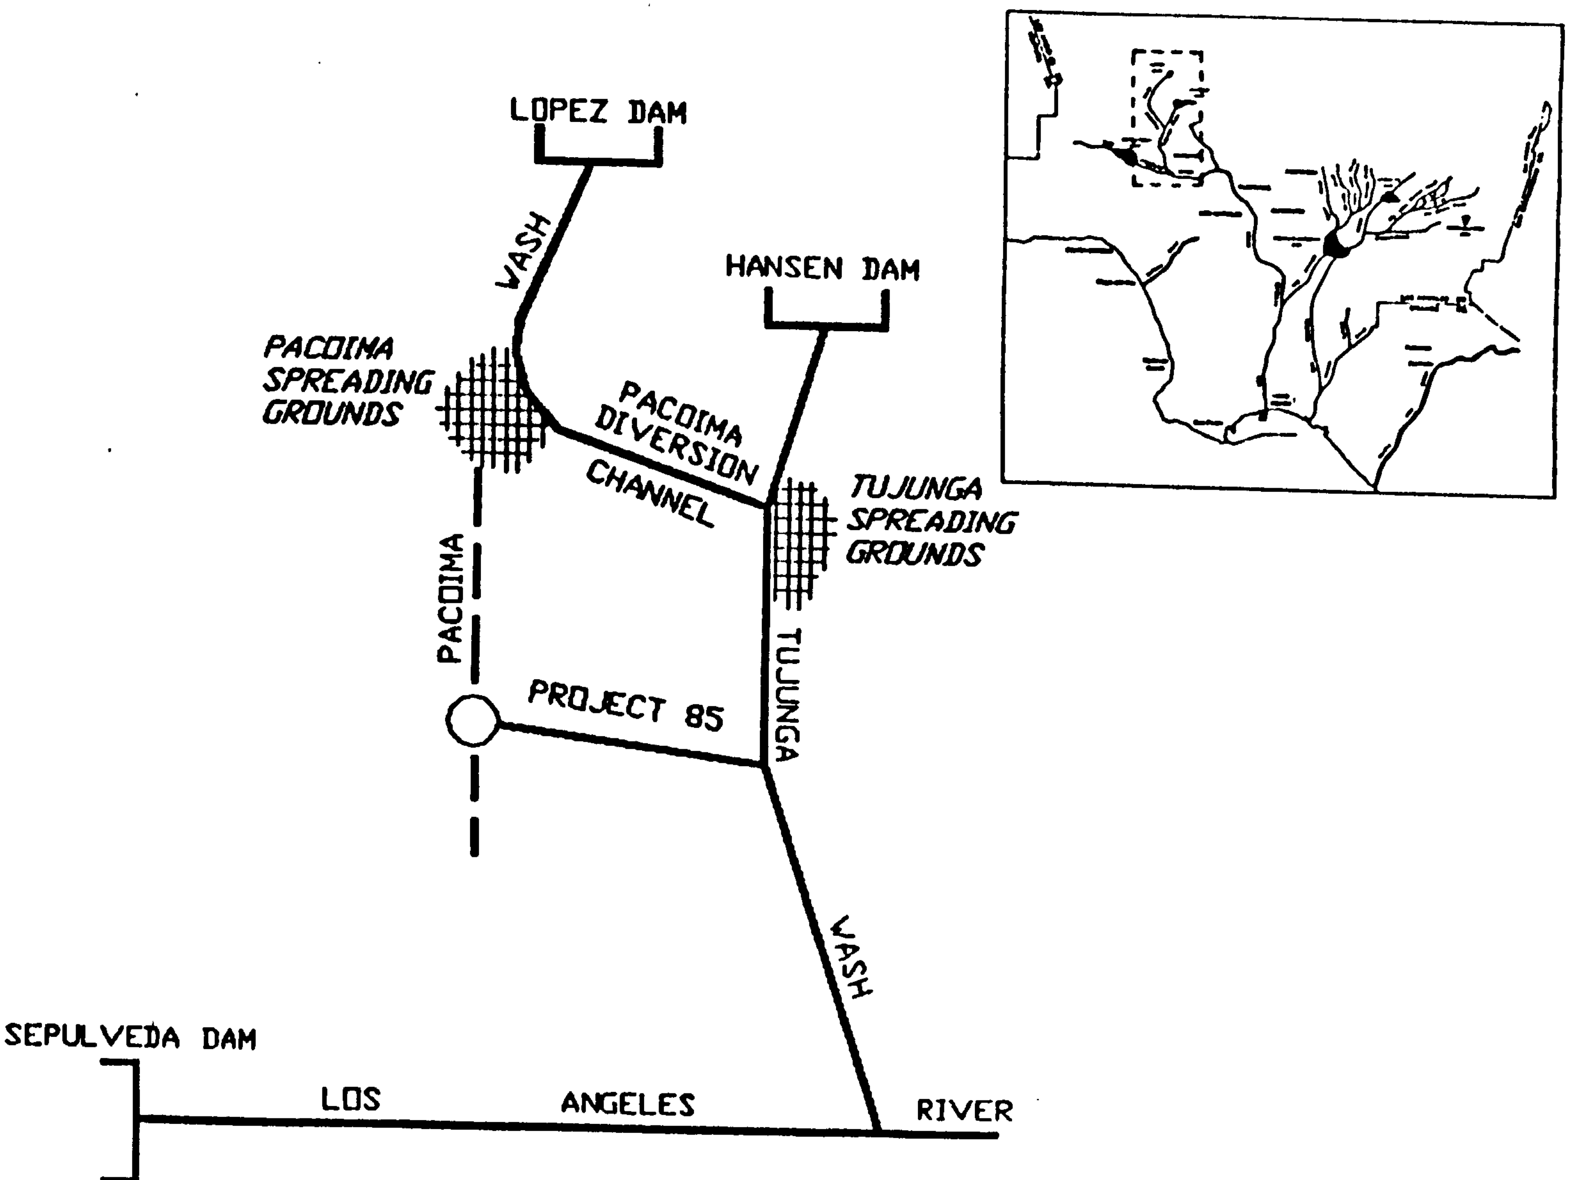

FIGURE 6 LOCATION OF POTENTIAL DETENTION BASINS AFFECTING TUJUNGA WASH

Tujunga Wash Spreading Grounds. This 188-acre spreading ground is located south of the Highway 101 and Interstate 5 interchange several miles south of Hansen Dam (see Figure 5). The existing inlet works have a capacity of 400 ft^3/s, and the spreading grounds have a capacity of 390 acre-feet. Deepening this area by 11 feet by removing 2.5 million cubic yards of earth would increase this capacity to 2,000 acre-feet.

This alternative shared the disadvantages of the Pacoima Spreading Ground alternative: It was costly and would have a limited impact on peak flows. As a stand-alone alternative, it was eliminated from further consideration.

Pacoima/Tujunga Basins Combined. Although each spreading ground would, by itself, have little impact on flood flows, a combination could reduce peak flows (at least for a period of time) by at least 9,600 ft^3/s and provide off channel storage of over 4,000 acre-feet.

This combination was evaluated, with the following conclusions:

1) Partly because of the cost of inlet and drainage structures, the cost of the combined alternative would be quite high, even without considering complex drainage structures;

2) The reach of Tujunga Wash where benefits would be realized currently has 70-year protection;

3) Therefore, annual NED benefits from the project would be exceeded by annual costs, and the benefit to cost ratio of the alternative would be substantially less than one-to-one.

Taylor Yard Detention Facility. The Los Angeles River flows out of the San Fernando Valley through a low-lying area bounded on the west by the Golden State Freeway and on the east by San Fernando Road. In this area, there is a railroad yard and a number of aging commercial structures. If cleared, excavated, and used for off-channel

VOL 12

1

5993

detention, this low-lying area could accommodate approximately 5200 acre-feet of storage. This would reduce peak flows into the downtown Los Angeles area.

Detention at this site would have only a minor impact on overall downstream flooding and minimal impact on damages because predicted depths in the downtown area which would be protected are not great and damage is estimated to be minor. It would not significantly reduce peak flows breaking out of the channel in the lower Los Angeles River; it would thus raise levels of protection only marginally. For this benefit to be achieved, a commercially valuable industrial and commercial area would have to be taken at significant cost. Weighed against the high social impact and the $60,000,000 cost of acquiring and excavating the basin (initial cost estimate), it would thus not be a justified project element.

Gravel Pits

Livingston-Graham and Conrock Sites. Gravel mining near Santa Fe Dam has created extensive gravel pits in the vicinity of the San Gabriel River. Two large, well situated pits have a combined capacity of over 59,000 acre-feet of storage. Mining operations at these pits are scheduled to be terminated after the turn of the century, and therefore they will be available for other uses. This is a significant potential off-channel storage area, given that the total capacity of the Corps flood control dams is about 120,000 acre-feet.

The gravel pits would have to be modified to be used for flood control. The existing quarries have nearly vertical walls which would have to be altered to a 2:1 (about a 33° angle) slope for stability. The poorly consolidated alluvium would be subject to slumping if the porous material surrounding the pits were saturated due to high groundwater or short-term flood water impoundment. The current walls are close to the San Gabriel River, the San Gabriel Freeway and local surface streets, any of which could be jeopardized by a significant wall failure.

Inlet weirs or pipelines would be constructed to divert flows into the gravel pits from the mainstem San Gabriel River. For these to be effective, they would have to be sized to accommodate flows of about 20,000 ft^3/s.

Additional modifications would have to be made to permit the gravel pits to drain rapidly following a major storm. This is necessary to restore storage capacity in anticipation of a subsequent storm event. Other major flood control facilities in the Los Angeles basin are designed to be drained in as little as two days; this is important because precipitation in southern California is often characterized in the winter by a series of storms, with storms arriving at intervals of one to five days. Modifying the gravel pits for drainage would require a tunnel to be constructed to a downstream point along the river below the grade of the gravel pit bottom; a long and costly tunnel would thus be a feature of this alternative. Other modifications might be needed, but these major features were considered in preliminary cost estimates.

Initial study indicated that the gravel pits would have a significant impact on volume inflow into Whittier Narrows Reservoir and could therefore reduce the scheduled releases from that facility to the Rio Hondo channel. The projected reduction in release to the Rio Hondo was up to 8,000 ft^3/s. This would eliminate the current inadequacy in channel capacity on the Rio Hondo but would not fully alleviate the flooding problem on the Los Angeles River. An initial decision was made to pursue this alternative further because of the high potential for both flood control and water conservation benefit. The cost of the storage was undefined at the time this decision was made. This alternative was not carried forward for detailed design and analysis, however, due to several factors:

1) There would be a significant cost in acquiring the rights to the gravel pits because current operators would have to be compensated for loss of potential income. The period of time projected for profitable operation is uncertain, but may extend well into the proposed flood control project's period of operation.

2) The City of Irwindale has developed plans for use of these gravel pits for other purposes, including filling the pits and developing them for commercial ventures. An area of existing groundwater would also be used for recreational purposes.

Use for flood control would complicate these plans and benefits from flood control use would have to be compared to the opportunity costs of more intensive development of the sites.

3) While reduction of inflows to Whittier Narrows Dam would possibly reduce the need to improve the Rio Hondo channel, it would have a less significant impact on the lower Los Angeles River because that problem is primarily a result of accumulated, uncontrolled drainage. Flood control benefits would thus be mainly limited to the Rio Hondo channel. The gravel pits are also located sufficiently upstream from the primary flood damage areas such that they do not provide an operationally flexible solution to downstream flooding compared to improvements closer to the inundated areas.

4) Grading to stabilize the gravel pits' side slopes would involve moving large quantities of material. Grading operations might require hauling material to other disposal sites or placement of any excess spoil in the pits themselves, thereby reducing the projected effective capacity of the pits. Movement of large quantities of material is generally very expensive.

5) Drainage of the pits within a short period of time would require a costly outlet works to be constructed. Pumps were initially considered but rejected because they cannot be relied on, especially given that they would remain idle for periods of 20-30 years. Tunneling was the preferred alternative, but the proposed tunnel would have to extend six miles to Whittier Narrows. An initial cost estimate of $100 million (excluding rights-of-way) raised total project costs significantly.

Based on an initial analysis, use of the gravel pits near Santa Fe Dam was not considered economically feasible.

<u>Strategy One (A) Summary: Integrate Flow-Retarding Facilities Into the System</u>

In part because of the nature of the flooding problem in the LACDA system and in part because of the lack of effective and cost-efficient sites for detention basins, no alternative involving new flow detaining facilities was carried forward for detailed analysis.

Strategy One: Reduce Inflow to Mainstem System

B. <u>Modify Existing Facilities</u>

Modify Existing Dams

Corps Facilities. There are a number of modifications possible at existing Corps flood control reservoirs: (1) increasing dam height and, as a result, reservoir capacity; (2) excavation of the basin to increase capacity; and (3) alteration of gates and spillways.

At Sepulveda and Whittier Narrows, raising the dam height was considered. Small increases in dam height at these sites would produce significant increases in storage because of the flat slope of the reservoir basin. This option was less attractive at Hansen and Santa Fe dams because those dams provide a satisfactory level of protection, and raising the dam would have only marginal impacts on total flood control storage. At the two potential sites, however, the cost of raising main embankments would be quite high because of the length of the embankments. In addition, development has occurred at the margins of the existing reservoirs, and raising the dams would mean that this urban development would be inundated during a significant flood. Acquisition of this property would be required, and this would not only be costly but disrupt existing communities. This option would be prohibitively costly and unacceptable, and it was therefore eliminated from further study.

Excavation in the reservoir to deepen it and thereby increase capacity was not considered at Sepulveda and Whittier Narrows reservoirs because of the extensive environmental and recreation development in these reservoir basins. It was considered at Santa Fe and Hansen Reservoirs where planned or existing excavation activities have already impacted some of these resources and where there are large areas which would be excavated.

Excavation is an extremely costly approach to increasing reservoir storage. Costs may be as high as several dollars per cubic yard excavated, and there are additional costs for hauling to a disposal site. Removal of a significant amount of sediment, enough to have an impact on downstream flooding, would involve increasing storage by more than 10,000 acre-feet. This is equivalent to approximately 50 million cubic yards, making costs for such a project exceed several hundred million dollars. This additional storage could not be below the existing grade of the outlet gates as it would not be drainable and would thus not be available for flood control. Providing new gates to solve this problem would be difficult and cost prohibitive. First, new gates constructed below the existing gate elevation could involve changes to the reservoir foundation. Second, new gate construction would be very costly, adding to the already high cost of sediment removal. Thus, excavation would have to occur in the upper elevations of the basin, away from gates and existing maintenance sediment removal operations.

Disposal of approximately 50 million cubic yards of spoil from this alternative would also have very significant costs. Available landfill sites are reaching capacity in Los Angeles, and the cost of hauling to sites outside of the basin would be prohibitive. It is unlikely that a suitable existing landfill site could be identified within an economical haul range. Creation of a site would have significant environmental consequences.

Sediment buildup behind the two dams in question is also an ongoing process. There are a number of factors which could cause massive sediment movement into the reservoirs prior to a significant flood event, which would therefore eliminate the excavated storage prior to peak flows. As such, this solution to flooding problems is not wholly reliable. Additionally, increasing storage in the upstream dams will not significantly affect the overall flooding condition. A reduction in reservoir releases of 4,000 ft^3/s during the 100-year event at Hansen Dam would require extensive excavation and yet would not compensate for the massive inflows to the system occurring from local drainage in downstream reaches.

Finally, Hansen Dam already provides control of the 200-year flood. Increasing its capacity would have very little effect on flooding on Tujunga Wash or reaches below because the flooding is a result of increased local drainage. Thus, excavation to increase reservoir capacity is cost prohibitive, ineffective, and potentially environmentally damaging at both the reservoir site and any disposal site. No excavation alternative was carried forward for final analysis.

Altering outlet structures may reduce net outflows from the reservoirs under some conditions and thereby somewhat reduce peak flows throughout the river system. This was initially considered at Sepulveda because its spillway design limits the ability to hold back flows from the reservoir. At this site, the gates and spillway could be modified to permit some reduction in outflow. However, significant reductions in outflow from the gates would not be possible because retaining additional water behind the dam to reduce peak flows early in a flood would increase the possibility of greater flooding later if inflow continued to exceed outflow.

In addition, gate/spillway alterations affect releases from the reservoirs only, and do nothing to solve the problem of increased local drainage flows in the lower river basins. Only a minor reduction in outflow is possible through gate/spillway modifications, and therefore there is only a very small benefit to be achieved. The cost of gate modifications is high as well.

Devil's Gate Dam. Devil's Gate dam on Arroyo Seco in Pasadena controls a watershed of approximately 32 mi^2. Reducing inflows to the Los Angeles River from this source would provide some additional protection to downtown Los Angeles. Reducing inflows from Arroyo Seco would mean that the reach of the Los Angeles River near downtown would be able to accommodate more of the local drainage. However, modification to Devil's Gate Dam would not reduce flows on the lower Los Angeles River enough to compensate for the massive local drainage inflows in that reach, and would therefore have only a minor impact in the area of greatest potential flood damages.

Devil's Gate Dam is currently operated under restrictions imposed by the State of California. It is unlikely that the renovations necessary in order to incorporate this facility as a flood control element would be an appropriate option. Removal and reconstruction might be considered, but given the existing need for operational restrictions, it might not be acceptable to reconstruct a facility on this site. The dam also has lost much of its capacity due to sediment buildup. Devil's Gate Dam is controlled by Los Angeles County, which has studied plans for both rehabilitation and replacement, and they have concluded that maintenance of the existing facility is the appropriate action at the present time. Therefore, modification/replacement of this facility was eliminated from further consideration.

Strategy One (B) Summary: Modify Existing Facilities

The impact of increasing upstream flood control storage does not result in significantly reduced flood flows downstream, due to inflow from uncontrolled, local drainage. As a result, no modification of existing reservoirs was found to make a significant contribution to a complete, cost-effective, acceptable plan for solving the flooding problem in the LACDA system.

Strategy Two: Convey More Water in the Mainstem System

A. Create New Conveyance Facilities

Pipelines

There are a number of ways of diverting flows from the LACDA system to reduce peak flows in the channels where capacity is too low to provide adequate protection. Transfer of water from one watershed to another via pumping stations/pipelines was initially given brief consideration, a possible alignment being from the LACDA basin to the Antelope Valley. This alternative, along with a diversion to Ballona Creek, was eliminated from consideration as a result of very high costs involved in moving the significant volumes of water needed to affect peak flooding. In addition, system maintenance costs would be extremely high because pumping facilities deteriorate when not in use.

Diversions of Rio Hondo releases to San Gabriel River

Transfer of flows at Whittier Narrows Dam from the Rio Hondo to the San Gabriel River was studied in somewhat greater detail. At present, the Rio Hondo is designed to receive all primary flood control releases from Whittier Narrows Dam. The original design of the Rio Hondo allowed for Whittier Narrows Dam flood control releases of 40,000 cfs. Due to increases in local inflow to the channel, the current maximum release rate into Rio Hondo is 36,500 cfs. The San Gabriel River below Whittier Narrows is essentially a spillway flow channel for Whittier Narrows Dam. Scheduled releases of 5,000 cfs are routinely made from Whittier Narrows Dam when the water surface elevation is between 200 ft and 228.5 ft NGVD (National Geodetic Vertical Datum). The gate invert on the Rio Hondo side is at elevation 184 ft and a pool 16 feet deep must be impounded before the San Gabriel outlet sill of 200 ft is reached. Above elevation 228.5 ft, the automatic spillway gates on the San Gabriel River outlet go into effect, and release rates escalate rapidly.

Initially, it appears that greater routine releases could be made to the San Gabriel River because the scheduled release of 5,000 cfs is lower than the receiving channel capacity of 13,500 cfs. This margin of 8,500 cfs is diminished in downstream locations by increasing local inflow. Above the confluence with Coyote Creek, the 100-year computed flow on the San Gabriel River is 17,200 cfs and the channel capacity is 20,000 cfs, leaving a margin of only 2,800 cfs. In order to convey substantially greater flood control releases, a significantly lower level of protection would be provided by the river channel, or it would require a structural upgrade to increase its capacity.

Expanding primary flood control releases to both the Rio Hondo and the San Gabriel River could shift flooding from one area to another, which would require extensive improvements to the San Gabriel system. It was not considered appropriate to solve a flooding problem by transferring the problem, and the associated damages, to another system. Therefore, in order to redirect some of the Rio Hondo flows, the San Gabriel River would most likely be converted from a soft-bottomed channel to a concrete invert channel and the channel capacity would have to be otherwise increased.

Immediately downstream from Whittier Narrows Dam the San Gabriel River is soft-bottomed channel for 7 miles. The remaining concrete channel is trapezoidal and extends 13.2 miles to the ocean. Converting the upstream reach to concrete channel would increase capacity from 13,500 ft^3/s to approximately 31,000 ft^3/s. This increase in capacity would have to be implemented through the remaining channel. Using parapet walls was determined to be the most cost-effective method of accomplishing this; this would require raising 22 bridges from 1.2 feet to 6.9 feet.

Increased San Gabriel River capacity would allow operation of Whittier Narrows Dam to be modified; the optimal theoretical use of the additional capacity in the San Gabriel River would mean filling the reservoir to 99% capacity during the 100-year event and limiting releases to the Rio Hondo channel to as little as 15,000 ft^3/s. This would eliminate the need to modify the Rio Hondo channel. There would still be significant flooding on the lower Los Angeles River, and protection would remain below the 100-year level. Furthermore, balancing releases to the two channels would require excellent field information and precise operational control, both of which are difficult to achieve during emergency operations.

The cost of improving the San Gabriel River would not be equally offset by reductions in costs on the Rio Hondo and Los Angeles River. In addition, the soft-bottomed reach of the San Gabriel River is a major environmental and groundwater recharge resource. Compensation for loss of groundwater recharge potential may require a 200+ acre parcel of land or provision of other, less expensive water supplies. Loss of any environmental resources would also require mitigation.

Finally, simultaneous work on the San Gabriel and lower Los Angeles Rivers would mean traffic impacts on two sets of bridges and general neighboorhood disruption in two areas rather than one. Given that the Rio Hondo-lower Los Angeles River channels are generally in a more disturbed urban (commercial and industrial) environment, the social impacts of construction in these areas would be lower than for the more residential San Gabriel River area.

There would thus be no cost advantage to diverting releases to the San Gabriel River, and the channel modification impacts would be greater than those experienced on the Rio Hondo-lower Los Angeles River. For these reasons, diversion of flows to the San Gabriel River, with attendant channel alterations of any sort, were considered to be unjustifiable.

Tunnels

A tunnel could be constructed along three possible alignments to divert water from either reservoirs or the mainstem channel system (Figure 6). A tunnel from Sepulveda Dam could divert water through the hills separating the San Fernando Valley and the Los Angeles basin and from there into the Pacific Ocean. Alternately, flow could be diverted from Arroyo Seco across the basin to the ocean. These alignments could reduce inflows to the mainstem Los Angeles River by up to 20,000 ft^3/s. A third alignment would involve diversion of flows from the Rio Hondo to Long Beach, virtually paralleling the river alignment.

An initial benefits analysis indicated that there would be only marginal benefits (annual benefits of only $1,620,000 for a 20,000 ft^3/s tunnel) from a diversion of water from Sepulveda Dam, and this option was dropped from consideration as costs would clearly exceed benefits. Potential benefits resulting from a tunnel of this capacity from the Arroyo Seco or the Rio Hondo were much more significant and a preliminary cost estimate was made to determine if tunnels were worthy of detailed consideration. The screening analysis was conducted for tunnels of 5,000, 10,000, and 20,000 ft^3/s capacity. For purposes of simplifying the analysis, the tunnel with the shortest route (which would have the least cost) from the Rio Hondo was evaluated (Table 7).

A large tunnel from either diversion site would have a significant impact on flooding. However, construction costs would be extremely high. Costs for the estimates shown on Table 7 were developed using current construction cost data from the Los Angeles Metrorail project and thus represent costs associated with tunneling under existing development in the Los Angeles basin.

Table 7.

Tunneling alternatives, benefits and costs (1988 $1,000)

Alignment and Capacity	Average Annual Benefits and Costs: Benefits	Costs	Net Benefit	B/C Ratio
Rio Hondo[a]				
5,000 ft^3/s	$13,480	$34,015	<$20,535>	0.40
10,000 ft^3/s	$19,730	$41,689	<$21,959>	0.47
20,000 ft^3/s	$25,980	$65,458	<$39,478>	0.40

a. Tunnel diversions from two other locations were also considered: a tunnel from Sepulveda Dam to the ocean and from Arroyo Seco to the ocean. These tunnels would have been longer and more costly than a tunnel from the Rio Hondo; they would also likely have either comparable or lower benefits. The Rio Hondo tunnel alternative was thus considerd to have the greatest potential for net NED benefits. Given that this preliminary analysis indicated a very low benefit-to-cost ratio for this alternative, the other tunnel alignments were also eliminated from further consideration.

Based on this preliminary design/cost analysis, it was apparent that even the shortest, least-costly tunnel alternative could not be justified when considering first costs alone. Operation and maintenance costs would further reduce the benefit-to-cost ratio for such a project. The heavily developed nature of the flood plain which raises construction costs due to the difficulties of tunneling in a developed area, thus makes tunneling an impractical alternative. Finally, it was also clear that a tunnel would not fully address the need for flood control in the lower Los Angeles River; additional structural works would also be required. Tunnels were therefore not carried forward for more detailed analysis.

New Channels and Aqueducts

New channels and aqueducts were considered, but a review of the LACDA system indicated that there are few alignments which would not pass through heavily developed areas. The most effective alignment for additional conveyance capacity is on the lower Los Angeles River, where the most efficient river course is the existing alignment. The costs of rights-of-way for new channels along other alignments when combined with the construction costs for new channels make this alternative too costly. In addition, new channels would severely disrupt existing neighborhoods. New channels were therefore eliminated from consideration.

There were similar constraints on potential aqueduct alignments within the LACDA system. One alignment considered would divert water from Lopez Reservoir to an aqueduct along a utility right-of-way and empty into Hansen Dam. This would reduce releases from Lopez Dam down Pacoima Wash. The additional flow into Hansen would not critically affect its storage capacity, but further analysis revealed that diverting releases from Lopez would not significantly reduce flooding on Tujunga Wash.

Aqueducts which are constructed over uneven ground require grade adjustment and significant new rights-of-way. Construction costs are quite high for this type of structure. After a cursory review of possible aqueducts, they were rejected as infeasible.

<u>Strategy Two (A) Summary: Create New Conveyance Facilities</u>

Diversions, including greater use of the San Gabriel River for primary flood releases from Whittier Narrows Dam, were not considered viable alternatives. New channels are prohibitively expensive. No alternatives were carried forward from this strategy.

Strategy Two: Convey More Water in the Mainstem System

B. Increase Existing Channel Efficiency

Alter Existing Channels

Channels may be altered in a number of ways to meet various project objectives. In the initial stages of planning, alteration of the channels solely for water conservation and environmental enhancement purposes was considered briefly. Alternatives included removing concrete channel inverts and perforating the inverts to permit groundwater recharge through the channel bottom. This type of alternative would have net adverse impacts to flood protection, however, because it would reduce the rate of flow in the already inadequate channel. Small sections might be feasible, but costs would be high with only minimum water conservation benefits; such approaches would need to be a part of a flood control alternative and not a stand-alone alternative.

There are a number of specific ways to increase the net capacity of the channel: raising channel walls, widening the channel, converting the channel from trapezoidal to rectangular, deepening the channel, changing the channel slope, and removing obstructions from the channel area. All of these techniques share the basic purpose of increasing flow in the channel by changing cross-section and/or slope. This group of alternatives was carefully explored during initial screening to determine which approaches would be best to pursue in detailed studies.

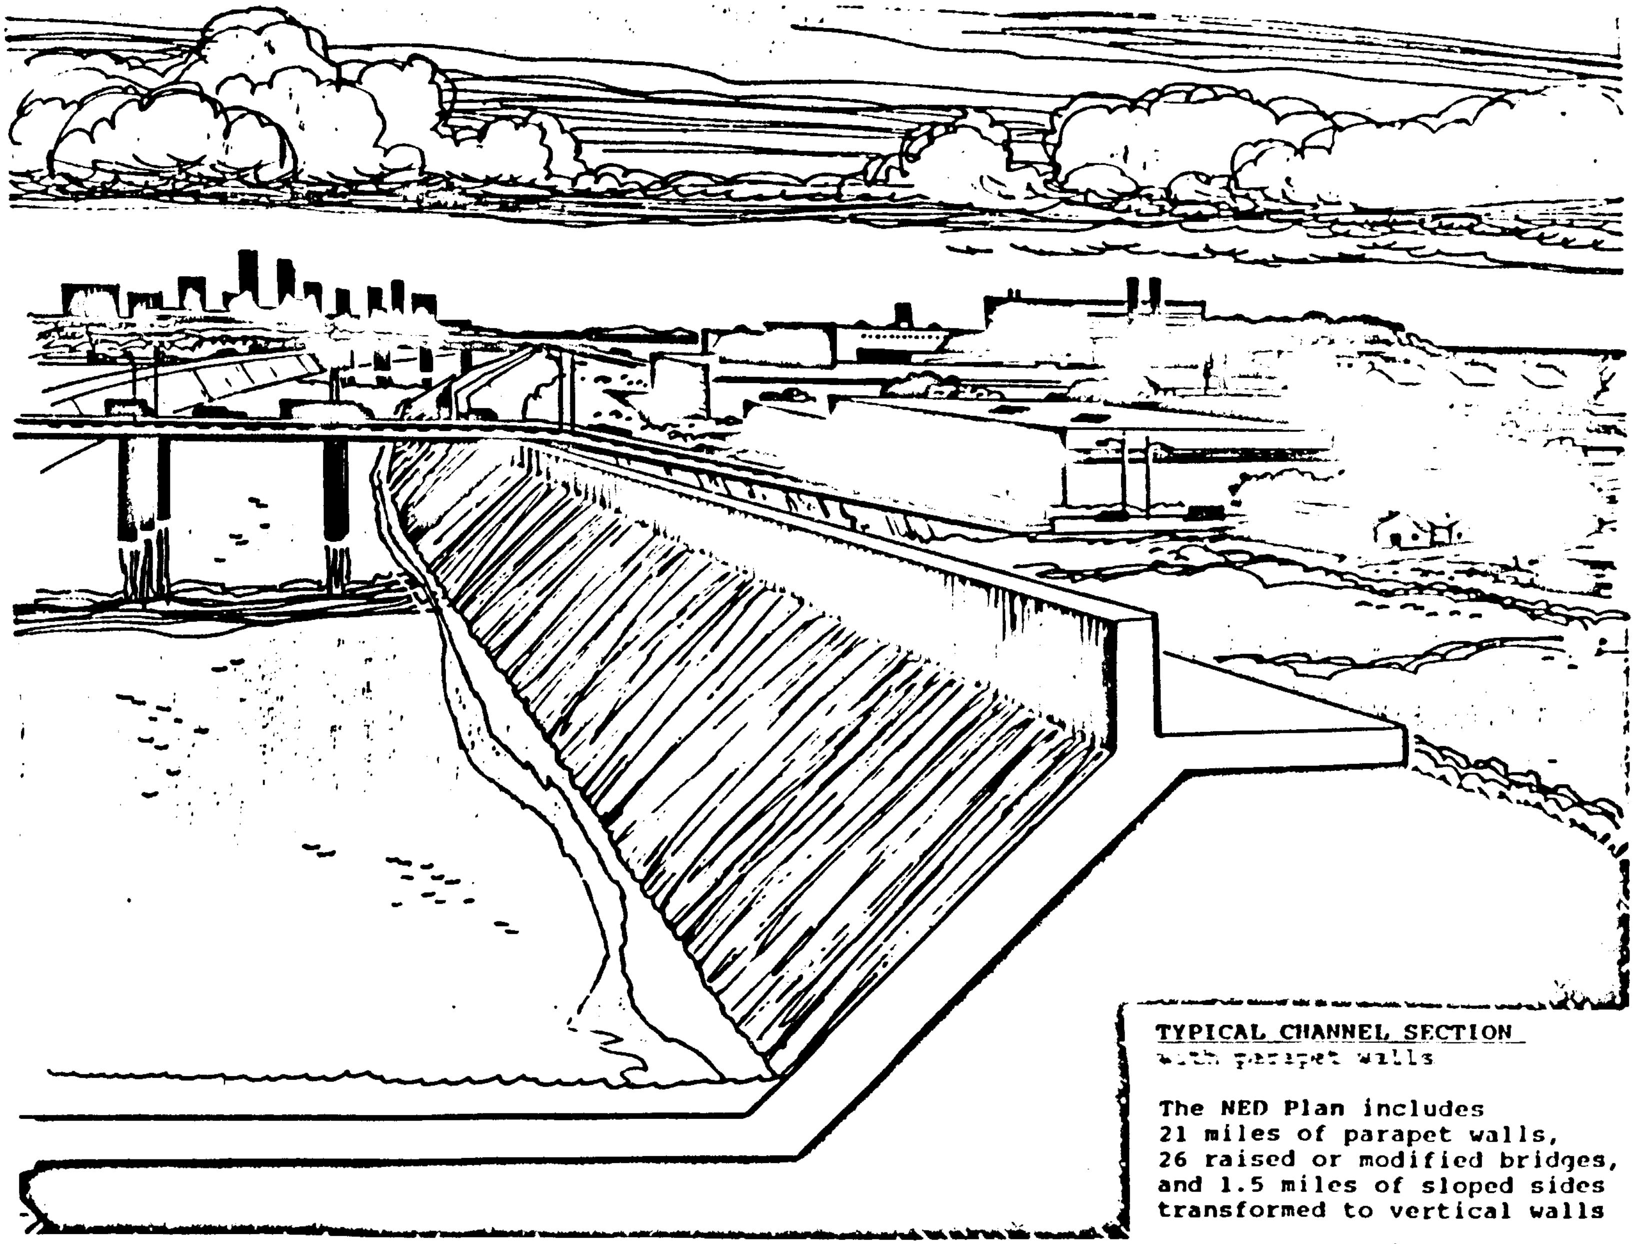
Raise Channel Walls. There are several ways to raise channel walls. First, the entire levee embankment can be raised. To accomplish this, the paved crest of the levee is removed and additional fill is placed on the crest and the levee back slope to raise the embankment to the desired height and widen the levee for stability. The crest pavement is then replaced. In many locations, raising the levee requires bridges to be raised because the low point of the bridge structure is the top of the existing levee. The disadvantages of raising levee walls are cost, encroachment onto limited rights-of-way, and the need to extend bridge span lengths and change abutment and pier structures because the levee crest is shifted away from the center of the channel.

A second approach is to construct parapet walls along the inner (channel side) edge of the existing levee crest. To accomplish this, the paving at the edge of the channel is removed, and a reinforced concrete foundation and wall is poured (Figure 7). This option also requires many bridges to be raised but, for the most part, does not require as many alterations in bridge abutment and pier alignments. Therefore, parapet walls are a less costly approach to raising channel walls.

Raising channel walls was evaluated for Reaches 1-5 (Los Angeles River-Rio Hondo system). In initial planning two levels of protection were evaluated to give a preliminary indication of the feasibility of this alternative: 100-year and 200-year protection. In all reaches where the river is an entrenched channel and overflows are confined to relatively narrow corridors adjacent to the existing channel right-of-way (Reaches 1-3), raising channel walls was found to have costs far exceeding benefits. For these reaches, the best preliminary benefit-to-cost ratio estimated was 0.6 for 200-year protection for Reach 1, Tujunga Wash from Hansen Dam to the Los Angeles River. For other reaches, benefit-to-cost ratios ranged from 0.1 to 0.5.

In the lower reaches of the river where levee armoring for protection of the exposed back side of the levee was an added design element, the initial economic analysis indicated that raising channel walls would have significant net NED benefits. Preliminary benefit-to-cost ratios for Reaches 4, 5, and 9 ranged from 3.1 for 100-year protection up to 4.1 for 200-year protection. For these lower project reaches, then, raising channel walls appeared to be a promising alternative; this alternative was carried forward for further consideration.

Widen Channel. Another possible approach to modifying the channel cross-section is to widen the channel while retaining the trapezoidal cross section of the channel. Channels may be widened in a number of ways. The most direct method is to remove existing walls, excavate, and reconstruct the channel. Another method is to construct a high flow system of side channels which run parallel to the mainstem channel and take flow only



TYPICAL CHANNEL SECTION
with parapet walls

The NED Plan includes
21 miles of parapet walls,
26 raised or modified bridges,
and 1.5 miles of sloped sides
transformed to vertical walls

FIGURE 8

when the capacity of the main channel is exceeded. A significant constraint on channel widening is the potential impact to existing bridges that would need to be reconstructed.

Side channels have the advantage of not requiring removal of the existing channel wall system, but the disadvantage of requiring additional rights-of-way and necessitating extensive bridge modifications. Because rights-of-way in most reaches of the Los Angeles River are severely constrained and their acquisition along with bridge modification would have very high costs, side channels were eliminated from further consideration.

A preliminary analysis of channel widening which would produce either 100-year or 200-year protection indicated that costs greatly exceed benefits in the upper reaches where the channel is entrenched and overflows are contained in a relatively small area. For example, widening of the reach from Sepulveda Dam to Arroyo Seco to provide 100-year protection would have annual flood damage reduction benefits of only $220,000 with annualized costs of over $15,312,000 for a benefit-to-cost ratio of less than 0.02. The net NED benefits of widening, again with the design feature of armoring the levee back slopes, exceed costs only in the lower reaches of the Los Angeles system, where the preliminary benefit-to-cost ratio was between 1.7 and 2.3. Channel widening was thus considered a potentially viable alternative in the lower reaches of the LACDA system.

Convert Trapezoidal Channel to Rectangular Channel. Modifying the channel cross-section can provide an additional conveyance capacity. Compared to a trapezoidal channel, a rectangular channel provides a larger area (channel cross section) for a given channel top width (and therefore right of way). Conversion would involve removal of channel walls, excavation, and reconstruction of the channel invert and walls with reinforced concrete. This is not an option on Tujunga Wash, where the channel is already rectangular, but it was evaluated for Reaches 2-5 on the Los Angeles River at 100-year and 200-year levels of protection. In some areas, these levels of protection could be achieved with a channel of composite geometry involving a partly rectangular and partly trapezoidal cross-section.

VOL 12

1 7/0/0

Conversion of trapezoidal channel to rectangular channel may, in some areas, permit channel capacity to be increased without affecting the bridges which span the river. This can be accomplished only if the conversion does not interfere with existing bridge piers and the abutment is set back from the edge of the channel. Some bridge abutments may be impacted by this alternative requiring reconstruction of the abutment.

An initial design and economic analysis indicated that the cost of constructing a rectangular channel would greatly exceed benefits except in the lower reaches of the Los Angeles River and along the Rio Hondo, where the project would include armoring of levee back slopes. In Reaches 4, 5, and 9 this conversion would be marginally justified with preliminary benefit-to-cost ratios of from 1.0 to 1.1. These benefit-to-cost ratios were substantially lower than those for lower-cost alternatives such as raising channel walls. This alternative would involve disposal of large amounts of concrete and excavated material taken from the old channel. Handling this material would be costly, and, given the limited availability of landfill sites in the Los Angeles basin, disposal might add significant cost if permits could not be obtained to use the nearest landfill sites. Nevertheless, the marginal justification of this approach in the lower reaches of the LACDA system resulted in a decision to carry channel conversion with armoring forward for further study.

Deepen Channels. In areas with adequate slope, it is often possible to deepen channels to increase the cross-section of the channel and therefore the channel capacity. Deepening, however, often has very high costs for several reasons. First, the existing channel slope must not vary too much or in such a way as to make this alternative impractical. Second, many existing utility lines run immediately beneath the channel invert and deepening thus requires extensive utility replacement. Third, deepening may require reconstruction of bridge piers and foundation works. Fourth, excavation and disposal of significant quantities of material is costly. For these reasons, deepening in most reaches of the LACDA system was not feasible. Deepening remained a consideration in Reach 4, the lower Los Angeles River.

In Reach 4, deepening of the downstream portion of the channel (Station 153+00 to the Pacific Ocean) would not involve the high cost of removing concrete invert as the channel is soft bottomed in this reach and protected by rip-rap. In addition, only seven bridges cross the channel in this reach. Thus construction costs were estimated to be in the $25,000,000 range for deepening this reach. Deepening this section would have uncertain impact on peak flows because the lower reaches of the channel have very little slope and seawater would move into the excavated channel area. Although the interaction of seawater with flood flows is not well understood hydraulically, additional net channel capacity would be expected from channel deepening. This alternative thus remained a viable option for further study, primarily in combination with other solution techniques.

Increase Channel Slope. Increasing flow velocity in the channel by increasing the channel slope has the effect of increasing total channel capacity. To effectively accomplish this, it must be possible to increase flow velocity throughout the entire reach from the initial point of channel slope modification to the ocean. If this cannot be done, it will be necessary to increase velocity through a developed reach where overflows would cause damages, and then make a compensating decrease in flow velocity in areas with greater channel capacity or increase the channel capacity to accommodate the higher water surface elevation. The uniform channel slope in the lower river (where most damages occur), makes this alternative infeasible. Increasing slope in an upper reach would merely increase problems in a lower reach. As a result, changing the slope of the channel was not given detailed consideration.

Armor Back Side of Levees. Under existing conditions, when flood waters in the leveed channel sections exceed the available channel capacity, water flows over the top of the levee and quickly erodes the unprotected, earthen levee back side. Levee failure leaves only the entrenched capacity of the channel to carry runoff to the ocean. The entrenched channel capacity is as much as 100,000 cfs less than the leveed channel capacity, causing the excess flow to pour into the flood plain. Armoring the back side of the existing levees was analyzed as an alternative that would protect against this catastrophic scenario.

Overflow areas were determined under the assumption that no levee failures occurred during events greater than channel capacity. Because armoring alone does not

VOL 12 1702

increase the level of protection offered by leveed channel sections, reaches with inadequate channel capacity still experienced levee overtopping for significant periods of time during the 100-year event. The overtopping problem is exacerbated by the fact that many bridges go to pressure flow which severely curtails their hydraulic capacity and creats an elevated backwater that pushes high volumes of flood waters out onto the flood plain. As a result, the areal extent of flood plain inundation due to overtopping was similar to the overflow area occurring with levee failure, although inundation depths were reduced.

The benefit resulting from a reduced flood depth was analysed as a stand alone alternative. The preliminary cost of armoring just the lower Los Angeles River was $24 million and resulted in a significant net benefit. Unfortunately, the Rio Hondo's level of protection is unimproved and the 25-year event still generates damages throughout the basin.

Armoring the Rio Hondo below Whittier Narrows Dam and the lower Los Angeles River would cost approximately $40 million and result in a benefit-cost ratio of greater than 6-to-1, although the net benefits are only moderate when compared to other alternatives. The greatest drawback to this approach, aside from it's failure to improve the existing flood frequency protection, is the fact that damages are significantly worse in the 50-year event. This results from the conveyance of all the flows that would have broken out of the Rio Hondo into the lower Los Angeles River. There the flows overtop the levees in numerous places, rather than only one location under the lower Los Angeles River armoring alternative. The flood plain damage locations shift downstream and are more severe than the lower Los Angeles River levee armoring alternative where breakouts and flooding are more evenly distributed on the system and less catastrophic in nature.

Levee armoring as a stand alone solution was not pursued as a comprehensive alternative because a) it shifted damages within the flood plain, b) it did not increase protection levels, c) it did not provide the greatest net benefits among the array of alternatives, and d) there were significant residual damages remaining in the basin.

Instead, levee armoring was analysed as a design element in all channel modification alternative

Reduce Channel Roughness. Some sections of the mainstem system have soft-bottom or cobblestone inverts and/or grouted stone channel walls. Use of these construction materials results in a high channel roughness coefficient and in turn reduces the channel's conveyance capacity. Providing a smoother overlay in these locations was investigated.

Constructing a concrete channel to replace the soft-bottom section of the San Gabriel River below Whittier Narrows Dam was disscussed previously, under Pipelines/Diversions. In the cobblestone Glendale section of the Los Angeles River, the existing vegetation is expected to either lay down as a smooth mat or be removed through scour during high flows. In either case, the channel capacity is not significantly reduced. Utilizing a concrete channel would be difficult due to the local high groundwater and the resulting environmental impacts. Trapezoidal, grouted stone channel reaches along the Rio Hondo and lower Los Angeles River could receive a concrete overlay to reduce the channel roughness. While this did not provide large increases in channel capacity, it was considered an effective element when used in combination with other channel modification techniques.

Modify Bridges

Bridges have an adverse impact on channel flows due to the backwater effect of piers and are a significant flood control problem when their abutments and/or piers constrict flow in the channel, when the lower deck of the bridge encroaches on the channel, or when piers catch debris and create a channel blockage. As a result, flood breakouts frequently occur in areas just upstream from bridge constriction points.

Eliminating all obstructions by completely reconstructing bridges so that there is a clear, high span with no piers extending from the channel is the best way to remove flow

VOL 12 1704

restrictions caused by bridges. This extremely costly alternative was not able to achieve an adequate level of protection in the mainstem channels. Upgrading of all bridges to clear span design as an overall flood control solution was eliminated from further consideration.

Less costly bridge modifications, such as raising spans and modifying bridge piers, were determined to be effective primarily in combination with other structural alternatives and were therefore carried forward as elements of other alternatives rather than as stand-alone approaches to flood damage reduction.

Strategy Two (B) Summary: Increase Existing Channel Efficiency

The cost and limited benefits of structural alterations to channels in the upper Los Angeles River system eliminated alternatives for these reaches. The existing adequate level of protection for the San Gabriel River and the very high cost and impacts associated with raising that level of protection eliminated structural alterations to the channel on this river system. Channel modifications, in particular raising channel walls and modifying the channel cross-section by either widening the channel or converting it to rectangular cross-section were found to have potentially large net benefits, either alone or in combination. Damage reduction measures that are limited in scope, but viable when combined with more comprehensive solutions include, deepening the Los Angeles River near its mouth, modifying bridges to improve conveyance, armoring levees to avoid catastrophic failure and providing grouted stone channel reaches with a concrete overlay.

Strategy Three: Damage Management

Non-structural or less centralized construction approaches are not generally effective in heavily developed urban areas with a large flood damage potential. They were given an evaluation, however, to determine if they could be useful components in an overall plan. The conclusions of this evaluation are listed below.

Relocation

Relocating structures threatened by flooding was considered in Reaches 1, 2, and 3 where the area flooded would be limited and relocations would be minimal. No relocation plan, however, had a benefit-to-cost ratio of greater than 0.04 (Tujunga Wash). This is due to the high cost of relocation, the value of the property in these areas, and the limited damages incurred. In downstream areas, relocation would be even less cost effective due to the very large area flooded.

Floodproofing

Floodproofing measures, such as raising structures above the flood plain, ring levees, and floodwalls, are too costly when applied to thousands of structures ranging from residences to major industrial plants to refineries. In addition, floodproofing is ineffective in areas such as the lower Los Angeles River basin where flood depths could exceed 10 feet and where flood flows from a failed levee would be extremely destructive in the vicinity of the levee break.

Floodfighting

To be effective, floodfighting efforts must be directed at preventing damage. Damage prevention requires adequate flood warning to permit evacuation and action to prevent major failure of the system. Given the short period of time - on the order of six hours - needed to reach peak flow and the many potential breakout points along the lower reaches of the LACDA system, it is not likely that breakout could be forecast precisely or that mobilization could occur rapidly enough to prevent overtopping of the levee system. In addition, flow over the levees in some locations could be several feet deep over a relatively long reach; a massive emergency response would be needed to respond to this magnitude of problem. Finally, there would be no assurance that floodfighting efforts would succeed.

Flood Plain Management/Insurance

There is significant damage potential within the existing flood plain. Continued efforts to avoid placing additional people and structures at risk will only marginally affect the current threat. The lower basin communities in the 100-year overflow area (except Downey and Bell Gardens) participate in a flood plain management program as part of the National Flood Insurance Program. While insurance coverage and risk assessment are appropriate endeavors in the flood plain, the magnitude of the flooding problem in the lower basin makes it imprudent to accept the potential flood threat. Prevention of damages is needed to ensure that major industrial areas are not severely damaged; the overall impact of flooding in the lower basin is too great for the entire region. Compensation for flood damages would also probably exceed several billion dollars following a major flood. This level of relief for damage which could be prevented at a much lower cost is unjustified.

Conclusions of Preliminary Screening

The primary conclusion of preliminary screening was that economically justified, effective flood damage reduction is limited to the Rio Hondo below Whittier Narrows Dam and the lower reaches of Los Angeles River. Measures in the upper basin either have an insignificant impact on the flooding problem downstream (caused by local runoff) or do not have adequate benefits within the upstream reaches to justify implementation. This is due to the nature of the problem on the LACDA system: rapid and massive local runoff swells the river at the point where it becomes a leveed system which can fail when overtopped. Also, it is not possible to constrain most structural approaches to a limited segment of the river channel where protection levels are low. Widening, deepening, and converting the channel from trapezoidal to rectangular all require increased conveyance capacity through the remaining downstream reaches. This raises the costs of an upstream alternative significantly. Because levee failure would inundate large areas to depths that could exceed 10 feet, damages are severe in the lower basin, and therefore justify structural measures.

Problems are not as serious on other reaches such as the Los Angeles River above the downtown area, where levels of protection range from 70-year to over 100-year. In these areas, damages would occur less frequently and would result in relatively minor residual damages such that extensive structural work is not justified. Nor is it justified to transfer damages from the Rio Hondo-Los Angeles River system to the San Gabriel River system, both from a policy view and from an economic view.

Innovative measures such as diversion tunnels, off-channel storage, and pumping to another watershed (Antelope Valley) or channel (Ballona Creek) would have the desired effect of reducing flows in the critical reaches of the channel, but costs would be prohibitive and would far outweigh projected flood damage reduction benefits. Other innovative approaches such as non-structural measures and watershed management were found to have negligible benefits at relatively high costs.

The result of initial screening was to focus the detailed alternative analysis on Reaches 4 and 5, and on three methods of modifying the mainstem channel: widening, converting trapezoidal channel to rectangular channel, and raising levee walls with parapet walls. Selective levee back slope armoring was included as a design element of each of these alternatives along with bridge modifications and concrete overlays for grouted stone sections. Deepening the channel bottom on the Los Angeles River near the ocean might also have a role in a comprehensive solution.

G. ALTERNATIVES CONSIDERED FURTHER

On the basis of preliminary screening and economic evaluation, improvements were found to be justified only for Reaches 4 and 5. The improvements given detailed study took the form of three different alternatives. All involved altering the flow characteristics of the lower Los Angeles River, which would in turn affect the water surface elevation along Compton Creek. Reach 9 was thus included in the detailed analysis of alternatives, with improvements in this reach generally limited to those that would be needed to compensate for impacts from the improvements on the mainstem system. All three alternatives carried forward for detailed consideration had two common elements:

1) Selected levee armoring in reaches where flows in excess of channel capacity were likely to break out of the channel.

2) Improvements to Compton Creek to compensate for potential impacts to this reach.

Each alternative was initially formulated at defined levels of protection, rather than optimized on a plan-by-plan basis to permit comparison on an equal basis. Given equal and already-defined levels of protection, it would be possible to evaluate plans almost entirely on the basis of cost. Environmental considerations would have a minimum impact on the cost or benefits from any project because all alternatives were confined to the existing channel rights-of-way or a thin strip of land immediately adjacent to the channel. Most of this land is already highly disturbed.

In addition, all alternatives would involve disruption of traffic and some utility relocations and service interruptions. Problems associated with issues such as disposal of materials excavated from the channel would be reflected in estimated project cost as well. None of the alternatives was thought to have a significant acceptability advantage compared to the other plans.

Given this approach, the least-cost alternative for a given level of protection would generally be the preferred alternative. This alternative could then be optimized to find the level of protection offering the greatest net NED benefits.

The alternatives evaluated (Figure 8A) in this final stage of plan development were:

1) Raising channel walls to provide 100/200-year protection.

2) Widening Reaches 4 and 5 to provide 100/200-year protection.
3) Converting trapezoidal channel to rectangular channel in Reaches 4 and 5 to provide 100/200-year protection.

H. EVALUATION OF ALTERNATIVES CONSIDERED IN DETAIL

ALTERNATIVE ONE: Raising Channel Walls in Reaches 4 and 5 100-year and 200-year Levels of Protection.

Placement of parapet walls along the crest of the existing channels (Figure 7) would effectively create a composite channel cross-section without requiring extensive demolition, excavation, and channel replacement. In most areas, walls would be raised only two to five feet to provide the desired level of protection. Raising the walls, however, means that all bridges currently built from the top of the existing levee or not providing adequate space to raise the channel height would need to be raised or otherwise modified. The considerable bridge-raising effort required for these alternatives is displayed in Tables 8 and 9 for the lower Los Angeles River and Rio Hondo, respectively. The economic question to be addressed, then, is whether cost savings for channel modification outweigh potential higher costs for bridge modifications.

As a part of this alternative, channel back slopes would be armored upstream of bridges and at the same potential breakout points in the Rio Hondo and lower Los Angeles River reach as provided for under other alternatives.

For these alternatives, an initial assumption was made that all bridges could be raised to any required level, including the freeway bridges (Santa Ana, Artesia, and San Diego Freeways). This assumption made it possible to evaluate levels of protection on the basis of cost alone.

- STEWART & GRAY IS NOT RAISED 0.3 FT

A total of 23.6 miles of channel would be included in this alternative; not all reaches would require increased wall height, and walls would taper to the existing levee surface in some reaches. The initial estimates of wall height to provide 100-year and 200-year levels of protection indicated that 200-year protection on the Rio Hondo would require walls less than 0.5 foot higher than for the 100-year level of protection. This is because releases from Whittier Narrows Dam are at the maximum during the 100-year event and do not increase for the 200-year event. On the lower Los Angeles River, the higher level of protection would require parapet walls from 2 to 4 feet higher than for the 100-year level of protection. Average wall heights for the reach would be from 2 to 5 feet, with the maximum height being approximately 8 feet. Parapet walls would have to be extended 900 feet up Compton Creek from its confluence with the Los Angeles River to accommodate the increased water surface elevation in the Los Angeles River.

The parapet walls would be one-foot-thick reinforced concrete. They would be placed at the inner margin of the existing access road/bicycle trail and joined to the edge of the existing channel side slope to form a continuous channel wall. The footing of the parapet wall would extend across the top of the levee and would be keyed into the top of the levee to resist sliding forces. The top surface of this footing would also serve as bike trail and maintenance access road.

Environmental Considerations

The actual parapet wall construction would have fewer construction impacts to the local area compared to the other alternatives, and there would be no significant disposal of materials from demolition and/or excavation. Traffic impacts would be approximately equal to or slightly greater than those of other alternatives. The parapet walls would not alter the existing soft-bottomed reaches of the lower river, and therefore would have minimal adverse impact in these areas. There would be a temporary increase in noise and dust during construction.

It is probable that there would be some recreation and aesthetic impacts. The walls would raise levee heights by up to 8 feet; for those residing along the river channel, this

VOL 12

would further block views. In some areas, the walls would add to an existing 15-foot high obstruction. Where local residents have constructed fences or planted shrubs and trees to obscure the view of the channel, the parapet wall would constitute a new intrusion. Aesthetic treatments to mitigate for this impact are limited. Additional plantings on the levee are hard to implement because they leave the levee susceptible to root damage and make detection of levee seepage difficult. Aesthetic treatment of the wall itself would be limited to texturing and painting. It is likely that in many places the wall would become a target for graffiti. The walls could also lower the aesthetics of the channel for recreation purposes. In areas where the walls are high, there would be no view across the channel. Aesthetic impacts would be greatest for the 200-year level of protection. These aesthetic impacts are unavoidable consequences of this approach to increasing channel capacity. Aesthetic treatment plans would have to be developed in coordination with local communities.

1 7028

Net Benefits

Based on preliminary designs, raising walls (plus armoring at selected sites) was found to be justified for the lower basin reaches, with benefit-to-cost ratios of from 3.1 (200-year) to 4.1 (100-year). On Reach 4 alone the benefit-to-cost ratios are 2.7 (200-year) to 4.0 (100-year). The greatest preliminary net annual benefits were for the sum of reaches 4, 5, and 9 with 100-year protection levels ($39,132,000). Estimated annual net benefits for this alternative were:

Reach 4:	100-year = $24,810,000;
	200-year = $23,250,000
Reaches 4, 5, and 9:	100-year = $39,132,000;
	200-year = $37,532,000

ALTERNATIVE TWO: Widening the Channel in Reaches 4 and 5
100-year and 200-year Levels of Protection.

This alternative is evaluated at two levels of protection, but there are relatively minor differences, so they may be described and evaluated together. The general technique involves removal of the existing leveed channel, setback of the existing levee, and reconstruction of the concrete trapezoidal channel. This also requires lengthening or raising numerous bridges and modification and realignment of bridge abutments and approach grades.

On the Rio Hondo, the 100-year channel design required up to an additional 56 feet in width; the 200-year, an additional 60 feet. The lower Los Angeles River 100-year channel design necessitates an additional 177 feet in the vicinity of the Century Freeway, the location needing the most widening. For the 200-year channel, an additional 237 feet in width is needed, and a longer stretch of channel is impacted. The wider 200-year-capacity channel also requires wider bridge spans and abutment modifications resulting in an increase in costs.

Two widening options were initially considered: widening along both sides of the channel and widening on one side only. Widening on one side was selected for detailed analysis because of the obvious cost advantages involved in having to remove only one channel wall. First, demolition costs would be reduced by one half. Second, the cost of channel wall replacement would be reduced by approximately 40 percent in most reaches due to a reduction in both quantities of materials and on-site preparation. In addition, the levee road on one side of the channel would remain intact and would thus not require replacement. Widening could affect bridge span length and approach slope and reconstruction of abutments would be necessary in some locations. Finally, many utility lines run parallel to the channel alignment and one-sided widening would reduce the number of utility line relocations, resulting in significant cost savings.

VOL 12

17029

As a part of this alternative, channel back slopes would be armored upstream of bridges and at other potential breakout points in the Rio Hondo and lower Los Angeles River reach. Also, reaches that currently have grouted stone sidewalls would be overlaid with concrete to improve the hydraulic efficiency.

VOL 12

Environmental Considerations

There would be no significant long-term environmental, socio-economic, or cultural resource impacts as a result of the channel widening above station 157+83 (Willow Street). All channel reaches involved are currently concrete or lined with grouted stone except for the lower reaches of the Los Angeles River. In the lower river area, the channel would be widened, but the soft-bottomed, rip-rap channel would not otherwise be altered. There would be a temporary impact to the environment in this reach. There would be some short-term loss of soft-bottomed habitat in the lower channel during construction, but the biological communities of this reach could be expected to be restored in a relatively short time following construction. This alternative would not affect significant cultural resources, nor would there be long-term socio-economic impacts of an adverse nature. There would be temporary increases in noise and dust, and significant traffic delays, during construction. Recreational use of the bike trail would be disrupted for short periods.

1 7030

Net Benefits

Based on preliminary designs, channel widening was found to be justified on Reach 4 alone and on Reaches 4, 5 and 9 in combination. The benefit-to-cost ratio on Reach 4 ranges from 2.2 (100-year) to 1.7 (200-year). The more comprehensive solution has benefit-to-cost ratios of 2.3 (100-year) and 2.0 (200-year).

Estimated annual net benefits for this alternative were:

Reach 4:	100-year = $18,299,000;
	200-year = $15,442,000
Reaches 4, 5 & 9:	100-year = $29,319,000;
	200-year = $28,010,000

ALTERNATIVE THREE: Conversion of Trapezoidal Channel to Rectangular Channel for Reaches 4 and 5 100-year and 200-year Levels of Protection.

The conversion alternative involves removal of the existing channel wall lining, excavation, and reconstruction of trapezoidal channel as concrete rectangular channel. This design has a greater cross-sectional area for a given top width than the trapezoidal channel. The design of the channel is similar for both levels of protection evaluated.

In some reaches, it was not necessary to convert the channel to a full rectangular cross-section to achieve the desired flood control; this was particularly true for the 100-year protection option. In these cases, a composite channel geometry was developed. A composite channel involves removal of the lower portion of the trapezoidal side slope and replacement of that section with a vertical wall section. The upper portion of the channel wall would remain trapezoidal, angling out from the top of the vertical section. Proposed channel characteristics for the 100-year and 200-year protection levels vary widely. On the Rio Hondo, the invert width of the trapezoidal channel is increased from the existing 100 feet to as much as 200 feet (fully rectangular cross-section) for both levels of protection. The lower Los Angeles River requires a rectangular cross-section as much as 200 feet wider for the 200-year design than the existing top width of the channel. The need for widening is greater on Reach 4, and in the 200-year as opposed to the 100-year design, but channel widening is necessary in numerous sections for both levels of protection.

As a result, this plan is essentially a channel widening alternative using a slightly different technique in construction. The additional channel widths needed in this alternative are not so great as those needed with the channel widening alternative, but significantly more earth would need to be excavated and removed. Also, in areas where a composite geometry is possible, breaking the concrete channel to construct the rectangular section would generally damage the remaining channel lining, and it would need to be completely replaced. Impacts to bridges are site specific, but an overall widening will necessitate bridge modifications and utility relocations.

As a part of this alternative, channel back slopes would be armored upstream of bridges and at other potential breakout points in the Rio Hondo and lower Los Angeles River reach.

Environmental Considerations

The conversion plans and channel widening plans have roughly equivalent impacts, except that there would be slightly less right-of-way required and thus a reduced need to impact additional lands along the channel alignment. Although there would be construction period noise, dust, air quality, and traffic impacts, there would be no long-term impacts from construction activities.

Net Benefits

Based on preliminary designs, conversion was found to be marginally justified with benefit-to-cost ratios ranging from 1.0 to 1.1. A detailed analysis of bridge and additional right-of-way costs is not included in these estimates; so more detailed net benefits may be expected to decreased somewhat.

Reach 4: 100-year = $1,469,000;
200-year = $ 455,000

Reach 5: 100-year = $4,895,000;
200-year = $3,467,000

ALTERNATIVE FOUR: NED PLAN

DETAILS OF THE PLAN IN SECTION 4, PAGE 122

VOL 12

1 7033

I. COMPARISON OF DETAILED PLANS

Evaluation Criteria

The comparison between adding parapet walls, channel widening, and conversion to rectangular cross-section was focused on economic considerations because of the very limited environmental, socio-economic, cultural resource, and aesthetic/recreational resource considerations.

Environmental, Social, Cultural Resource, Recreation, and Aesthetic Impacts

The primary differences in the plans from these perspectives are summarized below:

1) Environmental. The marine-estuarine resources of the lower Los Angeles River would be impacted by Alternatives 2 and 3 which involve construction activities in the soft-bottomed channel. Raising channel walls and armoring the levee back slopes would not have these impacts. These differences are considered relatively minor because of the degraded nature of the habitat in the channel and the relatively short reach of vegetative growth along the margin of the channel.

2) Socio-economic. There are virtually no differences in the socio-economic impacts of the alternatives as all are effectively confined to the existing rights-of-way for the channel (with only minor increases in rights-of-way required at some locations). All alternatives will affect traffic during construction to some degree.

3) Cultural resources. There are virtually no cultural resources affected by any alternative except for some impacts due to a few bridge modifications. In Reach 5, it would be necessary to move the historical marker for the Battle of San Gabriel near Washington Blvd, an action with minor and only temporary effects.

4) Recreation/aesthetics. There are some differences among alternatives in terms of their impact on recreation use of the channel rights-of-way. Significant channel widening would reduce the rights-of-way available for recreational trails and open space. Conversion of the channel to rectangular concrete channel might pose a safety hazard, and additional fencing could be necessary. Parapet walls would, in some reaches, completely block the view of the channel; in other areas they would have only limited aesthetic impacts for those using the channel trails.

None of these differences was considered significant enough to affect plan formulation, although potential mitigation for environmental impacts in lower Reach 4 would add somewhat to the costs of the widening and conversion alternatives.

Comparison of Alternatives: Economics

Based on analysis of the net benefits from 100-year and 200-year levels of protection, the alternative of raising channel walls has the highest net benefits and the lowest cost of the alternatives evaluated. It is clearly the most efficient method of correcting the flooding problem, as seen on Table 10. These preliminary costs did not involve detailed analysis of bridge costs or right-of-way, but compared to the other alternatives carried forward, raising walls stands out as the alternative of choice.

Table 10

Net benefits comparison,

first iteration, for Reaches 4, 5, and 9. ($1000)

Alternative	Average Annual Benefits	Annual Cost	Net Benefits	B/C Ratio
Parapet Walls				
100-year	51,800	12,668	39,132	4.09
200-year	55,600	18,068	37,532	3.08
Widening				
100-year	51,800	22,481	29,319	2.30
200-year	55,600	27,590	28,010	2.02
Conversion				
100-year	51,800	46,905	4,895	1.10
200-year	55,600	52,133	3,467	1.07

Analysis of Alternative Combinations

Although parapet walls appeared to be the obvious choice as an overall solution, an effort was made to examine logical combinations of parapet walls with channel widening and conversion in certain reach segments to determine if an optimum combination could be identified. This was done because each of the many bridges in the project reach presents a unique set of design constraints, and in some locations bridge reconstruction costs might exceed the cost of channel widening, for instance, within the existing bridge. Furthermore, practical design considerations may not allow every bridge to be raised as high as initially formulated.

To develop optimizations, the following factors must be considered:

1) The availability and affordability of needed rights-of-way;
2) The available room between the levee top and bridge soffet, as well as additional room between bridge abutments;
3) The transportation impacts of raising or reconstructing bridges;
4) The cost and extent of channel improvements needed to avoid bridge modifications.

An alternative that optimized these considerations was developed. Reconstruction of bridges that required very expensive modifications was avoided by widening the channel instead. Because long transitions are necessary to effect a change in channel width, other bridges nearby were also spared extensive modifications.

At the time this plan was being designed, detailed cost estimates for specific bridge modifications were only partially defined, and total costs contained approximately 50 percent contingencies. As a result, it was not possible to confidently select channel widening in specific reaches as less expensive than bridge raising and parapet walls. Because raising channel heights with parapet walls incurs significantly less expense than any other construction technique on the channel itself, it made sense as the greatest net benefit alternative. A widely varying combination plan (channel widening in some locations and raised channel walls in others) could not be confidently supported as having a greater economic efficiency. Therefore, the parapet wall/bridge modification alternative for the Rio Hondo and lower Los Angeles River would remain as the framework for the recommended plan. Value engineering in the Preconstruction Engineering and Design Phase may indicate where minor improvements can be made in the plan.

Designation of the NED Plan

Because it provides the maximum net benefits, raising the channel height using parapet walls and modifying the necessary bridges is the NED alternative. An additional element of this alternative is levee armoring that prevents catastrophic levee failure during larger than design events to be implemented in selected locations. This

Los Angeles River from the Rio Hondo confluence down to the ocean, and a portion of Compton Creek. In specific locations, should this solution be difficult to implement, alternatives will be evaluated during the Preconstruction Engineering and Design Phase.

This plan does not have major right-of-way requirements or environmental mitigation problems. It avoids significant construction modification of the existing channel while providing increased protection from flooding.

There are few aspects of this plan that lend themselves to other project purposes. No additional facilities are directly available for water conservation or increased recreation. Any impacts to existing recreation will be reversed so that all existing recreation elements remain intact. No opportunities for transportation or sediment management improvements are incorporated in this NED plan.

Optimization of the NED Plan

Having selected the format of the NED plan, it then became necessary to optimize the level of flood control protection the plan would provide in order to maximize net NED benefits. The 100-year net benefits were initially only 4 percent greater than the 200-year net benefits. Because there was no knowledge of the characteristics of the net benefits curve between these two levels of protection, additional levels were analyzed.

This optimization analysis was performed only for Reach 4. The level of protection provided by Reach 5, the Rio Hondo, was not optimized independently. There were no anticipated breakpoints in the Rio Hondo net benefits curve. Because the outflow from Whittier Narrows Dam is a fixed maximum, increasing the level of protection on the Rio Hondo is possible with very small increases in construction costs. Because Reach 5 discharges into Reach 4, a significant portion of its total flow and Reach 4 must be able to accomodate any increase in design flows, Reach 5 is not considered a separable element. This simplified the analysis and resulted in compatible project elements. The level of protection provided by the Rio Hondo was matched to the optimized level of protection provided by the lower Los Angeles River.

To optimize protection on Reach 4, additional hydrology, hydraulics, and design costs were developed for the 150-year, 250-year, and 300-year events. More refined cost estimates were developed for both the existing and new levels of protection. Damages avoided (i.e. benefits) for the varying levels of protection were developed by truncating the damage-probability curve at the assigned protection frequency. A new net benefit matrix was developed (Table 11), that included interest and amortization, and this information is displayed as a net benefits curve in Figure 9.

Table 11.
Incremental justification of raised parapet wall heights, Reach 4, lower Los Angeles River ($1000).

Level of Protection	NED Net Benefits (For optimization only)	B/C Ratio
100-year	$30,271	4.5
150-year	30,523	4.1
200-year	29,541	3.5
250-year	28,914	3.3
300-year	28,479	3.1

VOL 12

1 7040

R0050345

As seen in Table 11, the 150-year levee provides the maximum net benefits. Because of the dense urban development, additional increments of protection generate significant benefits to offset increased construction costs. The net benefits maximize at a level of protection below the 200-year because otherwise the Artesia Freeway (91) requires considerable construction modifications. The cost of raising freeway access ramps is substantial enough to reduce the overall net benefits. The associated transportation and social impacts must be avoided in order for the plan to remain acceptable.

It is conceded that the increase in net benefits between the 100-year and 150-year plans is small, on the order of 1 percent. Nevertheless, the analysis was performed with consistent levels of detail, and the indication that the net benefits curve increases above the 100-year level of protection is justification for selecting the 150-year level in this optimization procedure.

Following this initial determination that the optimum level of protection would be the 150-year level, a more precise hydraulic analysis was performed for the Artesia Freeway overcrossing segment of the river to determine the exact flow which would pass under the existing bridge. This analysis indicated that the capacity would be 164,000 ft^3/s with raised parapet walls, and more precise analysis of magnitude/frequency relationships indicated that this would be a 133-year flood event. Since the added cost of raising the Artesia Freeway overcrossing had been determined to be a controlling factor in the net benefits analysis, the optimum level of protection for this reach was then re-defined to be the 133-year flood.

Redesignation of the level of protection (from the nominal 150-year level to the 133-year level) hardly altered the shape of the net benefits curve (Figure 9). It shifted the crown of the curve to the left slightly; thus slightly fewer net benefits accrued to greater levels of protection, but the peak in net benefits remained at the level established by the upper limit of flow capacity under the Artesia Freeway.

VOL 12

NED Plan Design Refinements

Having selected a recommended level of protection, the Rio Hondo component was added, and the following design refinements were incorporated into the NED plan.

1) From just above the confluence of the Rio Hondo and the Los Angeles River to just downstream from Century Boulevard (where the Century Freeway will cross the river), the Los Angeles River channel would be converted from trapezoidal to concrete rectangular channel and slightly widened. This change was made because detailed design analysis indicated that the Union Pacific Railroad bridge would need to be raised approximately four feet at its intersection with the Rio Hondo and then quickly returned to its original elevation in order to pass under the Long Beach Freeway. This design violated grade requirements for railways and, as such, warranted an alternative solution. By widening the channel downstream, the water surface elevation was lowered sufficiently to avoid modifications to the railroad bridge.

   This change would also improve hydraulic characteristics of the channel at a point where significant turbulence is expected due to the confluence of two flows. By converting to rectangular channel, the water surface is lowered downstream of the confluence as well. This action will require that levees be reconstructed, and the east abutment of Imperial Highway be rebuilt.

2) Back slopes of the levees would be armored in four locations where a potential for overtopping exists (see Figure 10). Two of the locations are where freeway overcrossings will not be altered by the project (the Artesia and the Century Freeways). Thus, the lower decks of these overcrossings will begin to block flows which exceed the 133-year level. Armoring along about two thirds of a mile of channel would protect the area downstream of the concrete rectangular section of channel and the area near the Artesia Freeway-Long Beach Freeway interchange. Levee armoring would also be required for the reach upstream from the Union Pacific Railroad bridge on the Rio Hondo, as this bridge also

1 7042

would impede flows during events greater than the 133-year flood, creating a backwater. Compton Creek would be armored for approximately one mile upstream from its confluence with the Los Angeles River. These armored areas are the breakout points for flood levels greater than the design flood. Protection of the back slopes of the levee in these areas thus has the effect of eliminating the potential for levee failure throughout the project area. Levee armoring would be adequate to prevent levee failure during any event greater than the design event.

Adding the cost of these design refinements and including the Rio Hondo component provided a more comprehensive total project cost. The resulting benefit-to-cost ratios and net benefits for the project are different from those used to optimize the NED Plan level of protection. Updated costs and benefits are found in the description of the NED Plan.

SECTION FOUR: THE NATIONAL ECONOMIC DEVELOPMENT PLAN

A. THE NED PLAN

Plan Overview

The NED Plan addresses the area of most critical need in the LACDA System: the downstream reaches of the Los Angeles-Rio Hondo system. Improvements on reach 5 begin at Whittier Narrows Dam and extend downstream on the Rio Hondo to the confluence with the Los Angeles River. Improvements on the Los Angeles River (Reach 4) continue from the confluence with the Rio Hondo and extend downstream to the mouth of the river in Long Beach Harbor. A total of about 23 miles of channel is to be improved.

The objective of the improvements is to reduce the potential for damaging flood flows by providing increased levels of protection to the urbanized reaches of the Rio Hondo and lower Los Angeles River. The 133-year design level of protection was selected because of its maximum net benefits and the constraints on plan design imposed by the Artesia Freeway overcrossing. This level of protection was used as the basis for designing all plan elements for the NED Plan, with the exception of Compton Creek.

The following measures are employed individually and in combination to achieve this objective:

1) Vertical, reinforced concrete parapet walls of from two feet to eight feet in height would be constructed along the crest of the existing channel levees.

2) Conversion of 6950 feet of concrete trapezoidal to concrete rectangular channel would occur in the confluence area where parapet walls cannot be raised to the necessary height to provide adequate protection (at and just below the confluence of the Rio Hondo and the Los Angeles River).

3) Raise and/or modify bridges which currently are too low to permit 133-year flows to pass underneath them or which have other impacts on the hydraulic characteristics of the channel that make alteration of their design necessary. Twenty-seven of forty-three bridges in the project reach will be modified.

4) Armor the landward levee slope on both sides of the channel in selected locations (a total of about 2.2 channel miles in four separate areas) to prevent greater than design event overflows from eroding the earthen slope and subsequently causing the levee to fail.

5) Apply a concrete overlay to the grouted stone channel walls in the vicinity of the Rio Hondo-Los Angeles River confluence.

Figure 11 indicates the estimated NED Plan levels of protection for various specific channel locations in reaches 4 and 5. While higher levels of protection are shown in some locations, it must be understood that breakout at any point will inundate a wide area, depending on the side of the channel which is overtopped. Therefore, while variations in level of protection exist throughout each reach, the flood protection provided by the NED Plan is defined by the lowest level of protection in that reach.

While no improvements are proposed for upsteam reaches of the Los Angeles River, breakouts occur just south of downtown Los Angeles for events greater than the 100-year flood. This water moves into the flood plain and spreads south along the western edge of the Los Angeles River. In the 133-year event, these inundations are expected to be very shallow, but their existence prevents the NED Plan from fully providing 133-year protection throughout the plan's area of influence. For this reason, the average level of protection provided by the NED Plan is considered to be between the 100 and 133-year level; residual damages are assumed in most locations contiguous to reaches 4 and 5 for floods which exceed the 133-year event, and in some areas west of reach 4, for events greater than the 100-year flood.

Plan Components

Parapet Walls

Parapet walls will be constructed of reinforced concrete one foot thick. Their height will vary from section to section to reflect the changing water surface requirements at the particular location. The minimum wall height will be two feet and the maximum will reach eight feet. Transitions from one parapet wall height to another will be accomplished with an instantaneous change in height. The walls will thus not have the appearance of a monolith, but will be perceived as distinct sections of varying heights, thereby reducing the visual impact of the parapet wall system. As Tables 12 and 13 indicate, wall heights will vary significantly and irregularly. In one 300-foot reach of the Rio Hondo system, for example, an 8-foot high section will be sandwiched between a 4-foot high section upstream and a 5-foot high section downstream. Only 300 feet further downstream, the wall height will be only 2 feet. In some reaches, where hydraulic analysis indicates wall heights would be less than 0.5 feet, no parapet walls will be required. The parapet walls will be constructed on the channel side of the existing access road/bicycle trail system to permit their continued use along this reach of the river.

The parapet wall design will vary, depending on wall height and whether the levee is being armored on the landward side. Details of the different wall configuration/levee armoring combinations are shown in Figure 12.

At most bridges, the existing access road/bicycle trail located on the top of the levee either veers channel-ward and dips under the bridge or it descends the outside of the levee and passes through a tunnel in the bridge approach before rejoining the levee top. In the case of the tunnel, the parapet walls will simply join the bridge abutment and continue on the other side of the abutment. Where the road goes under the bridge, as you approach the bridge, the road will gradually rise to meet the top of the parapet wall and then descend with the parapet wall to the land side of the road. The descending road will connect with the existing road as it passes under the bridge, while the

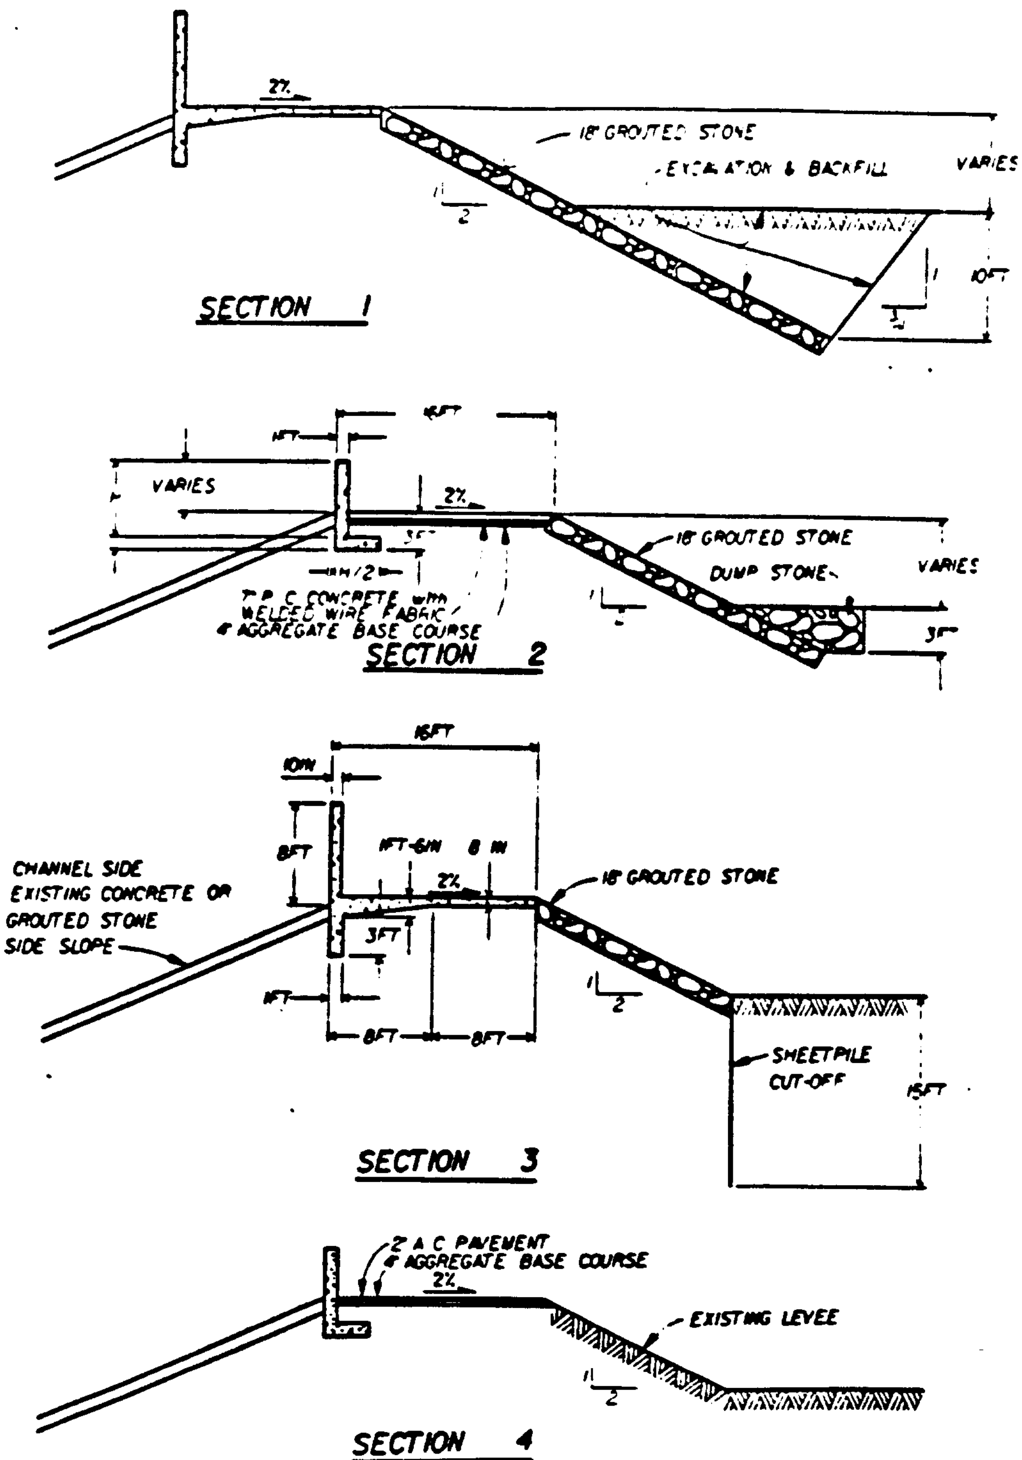

FIGURE 12

VOL 12

17049

R0050354

landward-side parapet wall joins the bridge abutment and continues again on the other side of the bridge.

The walls will alter the aesthetics of the system significantly when they exceed three to four feet in height, blocking some of the view across the river. For those living adjacent to the levee, the raised walls will further impinge on the visual landscape. To offset these impacts, the walls themselves may be treated with murals; a mural created and maintained by local community groups, such as the one in the Tujunga Wash channel, may be one option for improving the aesthetics of the parapet walls. Another possibility may involve the use of ivy to cover the walls.

R0050356

Conversion of the Channel to Rectangular Concrete-lined Channel

At the confluence of the Rio Hondo and the Los Angeles River, construction of both parapet walls and conversion of the channel to concrete-lined rectangular is required to accommodate flood flows. In this approximately 7000-foot reach, the anticipated flow of 158,000 ft^3/s is accommodated by converting the existing trapezoidal channel, with top width of approximately 390 feet, into a rectangular cross-section with a width of 420 feet. In addition to widening the channel approximately 30 feet, parapet walls as high as seven feet will be added to the sides of the Los Angeles River. The reduction in water surface elevation in the Rio Hondo is sufficient to avoid otherwise necessary modifcations to the Union Pacific Railroad bridge.

The channel modifications would require removal of the existing concrete in the channel and excavation of 560,000 yd^3 of earth. The vertical reinforced concrete walls will extend above the existing levee surface and will be cast in place. Because of the wider channel, the right (west) abutment of the Imperial Highway bridge will also need to be rebuilt.

Bridge Modifications

The bridge crossings in Reaches 4 and 5 are displayed in Figure 13. Twenty-seven of the forty-three total bridges would be affected: eighteen would be raised, one raised and modified, six modified only, one moved, and one removed to permit the design flow to pass underneath the bridge (Tables 14 and 15).

Raising of bridges will generally be accomplished by removal of the existing bridge and construction of a new bridge in its place. It had originally been thought that some bridges could be raised by elevating the bridge deck and adding height to the existing piers, but current seismic building codes make it necessary to replace the old piers.

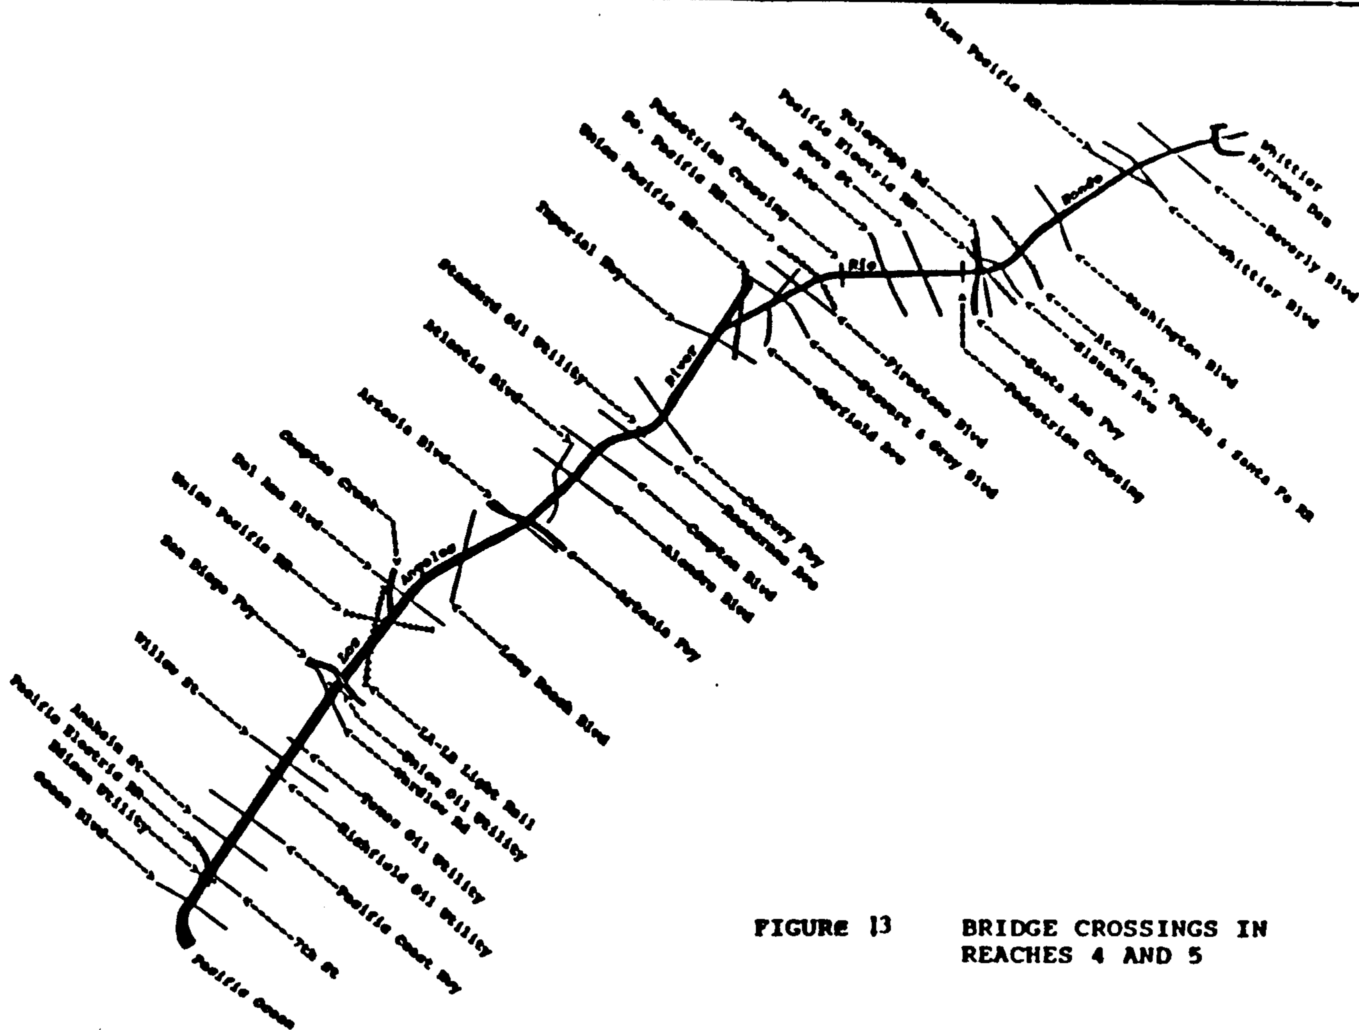

FIGURE 13 BRIDGE CROSSINGS IN REACHES 4 AND 5

Table 14. Los Angeles River Bridge Modifications

Bridge	Type	NED Plan Proposal
Lower Los Angeles River, moving downstream from Rio Hondo confluence		
Imperial Highway	Traffic	Reconstruct right abutment in conjunction with channel widening (trap. to rectangular channel) Traffic detour (requires lease of 1.7 acres)
Standard Oil	Utility	Raise 3.4 feet
Rosecrans Avenue	Traffic	Remove and reconstruct 3.9 feet higher Traffic detour required
Compton Boulevard	Traffic	Remove and reconstruct 2.7 feet higher Traffic detour (requires lease of 1.4 acres)
Atlantic Avenue	Traffic	Remove and reconstruct 6.3 feet higher Traffic detour (requires lease of 1.1 acres)
Long Beach Boulevard	Traffic	Remove and reconstruct 4 feet higher Traffic detour (requires lease of 1.0 acres)
Del Amo Boulevard	Traffic	Remove and reconstruct 5 feet higher Traffic detour (requires lease of 1.3 acres)
Union Pacific	Railroad	Remove and replace with two-pier, through-truss design Track detour (requires lease of 2.6 acres)
LA-Long Beach	Light Rail	Remove and reconstruct 3.3 feet higher Track detour (requires lease of 2.0 acres)
Texas Oil	Utility	Raise 2.8 feet
Willow Street	Traffic	Remove and reconstruct 4.2 feet higher Traffic detour (requires lease of 1.2 acres)
ARCO Oil	Utility	Remove and reconstruct 3.9 feet higher
Pacific Coast Highway	Traffic	Remove and reconstruct 3.1 feet higher Traffic detour (requires lease of 0.1 acre)
6th Street	Utility	Raise 1.6 feet
SPRR	Railroad	Remove and reconstruct 115 feet downstream

VOL 12

1 7054

Table 15. Rio Hondo Bridge Modifications

Bridge	Type	NED Plan Proposal
Rio Hondo, moving downstream from Whittier Narrows Dam to Los Angeles River		
Whittier Boulevard	Traffic	Remove and reconstruct 5 feet higher Traffic detour (requires lease of 1.4 acres)
Union Pacific	Railroad	Replace deck girder with through girder bridge, rebuild piers and abutments Rail elevation remains unchanged Track detour (requires lease of 1.9 acres)
Washington Boulevard	Traffic	Remove and reconstruct 4.8 feet higher Traffic detour (requires lease of 2.2 acres)
AT&SF	Railroad	Preserve superstructure Construct new piers 2.5 feet higher and rebuild abutments Track detour (no leased land needed)
Slauson Avenue	Traffic	Remove and reconstruct 2.2 feet higher Traffic detour (requires lease of 2.2 acres)
SPRR	Railroad	Remove and reconstruct 1.4 feet higher Track detour (requires lease of 1.3 acres)
Steel Bridge Sta. 218+45)	Pedestrian	Owned by LA Co. Parks and Rec. Out of service. Remove. Additional 3.6 feet elevation needed
Suva Street	Traffic	Remove and reconstruct 5.2 feet higher Traffic detour required
Florence Avenue	Traffic	Remove and reconstruct 3.5 feet higher Track detour (requires lease of 0.7 acres)
Timber Bridge (Sta. 129+50)	Pedestrian	Raise 5.3 feet
SPRR	Railroad	Remove and reconstruct 3.2 feet higher Track detour (requires lease of 1.5 acres)
Firestone Boulevard	Traffic	Remove and reconstruct 1.6 feet higher Traffic detour (requires lease of 1.8 acres)

For a typical bridge site, the following schedule will prevail:

A. Set up and staging at site	1 month
B. Build detour bridge	5 months
C. Demolish existing bridge	3 months
D. Build new bridge	12 months
E. Demolish detour bridge	3 months
F. Site restoration	1 month
Total	25 months

The detour bridge will require concrete pier construction and will utilize leased bridge decking of a steel through-truss design.

Traffic over the bridges in question is generally in the range of 20,000 to 50,000 cars a day; it will therefore be necessary to construct a detour for both directions of traffic before bridge raising may be accomplished. Given the volume of traffic, it will probably be necessary to provide a minimum of three lanes and preferably four lanes with two in each direction to accommodate traffic flow; most of the roads crossing the Los Angeles River are essential, major traffic corridors. Speed reductions would be necessary at these bridge crossings. Detours would require some construction right-of-way (approximately twenty-six acres total for twenty bridge sites); in some areas detours might impact existing structures.

An initial investigation for an impact analysis on traffic delays was governed by the goal to utilize existing transportation models and adapt them to reflect the impacts in the study area. The city of Long Beach utilizes a traffic simulation model to evaluate impacts on traffic flows of proposed roadwork. It is a trip based model of the Los Angeles Basin and upon input of a constraint it redistributes traffic to minimize the impact on the total system traffic time. The modified bridges that were input into the model are considered representative of the bridges that are affected along the entire LACDA project area. A base case was established and constraints were placed on Long Beach Boulevard, Pacific Coast Highway and Willow Street. Willow Street exhibited the most impact so it was used as a proxy for the estimation of delay times for the remaining bridges by applying a proportionate ratio based on traffic counts. The detour delay time was assumed to be the difference between the time to travel the detour route under constrained conditions and the time to travel the original route under base conditions. The approximate delay time is estimated to be less than five minutes per vehicle during peak hours. The value associated with these traffic delays are considered to be NED costs and will be included in the cost/benefit analysis in the Final Report.

Railway bridges and utility bridges will require less complex construction methods. The superstructures of railway bridges may be unfastened from piers and then removed as a unit by a crane while pier extensions are constructed. Detours may also need to be maintained for railroad traffic during construction. Utility bridges will be raised in a manner similar to raising rigidly framed bridges. Utility connections on either side of the bridge will be closed for a brief period of time while flexible connections are installed, then the bridge and the existing utility features will be raised simultaneously. The flexible connections will then be installed on a schedule to be coordinated with the various utilities involved.

Levee Armoring

As shown in Figure 10, there are four reaches totaling approximately 11,800 feet of channel that will receive protective armoring on the outer (landward) face of the levee on both sides of the channel. The objective of the armoring is to avoid erosion of the outer face of the earthen levee should an event greater than the design event occur. The armoring consists of an 18-inch-thick blanket of stones ranging from 4 to 18 inches in diameter. This blanket covers the earthen levee face and is grouted in place. The toe, or bottom edge, of the armoring needs to be protected because, otherwise, the force of the overtopping waters can erode under the armoring and still cause levee failure. To accomplish this, in areas of unconstrained right-of-way, the armoring will continue 10 feet below the ground surface as shown in Figure 14. Where adequate right-of-way is unavailable, dump stone or steel sheet piles would protect the toe of the armored levee.

Concrete Channel Overlay

Where the channel is currently grouted stone, predominantly in the vicinity of the Rio Hondo-Los Angeles River confluence, the channel roughness is not conducive to efficient conveyance of floodflows. These rougher areas will receive a smooth overlay consisting of a three-inch thick minimum concrete cover. The channel will be prepared by sandblasting, and then the concrete will be sprayed on the surface and smoothed.

VOL 12

17058

Compton Creek

Improvements on the Los Angeles River will lower water surface elevations on Compton Creek and provide a slightly greater than 50 year level of protection. However, a backwater situation remains that would induce the creek to overflow its existing walls during the 100-year event. To mitigate this, levees may be raised slightly and parapet walls three feet in height would be added along 900 feet of channel. A modified "L" wall will be used for stability, and a concrete apron would be extended to the existing channel armoring. The back side of the levees would also be armored along 5530 feet of channel, 4630 feet of which would be upstream from the section protected by parapet walls. In a 133-year design flood, this armored section would act as a weir, allowing sheet flow to pass over the levee without resulting in levee failure.

Operation and Maintenance

The Corps' primary operation and maintenance responsibility in the LACDA mainstem system involves the five Corps reservoirs and the Los Angeles River from below Tujunga Wash to just upstream of the Rio Hondo confluence. Except for various minor features, Los Angeles County operates and maintains the rest of the LACDA system. The reaches affected by the NED Plan are all currently maintained by the County. Increased operation and maintenance costs of the proposed project will be minor. Additional channel cleanout and routine repair will cost approximately $20,000 annually, with new bridge maintenance costing about $50,000 annually. Should extreme effort be required to remove graffiti from the parapet walls, some of these monies will need to be redirected.

Recreation Features

The NED Plan does not significantly alter the cycling and hiking trail system along the Los Angeles River and the Rio Hondo, although the aesthetics of this area are affected by the addition of parapet walls in some reaches. However, for much of the affected reach, the aesthetic quality of the trails is minimal, as the river passes through commercial and industrial areas and along the Long Beach Freeway The NED Plan will retain all existing recreation features that would be impacted by the project. Cycling and equestrian trails will be temporarily impacted by construction activities but will be returned to use in all of the reaches impacted by the plan. Unfortunately, there are no additional recreation features proposed at present. The cost of additional recreation facilitites would be borne by the local sponsor or another local entity. It is hoped that some additional recreation facilities can be incorporated during the planning and design phase after coordination with potential local sources of funding.

B. PLAN ACCOMPLISHMENTS

The NED Plan will provide between 100- and 133-year protection to approximately 75 square miles of intensively developed urban area, providing average annual flood damage reduction benefits estimated as $60.2 million, and reducing the 100-year flood plain from 82 square miles to 7 square miles (Figure 13). In addition, the plan will improve the safety of numerous bridges, many of which were designed prior to imposition of new seismic safety guidelines. Benefits from advanced replacement of bridges total $129,000 annually. The estimated annual benefits are shown in Table 16 below in October 1990 price levels. Details of the Economic Benefit Analysis are provided in Appendix G, the Economic Appendix.

TABLE 16
SUMMARY OF ANNUAL BENEFITS
LACDA NED PLAN

Damages avoided to structure and contents	$52,158,160
Vehicle damages avoided	6,249,000
Emergency Costs Avoided	1,109,000
Advanced Replacement of Bridges	129,000
Flood Insurance Overhead Costs Avoided	489,000
Freeboard	71,000
Total	$60,205,160

Although no improvements are recommended for the upper reaches of the Los Angeles River or the San Gabriel River system, the LACDA system as a whole will provide post-project protection from floods ranging from the 10 to 140-year event (Table 17). In areas with less than 100-year protection such as those in the upper reaches below Sepulveda and Hansen Dams, outbreaks from the entrenched channel are not extensive enough to justify a federally supported remedy.

C. RESIDUAL FLOODING

The NED Plan does not affect upper basin reaches, and residual flooding in these areas will be the same as for the without-project condition. In the lower LACDA basin, the NED Plan may have a minor impact on local flooding because of the increased difficulty locally generated runoff will have entering the channel during short periods of higher water surface elevations in the channel.

The primary impact is expected to be felt at the 13 pump plants on the Los Angeles River and the one pump plant on the Rio Hondo, which are operated by either Los Angeles County or the City of Long Beach. The flow peak has a duration of approximately six hours during which time the pump plants may be less efficient in delivering water to the mainstem system. This reduction in storm water handling capacity may require compensation by an increase in available short-term detention storage along the channel or additional pumping capacity. Local ponding would not be increased except for very rare flood events; much of the ponding anticipated would have occurred under the without-project condition because the levee walls are currently up to 15 feet above the surrounding ground in some areas.

An evaluation of interior drainage indicated that the existing interior flood condition is primarily nuisance street flooding, and damages were insignicant compared to flooding from mainstem overflows. The existing system's ability to deliver storm runoff to the mainstem channels will be evaluated along with the marginal impact the NED Plan may have on this capability during the Preconstruction, Engineering and Design phase of this project.

The NED Plan provides for between 100 and 133-year protection in the lower basin. For events of greater magnitude, flows would overtop the parapet walls and cascade down the levee back slopes in shallow sheet flow. The resulting flooding would be less destructive than under the without-project condition because (1) the drop from the vertical parapet wall to the pavement of the cycling trail-access road would act somewhat as a drop structure, reducing flow velocity, and (2) the levees in the protected sections would not fail during flood events greater than the 133-year flood. The post-project flood plain is shown for various storm recurrence intervals on Figure 13.

D. ADDITIONAL BENEFITS OF THE NED PLAN

The 133-year level of protection recommended in the improved reaches is the optimum level from an economic point of view, but there are other considerations which reinforce this recommendation. First, any greater level of protection would involve very significant traffic impacts on the Artesia Freeway-Long Beach Freeway interchange. It is likely that these impacts would be so significant as to raise project costs or to be a significant project disbenefit during the construction period. They would probably be socially unacceptable and could threaten local support for the project.

Second, the proposed level provides a margin of safety which may be needed if future improvements are made by local agencies in upstream system reaches. The final analysis of levels of protection for the lower Los Angeles River assumed that there would be some flooding in upper reaches of the river system, including downtown. This upstream breakout of flood flows has the effect of reducing the peak flow in the lower river for the short period when peak flows are anticipated in the LACDA system. The 133-year conveyance capacity assumes that there is no increase in the level of protection in the upstream reaches and that some of the peak flow which would otherwise reach the lower river is effectively "spread out" when the downtown area is flooded, albeit to a low depth and with only limited damages. If improvements are made in the future, then the level of protection provided by the NED Plan would be reduced by a small increment but not below the 100 year level of protection.

E. FIRST COSTS

The cost estimates for the NED Plan have been prepared in accordance with guidance provided in the following documents: EC 1110-2-263, Civil Works Construction Cost Estimating; EC 1110-2-538, Civil Works Cost Estimating, Code of Accounts; and EC 1110-2-1302, Cost Estimates, Planning and Design Stages. The work to be completed for this project was broken down into line items according to the code of accounts. The estimate was developed using quantities, drawings, and other data obtained from the design team. Unit prices were developed using labor rates and site specific conditions. Overhead, bond, and profit were separately computed and distributed to the unit prices. Contingencies were determined based on current uncertainties with the design, quantities, and/or unit prices. Cost summary spreadsheets were prepared based on the output from the M-CACES program in October 1990 price levels. The cost estimate by code of accounts for all the components of the NED Plan is presented in Table 18.

The estimated first cost of the NED Plan is $337,400,000, of which approximately $96.5 million is for improvements to the Rio Hondo channel and $209 million is for improvements of the Los Angeles River channel. Modifications to the confluence are estimated as $31.5 million. Of the total, approximately 53 percent is for bridge modifications and utility relocations. A summary of cost apportionment is displayed in Table 18 and reflects cost sharing requirements and procedures as stated in the Water Resources Development Act of 1986. The non-Federal share of the estimated cost of the NED plan is $168,700,000 (50%) and the Federal share is $168,700,000 (50%).

F. DESIGN AND CONSTRUCTION SCHEDULE

The present schedule consists of a 3 year Preconstruction, Engineering and Design phase (PED) lasting from September 1991 until August 1994. The General Construction period would last about eight years, from September 1994 until December 2002.

(1.) Immediately commencing with the initiation of PED, these work items will be scheduled for completion; LCA negotiations, mapping and surveying, geotechnical investigations, materials investigations, environmental mitigation analyses, economic validations, real estate and other acquisition plans, and hydrology and hydraulic studies. reek.

(2.) The second phase of the construction package consists of parapet walls and levee armoring along Compton Creek and the first set of final plans and specifications that mark the end of the PED phase and the beginning of the construction phase of the project. The work along Compton Creek will be based on a Basis of Design document that will address only the technical data pertinent to Compton Creek. Construction of the improvements to Compton Creek is expected to last about 18 months.

(3.) The third phase of the construction schedule is the Physical Model at the Waterways Experiment Station (WES). Due to several unstable flow regimes along the project length, considerable factors of safety in the form of increased height were added to some of the bridges spanning the Los Angeles River and Rio Hondo Channel. The mathematical models used to predict the project flowlines are particularly ill-suited for these hyraulic discontinuities. The WES model will be used to determine if any of the factors of safety employed may be reduced or perhaps preclude the modification of one or more of the bridges along the project length. The model construction will begin prior to initiation of PED.

(4.) The fourth phase of construction includes modification to utility and pedestrian bridges. These modification may be accomplished with no additional rights-of-way, no traffic impacts, and at a low cost. Construction of these modifications is expected to take approximately 15 months.

VOL 12 11076

(5.) The fifth phase of work includes the first group of highway bridge modifications for the Los Angeles River and the Rio Hondo Channel. These would be the bridges mentioned in the WES work phase that would have a relatively high likelihood of not requiring extensive modification. Construction of all highway bridges would be phased so that no more than two bridges on either river would be modified at the same time. At no time will two adjacent bridges be modified at the same time. Due to this constraint, the construction period may be as long as 7 years.

(6.) The second set of highway bridge modifications may have a construction period of approximately 6 years due to the same constraints as the first group of bridges

(7.) The channel work construction for the Rio Hondo, Los Angeles River and their confluence will proceed by seperate contract and construction will last approximately 3 years.

(8.) The final phase consists of the Federal responsibility of modification of seven railroad bridges. The construction period for all seven bridges would span approximately 5 years.

Table 20. Summary of Design and Construction Schedule

Phase	Start	Finish	Years
Design	1991	1994	3
Construction			
1. Channel Modifications Compton Creek	1994	2001	6
2. Utility and Pedestrian Bridges	1994	1995	1
3. Highway Bridges	1995	2000	6
4. Highway Bridges	1997	2002	5-1/2
4. Railroad Bridges	1997	2002	6
5. Channel Modifications	1996	1999	2-1/2

VOL 12

G. PLAN IMPLEMENTATION

Institutional Requirements

Under the Water Resources Development Act of 1986, the local sponsor for a project is responsible for:

1) Paying 5 percent of the cost of the project assigned to flood control during construction of the project,

2) Providing all lands, easements, rights of way, and dredged material disposal areas required only for flood control,

3) Performing all necessary relocations related to flood control, and

4) Providing that portion of the joint costs of lands, easement, rights-of-way, dredged materials disposal areas, and relocations which is assigned to flood control.

1

1079

The local sponsor is required to pay a minimum of 25 percent of total project costs assigned to flood control during construction if its contributions under the conditions listed above do not equal 25 percent of total cost attributable to flood control. All project costs for the NED Plan are attributable to flood control. Los Angeles County, as local sponsor, is required to provide all lands easements, rights-of-way and relocations (LERR) in support of the project. Because bridge modifications are part of LERR, Los Angeles County would normally be responsible for these costs. Bridge costs constitute 64 percent of the total project costs, and the ceiling on local sponsor fiscal participation is 50 percent. As a result, all project costs are divided evenly between Los Angeles County and the Federal government.

The local sponsor may be expected to waive application of the ability-to-pay test.

H. NON-FEDERAL SPONSOR RESPONSIBILITIES

The presently estimated non-Federal share of the total first cost is $168,700,000.

In addition, maintenance and operation of the project would cost local interests approximately $70,000 annually.

The local sponsor for the project is the Los Angeles County Flood Control District.

Requirements of local cooperation are specified below:

(1) Pay five percent of the cost of the project assigned to flood control during construction of the project, presently estimated at $16,870,000.

(2) Provide all lands, easements and rights-of-way, including suitable borrow and spoil disposal areas, necessary for construction and maintenance of the project, including associated mitigation measures, at a cost presently estimated at $5,611,400.

(3) Accomplish all relocations and alterations of buildings, roads, highways, bridges, storm drains, sewers, and utilities, at a cost presently estimated at $151,788,600.

(4) If, the value of the contributions required by the non-Federal interest is less than 25 percent of the project cost, the non-Federal interest shall pay during construction such additional amounts necessary so that the total contribution of the non-Federal interest is equal to 25 percent of the cost of the project assigned to flood control.

(5) Maintain and operate project facilities after completion in accordance with regulations to be prescribed by the Secretary of the Army at an average annual cost presently estimated at $70,000.

(6) Hold, and save the United States free from damages due to construction, operation, and maintenance of the project, excluding damages due to the fault or

negligence of the United States or its contractors, and free from water rights claims caused by construction and operation of the project.

(7) Prescribe and enforce regulations to prevent obstruction or encroachment on flood control works that would reduce their flood-carrying capacity or hinder maintenance and operation.

(8) Comply with the applicable requirements of the Uniform Relocation Assistance and Real Property Acquisition Policies Act of 1970.

(9) Comply with Section 221 of the Flood control Act of 1970.

(10) Publicize flood plain information in the areas where structural measures were not found justified and provide this information to zoning and other regulatory agencies for their guidance and leadership in preventing unwise development in the flood plain.

VOL 12

1 7081

SECTION FIVE: PUBLIC COORDINATION

Public coordination for this feasibility phase of the LACDA study included a series of public workshops in October 1987 at five locations in the LACDA basin. At these workshops, study staff, staff from LACDPW, and staff from the Federal Emergency Management Agency (FEMA) briefed over 150 workshop participants, including community leaders and members of the press. In addition, there have been regular comprehensive newspaper articles to ensure that the purpose and scope of the study has been adequately known to LACDA basin residents. Public review and comment of the proposed project was considered in formulation of the array of alternatives screened, as well as in evaluating alternatives.

The public was presented with a full array of alternatives to be considered, and their comments on these alternatives were given full consideration during all phases of the planning process.

Public meetings were able to reach only a small fraction of the basin's over 4 million residents; a public involvement program for an area so densely populated thus involved a number of other approaches.

First, personnel from the Los Angeles County Department of Public Works were involved in the planning effort from the beginning. Local officials, likely to be aware of local concerns and attitudes, were able to help guide the planning process toward measures which would be acceptable to the local communities.

Second, information about the project was made available to the public through the media. An initial problem analysis was made available in 1985, prior to plan formulation. A number of other press releases concerning the potential flooding problem and potential alternative solutions were made over a period of about four years.

Third, the recommendations of this planning effort will be presented to the Los Angeles County Board of Supervisors for critical review.

Fourth, public presentations of the data in this report will be made in various geographical areas of the LACDA basin. This will provide those with an intense interest in the project with an opportunity to comment in detail. Because these meetings will be attended by representatives of the local press, the discussions in these meetings may be locally reported. Thus the meetings will have the effect of informing a broad cross-section of the community about the various points of view related to the project. Presentations will consist of general introductions to the problem and the planning process, a detailed slide/video presentation, and an open question-and-answer period. An informational brochure will be available to all who attend the meetings and/or are currently on the project mailing list.

Finally, briefings and workshops may be held for public officials in the LACDA basin on a by-request basis at which an open forum discussion of issues may take place.

A record of public involvement efforts and the views of the public are on file in the Los Angeles District Office. For summary purposes, major issues raised during public involvement to date are listed and briefly described below:

1) The Need for Upgrading the LACDA System. Those present at public workshops did not initially understand the need for the upgrade of the system. There are several reasons for this. First, the LACDA system components have performed quite well over the past 40-50 years; during this time there has not been a flood exceeding current capacity. Thus the public perceives the system as highly reliable. Second, the concept of flood magnitude-frequency relationships is often difficult to grasp. Third, recent drought periods have focused public attention on problems caused by periods of low precipitation, rather than on infrequent flood periods. These issues have been successfully addressed in both public meetings and newspaper articles.

2) Factors influencing flooding. There were many questions regarding the interaction of factors which affect protection levels. Factors of apparent greatest concern were debris, releases from major reservoirs, and problems with trash and debris in the channels.

3) Project costs. There were numerous questions regarding the costs of the proposed project and community responsibility to cost share.
4) Alternatives. The primary concern regarding alternatives appeared to be their relative cost.
5) Local financing. There was concern over full participation of all affected communities in the project area.
6) Safety of the LACDA system. Concern over system safety focused on the potential for dam failure, which was explained as being very small, on precise identification of areas likely to be subject to levee failure, and on adequate flood fighting and evacuation programs.
7) Project delay. There was concern that a project might not be in place due to delays in project study and construction.
8) Specific project areas. There were a number of individual concerns related to resources and problems of specific features of the LACDA system. In particular, there was concern that upper basin environmental resources should not be impacted by a project. Specific safety issues were also raised.
9) Flood insurance. There were many questions regarding the cost and availability of flood insurance.
10) Local flooding problems. There were a number of questions regarding local street flooding and the potential for a project to solve these problems.

It is important to note that to date there has been no significant opposition to the proposed channel improvements in the areas under consideration. There are interests which oppose the continued use of concrete channels, preferring to return the existing channels to their natural state. Some opposition to the project is anticipated for these reasons, and traffic problems associated with raising and modifying bridges are anticipated to generate some opposition as well.

VOL 12

1 7084

VOL 12

SECTION SIX: CONCLUSIONS AND RECOMMENDATIONS

A. CONCLUSIONS

The District Engineer finds that the existing LACDA system lacks adequate capacity to prevent catastrophic flooding in the lower reaches of the Rio Hondo from Whittier Narrows Dam to the confluence with the Los Angeles River, and the Los Angeles River from this confluence downstream to the Pacific Ocean. Upgrade of the system capacity has been identified as a vital concern to communities in the lower LACDA basin. In addition, the District Engineer finds:

1) The primary cause of the existing system inadequacies is a substantial increase in local runoff from developed areas into an improved storm drain system.

2) Improved analysis methods and 50 years of additional hydrologic records also indicate that the design storms for portions of the LACDA system have a recurrence interval of only about 50 years (2% chance each year), and that therefore the system is not able to provide the desired level of performance expected from flood control facilities in highly developed urban areas.

3) The LACDA system has provided protection from major flooding in the basin for a period of almost 50 years but has an inadequate capability to protect the LACDA basin communities in the future.

4) The San Gabriel River element of the LACDA system provides 100-year or greater levels of protection and thus does not require upgrade.

5) There are no feasible sites for new reservoirs in the system watershed which could be utilized to reduce flooding in the LACDA system in a cost-beneficial manner. This is because the flooding is the result of local runoff in the downstream basin areas.

1705

6) Modification of existing Corps and local dams in the upper basin is not feasible due to high costs and lack of effectively controlling flooding.

7) There are no cost-effective diversion, off-channel storage, or non-structural measures which could be implemented to solve all or a portion of the flooding problem.

8) Transfer of flows from the Rio Hondo-Los Angeles River system to the San Gabriel system by diversion at Whittier Narrows Reservoir is not a cost-effective approach to the identified problems because it would require equally costly improvements to the San Gabriel River system channel in conjunction with needed improvements on the lower Los Angeles River.

9) Channel modifications in the upper LACDA basin areas are not justified economically because there is already a relatively high level of protection in these reaches of the LACDA system and because overflows in these reaches do not cause damages justifying the available costly solutions.

10) The most cost-efficient approach to modifying the existing channels in the lower LACDA basin is to raise the height of leveed sections of the river from two to eight feet using reinforced concrete parapet walls. This requires modification of twenty-seven bridges, primarily to accomodate the height of the parapet walls.

11) A 133-year conveyance capacity is optimum in the Rio Hondo and lower Los Angeles River reaches because higher levels of protection would require raising of major freeway overcrossings, including the interchange of the Long Beach and Artesia-Riverside Freeways, and a railroad overcrossing which passes beneath an existing freeway overcrossing. These actions would significantly raise costs for a project and would create massive socio-economic dislocations due to traffic interruptions.

B. RECOMMENDATIONS

I recommend that the plan described herein for flood control be authorized for implementation as a Federal project, with such modifications as in the discretion of the Chief of Engineers may be advisable, and subject to cost sharing, financing and other applicable requirements of Public Law 99-662 for this kind of project and as otherwise provided by law. The total first cost of the flood protection project at October 1990 price levels is $337,400,000. The Federal share is currently estimated at $168,700,000. This recommendation is made with the provision that the non-Federal interest will, prior to implementation, agree to the following:

1. Pay 5 percent of the costs of the project assigned to flood control during construction of the project.

2. Provide all lands, easements, rights-of-way, and dredged material disposal areas required only for flood control and perform all related necessary relocations.

3. Payment of additional funds during construction of the project in order to pay a minimum of 25 percent of the total project cost. In accordance with the Water Resources Development Act of 1986 (PL 99-662), the non-Federal share of the project cost shall not exceed 50 percent of the project cost assigned to structural flood control.

4. Maintain and operate without cost to the United States, all project facilities after completion in accordance with regulations prescribed by the Secretary of the Army.

5. Hold and save the United States free from damages due to construction, operation, and maintenance of the project, excluding damages due to the fault or negligence of the United States or its contractors, and free from water rights claims caused by construction and operation of the project.

6. Prior to installation or construction, prescribe and enforce regulations to prevent obstruction or encroachment on flood control works that would reduce their flood-carrying capacity or hinder maintenance and operation.

7. Comply with the applicable requirements of the Uniform Relocation Assistance and Real Property Acquisition Policies Act of 1970 (PL 91-646).

8. Comply with Section 221 of the Flood Control Act of 1970.

9. Publicize flood plain information in the areas concerned and provide this information to zoning and other regulatory agencies for their guidance and leadership on preventing unwise development in the flood plain.

The recommendations contained herein reflect the information available at this time and current Departmental policies governing formulation of individual projects. They do not reflect program and budgeting priorities inherent in the formation of a national Civil Works construction program nor the perspective of higher review levels within the Executive Branch. Consequently, the recommendations may be modified before they are transmitted to the Congress as proposals for authorization and implementation funding.

LOS ANGELES COUNTY DRAINAGE AREA (LACDA) REVIEW STUDY
DRAFT ENVIRONMENTAL IMPACT STATEMENT

Lead Agency: U.S. Army Corps of Engineers, Los Angeles District.

Cooperating Agency: County of Los Angeles, Department of Public Works.

<u>ABSTRACT</u>:

The LACDA Review Study is a system-wide approach to identifying means for improving the Los Angeles County Drainage Area flood control system. During the 40 years since its construction, its ability to provide a high level of protection has diminished. This is the result of an increase in surface runoff and an associated increase in flow from additional storm drains.

The proposed plan provides for the construction of concrete parapet walls along the existing channels of the lower Rio Hondo, Los Angeles River and Compton Creek. Selected areas of levee armoring are also part of the proposed action. Additionally, implementation of this project would necessitate the raising of numerous bridges crossing the channel.

Other alternatives were considered and found to be not feasible from an engineering, economic and/or environmental perspective.

SUMMARY

S.1 MAJOR FINDINGS AND CONCLUSIONS

Several alternative and plans were considered for improvement of the Los Angeles County Drainage Area (LACDA) to reduce the current flood potential in some portions of the system. Preliminary engineering and environmental analysis resulted in the screening out of all but two, plus the No Action alternative.

Continued flooding potential in portions of the LACDA system, particularly in the lower Rio Hondo and the lower Los Angeles rivers would be the consequense of implementation of the No Action alternative although there would be no environmental consequenses.

The proposed plan, consists of construction of parapet walls ranging in height from 2 to 8 feet along the top of the existing levee. This plan would necessitate the raising of numerous bridges along the Rio Hondo and Los Angeles rivers. Environmental impacts associated with the implementation of this alternative center around construction-related impacts, including noise and dust generation, traffic impacts and temporary disruption of bicycle and equestrian trails. Aesthetic impacts are also anticipated in conjunction with construction of the walls. It should be noted that the plan would reduce the flooding potential on the lower Los Angeles and Rio Hondo rivers, but would not correct the less severe upstream flooding potential.

The Modified Cross-section Alternative is a composite of Alternatives Two and Three in the Main Report, and consists of either converting existing trapezoidal channels into rectangular channels through construction of vertical retaining walls along the lower Rio Hondo and Los Angeles rivers, widening the existing trapezoidal channel, or a combination of both actions. This alternative would also include dredging the lower 2.5 miles of the Los Angeles River channel to a maximum of an additional 5 feet. Minimal bridge reconstruction would be involved with this alternative. Impacts associated with this alternative include the potential loss of approximately 6 acres of wetland, sedimentation impacts associated with construction and dredging, as well as noise and traffic related impacts. There would be additional public safety impacts associated with bike and equestrian trails along the river. Similar to the proposed plan, this alternative would increase flood protection in the lower Rio Hondo and Los Angeles Rivers, but afford no improvements in the upper Los Angeles River.

VOL 12

S.2 AREAS OF CONTROVERSY

Based upon public input at the March 1989 public scoping meetings, two areas of potential controversy are presented below. Other issues discussed at the scoping meetings are identified in Section 5.1 of this EIS.

S.2.1 Areawide Planning and Growth Management

1

Many communities in the flood plain, including the City of Los Angeles, are attempting to implement growth control strategies, and concern has been expressed that the magnitude of the proposed project may not be in line with other basin planning activities.

More specifically, the flow simulation model used by the Corps in designing the required improvement contains certain assumptions regarding development of currently undeveloped lands within the basin. It has been suggested that the proposed Corps project may be growth inducing as a result of these design assumptions and the "capacity" which is built in to handle flows from future areas of potential development.

7/102

Two aspects are important to note concerning this issue. The first has to do with what is growth inducing. The Corps model does assume a developed condition for certain currently undeveloped lands in the drainage area. The percentage of flow increase attributed to this development is about 2 percent of the total flow handled by the system, which and makes little difference in the magnitude of improvements proposed. The basin is considered already fully developed. Further, flood control structures, or lack thereof, do not limit growth in the manner that lack of water or sewer service limit growth. Lack of flood control facilities has not been an important factor historically in stopping development activity.

The second aspect of this growth-inducement issue is the fact that the primary areas of potential development exist in the drainage area headwaters, and the proposed system improvements are focused on the lower, downstream area of the drainage system. The present flood control inadequacies in the lower Los Angeles River and Rio Hondo need to be addressed. No upstream projects can alleviate the need to provide downstream solutions. An incrementally larger downstream solution can provide improved protection in a cost-effective manner. Additional improvements upstream are not effective from a flood control, economic, or environmental point of view.

S.2.2 <u>Project Economics</u>

The economic impact of the project on the cities within the 100-year flood plain was an issue of concern on the part of several participant representatives of local communities. The main issue was whether they would have to pay any costs of the project.

The cost of the project will be shared among the principal local, state, and Federal entities. The Federal government, through the Army Corps of Engineers, is responsible for between 50 and 75 percent of the total project costs. Non-federal interests are, therefore, responsible for between 25 and 50 percent of the total project costs. The local sponsor, the Los Angeles County Department of Public Works, will be responsible for paying this portion. It is possible that the State of California will reimburse up to 70 percent of the local outlay through its subvention program. The local sponsor's funds would come from the flood control budget and would be sufficient to cover project costs. Cities and communities within the lower river flood plain will benefit from the improvements, but will not be required to pay for any construction or maintenance.

S.3 UNRESOLVED ENVIRONMENTAL ISSUES

There are no unresolved environmental issues with the proposed plan.

S.4 RELATIONSHIP TO ENVIRONMENTAL QUALITY STATUTES AND OTHER ENVIRONMENTAL REQUIREMENTS

During the initial project planning and engineering process for the proposed action, consideration was given to the applicable environmental regulations and statutes affecting the environment. Table S.1-1 lists the statutes and indicates the degree of compliance achieved for each alternative. The applicable statutes are also briefly discussed below.

National Environmental Policy Act. This Environmental Impact Statement (EIS) has been prepared in accordance with the National Environmental Policy Act (NEPA) and the Army Corps of Engineers' Procedures For Implementing NEPA, dated March 1988. This EIS contains all sections of content required by NEPA, including a description of the alternatives under consideration as well as a description of environmental resources affected by the proposed alternatives. A description of the public involvement process is also included.

Fish and Wildlife Coordination Act. In compliance with this act, the Corps of Engineers initiated early coordination with the U.S. Fish and Wildlife Service (USFWS) and the California Department of Fish and Game (Appendix G). Through these consultations and associated field studies, it was determined that the proposed action would not require the use of a Habitat Evaluation Procedure (HEP). The channels of the Los Angeles and Rio Hondo drainages support little wildlife, except at the ocean interface. Also, the alternatives evaluation process determined that alternatives which would affect the biotic resources within flood control basins were infeasible. Consultation with these agencies will remain ongoing throughout the EIS process.

Endangered Species Act of 1973, as amended. The Endangered Species Office of the USFWS identified four species that are endangered or threatened in the area of the proposed action. The mouth of the Los Angeles River supports resident California least tern populations, and the area is also known foraging habitat for the California brown pelican. The other two listed species are the Nevins barberry and San Fernando Valley spine-flower. After assessing proposed impacts, the Corps and USFWS have determined, through the Biological Assessment (see Appendix C), that there will be no significant effect on the endangered species. As such, formal consultation pursuant to the Endangered Species Act is not required.

Executive Order 11988, Flood Plain Management. The proposed action is designed to maintain the integrity of the flood plain and to improve the capacity of the existing flood conveyance system. The proposed project complies with this Executive Order.

Executive Order 11990, Protection of Wetlands. Wetlands protection has been considered. No wetlands are affected by the construction activities.

National Historic Preservation Act of 1966, as amended. The Corps is in partial compliance with this act. Determinations of eligibility to the National Register of Historic Places (NRHP) for all of the bridges which will be modified have yet to be made. The State Historic Preservation Officer has been consulted in regard to the need for additional studies (36 CFR 800.4). These studies will be completed during the Preconstruction Engineering and Design phase and coordinated to bring the project into full compliance prior to any construction.

Clean Air Act of 1972, as amended. The South Coast Air Quality Management District (SCAQMD) is the agency with jurisdiction to enforce the Clean Air Act regulations and other relevant local air quality regulations. The project construction emissions have been compared to the threshold limits which trigger New Source Review Rules as defined by the Clean Air Act. The project does not exceed these threshold limits and therefore can be considered in compliance with the act. However, dust abatement measures have been proposed so that project construction operations will comply with SCAQMD Local Rule 403.

Clean Water Act of 1977, as amended. In compliance with the guidelines at the 40 CFR 230.10(c) (promulgated by the EPA under Section 404(b) of the Clean Water Act), no discharge of dredged or fill material due to this project shall be permitted which will cause or contribute to significant degradation of the waters of the United States. The Section 404(b)(1) Evaluation required by the Act appears as Appendix D. It concludes that the proposed discharge sites for the discharge of dredged or fill materials are specified as complying with the requirements of the guidelines, with the inclusion of appropriate and practical conditions to minimize pollution or adverse effects on the aquatic ecosystem. Compliance with Clean Water Act requirements exempting the project from State water quality certification will be effected by submission of this report to Congress and receiving project authorization.

Coastal Zone Management Act of 1972, as amended. Federal consistency review is required when Federal actions may have a direct effect on the coastal zone as defined by the subject act, the California Coastal Act and, specifically, the California Coastal Management Plan. The Corps of Engineers has had informal contact with California Coastal Commission staff relative to the requirements for consistency review. It has tentatively been decided that consistency review will be required because of the potential temporary disruption of recreational activities involving bike and hiking trails along the river and the potential for temporary restricted access to the coast. A coastal consistency determination is provided in EIS Appendix E.

Estuary Protection Act. In planning for use or development of water and land resources, all Federal agencies shall give consideration to estuaries and their natural resources and their importance for commercial and industrial developments. (16 U.S.C. 1224).

All project plans and reports affecting estuaries and their natural resources that are submitted to Congress shall contain a discussion by the Secretary of the Interior concerning the estuaries and their resources and effects of the project on them and his recommendation thereon. Ninety days are allowed after receipt of plans and reports for recommendations to be made. (16 U.S.C. 1224).

Estuary Protection Act. In planning for use or development of water and land resources, all Federal agencies shall give consideration to estuaries and their natural resources and their importance for commercial and industrial developments. (16 U.S.C. 1224).

All project plans and reports affecting estuaries and their natural resources that are submitted to Congress shall contain a discussion by the Secretary of the Interior concerning the estuaries and their resources and effects of the project on them and his recommendation thereon. Ninety days are allowed after receipt of plans and reports for recommendations to be made. (16 U.S.C. 1224).

The proposed action and alternatives do not affect an estuary.

Land and Water Conservation Fund Act of 1965, as amended. No financial assistance may be given under any other Federal program for any project with respect to which such assistance to a State has been given or promised under this statute. (16 U.S.C. 4601-8(f)(1)).

No property acquired or developed with assistance from the Land and Water Conservation Funds shall, without the approval of the Secretary of the Interior, be converted to other than outdoor recreation uses. (16 U.S.C. 4601-8(f)(1)).

In order to assure consistency of policies and actions under this Act with other related Federal programs and activities and to assure coordination of planning, acquisition and development assistance to states under the Act with other related Federal programs and activities, the President may issue regulations. (16 U.S.C. 4601-8(g)). There are no lands associated with the proposed project or alternatives that would be purchased with Land and Water Conservation Funds.

Federal Water Project Recreation Act, as amended. It is policy of the Congress and the intent of the Act that:

1. In planning any Federal navigation, flood control, hydroelectric, or multiple-purpose project, full consideration shall be given to the opportunities afforded by the project for outdoor recreation and fish and wildlife enhancement;

2. Planning for development of the recreational potential of Federal projects shall be based on coordination of use with existing and planned Federal, state, and local public recreation developments; and,

3. Construction agencies shall encourage non-Federal administration of project lands and water areas for recreation and fish and wildlife enhancement except where areas or facilities are proposed for certain situations including national recreation areas, national forests, and wildlife conservation areas. (16 U.S.C. 4601-12).

Some facilities within flood control basins and channels have been developed with Federal Water Project Recreation Act funds. None of these uses will be significantly altered or affected by the proposed project. The Secretary of the Interior will be consulted regarding the effect of the development.

Marine Protection, Research and Sanctuaries Act of 1972, (Ocean Dumping). This act regulates the dumping of material into ocean water and strictly limits dumping of material which would adversely affect human health, welfare or amenities, or the marine environment, ecological systems or economic potentialities.

Disposal of dredged material associated with the modified channel cross-section alternative (Main Report Alternatives Two and Three) has not been fully addressed in terms of quantifying toxicity of the material to be disposed. This would be required prior to disposal of this material to an ocean disposal site. This is not the recommended alternative for construction. The NED plan does not require ocean disposal.

Wild and Scenic Rivers Act, as amended. This drainage basin has been highly altered over most of it's area for many years. None of the streams in the area of study are suitable for designation under this act.

VOL 12

SECTION 1 - NEED FOR AND OBJECTIVES OF THE ACTION

1.1 STUDY AUTHORITY

Under congressional authority, the Los Angeles District of the U.S. Army Corps of Engineers is conducting a flood control study of the Los Angeles County Drainage Area (LACDA) project. The existing flood control system was constructed by the Corps of Engineers and the Los Angeles County Flood Control District (now part of the Department of Public Works) from the 1930s through the 1960s to protect the City of Los Angeles and other metropolitan areas in coastal Los Angeles County from flood damage. Increased urbanization resulting in increased runoff as well as changes in design criteria have resulted in an inadequate level of flood protection afforded by the LACDA system. The purpose of the study is to determine potential methods of increasing the level of flood control protection as well as assessing the environmental effects of modifying facilities. Figure 1.1-1 identifies the general project area.

Prior to 1914, little attention had been directed to the problem of flood control within the LACDA area. The Los Angeles County Flood Control District maintained exclusive authority for flood control from 1916 to 1935. A major flood in 1934 prompted Congress to pass the Emergency Relief Act of 1935 for construction of storm drains, permanent channel improvements and debris basins. The Flood Control Act of June 22, 1936 refined the mission of the Corps of Engineers from that of providing emergency relief to the permanent supervision of future flood control plans which permitted construction of flood control facilities on the Los Angeles and San Gabriel rivers. The Flood Control Act of June 28, 1938, and subsequent Flood Control Acts in 1941, 1944, 1946, 1950, 1954, and 1958 allowed for the completion of the LACDA system.

1.2 PUBLIC CONCERNS

Based on the public scoping meetings held on March 9, 1989, as well as prior meetings, the following are considered major public concerns:

- o Potential impact to wildlife, including areas behind the various dams; the aquatic vegetation in a small portion of the lower Los Angeles River; and potential impact to the California least tern.
- o Potential aesthetic impacts both from the parapet walls as well as from graffiti that the walls may invite.
- o Cumulative impacts associated with development within the LACDA area.
- o Potential impacts to recreation, including bicycle and equestrian trails.
- o Safety concerns associated with the LACDA system.
- o Economic concerns relative to the cost and funding share for LACDA improvements.
- o Concern over the NED plan and the feasibility of other alternatives.

1.3 PLANNING OBJECTIVES

The planning objectives of the LACDA Feasibility Study are as follows:

- o To reduce the potential for human suffering and possible loss of life due to catastrophic failure of the flood control system, wherever feasible;
- o To reduce flood damages originating from the study reaches by increasing the level of flood protection, wherever feasible;

VOL 12

1 7/1/2

- To provide, where feasible, project-related water conservation, recreation development, sediment management, transportation, and environmental enhancement opportunities.

A number of factors have gradually increased the flood threat to Los Angeles County. Analyses indicate that flood events as frequent as 25 years may exceed the capacity of the flood control channels and inundate certain urban areas, especially in the lower Los Angeles River (Reach 4). The low level of protection is attributable to the following factors.

- The original design storm for portions of the LACDA system is based on hydrology that now translates to an approximately 50-year flood;

- Intensive urbanization in the last fifty years has significantly increased the runoff response of the watershed, thereby increasing the maximum peak flow of water the system must handle during a major storm event;

- Greater understanding of freeboard requirements in leveed channel sections has lowered the calculated safe conveyance capacity of some portions of the LACDA channels below original design capacities;

This environmental impact statement describes and assesses the environmental impacts of the alternatives associated with various levels of flood protection within the LACDA system.

SECTION 2 - ALTERNATIVES

2.1 PLANS ELIMINATED FROM FURTHER CONSIDERATION

A range of solutions to reduce the flood threat along the Los Angeles River and the Rio Hondo has been considered by the Corps of Engineers during the initial plan formulation phase of the study. Two stages of analysis were conducted to determine the most feasible alternatives. The first step entailed a general screening and preliminary analysis of many varied alternatives which were listed under the heading of heading of "Strategies" in the main report (Table 5). Several plans were considered and initially rejected. Those passing the primary screening process were analyzed in a more intensive manner. Those passing the second screening were analyzed in further detail. Table 2.1-1 summarizes the various factors used to reject these alternatives from further consideration.

2.1.1 Plans Considered and Initially Rejected

2.1.1.1 Integrate Flow Retarding Facilities into the System

Providing flow retarding facilities other than new flood control dams was eliminated from consideration. This alternative would involve providing additional flood detention facilities in the form of underground reservoirs or aquifers, designation and maintenance of floodways, or discharge of flood flows to wetlands. All of these possibilities have major drawbacks. Underground reservoirs are very expensive and could not be built large enough to be effective. Use of aquifers requires that surface recharge areas be provided. Significant new recharge areas are scarce in the Los Angeles area. Also, recharge does not occur rapidly and is not responsive to rapid runoff events. Designation of floodways is not feasible in urban Los Angeles since development occurs directly adjacent to channels and rivers. Discharge to wetlands is not feasible since an insignificant amount of wetlands exists in the locations where discharging would be most effective.

VOL 12

1716

Table 2.1-1

SUMMARY OF ALTERNATIVES CONSIDERED

Plans Initially Rejected	Ability to Meet Objective	Feasibility	Environmental Factors	Cost/Benefit Ratio	Reason for Rejecting
PLANS INITIALLY REJECTED					
Flow Retarding Facilities	Will not meet objective	Not feasible	Positive	Not computed, but very low	Not effective or implementable
Construct New Dams	May meet objective	No feasible sites found	Major environmental impacts	Not computed but very low	Not feasible plus major environmental impact
Detention Basins	Would not accomplish objective	May be feasible	Soil disposal impacts	Low benefit-to-cost ratio	Not cost effective
Gravel Pits	May meet objective	Questionable feasibility; will require tunnel or pumps	Some impacts anticipated	Low benefit-to-cost ratio	High cost/availability of sites
Increase Height of Existing Dams	May partially accomplish objective	Feasibility questionable	Possible substantial biological impact; land acquisition impact	Not computed	Environmental impact and may not be feasible
Increase Volume of Existing Dams	May partially accomplish objective	Is not feasible	Significant biological impacts	Not computed	Feasibility and environmental impacts
Modify Gates and Outlet Design in Existing Dams	Will not accomplish objective by itself	Feasible, but will not achieve objective	May create significant impact	Not computed	Will not accomplish objective
Renovate Devils Gate Dam	Would not accomplish objective	May not be feasible	May create significant impact; historic implications	Not computed, but very low	Will not accomplish objective, not feasible
Reoperate Existing Dams	Will not accomplish objective	May be feasible	Potential significant biological impact	Not computed	Environmental and feasibility considerations
New Flood Conveyance Facilities	May meet objectives	Probably not feasible	May have substantial impacts	Not computed but very low	Feasibility/cost and impacts
Expand Capacity of San Gabriel	May partially accomplish objective	Feasibility questionable	Will eliminate soft bottom	Low compared to NED project	Feasibility/greater construction impacts/potential

Table 2.1-1 (Continued)

SUMMARY OF ALTERNATIVES CONSIDERED

Plans Initially Rejected	Ability to Meet Objective	Feasibility	Environmental Factors	Cost/Benefit Ratio	Reason for Rejecting
Deeping Existing Channels	May partially meet objectives	Feasibility questionable	May create substantial impacts/soil disposal, utility disruptions	Low compared to NED project	High cost/soil disposal/utility problems
Damage Management	Will not accomplish objective	Not feasible	No additional impacts from present	Not computed	Will not accomplish objectives
PLANS CONSIDERED FURTHER					
Raise Channel Walls and Modify Bridges	Will accomplish objective	Feasible	Construction impacts significant, especially bridges	B/C = 1.7	Studied in detail
Modification of Channel Cross-Section	May accomplish objective	Feasible	Construction impacts significant	Not computed Greater than unity	Studied in detail

VOL 12

2.1.1.2 New Dams

In order to reduce peak flood flows on the Rio Hondo and Los Angeles rivers, it may be possible to construct an additional flood control dam(s). This would have the effect of providing an additional major flood flow detention facility which could reduce peak flows in channels downstream. From an economic standpoint, land acquisition and construction of a new major flood control dam would be very expensive. No feasible site has been identified in a location which would provide effective flow detention for the Rio Hondo and Los Angeles River. Also, the inevitable conversion of existing uses to that of flood control would not have a high level of public acceptance even though some recreational benefits are possible. Alternatives involving construction of new dams were not considered feasible and were eliminated from further consideration.

2.1.1.3 Detention Basins

Pacoima Spreading Grounds. Adaptation of the existing Pacoima spreading grounds at the confluence of the Pacoima Diversion Wash and Pacoima Wash was considered to accommodate occasional flood flows. The existing spreading grounds, which contain approximately 153 acres (62 ha), would be excavated to a uniform 15-foot (4.6 m) depth creating a volume of 2,200 acre-feet (2.7 million m^3). Control works for the Pacoima Wash would inlet water directly to the detention facility. The outlet works would include a gated outlet delivering flow to Pacoima Wash.

This alternative would only influence portions of Tujunga Wash. Due to the limited flood damage reduction, this is not a cost-effective flood control solution. It was therefore dropped from further consideration.

Tujunga Wash Spreading Grounds. This is a similar facility to the Pacoima Spreading Grounds. It is located at the confluence of the Pacoima Diversion Channel and Tujunga Wash. It is not a cost-effective solution to local flood control and is not considered further.

1 7/1/9

Taylor Yard Detention Facility The existing Taylor Railroad Yard contains approximately 200 acres (81 ha) and is located in the Los Angeles Narrows area generally south of the Glendale Freeway between the Los Angeles River and San Fernando Road. The site was considered for use as a temporary flood flow detention facility. All existing facilities would be removed and the site would be excavated to a uniform 29 feet (9 m) in depth providing approximately 4,500 acre-feet (5.5 million m^3) of detention storage capacity. The site might double as a spreading ground during non-detention periods. New inlet/outlet works would be provided.

This alternative was rejected primarily on a cost-benefit basis as the upstream modifications would be very costly while only creating moderate benefits, and since projected flooding in the downtown Los Angeles area would only create relatively low levels of property damage. There would also be substantial impacts associated with extensive excavations and the disposal of large quantities of earth. Furthermore, the availability of the Taylor Yard is questionable since a development proposal has recently been submitted to local planning authorities.

2.1.1.4 Gravel Pits

Two possible gravel pit sites that could be used as off-channel flood storage were identified in the Irwindale area. The Livingston-Graham-El Monte pit has an approximate potential volume of 40,000 acre-feet (49.4 million m^3) with a surface area of approximately 415 acres (168 ha). The Conrock-Durbin pit has an approximate volume of 41,000 acre-feet (50.6 million m^3) with a total surface area of 365 acres (148 ha).

An inlet to the detention pits would be taken directly from the San Gabriel River channel either as a side flow weir or as a valved, operable reinforced concrete inlet. The amount of water that would be diverted would depend on the frequency of event for which this element is used.

VOL 12

1 7 / / 2 /

The existing vertical walls of the quarries would need to be worked to create more gradual side slopes (2:1) and/or stabilized to preclude slippage. Water conservation is a side benefit of this element, either as direct infiltration or by recharge when subsequently returned to the river.

This alternative was rejected from further consideration due to the high cost involved with acquiring the gravel pits, as well as the costs involved with construction of a tunnel or a series of high volume pumps for evacuation. Since the sites are still used for gravel extraction, the Corps would be required to pay for the cost of the unused sand and gravel resources as well as for the costs of the pits themselves. These sites are also proposed for redevelopment by the City of Irwindale, and their acquisition for flood control would impair these plans.

2.1.1.5 Modify Height of Existing Dams

Increasing the capacity of existing flood regulating reservoirs by adding height to the structure was considered. By increasing capacity at major basins, peak flows in channels can be reduced, but not to a wholly satisfactory level. Increasing the height of the dams means that the flood pool elevation and surface coverage would also increase. The additional acreage covered would have to be acquired and managed by the Corps. Land acquisition costs would be significant. Also, the two dams that have the greatest potential benefits from increased capacity, Sepulveda and Whittier Narrows, are most problematical from the standpoint of acquisition of additional land. Increasing the height of existing dams would require expensive structural upgrades, including possible modification of gates and outlet structures. The alternative of increasing the height of existing dams is not considered feasible and is eliminated from further consideration.

2.1.1.6 Modify Volume of Existing Dams

This alternative increases the capacity of existing flood regulating reservoirs by excavation and deepening. Preliminary engineering has determined that the excavation of a significant flood-reducing volume at existing dams has questionable cost effectiveness and feasibility. The excavations currently underway at Hansen Dam and planned for Santa Fe Dam will remove millions of cubic yards of silt and gravel. These maintenance excavations do not increase the capacity of the flood control system, but retain space in the debris pool for future incoming sediment. Disposal of the material may be problematical, and future sediment inflow could render this alternative ineffective. In addition, most of the basins now contain significant biological resources which would be impacted by any major excavation project. Thus it appears that only maintenance-oriented silt removal is feasible at flood control dams and that excavation within flood control dams is not a viable method of increasing system capacity. This alternative will not be considered further in this study.

VOL 12

1/7/22

2.1.1.7 Modify Gates and Outlet Design in Existing Dams

This alternative attempts to reduce peak flood flows through modification of the gate and outlet works at flood control basins. Of the five major flood control dams, Sepulveda has been identified as the most likely candidate for such modifications because of its unique spillway design. The main disadvantage of this alternative is that gate modifications alone cannot effect significant reduction in peak flow volumes. The channels downstream of dams were designed in conjunction with the existing outlets, and discharge flows from the dams can be modified only to a certain degree without making changes to the channels as well. In addition, structural improvements modifying gate and outlet works would be expensive relative to the benefit received. For these reasons, modification of gates and outlet design at existing dams will not be considered further in this study.

2.1.1.8 Renovate Devil's Gate Dam

This alternative calls for the renovation of the existing Devil's Gate Dam on Arroyo Seco. Although this alternative would have no appreciable flood control benefit for the lower Los Angeles River, it may provide an increment of protection for downtown Los

Angeles. However, structural renovation was considered to be too expensive. The dam is also considered to have historical significance which must be considered in any renovation project. This alternative has been eliminated from further consideration since it does not alleviate any flood threat in target areas of the lower Los Angeles River, and its feasibility and cost effectiveness is questionable.

VOL 12

2.1.1.9 Re-operation of Existing Dams

Re-operation (or re-regulation) of existing dams involves changing the basic operating criteria of the dams during the rainy season in an effort to change the peak runoff volumes discharged to the channels. This alternative cannot eliminate flooding inadequacies in the LACDA basin. Implementation may reduce the flood threat in some locations but has the potential to increase the flood threat elsewhere as a result. Furthermore, the rapid response time of flood events in the LACDA system would require accurate and prompt transmission of field data and immediate operational response to the information. These constraints jeopardize the viability and reliability of the alternative. As a result, this alternative will not be considered further in this study.

1723

2.1.1.10 Construct New Conveyance Facilities

Options to convey additional flood flows include construction of new aqueducts, pipelines, tunnels and/or channels. Overland options such as channels and aqueducts have the major problem of the high cost of obtaining new rights-of-way. The construction of underground options would also be very costly and construction limitations would probably not allow the building of structures large enough to handle a sufficient capacity. The costliness of these options makes them infeasible, and therefore the construction of new conveyance facilities will not be considered further.

2.1.1.11 Expand Capacity of San Gabriel River

As an option to constructing improvements to the Los Angeles River channel, flood conveyance capacity of the San Gabriel River channel could be expanded instead, and flows could be diverted from Los Angeles River to San Gabriel River through re-regulation of Whittier Narrows Dam. This option has low feasibility from both policy and technical perspectives. Improvements would have to be constructed along San Gabriel River similar to those proposed for the Los Angeles River. Modification of the San Gabriel River channel would not be easier or less costly than modifications of the Los Angeles River. Additional improvements would call for eliminating extensive areas of soft bottom along the San Gabriel, involving attendant water rights implications. Significant environmental mitigation would also be required. Thus, benefit-to-cost considerations actually would be less favorable compared to improving the lower Los Angeles River.

Currently, the San Gabriel River provides more than 100-year protection to the flood plain, which is significantly better than the lower Los Angeles River provides. Improving the San Gabriel River channel and burdening it with additional flows is not considered desirable or feasible and will not be considered further.

2.1.1.12 Alter Existing Channels

As an option to increasing the existing channel efficiency, it is possible to excavate and deepen channels to increase flood conveyance capacity. This alternative would have very high costs, perhaps comparable to construction of new channels. Existing concrete channel inverts would be removed, the channels deepened, and new concrete inverts placed. Those sewer pipelines and other utilities which presently run beneath the channel invert would have to be relocated at great expense, and extension and possibly reconstruction of bridge piers would be necessary. Earth moving/hauling would be an extensive undertaking which could only be accomplished during non-rainy months. This option has a low benefit-to-cost relationship and has been eliminated from further consideration.

2.1.1.13 Damage Management Alternative

This alternative would focus on measures to reduce the extent of property damage rather than improving the flood control system. These measures would focus upon four basic features including relocation, flood-proofing, flood-fighting and flood plain management/insurance.

Relocation is impractical in the lower reaches of the LACDA basin due to the extensive area impacted. On upper reaches such as Tujunga Wash, this alternative has a poor benefit-to-cost ratio due to the high value of real estate and relatively low flood damage potential.

Flood-proofing would involve the use of dikes and other structures to reduce the extent of damage to structures. Other measures would involve the raising of structures above flood plain levels and the use of materials to minimize damage on ground floors of buildings.

Flood-fighting would involve the use of sandbagging and other emergency measures to reduce the extent of flooding during a major event storm. This could reduce the magnitude of an event but relies on having sufficient warning time in order to respond effectively.

Flood plain management and insurance are currently in place in the majority of the LACDA basin. This does not diminish the existing flood threat but provides for future regulation of flood plain development and an opportunity for financial recovery in the event of flood damage. In a significant flood event, the insurance payout could be in the billions of dollars.

These alternatives were not considered feasible nor did they achieve the study objective. They were no longer considered in this study.

2.2 NO-ACTION ALTERNATIVE

Under the No Action Alternative, no modifications to the LACDA system other than that associated with general operation or maintenance will be provided. There will continue to be a flood threat on portions of the LACDA system, most notably in the lower Los Angeles River near the City of Long Beach where flood protection of only a 40-year level is provided in some areas.

This alternative would involve no new construction and therefore cause no construction-related environmental impacts. In the event of flood flows exceeding the capacity of the system, the levees would be overtopped and could fail due to erosion on the back side of the levee. This would cause general flooding within the City of Long Beach and adjacent areas which would have the potential for loss of life and severe property damage to residential, industrial and commercial properties as well as public facilities. It is estimated that property damage could exceed $2 billion for a 100-year flood.

There would be severe disruption of transportation systems and the potential for toxic material spills and other water quality impacts. There would also be considerable expenditure of energy and other non-renewable resources associated with the rebuilding of flood damaged areas.

2.3 ALTERNATIVES CONSIDERED IN DETAIL

This section provides a description of the alternatives that can accomplish the project objectives and that will be analyzed in detail in this EIS. The action which is contemplated by the Corps has multiple objectives which include:

- Reducing peak flood flows in target areas of the LACDA system,
- Increasing system flow capacity and/or reducing flood-related damage in areas subject to flooding.

The physical and operational aspects of the alternatives which meet these objectives are described below.

VOL 12

1

7127

2.3.1 NED Plan of Improvements (Main Report Section 4)

The National Economic Development (NED) Plan alternative would provide between 100- and 133-year protection for the Rio Hondo and lower Los Angeles Rivers through the implementation of various physical and structural improvements. The proposed improvements fall into the following categories of modification: (1) construction of parapet walls of various heights along the tops of channel levees; (2) raising or modifying traffic, railroad, utility and pedestrian bridges to accommodate higher channel walls; (3) miscellaneous armoring of the levees with stone to prevent wash out;
(4) channel widening at the confluence of the Rio Hondo and Los Angeles rivers; and
(5) overlaying some existing grouted stone channel sides with concrete. It is anticipated that the overall project will require approximately nine years to construct.

2.3.1.1 Parapet Walls (NED Plan)

Parapet walls would be provided on the tops of existing levees on the Rio Hondo Channel and lower Los Angeles River for nearly the entire length of the reaches from Whittier Narrows to the Pacific Ocean. Wall heights would range in height from two to eight feet (0.7 to 2.4 m). Figure 2.3-1 illustrates a typical section detail for a parapet wall. Tables 2.3-1 and 2.3-2 provide information on the location and extent of proposed parapet walls for the lower Los Angeles River and Rio Hondo, respectively. Figures 2.3-2 and 2.3-3 provides a schematic of the maximum parapet wall height by area for each major segment. Concrete would be supplied by batch plants in the area with aggregate coming from the Irwindale area.

2.3.1.2 Raising of Existing Bridges (Main Report NED Plan)

In order to provide parapet walls continuously along the channels, many of the vehicle, railroad and utility bridges which cross the channels must be raised in height. The required height adjustments range from 1.6 to 6.3 feet (0.5 to 1.9 m) for the lower Los Angeles River, and 1.4 to 5.3 feet (0.4 to 1.6 m) along the Rio Hondo.

Of the 25 bridges which cross the lower Los Angeles River, 15 need to be significantly modified. Twelve of the 18 bridges over the Rio Hondo are proposed to be significantly modified. Table 2.3-3 lists the bridges that must be raised and the required height increase for the lower Los Angeles and Rio Hondo. Figures 2.3-5 and 2.3-6 delineate the approximate location of each of these bridges. Raising of these bridges would entail closure for up to an 18-month period. Detours will be provided at most bridges in order to lessen the impact to traffic during the construction period. The proposed detours are summarized in Table 2.3-3. In general, temporary roadway bridges of at least four lanes will be constructed immediately upstream or downstream of the existing bridge. Construction of these bridges may require use of right-of-way in the vicinity of the bridge, as shown in Table 2.3-4. Temporary railroad bridges will also be constructed in a similar manner. Pipeline bridges are not anticipated to require temporary replacement since the construction period to raise these bridges will be much shorter than for railroad and roadway bridges. The bridges are proposed to be constructed in five phases to reduce the intensity of cumulative and adjacent bridge closures.

2.3.1.3 Levee Armoring (NED Plan)

Existing levees would be strengthened by armoring the back slope at selected locations with grouted stone. The specific reaches to receive armoring are shown in Figure 2.3-4. In each location shown on Figure 2.3-4, it is assumed that back sides of both levees will be armored to prevent erosion of the back of the earthen levee in case they are overtopped. Approximately 21,000 cubic yards (15,960 m^3) of grouted stone will be required for the armoring operation. Stone armoring would be delivered from the San Gabriel Rock Quarry or from locations at Santa Catalina Island, San Juan Capistrano, Corona, Colton or Riverside. Stone would be hauled to the site via truck.

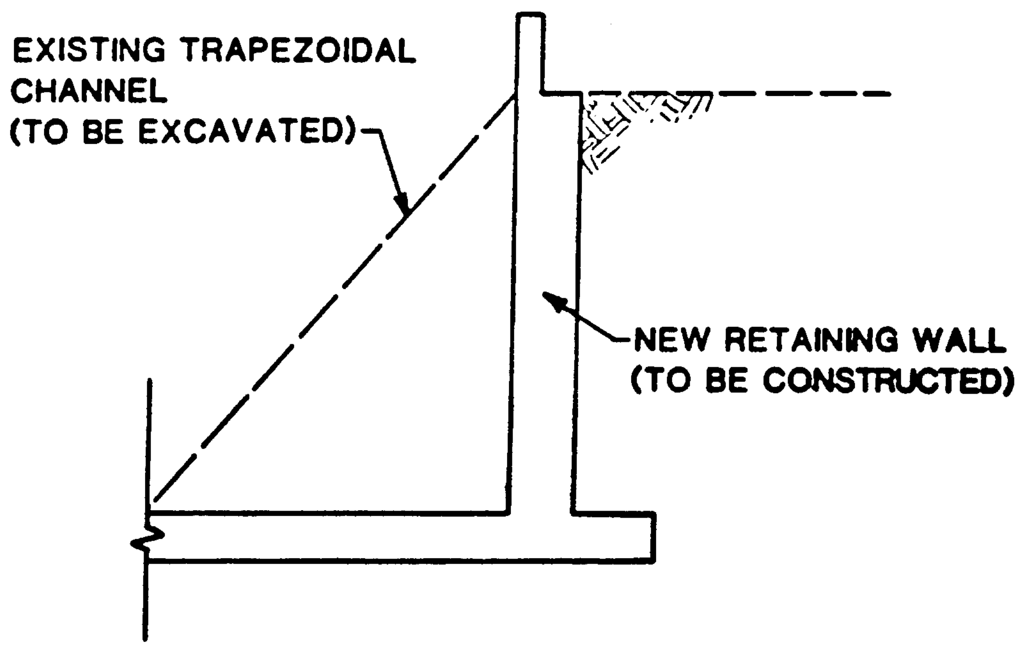
6111-5/89



CONCEPTUAL DESIGN OF CHANNEL WIDENING ALTERNATIVE

FIGURE 2.3-7

VOL 12

17145

VOL 12

2.3.1.4 Widening Channel at Confluence (NED Plan)

At and just downstream of the Rio Hondo-Los Angeles River confluence, a 7000 foot section of the Los Angeles River would be converted from trapezoidal to rectangular cross-section and widened 30 feet. Parapet walls would be constructed on the rebuilt channel walls. Approximately 453,000 cubic yards of excavated material would need to be transferred to a landfill disposal site.

2.3.1.5 Application of Concrete Overlay (NED Plan)

The existing grouted stone channel walls in the vicinity of the Rio Hondo-Los Angeles River confluence will be overlaid with concrete to reduce hydraulic friction and improve channel flow characteristics.

2.3.1.6 Construction (NED Plan)

Overall, construction of the NED alternative will require approximately nine years. Bridge modifications will be accomplished prior to parapet wall construction so that the wall construction can proceed smoothly. Each bridge modification could take from eighteen to thirty months to complete. Tables 2.3-5 and 2.3-6 summarize the personnel and equipment required for construction of this alternative. It should be noted that these are estimates only. An individual contractor may modify the equipment and personnel use.

VOL 12

2.3.1.7 Additional Flood Protection (NED Plan)

An additional level of flood protection (up to 250-year protection) could be provided to the flood plain on the lower Los Angeles and Rio Hondo rivers by adding height to the proposed parapet walls and raising additional bridges. In most cases, parapet walls could be increased in height by less than two feet (compared to the NED protection levels) to accomplish the additional protection.

A major drawback of this alternative would be the necessity of closing bridge ramps over the Los Angeles River on the Artesia Freeway (Freeway 91). The NED plan (100- to 133-year level of protection) represents the greatest level of flood protection without necessitating the raising of the Artesia Freeway bridges.

2.3.2 Modified Channel Cross-section Plan of Improvement (Main Rpt. Alts. 2 and 3)

1-7/47

This alternative would entail the widening and/or converting from trapezoidal to rectangular cross-section of the Los Angeles and Rio Hondo channels in the same reaches as the NED project rather than the construction of the parapet walls. The alternative would involve reconstruction of the trapezoidal channel to a rectangular channel along most of the reaches. The last approximately 2.5 miles (4 km) of the Los Angeles River (from Willow Street to the river mouth) would be dredged out to a maximum of five feet below the current channel bottom (invert). The general characteristics of this alternative are described below. The entire project construction would last an estimated six years.

2.3.2.1 Reconstruction of Channel Walls (Main Report Alternatives 2 and 3)

Under this alternative, the existing concrete trapezoidal channel walls would be removed on one side or possibly both sides of the channel. The concrete, as well as a portion of the existing levee, would be removed. A vertical concrete retaining wall would be poured in place. Additionally, a parapet wall of a maximum of 3 feet (0.9 m) would be placed on top of the wall in some locations. Bicycle and other trail systems would remain in approximately the same location as present. Figure 2.3-7 provides a conceptual drawing of the anticipated design.

Equipment required for this aspect of construction would include cranes, excavators and jackhammers for concrete removal. Bulldozers and wheeled loaders would be required to fill up to 100 trucks per day of concrete and other material. These would be hauled away from the site for disposal. Depending upon the location, some of this material could be placed behind the existing levee, but most would be hauled to a landfill or Pier J in Long Beach Harbor. It is anticipated that up to 100 ready-mix concrete trucks would be required on a daily basis for construction of the new vertical retaining wall. Construction activities at any one location would last up to one year.

Although some modifications of bridge supports may be required, it is not anticipated that many bridges would have to be raised. Therefore, most existing bridges would not require reconstruction and would remain in operation throughout the proposed project. It is also anticipated that only a few additional feet behind the existing footprint of the levee would be required for channel modifications.

Approximately the same amount of armoring as described for the NED project would be required. The locations for channel armoring may vary from the NED project. Exact locations for armoring would be determined during final engineering design.

Utilities	No impact	Potentially significant temp. impacts	Potentially significant temp. impacts

2.3.2.2 Dredging Operations (Main Report Alternatives 2 and 3)

The 2.5 mile (4 km) segment of the Los Angeles River from the river mouth to Willow Street would be dredged rather than widened. Although precise dredging requirements are not now known, the maximum depth of dredging would be 5 feet (1.5 m). A diesel-powered dredge would be used in the channel. Removed material would be either loaded on barges and disposed of at a deep water disposal area (probably LA-2 or LA-3) or loaded onto trucks and transported to approved onshore disposal areas such as Pier J in Long Beach. Assuming that removal of the 5 feet (1.5 m) of material were required for all portions of the reach, up to 560,000 cubic yards (425,600 m^3) of material would be dredged and require disposal.

2.4 COMPARATIVE IMPACTS OF ALTERNATIVES

Project impacts are presented in table format in Table 2.4-1 to provide a comparison of the project alternatives.

2.5 ENVIRONMENTAL COMMITMENTS (MITIGATION COMMITMENTS)

Mitigation measures proposed for the project alternatives are as follows:

2.5.1 Land Use

2.5.1.1 No Action Alternative

No Impacts.

VOL 12 1751

VOL 12

2.5.1.2 NED Plan Alternative (Main Report)

Mitigation for use of the various properties identified in Table 2.3-4 would include financial compensation and full replacement of the site after construction activity has ceased.

2.5.1.3 Modified Channel Cross-section Alternative (Main Report Alts. 2 and 3)

Mitigation measures for activities which encroach upon adjacent uses are presented under other resource sections within this document, including noise, air quality and traffic.

2.5.2 Air Quality

2.5.2.1 No Action Alternative

No Impacts.

2.5.2.2 NED Plan Alternative (Main Report)

o Frequent watering of the construction area to limit dust emissions from on-site equipment and off-site trucks accessing the project,

o Provisions for terminating operations during strong Santa Ana wind conditions,

o Good maintenance, involving proper tuning of off-road heavy equipment to reduce combustion source air emissions (especially NOx),

o Control of diesel fuel quality (low sulfur content),

1
7/152

o Site activity control/termination during Stage II smog episodes,

o Contractor participation in the AQMD mandatory rideshare program (Regulation XV).

2.5.2.3 Modified Channel Cross-section Alternative (Main Report Alts. 2 and 3)

Mitigation measures are the same as listed above in Section 2.5.2.2.

2.5.3 <u>Water Quality</u>

2.5.3.1 No Action Alternative

No Impacts.

2.5.3.2 NED Plan Alternative (Main Report)

Whenever possible, work within the channel will be confined to low flow periods. Downstream sediment basins will be constructed in order to trap sediments from construction operations. Refueling of equipment near the channel will be limited and closely monitored.

2.5.3.3 Modified Channel Cross-section Alternative (Main Report Alts. 2 and 3)

Sedimentation basins will be constructed downstream of construction activities. A hydraulic cutterhead dredge will be used to minimize turbidity in the channel. Use of these methods should reduce impacts to insignificant levels.

VOL 12

1 7/53

2.5.4 Noise

2.5.4.1 No Action Alternative

No Impacts.

2.5.4.2 NED Plan Alternative (Main Report)

- o A line-of-sight break between noise sources and the nearest sensitive receptors is a the critical factor in maintaining project activity noise impacts at unobtrusive levels. This would be accomplished by placement of a temporary berm to shield residences and other receptors from construction activity. In areas where land is accessible and available, a large berm would reduce noise levels by as much as 20 dB.

- o In areas of extreme noise conditions where berms are not feasible, either construction of temporary walls to serve as noise barriers or additional limits on work hours will be warranted to protect these sensitive receptors.

- o Smaller, and therefore less noisy, construction equipment will be evaluated for use in the preconstruction engineering design phase in some sensitive construction areas such as parapet walls near sensitive noise receptors.

- o Because of the increased noise sensitivity during quiet hours, time limits on allowable on-site equipment operations are normally made a condition on construction permits. No on-site activities would be permitted before 7:00 AM weekdays and not before 8:00 AM on Saturdays, and not at all on Sundays or holidays because the noise background is lower on those days and project impacts will become more distinct when they are not blended into the background noise environment. No construction activities would occur after 7:00 PM.

- o No effective mitigation is available for the use of pile drivers.

VOL 12

1754

2.5.4.3 Modified Channel Cross-section Alternatives (Main Rpt. Alts. 2 and 3)

Noise mitigation measures are identical to those described in Section 2.5.4.2 for the NED Alternative except that pile drivers are eliminated and as such, there are no concerns of mitigation for that equipment.

2.5.5 Biological Resources

2.5.5.1 No Action Alternative

No Impacts.

2.5.5.2 NED Plan Alternative (Main Report)

- o The wetland areas in the lower most portion of the Los Angeles river will not be destroyed by construction activities. This area will be monitored to assure that no activities or materials are discharged in this area.

- o In order to prevent impacts to nesting birds in the wetland as well as not to disturb foraging activities of the least tern and brown pelican, activities will not be conducted from April through September in the last one-mile reach of the river near the river mouth. This would result in no adverse effects on the species.

2.5.5.3 Modified Channel Cross-section Alternative (Main Report Alts. 2 and 3)

- o Disturbance to the wetland area can be mitigated through replacement of habitat near the channel area. Mitigations as described under the NED Plan would result in no adverse effect on the species.

- o A hydraulic cutterhead dredge will be used to reduce the degree of turbidity. If chemical testing indicates that dredge specimens are highly contaminated, dredging operations would be restricted to periods of slack tide and low or no river flow. Contaminated sediments would be disposed of at an approved facility and/or site.

VOL 12

2.5.6 Cultural Resources

2.5.6.1 No Action Alternative

No Impacts.

2.5.6.2 NED Plan Alternative (Main Report)

o The Corps shall complete compliance with Section 106 of the National Historic Preservation Act prior to the initiation of construction. 1

o Prior to implementation of the project, an evaluation and determination of National Register of Historic Places eligibility for all bridges which will be modified must be made. This step has been partially completed. There are still four bridges on the Rio Hondo that must be evaluated by a qualified historian and results coordinated with the State Historic Preservation Officer and the Advisory Council on Historic Preservation.

o If any bridges are determined to be NRHP eligible which would be modified, mitigation would be required. It is assumed that mitigation would consist of HABS/HAER recordation. These mitigation measures would have to be agreed to in a Memorandum of Agreement between the Corps, the California State Historic Preservation Officer and the Advisory Council on Historic Preservation. Execution and implementation of the MOA would constitute compliance with Section 106 of the National Historic Preservation Act.

7/56

2.5.6.3 Modified Channel Cross-section Alternative (Main Report Alts. 2 and 3)

No Impacts.

2.5.7 Transportation

2.5.7.1 No Action Alternative

There is no change; therefore, mitigation is not an issue.

VOL 12

1 7157

2.5.7.2 NED Plan Alternative (Main Report)

- o Schedule construction traffic to off-peak hours;
- o Utilize the river channel for construction vehicle traffic and vehicle staging whenever possible;
- o Avoid reducing traffic capacity on two adjacent bridges simultaneously, if possible;
- o Utilize signing and flagmen where construction equipment interface with public traffic;
- o Institute public information programs to enable motorists to avoid congested areas:
    - Place large signs far enough in advance of potentially impacted roadway segments to allow motorists opportunity to alter their routes,
    - Place public notices in local newspapers and cable TV bulletin boards,
    - Distribute mailers in the project area.

2.5.7.3 Modified Channel Cross-section Alternative (Main Report Alts. 2 and 3)

- o Schedule construction traffic to off-peak hours;
- o Utilize the river channel for construction vehicle traffic and vehicle staging whenever possible;
- o Establish an on-site batch plant to mix concrete.
- o Utilize an ocean dredged material disposal site, if possible;

- Utilize signing and flagmen where construction equipment interface with public traffic.

2.5.8 <u>Recreation and Aesthetics</u>

2.5.8.1 No Action Alternative

No Impacts.

2.5.8.2 NED Plan Alternative (Main Report)

- No equally satisfactory alternative exists for mitigation of the rerouting of recreational trails during construction. While construction occurs on the bike path, the possibility exists of using the west side of the levee and surface streets for bicyclists, although this is less appealing due to the presence of automobiles. No mitigation exists for equestrian users. This impact is temporary for the duration of construction (approximately one year) between recreational trail access points.

- Mitigation for the loss of aesthetic views includes the design of trails on the levee top such that views are provided of the land areas to the outside of the channels. This could also include the planting of shubbery in accessible areas and the possible development of additional strip park areas. The development of additional park areas could serve to provide additional recreational resources within communities adjacent to the channel and could be developed under a joint agreement with those communities. As an alternative, mitigation could be provided by the strategic setting of areas of large potted plants or built-in planters and designed seating areas/rest stops at areas along the trails. These measures would result in aesthetic conditions which are improved over existing conditions. These options will be evaluated during the Preconstruction Engineering and

VOL 12

1159

Design phase when the final project designs and the availability of local fiscal support are known.

- Mitigation measures for the problem of graffiti on the parapet walls include coating the walls with a material such that clean up is easier and incorporating graffiti removal into maintenance activities. There is also a potential that murals could be painted in some areas by the local sponsor(s).

- Mitigation measures include determining whether a temporary bike path can be routed so that access to the coast is still available to recreation users.

2.5.8.3 Modified Channel Cross-section Alternative (Main Report Alts. 2 and 3)

- As described in Section 2.5.8.2, no safe, feasible mitigation exists for the rerouting of recreational trails during construction. The possibility exists of using surface streets for bicyclists, although safety hazards exist for accidents with automobiles. No mitigation exists for equestrian users. This impact is temporary for the duration of construction between recreational trail access points.

- No loss of aesthetic views will occur except for the potential loss of wetlands areas. General mitigation measures include the design of trails on the levee top such that views are provided of the land areas to the outside of the channels. This could also include the planting of shubbery in accessible areas and the possible development of additional strip park areas. The development of additional park areas could serve to provide additional recreational resources within communities adjacent to the channel and could be developed under a joint agreement with those communities. As an alternative, mitigation could be provided by the strategic setting of areas of large potted plants or built-in planters and designed seating areas/rest stops at areas along the trails. These measures would improve aesthetic conditions over existing conditions. These options may be evaluated during the Preconstruction Engineering and Design phase when the final project designs and the availability of local fiscal support are known.

VOL 12

o Mitigation measures for the problem of graffiti on the parapet walls includes coating the walls with a material such that clean up is easier and incorporating a routine graffiti removal program into maintenance activities. There is also a possiblity that murals could be painted on the walls.

2.5.9 Public Safety

2.5.9.1 No Action Alternative

No changes are being made; therefore, mitigation is not an issue.

2.5.9.2 NED Plan Alternative (Main Report)

o Mitigation for safety impacts along trails at channel levees requires that the trails be closed between trail access points for the duration of construction along that segment. No equally satisfactory alternative exists for the rerouting of recreational trails during construction. Surface streets provide a less appealing alternative for bicyclists. No mitigation exists for equestrian users. This impact is temporary for the duration of construction between recreational trail access points.

o Mitigation includes that fencing and barriers be placed around areas of construction and that construction equipment be placed in areas at night that are secured from the gene.al public. Also, warning signs will be placed in appropriate locations to warn pedestrians and motorists of potential safety hazards.

o Mitigation for trucks delivering materials to and taking materials from construction sites includes the limitation of activity during peak traffic hours and during hours when children are traveling to and from school. Additionally, signs and flagmen will be used in areas to direct traffic where necessary.

o The potential for release of toxic material is also reduced if flood potential is reduced.

1 7 1 6 1

2.5.9.3 Modified Channel Cross-section Alternative (Main Report Alts. 2 and 3)

- Mitigation for safety impacts along trails at channel levees requires that the trails be closed between trail access points for the duration of construction along that segment. No equally satisfactory alternative exists for the rerouting of recreational trails during construction. Surface streets provide a less appealing alternative for bicyclists. No mitigation exists for equestrian users. This impact is temporary for the duration of construction between recreational trail access points.

- Mitigation for the vertical drop of the channel walls includes placing a chain-link or other fencing on top of parapet walls to a minimum combined height of seven feet (2.1 m). This will provide for safe use of the trail system. An alternative would be to build the parapet walls to a height of seven feet (2.1 m), although this results in a "closed-in" feeling, reduces aesthetics and provides more opportunity for graffiti on solid walls.

- Mitigation for trucks delivering materials to and taking materials from construction sites includes the limitation of activity during peak traffic hours and during hours when children are traveling to and from school. Additionally, signs and flagmen will be used in areas to direct traffic where necessary.

2.5.10 Utilities

2.5.10.1 No Action Alternative

No Impacts.

VOL 12

1 7 1 6 2

2.5.10.2 NED Plan Alternative (Main Report)

Close coordination with the pertinent utilities will help mitigate any impacts. Disruption to service will be minimized.

2.5.10.3 Modified Channel Cross-section Alternative (Main Rpt. Alts. 2 and 3)

Mitigation includes that affected utility lines be moved or replaced in conjunction with construction activities. Disruption to service will be minimized.

SECTION 3 - AFFECTED ENVIRONMENT

3.1 INTRODUCTION

This section describes existing environmental conditions relative to areas affected by the proposed action of the NED Plan and modified channel cross-section alternative. The project study area is composed of two distinct sub-areas, and affected environment descriptions have been provided for these two areas, as appropriate. One study subarea is the existing flood overflow area. This includes both the 500-year and 100-year flood plains (or overflow areas). The 100-year flood plain is important since this subarea will be almost entirely eliminated by the alternatives to the proposed action. The existing conditions in the flood plains are covered to a general level of detail. The lower Los Angeles and Rio Hondo Rivers were analyzed more intensively since any impacts would occur in these areas.

3.2 STUDY AREA OVERVIEW AND FLOOD OVERFLOW AREA DEFINITION

The area of primary interest for the LACDA Review Study includes the major interconnected channels within the LACDA flood control system. Specifically, this general area includes all of the Los Angeles River below Sepulveda Dam, its Tujunga Wash tributary below Hansen Dam, the Rio Hondo between Whittier Narrows Dam and the confluence with Los Angeles River, the San Gabriel River below Santa Fe Dam, and Compton Creek. The reach designations for LACDA channels of interest to this study are shown on Figure 3.2-1 and listed in Table 3.2-1.

Table 3.2-1

REACH DESIGNATIONS FOR LACDA SYSTEM MAIN CHANNELS

Reach	Location
1	Tujunga Wash Channel - Hansen Dam (499+88.27) to the Los Angeles River (7+00)
2	Upper Los Angeles River - Sepulveda Dam (969+88.83) to Arroyo Seco Confluence (1273.10)
3	Los Angeles River - Arroyo Seco Confluence (1273+10) to Rio Hondo Confluence (614+52.50)
4	Lower Los Angeles River - Rio Hondo Confluence (641+52.50) to Pacific Ocean (16+00)
5	Rio Hondo Channel - Whittier Narrows Dam (442+23.71) to Los Angeles River (7+00)
6	San Gabriel River - Whittier Narrows Dam to Imperial Highway
7	San Gabriel River - Imperial Highway to Pacific Ocean
8	San Gabriel River - Santa Fe Dam to Whittier Narrows Dam
9	Compton Creek

Flood size predictions are made by the Corps of Engineers based on potential rainfall and runoff rates. Floods are also categorized in terms of their statistically projected frequency. A 10-year flood has a 10 percent chance of happening every year, while a 100-year flood has a one percent chance of occurrence every year, and a 500-year flood has a 0.2 percent chance of occurrence every year. However, flood risk increases over long periods of time. A 50-year flood has an 85 percent chance of occurring one or more times over a 100-year period. A 100-year storm has a 65 percent chance of occurring once in 100 years.

Presently, portions of the LACDA system do not have the capacity to prevent flooding from the 100-year flood. The majority of the flood control system was built in the 1930s and 1940s. Since that time, there has been substantial urbanization within the study area with accompanying increases in storm water runoff to channels. This is a result of an increase in impervious surfaces and the increased effectiveness of the storm drain system. Several key portions of the flood control system within the study area could overflow during a 50-year flood.

The 100-year flood overflow area is delineated on Figure 3.2-2. The overflow from a 100-year flood would cover approximately 82 square miles (212 km^{fect} developed areas in the San Fernando Valley near the Los Angeles River and Tujunga Wash, downtown Los Angeles near the Los Angeles River, and a large area bordering the Los Angeles River and the Rio Hondo that encompasses parts of Bellflower, Burbank, Carson, Cerritos, Compton, Downey, Glendale, Lakewood, Long Beach, Lynwood, Montebello, Paramount, Pico Rivera, and South Gate, in addition to some Los Angeles County territory. In some localized areas, flood waters could be as deep as eight to ten feet (2.4 to 3.1 m). Most areas, however, could experience flooding of one to four feet (0.3 to 1.2 m).

The 500-year overflow area also is delineated on Figure 3.2-2. The overflow from a 500-year flood would cover nearly 200 square miles (518 km^2), virtually all of which is urban development. A 500-year flood would cover all of the areas affected by the 100-year flood and, in addition, would cover a large area of central Los Angeles, additional areas in the San Fernando Valley and large portions of the cities of Artesia, Bell, Cudahy, Hawaiian Gardens, Huntington Park, Maywood, Norwalk, Santa Fe Springs, Seal Beach, Vernon and Whittier. There are 26 cities, some Los Angeles County territory, and some Orange County territory within the 500-year overflow area.

Table 3.2-2 provides an estimate of the area covered by flood flows in each major channel reach within the study area for both the 100-year and 500-year floods.

3.3 LAND USE AND SOCIAL CONCERNS

3.3.1 Flood Overflow Areas

The 100- and 500-year flood overflow areas overlay a highly diverse urban environment. The total population within Los Angeles County in 1989 was approximately 8,700,000 persons. The Corps of Engineers estimates that 1,200,000 people reside in the 500-year overflow area, or about 15 percent of the County population. Total employment in the Los Angeles-Long Beach Partial Metropolitan Statistical Area (PMSA), which covers approximately the same area as Los Angeles County, as of 1983 was 4,000,000. The highest employment category is the service sector, with 1,090,000 jobs, followed by manufacturing, with nearly 900,000 employed. Los Angeles County is projected to continue growing through the year 2000. Population and employment trends for the 500-year flood overflow area will be similar to those of the PMSA as a whole; thus population within the 500-year overflow area could reach 1,800,000 by the year 2000.

Land use within the 500-year overflow area is highly diverse with residential, commercial, industrial and public uses spread throughout the area. However, there are high concentrations of particular property categories. Downtown Los Angeles is highly commercial, while there is a concentration of industrial facilities in the area of the lower Los Angeles River below the Compton Creek confluence. The San Fernando Valley is predominantly residential with corridors and pockets of commercial and industrial activity. The area of the San Gabriel River below Imperial Highway is largely residential.

Overall, the total value of improvements within the 500-year flood plain is approximately $40 billion, of which about 50 percent is attributable to single-family residences.

Table 3.2-2

SUMMARY OF AREA FLOODED
(in square miles)

Reach	500-Year Flood	100-Year Flood
Reach 1	11.1	2.0
Reach 2	7.2	1.8
Reach 3	52.6	1.7
Reach 4	46.2	38.5
Reach 5	12.3	12.3
Reach 6	18.2	0.0
Reach 7	50.4	25.7
TOTAL	198.0	82.0

NOTES: Reach definitions are indicated in Figure 3.2-1 and described in Section 2.

Reach 7, 500-year flood includes 4.8 square miles of shallow flows over Seal Beach U.S. Naval Weapons Station and Seal Beach National Wildlife Refuge.

There is not a significant amount of open space in the flood overflow area since the bulk of the area is highly developed. Most open space is associated with recreational facilities such as parks, golf courses and sport fields. Other substantial open space which occurs in the flood plain includes the major water spreading grounds, i.e., the coastal grounds along Rio Hondo and the San Gabriel grounds along the San Gabriel River, and includes the wetlands areas in Seal Beach under control of the U.S. Navy.

The Corps of Engineers has conducted land use surveys in the 500-year overflow area and has tallied the number of damageable structures in each land use category. The inventoried flood plain land use improvement categories included residential use (single-family, multi-family and mobile homes); commercial uses (including retail outlets, hotels and privately-owned offices); industrial uses (including manufacturing plants, research and engineering facilities, warehouses, business parks and construction yards); and public use (including schools, hospitals, churches, public organizations and offices, and police and fire stations). Tables 3.3-1 and 3.3-2 provide data on the number of damageable units by channel reach for the 500-year and 100-year overflow areas respectively.

3.3.2 Land Use Adjacent to Channel Reach Construction Reaches

3.3.2.1 Lower Los Angeles River

The generalized land uses adjacent to this reach are shown in Figure 3.3-1. The predominant use within 2,000 feet (610 m) on either side of the channel is residential. Industrial uses are also prevalent along this reach. Public parks, golf courses and public structures occur throughout the channel study zone; however, many of these features are linear and border the channel. There are six schools whose property is either wholly or partially within 2,000 feet (610 m) of the channel. No churches or hospitals are located within this zone.

3.3.2.2 Rio Hondo Channel

The generalized land uses along the Rio Hondo, Reach 5, are shown in Figure 3.3-2. As with most areas of the LACDA, the uses are mixed, with residential and industrial being the predominant types. There is a substantial amount of public-controlled land in this reach, primarily due to the large spreadings grounds at mid-reach. Three schools are located within 2,000 feet (610 m) of the channel, and no churches or hospitals were identified in this area near construction zones.

3.4 AIR QUALITY

3.4.1 Climatic and Ambient Air Quality Factors

The project is located within the South Coast Air Basin, which is monitored by the South Coast Air Quality Management District (SCAQMD). The distinctive climate of the basin is determined by its terrain and geographical location. The basin is a coastal plain with connecting broad valleys and low hills, bounded by the Pacific Ocean in the southwest quadrant, and with high mountains forming the remainder of the perimeter. The general region lies in the semi-permanent high pressure zone of the eastern Pacific. As a result, the climate is mild, tempered by cool sea breezes. This usually mild climatological pattern is interrupted infrequently by periods of extremely hot weather, winter storms, and Santa Ana winds.

The SCAQMD and the California Air Resources Board (CARB) maintain a network of air quality monitoring stations within the basin. The stations monitor the surrounding air for the presence of ozone (O_3), carbon monoxide (CO), sulfur dioxide (SO_2), nitrogen dioxide (NO_2), suspended particulate matter (PM_{10}), lead (Pb), sulfate (SO_4), and nitrate (NO_3). Excepting nitrate, these are pollutants for which the State and Federal governments have established air quality standards and, in some cases, episode criteria. Table 3.4-1 contains current Federal and State air quality standards.

Existing levels of air quality near the project channel and in 100-year and 500-year flood overflow areas can be inferred from ambient air quality measurements from seven air quality monitoring stations located in reasonable proximity. These stations include Los Angeles, West Los Angeles, Long Beach, Reseda, Burbank, Azusa and Lynwood. Data is summarized in Table 3.4-2.

The South Coast Air Basin remains a non-attainment area for all State and Federal ambient air standards except lead and sulfur dioxide. Ozone and particulate standards are exceeded throughout the Basin, carbon monoxide standards in about one-fourth of the Basin, and nitrogen dioxide and sulfate standards only in specific portions of Los Angeles.

Table 3.4-1

STATE AND FEDERAL AMBIENT AIR QUALITY STANDARDS AND EPISODE CRITERIA

AMBIENT AIR QUALITY STANDARDS, 1987

Air Pollutant	California: Concentration	California: District Method	Federal: Primary	Federal: Secondary	Federal: Method[a]

SOURCE: SCAQMD, 1987

All monitoring stations in the study area recorded frequent exceedances of the ozone standard. Only the west Los Angeles, Long Beach and Azusa stations did not exceed the Federal carbon monoxide standard. Suspended particulate concentrations were particularly severe at the Los Angeles, Burbank and Azusa stations (Reaches 3, 2 and 6, respectively).

Although the study area has notoriously unhealthful air quality, there is an encouraging improvement trend. The number of second stage alerts for ozone (1 hour >0.35 ppm) has decreased dramatically from a recent high of 23 in 1978 to only one episode in 1988.

3.4.2 Air Quality in Channel Reach Construction Zones

3.4.2.1 Lower Los Angeles River

A major source of localized air pollution along this reach is the Long Beach Freeway. The freeway parallels the river for the entire length of Reach 4 (from the ocean to the confluence with Rio Hondo). Other important air pollutant generators include miscellaneous industrial uses, agricultural operations and the numerous unpaved lots that are used for equipment storage and other unauthorized uses.

3.4.2.2 Rio Hondo Channel

Vehicular sources contribute to localized air quality degradation along this reach, however, not to the extent that occurs along Reach 4. In addition to industrial uses, the unpaved and unvegetated spreading grounds are a major source of suspended particulates.

VOL 12

17183

3.5 WATER QUALITY

3.5.1 Flood Plain Area

3.5.1.1 Surface Water

The flood plain area is located within the urban environment with the LACDA system serving as the principal drainage for the area. Water quality in the region is generally poor due to mixing of the runoff with contaminants on roadways and other areas. Grease, heavy metals and other particulates are of substantial concern.

3.5.1.2 Groundwater

Total dissolved solids (TDS) are high in portions of the Coastal Plain as a result of seawater intrusion. The West Coast Basin has the highest average TDS; in 1982, it averaged 1441 mg/l. TDS in the Santa Monica-Hollywood and Central Basins averaged 924 and 407 mg/l, respectively (LACFCD, 1982). Because these figures are averages over entire basins, they may not be representative of the water actually used. For example, the high TDS for the West Coast Basin is probably partly due to seawater intrusion in some wells.

Iron and manganese occasionally exceed standards in some wells. This sporadic problem is not a health hazard. High iron and manganese tend to precipitate as hydroxides and stain laundry and porcelain fixtures and can cause the taste and color of water to be objectionable.

In addition to the general contaminants, the groundwater is subjected to many contaminants associated with hazardous waste from underground storage tanks and other sources.

3.5.2 Los Angeles, Rio Hondo and Compton Creek Channels

3.5.2.1 Surface Water

The Los Angeles River receives substantial contribution from urban sources during rainy periods. The main channel through the coastal plain is primarily impervious, which reduces groundwater recharge.

Recent water quality data for the Los Angeles River collected during dry weather flow conditions is shown in Table 3.5-1. It shows average water quality data for Firestone Boulevard and Wardlow Street in Long Beach. Of the constituents measured, coliforms and heavy metals tended to vary the most from one sample to the next. Since the Los Angeles River system drains the heavily urbanized portion of the basin, runoff to channels will sometimes contain significant levels of oil, grease and other hazardous residues. Field visits to LACDA facilities have confirmed that surface flows have contained an oil sheen, and some silts and debris removed from channels have had a black tar-like color even after being dewatered. This problem is especially prevalent in the Los Angeles River channel and in the Compton Creek channel.

Phosphorus concentrations are not significantly elevated at the downstream locations being measured but can be presumed to be higher to those upstream portions of the Los Angeles River receiving treatment plant effluent. Some of the phosphorus and nitrogen content is expected to be assimilated by the existing vegetation in the cobbled section of the river near Glendale/Atwater.

The Compton Creek channel experiences additional water quality problems due to dumping of oils and other toxics into the channel by illegal dischargers. Maintenance personnel have noted considerable oil and other contaminants within this area.

3.5.2.2 Groundwater

The groundwater within the immediate vicinity of the channel approximates groundwater characteristics for the entire basin. Since most of the channel has a paved bottom, the recharge from the river is minimal.

3.6 NOISE

3.6.1 Flood plain Noise Considerations

3.6.1.1 Noise Standards

Time variations in noise exposure are typically expressed in terms of a steady-state energy level equal to the energy content of the time varying period (called Leq), or, alternately, as a statistical description of the sound level that is exceeded over some fraction (10, 50 or 90 percent -- called L10, L50 and L90, respectively) of a given observation period. Finally, because community receptors are more sensitive to unwanted noise intrusion during the evening and at night, state law requires that for planning purposes, an artificial dB increment be added to quiet time noise levels to create a 24-hour noise descriptor called the Community Noise Equivalent Level (CNEL). Some communities use a different 24-hour noise descriptor called day-night average level, or Ldn. CNEL and Ldn are statistically similar and usually are calculated to within 1 dB of one another.

A maximum interior CNEL of 45 dB(A) is mandated for multiple family dwellings, and is considered a desirable noise exposure for single family dwelling units as well. Since typical noise attenuation through residential structures with closed windows is 20 dB or more, an exterior noise exposure of 60 dB CNEL is thus typically the design exterior noise for new residential dwellings in California. Because commercial or industrial uses are not occupied on a 24-hour basis, the same exterior noise exposure standard generally does not apply for these less noise-sensitive land uses.

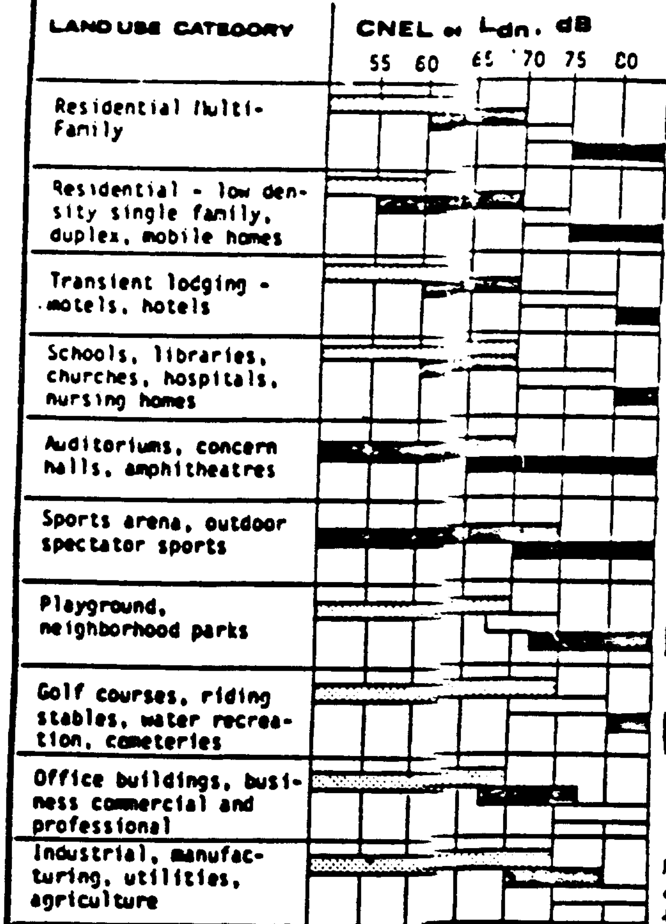
The interior noise exposure guideline and its relationship to acceptable exterior structural noise loading forms the basis for the noise elements or zoning and noise ordinances from the various jurisdictions in the study area. The Southern California Association of Governments (SCAG) has developed a noise/land use compatibility matrix applicable to the study area (see Figure 3.6-1). The land-use compatibility guidelines are exactly that; i.e., they are advisory guidelines.

Noise ordinances generally have specific noise emissions standards on individual sources, and therefore apply most directly to the proposed project elements. Such standards apply at the nearest point of normal site occupancy in outdoor areas or at the closest window/door to the adjacent noise source. Controlling noise emission rates, maintaining an adequate distance buffer between the source and the nearest sensitive receptor, and use of physical line-of-sight breaks are all potential measures by which the standards can be maintained along the project corridor.

However, it should be noted that most communities do not regulate the noise emissions from construction except through controls on the hours of operation. The lack of such standards, plus the fact that the LACDA channels form a boundary between several jurisdictions where it should be difficult to allocate impact responsibility to only one community, suggest the use of SCAG noise/land use compatibility guidelines as a more appropriate source of noise standards for the project noise impact assessment.

VOL 12

17188



INTERPRETATION

NORMALLY ACCEPTABLE

Specified land use is satisfactory, based upon the assumption that any buildings involved are of normal conventional construction, without any special noise insulation requirements.

CONDITIONALLY ACCEPTABLE

New construction or development should be undertaken only after a detailed analysis of the noise reduction requirements is made and needed noise insulation features included in the design. Conventional construction, but with closed windows and fresh air supply systems or air conditioning will normally suffice.

NORMALLY UNACCEPTABLE

New construction or development should generally be discouraged. If new construction or development does proceed, a detailed analysis of the noise reduction requirements must be made and needed noise insulation features included in the design.

CLEARLY UNACCEPTABLE

New construction or development should generally not be undertaken.

SOURCE: In part taken from "Aircraft Noise Impact Planning Guidelines for Local Agencies", U.S. Dept. of Housing and Urban Development, TE/NA-472, November 1972.

LAND USE COMPATIBILITY FOR COMMUNITY NOISE ENVIRONMENTS

FIGURE 3.6-1

VOL 12

17189

3.6.1.2 Noise Characteristics in Flood Overflow Areas

The channels within the LACDA system are characterized by a wide diversity of ambient noise. Adjacent freeways, railroad crossings, quarry and industrial operations, commercial, residential areas and parks and golf courses run adjacent to the channels. Strong variations in noise levels will occur over relatively short distances as these land uses change. However, even with all these land uses, the primary existing noise source along the flood control channels is almost exclusively from vehicular noise throughout the greater urbanized area. There are some portions of channels which experience high noise levels from traffic as well as other sources. These include the commercial/industrial areas such as Compton Creek, and areas in close proximity to aircraft noise such as channels near Hansen Dam and Sepulveda Dam, which are near local airfields.

The quietest areas in the Los Angeles River system are in the most remote locations such as along the edge of Griffith Park or in Haines Canyon. Areas adjacent to residential areas, and parks and golf courses also tend to have quieter noise levels. However, most of these areas are not much quieter than background noise levels in developed areas in the general vicinity of the channels.

The range of noise levels will vary from 45 dB within the quiet park setting to about 74 dB for those areas adjacent to freeways. Given the logarithmic nature of the decibel scale, the areas near the freeways are 30 times noisier than in the riverbank locations away from intensive traffic noise sources (Mitech, 1988).

3.6.2 <u>Noise Characteristics in Channel Reach Construction Zones</u>

3.6.2.1 Lower Los Angeles River

The most significant noise generator along Reach 4 is the Long Beach Freeway, which traverses adjacent to the river on the west side. Several major arterial streets cross the channel as does the San Diego (Interstate 405) and Artesia (Highway 91) freeways.

These are considered secondary sources of noise. There are also two active railroad bridges which cross Reach 4. Noise levels along the river in proximity to roadways will range from 70 dBA to 75 dBA Ldn.

For purposes of this study, all residential uses and public uses such as schools, hospitals and churches are considered sensitive to noise generation. These uses are mapped on Figure 3.3-1 (see Section 3.3) and occur throughout the reach.

3.6.2.2 Rio Hondo Channel

Major noise generators along Reach 5 include traffic on major arterials which cross the channel and railroad operations which cross Reach 5 at four locations. Traffic is particularly loud in the vicinity of the Santa Ana Freeway (Interstate 5), which crosses the channel. Somewhat more quiet than Reach 4, noise levels are expected to range from 64 to 69 Ldn along this reach.

Land uses adjacent to the reach within sound range of construction activities are mapped on Figure 3.3-2. Numerous residential areas and three schools are considered sensitive noise receptors.

3.7 BIOLOGICAL RESOURCES

3.7.1 Overview of LACDA System

The LACDA system consists of a series of dams and a flood control system that protects the greater metropolitan Los Angeles area. Key components of the system include Lopez, Hansen, Sepulveda, Santa Fe and Whittier Narrows Dams and the Los Angeles, San Gabriel, Rio Hondo and Ballona Channels. The Corps of Engineers (COE/LAD 1986) as well as the U.S. Fish and Wildlife Service (USFWS 1984, USFWS 1987) have inventoried the resources of the entire LACDA system. The purpose of the discussion in this section is to provide a summary of the biological resources of the entire system.

Table 3.7-1 provides an inventory of the listed and candidate plant and animal species known to occur within the LACDA system. The species of most notable concern is the least Bell's vireo, which occurs or potentially occurs at Hansen Dam, Whittier Narrows Dam and Santa Fe Dam, as well as in a portion of the San Gabriel River Channel.

3.7.1.1 Lopez Dam

Lopez Dam is the smallest of the dams within the LACDA system and has undergone considerable siltation. Other than functioning as an open space wildlife habitat, the area has little biological value.

3.7.1.2 Hansen Dam

Hansen Dam contains a rather diverse assemblage of vegetation communities, including willow riparian, riparian scrub, alluvial scrub, coastal sage scrub, oak woodland and old field habitats. The area supports a rather diverse assemblage of wildlife and is an excellent wildlife habitat even though significant portions of the area have been disturbed by sand and gravel extraction activities. The area is a known nesting habitat for the endangered least Bell's vireo and is potential habitat for the endangered slender-horned spineflower.

3.7.1.3 Sepulveda Dam

The Sepulveda Dam basin serves primarily as a recreation area. The area does contain old field habitats and some riparian habitat. It serves as a good open space wildlife habitat and supports many avian species as well as other species adapted to urban influenced environments. The area serves as a wintering area for the Canada goose and also supports populations of the candidate tri-colored blackbird.

Table 3.7-1

SUMMARY OF THREATENED, ENDANGERED AND CANDIDATE SPECIES IN LACDA SYSTEM

Species	Status	Facility: Lopez Dam	Hansen Dam	Sepulveda Dam	Santa Fe Dam	Whittier Narrows Dam	Los Angeles River	San Gabriel River
San Diego Horned Lizard	C	P	P		K			
Least Bell's vireo	E		K		P	K		K[1]
California least tern	E						P[2]	P[2]
Tri-colored blackbird	C							
California brown pelican	E						P[2]	P[2]
Black-tailed gnatcatcher	C	P	P		P			
Slender-horned spineflower	E		P		P			
Nevin's barbery	PE		P					
San Fernando Valley spineflower	PE		P

Source: ????????

VOL 12

1

7-1-94

THIS PAGE INTENTIONALLY LEFT BLANK
INTENDED FOR FUTURE REVISION

3.7.1.4 Santa Fe Dam

The Santa Fe Dam basin contains a rather unique assemblage of alluvial scrub -- a brushland area that has adapted to periodic flooding and scouring. The area also contains a small riparian area and old field and turfed areas. A small portion of the basin is potential habitat for the endangered least Bell's vireo and slender-horned spineflower and the candidate San Diego coast horned lizard and black-tailed gnatcatcher.

3.7.1.5 Whittier Narrows Dam

The Whittier Narrows Dam basin consists of rather extensive riparian development due primarily to revegetation efforts within the wildlife sanctuary areas. This area supports a wide variety of avian species and functions as a good wildlife area. The area is known nesting habitat for the least Bell's vireo as well as potential habitat for the candidate black-tailed gnatcatcher and tri-color blackbird.

3.7.1.6 Los Angeles River System

With the exception of the mouth of the river at the Pacific Ocean and a reach near Glendale, the majority of the 55 miles of the Los Angeles River from Sepulveda Basin to the Pacific Ocean contains concrete-lined channels surrounded by urbanized areas. These sections contain only weedy species growing within cracks or joints of the channel. Included in the Los Angeles River system is Compton Creek. This creek contains a soft-bottomed section upstream of its confluence with the Los Angels River.

The soft (unpaved) channel bottom of Compton Creek is characterized by degraded riparian association dominated by bulrush along with groundcover composed of ruderal weed species. Arroyo willow saplings are widely scattered through this strip. Since public access is possible, the vegetation shows sign of continual trampling. Furthermore, heavy accumulations of trash and debris dropped into the channel by illicit dumpers have collected in the vegetation. The willow canopy and understory components necessary for least Bell's vireo habitat are not evident, and there are no potential vireo sites in this reach. Other avian species occupying the channel were shorebirds and some raptors.

The Glendale reach of the Los Angeles River channel is alternately cobblestone and concrete invert. This reach is dominated vegetatively by a highly degraded riparian association, primarily a combination of cattails and bulrush with numerous patches of giant reed. Arboreal vegetation is primarily made up of a few of Gooding's willow, which together do not form an overstory. Mulefat is present but not sufficient to form an understory. Ground cover is a dense mat of grasses, forbs and ruderal species which generally cover the alluvial sediments which support them. In most areas, the riparian habitat community is very narrow with a ribbon of a single width of trees. In some instances, such as in the channel adjacent to Ralphs Grocery Warehouse, the vegetative mantle covers the alluvial deposit so thickly and completely as to obscure the concrete invert along that reach. Here, as in other places, this vegetation is transitory, unable to withstand moderate channel flows. Ability to see the concrete invert is further masked by substantial trash deposits.

Since soft bottom channels are prone to significant scour, a majority of this vegetation would be lost during years with frequent high steam flows. During years when only low to moderate flows occur, this vegetation can become dense.

The area also serves as a wildlife habitat for shore birds and other species. The lower portion of the river is potential foraging habitat for the brown pelican and California least tern.

3.7.1.7 San Gabriel River Channel

The majority of the San Gabriel River channel is paved and therefore contains little in the way of biological resources. An approximately five-mile (8 km) stretch of the river from Santa Fe Dam to Valley Boulevard has a soft bottom but is cobbly and supports only scattered vegetation. An approximately seven-mile (11.3 km) stretch below Whittier

VOL 12

1/7/96

Narrows Dam contains rather dense riparian vegetation in some areas and supports native wildlife, potentially including the endangered least Bell's vireo. An area in the lower San Gabriel River between Westminster Avenue and the San Diego Freeway supports emergent vegetation of a rather low density. As with the lower Los Angeles River, the lower San Gabriel River is potential foraging habitat for the endangered brown pelican and California least tern.

3.7.2 Biological Resources Within the 100-Year Flood plain of the Los Angeles River

The flood plain within the Los Angeles River is primarily urbanized and contains little native vegetation. The dominant vegetation form includes landscaped areas containing turf and ornamental trees and shrubs. These are associated with landscaping around parks, homes and commercial establishments. Some areas near the riverbed and under power line easements are still in agriculture and grow a variety of ornamental plants and cash crops.

This area supports wildlife typical of urban areas, including such species as English sparrow, starling, crow, blackbirds, mocking bird and domestic pigeon. The larger open space areas near the river could support such species as the American kestrel and burrowing owl.

No threatened or endangered or candidate plant or animal species are expected to occur in this area.

3.7.3 Biological Resources Within the Channel Reach Construction Zones

3.7.3.1 Lower Los Angeles River

Vegetation

VOL 12

With the exception of an approximately 2.5-mile (4 km) section near the mouth of the river, the entire stretch of river is completely channelized, including pavement of the river bottom. With the exception of an occasional plant growing within cracks as well as ruderal species growing adjacent to the levees, the area is essentially void of vegetation.

An approximately 1.5-mile (2.4 km) stretch of the river from Anaheim Street to Willow Street contains areas along both sides of the banks where siltation has taken place, allowing a 10- to 15-foot (3.1 to 4.6 m) wide belt of vegetation to grow. This area contains rushes, cattail, willow and mulefat, as well as many ruderal species such as castor bean.

Compton Creek is tributary to the lower Los Angeles River. Almost all of Compton Creek, with the exception of a two-mile segment of the creek, is channelized and contains very little, if any, vegetation. The soft-bottom portion of the channel contains both ruderal species such as castor bean and Arundo (giant reed) and some scattered riparian species such as mulefat, bulrush, and a few small willow.

The Glendale reach alternates cobblestone and concrete invert for approximately six miles. These areas are dominated by species common to degraded riparian associations, including cattails, bulrush and Arundo (giant reed). There are scatterings of native sycamores and some willow.

1798

Wildlife

In general the Los Angeles River channel has only low value for wildlife. It serves as an open space area for wildlife and provides resting habitat for shore birds. The edges of the area in some locations may provide limited foraging for raptor species. The channel may function somewhat as a wildlife movement corridor. The vegetated area near the mouth is nesting habitat for such species as red-wing blackbirds and is considered of moderate to high wildlife value. It may also support shore birds and some riparian obligate species since some cover is afforded in that area.

Most of the Compton Creek Channel and Glendale reach have very low wildlife value. The area with the cobblestone bottom has moderate wildlife value and would be expected to provide habitat for species generally adapted to an urban environment.

The portion of the lower Los Angeles River that has an unlined, soft substrate bed extends from Willow Street to the mouth of the river at Queensway Bay in Long Beach. This area is influenced by tidal waters entering the mouth of the river and fresh water flowing from upriver sources. At high tides the seawater extends upriver to an area approximately midway between Pacific Coast Highway and Willow Street.

Aquatic Resources

The salinity in this section of the river would range from fresh water just below Willow Street to varying degrees of brackish water further down river depending on the amount of fresh water input and the height of the tide.

No recent biological sampling of the area has occurred; however, through discussions with local experts and individuals conducting other scientific studies in the area and from a study of the Santa Ana River, a prediction of the likely aquatic species can be made.

The area of the river near the mouth would be expected to have many of the same fish species found in the adjacent Queensway Bay. These include Engraulis mordax (northern anchovy), Seriphus politus (Queenfish), Genyonemus lineatus (white croaker), Anchoa delicatissima and Anchoa compressa (slough and deep-body anchovys), Paralabrax nebulifer (barred sand bass), Cymatogaster aggregata (shiner surfperch), and young Paralichthys californicus (California halibut). Invertebrates living on the rip-rap rock sides of the channel near the mouth would probably include sea urchins (Stronglyocentrotus purpuratus), snails, and barnacles (Balanus spp.), as well as various species of algae. Polychaete worms, clams, anemones, and tunicates would be expected on the soft bottom.

Further upriver where salinities are more varied, Atherinops affinis (topsmelt), Leptocottus armatus (Pacific staghorn sculpin), Clevelandia ios (arrow goby), Gillichthys mirabilis (longjaw mudsucker), and Hypsopsetta guttulata (diamond turbot) would be likely fish species in addition to E. mordax, C. aggregatta, and P. californicus.

Between Pacific Coast Highway and Willow Street where the river is predominantly freshwater, fish species from upriver could be found. These freshwater and brackish water tolerant species include Ictalurus spp. (catfish and bullhead), Cyprinus carpio (carp), Gambusia affinis (mosquitofish) and Tilapia spp. The presence of these species would depend on the flow volume of the river. After heavy rain storms when the volume in the river is large, it is likely that most freshwater species would be washed out to sea.

Threatened and Endangered Species

The lower river and mouth of the river may be foraging habitat for the endangered brown pelican and California least tern. With these exceptions, no other listed or candidate species is expected to occur in the area.

No threatened, endangered, or candidate plant or wildlife species are known or expected to occur in Compton Creek.

3.7.3.2 Rio Hondo

Vegetation

This section of the Rio Hondo (Reach 5) is channelized with a paved bottom. Except for plants growing in concrete cracks, little vegetation is present.

The spreading grounds adjacent to the channel also contain some ruderal species; however, frequent weed abatement activities tend to limit this vegetation.

VOL 12

1

7201

THIS PAGE INTENTIONALLY LEFT BLANK
INTENDED FOR FUTURE REVISION

VOL 12 . 1 7202

Wildlife

The channel area tends to have very limited wildlife value and functions, at best, as an open space wildlife habitat. The spreading grounds may serve as fair habitat for shorebirds when water is present.

Aquatic Resources

Since the entire channel is paved, no aquatic resources exist in the channel.

Threatened and Endangered Wildlife Species

No threatened, endangered, or candidate plant or animals species are known or have a potential to occur in this area.

3.8 CULTURAL RESOURCES

3.8.1 Flood Overflow Areas

The general flood overflow areas were not surveyed as a part of this study. The area is urbanized, and most cultural resources would have been substantially disturbed. Historic buildings and other structures do exist in the area.

3.8.2 Cultural Resources in Lower Channel Areas

3.8.2.1 Lower Los Angeles River

The portion of the Los Angeles River from Imperial Highway to the Pacific Ocean was surveyed for the presence of historic and cultural resources in 1976 (Stickel 1976). Prior to the field survey, a literature search was conducted through a number of local institutions and individuals. The entire route of the Los Angeles River from the Pacific Ocean to the Rio Hondo was examined in the field by a team of surveyors. No historic resources were identified in this inventory effort.

A records search was conducted in 1984 for this area as part of an overall records search for Los Angeles County Drainage Area (Cottrell et al. 1985). The records search through the UCLA Archaeological Survey revealed that no additional studies had been conducted in this area. An historic records search conducted as part of the LACDA Review Study (Van Wormer 1985) identified no historic properties in the area. As part of the LACDA feasibility study, Hatheway (1986) conducted an architectural and historic assessment of the Southern Pacific "Horseshoe" Bridge in Long Beach and the Union Oil Suspension Pipeline near the 405 Freeway which cross the river in this area. Both of these structures were determined to be too new to be potentially eligible for the National Register.

No properties eligible for the National Register were found to be present along the levees where impacts from flood wall construction would occur. An assessment of the bridges to be affected by the project concluded that none of the 14 bridges to be affected were eligible for listing in the National Register. All of these bridges are less than 50 years old. A field survey was conducted by the Corps of Engineers in 1989 along Compton Creek. No historic properties were encountered along the reach, which is to undergo levee armoring.

3.8.2.2 Rio Hondo Channel

A number of previous studies have been conducted for this stretch of the Rio Hondo (Reach 5). The Rio Hondo channel (a 100-foot [30.5 m] wide corridor along the channel) was surveyed in 1976 (Stickel 1976) with negative results. A historic overview of the Whittier narrows basin revealed that the Battle of the San Gabriel was fought

VOL 12

along this stretch of the Rio Hondo (Lindsey and Schiesl 1976). A records search was conducted in 1984 for this area as part of an overall records search for LACDA (Cottrell et al. 1985). The records search through the UCLA Archaeological Survey revealed that no additional studies had been conducted in this area. An historic records search conducted as part of the LACDA Review Study (Van Wormer 1985) identified two historic properties in the area. These are the Whittier Narrows Dam and the Whittier Road Bridge. As part of the LACDA Feasibility Study, Hatheway (1986) conducted an architectural and historic assessment of the Union Pacific Railroad bridge which crosses the Rio Hondo.

An additional records search conducted as part of the current study identified the Rio Hondo Spreading Grounds as an historic property. In addition, the Gabrielino village of Chokishnga was identified as possibly having been located in the vicinity.

For the present study, an archaeological and historic survey was conducted on January 17, 1989, by Stephen Dibble and Steven Schwartz, both archaeologists employed by the U.S. Army Corps of Engineers, Los Angeles District. The survey was accomplished by both surveyors walking along each levee and surveying the levee and any open land located adjacent to the levee. For most of the stretch, the levee was abutted by the right-of-way fence, which did not allow for much area beyond the levee to be inspected. However, in a few places, as much as 100 additional feet (30.5 m) were surveyed.

1204

Each of the previously identified sites, as well as those discovered as part of the present survey, are described by site number.

RH-1 Site of the Battle of San Gabriel River

On January 8, 1847, the battle of the Rio San Gabriel was fought between American forces commanded by Captain Robert F. Stockton, U.S. Navy, Commander in Chief; Brigadier General Stephen W. Kearney, U.S. Army; and Californios commanded by General Jose Maria Flores. American troops, after securing northern California, landed in San Diego and headed north to connect with the northern units and secure the state.

VOL 12

This was the final battle between American and Mexican forces before Los Angeles was captured by the Americans. The site is listed as California Historical Landmark No. 385. A monument has been placed at Washington Boulevard and Bluff Road. The battle actually appears to have occurred about two miles north of the marker on and below the bluffs between Whittier Boulevard and Mines Avenue.

RH-2 Rio Hondo Spreading Grounds

The spreading grounds are listed as a Landmark of the American Society of Civil Engineers. The Landmark covers all 29 spreading grounds of the Los Angeles County Flood Control District. They are designed to retain and conserve thousands of acre feet of spring runoff annually and return it to the underground water table. The various spreading grounds were constructed beginning in 1917.

RH-3 Union Pacific Rio Hondo Bridge (No. PTD 10.77)

1205

The structure consists of three steel girder spans which rest on two concrete piers spaced equidistant within the channel. The structure is of well deck design, and wooden sleepers rest on steel girders. On either side of the single track there is a wooden plank walkway. Each end of the structure rests on concrete abutments which are located at the top of the adjacent levees. The structure is in good condition and appears to be altered only by the addition of two oil pipelines which are welded to the side of the structure. The bridge was evaluated by Hatheway in 1986 for the Corps of Engineers. Hatheway concluded that, "This structure is not a rare example of its type, nor does it exhibit any unusual features relating to workmanship, design, scale/span, or materials." Therefore, this structure is not a significant historic property.

RH-4 Firestone Boulevard Bridge

This is a concrete highway bridge across the Rio Hondo. It has the date of 1932 impressed in the concrete of the west abutment. It consists of a concrete roadway on concrete arches. This bridge has yet to have been evaluated as to its National Register eligibility.

RH-5 Southern Pacific Railroad Bridge

The structure is of well deck design with the girder both above and below the deck, with squared ends. The structure has three spans on concrete piers spaced equidistant within the channel. The structure supports a single railroad track. This Bridge has yet to have been evaluated as to its National Register eligibility.

RH-6 Southern Pacific Railroad Bridge

The structure is of plate girder above deck design with squared ends. The structure consists of three spans on concrete piers spaced equidistant within the channel. Bridge has "P.E. Ry." painted on it, perhaps indicating it was at one time part of the Pacific Electric Railway system. This Bridge has yet to have been evaluated as to its National Register eligibility.

RH-7 Atchison Topeka and Santa Fe Railroad Bridge

Steel plate girder above-and-below deck structure with one rounded and one squared end. The structure is supported on three concrete piers placed equidistant within the channel. This Bridge has yet to have been evaluated as to its National Register eligibility.

RH-8 Union Pacific Railroad Bridge

This is a steel plate girder below-deck structure. It consists of six spans with two approaches. It has one track and a steel grate walkway on either side. It is supported on concrete piers placed in the channel and in the spreading basins to the west.

VOL 12

1
7207

R0050512

RH-9 Whittier Boulevard

This structure is composed of four spans of steel truss with a concrete deck. The structure was evaluated by CalTrans (California Bridge Inventory; Route 72, Bridge 4), who determined it ineligible for the National Register of Historic Places (Category 5). Therefore, this structure does not represent a significant historic property.

RH-10 Beverly Boulevard Bridge

This is a steel girder bridge, the center span of which has been replaced with a concrete arch. It is supported on wooden pilings which have concrete reinforcements at the base. It has an asphalt-over-wood deck supporting four lanes of traffic. The integrity of this structure has been significantly compromised. The center span of the bridge is now concrete, and concrete reinforcements have been added to the piers. Due to the compromised integrity, it is unlikely that this structure represents a significant historic property.

RH-11 Chokishnga

The village of Chokishnga has been associated with the site of the Jaboneria (Spanish soap factory) (Reid: Letter 1; Kroeber 1925), however, it is unclear as to the location of the Jaboneria. Johnston (1962:84) lists Chokishnga as an historic Gabrielino village on the west side of the present Rio Hondo, just a little south of Telegraph Road. This village would be in the general vicinity of the study area.

3.9 TRANSPORTATION

3.9.1 Flood Overflow Areas

3.9.1.1 100-Year Overflow Area

Traffic within the LACDA boundaries is notoriously heavy. Peak-hour traffic on major roadways and freeways is usually congested, with stoppages occurring frequently on freeways and traffic backed up at surface street intersections.

The LACDA 100-year flood plain includes areas of heavy urbanization and major roadway and freeway thoroughfares. Some areas wholly or partially contained in the flood plain include the San Fernando Valley, Los Angeles, Pico Rivera, Downey, Lynwood, Compton, Paramount, Bellflower, Lakewood, Carson, and Long Beach. Most Los Angeles area freeways, including Ventura (101, 134), Golden State/Santa Ana (5), Santa Monica (10), Pomona (60), Long Beach (710), Artesia (91), and San Diego (405) cross or run through the 100-year flood plain.

Table 3.9-1 gives the major roadways and freeways that cross or are within the 100-year flood plain, by city. Each of the roadways and freeways listed are heavily utilized, especially during peak-hour commuter traffic. Most freeways are at capacity with no plans for expansion. As the population of the Los Angeles area continues to increase, the volume of traffic and amount of roadway and freeway congestion will also increase. Since flood control channels parallel major freeways (Ventura, Golden State, Long Beach, San Gabriel), potential flood conditions could restrict freeway access from the major roadways which enter these freeways, creating a severe traffic problem.

VOL 12

1 7 2 1 1

VOL 12

3.9.1.2 500-Year Overflow Area

The area affected by the LACDA 500-year flood plain includes all of the 100-year flood plain, plus additional areas mainly in Van Nuys, Sherman Oaks, Los Angeles, Norwalk, Los Alamitos, and Seal Beach. Additional areas of freeway covered by the 500-year flood plain include portions of the Hollywood (170), Harbor (110), Santa Monica (10), and San Gabriel (605) freeways.

The number of major roadways and the size of the areas affected is considerably higher within the 500-year flood plain boundaries. These roadways are predominantly located in developed, heavily urbanized areas, and traffic flow is heavy during peak-hour periods.

The additional major roadways and freeways that cross, or are within the 500-year flood plain, are listed in Table 3.9-2. These additional areas are centered around portions of the Hollywood Freeway, Harbor Freeway and San Gabriel Freeway, and any impairment to vehicle access in these areas would create traffic backups and congestion, especially during the commuter rush hour.

1 7 2 1 2

3.9.2 Traffic Conditions Within Channel Reaches

3.9.2.1 Lower Los Angeles River

Six freeway overpasses, eleven roadway bridges and three railroad bridges cross the Los Angeles River from Imperial Highway south to Ocean Boulevard.

Average Daily Traffic counts (ADT) for major roadways and freeways in the vicinity of the Los Angeles River Channel, both crossing the channel and adjacent to it, are shown on Figure 3.9-1. This figure illustrates the heavy amount of existing traffic in this highly urbanized area. During peak traffic hours, the freeways and most major roadways in the area are heavily congested with little, if any, excess traffic carrying capacity available. Traffic speeds on the Long Beach freeway (710) during peak hours are estimated at

35-37 mph, with stoppages and backups commonly occurring in the event of an accident or stopped vehicle (Gus Martin, Information Officer, CALTRANS, February 9, 1989).

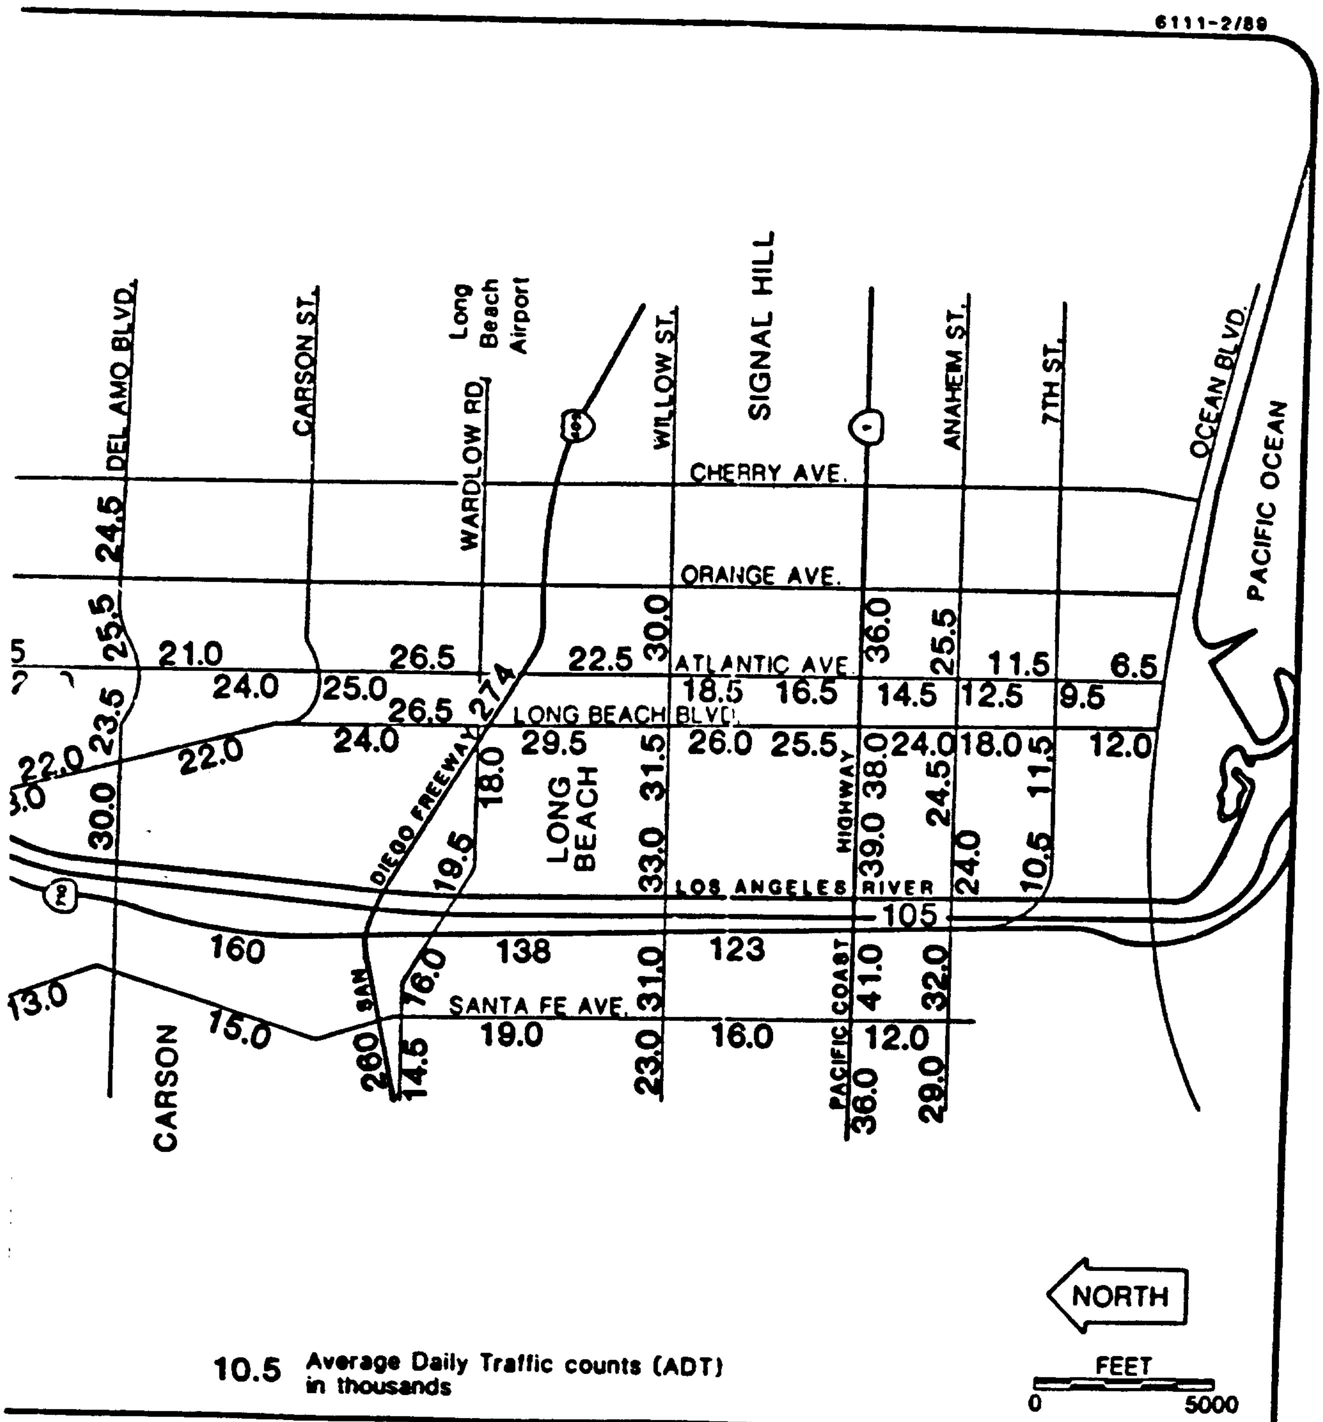
LOWER LOS ANGELES RIVER – REACH 4 AVERAGE DAILY TRAFFI

1 7 2 1 6

R0050521



OUNTS

FIGURE 3.9-1

R0050522

Public Works projects currently underway or proposed for the near future which have the potential to affect traffic in the area include construction of the Century freeway (105), which crosses the Los Angeles River Channel south of Imperial Highway and is scheduled for completion in the fall of 1993; the Los Angeles to Long Beach Light Rail, which crosses the channel north of the San Diego Freeway and is also scheduled for completion in 1993; and a joint Port of Long Beach-City of Long Beach project to improve Long Beach Freeway offramps to Ocean Boulevard and Harbor Scenic Drive near the outlet of the Los Angeles River in Long Beach Harbor, scheduled for completion the summer of 1990 (Doug Failing, CALTRANS, February 9, 1989).

Future traffic conditions in the lower Los Angeles River area are expected to be worse than at present. Improvements to surface streets will do little more than maintain the current level of service. At this time there are no plans to increase the capacity of the Long Beach Freeway, the major thoroughfare for commuter traffic in the area (Doug Failing, CALTRANS, February 9, 1989).

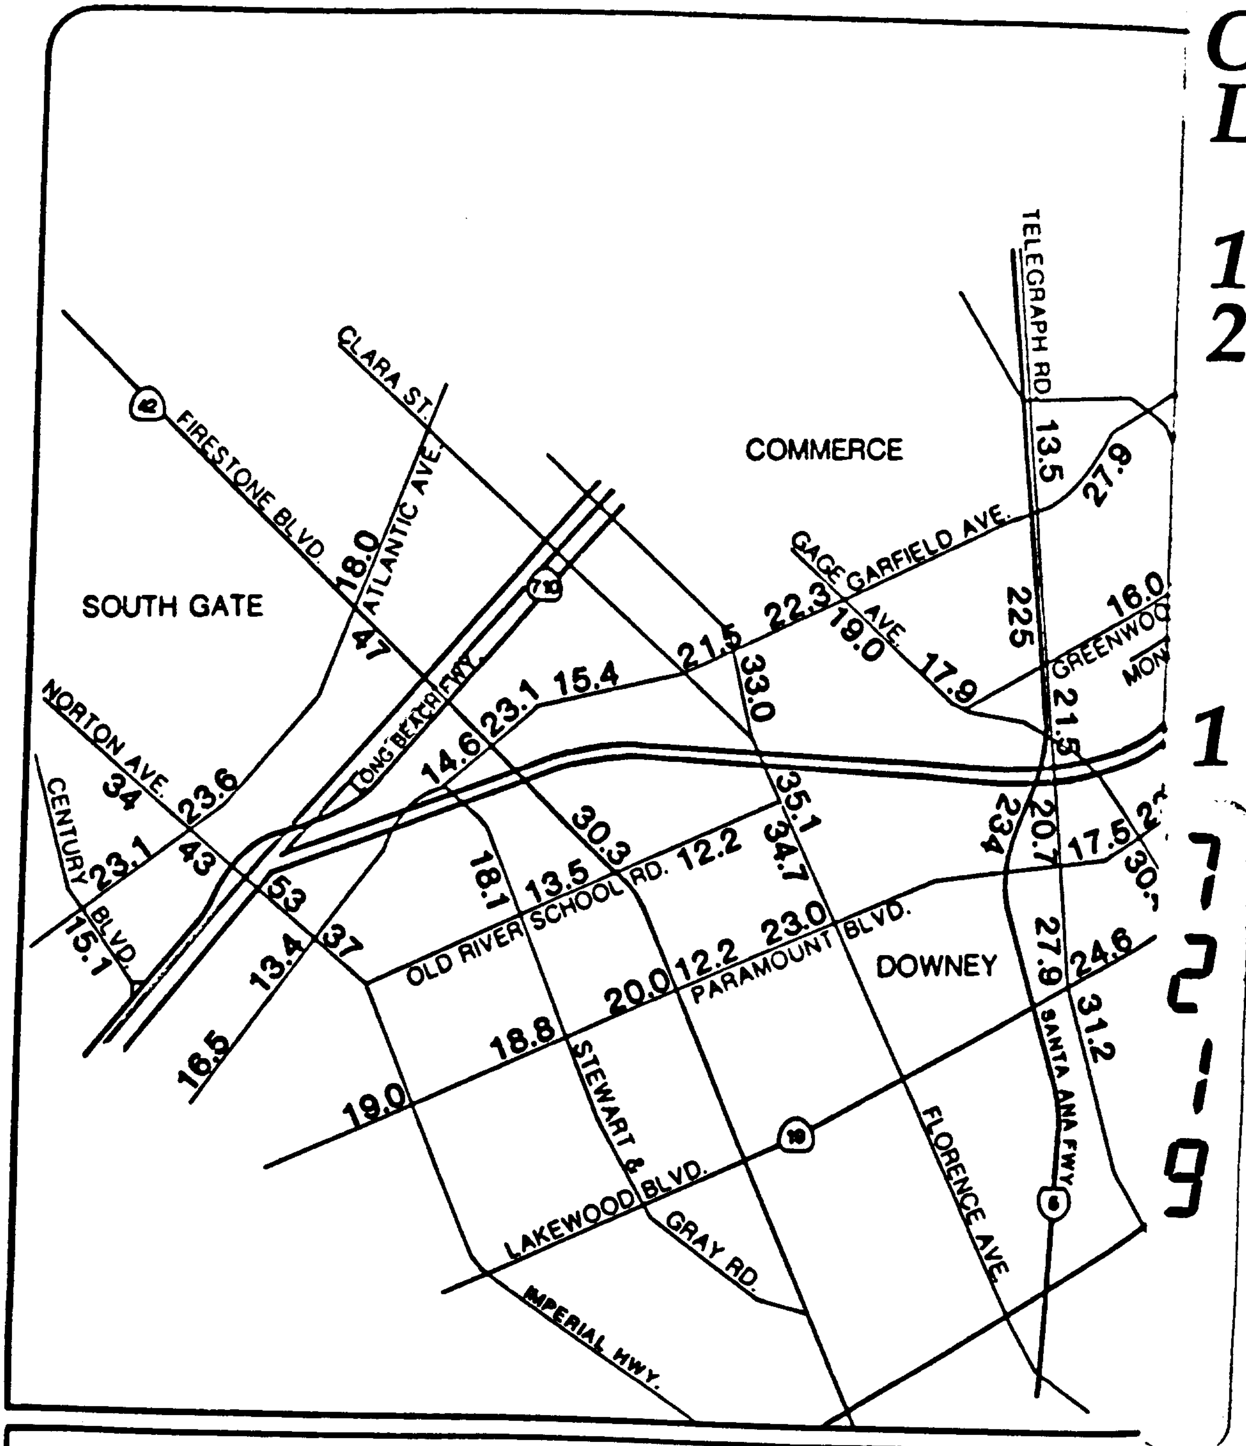
3.9.2.2 Rio Hondo Channel

The Rio Hondo Channel improvement area extends from Whittier Narrows Dam southwest to the Los Angeles River. This reach of the LACDA study area passes through the cities of Montebello, Pico Rivera, Bell Gardens, Downey, and South Gate.

From Beverly Boulevard southwest to the Los Angeles River, ten roadways, one freeway, and five railway bridges cross the Rio Hondo Channel.

The existing traffic counts (ADT) for the major roadways and freeways crossing, or in the vicinity of, the Rio Hondo Channel are shown in Figure 3.9-2. Traffic in this highly urbanized area is heavy, with congestion and backups common at major street intersections during peak periods.

VOL 12



RIO HONDO CHANNEL - REACH 5 AVERAGE DAILY TRAFFIC COU

1 7-2-9

R0050524

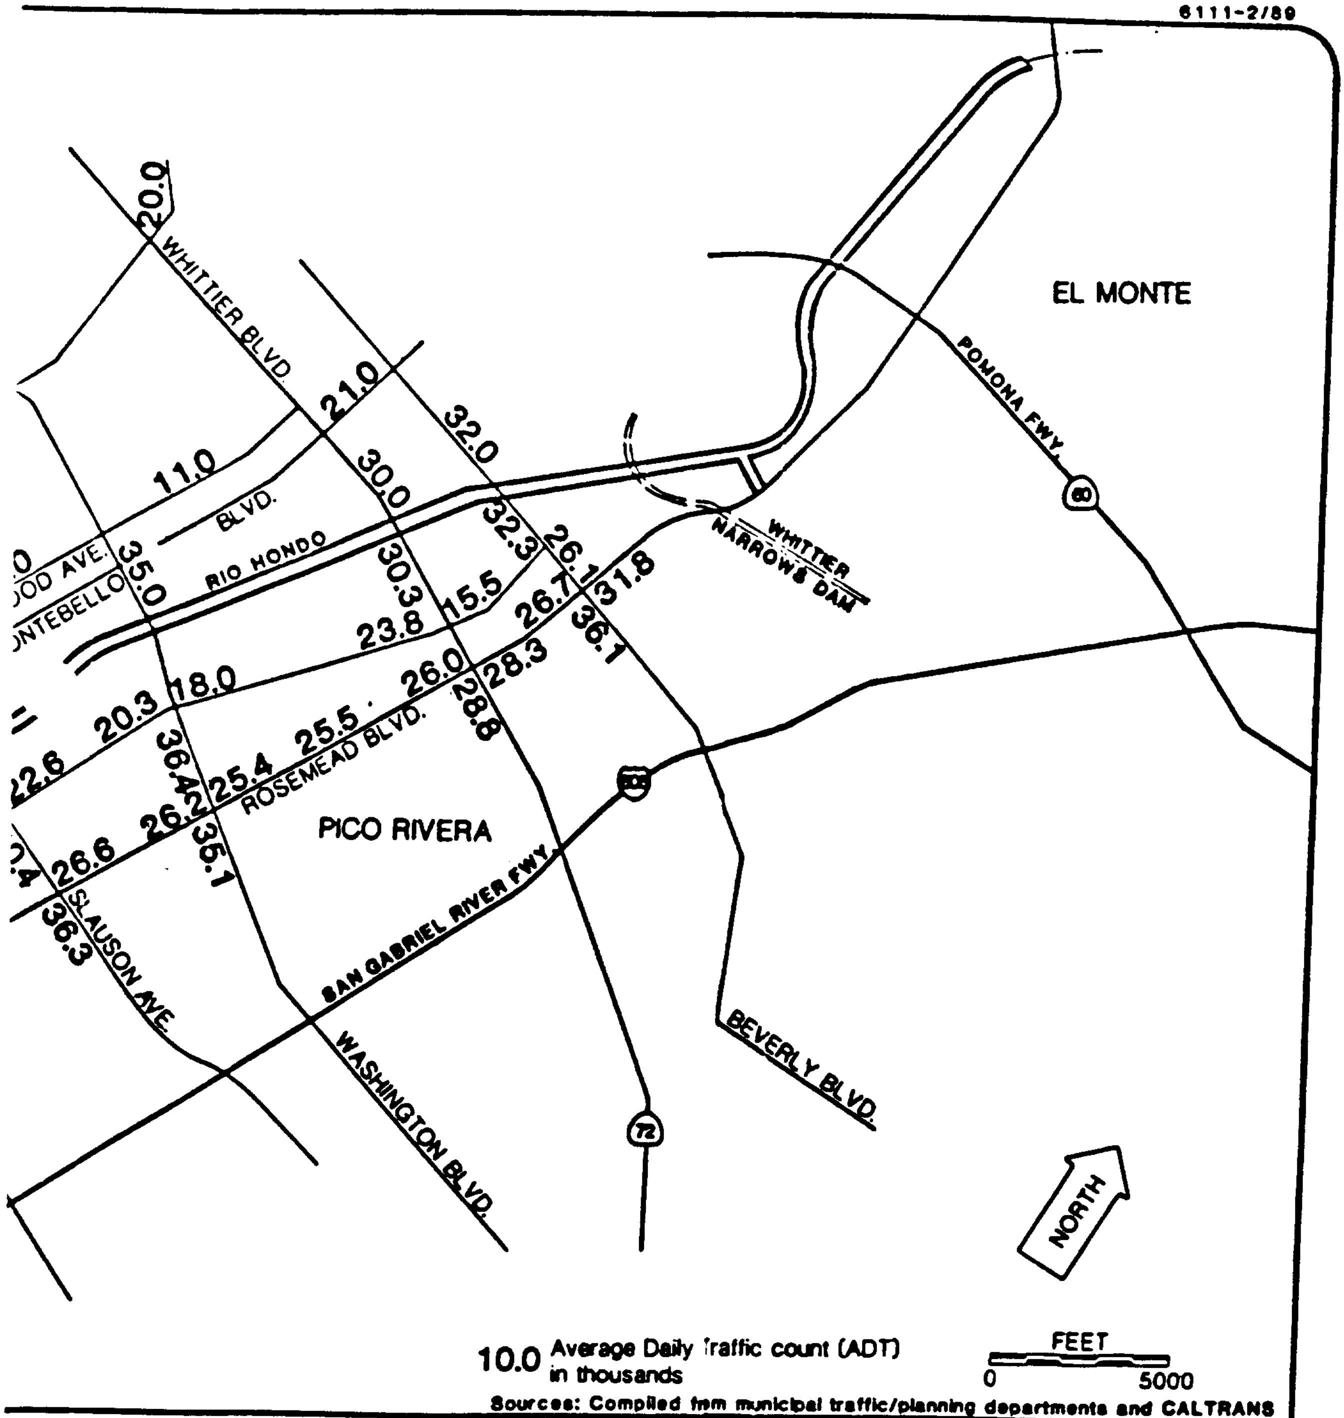


FIGURE 3.9-2

VOL 12

1 7220

R0050525

The Santa Ana Freeway (5), which is the only freeway that crosses the channel, is a heavily utilized commuter link from Los Angeles County to Orange County. Average daily traffic counts are 225,000 vehicles north of the channel and 234,000 vehicles south of the channel. During peak periods, traffic on this freeway is usually heavy.

The volume of traffic in the vicinity of the Rio Hondo Channel is expected to increase. Restrictions to traffic capacity due to construction (or other projects), would aggravate existing situations and increase the level of congestion and vehicle slowing or stopping.

3.10 RECREATION AND AESTHETICS

3.10.1 Flood Plain Overview

Recreation activities within the identified project area include a large variety of parks, community recreation centers and country clubs, public and private golf courses, tennis and racquet facilities, picnic and camping, ballfields, and equestrian facilities. Park areas range from small, local community park/playgrounds to large city and regional parks such as Griffith and Elysian Parks which border the Los Angeles River; El Dorado Park bordering the San Gabriel River; as well as other major recreational park facilities located within the 100-year flood plain.

Bike/pedestrian and equestrian trails and wildlife trails also run through most of the length of the channels and meander through the dam facilities. Trail systems such as the San Gabriel River Trail and Lario Trail include bike paths which use the service roads on top of the channel levees. Equestrian trails also follow these systems separated, where possible, from the bike path, though sometimes only by a narrow unpaved strip of earth. Often the equestrian trails end at undercrossings and horses must share the path at that point with bikes and pedestrians. In many areas the equestrian and bike trails share the same black-topped trail.

Recreational access to the channel bike and equestrian trails is mostly via crossing streets which intersect the channel. A gate in the fencing provides access. Most gates include a bar across the gate which prohibits motorized vehicles from entering the area. Many park and other recreational facilities abut the channel; yet direct access to the channel is mostly very limited. Direct access to the channel is provided by gated access points or from connecting trails.

The general public typically has views of the channel only from freeways and cross streets. At ground level, embankments rise up to the elevation of either bike/pedestrian or maintenance roads on the sides of the channel, effectively blocking views of the channel and structures on the far side of the channel. Only the tops of structures across the channel are sometimes visible. Several power line easements with high towers and lines also parallel the channel in some areas.

Some homes have back fence lines which abut the bike trails with no separation or buffers. These homes either have chain-link or block wall fences. The homes are located at an elevation such that no views of the channel or bike path exist for one-story homes with block walls. Only those homes which are two-story or have chain-link fencing may have some view of the bike path and channel.

3.10.2 Recreation and Access Considerations Along Channel Construction Reaches

A detailed study has been prepared for the purpose of identifying recreation facilities bordering the LACDA flood control system (see LACDA Review Study Technical Documentation Report for Recreation). This inventory describes in detail all facilities located within the basins and channels, including constructed elements that make up each facility. Recreational access (bike and equestrian) routes and links between the system and neighboring facilities are identified and located on detailed maps in the review.

A Final Design Memorandum was also prepared which details the aesthetics and designs for equestrian and bike recreational facilities for the length of the Lario San Gabriel river trail system. This system includes the upper and lower San Gabriel River, the upper and lower Rio Hondo Channel and the lower Los Angeles River systems. Specific design criteria and plans are laid out for not only trails but also access ramps and bridges, rest areas and appropriate landscaping. Some of this design work has been implemented and is shown in the Recreation Technical Documentation Report.

Recreational facilities for those channel corridors and portions of corridors which will be affected by channel construction improvements are in the LACDA Recreation Review study. These activities will primarily affect the lower Los Angeles River (Reach 4) and the Rio Hondo Channel (Reach 5). These facilities are provided in map form in Figures 3.10-1 and 3.10-2.

3.10.2.1 Lower Los Angeles River

The lower Los Angeles River is characterized as a concrete-lined channel surrounded by a highly urbanized/industrialized area. Vegetation in the channel is sparse with only small patches of weeds appearing at cracks or joints in the channel. The exception to this is a wetlands area in the channel from Willow Street south to Anaheim Street.

Bordering the channel is a mix of residential, commercial, industrial areas contrasted with established parks, equestrian facilities and golf courses. The parks, equestrian facilities and golf courses are located primarily along the east border, some having direct access to the bike and equestrian trails.

The bike and equestrian trails run the length of Reach 4, actually extending from the Pacific Ocean north to the confluence with Rio Hondo Channel. North of the Rio Hondo Channel the trails continue on the west levee of the Los Angeles River.

Concrete bike/pedestrian and dirt equestrian paths run along the top of the east levee from Willow Street north. Only a bike trail abuts the channel from the ocean north to Willow Street. Both the bike path and west levee top provide access for maintenance of the channels. The entire channel reach boundary is chain-link fence except where public access to the trail and adjacent facilities is provided.

LOWER LOS ANGELES RIVER - REACH 4 RECREATION FACILITIES

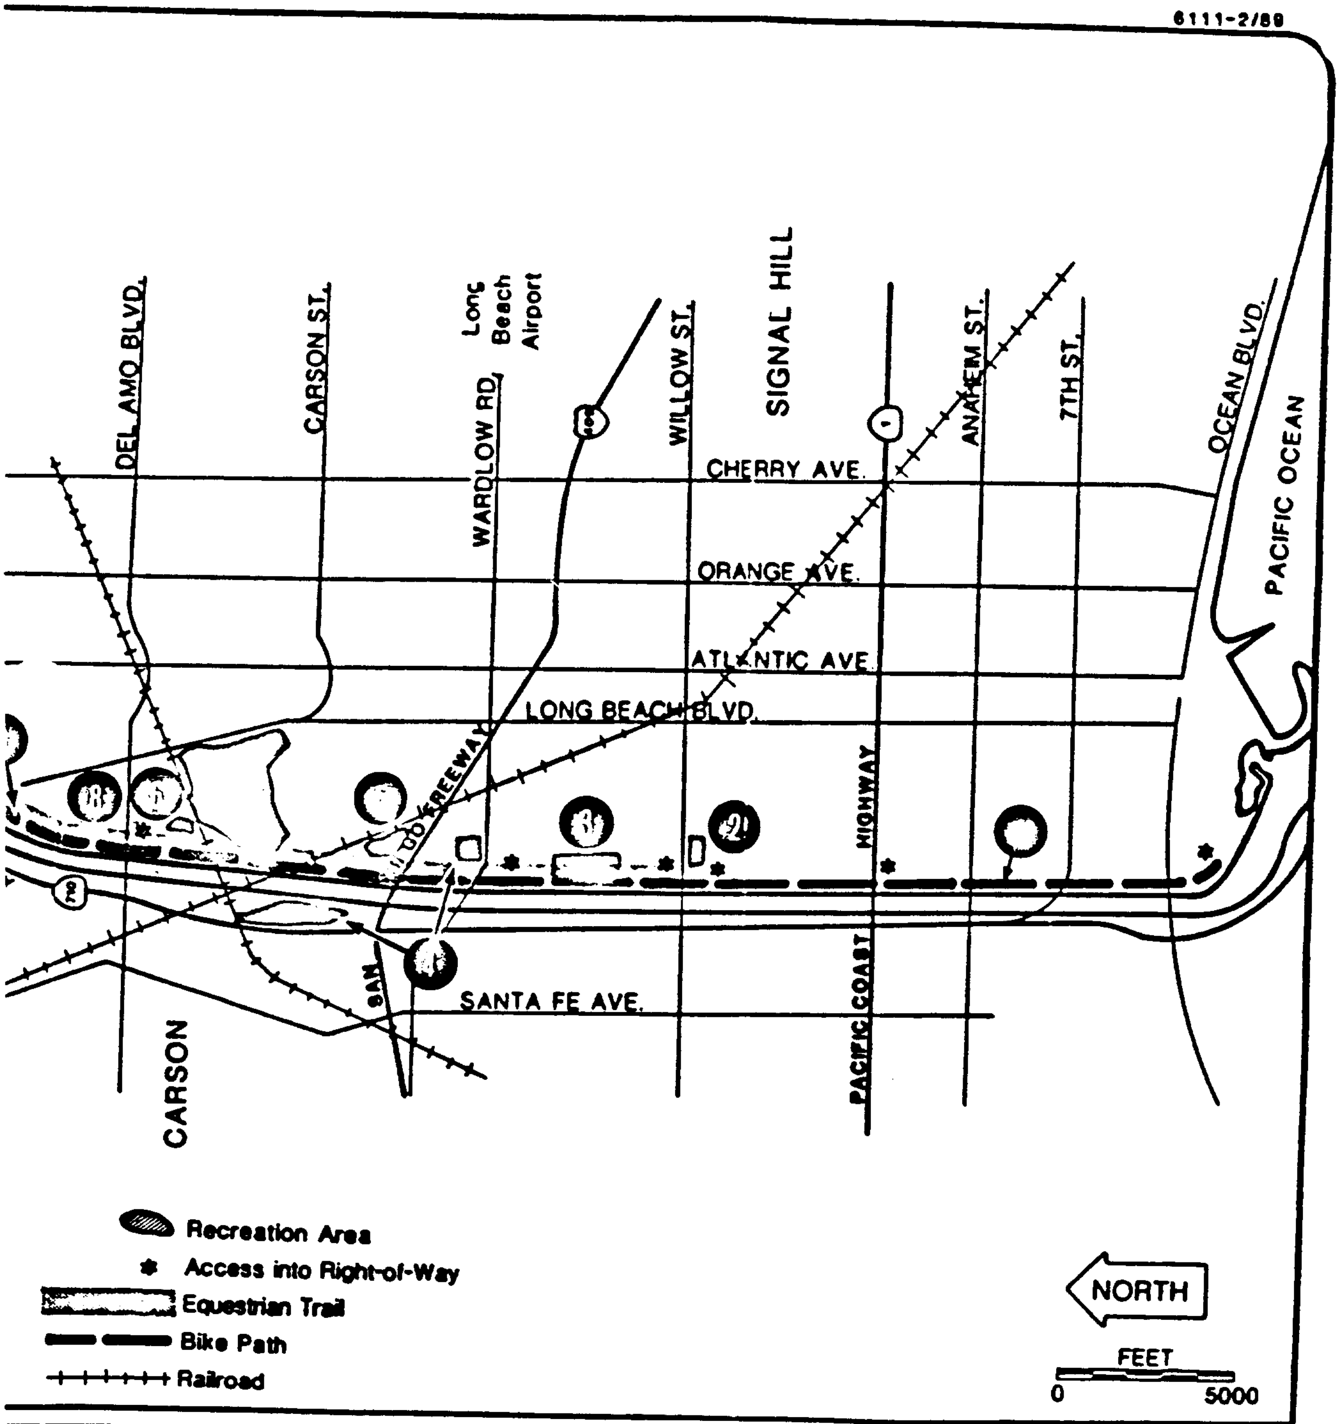

FIGURE 3.10-1

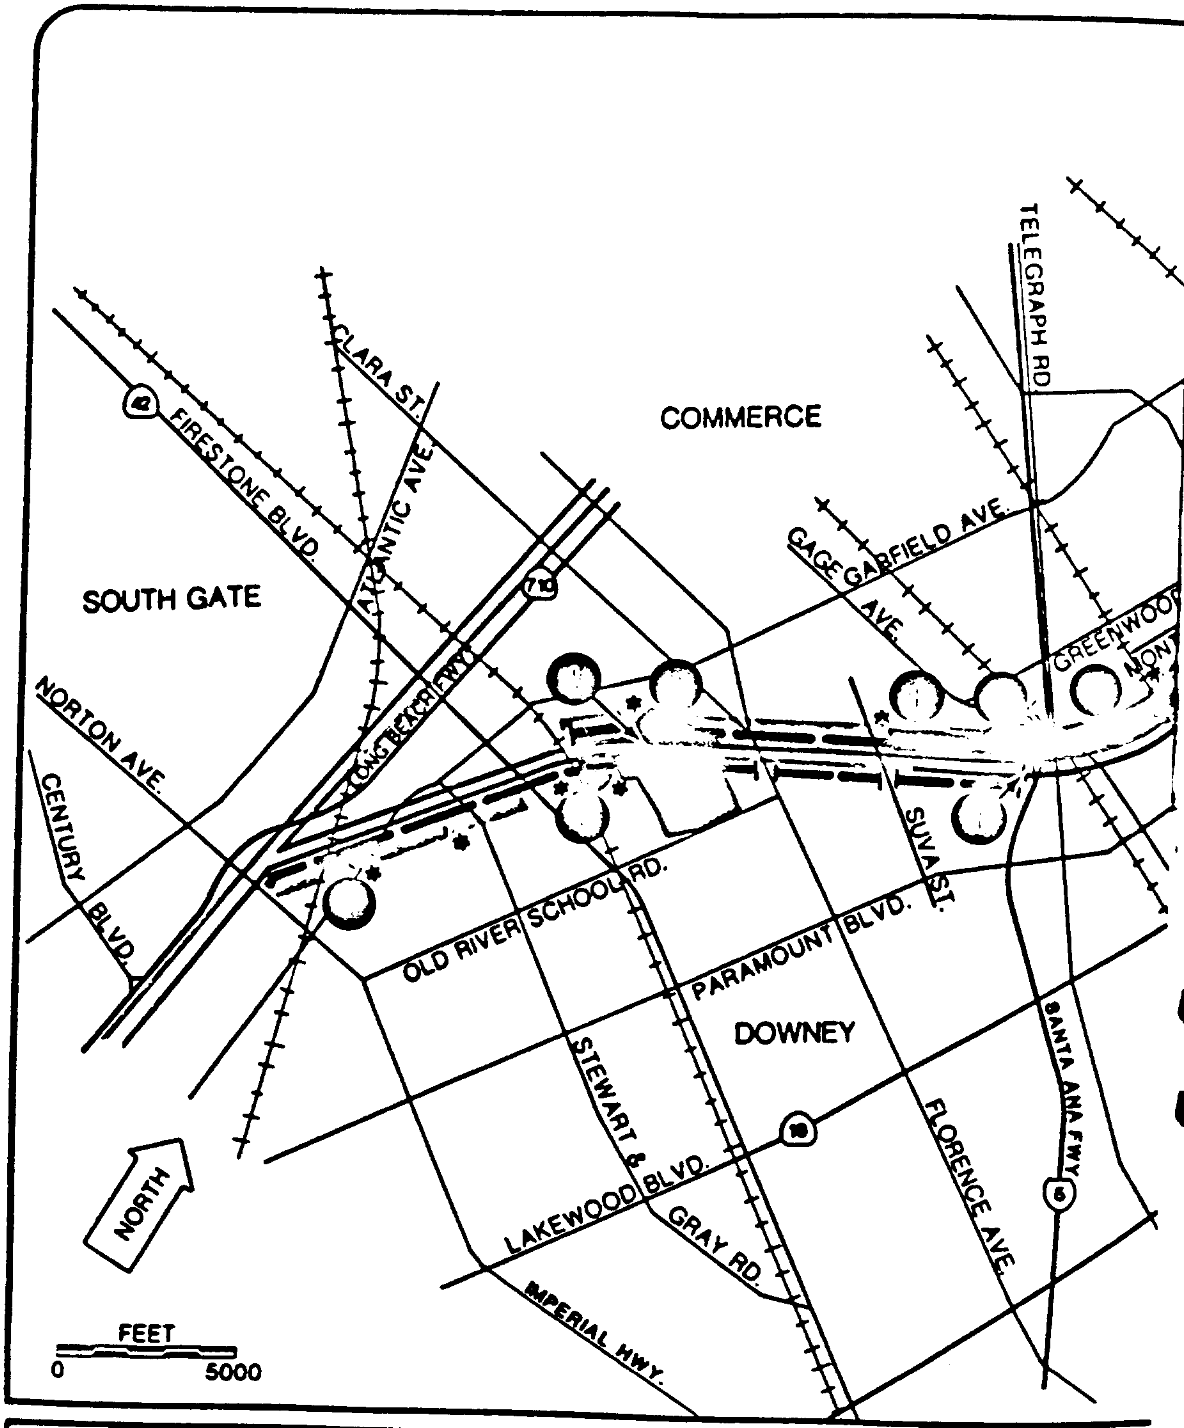
VOL 12

1 7226



RIO HONDO CHANNEL - REACH 5 RECREATION FACILITIES

VOL 12 1

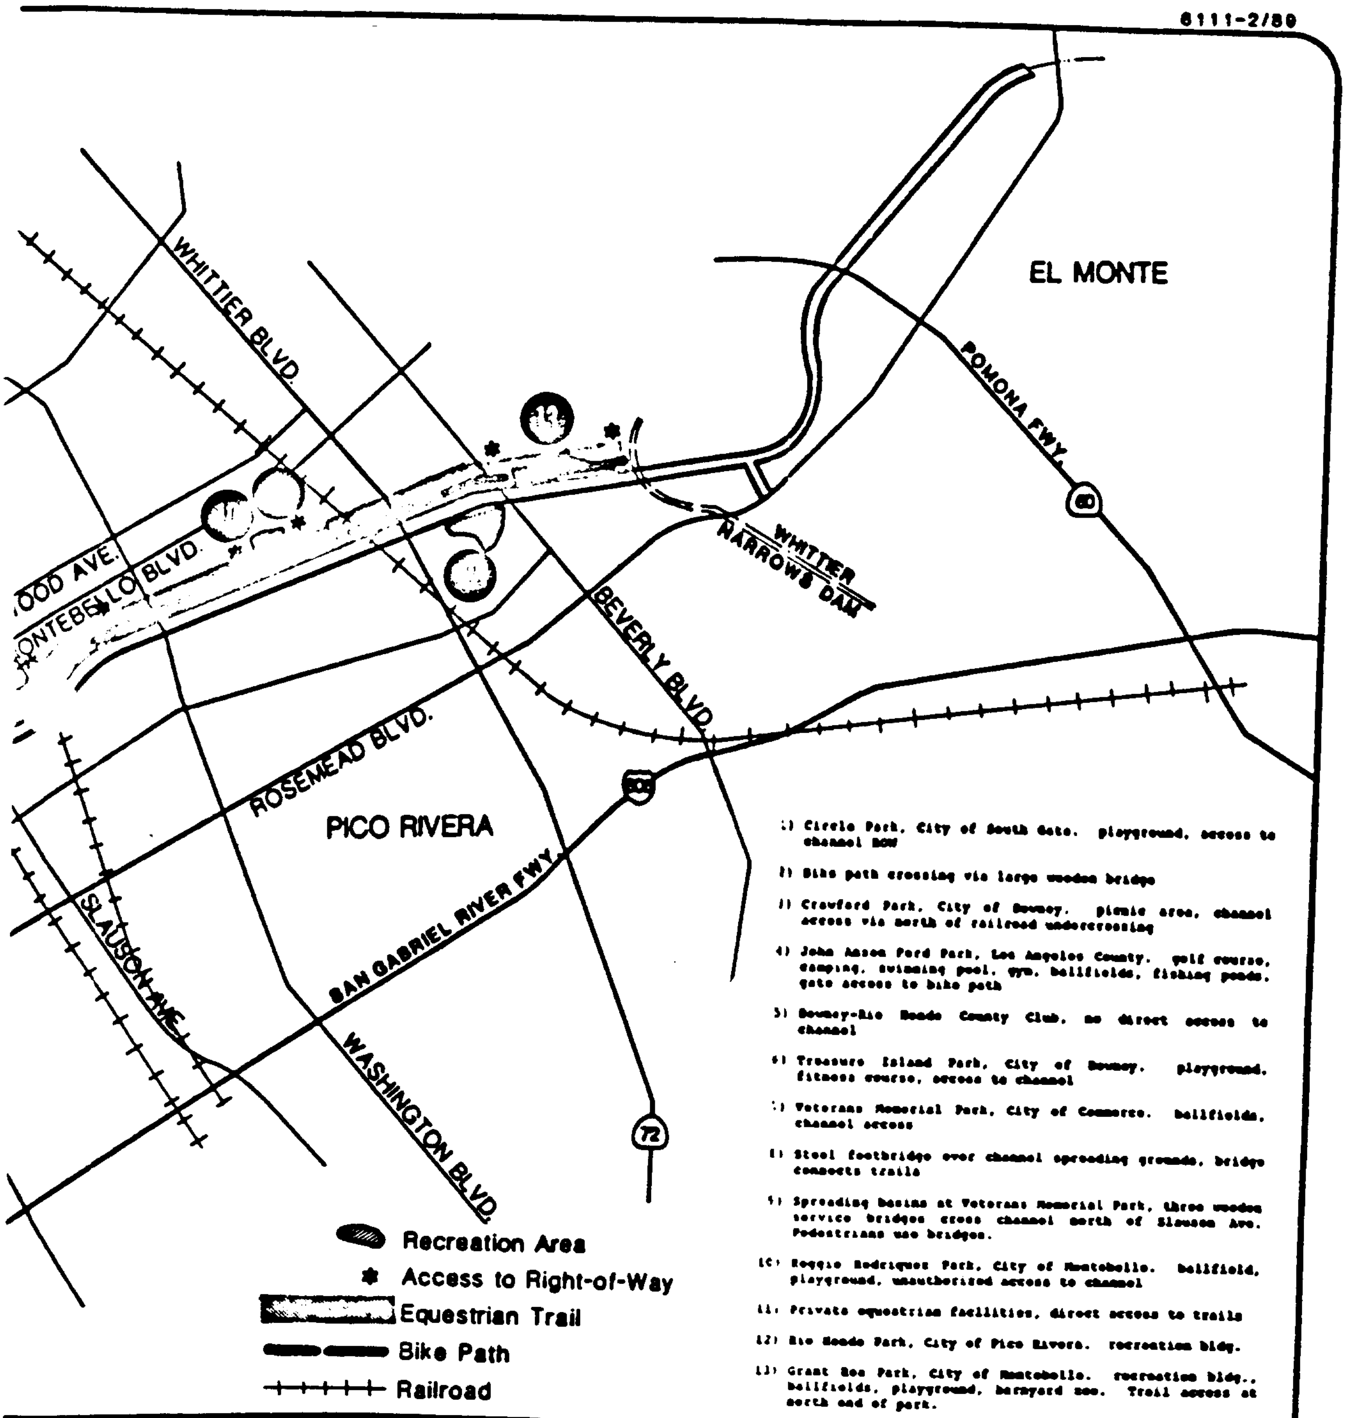


FIGURE 3.10-2

VOL 12

1 1228

Some key elements of the lower Los Angeles River which have direct access to the trail system include a small greenbelt park and DeForest Park in Long Beach, East Compton Park, Banana Park in Paramount, Hollydale Park in South Gate and four equestrian facilities. In addition, equestrian staging areas and wide open equestrian fields are located at the midpoint and at the upper end of this reach. Additional access points are provided at cross streets in the area.

Trail users are primarily visually exposed to the concrete channel and surrounding land uses. Except for the wetlands area in the channel between Willow Street and Anaheim Street, areas of aesthetic value include strip park areas abutting the channel to the east such as DeForest Park.

The lower segment of the lower Los Angeles River between Anaheim Street and Ocean Boulevard is within the coastal zone. As such, the proposed project must be reviewed with regard to impacts to recreational use and access to coastal areas, as well as consistency with the Coastal Act. The bike trails provide access to coastal recreation areas, and small boats, and bank fisherman take advantage of the resources of the lower Los Angeles River.

3.10.2.2 Rio Hondo Channel

The Rio Hondo Channel is also characterized as a concrete-lined channel surrounded by a highly urbanized/industrialized area. Weeds are the only vegetation within the channel and typically grow between cracks and joints in the channel. The channel is bordered by a mix of land uses, including residential, commercial, industrial as well as recreational. Spreading basins are located just north of the Santa Ana Freeway on the west side of the channel.

Bike, equestrian and pedestrian trails (Lario Trail system) run most of the length of the Rio Hondo system. Concrete bike and some dirt equestrian trails run on the east side of the channel from the confluence with the Los Angeles River to the Santa Ana Freeway, and bike and equestrian trails run on the west side of the channel from north of

Firestone Boulevard to Whittier Narrows Dam. Between the Southern Pacific Railroad bridge (north of Firestone Boulevard) and the Santa Ana Freeway, the trails run on both sides of the channel. Two bike/pedestrian/equestrian bridges connect the trails with a large wooden bridge at the south end and a steel footbridge just south of the freeway on the north end.

Access to the parks and recreational facilities along the channel are provided through numerous ramps from park areas as well as cross streets. Maintenance vehicles enter the reach at many of the numerous cross streets and use both sides of the channel, including the trails, for maintenance. Maintenance vehicle access to the channels can also be obtained from Whittier Narrows Dam.

Recreational areas having access to Reach 5 include Circle Park in South Gate; Crawford Park and Treasure Island Park in Downey; John Anson Ford Park, under the County of Los Angeles jurisdiction; Veterans Memorial Park in Commerce; and Grant Rea Park in Montebello. Private equestrian facilities near the north end of Reach 5 also access the trails. These areas provide pleasing aesthetics along the trails in addition to being available to trail users as places to relax.

3.11 PUBLIC SAFETY

3.11.1 Flood Plain Overview

The potential of a 100-year and 500-year flood occurring was previously described in Section 3.2. Presently, portions of the LACDA system do not have the capacity to prevent flooding from even a 100-year flood. Large floods occur infrequently, but their magnitude of destruction is enormous. A tabulation of damagable units is presented as Tables 3.3-1 and 3.3-2 in Section 3.3. for the 100- and 500-year events.

Although a flood with a 100-year or greater frequency has not occurred in the 20th Century, there remains a one-in-a-hundred chance that it may be equalled or exceeded in any single year. Such an event could impact almost 82 square miles (212 km^2) with flood waters in localized areas as deep as 8 to 10 feet (2.4 to 3.1 m). Most areas could experience flooding of from 1 to 4 feet (0.3 to 1.2 m).

Significant impacts exist for public safety if a 100-year event were to occur. Potential dangers include being trapped in structures or automobiles, being swept into flood waters, or aftereffects of a major event such as inaccessibility to food and water, and effects of standing water, including the spread of mosquitoes and other pests and disease.

Additional significant public safety and health problems could occur from toxic and hazardous materials being washed into the environment. A large number of industrial facilities are located within the flood plain and at locations adjacent to the channels. Many of the facilities have materials stored in drums or use potentially hazardous materials in their operations.

3.11.2 Public Safety Considerations Along Channel Construction Reaches

The trail systems provide for the safety of recreational users in that the trails separate the users from automobile traffic. Bike trails run along the top levee parallel to the channel with crossings provided underneath roadways and freeways. In general, there is no fencing or protection provided for users riding or falling down the embankments to the channel bottom. This condition has the potential to result in injury to the trail user.

Occasionally, maintenance vehicles will obstruct the trail, causing trail users to have to go around such vehicles. Trails are sometimes closed for major maintenance and construction activity.

In some areas of the trail systems, equestrian as well as bicyclists and pedestrians share the same pathways. While some of the equestrian trails are separated, even if only by narrow strips of earth, most equestrian trails end at undercrossings and share the same pathways with bikes and pedestrians.

VOL 12

1

7231

No specific issues of traffic safety on surface streets have been noted. Traffic on surface streets in the areas of proposed construction are comparable to other areas of Los Angeles.

As mentioned above, large numbers of industrial facilities are located adjacent to the channels. Many of the facilities contain materials which may be toxic or hazardous if released.

3.12 PUBLIC UTILITIES

The study area is highly developed, and contains a great diversity of utility systems including natural gas, potable water, electrical lines (above and underground), telephone lines, petroleum lines, and similar utilities. These lines cross the river under the channel, on roadway and highway bridges and on special pipeline bridges. A detailed, comprehensive inventory of all utilities crossing the river has not been conducted. Each of the bridges have vaults which are expected to contain all or most all utilities. Additionally, utilities cross under the channel throughout the two reaches.

VOL 12

SECTION 4 - ENVIRONMENTAL EFFECTS

(A table of environmental commitments, Table 4.11, can be found at the end of this section.)

4.1 LAND USE AND SOCIAL CONCERNS

Land use impacts are considered significant if the construction activity or completed project is inconsistent with land use policy or planning. The plans include relevant zoning ordinances, general plans, resource management plans, recreation master plans, water supply master plans and redevelopment agency plans. Significant impacts will also occur if a proposed use is inconsistent with existing adjacent land uses in the area, even if both are allowed.

4.1.1 No Action Alternative

4.1.1.1 Impacts

The No Action Alternative will result in no land use impacts to the lower Los Angeles River and Rio Hondo areas. Land use will remain the same as present with no impact on land use planning or policies.

4.1.1.2 Mitigation Measures

No impacts are anticipated so no mitigation is required.

1

7233

4.1.2 NED Plan Alternative (Main Report NED Plan)

4.1.2.1 Impacts

Flood Overflow Areas (Main Report NED Plan)

The NED Alternative will have no effects on existing or proposed land use policy or planning. Regarding future planning, including a potential growth management plan, even though project hydrology assumes that some candidate urban areas that are not presently developed will be developed, these areas contribute only 2 percent of the total flow in the project area. This 2 percent figure is considered insignificant from the standpoint of channel design; thus no land use impacts from area development are anticipated.

This alternative will not reduce the area of inundation or the frequency of occurrence of a 500-year flood event, nor will it effect more frequent flooding events in the upper reaches of LACDA. It may, however, reduce the potential depth of inundation of various areas subject to deep flood waters. The NED alternative will nearly eliminate the 100-year area of inundation in Reaches 4 and 5 (Figure 4.1-1). Elimination of the 100-year area of inundation will save 135,931 structures out of a total of 141,508 presently existing within the 100-year overflow area (see Table 3.3-2).

Land Use Adjacent to Channel Construction Reaches (Main Report NED Plan)

Construction activity will be limited to existing right-of-way property where possible. A list of bridge detour locations that may require use of adjacent land is presented in Table 2.3-7. These uses of land are inconsistent with present uses and may result in potential safety impacts. This incompatible land use occurs due to the necessity of providing mitigation for traffic impacts.

Construction activity may also encroach upon certain residential areas, and especially commercial/industrial areas, where the back fences of these properties are directly adjacent to the levees. Construction activity, including the use of heavy equipment and loud equipment, will result in a temporary land use which is inconsistent with adjacent uses. Resultant impacts may include noise, air quality and traffic impacts. The specific impacts and mitigations for these encroachment activities are presented in the appropriate resource sections within this document.

4.1.2.2 Mitigation Measures

Mitigation for use of the various properties for the temporary construction of a traffic detour includes full financial compensation and replacement of the sites after construction activity ceases.

4.1.3 Modified Channel Cross-section Alternative (Main Rpt Alts. Two and Three)

4.1.3.1 Impacts

Flood Overflow Areas

Impacts are identical to those presented for the NED Alternative in Section 4.1.2.1 above. No impacts will occur to land use planning or policy. This alternative will eliminate the 100-year area of inundation in the lower LACDA basin.

Land Use Adjacent to Channel Construction Reaches

Construction activity will generally be limited to available right-of-way property. Construction activity may, however, encroach upon certain residential and commercial/industrial areas, especially where the back fences of these properties are directly adjacent to the levees. Construction activity, including the use of heavy

VOL 12

equipment and loud equipment, will result in a temporary land use which is inconsistent with adjacent uses. Resultant impacts may include noise, air quality and traffic impacts. The specific impacts and mitigations for these encroachment activities are presented in the appropriate resource sections within this document.

4.1.3.2 Mitigation Measures

Mitigation measures for activities which encroach upon adjacent uses are presented under other resource sections within this document, including noise, air quality and traffic.

4.2 AIR QUALITY

Air quality impacts are considered significant if one or more of the following criteria are exceeded:

- Emissions result in exceedance of state or Federal air quality standards;
- Emissions at or greater than 1 percent of emissions for a potential pollutant within the subarea of the South Coast Air Basin;
- Release of hazardous non-critical pollutants into the atmosphere;
- Generation of dust exceeding SCAQMD Rule 403.

17236

4.2.1 No Action Alternative

4.2.1.1 Impacts

The No Action alternative would not cause any direct impacts to the existing air quality in the project area.

4.2.1.2 Mitigation Measures

No mitigation is required.

4.2.2 NED Plan Alternative (Main Report NED Plan)

4.2.2.1 Impacts

All air impacts are short term and construction related. No significant long-term, permanent impacts are expected to occur as a result of this project.

Impacts to air quality from the NED alternative could come from dust generated during construction activities and pollutants released from internal combustion engines of on- and off-site construction equipment.

The major sources of dust include soil disturbance, travel on unpaved surfaces, and loading/unloading of dusty material. These scattered sources of particulates, referred to as fugitive dust, are difficult to quantify. Therefore, the impact on the surrounding areas is not easily assessed. If regular watering of potential dust-generating areas is performed, impacts from construction activities should be minimal. However, during Santa Ana wind conditions, construction activities could potentially generate significant levels of suspended dust particles.

Internal combustion engines will produce combustion pollutants from on-site heavy equipment and off-site trucks hauling material and delivering concrete. The daily equipment combustion emissions during a maximum 12 hour workday from project-related mobile source emissions have been calculated in Table 4.2-1. These calculations were based on an estimated equipment list (see Table 2.3-6) which assumes that all

equipment operates at 60 percent of maximum load. Construction employee commuting and light-duty pickup use was not included, but emissions from these activities are generally much less than on-site heavy equipment and off-site trucks.

Table 4.2-1

VOL 12

17239

R0050544

Total daily emissions range from about 100 to 150 pounds (45 to 67.5 kg) per day for exhaust particulates, hydrocarbons, and SO_2, to close to 1,000 pounds (450 kg) per day for carbon monoxide and over 1,500 pounds (675 kg) per day for NOx. A large portion of these emissions are from hauling materials such as concrete and other materials. These emissions could be dispersed over a larger area, depending on where material trucked to the site originates from and where material removed will be disposed.

A comparison with existing subregional emissions from AQMD Source Receptor Areas (SRA) 4, 5, 11, and 12 (Long Beach, Whittier, Pico Rivera, and Lynwood, respectively), indicates that the project contribution to the CO, ROG, and NOx burden is adverse, yet below the level of significance (1 percent of the subarea total).

4.2.2.2 Mitigation Measures

Discretionary mitigation measures to control project emissions center primarily on fugitive dust control not amenable to standard dust control technology. Mitigation measures for inclusion in project planning include:

o Frequent watering of the construction area to limit dust emissions from on-site equipment and off-site trucks accessing the project,

o Provisions for terminating operations during strong Santa Ana wind conditions.

In addition to dust control measures, there are mitigation measures from non-particulate sources that will be implemented, and thus should be given consideration where appropriate. Such measures include:

o Good maintenance, including proper tuning of off-road heavy equipment, to reduce combustion source air emissions (especially NOx),

o Control of diesel fuel quality (low sulfur content),

VOL 12

1 7 2 4 0

- Site activity control/termination during Stage II smog episodes,
- Contractor participation in the AQMD mandatory rideshare program (Regulation XV).

4.2.3 Modified Channel Cross-section Alternative (Main Rpt. Alts. Two and Three)

4.2.3.1 Impacts

All air quality impacts are short term and construction related. No significant long-term, permanent impacts are expected as a result of this project.

Excavation of excess material during conversion or widening, travel on unpaved surfaces, and other construction elements have traditionally been associated with dust generation which may create localized dust nuisances near the activity. Improved control technology, however, in conjunction with emission rules and restrictions on certain operations developed by the AQMD, has led to a substantial reduction in emission levels. The major source of emissions from controlled construction activities is therefore from scattered sources not amenable to control (called fugitive emissions).

Dust emissions associated with the proposed project include a wide variety of activities such as excavating the material from the channel sides, moving material to a disposal site, and constructing the new channel walls. In addition to fugitive dust, project activities will entail the generation of combustion emissions from mobile equipment to extract the material, haul material to a disposal site, and bring concrete to construct channel walls. Soft-bottom river sediments will be dredged from the last 2.5 mi (4 km) of the lower Los Angeles River. The diesel dredge employed for this project will contribute additional combustion emissions as will haul trucks or barges used to transport the dredged material to a suitable disposal site.

The daily equipment combustion emissions during a maximum intensity workday from estimated project-related mobile source emissions have been calculated in Table 4.2-2.

VOL 12

1 7 2 4 1

These calculations were taken from the analysis of a similar project proposed on the Santa Ana River (MITECH 1988) with the addition of the dredging activities which are based on emission factors published by the EPA in its "Compilation of Air Pollution Emissions Factors - AP-42", assuming a worst-case scenario of using haul trucks for dredged material disposal.

Total daily emissions range from about 250 pounds (112.5 kg) per day for exhaust particulates, hydrocarbons, and SO_2 to over 800 pounds (360 kg) per day for CO and just under 2,000 pounds (900 kg) per day for NOx. The majority of these emissions are from vehicles used for hauling material. Emission values could possibly be reduced somewhat if dredged material were barged to an ocean disposal site, depending on the distance to that site. Also, emissions could be reduced if an electric dredge can be utilized.

Comparison with existing subarea emissions (SRAs 4, 5, 11, and 12) indicates that the contribution from the project to the CO and NOx burden, while adverse, is below the level of significance (1 percent of the subarea total).

4.2.3.2 Mitigation Measures

The dredging operations associated with modifying the channel cross-section will require an air quality permit from the South Coast AQMD which will establish control limits on emissions. Discretionary mitigation measures to control project emissions center primarily on fugitive dust control not amenable to standard dust control technology. Mitigation measures to be considered for inclusion in project planning include:

- o Frequent watering of the construction area to limit dust emissions from on-site equipment and off-site trucks accessing the project,

- o Provisions for terminating operations during strong Santa Ana wind conditions.

VOL 12

1 7243

In addition to dust control measures, there are mitigation measures from non-particulate sources that may possibly be implemented, and thus should be given consideration where appropriate. Such measures include:

- o Good maintenance, including proper tuning of off-road heavy equipment, to reduce combustion source air emissions (especially NOx),
- o Control of diesel fuel quality (low sulfur content),
- o Site activity control/termination during Stage II smog episodes,
- o Contractor participation in the AQMD mandatory rideshare program (Regulation XV).

4.3 WATER QUALITY AND FLOOD POTENTIAL

Impacts to water quality are considered significant if activities result in a violation of existing water quality standards, result in substantial release of toxic materials or exacerbate existing water quality problems.

Impacts are also considered significant if the project results in an increase in flood potential in a particular reach of the river.

4.3.1 No Action Alternative

4.3.1.1 Impacts

Implementation of the No Action Alternative will result in no increase in sedimentation or creation of any additional water quality impact. The Los Angeles and Rio Hondo rivers would continue to experience water quality problems associated with urban runoff and illegal discharge of toxic materials. No wetlands shall be affected as a result of this alternative.

If the No Action Alternative were implemented, the existing flood potential in the lower Los Angeles and Rio Hondo rivers would continue.

4.3.1.2 Mitigation Measures

Other than continuing flood warning programs and the potential use of upstream retention basins, no mitigation is proposed.

4.3.2 <u>NED Plan Alternative (Main Report NED Plan)</u>

4.3.2.1 Impacts

Since most of the construction activities are proposed to take place on top of the existing channel walls, there would be no sedimentation impacts associated with parapet wall construction. Where channel widening would occur as well as wall construction possibly at bridges, there would be a potential for significant sedimentation impacts associated with excavation and movement of materials. This impact could become significant during moderate river flows. There is also a potential that toxic material such as diesel fuel could be accidentally discharged by construction equipment and operations. This impact could also be significant.

Implementation of this alternative would result in the 100-year flood plain being contained to the lower Los Angeles River channel and the channel of the Rio Hondo river. There would be no change in upstream flood potential. No wetlands shall be effected as a result of this alte rnative.

4.3.2.2 Mitigation Measures

Whenever possible, work within the channel will be confined to low flow periods. Downstream sediment basins will be constructed in order to trap sediments from construction operations. Refueling of equipment near the channel will be limited and closely monitored.

VOL 12

4.3.3 Modified Channel Cross-section Alternative (Main Rpt. Alts. Two and Three)

4.3.3.1 Impacts

Implementation of this alternative will result in potential significant sedimentation impacts asssociated with both construction of new channel walls and dredging in the downstream portion of the Los Angeles River. Of particular concern is the potential impact of this sedimentation on aquatic resources within the portion of the river near its mouth. This impact is described in Section 4.5.

Depending upon the disposal method employed, there would be a potential impact to water quality if ocean disposal in LA-2 or LA-3 were to occur. Assuming this material meets standards for ocean disposal, no significant impact is anticipated.

As with the NED project, this alternative will contain the 100-year flood plain within the channel of the lower Los Angeles and Rio Hondo rivers. Flood potential within the upper portion of the Los Angeles River will not be changed.

1 7246

4.3.3.2 Mitigation Measures

Sedimentation basins will be constructed downstream of construction activities. A hydraulic cutterhead dredge will be used to minimize turbidity in the channel. Use of these methods will reduce impacts to insignificant levels.

Chemical testing and/or bioassays of sediments will be conducted as necessary to assure all materials meet ocean disposal or other disposal standards.

Chemical testing and/or bioassays of sediments will be conducted as necessary to assure all materials meet ocean disposal or other disposal standards.

VOL 12

4.4 NOISE

Noise impacts are considered significant if they exceed established noise exposure standards, or if there are unique, noise-sensitive receptors within the zone of primary project activity noise impacts.

Because most communities do not regulate noise from construction except through controls on hours of operation, noise/land use compatibility guidelines are used as the standard for the project noise impact assessment (see Section 3.6.1.1).

4.4.1 No Action Alternative

4.4.1.1 Impacts

The No Action Alternative results in no construction activity occuring along the LACDA system. Noise levels remain as in existing conditions with no construction impacts occuring.

4.4.1.2 Mitigation Measures

No mitigation measures are required.

4.4.2 NED Plan Alternative (Main Report NED Plan)

4.4.2.1 Impacts

Land use in the vicinity of the channel corridors proposed for construction were described in Land Use (Section 3.3). Figures 3.3-1 and 3.3-2 show general land uses along the reaches and identify sensitive receptors. Six schools are within 2,000 feet (610 m) of the channel in the lower Los Angeles River, while three schools are within 2,000

1 7248

feet (610 m) of the channel along Rio Hondo Channel. No hospitals or churches were identified along either reach. No wetlands shall be effected as a result of this alternative.

A listing of equipment estimated for use for construction of this alternative is presented in Table 2.3-6. Equipment is presented for the various activities of parapet wall construction, armoring and bridge construction.

Parapet Wall Construction (Main Report NED Plan)

The worst-case condition arises from construction activity immediately adjacent to homes and sensitive receptors along the levees. It is assumed that parapet wall construction will occur in phases along the length of the channel on both sides. Construction will entail the drilling and use of a backhoe to form a trench in the levee for a foundation for the wall. While this effort moves to the next section, forming of the wall and placing concrete will occur at the former location. Thus, construction can occur on a continuous basis along the reach. Wall construction in any one location should take several weeks.

Because the number of vehicles that will be working in one section at one time is not exactly determined, an average exposure level of 85 dB for heavy equipment at 50 feet (15.3 m) from the source, and an 80 dB source strength at 50 feet (15.3 m) for haul trucks and ready-mix concrete mixers will be used for analysis. In an assumed situation where two pieces of heavy equipment and two trucks are working in sufficiently close proximity such that they could be considered as a single point source emissions source, then it would take about 3,000 to 4,000 feet (915 to 1,220 m) of normal noise propagation before the construction noise would blend into the environment, depending on other background noise. Noise contours from intensive on-site construction activities are as follows:

VOL 12

11249

Sound Level	Distance from Source
89 dB	50 feet (15.3 m)
83 dB	100 feet (30.5 m)
77 dB	200 feet (61 m)
65 dB	800 feet (244 m)
63 dB	1,000 feet (305 m)
59 dB	1,470 feet (448 m)
57 dB	1,770 feet (540 m)
55 dB	2,090 feet (637 m)
49 dB	3,140 feet (958 m)

Impacts will vary from being significant adverse impacts to being adverse impacts depending on the specific activity ongoing at any one time and the level of background noise in the immediate area. Significant impacts will occur in areas where residential back fencelines are directly adjacent to the levee. Impacts will be reduced near freeway overcrossings due to the high background levels. Dwellings near the Golden State Freeway (Interstate 5) for example, experience noise intrusion which exceeds noise land use compatability standards without project implementation.

Armoring (Main Report NED Plan)

Noise sources associated with levee armoring activities include bulldozers, backhoes and grout pump trucks in addition to various other equipment and trucks. Noise impacts from armoring will be similar to other construction activities but confined to the specific armoring areas as shown in Figure 2.3-4.

Impacts from armoring will be less adverse at the locations proposed near the Artesia and Century Freeways due to the high background concentration of noise existing in the area from freeway noise and construction noise, respectively. It is possible that impacts will blend in with background noise such that no impacts occur from armoring operations in these two locations. Impacts from armoring will be more adverse along the Rio Hondo, although, again, not as intrusive as construction of parapet walls, due to shielding by channel embankments.

VOL 12

Bridge Construction (Main Report NED Plan)

Bridge construction encompasses the raising of existing structures and total replacement in some locations. Bridge raising could take as much as 2-1/2 years for each bridge. This entails construction of a temporary bridge to be used as a detour while the existing structure is being demolished and rebuilt. A temporary bridge will most likely be constructed by standard construction techniques except that it will have a temporary, unfinished surface which can be lifted and moved for use in another temporary bridge downstream.

Bridge construction requires the use of large cranes, backhoes, bulldozers, other heavy equipment as presented in Table 2.3-6, and pile drivers for support of the piers. Pile drivers will be required for anchoring of temporary bridges and the widening and anchoring of existing supports for bridges being raised.

Impacts will vary with the level of background noise and land use in the area of bridge construction. Residential areas will experience the greatest impact from bridge construction. The combined impact of several pieces of heavy equipment will raise existing noise levels by 5 to 10 dB during hours of operation adjacent to residential areas. Atop this general noise increase will be a steady "thunk-thunk" when pile drivers are in operation. Pile driver noise will reach 75 dB with each drop of the drive hammer. Such noise is highly irritating because of its repetitive nature.

1

7251

4.4.2.2 Mitigation Measures

All noise impacts are short term and construction related. No significant long-term, permanent impacts are expected to occur from this project. Mitigation for construction impacts include incorporation of the following measures:

- A line-of-sight break between noise sources and the nearest sensitive receptors is the critical factor in maintaining project activity noise impacts at unobtrusive levels. This could be accomplished by placement of a temporary berm to shield residences and other receptors from construction activity. In areas where land is accessible and available, a large berm could reduce noise levels by as much as 20 dB.

- In areas of extreme noise conditions where berms are not feasible, either construction of temporary walls to serve as noise barriers or additional limits on work hours may be warranted to protect these sensitive receptors.

- Smaller, and therefore less noisy, construction equipment will be evaluated for use in sensitive construction areas such as parapet walls during the Preconstruction Engineering and Design phase.

- Because of the increased noise sensitivity during quiet hours, time limits on allowable on-site equipment operations are normally made a condition on construction permits. No on-site activities will be permitted before 7:00 AM weekdays, not before 8:00 AM on Saturdays, and not at all on Sundays or holidays because the noise background is lower on those days and project impacts will become more distinct when they are not blended into the background noise environment. No construction activities will occur after 7:00 PM.

No effective mitigation is available for the use of pile drivers.

4.4.3 Modified Channel Cross-section Alternative (Main Rpt. Alts. Two and Three)

4.4.3.1 Impacts

VOL 12

Reconstruction of Channel Walls (Main Report Alternatives Two and Three)

Under this alternative, the existing trapezoidal walls will be removed from one or both sides of the channels. Either the trapezoidal shape will be retained, but widened, or the shape will be converted from trapezoidal to rectangular. Equipment required includes cranes, excavators and jackhammers for concrete removal. Bulldozers and wheel loaders would be required to fill up to 100 trucks per day with concrete and other material to be hauled away from the site for disposal. Depending on the location, some of this material could be placed behind the existing levee, but most would require trucking off site. It is estimated that up to 100 ready-mix concrete trucks would be required on a daily basis for construction of new vertical walls. Construction would last in any one location for up to one year.

Bridges are not required to be raised; however, modification to some bridge supports will be required.

The impact of any single piece of equipment will not be substantial, but the combined noise effects of a large number of pieces of equipment working in the channel at one time will be significant, raising the existing noise levels behind quiet residential areas by 5 to 10 dB during hours of operations. The impact will lessen for construction operations operating in areas where background levels are already high or already exceed community noise ordinance levels, such as near freeways.

1 7253

Dredging Main Report Alternatives Two and Three)

The 2.5-mile (4 km) segment of the Los Angeles River from the river mouth to Willow Street would be dredged a maximum of five feet (1.5 m). A diesel-powered dredge should be used in the channel. Removed material will be either loaded on barges and disposed of at a deep water disposal area or loaded onto trucks and hauled off site. An alternative disposal site for material unsuitable for ocean siposal is Pier J at Long Beach Harbor. This site could be used to completely contain any materials away from exposure to the environment.

Dredging operations will not create significant noise impacts from the Pacific Coast Highway to the ocean mouth. Most land use in this area is industrial. A background humming sound will result from the operation. Impacts from Pacific Coast Highway north to Willow Street will be more noticable to the residential areas bordering the channel. Again, a backgound humming will emanate from the channel. However, trucking operations hauling material off site will result in noise impacts within residential neighborhoods. Impacts will vary in significance with the distance of the receptor from the site and the routing of the trucks.

4.4.3.2 Mitigation Measures

Noise mitigation measures are identical to those described in Section 4.4.2.2 for the NED Alternative except that pile drivers should not be needed and, therefore, there are no concerns of mitigation for that equipment.

4.5 BIOLOGICAL RESOURCES

Impacts to biological resources are considered significant if they result in loss of one or more acres (0.4 ha) of wetland habitat, cause mortality in aquatic organisms or adversely affect the continued existence of an endangered, threatened or candidate species.

4.5.1 No Action Alternative

4.5.1.1 Impacts

Implementation of the No Action Alternative will result in no impact to biological resources since no activites in the channel areas will take place.

4.5.1.2 Mitigation Measures

VOL 12

1 7255

No mitigation measures are required.

4.5.2 NED Plan Alternative (Main Report NED Plan)

4.5.2.1 Impacts

Vegetation

Since the construction activities will be primarily limited to the river channels, no impact to vegetation is anticipated with construction of the concrete walls.

There will also be potential disturbance to vegetation on the outside of the river channel due to bridge raising, levee armoring and other construction activities. Because this vegetation is either landscaped or ruderal areas, no significant impact is anticipated assuming that landscaped areas are replaced. There will be an adverse, but not significant, impact to the Compton Creek Channel since this area contains rather sparse and, primarily, introduced species.

Wildlife

No significant adverse direct impacts to wildlife resources are anticipated through the implementation of the alternative since no productive wildlife habitat will be affected. Additionally, noise from construction operations may affect breeding bird species.

Aquatic Resources

Since work in the channel will be limited, no impact to aquatic resources is anticipated as a result of implementation of the alternative from actual construction. If diesel fuel or other toxic material is spilled, impacts in downstream areas could be adverse.

VOL 12

Threatened and Endangered Species

No loss of foraging habitat of the California least tern and California brown pelican are anticipated. Noise and other activities on the levee walls in the lower portion of the Los Angeles River could affect foraging patterns of these species. This impact is potentially significant, but can be reduced to insignificant (i.e. no threat to continued existence of the species) through conducting activities in the lower channel from September to March on the last one-mile reach of the Los Angeles River. See Appendix C for the biological assessment.

4.5.2.2 Mitigation Measures

The wetland areas in the lower most portion of the Los Angeles River will not be destroyed by construction activities. This area will be monitored to assure that no activites or materials are discharged in this area.

In order to prevent impacts to nesting birds in the wetland as well as not to disturb foraging activities of the least tern and brown pelican, activities will not be conducted from April through September in the last one-mile reach of the river. This would reduce any impact that would adversely affect the species to no effect.

To avoid discharges of pollutants to the stream from refueling and maintenance work on equipment, refueling will be limited near the channel and closely monitored if it must be accomplished near the channel.

17257

4.5.3 Modified Channel Cross-section Alternative (Main Rpt. Alts. Two and Three)

4.5.3.1 Impacts

Vegetation

Implementation of this alternative may result in the loss of approximately six acres (2.4 ha) of wetland habitat along the lower portion of the Los Angeles River due to dredging activities. This impact is considered significant. Other than loss of ruderal species in the Compton Creek Channel, no other adverse impact is anticipated to vegetation.

Wildlife

There may be a significant impact to wildlife species associated with the loss of the wetland within the lower portion of the Los Angeles River. No other adverse impact is anticipated to wildlife resources.

Aquatic Resources

Removal of sediment from the lower Los Angeles River will create short-term impacts due to dredging. The most direct impact is the destruction of soft-bottom benthic organisms associated with the disturbed sediments. Once dredging is completed, recolonization of the affected area would commence. Field studies of dredged areas have shown that recolonization occurs within two weeks to three years after the dredging stops (McCauley, Parr, and Hancock 1977; Oliver et al. 1977; Rosenberg 1977). It is expected that the benthic community will recover at the shorter end of this range. Oliver et al. (1977) found that shallow water communities inhabiting highly variable and frequently disrupted physical environments rebounded or recovered in less time from experimental disturbances than those found in less variable and more benign conditions.

VOL 12

1 7258

VOL 12

The impact to the benthic organisms, although adverse, would be short term and insignificant.

Fishes occupying the proposed dredging area would be impacted, especially those who utilize the benthic environment for foraging. The loss of habitat, physical disruption, and environmental disturbance could cause stress and mortality. Fish and other mobile organisms should, however, avoid the dredging area and relocate to undisturbed areas. Therefore, impacts to fish are considered short term and insignificant.

Potential changes in water quality in the form of pollutants, toxic materials, and trace metals may result due to resuspension of bottom sediments during dredging activities. Temporary increases in turbidity and suspended solids levels, along with associated decreases in dissolved oxygen may also occur. Any appreciable increase in turbidity may cause clogging of gills and feeding appendages of fish and filter feeders. If a cutterhead dredge is utilized for removal of sediment, turbidity should be confined to within 200 to 500 feet (61 to 153 m) of the dredge unless a strong current exists, which would extend the range of turbidity. Should it be necessary to use a clamshell dredge, turbidity could be more extensive.

1259

The greatest potential for impact generally lies with the resuspension of materials that are toxic or harmful to organisms, either directly or through bioaccumulation. Because the dredging that is proposed in conjunction with this alternative is for an active river bed, potentially harmful suspended material could be discharged to the ocean waters surrounding the river mouth.

Bioassays and bioaccumulation tests were recently performed on sediments located at the mouth of the Los Angeles River in conjunction with possible dredging and disposal at the LA-2 offshore dredged material disposal site (Marine Bioassay Laboratories 1988). Results of these analyses indicated that copepods exposed to elutriates of sediments showed statistically elevated mortalities, while test organisms exposed to sediments during the solid phase bioassay showed no significant mortality. However, bioaccumulation tests on organisms exposed to sediments for a 20-day period revealed elevated levels of cadmium, lead, and zinc in their tissues.

Sediments proposed for dredging under the modified channel cross-section alternative should be similar to the sediments tested from the river mouth. Consequently, the effects of resuspension of material in the sediments should be similar to the effects noted during the bioassay analyses. Increased mortality to copepods and bioaccumulation of certain metals by benthic invertebrates could be expected. Use of a cutterhead dredge could be used to reduce the amount of material resuspended.

Although similar to sediments from the river mouth, bioassays of the sediments from the lower Los Angeles River would be necessary to determine their proper disposal. If these analyses indicated a higher level of contamination, dredging operations could be limited to periods of slack tides and low or no river flow to further reduce the potential impacts of resuspension of contaminants. An alternative exists to dispose of contaminated material at Pier J in Long Beach where it could be completely contained and segregated from the environment.

<u>Threatened and Endangered Species</u>

Dredging activities will have a potential to affect foraging habitat for the California least tern and California brown pelican. Habitat will remain after dredging; however, this impact is considered to be significant but mitigable to insignificant levels (no effect) by conducting dredging operations between late September and March on the last one-mile reach of the Los Angeles River. See Appendix C for the biological assessment.

4.5.3.2 Mitigation Measures

Loss of the wetland area can be mitigated through restoration of habitat near the channel area. Although soft bottom habitat will remain after dredging, the channel will be lowered so that this wetland may not be re-established. Therefore, creation of small pockets of wetlands adjacent to the channel that would support small areas of marsh and/or riparian vegetation would replace wildlife habitat lost by dredging.

VOL 12

1

7260

A hydraulic cutterhead dredge should be used to reduce the degree of turbidity. If further bioassays indicate that dredge specimens are highly contaminated, dredging operations should be restricted to periods of slack tide and low or no river flow.

The possibility of adversely affecting the least tern can be reduced to no effect through restriction of dredging operations to September through March in the last one-mile reach of the river.

4.6 CULTURAL RESOURCES

Impacts to cultural resources are considered significant if project implementation results in the loss of a historic, prehistoric or paleontologic resource without proper testing and evaluation.

4.6.1 <u>No Action Alternative</u>

4.6.1.1 Impacts

No impact to cultural resources will occur since construction activites would not occur with this option.

4.6.1.1 Mitigation Measures

No mitigation is required.

4.6.2 <u>NED Plan Alternative (Main Report NED Plan)</u>

4.6.2.1 Impacts

No impact to cultural resources on the Los Angeles River or Compton Creek will occur since no National Register sites are present.

Twelve bridges along the Rio Hondo Channel will have to be modified, which would have an adverse effect on any property eligible for the National Register. The Corps of Engineers has yet to determine the National Register eligibility of four of the bridges. The Corps' eligibility determination will have to be provided to the State Historic Preservation Office (SHPO) for their concurrence pursuant to Section 106. An evaluation will be done by a historian during the Preconstruction Engineering and Design phase.

4.6.2.2 Mitigation Measures

If any bridges are determined to be National Register eligible, mitigation measures will be developed in consultation with the California State Historic Preservation Officer and the Advisory Council on Historic Preservation pursuant to Section 106 of the National Historic Preservation Act (36 CFR 800). These measures would be agreed to in a Memorandum of Agreement. This will be done during the Preconstruction Engineering and Design phase and in place prior to construction.

4.6.3 Modified Channel Cross-section Alternative (Main Rpt. Alts. Two and Three)

4.6.3.1 Impacts

Since construction activities will be limited to the channel, no impact to bridges or other cultural resources will be affected.

4.6.3.2 Mitigation Measures

No mitigation is required.

VOL 12

17262

4.7 TRANSPORTATION

Some traffic delays on surface streets will occur during raising of the roadway bridges shown in Figures 2.3-5 and 2.3-6. The proposed schedule and estimated impact duration is shown below:

DRAINAGE AREA	BRIDGE	IMPACT DURATION
Rio Hondo	Whittier Blvd.	Oct 1995 to Oct 1997
	Slauson Blvd.	Jul 1997 to Jul 1999
	Florence Blvd.	Apr 1998 to Apr 2000

	Atlantic Blvd.	Apr 1998 to Apr 2000
	Rosecrans Ave.	Apr 2000 to Apr 2002

This schedule reflects a staggering of construction times for adjacent bridges, to insure that if a motorist does decide to detour to the next nearest bridge it will not have an impacted traffic flow. Bridge work and detouring patterns will vary according to the local conditions. Proposed detours are summerized in Tables 2.3-3 and 2.3-4. Table 2.3-7 lists the land uses that may be effected by detours.

All traffic impacts are construction related and temporary. It is estimated that actual construction time for each bridge will not exceed twelve (12) months. The maximum length of time for traffic delays in crossing these bridges have been calculated to amount to less than 5 minutes per vehicle, compared to non-construction traffic flow. None of the freeways that cross these drains will need to be modifided for this project.

The railroad bridge crossings scheduled for modification will have temporary structures built to accomodate traffic during construction. The utility crossings of the river will be dealt with, where necessary, by the owner. In all cases the construction process will be handled so that commerce can be carried across the river in an expeditious manner.

Two (2) pedestrian bridges are scheduled to be raised, with construction taking approximately one week. Impacts will be negligible.

4.7.1 No Action Alternative

4.7.1.1 Impacts

If the No Action Alternative is chosen, there would be no significant impacts to traffic directly resulting from the project. No bridges would be closed and no detours imposed. This alternative would not increase the amount of construction vehicles in the area that could add to and increase the level of congestion on surface streets and freeways.

However, indirect impacts to transportation could result from the No Action Alternative. Since no improvements to the LACDA system would be made, the occurrence of flood conditions above the current capacity would result in flooding to a large portion of the Los Angeles Basin (see Figure 3.2-2). This flooding would cause major short-term transportation impacts in addition to other serious damage. Not only would traffic be severely restricted during flood conditions, but the cleanup and reconstruction of damages would prolong the impacts.

4.7.1.2 Mitigation Measures

Mitigation includes flood management planning which, as discussed in Section 2.1.1.13, is not effective enough to prevent major property damage, possible loss of life and serious disruption to traffic patterns. Also it is not practical to incorporate a major flood proofing program in an area as heavily developed as Los Angeles.

VOL 12

1 7 2 6 5

4.7.2 NED Plan Alternative (Main Report NED Plan)

4.7.2.1 Impacts

Parapet Walls (Main Report NED Plan)

Parapet walls would be constructed on the tops of the existing levees for nearly the entire lengths of Reach 4 and Reach 5. Construction vehicles required for this project would typically include backhoes, bulldozers, drilling rigs, graders, concrete trucks, compactors, and water trucks, as well as various light duty trucks (see Tables 2.3-5 and 2.3-6). Significant impacts to existing traffic conditions could result from construction vehicle traffic increasing the level of congestion during the peak traffic periods. This impact could be reduced if construction vehicles traveled to and from the sites during off-peak hours and avoided the use of major commuter thoroughfares whenever possible.

Construction vehicles would access the levees via the bike/ pedestrian trails and service roads which are located on top of the levees. A concrete bike/pedestrian trail runs along the entire length of the east levee on Reach 4 and on parts of the east and west levees of Reach 5, while concrete and dirt service roads are present in areas without bike trails (see Section 3.10.2.1). Access to the service roads is available adjacent to most roadway overpasses, and to the bike/pedestrian trails at irregular intervals along each reach (see Figures 3.10-1 and 3.10-2). Impacts to existing traffic could occur if construction related vehicles blocked traffic lanes on major streets while waiting to enter service road entrances. This can be minimized through the use of signs and signalmen. The bike/ pedestrian trails are accessed from smaller noncommuter roads, often in proximity to recreational facilities. Impacts to existing traffic from vehicles utilizing the bike/pedestrian trails would be adverse but not significant. Impacts to recreational facilities are discussed in Section 4.8.

As noted in Section 2.3.1.3, conversion of the channel from trapezoidal to rectangular to widen the channel would occur only along a short reach. This would involve removal of the concrete lining, excavation of earthen material, and pouring of a vertical concrete retaining wall. This would require the use of jackhammers, earthmoving equipment,

VOL 12

1 7 2 5 6

trucks to haul out the material, and concrete trucks. As stated above, these construction vehicles could cause traffic impacts unless truck traffic was restricted to off-peak hours and the riverbed utilized whenever possible. The project site could be accessed from the bike/pedestrian trails and service roads on the levees and entrances leading into the channels. Under normal non-flood conditions, vehicles could travel along the concrete-lined channels, restricting the area of traffic impacts to the entrance/exit locations of the channels.

Levee Armoring (Main Report NED Plan)

Impacts to traffic as a result of levee armoring would be similar to those for parapet wall construction. Various construction vehicles (see Tables 2.3-5 and 2.3-6) would access the levees from the bike/pedestrian trails and service roads. These would include trucks hauling numerous loads of rock rip-rap. A significant impact to existing traffic could result from construction vehicle commuting during peak-hour periods. Restriction of construction traffic to off-peak hours and utilization of the river channel for construction traffic would reduce impacts to a level of insignificance.

Modification of Existing Bridges (Main Report NED Plan)

The modification of 15 bridges crossing the lower Los Angeles River and 12 spanning the Rio Hondo will cause significant impacts to the traffic flow for a large area surrounding each bridge under construction. Temporary bridges of at least four lanes will be provided as detours for most bridges requiring modification (see Tables 2.3-3 and 2.3-4). Impacts to traffic could occur during the construction of detour bridges, raising of the existing bridges, and removal of the detour bridges.

During construction of the temporary detour bridges, construction vehicle traffic could increase the level of congestion, significantly impacting the existing traffic conditions. This impact could be lessened by restricting construction traffic to off-peak hours and making use of the river channels to move vehicles whenever possible. Additional impacts could occur from incidental slowing as drivers observe the construction process. This type of vehicle slowing, referred to as "rubbernecking", could affect traffic several intersections back if the level of congestion is already high, as during peak commuter periods.

The demolition and reconstruction of a bridge will create similar impacts from construction vehicle traffic as did constructing the temporary bridges. Vehicles coming to and from the site during peak periods could add to the already-congested conditions. Although detour bridges will allow a continuation of the traffic flow, lanes will be narrower and vehicles will have to make an abrupt jog to the side of the existing bridges as they follow the detour, both of which will cause vehicle slowing. This impact will be most severe during heavy traffic periods, with traffic affected several intersections away and on cross streets in the vicinity. The Long Beach (710), Artesia (91), and Santa Ana (5) freeways could be affected since several streets requiring bridge modifications have offramps from one of these freeways. Backups of traffic onto the freeways could occur if the streets are too congested to accommodate the flow of traffic.

After bridge modification is complete and traffic resumes the normal route, the temporary detour bridges will be removed. Construction vehicles associated with this process could impact existing traffic if congestion increases due to their presence. These impacts are similar to construction of the temporary bridges.

As discussed in Section 2.3.1.4, it will take approximately 2-1/2 years to modify each bridge, and construction of bridges will be in three phases to reduce the intensity of cumulative bridge closures. If two or more adjacent bridges were modified simultaneously, impacts to traffic would be greatly increased. Impairment of traffic capacity on two adjacent bridges at the same time will be avoided if possible.

4.7.2.2 Mitigation Measures

Mitigation measures proposed to lessen potential traffic impacts of the proposed NED alternative include:

- Construct adequate detour bridges;
- Schedule construction traffic to off-peak hours, where possible;
- Utilize the river channel, or other off street routes, for construction vehicle traffic and vehicle staging, whenever possible;
- Avoid reducing traffic capacity on two adjacent bridges simultaneously, if possible;
- Utilize signing and flagmen where construction equipment interface with public traffic;
- Restrict the availability of left turn options, and other traffic restricting behaviors, near the construction area;
- Institute public information programs to enable motorists to avoid congested areas:
  - Place large signs far enough in advance of potentially impacted roadway segments to allow drivers the opportunity to alter their routes BEFORE entering the construction area,
  - Place public notices in local newspapers and on cable TV bulletin boards,
  - Distribute mailers in the project area.

4.7.3 Modified Channel Cross-section Alternative (Main Rpt. Alts. Two and Three)

4.7.3.1 Impacts

Reconstruction of Channel Walls (Main Rpt. Alts. Two and Three)

VOL 12

11729

Widening or conversion of the channel walls will require heavy construction equipment, including cranes, excavators, jackhammers, bulldozers, and loaders, as well as haul trucks and concrete trucks. As stated in Section 2.3.2.1, up to 100 haul trucks a day would be required to remove the concrete and other material from the project, and the same number of ready-mix concrete trucks per day could be necessary to construct the new walls. Construction vehicle traffic could significantly impact existing traffic, most notably during the peak commuter periods.

Construction vehicles confined to the channel, bike/pedestrian trails and service roads should not impact adjacent street traffic. However, haul trucks removing material from the site and concrete trucks delivering material to the site could potentially impact traffic in the area. These impacts would be in the form of increased congestion, causing backups at intersections and freeway onramps, and would add to the high level of congestion currently present on most major roads in the project area. Restricting haul and concrete truck traffic to off-peak hours would lessen the impacts. Establishment of an on-site batch plant for mixing concrete would also reduce the number of construction vehicle trips.

Levee armoring would occur at certain sections of the channel. The impacts on traffic would be similar to those listed for armoring in the NED alternative (Section 4.7.2).

<u>Dredging Operations (Main Report Alternatives Two and Three)</u>

The impact to traffic from dredging operations depends on the mode of sediment disposal. If dredged spoil is loaded on a barge and disposed at an approved offshore dump site, no significant impacts to existing traffic should occur. However, if dredged material is loaded in trucks for disposal at an approved landfill, impacts to existing traffic could occur from the increased congestion from haul trucks. If land disposal is required, haul trucks could be restricted to off-peak hours to reduce impacts to traffic.

4.7.3.2 Mitigation Measures

Mitigation measures proposed to lessen potential traffic impacts of the proposed alternative to widen and dredge the channel include:

- o Schedule construction traffic to off-peak hours, where possible;
- o Utilize the river channel for construction vehicle traffic and vehicle staging whenever possible;
- o Establish an on-site batch plant to mix concrete and haul aggregate to the site at night;
- o Utilize an ocean-dredged material disposal site, if possible;
- o Utilize signing and flagmen where construction equipment interface with public traffic.

4.8 RECREATION AND AESTHETICS

Recreation impacts are considered significant if construction activity interferes with or causes closure of recreational facilities or poses a safety hazard to recreational users, resulting in the need to close a facility.

Visual impacts are considered significant if construction of walls for flood control block existing visually sensitive areas. The problem of constructed walls serving as a potential surface for graffiti is considered an adverse impact in areas of public viewing.

4.8.1 <u>No Action Alternative</u>

4.8.1.1 Impacts

VOL 12

1721

Under the No Action Alternative, no impacts will occur from construction activities to recreational users. There will be no need to close sections of the trails. No visual impacts will occur, and the wetlands will remain in their present condition in the lower area of the Los Angeles River. There will be no potential for graffiti on parapet walls, as these walls will not be built.

Also, no additional improvements to recreational or visual resources will occur under this alternative, but there may be impacts from the exposure to flooding.

4.8.1.2 Mitigation Measures

No recreational or visual impacts will occur; thus no mitigation measures are required.

4.8.2 <u>NED Plan Alternative (Main Report NED Plan)</u>

4.8.2.1 Impacts

Construction of proposed improvements require that construction vehicles and equipment have access to the channel. In areas where parapet walls will be provided along the tops of existing levees, construction will occur on the levees on both sides of the channel and will require that recreational trails be closed in areas of construction for the duration of construction. This results in significant recreational impacts during the construction period.

Within Reach 4, the wetlands area existing between Willow Street and Anaheim Street will no longer be visible as parapet walls will be constructed along both reaches. This will result in the loss of viewing the wetlands area and is considered a significant visual impact. Parapet walls over three feet (0.9 m) in height will restrict bicyclists' views, and walls over five feet (1.5 m) in height will restrict pedestrian views of the channel and areas across the channel. This also results in an adverse significant impact for a worst-case assumption that views are aesthetically pleasing in and across the channel. Wall construction also results in a loss of the sense of openness or the production of a "closed-in" feeling to trail users. Other visually sensitive areas such as park areas abutting and outside of the channel, will be visible from the trails after construction, and no impacts will occur.

The potential exists for adverse impacts from graffiti on constructed parapet walls along the proposed areas of construction. This will be visible from homes and business along areas of the reach and to users of highways and streets crossing the channel.

Construction activities in the lower area of the lower Los Angeles River will result in policy impacts with the Local Coastal Plan. The inconsistency of the project with the Local Coastal Plan results from problems with recreational access to the coastal recreation areas. These include the temporary impacts that construction activity will have on the closure of the bike path along the river channel and the resultant inaccessibility to the coast by this avenue.

4.8.2.2 Mitigation Measures

No equally satisfactory mitigation exists for the rerouting of recreational trails during construction. While construction occurs on the bike path, the possibility exists of using the west side of the levee and surface streets for bicyclists, although this is less appealing due to the presence of automobiles. No mitigation exists for equestrian users. This impact is temporary for the duration of construction between recreational trail access points.

Mitigation for the loss of aesthetic views includes the design of trails on the levee top such that views are provided of the land areas to the outside of the channels. This could also include the planting of shubbery in accessible areas and the possible development of additional strip park areas. The development of additional park areas could serve to provide additional recreational resources within communities adjacent to the channel and could be developed under a joint agreement with those communities. As an alternative, mitigation could be provided by the strategic setting of areas of large potted plants or built-in planters and designed seating areas/rest stops at areas along the trails. These measures would result in aesthetic conditions which are improved over existing conditions. These options will be evaluated during the Preconstruction Engineering and Design phase when the final designs are available.

Mitigation measures for the problem of graffiti on the parapet walls include providing a textured surface on the walls, coating the walls with a material such that clean up is easier and incorporating a routine graffiti removal program into maintenance activities.

Mitigation includes that a temporary bike path be determined and routed such that access to the coast is still available to recreation users.

4.8.3 Modified Channel Cross-section Alternative (Main Rpt. Alts. Two and Three)

4.8.3.1 Impacts

The conversion of the channel cross-section results in the construction of three-foot (0.9 m) high parapet walls along the channel levees. This construction will result in closure of the recreation trails between major access points and is a significant recreational impact during construction.

Parapet walls of up to three-foot (0.9 m) heights will not block views; therefore, no aesthetic impacts will result. However, safety impacts (see Section 4.11.3) require an additional three to four feet (0.9 to 1.2 m) of chain-link fencing on top of the parapet walls. While this will be adverse, it will not result in significant aesthetic impacts. This alternative does, however, eliminate the wetlands area near Anaheim Street, which results in a significant visual impact. Other visually sensitive areas such as park areas abutting and outside the channel will be visible from the trails after construction, and no impacts will occur.

VOL 12

1274

The potential exists for adverse impacts from graffiti on constructed parapet walls along the proposed areas of construction. This will be visible from homes and business along areas of the reach and to users of highways and streets crossing the channel.

Project differences with the Local Coastal Plan is the same as that described for the NED Plan Alternative in Section 4.8.2 with the additional, if temporary, impacts from dredging operations which will occur to fisherman and small-craft boaters who use the mouth of the river for fishing and recreation.

4.8.3.2 Mitigation Measures

As described in Section 4.8.2.2, no equally satisfactory alternative exists for mitigation for the rerouting of recreational trails during construction. The possibility exists of using surface streets for bicyclists, although this is less appealing due to the presence of automobiles. No mitigation exists for equestrian users. This impact is temporary for the duration of construction between recreational trail access points.

No loss of aesthetic views will occur except for loss of wetlands areas. General mitigation measures include the design of trails on the levee top such that views are provided of the land areas to the outside of the channels. This could also include the planting of shubbery in accessible areas and the possible development of additional strip park areas. The development of additional park areas could serve to provide additional recreational resources within communities adjacent to the channel and could be developed under a joint agreement with those communities. As an alternative, mitigation could be provided by the strategic setting of areas of large potted plants or built-in planters and designed seating areas/rest stops at areas along the trails. These measures would improve aesthetic conditions over existing conditions. These options will be evaluated in the Preconstruction Engineering and Design phase when the final designs are available.

Mitigation measures for the problem of graffiti on the parapet walls include providing a textured surface on the walls, coating the walls with a material such that clean up is easier and incorporating a routine graffiti removal program into maintenance activities.

Mitigation measures for inconsistency with the Local Coastal Plan are the same as described above in Section 4.8.2.2.

VOL 12

1 7276

4.9 PUBLIC SAFETY

Safety impacts are considered significant if construction activity poses a safety hazard to the general public. Safety impacts also are considered significant if the completed structure poses a safety hazard to recreation users and the general public.

4.9.1 No Action Alternative

4.9.1.1 Impacts

Flood Overflow Areas

The area of inundation included within the 100- and 500-year flood events includes a great number of waste and hazardous waste materials which could be released into the environment during an event. This is especially true for the lower Los Angeles River inundation area which includes a great number of industrial areas adjacent to the channel. A significant safety impact could result from release of toxic substances.

Safety Adjacent to Channel Construction Reaches

Safety impacts along the recreational trails include the existing hazard of having no barrier on the trails for the steep trapezoidal embankment and the sharing of some portions of the trails by both bicyclists and equestrian users. No other safety impacts occur in the area.

4.9.1.2 Mitigation Measures

Mitigation for the release of toxic materials in flood overflow areas can be partially accomplished by flood prevention planning. The impact remains significant, however.

VOL 12 17277

Mitigation of the safety impacts of having no barriers along recreational trails could be eliminated by construction of parapet walls or incorporation of fencing along the levees and the separation of bicycle and equestrian trails by redesign and widening. This would result in an improvement in safety on the existing recreational trails.

4.9.2 NED Plan Alternative (Main Report NED Plan)

4.9.2.1 Impacts

Flood Overflow Areas

The NED Alternative will result in the elimination of the 100-year area of inundation that results from channel failure along Reaches 4 and 5. This will result in the elimination of hazardous and toxic materials being released into the environment during a 100-year or less event. This results in a beneficial impact to public safety.

Safety Adjacent to Channel Construction Reaches

Construction activities which are proposed to occur along the levees on the sides of the channel where recreational trails exist will result in significant safety impacts to trail users during construction.

The existing hazard of having no barrier on the trails along the steep trapezoidal embankment will be eliminated by construction of the parapet walls. This results in an improvement in safety features on the recreational trails.

Safety aspects related to the raising of bridges include impacts to vehicular and pedestrian traffic in the vicinity of construction. Vehicular traffic rerouting to the temporary bridges will be slowed to the point that no significant safety impacts should occur. Construction activity will be primarily confined to existing right-of-way, with the exception of the detour at Del Amo Boulevard where a portion of a school yard will be required. Potential significant safety impacts could occur from children trying to cut across construction areas.

Trucks hauling materials in and out of construction areas also pose potential safety hazards to the general public. A significant safety risk may result in areas of residential neighborhoods and around schools.

4.9.2.2 Mitigation Measures

Mitigation for safety impacts along trails at channel levees requires that the trails be closed between trail access points for the duration of construction along that segment. No equally satisfactory alternative exists for the rerouting of recreational trails during construction. Surface streets provide a less appealing alternative for bicyclists. No mitigation exists for equestrian users. This impact is temporary for the duration of construction between recreational trail access points.

Mitigation includes that fencing and barriers be placed around areas of construction and that construction equipment be placed in areas at night that are secured from the general public. Also, warning signs should be placed in appropriate locations to warn pedestrians and motorists of potential safety hazards.

Mitigation for trucks delivering materials to and taking materials from construction sites includes the limitation of activity during peak traffic hours and during hours when children are traveling to and from school. Additionally, signs and flagmen will be used in areas to direct traffic where necessary.

While not a project impact, an additional measure could be incorporated into project design which would provide for separation of bicycle and equestrian trails. This would further serve as a safety feature for trail users and will be evaluated during the next phase of study.

4.9.3 Modified Channel Cross-section Alternative (Main Rpt. Alts. Two and Three)

4.9.3.1 Impacts

Flood Overflow Areas

The widening and conversion alternative will result in the elimination of the 100-year area of inundation. This will result in the elimination of hazardous and toxic materials being released into the environment during a 100-year or less event. This results in a beneficial impact to public safety.

Safety Adjacent to Channel Construction Reaches

Reconstruction of channel walls and construction of three-foot (0.9 m) high parapet walls proposed for this alternative will result in significant safety impacts to trail users during construction.

With conversion, the vertical concrete walls which will replace the existing trapezoidal walls pose a significant increase in safety hazards to users of the trail. Instead of an angular drop upon which someone could roll down, there will be a straight drop down. This is combined with only a three-foot (0.9 m) high parapet wall, which is not high enough to provide safety to bicycle or equestrian users. This combination results in a significant adverse safety impact.

There would be no increase in safety hazards in areas of channel widening.
No impacts are expected from channel dredging activity.

Trucks hauling materials in and out of construction areas also pose potential safety hazards to the general public. A significant safety risk may result in areas of residential neighborhoods and around schools.

4.9.3.2 Mitigation Measures

Mitigation for safety impacts along trails at channel levees requires that the trails be closed between trail access points for the duration of construction along that segment. No equally satisfactory alternative exists for the rerouting of recreational trails during construction. Surface streets provide a less appealing alternataive for bicyclists. No mitigation exists for equestrian users. This impact is temporary for the duration of construction between recreational trail access points.

Mitigation for the vertical drop of the channel walls associated with conversion includes placing a chain-link or other fencing on top of parapet walls to a minimum combined height of seven feet (2.1 m). This will provide for safe use of the trail system. An alternative would be to build the parapet walls to a height of seven feet (2.1 m), although this results in a "closed-in" feeling, reduces aesthetics and provides more opportunity for graffiti on solid walls.

Mitigation for trucks delivering materials to and taking materials from construction sites includes the limitation of activity during peak traffic hours and during hours when children are traveling to and from school. Additionally, signs and flagmen will be used in areas to direct traffic where necessary.

While not a project impact, an additional measure could be incorporated into project design which would provide for separation of bicycle and equestrian trails. This would further serve as a safety feature for trail users and will be evaluated during the next phase of study.

4.10 UTILITIES

Impacts to public utilities are considered significant if the project results in the replacement or transference of utility lines.

VOL 12 1728/1

4.10.1 No Action Alternative

4.10.1.1 Impacts

This alternative will require no construction activity, thus no displacement or replacement of utilities is required. No impacts will occur other than those associated with periodic flooding in the flood plain.

4.10.1.2 Mitigation Measures

No mitigation is required.

4.10.2 NED Plan Alternative (Main Report NED Plan)

4.10.2.1 Impacts

The NED Alternative requires the raising of bridges which includes several utility lines. A listing of identified bridges was presented in Tables 2.3-3 and 2.3-4 in Section 2. Not all utilities have been identified for the reaches proposed for construction. Significant impacts will occur due to the requirement that these lines be moved. Some temporary disruption of service may result.

4.10.2.2 Mitigation Measures

Mitigation includes that the lines be raised or moved in conjunction with the raising of the automobile bridges. Disruption to service will be minimized.

VOL 12

1 7282

4.10.3 Modified Channel Cross-section Alternative (Main Rpt. Alts. Two and Three)

4.10.3.1 Impacts

Potential impacts may occur to utilities if such utilities are buried within the trapezoidal portions to be widened or removed from the channels. Significant impacts will occur due to the requirement that the lines be moved. Some temporary disruption of service may result.

4.10.3.2 Mitigation Measures

Mitigation includes that the lines be moved or replaced in conjunction with construction activities. Disruption to service will be minimized.

SECTION 5 - PUBLIC INVOLVEMENT

5.1 PUBLIC INVOLVEMENT PROGRAM

The Corps of Engineers has conducted several public workshops as well as formal scoping meetings to inform the general public and various agencies of the proposed action and to solicit their comments. A Notice of Intent to prepare an EIS was published in the Federal Register (Appendix B) which requested comments from all parties on the proposed project.

Early in the design process, the Corps of Engineers and the Los Angeles County Department of Public Works hosted a series of public workshops to acquaint the public with the LACDA Review Study. Approximately 150 people attended five workshops held over a three-week period in October of 1987. The meetings were held in Glendale, Studio City, Downey, Carson and Long Beach. A representative of the Federal Emergency Management Agency (FEMA) was present at each meeting to discuss the Federal Flood Insurance Program. A summary of the questions and answers provided at the workshops is included in the Appendix A of this EIS.

On March 9, 1989, the Army Corps of Engineers and the Los Angeles County Department of Public Works held two environmental scoping meetings to give the public an update on the progress of the study and to provide the attendees with an opportunity to identify and comment on potential environmental impacts of the proposed action or alternatives that the Corps should consider in preparing the EIS.

Approximately 60 representatives of Federal, State and local agencies and the general public at large attended the meetings that were held in Los Angeles and Lakewood. A list of persons attending, as well as a summary of the comments made at these scoping meetings, is contained in Appendix A of this EIS.

Public comments received at the scoping meetings centered around four topical areas which included environmental concerns; economic concerns; the National Economic

Development, or NED, Plan; and miscellaneous questions. The Corps of Engineers provided an answer to most of the comments at the meeting and a brief is provided where necessary in Appendix A. In addition, the comments have been considered and information incorporated as appropriate into the various environmental issue sections of the EIS. Comments about project economics and details of the NED Plan have been addressed in the description of the proposed action and in discussion of alternatives considered in the EIS.

Two new alternatives were suggested at the scoping meetings. One alternative involved the injection of polymers into the channels at strategic locations to change the flow of water, possibly avoiding the need to raise bridges. This technology has not been proven on the scale of flows within the Los Angeles River and is not considered feasible.

The other alternative involved construction of a large tunnel to carry flows, as opposed to constructing surface facilities. Tunneling has been considered as a possible component of alternatives involving flow diversion. The disadvantages of tunneling compared to the alternative of parapet walls has to do with magnitude of the construction project and construction cost. To carry the significant portion of the flow of the L.A. River flow, a tunnel would have to be tens of meters in diameter, which would be excessively costly and of questionable feasibility. It would also take much longer to build than most surface alternatives considered and would be more difficult to maintain.
Qualitatively, this alternative has an unfavorable benefit-cost relationship and is considered not feasible.

5.2 REQUIRED COORDINATION

The Corps of Engineers staff has coordinated both formally and informally with various agencies to obtain pertinent information, to inform them of the proposed action and to solicit from them informal comments relative to their areas of jurisdiction or expertise. In some cases, contacts were by letter and represent formal consultations required by various Federal statutes and legislation. Other contacts were informal and done by telephone at the staff level. Contacts were made with the following agencies informally:

- U.S. Department of Agriculture
- California Regional Water Quality Control Board
- California Coastal Commission
- South Coast Air Quality Management District
- Los Angeles County Department of Public Works
- Los Angeles County Department of Parks and Recreation

The Corps is consulting with the following agencies relative to the proposed action:

- U.S. Fish and Wildlife Service
- National Marine Fisheries Service
- California State Historic Preservation Office
- California Department of Fish and Game

Formal coordination of the EIS with the many involved public agencies will continue throughout the EIS review and approval process.

The scoping process and meetings, as described in the previous section, is another element of the required coordination that has been conducted by the Corps. Additionally, the Notice of Intent to prepare an EIS was published in the Federal Register on Monday, February 13, 1989 (See EIS Appendix B for a copy of this notice and the responses received to date).

5.3 STATEMENT RECIPIENTS

EIS Appendix F will contain a list of Draft EIS recipients in the Final Report.

5.4 PUBLIC VIEWS AND RESPONSES

This will be provided in the Final EIS.

SECTION 6 - LIST OF PREPARERS

The following persons participated in the preparation of this document.

Preparer	Discipline	Experience	Role in EIS Preparation
Corps of Engineers Staff			
Pat Luvender	Economics	10 yrs	Project Manager
Jon Sweeten	Engineering	5 yrs	Project Manager
Ira Arzt	Engineering	10 yrs	Project Manager
Ronald Lockmann	Geography	7 yrs	Environmental Coordinator
Marie Campbell	Geography	2 yrs	Environmental Coordinator
Kathleen Kunyz	Geography	5 yrs	Environmental Coordinator

SECTION 8 - PERSONS CONTACTED AND REFERENCES CITED

8.1 PERSONS CONTACTED

During preparation of the Draft EIS, various agencies and individuals were contacted to determine issues relative to each agency's area of responsibility. A list of the agencies and individuals contacted is included below.

1. State of California
   Regional Water Quality Control Board, Los Angeles Region
   Mr. Mike Sowby

2. California Coastal Commission
   Coastal Consistency
   Mr. Jim Raives

3. South Coast Air Quality Management District
   Office of Planning and Analysis
   Mr. Brian Farris

4. U.S. Department of Agriculture
   Soil Conservation Service
   Mr. Richard L. Campbell

5. County of Los Angeles
   Department of Public Works
   Mr. Larry Ammon
   Mr. Donald Jordan
   Mr. Mike Anderson

6. County of Los Angeles
   Department of Parks and Recreation

Mr. Tom Dittmar

7. City of Los Angeles

Questions and Answers
Los Angeles County Drainage Area Study
LACDA

Introduction

In October 1987, the Los Angeles District of the U.S. Army Corps of Engineers (Corps) and the Los Angeles County Department of Public Works (County) hosted a series of public workshops to acquaint the public with the Corps' Los Angeles County Drainage Area (LACDA) Flood Control Study currently underway. A representative of the Federal Emergency Management Agency (FEMA) was present at each meeting to discuss the Federal Flood Insurance Program.

Approximately 150 people attended five workshops held over a three-week period in Glendale, Studio City, Downey, Carson, and Long Beach. Workshop participants were invited to ask questions and express their concerns, ideas, and wishes about what planners should consider in designing improvements to the LACDA system.

This summary presents the questions and answers discussed during the five workshop series, as well as other commonly-asked questions that have been posed to the Corps, County, or FEMA representatives since the workshops occurred.

We first present LACDA study issues of general interest, followed by those concerning particular communities, then by those related to FEMA issues. The material is presented in the form of Questions and Answers or Comments and Responses.

The Need for the Current Study

Q. How did the Corps get involved in this study?

A. The County requested Corps participation in a study to find ways to upgrade the current system. In doing so, the County became the local sponsor of the study. This means that the County and the Corps are study partners, and the Corps coordinates with the County on all aspects of the planning process.

Q. Why is the upgrade necessary?

A. The Corps and the County built the existing flood control system to control the largest flood likely to strike the basin, as predicted in the 1930's, based on the information they had available at that time. Since then, we have accumulated much more data relating to flood size and frequency. In addition, conditions that affect flooding have changed over the years, and the system is no longer capable of protecting large areas of the basin. There are several reasons for this:

- Development over the past 50 years has steadily increased floodwater runoff.
- New storm drains that serve this development discharge into the flood control system and increase peak flows in the flood control channels.
- Trapped sediment flowing into the 20 reservoirs is decreasing their flood control capacity.

Q. How much of the land in the basin is now impermeable, and how is this determined?

A. About 40 percent of the land is considered impermeable. Man-induced impermeability is a result of how the land is used. The more developed an area is, the greater the impermeability. Tables have been developed which assign a percent impermeability to various types of land use. Summing the fractions of the various land uses in the basin results in 40 percent impermeability of the overall area.

Q. How do you know that runoff has actually increased?

A. For many years, we have had rain gauges throughout the basin to measure precipitation and stream gauges in the Los Angeles River to measure flows. Data has been recorded since the late 1800's. Since that time, we have seen a 40 percent increase in runoff created by the same amount of rainfall.

Q. What is a 100-year flood? a 500-year flood?

A. Analysts describe floods of different sizes in terms of their statistically projected frequency. For example, a 100-year flood is the size flood that has a 1 percent chance of occurring each year; a 500-year flood has a 0.2 percent chance of happening in any year.

Q. Is it possible to have two 100-year floods in a single year?

A. Yes. Flooding is caused by a combination of factors: where the storms are located, how many storms there are, how closely together they occur, and the saturation level of the ground prior to the storm. Therefore, although the probabilities are against it, it is possible to have multiple 100-year floods in a single year.

Q. What was the size of the 1938 storm? the 1980 storm?

A. At the time of the 1938 flood, the statistical theory on frequency had not yet been applied to floods. However, based on historical data, we estimate that it was probably about a 50-year flood. The 1980 storm was about a 40-year flood in the downstream portions, and about a 70-year flood in the upper reaches.

Q. Would the water during a 500-year flood be deeper or more shallow than in a 100-year flood?

A. A 500-year flood would be slightly deeper than a 100-year flood and would cover a greater area.

R0050607

Q. What is the current release rate from LACDA dams?

A. There is no set rate of release. The LACDA system is very complex, with four flood control dams interacting with and impacting on each other. The amount of water released depends on, among other things, which of the four flood control dams is being considered, the amount of water in the dam, the rate at which additional runoff is coming into the dam, and weather forecasts.

Q. What are current channel capacities?

A. The channel below Sepulveda Dam can convey 17,000 cubic feet of water per second (cfs); in the area of downtown Los Angeles, the channel capacity is 110,000 cfs; at the mouth of the Los Angeles River, the capacity is 130,000 cfs.

Q. What are the flow rates for 100-year and 500 year floods?

A. The 100-year flow rate out of Sepulveda Dam is 17,000 cfs; the 500-year flow rate, 77,600 cfs. In downtown Los Angeles, the 100-year flow rate is 118,000 cfs; the 500-year flow rate, 177,000. At the mouth of the Los Angeles River, the 100-year flow rate is 174,000 cfs; the 500-year flow rate, 227,000 cfs.

Velocities in the channel are approximately 15 to 20 miles per hour; outside the channel, the velocities are minimal.

Q. Why can't you just clean the silt and debris out of the reservoirs—especially at Hansen Dam?

A. Although it is relatively easy to remove large pieces of debris from the reservoirs (something that is done as needed), removing the silt is a slow and costly job. The Corps has issued permits to several sand and gravel companies to mine the silt at Hansen Dam.

Q. Why were the reservoirs built with only a 50-year life in the first place?

A. A project has two kinds of "lives": an economic life and a structural life. The structural life of a dam is indefinite, given a reasonable amount of upkeep and maintenance. The economic life is the period of time used to calculate the economic usefulness of the project. It is a factor in determining the benefit/cost ratio when assessing construction feasibility.

When engineers design a dam, they allow space in the reservoir for the accumulation of sediment over time. The amount of time it takes to fill the sediment storage space in a dam is the economic life. If a longer economic life is desired, a larger sediment storage area is needed, and the cost of building the project is increased. So the economic life has to be a period of time that is practical and yet cost effective. An economic life for dams of 50 years is considered the most efficient for this purpose although in some circumstances a 100-year economic life can be justified.

Hansen Dam, which was built in 1938, is now reaching the end of its economic design life of 50 years. This only means that the sediment storage area is almost full; the reservoir itself is not full. The space in the reservoir reserved for flood control is still fully intact.

Q. How much of the flooding can be attributed to obstructions such as bridge supports?

A. About 90 percent of the overflow can be indirectly related to bridge structures affecting channel flows.

Q. What kind of debris can be expected from a 100-year flood? boulders? houses?

A. Due to the numerous debris basins in the foothills, as well as the flood control dams themselves, very little sediment gets into the channels. Even if there were significant overland flow, its low velocity would carry very little debris into the channels.

Q. Could the debris back up to create its own dam?

A. If there were large enough chunks of debris such as that which would result if a bridge collapsed, yes, the debris could create its own dam. However, this is extremely unlikely. Under normal flooding conditions, there is no chance that debris would build up in the main channels to form a dam, and the chances are very slight on the unregulated streams.

Q. Might some of the debris get all the way to the ocean, creating the need for dredging?

A. As very little debris gets into the channels, there is no concern that a dredging problem will be created at the ocean due to channel flow. However, overland flow from a large flood would pick up a significant amount of trash and debris, which would be carried to the harbor. Whether this would create a need for dredging would depend on the size of the flood and the amount of debris.

Q. Is it possible to remove debris during flood conditions?

A. Yes. However, due to the difficulties involved, the disadvantages far exceed the advantages except in extraordinary circumstances. At the dams, cranes have been used to remove debris from the trash racks if it affects the outflow of water during flood releases.

Q. Are some of the dams in the system not under Corps control?

A. All of the single-purpose flood control dams are under Corps control. The County dams were built for water supply; however, a certain amount of space is reserved for flood control.

Q. Some County dams—for example, Morris and Cogswell—are silting up. What effect does that have on the current level of protection?

A. The silting up of the County dams has no effect on the flood control capacity of the LACDA system because the space for flood control storage is reserved. It is the water conservation storage space that is being impacted.

Q. In 1980 did anyone actually see water up to the top of the channels, or did they see only the debris?

A. There were numerous reports by residents living along the upper channels stating that they did see water to the top of the channels. Along the lower channels, our best evidence is the location of the debris.

Q. Is some of the LACDA system simply in need of repair?

A. Some of the channels do need maintenance, and the County has

VOL 12

1 7 3 0 3

a repair program under way. The Corps is also working to repair channels under our LACDA Rehabilitation Project. However, these repairs are really just part of ongoing operation and maintenance and have nothing to do with the need for the overall system improvements to provide a greater level of protection.

Q. It seems that the acceptable level of damage in Los Angeles is much lower than for other parts of the country that experience major floods almost every year. Does Los Angeles just have higher standards than the rest of the nation?

A. The Corps cannot build a project unless it has a favorable benefit/cost (B/C) ratio. In other words, the benefits of building a project have to be equal to or greater than the cost. The cost of building a given flood control project are about the same throughout the country, but due to the Los Angeles area's dense urbanization and the resultant high land values, favorable B/C ratios are more common than in less-developed areas.

Q. Do you assess damages based on standing or running water?

A. Damages are assessed based on a composite of the depth of the standing water and the velocity of the running water.

Project Costs and Cost-Sharing

Q. How much will this project cost?

A. The cost of the project could range from $50 million to $450 million, depending on the plan selected.

Q. Do you take inflation into account in doing your cost estimates?

A. Yes. We use a weighted average of the Consumer Price Index for the benefits, and we update the costs from the Engineering News Record Construction Cost Index.

Q. What share will be paid by the local sponsor?

A. As a part of the Water Resources Development Act of 1986, Congress has established new guidelines for cost sharing on water resources projects. Non-Federal interests must now pay at least 25 percent, but not more than 50 percent, of the flood control costs of the project. Costs associated with recreation are shared equally between the Federal government and the local sponsor.

To determine the 25 to 50 percent non-Federal share, the guidelines say that local interests must pay for 5 percent of total project costs and for all lands, easements, and rights-of-way, dredged material disposal areas, and relocations, up to a total share of 50 percent.

Q. Where does the local sponsor get its money?

A. The local sponsor may provide its share through use of existing general revenue funds, through reimbursement from the state, or through benefit assessments.

Q. Could money for the project be raised by the sale of air rights over the channels?

A. The issue of whether the Federal Government will consider leasing or selling air rights over the channels will not be addressed until this overview study is completed. Also, the amount of funds that could be raised by this means would be insignificant compared to the total cost.

Q. Is the Federal funding already in place?

A. The Corps has funding to continue its study through 1989. Once the study is completed, the Corps will submit a report recommending solutions. The report will go first to the Corps' South Pacific Division Office in San Francisco, then on to the Office of the Chief of Engineers, the Secretary of the Army, and, finally, to Congress for authorization and funding. It is a long process, and the earliest date at which funding for construction would be available is in the mid-1990's. As such, there are no funds already earmarked for construction.

The Study Itself and Alternatives Under Consideration

Q. What is most economical: widening or deepening the channel?

A. It has been determined that deepening the channel would not be cost efficient due to the fact that the utility lines are located not far beneath the surface. Therefore, raising the levees is being considered, which would have the same practical effect as deepening the channel.

Current estimates are that it would cost $370 million to raise the levees and at least $600 million to widen the channel.

Q. How much higher or wider would the channels be?

A. At this stage in the study, it looks as though we would have to raise the levees from 2 to 8 feet, depending on the area. The average increase in height would be between 2 and 4 feet.

We would probably need to widen the channels from 0 to between 300 and 400 feet—again depending on the area.

Q. How much capacity would you gain by strengthening the walls of the channels?

A. The capacity of the channels, or volume of water they can carry, is not determined by the strength of the walls—it is strictly a problem of channel size.

Q. Will all of the channels be completely concrete?

A. The channels will not be changed from whatever they are now—that is, concrete-bottom channels remain concrete, and soft-bottom (dirt) channels will remain so.

Q. Does the Corps look at high tide and offshore wind to determine how much water goes over the levees during each?

A. Due to the fact that the Los Angeles and San Gabriel river channels slope such that the water almost falls into the ocean at the rivers' mouths, high tides and strong offshore winds do not impede the flow into the ocean.

Q. If the levees are raised, will the pumping flow change?

A. Yes. With the rise in height, pumps with a greater capacity will be needed to raise the water the increased distance.

VOL 12

1 7304

VOL 12

Q. Why isn't a tunnel feasible? It appears that $2.5 billion in benefits should justify a $700 million expenditure.

A. $2.5 billion is the total damages that would result from the design flood. The tunnel would not prevent all of the damages, only about $300 million worth. Benefits of $300 million versus costs of $700 million provide a B/C ratio of only 0.4.

Q. What is a baffle block?

A. Baffle blocks are concrete blocks arranged in a checkerboard pattern intended to dissipate the flow energy of the water's potentially destructive force.

C. The Public Utilities Commission and California Department of Transportation should be involved in this study.

R. Both the Public Utilities Commission and the California Department of Transportation will be involved, when appropriate, during the study, detailed design, and construction phases of the project.

C. Some areas of the basin have groundwater located only 2 feet below the surface. The Corps should consider this when estimating runoff.

R. Increased runoff in areas with groundwater close to the surface is not really a factor that needs to be considered. Much of the basin already impervious, resulting in flood flows running off immediately. But even in areas that are not impervious, the water runs off when the soil's infiltration capacity is exceeded. The level of the groundwater only marginally affects the soil's infiltration capacity and would therefore have no effect on the peak flow.

Q. Does the Corps look at tributary areas to assess the potential impacts of runoff and debris? Can any of that be controlled before it reaches the basin?

A. There are 87 debris dams in the foothills surrounding the Los Angeles basin. These debris dams, combined with the county's water supply dams and the Corps' flood control dams, trap almost all of the sediment being contributed by the tributary areas. A very small percentage of the debris reaches the channels.

Regarding runoff, the channels in the tributary areas currently provide 100-year protection. Appropriate sites to further control tributary flow into the rest of the system are already developed. In addition, most of the downstream flooding problem results from uncontrolled inflow from the urban drainage system into the central L.A. basin.

C. The Corps should also take into account the inadequacy of the storm drain system and how that increases flows into the LACDA system.

R. Actually, it is the efficiency of the storm drain system, not its inadequacy, that contributes to the flooding problem on the mainstem channels of the LACDA system. If the storm drain system were less efficient, less water would be conveyed to the channels, and there would be localized ponding in the streets and other poor drainage areas—much like what occurred prior to the upgrading of the storm drain system in the 1960's. At that time, even small storms caused street flooding all over the city.

Q. What control does the Corps have over land use on right-of-way lands, including air rights?

A. The Corps has the ultimate say as to the use of the rights-of-way adjacent to and above the channel.

Q. How long will it take to complete the project once it is begun?

A. Depending on the selected plan, 5 to 7 years.

Q. What if Congress does not authorize the plan?

A. The Corps will identify the most economical plan. If Congress does not authorize the plan, no Federal funds would be available for construction.

Q. If the City of Los Angeles disapproves the plan, but the County, other affected cities, and Congress approve it, would you go ahead with the project?

A. The Corps coordinates with the County of Los Angeles, who is the local sponsor for the project. The County, in turn, coordinates with all the local elements that would be affected by the project and makes sure that their concerns are addressed during planning of the project. This coordination should ensure that the resulting plan is acceptable to all.

Q. How can individuals facilitate the approval process?

A. The best way for individuals to help the planning process along is to continue to make the Corps aware of public desires and concerns at the public workshops it will hold throughout the study and at the formal public meeting that takes place when the Corps issues its draft report.

The public can influence the approval process by letting local and Federal Government representatives know of the importance of the project to their constituents.

Q. Can the public go to the Corps offices and get tracings of the overflow maps?

A. Yes, with an appointment.

Environmental and Recreational Issues

Q. Is the Corps doing an Environmental Impact Statement (EIS) on this project?

A. Yes. We are conducting our environmental studies concurrently with our engineering studies, and our study report will include an EIS.

Q. Will there be continuous bike trails from the dams to the ocean? How much coordination is the Corps doing with the cities along the river and the Bike Advisory Committee on this issue?

A. It is uncertain at this time. Any new recreation would have to be cost shared 50-50 by the local sponsor. Any impacts to existing bike trails due to channel improvement would be mitigated.

Q. Will there be any equestrian trails along the channels?

A. The situation regarding equestrian trails is the same as with bike trails.

1 7305

R0050610

Social Impacts and Public Safety

C. We are concerned about inverse condemnation of our property between the time the new FEMA maps come out and the time the Corps completes its upgrade.

R. Inverse condemnation results when part of a person's lot is condemned by a public agency for a public works project under that agency's power of eminent domain, causing the remaining part of the property to be reduced in value. Neither FEMA (who is merely delineating new flood control maps) nor the Corps (who is only modifying existing channels) expect to be condemning any land.

People may be concerned that the value of their property will decrease—if it is going to be located in the floodplain on the new maps—between the time the maps come out and the LACDA project is completed. Contrary to what one might expect, case studies show that changes in floodplain delineations do not significantly affect property values.

) Are property values near the channels lower than in surrounding areas?

A. According to real estate surveys, there is no noticeable difference in property values between houses near channels and those that are not.

Q. When large predominantly concrete structures such as freeway overpasses and flood control channels and bridges are built in a residential or retail store area, does the area tend to change to primarily industrial use?

A. There is no indication that the area will change its character, unless the zoning laws are changed.

Q. Will the Corps' report include evacuation plans?

A. No. However, the Corps will work with city and county governments, providing information on potential flooding so that local authorities can develop plans for their areas. South Gate, for example, already has a disaster preparedness plan, as does the County Sheriff's Department.

Q. Will the Corps be involved in mobilization during a flood emergency?

A. Yes. The Corps Emergency Operations Center will coordinate with the Sheriff's Department and local police and fire agencies; assist in sandbag and evacuation efforts, and provide technical expertise.

Q. How much advance warning can we expect, and what kind of warning system is there?

A. Due to the hydrology of the L.A. area, the warning time for a major flood would be very short—3 to 6 hours. It is the responsibility of the local government entities, with the help of the Corps, to develop their flood warning systems.

Q. Has the Corps looked at possible seismic activity resulting from the storage of water behind the dams?

A. Yes. Computer modeling and studies have been conducted indicating that, theoretically, retaining water behind a dam can induce seismic activity. However, the amount of water would have be very great (water depth greater than 200 feet), and it would have to be impounded behind the dam for many months. Even then, the size of the quakes would be small—3 to 4 on the Richter scale.

Q. How safe are the dams in the event of a large earthquake while they are full of water?

A. Seismic analyses have been done on all of the dams. The criteria of each analysis include the following conditions: water up to the spillway crest and the maximum credible earthquake for the particular fault (8.5 on the San Andreas, 6.5 on the Whittier-Elsinore faults). The result of the analysis in all cases was that negligible damage to the dam would result under these conditions, with no failure taking place.

C. We are concerned that massive releases of water from the dams could seriously threaten Long Beach.

R. If there is a very large flood event, the dams would spill over the top, and, yes, it is probable that certain areas of Long Beach would be flooded.

Q. What is the difference between dam spillover and dam failure?

A. All dams are designed to include a spillway over which water will flow if the dam's gates cannot let water out of the reservoir as quickly as it is flowing in and the reservoir becomes too full. The spillway is there to protect the dam itself and to help guide excess water into flood control channels (the channels themselves, of course, may be full at that time). Dam failure occurs when the embankment of the dam breaks and water pours uncontrolled and unguided from the reservoir. This event is extremely unlikely. In fact, no dam built by the Corps of Engineers has ever failed.

Q. Can you determine where levees are likely to be breached?

A. The levees would most likely be breached at bridge-sites where the bridge structures themselves could restrict the flow. This would occur, for example, with some of the older bridges that extend downward into the channel area. On the other hand, debris could get caught on a bridge pier in an unpredictable manner and in turn catch more debris, thereby restricting flow and causing an overflow condition. The location of this cause of overflow is impossible to identify.

Q. Since the threat from levee failure is so great, why don't you armor them right now?

A. The Corps must wait for authorization and funding from Congress before it can proceed with any structural improvements on the LACDA system. And, as previously stated, there are many steps, including the completion of an EIS, that we must complete before Congress will give its approval.

Q. If alternative sources of funding can be found, could the levees be armored now? From whom would permission be required?

A. If local funds were raised, the levees could be armored by either (1) the Corps through our *Work for Others* program, or (2) the County, using the Corps plan or securing Corps approval of a County plan.

VOL 12

1 7 3 0 6

R0050611

VOL 12

1 7 3 0 7

Q. Is the Corps looking at companies in the overflow area that store hazardous waste to determine how well protected they are?

A. Yes. This is a major concern to us. However, determining these companies' locations and how they are situated with respect to flooding is a local responsibility. Currently, the local fire departments are charged with the duty of inventorying these companies.

Q. Is the Corps considering in its benefits assessment the loss of land use if land is poisoned by chemical or other hazardous waste?

A. Yes, we are addressing this issue. We are identifying toxic waste dumps within the floodplain and plan to discuss potential damages from their flooding in the Final Report in qualitative terms. It would be very difficult, if not impossible, to try to put this problem into quantitative terms.

Q. What if the system is under construction when a flood occurs?

A. The Corps develops its construction schedules to minimize risk. For example, we schedule construction for the non-flood season (late spring and summer).

Q. Will the Corps' plan include security measures to prevent people from using the channels for recreational purposes (for example, rafting on the river during flood flows)?

A. All of the Corps channels, with the exception of trapezoidal channels used for recreation, are lined with chain-link fence for safety purposes.

Individual Areas of Concern

Sepulveda Basin

Q. How will construction within the Sepulveda Basin—for example, the proposed arts park and the sanitation facility—affect the storage capacity of the reservoir?

A. The impact of building these structures within the basin will be estimated, and any loss of flood control capacity will be compensated through excavation of another part of the basin.

Q. In the event of a flood, is the sanitation facility a threat to groundwater?

A. No. In the event of a flood, the treatment plant will return the untreated material to the main trunk sewer line, which leads to the Hyperion treatment plant.

Glendale Area

Q. Will the levee at Atwater be raised?

A. No.

C. The residents of Elysian Valley are concerned about protecting the natural environment of the area.

R. It is unlikely that this area will be affected by any plan.

Q. Currently, the channel fills up with junk like old shopping carts and appliances, as well as with boulders left by flood waters. This is especially true around the Figueroa Street bridge. Will maintenance improve after new construction?

A. At this time, due to manpower constraints, the Corps can clean up the channels only once a year in the late spring or summer before the flood season starts or if there is a special complaint. The LACDA project will not affect this situation; only allocation of additional funds for maintenance can change it.

Whittier Narrows Dam

Q. What level of protection does Whittier Narrows Dam provide?

A. A dam and its downstream channels are designed to work together as a unit. The dam holds back flood water and then releases it at a rate that the channel can handle. But the dam itself cannot be described as providing a particular level of protection. It can hold a certain volume of water. When that level is exceeded, water begins flowing over the spillway. At that time, the release rate becomes uncontrolled because there are no gates or valves on the spillways. Spillway flow will begin when the dam is full. Although this may result in some flooding downstream, it protects the dam from failing catastrophically.

Q. What damage might be caused by increasing the capacity of the dam?

A. More rights-of-way would be required, creating the need for an acquisition process. However, this alternative is no longer under consideration because of cost considerations.

Q. There is no protection on the east side of the dam. Could the bar erode?

A. There is potential for some small amount of erosion, but the impacts would be so slight that they would not significantly affect the protection provided by the dam.

Q. How much warning time would there be in the event of an overspill or failure of the dam?

A. If the dam were to overspill, there would probably be a warning time of one to three hours, depending on the rate the dam was filling. If the dam failed all at once, there would be no warning. If it failed in stages, there would be more time, depending on the rate of failure. However, the probability of the dam failing is very remote—no Corps dam has ever failed.

Q. What is the significance of cleaning 780,000 cubic feet of sediment out of the dam?

A. Relative to flood control, this is not a significant amount of sediment. However, the County is interested in increasing the size of the water conservation pool, thereby increasing the amount of water that could be conserved.

San Gabriel and Rio Hondo Rivers

Q. Is the Corps studying Rio Hondo and San Gabriel rivers as part of this study?

A. Although the San Gabriel River is part of the LACDA system, it is not a major part of the study because it currently provides 100-year protection. The Rio Hondo, however, is currently being considered for improvements.

Q. Why was surplus land along the San Gabriel River first bought for right-of-way and then sold for development?

A. When a project was first being considered for LACDA, it was thought that the channels would need to be significantly wider. Therefore, the County purchased rights-of-way based on what was deemed to be needed at that time. With the subsequent scaling down

R0050612

of the project, the County is returning the extra right-of-way to private use.

South Gate

Q. What is the purpose of the railing along the levees in the South Gate area?

A. The railings are there for safety purposes.

Long Beach

Q. The Long Beach Freeway often floods. Will the project solve that problem?

A. No. The flooding of the Long Beach Freeway is due to local drainage problems and is therefore a local problem.

Q. Because Long Beach is at greatest risk from flooding, will the most money be spent there?

A. Because the damages are highest in Long Beach, providing protection there produces the greatest benefits. Therefore, more costly solutions can be justified for Long Beach compared to other areas.

Carson

Q. There is a lot of street flooding in this area in places not included on the Corps' map. What will be done about that problem?

A. Localized street flooding is a local (county, city) issue. However, in developing its plans, the Corps will make certain that nothing it does will increase the problems of localized street flooding.

Suggested Alternatives

Meeting attendees made the following suggestions for alternatives they want the Corps to consider during its study:

- Reforestation as one way to reduce the flow of sediment into the reservoir.
- The use of polymers to increase flow capacities in existing channels.
- Corps and County coordination with communities in the floodplain to limit development and encourage increased use of open space.
- Incorporation of new spreading grounds and reservoirs into the project to add to the local groundwater supply, as well as to keep some of the runoff from flowing into the flood control channels.
- Rerouting the Los Angeles River to its original path.
- Using freeways as floodways since they are already armored.
- Building another earthen dam out of dredged material from Hansen Dam.
- Coordinating flood control with the sewer system to allow the outflow of some flood water through the sewers to the Hyperion treatment plant.
- Increasing the slope of the channel to increase flows.
- Helping cities develop local flood control plans compatible with the overall Corps plan that local governments can undertake immediately.

The Corps is already looking at some of these alternatives as part of its study. It will consider other suggestions from a cost-benefit standpoint as it must with all alternatives. It appears, for example, that rerouting the Los Angeles River to its original path would be prohibitively expensive because of the enormous amount of development that has taken place along that route.

FEMA and the National Flood Insurance Program

Q. What is the relationship between the Corps and FEMA studies and why don't they use the same overflow maps?

A. They are two independent studies. The Corps produces maps to show average flood depths for relatively large areas only in order to estimate dollar damage—an essential calculation in evaluating the cost effectiveness of alternative flood control improvements under study.

On the other hand, FEMA prepares Flood Insurance Rate Maps (FIRM Maps). These maps consider more specific flood depths for smaller areas in order to make certain that the rates you pay are consistent with the risks you face.

Q. Will the FEMA maps be accurate enough to identify individual land parcels?

A. The FEMA maps will have a scale of 1"= 500', not detailed enough to identify individual parcels. It is possible to gain exemption from paying higher risk insurance rates if an individual parcel is actually higher in elevation than the general area FEMA maps indicate. It is up to the parcel owner to know or find out what the elevation of his property is if this exemption is desired.

Q. Why can't the Corps use the FEMA maps?

A. The FEMA maps will not be completed in time for the Corps to use them in its study.

Q. Is flood insurance required?

A. Flood insurance is required if your local community participates in the National Flood Insurance Program (NFIP) and if you take out a Federally insured loan to buy, refinance, or remodel a structure that is in the 100-year floodplain.

Q. Is it as expensive as earthquake insurance?

A. Flood insurance can cost anywhere from 10¢ to $5.00 per $100 of property value based on which zone the property is located in and how much coverage is desired. By comparison, earthquake insurance generally costs about $2.00 per $1,000 dollars of property insured.

Q. Are insurance companies required to provide flood insurance?

A. No. The insurance companies are not providing the insurance; the NFIP is. The insurance companies simply write the policies and claims and send in the paperwork to the NFIP so that it doesn't have to hire its own policy writers and claims people. The insurance companies charge the NFIP a fee for policy and claim processing.

Q. Who is eligible to participate in the National Flood Insurance Program?

A. Only those people living in a community that is a participant in the program.

Q. Which cities in the LACDA area are *not* participants?

A. Bell Gardens and Downey are not participating today. However, it is likely that they will participate once a the revised FIRM maps have identified a flood threat. The final versions of the maps are due out by early 1991, although the process of reviewing draft revisions will begin during 1989.

VOL 12

1 7308

R0050613

Q. Have all non-participating cities been notified about the program?

A. FEMA sends information about the program to non-participating cities once a year.

Q. What must cities do to become participants?

A. They must agree to institute zoning and permit regulations that reduce future flood risk. For example, they must agree that all new buildings be elevated 1 foot above the 100-year floodplain.

Q. Must both residential and commercial property be elevated 1 foot? That could be very expensive for people building a large structure.

A. All new construction, both residential and business, must be 1 foot above the 100-year floodplain.

Response Summary

Public Environmental Scoping Meetings
on the
Los Angeles County Drainage Area
Review Study

March 9, 1989

On March 9, 1989, the U.S. Army Corps of Engineers, Los Angeles District, and the Los Angeles County Department of Public Works held two environmental scoping meetings to give the public an opportunity to learn more about a proposed flood control improvement plan for the **Los Angeles County Drainage Area (LACDA)** and to identify and comment on potential environmental impacts from that plan and its alternatives that the Corps should consider in preparing the study **Environmental Impact Statement (EIS)**.

Approximately 60 representatives of Federal, state, and local governments and the public at large attended the meetings that were held in Los Angeles and Lakewood.

Public comments and questions were on the following topics:

- **Environmental concerns - areawide planning, wildlife, aesthetics, recreation, safety, groundwater recharge, and public involvement**
- **Economic concerns**
- **The National Economic Development (NED) Plan**
- **General Questions**

Corps responses, where appropriate, appear in brackets [ ].

R0050615

VOL 12

Environmental Concerns

Areawide Planning

Meeting attendees pointed out the following areawide planning and study issues that the Corps should consider in its environmental analyses:

- Potential environmental impacts throughout the LACDA system, not just in the areas to be improved - especially how protection of downstream areas might affect areas upstream.
- The impact of a potential new City of Los Angeles growth management plan on environmental effects examined by the Corps - including the possibility of scaling down the Corps plan if it becomes evident that projected development will not be allowed to take place.
- The interrelation of all development plans in the basin (especially in the constantly changing west San Fernando Valley), so that the assessment of impacts for each plan is not considered in a vacuum.
- Possible changes to Corps findings based on changes brought about by other types of projects.
- The potential for development in the mountains that comprise the LACDA watershed and that potential's effect on Corps environmental findings.
- Long-developed lower reaches of the basin having to bear the impacts of construction instead of the San Fernando Valley where more recent development has overstressed the system.

[The proposed plan addresses an existing system deficiency, and the project design is not affected by potential future development. Other concerns will be addressed, where possible, in the EIS/Final Report.]

Wildlife

Some people, expressing concern that construction near the mouth of the Los Angeles River would have negative effects on the endangered least tern, asked the Corps to address that possibility in its EIS.

[The least tern will not be significantly impacted.]

Aesthetics

Representatives of several cities said that the proposed parapet walls might invite graffiti both during and after construction.

[Unfortunately, this is probably true.]

1731

Some also wondered how visible the walls would be from local homes, businesses, and streets.

[Visibility would depend on location.]

Representatives of Downey expressed hope that the project would in some way help in their plans to limit growth and provide additional open space.

Recreation

The primary recreation interest people have is in preserving (and perhaps enhancing) the existing equestrian and bicycle trails along the Los Angeles River.

[The project will preserve existing trails.]

Safety

Representatives of cities in the downstream area along the Los Angeles River recommended:

- There be an early warning system in place in the event of a major flood.

  [One is already in place and is continually upgraded.]

- The parapet walls be reinforced and the levees armored to prevent catastrophic failure in the event of overtopping.

  [This is part of the proposed design.]

- The project be designed and built with the potential for a major earthquake in mind.

  [Existing design standards regarding safety during earthquakes have been met.]

An additional safety issue concerned the need for periodic checks of the Sepulveda Dam when the Corps' new water control plan goes into affect.

[The Corps routinely monitors the performance of all of its dams.]

Groundwater Recharge

One person suggested that detention basins built for the project double as groundwater recharge basins.

[This will be done where feasible.]

Public Involvement

Some people expressed dismay that so few members of the public or representatives of special interest and environmental groups had attended the March 9 scoping meetings.

VOL 12

1 7 3 1 2

They asked that the Corps be certain that groups such as the Sierra Club be informed when the draft EIS becomes available.

[They are on the Corps' mailing list and receive notices. If anyone has names of groups or individuals who would be interested, they will be added to the mailing list.]

Economic Concerns

Several people asked about the financial impact the project would have on cities in the 100-year floodplain. Their questions were:

- How much would the cities have to pay as part of the federal/local sponsor cost-sharing agreement?

  [The current county flood district tax levee will be sufficient to pay 30% of the local share. The remaining percentage of the local share would come from a state grant program.]

- What relief from Federal Emergency Management Agency (FEMA) flood insurance costs would the completed project provide?

  [The 100-year floodplain, as officially designated by FEMA in 1990, would essentially be eliminated and structures designated in this area of the floodplain would no longer be required to carry flood insurance.]

A representative of the Los Angeles County Department of Public Works explained the cost-sharing arrangements:

- Local interests would be responsible for at least 25 percent, but not more than 50 percent, of the total project cost. That amount would include purchase of all needed lands and rights-of-way.
- Of the local share, 70 percent would be paid by the State of California.
- The remaining 30 percent of the local share would come from Los Angeles County flood control funds.

Some people at the meetings expressed concern that using the county funds would limit the amount of new construction or repair work the county would be able to do on such things as storm drains.

[The County will not reduce its maintenance efforts and will allocate this project significant resources but will still pursue a variety of construction projects.]

Others said they expected it to be difficult to get the state and Federal funding.

[Funding is always difficult.]

VOL 12

1-7/3/3

VOL 12

The other main economic issue dealt with the 100-year flood overflow areas identified by new FEMA maps. Participants stated a great deal of concern about the cost of meeting Federal flood insurance requirements in areas newly identified as at risk. People representing cities in the floodplain encouraged the Corps to move toward construction as quickly as possible and said that they would contact their local Congressional representatives to voice support for the project. One person said that if funding was slow in coming, the Corps should stage its construction to maximize the flood protection achieved in each stage.

[This will be considered in construction scheduling.]

The National Economic Development (NED) Plan

People detailed a number of concerns and asked several question about the potential plan presented by the Corps (the NED plan) and other alternatives.

Expressing preference for the the tunnel alternative, one participant questioned how the Corps arrived at a negative benefit-to-cost ratio for the tunnel when the cost of tunneling would be so much less than the $2-1/2 billion in damages that would be prevented.

[It was explained that benefits and costs have to be annualized for each size flood that could occur. This method results in the cost of tunneling being significantly higher than the benefits provided.]

Another person stated that the Corps plan should be developed to solve the flooding problem permanently--not just for another 50 years or so.

[The Corps has considered probable development in the future.]

People suggested that the Corps consider the following issues in developing the recommended plan:

- The possibility of injecting polymers in selected areas to help pass water more quickly at problem spots.

  [This is not a practical solution. First, it is untested methodology and the logistics of when and how the polymers would be injected have not been determined. In addition, the polymers would eventually flow out to the ocean, generating pollution.]

- Whether the new bridges on the Artesia and Century freeways would be high enough.

  [Yes, they will be.]

- Whether the light-rail track being built between Los Angeles and Long Beach is above the floodplain.

  [It will be after the project is completed.]

1734

- The use of bridges as dikes by sandbagging or otherwise fortifying their bases.

  [Due to hydraulic considerations, this is not a viable alternative.]

- In calculating flood flows and project life, the siltation of upstream dams, including who is responsible for maintenance of those dams.

  [This is considered during plan formulation.]

- The possibility of assigning air rights over the channel, especially in the Long Beach area where space for housing and new businesses is becoming scarce.

  [Because this limits channel access and future channel improvement possibilities, it is discouraged as a large-scale concept.]

Questions about the potential project included the following:

- What would be the total project cost?

  [Approximately $300 million first cost.]

- Would the project have any effect on the Lakewood storm drain system that is nearing capacity?

  [No. Storm drains are local systems.]

- Why is there no plan for improvements to the San Gabriel River?

  [This river doesn't have a deficiency. It is basically used as a relief system from Whittier Narrows Dam.]

- How much additional right-of-way would be needed through Paramount?

  [None is currently anticipated.]

- What would be done in the Rosecrans/Freeway 91 area?

  [Parapet walls would be raised to the full extent possible and the levees armored.]

- Would all bridges have to be completely rebuilt in order to raise them?

  [Newer bridges are built in a modular fasion and can be jacked up in one piece. Older bridges would have to be rebuilt, however.]

VOL 12

1 7 3 1 5

- What is the projected flow capacity at Firestone Avenue and Imperial Highway?

  [The existing capacity, in cubic feet per second, is as follows:

	Existing	Proposed
Firestone @ LAR	110,000	110,000
Firestone @ RH	36,500	50,300
Imperial @ LAR	132,000	164,000]

General Questions:
the LACDA System and Corps Policy

- Are the mouths of the Los Angeles and San Gabriel rivers the same height above sea level?

  [They are both at sea level.]

- Is the 100-year flood elevation higher than the gates on the Sepulveda Dam?

  [Water does flow over the spillway gates during a 100-year event but in an anticipated and controlled fasion.]

- Does the Corps hire outside contractors to do its construction work?

  [Yes, they do.]

FEDERAL REGISTER NOTICE OF PROJECT

VOL 12

1 7320

Office of the Secretary

Defense Science Board Task Force on Technological and Operational Surprise; Closed Meeting

ACTION: Notice of Advisory Committee Meetings.

SUMMARY: The Defense Science Board Task Force on Technological and Operational Surprise in the U.S.-Soviet Military Competition will meet in closed session on March 2-3, 1989 at the DIAC Building, Bolling AFB, Washington, DC.

The mission of the Defense Science Board is to advise the Secretary of Defense and the Under Secretary of Defense for Acquisition on scientific and technical matters as they affect the perceived needs of the Department of Defense. At this meeting the Task Force will evaluate the potential for technological and operational surprise in the U.S.-Soviet military competition.

In accordance with section 10(d) of the Federal Advisory Committee Act, Pub. L. 92-463, as amended (5 U.S.C. App. II (1982)), it has been determined that this DSB Task Force meeting concerns matters listed in 5 U.S.C. 552b(c)(1) (1982), and that accordingly this meeting will be closed to the public.

February 7, 1989.

Linda M. Bynum,

Alternate OSD Federal Register Liaison Officer, Department of Defense.

[FR Doc. 89-3297 Filed 2-10-89; 8:45 am]

BILLING CODE 3810-01-M

Defense Science Board Task Force on Strategic Force Modernization Program; Meeting

ACTION: Change in Date of Advisory Committee Meeting Notice.

SUMMARY: The meeting of the Defense Science Board Task Force on Strategic Force Modernization Program scheduled for March 2-3, 1989 as published in the Federal Register (Vol. 53, No. 248, Page 52213, Tuesday, December 27, 1988, FR Doc. 88-29659) will be held on March 28-29, 1989.

February 7, 1989.

Linda M. Bynum,

Alternate OSD Federal Register Liaison Officer, Department of Defense.

[FR Doc. 89-3298 Filed 2-10-89; 8:45 am]

BILLING CODE 3810-01-M

Special Operations Policy Advisory Group, Closed Meeting

The Special Operations Policy Advisory Group (SOPAG) will meet on 17 February 1989 in the Pentagon, Arlington, Virginia to discuss sensitive, classified topics.

The mission of the SOPAG is to advise the Office of the Secretary of Defense on key policy issues related to the developments and maintenance of effective Special Operations Forces.

In accordance with section 10(d) of P.L. 92-463, the "Federal Advisory Committee Act," and section 552b(c)(1) of Title 5, United States Code, this meeting will be closed to the public.

Linda M. Bynum,

Alternate OSD Federal Register Liaison Department of Defense.

February 7, 1989.

BILLING CODE 3810-01-M

Corps of Engineers, Department of the Army

Intent To Prepare a Draft Environmental Impact Statement (DEIS) for the Los Angeles County Drainage Area (LACDA) Review Study, Los Angeles County, CA

AGENCY: U.S. Army Corps of Engineers, DoD.

ACTION: Notice of intent.

SUMMARY: This study is designed to develop a system-wide approach to identifying means for improving the capabilities of the Los Angeles County Drainage Area flood control system. During the 40 years since its construction, the ability of the system to provide a very high level of protection has diminished. This has resulted from an increase in surface runoff, loss of groundwater percolation and associated increases in contributory flow from additional storm drains.

FOR FURTHER INFORMATION CONTACT: Questions about the proposed action and Draft Environmental Impact Statement can be answered by Ronald F. Lockmann, CESPL-PD-RN, P.O. Box 2711, Los Angeles, California 90053-2325, (213) 894-5414.

SUPPLEMENTARY INFORMATION:

1. Proposed Action

The tentatively selected plan for flood control in the Los Angeles County Drainage Area system, Los Angeles County, California, consists of the following: Levee armoring and raising channel walls along the Rio Hondo, the Los Angeles River (LAR) from Atlantic Boulevard to the Ocean; and Compton Creek: armoring the backside (outside) of the LAR from Atlantic Blvd. to Pacific Ocean, Rio Hondo (entire) and Compton Creek from Willowbrook to the LAR would avoid catastrophic failure of the levees if they are overtopped. The linear distance of the armoring would be about 28 miles. Accessibility to the channel would not be impacted. Raising the channel walls would also include channel conversion to trapezoidal where necessary and extension of bridge piers where possible. environmental enhancement, habitat improvement, or mitigation will not be included in this plan.

2. Alternatives

Alternatives considered during the planning process include 2 plans with detention or spreading ground possibilities (that of deepening Tujunga and Pacoima Spreading grounds; that of using Santa Fe gravel pit as a detention basin).

3. Scoping Process

A scoping meeting will be held to obtain community input to assure that all concerns are identified and addressed in the EIS/EIR. A separate public scoping notice will be sent to the public to identify time and location of the meeting and to solicit public comment. The specific date, time and meeting location will be published in local newspapers. The Corps has initiated coordination efforts with appropriate federal, state and local agencies to resolve potential problems relating to involved biological resources communities.

4. Future Public Meetings

A public meeting will be scheduled to discuss and obtain public comment.

5. Publication of DEIS

The Draft Environmental Impact Statement is expected to be available to concerned agencies and the interested public for review and comment in mid-1989.

Date: January 19, 1989.

Tadahiko Ono,

Colonel, Corps of Engineers, District Engineer.

APPENDIX C

BIOLOGICAL ASSESSMENT

VOL 12

BIOLOGICAL ASSESSMENT

I. Introduction

The Los Angeles District of the Army Corps of Engineers (COE), has determined that the proposed Los Angeles County Drainage Area Review will not adversely affect any species listed pursuant to the Endangered Species Act. Those species that occur in the study area include least Bell's vireo, California least tern, California brown pelican and the slender-horned spineflower.

The purpose of a biological assessment is to evaluate the potential effects of a Federal action (project) on listed and proposed listed species and designated and proposed critical habitat and determine whether any such species or habitat are likely to be adversely affected by the Federal action (project). The biological assessment is also used in determining whether formal consultation or a conference is necessary {Federal Register 51(106): Section 402.12(a), pg. 19960, 3 June 1986}. The contents of the biological assessment are at the discretion of the Federal agency and are dependent on the nature of the Federal action.

II. Project Description

Under congressional authority, the Los Angeles District of the U.S. Army Corps of Engineers is conducting a flood control study of the Los Angeles County Drainage Area (LACDA) project. The existing flood control system was constructed by the Corps of Engineers and the Los Angeles County Flood Control District (now part of the Department of Public Works) from the 1930s through the 1960s to protect the City of Los Angeles and other metropolitan areas in Los Angeles County from flood damage. Increased urbanization resulting in increased runoff, as well as changes in design criteria, has resulted in an inadequate level of flood protection afforded by the LACDA system.

The NED Plan (proposed alternative) addresses the area of most critical need in the LACDA: the downstream reaches of the Los Angeles-Rio Hondo system. Planned improvements begin at Whittier Narrows Dam and extend downstream on the Rio

1 7 3 2 2

Hondo to the confluence with the Los Angeles River. Improvements on the Los Angeles River continue from the confluence with the Rio Hondo and extend downstream to the mouth of the river in Long Beach Harbor. A total of about 23 miles of channel is to be improved.

The NED plan consists of five elements: 1) parapet walls, 2) raising bridges, 3) levee armoring, 4) widening a portion of the Rio Hondo and Los Angeles rivers at their confluence, and 5) application of a concrete overlay.

A. Parapet Walls

Parapet walls would be provided on the tops of existing levees on the Rio Hondo Channel and lower Los Angeles River for nearly the entire length of channel from Whittier Narrows to the Pacific Ocean. Wall heights would range from 2 to 8 feet (0.7 to 2.4 m).

B. Raising Existing Bridges

In order to provide parapet walls along the channels, many of the vehicle, railroad and utility bridges which cross the channels must be raised in height. The required height adjustments range from 1.6 to 6.3 feet (0.5 to 1.9 m) for the lower Los Angeles River, and 1.4 to 5.3 feet (0.4 to 1.6 m) along the Rio Hondo.

Of the 25 bridges which cross the lower Los Angeles River, 15 need to be modified. Twelve of the 18 bridges over the Rio Hondo are proposed to be modified.

C. Levee Armoring

Existing levees would be strengthened by armoring the back slope at selected locations with grouted stone. The back sides of levees will be armored to prevent erosion of the earthen levee in case they are overtopped.

VOL 12

17323

VOL 12

1

7324

THIS PAGE INTENTIONALLY LEFT BLANK
INTENDED FOR FUTURE REVISION

D. Widening Channel at Confluence

At and just downstream of the Rio Hondo-Los Angeles River confluence, a 7000 foot section of the Los Angeles River would be converted from trapezoidal to rectangular cross-section and widened 30 feet. Parapet walls would be constructed on the rebuilt channel walls.

E. Application of Concrete Overlay

The existing grouted stone channel walls in the vicinity of the Rio Hondo-Los Angeles River confluence will be overlaid with concrete to reduce hydraulic friction and improve channel flow characteristics.

III. Species Accounts

A. Slender-Horned Spineflower

1. Natural History

a. Distribution

Dodecahema (Centrostegia) leptoceras (CELE) is a very rare species, known to occur in only four small, isolated populations which together occupy less than 4 hectares (10 acres; U.S. Fed. Reg. 1986). These sites are: 1) near Devore, 2) 1.5 miles east of Valle Vista, 3) Temescal Canyon, and 4) near Highland in the Santa Ana River Wash, and 5) in Bautista Canyon (found by the U.S. Forest Service in 1987).

b. Habitat Requirements/Life History

CELE is generally found on sandy, old-formation benches that are free from introduced annual grasses and lack evidence of surface disturbance (Reveal and Krantz 1979). CELE is most commonly associated with mature soft chaparral or in association with a sparse cover of dwarf annuals, mosses, liverworts, and lichens.

2. "No Effect" Determination

Currently the only location where CELE potentially could occur is behind Hansen Dam in the LACDA system. The proposed alternative does not modify operations or uses in the Hansen Dam basin, so the with-project and without-project conditions are identical. Given no changes or impacts and no known populations, the COE has determined there would be no adverse effect to CELE.

B. California Least Tern

1. Natural History

a. Distribution

The California least tern (Sterna antillarum browni) is sparsely distributed in small colonies from San Francisco Bay to the Mexican border with additional small groups along the west coast of Baja California.

b. Habitat Requirements/Life History

The State and Federally endangered California least tern is a migratory, water-associated bird which returns to coastal California from Central America to breed between April and September. It is dependent upon undisturbed, sandy, open areas near coastal embayments or river mouths for suitable nesting habitat. The embayments, river mouths, and areas upstream of the river mouths within an approximate two mile range of nests serve as primary foraging habitat for least terns during nesting.

2. "No Effect" Determination

The California least tern has been identified as potentially foraging in the project area in association with the Los Angeles River and the San Gabriel River. There were no known or potential nesting sites identified within the study area. The currently proposed project could potentially impact the least tern due to some upstream turbidity associated with bridge raising and noise associated with the construction of the parapet walls in the areas where least terns potentially forage. The COE has determined that the proposed project alternative would have no adverse effect on the California least tern due to a commitment to restrict construction in the lower reaches of the Los Angeles River. Construction would only occur from September to March on the last one-mile reach of the Los Angeles River. The proposed project alternative does not modify the San Gabriel River and as such there will be no adverse effect on the species.

C. California Brown Pelican

1. Natural History

a. Distribution

The California brown pelican (Pelecanus occidentalis californicus) ranges from southern British Columbia to Central America. A major segment of the population of this subspecies occupies the coast from central Baja California to northern California.

b. Habitat Requirements/Life History

The California brown pelican is associated with beaches, bays, and tidal estuaries and only rarely with fresh water. It feeds exclusively on fish. The brown pelican is at its highest numbers along the coast of California from late summer to late fall during the nonbreeding season. The brown pelican nests primarily on offshore islands (e.g. Channel Islands).

2. "No Effect" Determination

The California brown pelican has been identified as potentially foraging in the project area in association with the Los Angeles and San Gabriel Rivers. Foraging is the only activity that could be affected. The potential effects would be the possibility of increased turbidity from construction upstream and noise from construction of

VOL 12

1

7327

the parapet walls. The COE has determined that the proposed project alternative would have no adverse effect on the California brown pelican due to a commitment to restrict construction in the lower reaches of the Los Angeles River. Construction would only occur from September to March on the last one-mile reach of the Los Angeles River. The proposed project alternative would not disturb any important brown pelican roosts. The San Gabriel River is not a part of the proposed alternative; hence, there would be no adverse effect on pelican foraging in the area.

D. Least Bell's Vireo

1. Natural History

a. Distribution

The least Bell's vireo (vireo bellii pusillus) is a small migratory bird whose breeding range is restricted to two localities in the Salinas River Valley; one locality along the Amargosa River; numerous small populations in southern California south of the Tehachapi Mountains; and in northwestern Baja California, Mexico.

b. Habitat Requirements/Life History

The least Bell's vireo arrives in its breeding habitat in mid-March to early April and departs in late August and September for its wintering range in Mexico. Least Bell's vireos are known to nest primarily in willows but also use a variety of shrubs, trees and vines. These passerine birds forage in riparian and adjoining chaparral habitat. In addition to loss of habitat, species decline is severely accelerated by nest parasitism by the brown-headed cowbird.

2. "No Effect" Determination

The least Bell's vireo has been identified as being present or possibly present at Hansen Dam, Santa Fe Dam, Whittier Narrows Dam, and in the San Gabriel River downstream of Whittier Narrows Dam. The proposed project alternative for LACDA would not cause any change in the conditions behind the dams or on the San Gabriel

VOL 12

1728

River; hence not impacting any species present.

404B(1) DETERMINATION

THE EVALUATION OF THE EFFECTS

OF THE DISCHARGE OF DREDGED OR FILL MATERIAL

INTO THE WATERS OF THE UNITED STATES

LACDA REVIEW PROJECT

1

7330

VOL 12

THE EVALUATION OF THE EFFECTS
OF THE DISCHARGE OF DREDGED OR FILL MATERIAL
INTO THE WATERS OF THE UNITED STATES
LACDA REVIEW PROJECT

I. INTRODUCTION. The following evaluation is provided in accordance with Section 404(b)(1) of the Federal Water pollution Control Act Amendments of 1972 (Public Law 92-500) as amended by the Clean Water Act of 1977 (Public Law 95-217). Its intent is to succinctly state and evaluate information regarding the effects of discharge of dredged or fill material into the waters of the U.S. As such, it is not meant to stand alone and relies heavily upon information provided in the environmental document to which it is attached.

II. PROJECT DESCRIPTION

A. Location: Los Angeles County Drainage Area (LACDA). Construction is proposed in the lower portion of the Los Angeles River, the portion of the Rio Hondo River below Whittier Narrows and the lower portion of Compton Creek.

B. General Description: Material to be discharged includes sediment from dredged material in the lower Los Angeles River (channel widening alternative only). Other discharges will be incidental to construction activities in the channels.

The National Economic Development (NED) project alternative consists of construction of parapet walls on top of existing levees within the lower Los Angeles River, Rio Hondo Channel and lower Compton Creek. Limited channel widening and extensive bridge modifications will be required for this alternative. No dredging is proposed.

C. Authority and Purpose: Sections 1.1 and 1.3 of the EIS provide a description of the authority and purpose of the proposed action. The authority includes the Emergency Relief Act of 1935 and the Flood Control Acts of June 22, 1936 and August 8, 1941.

D. General Description of Dredged or Fill Material: The dredged material consists of soft sediments in the lower Los Angeles River. These sediments may be

1733 1

contaminated from urban runoff. Section 4.5.3 of the EIS discusses these impacts.

E. Description of Proposed Discharge Site: The exact method of disposal has not been determined. It is assumed that the dredged material meeting ocean disposal standards will be disposed of in a deep water disposal site (LA-2 or LA-3). Any material not conforming to standards will be disposed of at an approved onshore disposal site.

F. Description of Disposal Method: It is anticipated that the material will be transported to offshore disposal sites via barge and then dumped directly from the barge. On-land disposal will be via truck delivery to approved disposal facilities.

III. FACTUAL DETERMINATATION

A. Disposal Site Physical Substrate Determinations:

1. Substrate Elevation and Slope:

Impact: __X_ N/A ____ Insignif. _____ Signif.

2. Sediment Type:

Impact: __X_ N/A ____ Insignif. _____ Signif.

3. Dredged/Fill Material Movement:

Impact: __X_ N/A ____ Insignif. _____ Signif.

4. Physical Effects on Benthos (burial, changes in sediment type, composition, etc.):

Impact: ____ N/A __X_ Insignif. _____ Signif.

This material will be disposed of in an approved site where previous environmental documents have been prepared.

5. Other Effects

Impact: __X_ N/A ____ Insignif. _____ Signif.

VOL 12 1-7332

6. Actions taken to Minimize Impacts

Needed? __X_ YES ____ NO

If Needed, Taken:

__X_ YES ____ NO

Specific measures to reduce turbidity are proposed.

B. Effect on Water Circulation, Fluctuation, and Salinity Determinations:

1. Effect on Water. The following impacts were considered:

a. Salinity	___N/A	_X_Insignif.	___Signif.
b. Water Chemistry (pH, etc.)	___N/A	_X_Insignif.	___Signif.
c. Clarity	___N/A	_X_Insignif.	___Signif.
d. Color	___N/A	_X_Insignif.	___Signif.
e. Odor	___N/A	_X_Insignif.	___Signif.
f. Taste	___N/A	_X_Insignif.	___Signif.
g. Dissolved gas levels	___N/A	_X_Insignif.	___Signif.
h. Nutrients	___N/A	_X_Insignif.	___Signif.
i. Eutrophication	_X_N/A	___Insignif.	___Signif.
j. Others	_X_N/A	___Insignif.	___Signif.

2. Effect on Current Patterns and Circulation. The potential of discharge or fill on the following conditions were evaluated.

k. Current Pattern and Flow	___N/A	___Insignif.	_X_Signif.
l. Velocity	___N/A	_X_Insignif.	___Signif.
m. Stratification	___N/A	_X_Insignif.	___Signif.
n. Hydrology Regime	___N/A	_X_Insignif.	___Signif.

3. Effect on Normal Water Level Fluctuations. The potential of discharge or fill on the following were evaluated.

o. Tide	_X_N/A	___Insignif.	___Signif.
p. River Stage	_X_N/A	___Insignif.	___Signif.

4. Action Taken to Minimize Effects:

None Required

C. Suspended Particulate/Turbidity Determinations at the Disposal Site

1. Expected Change in Suspended Particulate and Turbidity Levels in Vicinity of Disposal Site

Impact: ___N/A _X_Insignif. ___Signif.
Documentation: Increases of suspended sediments and turbidity will be short term during discharge of dredged material. These levels are expected to return to pre-project levels almost immediately.

2. Effects (degree and duration) on Chemical and Physical Properties of the Water Column:

a. Light Penetration	___N/A	_X_Insignif.	___Signif.
b. Dissolved Oxygen	___N/A	_X_Insignif.	___Signif.
c. Toxic Metals and Organics	_X_N/A	___Insignif.	___Signif.
d. Pathogen	_X_N/A	___Insignif.	___Signif.
e. Esthetics	___N/A	_X_Insignif.	___Signif.
f. Others	_X_N/A	___Insignif.	___Signif.

3. Effects of Turbidity on Biota: The following affects of turbidity on biota were evaluated:

g. Primary Productivity	___N/A	_X_Insignif.	___Signif.
h. Suspension/ Filter Feeders	___N/A	_X_Insignif.	___Signif.
i. Sight Feeders	___N/A	_X_Insignif.	___Signif.

4. Actions Taken to Minimize Impact: Potential for dredging only after slack tide.

D. Contaminant Determination

The following information has been considered in evaluating the biological availability of possible contaminants in dredged or fill material.

3. Physical characteristics X

4. Hydrography in relation to known or anticipated sources of contaminants X

VOL 12

11334

5. Results from previous testing of any material or similar material in the vicinity of the project X

6. Known, significant, sources of contaminants (e.g. pesticides) from land runoff or percolation .... --

7. Spill records for petroleum products or designated (Section 311 of CWA) hazardous substances .... --

8. Other public records of significant introduction of contaminants from industries, municipalities or other sources X

9. Known existence of substantial material deposits of substances which could be released in harmful quantities to the aquatic environment by man-induced discharge activities X

10. Other sources (specify) .... --

An evaluation of the appropriate information above indicates that there is reason to believe the proposed dredge or fill material is not a carrier of contaminants, or that levels of contaminants are substantively similar at extraction and disposal sites and not likely to constraints. The material meets the testing exclusion criteria.

_X_ YES ___ NO

Impact: ___N/A _X_Insignif. ___Signif.

VOL 12 1735

A. Effect on Aquatic Ecosystem and Organization Determinations. The following ecosystem effects were evaluated:

1. On Plankton ___N/A _X_Insignif. ___Signif.
2. On Benthos ___N/A _X_Insignif. ___Signif.
3. On Nekton ___N/A _X_Insignif. ___Signif.
4. Food Web ___N/A _X_Insignif. ___Signif.
5. Sensitive Habitats:
   a. Sanctuaries, refuges _X_N/A ___Insignif. ___Signif.
   b. Wetlands _X_N/A ___Insignif. ___Signif.
   c. Mudflats _X_N/A ___Insignif. ___Signif.
   d. Eelgrass beds _X_N/A ___Insignif. ___Signif.
   e. Riffle and Pool Complexes _X_N/A ___Insignif. ___Signif.
6. Threatened & Endangered Species ___N/A _X_Insignif. ___Signif.
7. Other Wildlife (grunion) ___N/A _X_Insignif. ___Signif.
8. Actions to Minimize Impacts
   None necessary as impacts will be short-term.

B. Proposed Disposal Site Determinations. Is the mixing zone for each disposal site confined to the smallest practicable zone?
___N/A _X_Insignif. ___Signif.

C. Determination of Cumulative Effects of Disposal or Fill on the Aquatic Ecosystem.
Impacts: ___N/A _X_Insignif. ___Signif.

D. Determination of Indirect Effects of Disposal or Fill on the Aquatic Ecosystem.
Impacts: ___N/A _X_Insignif. ___Signif.

IV. FINDING OF COMPLIANCE

A review of the proposed project indicates that:

a. The discharge represents the least environmentally damaging practicable alternative and if in a special aquatic site, the activity associated with the discharge must have direct access or proximity to, or be located in the aquatic ecosystem to fulfill its basic purpose

_X_ YES ___ NO

VOL 12

1 7 3 3 6

VOL 12

b. The activity does not appear to: 1) violate applicable state water quality standards or effluence standards prohibited under Section 307 of the CWA; 2) jeopardize the existence of Federally listed endangered or threatened species or their habitat; and 3) violate requirements of any Federally designated marine sanctuary.

_X_ YES ___ NO

c. The activity will not cause or contribute to significant degradation of waters of the U.S. including adverse effects on human health, life stages or organisms dependent on the aquatic ecosystem, ecosystem diversity, productivity and stability, and recreational, aesthetic, and economic values;

_X_ YES ___ NO

d. Appropriate and practicable steps have been taken to potential adverse impacts of the discharge on the aquatic ecosystem.

_X_ YES ___ NO

1 7337

1 A negative response indicates that the proposed project does not comply with the guidelines.

VOL 12

1

7338

APPENDIX E

COASTAL CONSISTENCY DETERMINATION

APPENDIX E - COASTAL CONSISTENCY DETERMINATION

This appendix provides the information necessary to determine the proposed action's consistency with the provisions of the California Coastal Act of 1976. Federal consistency review provisions are provided in the Federal Coastal Zone Management Act.

VOL 12

I. TYPE AND DESCRIPTION OF THE PROPOSED ACTION

The Army Corps of Engineers proposes to improve the flood conveyance capabilities of the Los Angeles County Drainage Area flood control system. The proposed NED Plan includes construction of concrete parapet walls along the existing channel levees of the Rio Hondo, the lower Los Angeles River and Compton Creek. Selected areas of levee armoring are also associated with the proposed action. Implementation of the NED Plan would also necessitate the raising of numerous street bridges crossing the affected channels.

The coastal zone boundary with respect to the proposed action covers the area from Ocean Boulevard upstream to Anaheim Street. This area is under the jurisdiction of the Port of Long Beach for coastal permitting.

Under the NED Plan alternative, the only modifications made to the Los Angeles River channel within the coastal zone area would be the construction of parapet walls on both channel levees for the entire reach. Wall heights would range between 3 and 5 feet.

The proposed action is considered a direct Federal activity for purposes of coastal consistency determination. Specific details of the proposed action and alternatives, with appropriate illustrations, are included in Section 2 of the main body of this EIS.

1 7339

II. COASTAL RESOURCE PLANNING AND MANAGEMENT POLICIES

The coastal resource planning and management policies applicable to the proposed action are listed below along with an analysis of the relationship to proposed alternatives.

A. Public Access

1. Section 30211

Development shall not interfere with the public's right of access to the sea where acquired through use or legislative authorization, including, but not limited to, the use of dry sand and rocky coastal beaches to the first line of terrestrial vegetation.

Relationship to Policy

NED Plan Alternative - This alternative will not physically interfere with public access to the sea within the coastal zone. Construction of parapet walls along river levees could temporarily restrict use of bicycle trails which provide access to the coastal area. These trails will be fully restored after construction and no long-term effects will occur. Also, efforts will be made to route bicycle traffic around construction areas utilizing existing, available bike trails on streets. This alternative will not significantly impact public access to the coastal zone.

B. Recreation

1. Section 30220

Coastal areas suited for water-oriented recreational activities that cannot readily be provided at inland water areas shall be protected for such uses.

Relationship to Policy

VOL 12

1 7 3 4 0

NED Plan Alternative - This alternative will not affect the amount of area devoted to water-oriented recreation.

2. Section 30223

Upland areas necessary to support coastal recreational uses shall be reserved for such uses, where feasible.

Relationship to Policy

NED Plan Alternative - The bicycle trail along the eastern Los Angeles River levee is used as an important point of non-vehicular access to the coastal zone recreation resources. Bike trails will be temporarily impacted by parapet wall construction, and will be fully restored after construction. As stated previously, efforts will be made route bicycle traffic around construction areas using existing available bike trails on local streets.

C. MARINE ENVIRONMENT

1. Section 30230

Marine resources shall be maintained, enhanced, and where feasible, restored. Special protection shall be given to areas and species of special biological or economic significance. Uses of the marine environment shall be carried out in a manner that will sustain the biological productivity of the coastal waters and that will maintain healthy populations of all species of marine organisms adequate for long-term commercial, recreational, scientific, and educational purposes.

Relationship to Policy

VOL 12 17341

NED Plan Alternative - This alternative would not involve any disturbance to marine resources.

2. Section 30231

The biological productivity and the quality of coastal waters, streams, wetlands, estuaries, and lakes appropriate to maintain optimum populations of marine organisms and for the protection of human health shall be maintained and, where feasible, restored through, among other means, minimizing adverse effects of waste water discharges and entrainment, controlling runoff, preventing depletion of ground water supplies and substantial interference with surface water flow, encouraging waste water reclamation, maintaining natural vegetation buffer areas that protect riparian habitats, and minimizing alteration of natural streams.

Relationship to Policy

NED Plan Alternative - No alteration of wetlands will occur as a result of the implementation of this alternative.

3. Section 30233

(a) The diking, filling, or dredging of open coastal waters, wetlands, estuaries, and lakes shall be permitted in accordance with other applicable provisions of this division, where there is no feasible less environmentally damaging alternative, and where feasible mitigation measures have been provided to minimize adverse environmental effects, and shall be limited to the following:

VOL 12

17342

(5) Incidental public service purposes, including but not limited to, burying cables and pipes or inspection of piers and maintenance of existing intake and outfall lines.

VOL 12

Relationship to Policy

NED Plan Alternative - The proposed project has public service purposes in providing flood control protection to a significant portion of the population within the Los Angeles basin. Use of the existing channel for flood control modifications is necessary in that there are no feasible alternatives that could be implemented which would not utilize the channel. (See also Section 2.1 of the EIS for a description of other alternatives considered but eliminated from consideration.)

(b) Dredging and spoils disposal shall be planned and carried out to avoid significant disruption to marine and wildlife habitats and water circulation. Dredge spoils suitable for beach replenishment should be transported for such purposes to appropriate beaches or into suitable long shore current systems.

17343

Relationship to Policy

NED Plan Alternative - No dredge spoil disposal is required under this alternative.

4. Section 30236

Channelizations, dams, or other substantial alterations of rivers and streams shall incorporate the best mitigation measures feasible, and be limited to (1) necessary water supply projects, (2) flood control projects where no other method for protecting existing structures in the floodplain is feasible and where such protection is necessary for public safety or to protect existing development, or (3) developments where the primary function is the improvement of fish and wildlife habitat.

Relationship to Policy

NED Plan Alternative - This alternative is a necessary component of the flood protection system for the greater Los Angeles County Drainage Area. The action involves modification of an existing flood control channel.

5. Land Resources

Land Resource policies are not applicable since no land resources within the coastal zone will be affected by project alternatives.

6. Development

The proposed action is not considered new development, thus the policies in this article do not apply.

7. Industrial Development

The proposed action is not considered industrial development thus the policies of this article do not apply.

III. CONSISTENCY DETERMINATION AND CERTIFICATION

It has been determined by the Los Angeles District Corps of Engineers that, based on a review of the applicable sections of the Coastal Zone management, the proposed Los Angeles County Drainage Area Study is consistent with the applicable sections of the

California Coastal Act of 1987 to the maximum extent practicable. The Corp has determined that the proposed plan, the NED plan, is the most feasible alternative and that feasible mitigation measures have been included to minimize adverse environmental effects. This finding is based on the attached Draft Environmental Impact Statement (DEIS) for the Los Angeles County Drainage Area study, appendixes, and coordination.

Re: Draft Fish and Wildlife Coordination Act Report for the Los Angeles County Drainage Area (LACDA) Review Study, Los Angeles County, California

Dear Colonel Thomas:

Enclosed for your review is our draft Fish and Wildlife Coordination Act Report which evaluates the alternatives currently being considered in the referenced project. A copy of this report has also been provided to the California Department of Fish and Game for their review.

This draft report has been prepared under the authority of, and in accordance with, provisions of the Fish and Wildlife Coordination Act (48 Stat. 401, as amended; 16 U.S.C. et seq.). This report is intended to assist your agency in the preparation of the Feasibility Study for this project.

We look forward to continued cooperation on this project. If you have any questions on this draft report, please contact John Hanlon at (714) 643-4270.

Sincerely,

Brooks Harper

PREFACE

This document constitutes the U.S. Fish and Wildlife Service's (Service) draft report on the Los Angeles County Drainage Area (LACDA) Review Study, Los Angeles County, California. It is being prepared under the authority of the Fish and Wildlife Coordination Act, P.L. 85-624, Section 2(b) and in keeping with the spirit and intent of the National Environmental Policy Act. This report is expected to have the endorsement of the California Department of Fish and Game.

The goals of the Service in its study involvement are, (1) to evaluate the impact of the principal alternative on fish and wildlife resources, their habitat and their utilization by the public, (2) to identify and evaluate the least environmentally damaging alternative, and (3) to recommend methods for preserving, compensating, and enhancing fish and wildlife resources.

In assessing the environmental conditions, as well as the needs and opportunities for fish and wildlife that would exist under the various alternatives analyzed, the Service employed its best professional judgment, using available research reports and literature.

VOL 12

A. GENERAL DESCRIPTION OF THE PROJECT AREA AND INTRODUCTION

The Los Angeles Drainage Area (LACDA) encompasses approximately 2,000 square miles. Components of the LACDA system include 5 Corps of Engineers' flood control basins, 16 Los Angeles County flood control basins, and 4 natural sections of streams. Except for the lower reaches of the San Gabriel River, all the components of the LACDA system lie in the San Gabriel Mountains or in the floodplain directly below them. Figure 1 shows the LACDA system. Ultimately, all the water flows into the Los Angeles or San Gabriel Rivers and empties into the Pacific Ocean at Long Beach Harbor.

1 7358

The LACDA Review is a study for flood control. Protection of environmental values within the project area is also to be considered. The LACDA system, built between 1940 and 1960, has been described by the Corps of Engineers (Corps) as outmoded and no longer adequate to meet existing conditions. Urban development has resulted in a decrease in groundwater percolation as ground surfaces were altered and became impervious. This resulted in increased surface runoff into the system and heightened the potential for flooding.

B. PROJECT DESCRIPTION

The Corps originally considered 5 alternatives to address the flood control problem: 1) structural modifications to existing structures (drains and channels); 2) re-regulation of the existing reservoirs; 3) re-regulation of and structural modifications to the existing reservoirs; 4) re-regulation of existing structures and construction of new structures; and 5) re-regulation and modifications to existing structures and construction of new structures.

Alternative 1, structural modifications to existing drains and channels, is the selected alternative. This alternative addresses the downstream reach of the Los Angeles - Rio Hondo system. Improvements will begin at the Rio Hondo outlet from Whittier Narrows and extend the entire length of the Rio Hondo Channel. Improvements on the Los Angeles River begin at the confluence with the Rio Hondo Channel and extend to the mouth of the river in Long Beach Harbor. A total of about 23 miles of channel are to be modified.

The objective of the structural improvements is to provide greater flood protection to the urbanized reaches of the Rio

VOL 12

17359

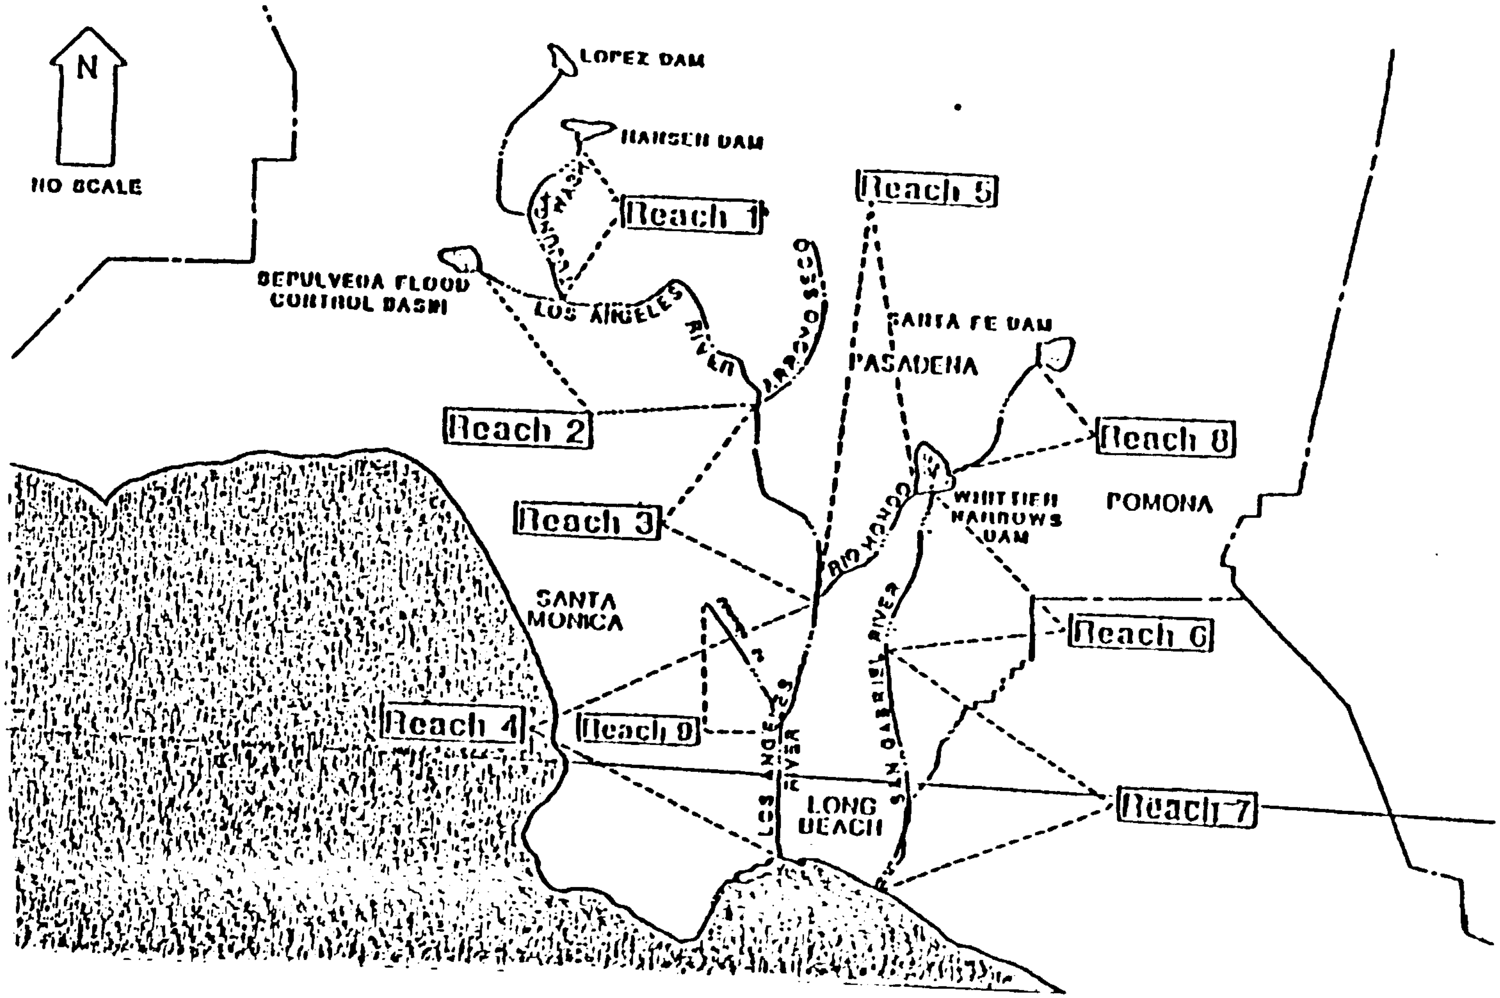

Figure: 1

R0050665

Hondo and lower Los Angeles River. The 133-year level of protection was selected because of its maximum net benefits and the constraints on plan design imposed by the Artesia Freeway overcrossing. Three measures are used individually and in combination to achieve this objective:

1) Vertical reinforced-concrete parapet walls of from 2.0 feet to 8.0 feet in height constructed along the crest of the existing channel levees.

2) Conversion of 6950 feet of concrete trapezoidal to concrete rectangular channel in a reach where parapet walls cannot be raised to the necessary height to provide adequate protection (at and just below the confluence of the Rio Hondo and the Los Angeles River).

3) Raising and modifying bridges which currently are too low to permit 133-year flows to pass underneath them or which have other impacts on the hydraulic characteristics of the channel which make alteration of their design necessary. Twenty-four of forty-one bridges in the project reach will be modified.

4) Armoring of the landward levee slope on both sides of selected reaches (a total of about 2.2 miles) to prevent overflows from eroding the levee.

(PLAN COMPONENTS)

<u>Parapet Walls</u>

Parapet walls will be constructed of one foot thick reinforced concrete. Their height will vary from reach to reach to reflect the changing requirements of the system. Transitions from one reach to another will be accomplished with an instantaneous change in height. In some reaches, where hydraulic analysis indicates wall height would be less than 0.5 feet, no parapet walls will be constructed. The parapet walls will be constructed on the channel side of the existing access road/bicycle trail system to permit continued recreation use along this reach of the river.

The parapet wall system will pass beneath or abut against all bridges. The existing bicycle trails veer channelward and dip into the channel as they pass below many of the bridges. The parapet walls will necessitate that the trails be elevated to the level of the top of the parapet walls to pass over them.

This will be located far enough from the bridge overpasses that the bicycle trail can reconnect with the existing underpass configuration.

Parapet walls would be constructed by connecting the new walls at the immediate junction of the existing channel wall and the asphalt-paved access road and bicycle trail. Walls will be reinforced with 3/4-inch diameter steel dowels sunk nine inches into the existing levee on 4-1/2 foot centers.

Conversion of the Channel to Rectangular Concrete-lined Channel

At the confluence of the Rio Hondo and the Los Angeles River, both parapet walls and the conversion of the channel from trapezoidal to rectangular is required to accommodate flood flows. In this approximately 7,000 foot reach, the anticipated flow of 158,000 ft^3/s is accommodated by converting the existing trapezoidal channel, with a top width of approximately 390 feet, into a rectangular cross-section with a width of 420 feet. In addition to widening the channel approximately 30 feet, parapet walls as high as seven feet will be added to the channel sides.

VOL 12 17363

This reduces the water surface elevation in the Rio Hondo sufficiently to avoid otherwise necessary modifications to the Union Pacific Railroad bridge.

Bridge Modifications

Twenty-four bridges must be either raised (21), raised and modified (1), modified (1), or moved (1) to permit the design flow to pass underneath the bridge. Only one of these structures has historic value - the railroad bridge near the mouth of the Los Angeles River which will be moved 115 feet downstream but will otherwise not be altered.

Raising of bridges will generally be accomplished in two ways. First, some bridges are suitable for raising using jacks to raise the entire bed while pier extensions are placed beneath them. Some bridges must be demolished and then replaced. The primary criteria for making this decision was the construction of the existing bridge and whether the bridge needed to be raised more than 10 percent of pier height to achieve project objectives. Raising a bridge to a greater height is not considered feasible for structural reasons.

VOL 12

17364

C. EXISTING CONDITIONS AND FUTURE WITHOUT THE PROJECT

The present environment of the project area consists entirely of concrete-lined channels with access roads and bike trails along one or both sides. No natural habitat exists. It is anticipated that without the project there will be no increase in natural habitats or wildlife values.

D. ANALYSIS OR IMPACTS AND FUTURE WITH THE PROJECT

No fish, wildlife, and habitat impacts are anticipated with the project. Presently there are no natural habitats nor fish and wildlife resources in the project impact area.

E. SUMMARY OF IMPACTS

Due to the fact that there are no fish and wildlife resources nor natural habitats in the project's impact area, there are no ecological impacts.

F. MITIGATION PLAN

Since there are no fish, wildlife, and habitat impacts in the project's impact area, no mitigation is required.

(8)

G. RECOMMENDATIONS FOR THE RECOMMENDED ALTERNATIVE

The Service has no recommendations to offer since there are no ecological values to the existing environment and that the project would not enhance nor degrade the existing environment.

Office Supervisor

Re: Flood Control Project Along Compton Creek, Rio Hondo, and Los Angeles Rivers

Dear Mr. Joe:

Thank you for consulting with us under 36 CFR 800.4.

The project as envisioned consists of raising and armoring existing levees along the Rio Hondo and Los Angeles Rivers. This will require raising, or in a few cases moving, 26 bridges.

Some of the bridges have been evaluated under CalTrans' bridge survey, others still require significance evaluations. We suggest you contact Steve Mikesell of Caltrans at (916) 920-7671 concerning bridge evaluations.

Most of the planned levee armoring appears to be taking place along Compton Creek, but little other information is included. Assuming at least some of this area is relatively undisturbed, you should conduct an identification of archaeological resources in areas within the APE likely to yield them.

If you have any questions, please contact Nicholas Del Cioppo, State Archaeologist II, at (916) 322-4419.

Sincerely,

for Kathryn Gualtieri
State Historic Preservation Officer

STATE OF CALIFORNIA

STATE WATER RESOURCES CONTROL BOARD

In Re: Petition of Natural Resources Defense Council, Inc., regarding WDR/NPDES Order No. 90-079	REGIONAL BOARD'S RESPONSE TO PETITION FILE No. A-693

VOL 12

I.

INTRODUCTION

On June 18, 1990, the California Regional Water Quality Control Board, Los Angeles Region (Regional Board) adopted an NPDES permit for Stormwater/Urban Runoff Discharge in Los Angeles County (Order No. 90-079), with the Los Angeles County Department of Public Works as the principal permittee and seventeen municipalities as co-permittees, under the Clean Water Act, Section 402 (p). The permit was the culmination of several months of planning and discussion with the Stormwater Work Group made up of applicants, state and federal representatives, and environmental groups.

1 7382

The Regional Board handled the stormwater runoff issue under significant circumstances. First, the EPA's regulations on the subject had not (and still have not) been promulgated, and yet the Regional Board is under a legislative deadline in the Clean Water Act to issue permits for municipal stormwater discharges.

Second, there is a glaring lack of technical data regarding such critical matters as appropriate effluent limitations and control methods, how and where they should be measured, how they can be controlled, what control measures should be applied and where. Despite the lack of applicable EPA regulations and technical information, there was a strong desire among the Stormwater Work Group to develop a permit that will be in place to help control pollutants in stormwater discharges as early as the next rainy season.

The NPDES permit, which is the subject of this petition, enjoys substantial support of several parties, including the eighteen dischargers, several environmental groups[1] notably Heal the Bay, Sierra Club and American Oceans Campaign, as well as the Environmental Protection Agency (EPA.)[2] Despite its shortcomings, the permit represents the Regional Board's best effort, given the circumstances, to establish a programmed approach to deal with a large and complex problem for which there exists sparse guidance. Faced with hard choices, that of issuing no permit and having to go through another rainy season with <u>no controls whatsoever</u>, or issuing a permit which, despite its imperfections, attempts to reduce pollutants in stormwater discharges in a systematic manner,

2. See letter dated February 28, 1990, from Keith A. Takata, Acting Director, Water Management Division, EPA, to Dr. Robert P. Ghirelli, Executive Officer, Regional Board.

the Regional Board elected the active approach that will make substantial inroads in mitigating this problem.

II.

RESPONSES TO SPECIFIC CONCERNS

1. The Natural Resources Defense Council (NRDC) asserts that the permit fails to impose enforceable standards.

The Regional Board staff agrees that some form of effluent limitations or guidelines will be necessary <u>eventually</u> to ensure that water quality objectives are being met. To this end, the permit provides two surrogate water quality parameters as guidance standards for early action control.[3] The significance is again recognized in Finding 19 by the statement, "water quality objectives will be developed by Board staff, when sufficient information becomes available.[4]

Some Water Quality criteria presently exist, such as the California Ocean Plan[5] standards. However, staff believes that such criteria are inappropriate and ill-suited for translation to stormwater quality criteria or transposition to stormwater

discharge standards. For example, effluent quality requirements set forth in the California Ocean Plan such as "monthly averages, weekly averages, 6-month median, daily maximum, and instantaneous maximum" were developed for non-stormwater runoff applications and cannot be readily translated into criteria for stormwater discharges.[6] There is general agreement on the characteristics of stormwater runoff. Storm water is an intermittent pollutant source representing shock loadings, short in duration, and highly variable in impacts on receiving waters. These characteristics defy the application of traditional water quality criteria to storm water.[7]

Furthermore, water quality objectives cannot be enforced without established points of compliance. The State Water Resources Control Board is currently in the process of adopting regulations to designate "mixing zones" in order to define the points of application of water quality objectives.[8] A mixing zone is a certain volume of receiving water allocated for mixing with waste discharge and within which parameter values greater than water quality objectives are not considered to be violations of requirements. However, for stormwater discharges into rivers and

VOL 12 1385

streams, the diversity of receiving waters makes a single mixing zone strategy infeasible. Without further guidance on how to determine points of application of water quality standards and points of compliance for stormwater discharges, any numerical limit set will be confusing and futile, especially when the storm drain system includes major waterways which have been modified to facilitate the movement of stormwater, as is the case in Los Angeles County.

In order to put the issues facing the Regional Board into perspective, it is important to note that the storm drainage system in Los Angeles County is designed with several thousand outfalls[9] to reduce the threat of potential flooding from stormwater flows. Such flows are often intermittent and characterized by very high flow rates occurring over short intervals of time. A single storm event with a recurrence interval of less than 2 years (rainfall intensity-duration probability >98%) may discharge as much as five billion gallons to Los Angeles coastal waters over a 48-hour period through the complex system of storm drains. The maximum discharge rate for such a storm may be as much as 8,480 cubic feet per second (cfs) compared to a low flow rate of less than 95 cfs.[10] The pollutants transported in the storm water derive from runoff that drains over lands used for a wide variety of activities. Typical

---

9. John Mitchell, Chief, Water Quality Section, Department of Public Works, County of Los Angeles, estimates that there exist more than 5,000 storm drain outfalls that are owned and operated by the County agency alone.

10. Stormwater Runoff in Los Angeles and Ventura Counties. H. Schaefer and R. Gossett, 1988. SCCWRP Contribution C292. 86pp.

pollutant concentrations in storm water in Los Angeles County tend to range over three orders of magnitude during the course of a storm event.[11]

With the present limited information available to the Regional Board staff, it is virtually impossible to establish technically appropriate and enforceable effluent limits. Were the Regional Board staff to attempt to set effluent limits at this time, such limits would be highly vulnerable to challenge as arbitrary, and the exercise would undermine the permittees' efforts to reduce stormwater pollution through a comprehensive stormwater management program.

California Water Code Section 13000 declares that the Legislative Policy is, in part, "... activities and factors which may affect the quality of the waters of the state shall be regulated to attain the highest water quality which is reasonable, considering all demands being made and to be made on those waters and the total values involved, beneficial and detrimental, economic and social, tangible and intangible". The incorporation in the permit of inappropriate or burdensome standards is inimical to this policy, because it would defeat the attainment of the highest water quality that is reasonable under the circumstances.

11. Ibid. See Appendix

VOL 12 17387

VOL 12

2. The Petitioner argues that the permit fails to require that the Dischargers adopt discharge controls to the Maximum Extent Practicable.

The NRDC cites the National Urban Runoff Program (NURP) conducted by EPA between 1978 and 1982. However, that program evaluated only a limited number of techniques, and the effectiveness of control methods tested tended to vary with the characteristics of drainage basins, patterns of pollutant loadings, and multiple site-specific variables.[12] Other subsequently published lists of control measures suitable for stormwater quality management recommend approaches which target available resources and prioritize control programs to site specific conditions.[13] An a priori determination and identification of maximally 'effective management practices' cannot be performed without more complete information on business activities, land use patterns, and other factors that contribute to stormwater contamination within subject drainage areas. Some of this information currently exists but is not in a readily usable form.

---

12. For a summary of the control effectiveness of methods tested at the local level in the NURP study, see, Final Report of the Nationwide Urban Runoff Program, Water Planning Div., USEPA, Washington, D.C., 1983. 9-11 - 9-18.

13. See, 'Urban Targeting and BMP Selection: An Information and Guidance Manual for State NPS Program Staff Engineers and Managers', 1989, USEPA, Chicago, IL, No. 68-C8-0034, and 'Controlling Urban Runoff: A Practical Manual for Planning and Designing Urban BMPs', T.R. Schueler, 1987, Metropolitan Washington Council of Governments.

1738 8

As an example, catch basin cleaning[14] which NRDC cites as an important management practice, may reduce the toxic loading of runoff, but there is no hard evidence to support the view that it is an <u>effective</u> management practice to reduce toxic contamination of storm water[15]. Catch basin cleaning tends to remove visible debris and floatable objects which represent more of an aesthetic problem rather than one of toxicity. Any attempt by Regional Board staff to prescribe stormwater pollution control measures, in the absence of a clear understanding of pollutant sources and site specific characteristics of drainage areas, will frustrate permittees' ability to optimize the use of finite resources in effective management of stormwater pollution.

Board staff will be able to better evaluate the suitability of control measures to be proposed per permit requirements, once studies currently underway have been

---

14. NRDC cites catch-basin cleaning as an important management practice that should have been prescribed by the permit. See NRDC's Petition for Review to the State Water Resources Control Board, Pgs. 7 and 8.

15. The City of Los Angeles has proposed to study the nature of catch-basin debris. Sediment analysis will be included in order to evalute pollutant concentrations. Phil Richardson, Division Engineer, Stormwater Division, City of Los Angeles, in an address to the Santa Monica Bay Restoration Project's Management Committee Storm Drain Committee on October 3, 1990.

VOL 12

1 7389

VOL 12

17390

completed,[16] and relevant information requested of permittees is submitted.

Additionally, the Regional Board staff is concerned that premature prescriptions may impede the creation of alternative solutions to non-point source pollution problems. For example, the City of Santa Monica is addressing the catch basin issue by painting sign markings and installing covers over catch basins during the dry months. This measure will likely reduce the accumulation of catch-basin debris. The covers will be removed before the onset of the rainy season[17]. Such measures would achieve the same ends as the suggested increased frequency of catch basin cleaning.

3. The Petition asserts that the permit fails to impose a three-year timeline for compliance.

The Clean Water Act provides that stormwater permits shall require compliance with the Act and with regulations to be

---

16. A State Best Management Practices Manual is under preparation by the statewide Stormwater Quality Task Force. In addition, the Santa Monica Bay Restoration Project has contracted the University of California at Los Angeles, to develop an early action Best Management Practices program for the Santa Monica Bay watershed under its 'Assessment of Non-Point Sources of Contaminants to Santa Monica Bay'. This report is due to become available in early June, 1991.

17. Stan Scholl, Director, Department of General Services, City of Santa Monica, In a presentation to members of the Santa Monica Bay Restoration Project's Management Committee Storm Drain Committee on August 22, 1990. The Storm Drain Inlet Cover and Signage Program was inaugurated on September 21, 1990.

enacted by EPA within three years following issuance of the permit. The essential elements defining compliance for stormwater discharges are not provided in the Clean Water Act. Rather, the EPA and the States were left to decide on how such discharges ought to be regulated. The permit was issued without benefit of interpretive regulations and without a clear indication of when those regulations might be expected.

The Regional Board interprets "compliance" as instituting a viable stormwater management program to achieve a reduction in stormwater pollution of water bodies in Los Angeles County to the maximum extent practicable. The permit, which, to the Regional Board staff's knowledge, is one of the first of its kind in the nation, contains phased requirements and a schedule for implementation of control activities, which will ensure compliance within three years. Los Angeles County encompasses an area of 4,083 square miles with about 40% of that area consisting of industrial, commercial, and residential sites, and lands under development. The networking storm drain system within this area traverses the jurisdiction of 87 different local governmental entities (the County government and separate cities) which will all eventually be co-permittees. The population that is served by the system numbers more than 8.7 million[18], roughly 35 times the population contemplated in the Clean Water Act. The complexity and enormity of the area subject to the permit necessitates a flexible and

18. Population total based on preliminary estimates by U.S. Department of Commerce, Bureau of Census', 1990 Census.

cooperatively-developed approach towards managing stormwater pollution to achieve the objectives of the Clean Water Act.

III.

CONCLUSION

The permit attempts to come to terms with a massive and complex problem. It represents a voluntary and cooperative approach by the parties to reduce stormwater pollution loadings. More stringent alternatives may realistically be expected to lead to delay, confusion, unenforceability, and litigation, with the practical consequence of no reduction in stormwater pollution loadings. The Regional Board believes that, given the unique characteristics of the area being served by Los Angeles County and co-permittees, and given the likelihood of success over available alternatives, the permit should be upheld by the State Board.

VOL 12

WASTE DISCHARGE REQUIREMENTS, STORMWATER/URBAN RUNOFF DISCHARGE FOR LOS ANGELES COUNTY AND CO-PERMITTEES (ORDER NO. 90-079)

1

7393

STATE OF CALIFORNIA
CALIFORNIA REGIONAL WATER QUALITY CONTROL BOARD
LOS ANGELES REGION

VOL 12

ORDER No. 90-079

NPDES NO. CA0061654 (CI 6948)

WASTE DISCHARGE REQUIREMENTS STORMWATER/URBAN RUNOFF DISCHARGE for LOS ANGELES COUNTY and CO-PERMITTEES

The California Regional Water Quality Control Board, Los Angeles, (Regional Board) finds :

1. The County of Los Angeles, in cooperation with the following cities : Agoura Hills, Beverly Hills, Culver City, El Segundo, Hermosa Beach, Inglewood, Los Angeles, Manhattan Beach, Rancho Palos Verdes, Redondo Beach, Rolling Hills Estates, Rolling Hills, Santa Monica, Torrance, West Hollywood, and Westlake Village, has submitted a report of waste discharge (NPDES permit application) dated March 15, 1990 for issuance of waste discharge requirements for the County of Los Angeles and other cities tributary to Los Angeles County (excluding Antelope Valley) under the National Pollutant Discharge Elimination System. (NPDES Permit No. CA0061654).

2. The discharges consist of surface runoff generated from various land uses in all the hydrologic drainage basins which discharge into water courses flowing into water bodies in Los Angeles County. The quality of these discharges varies considerably and is affected by land use, basin hydrology and geology, season, and the frequency and duration of storm events. The constituents of concern and significance in these discharges are: total and fecal coliform and enterococci bacteria, total suspended solids, biochemical oxygen demand, oil and grease, heavy metals, nutrients, polychlorinated biphenyls, polycyclic aromatic hydrocarbons, pesticides and herbicides, and petroleum hydrocarbons.

17394

3. The objective of this permit is to develop a timely, comprehensive, and cost-effective stormwater pollution control program to minimize pollutants in urban runoff/stormwater discharges to water bodies in Los Angeles County.

4. Due to the complexity and networking of drainage facilities within and tributary to Los Angeles County, the county and adjacent areas discharging storm water into Los Angeles County are divided and prioritized into five drainage basins for the implementation of the permit. The owners/operators of all facilities impacting stormwater quality will be ultimately a party to these waste discharge requirements. The County of Los Angeles together with the cities identified above, the initial parties filing for the system-wide permit, are 'Permittees', with the County of Los Angeles as the 'Principal Permittee' and the rest as 'Co-Permittees'. All other cities and recognized entities such as Caltrans, college/university campuses, hospitals, parks, agricultural areas, real estate developments and waste disposal facilities identified in this Order, are designated 'Co-Participants'. A 'Co-Participant' will be a 'Co-Permittee' upon becoming an active party to the permit.

Attachments 1 and 2 show, respectively, the list of cities and a partial list of entities designated as Co-Participants for this permit. The list of entities will be revised as necessary.

5. The County of Los Angeles, as the 'Principal Permittee', will obtain the cooperation of 'Co-Participants' to become 'Co-Permittees'. The Regional Board has the discretion and authority to require non-cooperating cities and/or entities to become 'Co-Permittees' or obtain individual stormwater discharge permits, pursuant to 40 CFR 122.26 (a).

6. Los Angeles County as the 'Principal Permittee' is the permit coordinator responsible for general administration of this Order, and coordinating cooperation by 'Co-Permittees', including but not limited to the implementation of local self-monitoring programs and Best Management Practices, and the preparation and submittal of reports required by this Order.

7. Los Angeles County obtains its authority to :

- control pollutants in stormwater discharge
- prohibit illegal discharges and control spills
- require compliance and carry out inspections

VOL 12

1 7 3 9 5

of drainage facilities in the County of Los Angeles from the Los Angeles County Flood Control Act and various county ordinances which address industrial wastes and waste discharges within the unincorporated areas of Los Angeles County and contract cities. 'Co-Permittees' with the status of incorporated cities have various forms of legal authority in place, such as charters, State Code provisions for General Law cities, city ordinances and applicable portions of Municipal Codes and the State Water Code, to regulate stormwater/urban runoff discharges.

8. The division and prioritization of Los Angeles County and adjacent areas into five drainage basins for program implementation are based on hydrological characteristics of the watersheds, perceived importance and beneficial uses of water bodies, and the existence of an adequate infrastructure for program implementation. The five drainage basins are :

I	:	Santa Monica Bay Drainage Basin
II	:	Upstream Los Angeles River Drainage Basin, to and including Sycamore Canyon Channel (San Fernando Valley);
III	:	Upper San Gabriel River (San Gabriel Valley) Drainage Basin.
IV	:	Lower Los Angeles River Drainage Basin
V	:	Lower San Gabriel River Drainage Basin; and Santa Clarita Valley Basin.

Attachment 3 shows a map of Los Angeles County with the boundary delineations of the five drainage basins.

Attachment 4 shows Co-Participant cities in Los Angeles County (and their respective populations).

[Note: Detailed maps of the Los Angeles County storm drain system with boundary delineations of drainage basins are available for review at the Regional Board Office.]

9. A number of studies on stormwater/urban runoff pollution in the permit areas has been conducted by agencies such as the City of Los Angeles, the Southern California Coastal Water Research Project and the Southern California Association of Governments. These studies indicate stormwater/urban runoff contributes significantly to the deterioration of the quality of water bodies in Los Angeles County.

The University of California at Los Angeles, under the sponsorship of the Santa Monica Bay Restoration Project, is currently compiling and summarizing data and information on stormwater/urban runoff discharges for the Santa Monica Bay watershed.

10. The Los Angeles County Department of Public Works has an active surface water quality monitoring program in the permit area, comprising twenty-eight monitoring stations located at principal storm drains and water conservation facilities. The Surface Water Quality Monitoring Program comprises the collection and analysis of dry weather water samples for general minerals, pesticides, total petroleum hydrocarbons, heavy metals and bacteria (total and fecal coliform, KF streptococci and enterococci). Volatile organic constituents are tested semi-annually at selected stations. Stormwater runoff is monitored three to four times annually at twenty-one stations for minerals, pesticides, heavy metals (total and dissolved), bacteria, total and organic suspended solids, oil and grease, biochemical oxygen demand, total organic carbon and volatile organics.

11. The Los Angeles County Department of Public Works and some cities have on-going activities that reduce stormwater/urban runoff pollutant loads. These activities include periodic catch-basin cleaning and street sweeping, public information on proper disposal of household hazardous waste, and emergency responses to reports of illegal dumping, illicit disposal, illegal connections, and industrial waste spills. The Los Angeles County Department of Public Works also participates and coordinates action with local, State, and Federal agencies responding to spills and illegal dumping reports that threaten surface waters.

12. The Regional Board currently regulates industrial process and point source non-process wastewater and stormwater discharges to storm drain systems through NPDES permits. Point source discharges including stormwater will continue to be regulated by the Regional Board. An information system will be developed and maintained to update pollutant loadings to designated

VOL 12

1 7 3 9 7

drainage facilities and water bodies from permitted point source discharges.

13. The State Water Resources Control Board (State Board) adopted a Water Quality Control Policy for the Enclosed Bays and Estuaries of California on May 16, 1974. The policy provides that the discharge of industrial process waters to enclosed bays and estuaries shall be prohibited. Storm water and urban runoff are not considered industrial process waters for the purpose of that policy.

14. The State Board adopted a revised Water Quality Control Plan for Ocean waters of California (Ocean Plan) on March 22, 1990, which amended the Plan adopted on September 22, 1988. The Plan contains water quality objectives for the coastal waters of California.

15. The Regional Board adopted a revised Water Quality Control Plan for the Los Angeles River Basin (Basin Plan) on November 27, 1978. The Basin Plan incorporates the Ocean Plan, and contains water quality objectives for the basin, including the beneficial uses of water bodies.

16. The beneficial uses of water bodies in Los Angeles County and their tributary streams include contact water recreation, non-contact water recreation, wildlife habitat, preservation of rare and endangered species, marine habitat, estuarine habitat, fish migration, fish spawning, industrial service and process supply, agricultural water supply, shellfish harvesting, navigation, commercial and sport fishing, and groundwater recharge.

17. Section 405 of the Water Quality Act of 1987 added Section 402(p) to the Clean Water Act of 1972 to require the Environmental Protection Agency (EPA) to establish regulations for stormwater/urban runoff discharge under the National Pollutant Discharge Elimination System (NPDES).

18. The Federal Clean Water Act allows EPA to delegate its NPDES permitting authority to States with an approved environmental regulatory program. The State of California is one of the delegated States. The Porter-Cologne Act (State Water Code) authorizes the State Board, through its Regional Boards, to regulate and control the discharge of pollutants into waters of the state and tributaries thereto.

19. Although Water Code Section 13263 (a) requires that waste discharge requirements issued by Regional Boards shall include provisions to implement water quality based objectives, numerical water quality standards

VOL 12

1 7 3 9 8

are not provided in this Order. Information is not available to establish appropriate numerical limits, and determine locations where permittees shall be made accountable. The requirements in this Order will provide the necessary information while concurrently achieving reductions in pollutant loads to water bodies from stormwater/urban runoff discharges. Numerical water quality objectives will be developed by Board staff for consideration in the permit renewal process and utilized for the evaluation of Best Management Practices.

20. Due to the significance of the Los Angeles County Stormwater/Urban Runoff Program, the Regional Board, in recognition of the need for public involvement and participation in the development and implementation of an effective program will conduct at a minimum an annual workshop, prior to approving plans submitted by Permittees, to solicit comments and to inform the public of the progress of the program. Comments presented will be referred to Los Angeles County for response.

21. Stormwater/urban runoff discharges to drainage facilities that cross County boundaries and Regional Board jurisdictions, and which are regulated under NPDES permits, are the regulatory responsibility of those agencies issuing the permits.

22. The issuance of waste discharge requirements for this discharge is exempt from the provisions of the California Environmental Quality Act (CEQA); Chapter 3 (commencing with Section 21100) of Division 13 of the Public Resources Code in accordance with Water Code Section 13389.

The Board has notified the Permittees and interested agencies and persons of its intent to issue waste discharge requirements for this discharge and has provided them with an opportunity to submit their written views and recommendations.

The Board, in a public hearing, heard and considered all comments pertaining to the discharge and to the tentative requirements.

This Order shall serve as a National Pollutant Discharge Elimination System permit pursuant to Section 402 of the Federal Clean Water Act, or amendments thereto, and shall take effect at the end of ten days from the date of its adoption provided the Regional Administrator, EPA, has no objections.

IT IS HEREBY ORDERED that the Permittees, in order to meet the provisions contained in Division 7 of the California Water Code and regulations adopted thereunder,

CA0061654

and the provisions of the Clean Water Act as amended and regulations and guidelines adopted thereunder, shall comply with the following:

1.0 COMPLIANCE

1.1 The Permittees and Co-Permittees shall comply with the requirements contained in this Order according to the following schedule:

	DRAINAGE BASIN	STARTING DATE FOR COMPLIANCE WITH REQUIREMENTS
I.	Santa Monica Bay	July 1, 1990
II.	Upper Los Angeles River (San Fernando Valley)	July 1, 1992
III.	Upper San Gabriel River (San Gabriel Valley)	July 1, 1992
IV.	Lower Los Angeles River	July 1, 1993
V.	Lower San Gabriel River and Santa Clarita Valley	July 1, 1993

2.0 REQUIREMENTS - YEAR 1

2.1 For each Drainage Basin, prepare and submit to the Regional Board within 12 months of the starting date for compliance, according to the schedule under 1.1:

2.1.1 Water quality data and flow data from 1980 to the present to facilitate identification of sources of pollutants present in discharges from the prioritized drainage basin. "Drainage areas" in the drainage basin are to be reported and the "drainage areas" associated with each drainage basin clearly identified.

VOL 12

17400

R0050705

For purposes of stormwater/urban runoff, a "drainage area" is defined as a subdivision of a drainage basin which is unique in land use patterns, and pollutant characteristics and loadings.

2.1.2 The 90th percentile value for the water quality parameters, (i) Total Suspended Solids (TSS), and (ii) Oil and Grease, from the data set of all wet weather samples collected from 1980 to the present. These data will be used to establish guidance for early action control of stormwater pollution.

The 90th percentile for a given water quality parameter is defined as the concentration value exceeded in ten percent of the samples of the reference data set.

2.1.3 Additional information of a qualitative nature that would contribute to isolating and identifying sources of problems. Such information should include but not be limited to visual observations of factors exacerbating stormwater contamination, principal land use classifications and Standard Industrial Code (SIC) categories of facilities in "drainage areas", and a description of soils, dumps, landfills, waste disposal sites and Resource Conservation and Recovery Act (RCRA) facilities associated with each area.

2.1.4 Monthly precipitation data from rain gauge stations, relevant to the drainage basin, for the years 1980 to the present, and an estimate of the area of impervious surfaces (including paved areas and building roofs) within each "drainage area".

2.1.5 Documentation of existing procedures to detect and address illegal discharges and illicit disposal practices.

2.1.6 Documentation of existing practices and improvement plans to control pollutants in stormwater/urban runoff from construction sites.

2.1.7 Documentation of existing stormwater/urban runoff management practices and existing Best Management Practices (BMPs) for the control of pollutants in discharges from residential, commercial and industrial areas.

For purposes of this permit, a Best Management Practice is defined as a stormwater quality management practice that has been demonstrated to reduce stormwater/urban runoff constituents of concern in studies in the United States and elsewhere, or a stormwater/urban runoff quality management practice that can significantly control stormwater/urban runoff pollution.

VOL 12

1 7401

2.1.8 Plan with schedule of implementation, for approval by the Executive Officer, of early action BMPs.

For purposes of this permit, an early action BMP is defined as an existing stormwater/urban runoff quality management practice that is optimized to the maximum extent practicable (MEP) in efficiency for the control of stormwater runoff pollution, such as improving the frequency of storm drain catchment basin cleaning or the stricter enforcement of existing regulations, or a BMP that is not specific to stormwater/urban runoff constituents or "drainage area" in its constituent removal capacity and can be applied on a system-wide basis, such as public outreach and educational programs.

For purposes of this permit, maximum extent practicable means to the maximum extent possible, taking into account equitable considerations of synergistic, additive and competing factors, including but not limited to gravity of the problem, fiscal feasibility, public health risks, societal concern, and social benefits.

The Principal-Permittee, in the submittal of plans and schedules to the Executive Officer, shall demonstrate that public input has been obtained.

For purposes of this permit, public input is demonstrated by, (i) disseminating the notice of availability of plans for review and comment, to the public at large, environmental groups, Federal, State and local officials and other interested parties, and (ii) addressing concerns expressed by the public.

The Board may modify the plans in response to public input received at the Board during its comment/review period. Permittees are required to implement the original or modified plan on approval by the Executive Officer.

2.1.9 A workplan for the development of a stormwater/urban runoff monitoring program, for approval by the Executive Officer, to include but not be limited to the following information :

- listing of constituents and parameters to be monitored and the rationale for their choice.
- listing of monitoring locations and the rationale for their choice.
- listing of sampling methodology of choice and frequency of sampling for both wet weather and dry weather flow.
- supplementary information that influences the design of the monitoring plan.

The Principal-Permittee, in the submittal of the workplan to the Executive Officer, shall demonstrate that public input has been obtained.

2.1.10 Documentation that each Permittee, individually and/or jointly, through the establishment of a joint powers authority or a stormwater utility, possesses adequate legal authority to operate and manage stormwater/urban runoff quality management programs, and/or plans to obtain the necessary legal authority to regulate illegal discharges and illicit disposal practices into storm drains, and to prosecute violators.

3.0 REQUIREMENTS - YEAR 2

3.1 For each Drainage Basin, prepare and submit to the Regional Board, for approval by the Executive Officer, within 24 months of the starting date of compliance, according to the schedule under 1.1:

3.1.1 A monitoring program based on the approved workplan. This program shall be designed to:

- detect accurately the constituents and parameters of concern, in discharges indicated in the workplan, and to identify their possible sources.
- identify illegal dischargers and/or locations of illicit disposal practices.

Monitoring reports for this program shall be submitted according to the format and frequency to be approved by the Executive Officer.

3.1.2 Plan with schedule of implementation for additional BMPs, judged appropriate for each city or drainage basin, to control pollutants from residential, commercial and industrial sites to the maximum extent practicable.

Both structural and non-structural BMP measures are to be evaluated at the MEP standard. Examples of non-structural measures include catch basin cleaning, street sweeping and public education, while controls such as detention/retention basins, first flush diversions, grassy swales and porous pavements are examples of structural measures.

VOL 12

17403

3.1.3 Plan with schedule of implementation of procedures to detect and eliminate illegal discharges and illicit disposal practices.

3.1.4 Plan with schedule of implementation of measures to control pollutants in surface runoff from construction sites.

The Principal Permittee, in the submittal of plans and schedules (items 3.1.2, 3.1.3, and 3.1.4) to the Executive Officer shall demonstrate that public input has been obtained. The Board may modify the plans in response to public input received at the Board during its comment/review period. Permittees are required to implement the original or modified plans on approval by the Executive Officer.

3.2 Evidence of satisfactory progress of implementation of plan and schedule for early action BMPs.

3.3 Evidence of all requisite legal authority to regulate illegal discharges and illicit disposal practices to drainage facilities, and to prosecute violators.

4.0 REQUIREMENTS - YEAR 3

4.1 For each Drainage Basin, submit to the Regional Board, within 36 months of the starting date of compliance, according to the schedule under 1.1, the following:

4.1.1 Evidence of satisfactory progress of implementation of plan and schedule for early action BMPs and additional BMPs.

4.1.2 Evidence of implementation and progress of procedures to detect and eliminate illegal discharges and eliminate illicit disposal practices.

4.1.3 Evidence of implementation and progress of measures to control pollutants in surface runoff from construction sites.

5.0 EXPIRATION AND RENEWAL

5.1 This Order expires on June 18, 1995.

5.2 The Permittees shall file a report of waste discharge (ROWD), not later than 180 days before the expiration date, as application for reissuance of waste discharge requirements. This report of waste discharge shall include but not be limited to the following:

VOL 12

17404

VOL 12

5.2.1 Summary of the results of the monitoring program.

5.2.2 Summary of BMPs implemented and evaluations of their effectiveness.

5.2.3 Summary of procedures implemented to detect illegal discharges and illicit disposal practices and an evaluation of their effectiveness.

5.2.4 Summary of measures implemented to control pollutants in surface runoff from construction sites and an evaluation of their effectiveness.

5.2.5 Evaluation of the need for additional BMPs, source control, and/or structural control measures.

5.2.6 Proposed plan of stormwater/urban runoff quality management activities that will be undertaken during the term of the next permit.

I, Robert P. Ghirelli, Executive Officer, do hereby certify that the foregoing is a full, true, and correct copy of an order adopted by the California Regional Water Quality Control Board, Los Angeles Region, on June 18, 1990.

ROBERT P. GHIRELLI, D.Env.
Executive Officer

WRITTEN COMMENTS IN SUPPORT OF WASTE DISCHARGE REQUIREMENTS

Heal the Bay
1650A TENTH STREET
SANTA MONICA CALIF 90404
TELEPHONE 213 399 1146

VOL 12

Los Angeles Regional Water Quality Control Board
101 Centre Plaza Drive
Monterey Park, CA. 91754-2156

Dear Board Members, June 18, 1990

First of all, I would like to commend the staff of the Regional Board, the Santa Monica Bay Restoration Project, the L.A. County Department of Public Works and the 16 co-permittee cities in the Santa Monica Bay watershed for developing and agreeing to the draft urban runoff discharge permit in record time. Heal the Bay strongly agrees that the development of an NPDES permit separate from the EPA final regulations was the most prudent course of action to follow.

However, we do feel that the permit has the following shortcomings:

1) There are no enforcement provisions spelled out in the permit. These comments refer to Sections 2.1.8 and 3.1.2 (early action BMPs), 2.1.9 and 3.1.1 (monitoring program requirements and implementation), 2.1.10 and 3.3 (development of enforcement authority of permittees and co-permittees), 3.1.3 and 4.1.2 (illegal discharge and illicit disposal control programs and implementation) and 3.1.4 and 4.1.3 (control of runoff from construction and implementation). We understand that all NPDES permits are enforceable under the Clean Water Act by the Regional Boards. However, nowhere in this permit is that stated. Our question is, "Specifically, what are the enforcement powers of the Board if the permitting agency or co-permitting cities are in violation?" For example, if a city agrees to a series of early action BMPs and then refuses to implement them because of budget constraints, what recourse is available to the Board to ensure compliance?

1
7
4
2
7

2) We strongly suggest that a list of BMPs acceptable to the Board is developed as soon as possible. Putting all of the burden of approval of BMPs on a case by case basis for the executive officer makes it extremely difficult to implement a standardized program for pollution reduction in runoff. Please get input on BMPs for the list from the permitting agency, co-permittees, Dr. Mike Stenstrom et al., and various environmental groups.

3) Section 2.1.2 brings up the concept of a 90th percentile value for the water quality parameters, oil and grease (O+G) and total suspended solids (TSS). The first sentence of the section is lacking a verb, so the intent of the sentence is unclear.

Secondly, the whole reason I brought up the concept to begin with was in order for the Board to develop some numerical water quality standards during the life of the initial permit that a) were enforceable, b) made sense, were relatively inexpensive and were feasible, c) only initially required monitoring of those stormdrains (near the outfalls) that discharged to the ocean year round, and d) were conservative enough that only runoff with the worst water quality would be initially impacted. Also, if O+G and TSS are reduced in runoff, then the great majority of the more toxic contaminants are reduced as well. After all, the purpose of this permit is to reduce the mass pollutant load in runoff and toxicity of runoff.

I felt like the proposed numerical standards were an extremely reasonable compromise position. It's not like we demanded for Table B of the California Ocean Plan to become the numerical standards. I have no idea what "guidance for early action control of stormwater pollution" means. I assume that the guidance values for TSS and O+G at least will be used as baseline values to judge the removal efficiencies of the proposed BMPs. Without any numerical TSS and O+G baseline criteria, the Board, the permittee and the co-permittees lose a great deal of enforcement leverage against cities or businesses that are out of compliance with the permit.

The last comment that I have refers to the process of permit development. Heal the Bay played an active role through the Santa Monica Bay Restoration Project in deciding that pursuing an "early" permit was the correct course of action. However, when it came to permit development, we were told that we were not welcome in the process. After the draft of the permit was available for public comment, we made extensive formal comments and provided numerous informal comments to strengthen the permit. Unfortunately, it became abundantly clear that our late inclusion in the permit development process was far too late to make a significant difference.

I did not bring up this point today in order to cause trouble. I brought it up to remind everyone that on this pollution issue, we are all on the same side. Together, we are all learning about the physical, chemical, biological and regulatory characteristics of runoff. Heal the Bay fells like they have a lot to offer on the development of BMPs and the implementation of the permit. In the future, please include us in the process as much as possible.

Sincerely,

Mark Gold

VOL 12

June 18, 1990

Xavier Swamikannu
California Regional Water Quality
Control Board
101 Centre Plaza Drive
Monterey Park, CA 91754-2156

Dear Mr. Swamikannu:

On behalf of American Oceans Campaign, a national environmental organization dedicated to the preservation and protection of our oceans, we submit the following comments on the Regional Board's Draft Order of the NPDES Permit to control urban runoff/stormwater discharges in the Los Angeles area.

Coastal non-point source pollution is the most significant source of water pollution in the Los Angeles area and is constantly increasing in magnitude due to population growth and urban development in this region. In view of this, we are very appreciative of the tremendous efforts of the Board's staff to draft this permit and to bring together all of the entities involved to work in a cooperative manner to address this problem.

Our main concern focuses on the failure to include express enforcement language within the body of the permit. We believe this is absolutely necessary to improve the quality of the water which is certainly the main point of this permit process.

With reference to Item 19 of the Draft Permit, AOC strongly recommends that numerical guidelines be developed by Board staff as soon as possible. Information and data alone will not improve water quality without express numerical guidelines just as monitoring alone will do nothing without strict enforcement provisions. A case in point is the case of the County Public Works Department that has done extensive monitoring over the past twenty years but the data collected was never made known to the public nor has this data done anything to improve the quality of our water.

With reference to Item 2.1.2, AOC strongly believes that the reference to "guidelines" is vague and ambiguous and recommends that the first numerical standards set should be for Total Suspended Solids and Oil and Grease because if you take care of these pollutants first, this addresses most of the problems.

1-7429

R0050734

With reference to Item 2.1.8, AOC believes that it is imperative that all early BMPs be approved by the Executive Director of the Board. AOC also recommends that an enforcement mechanism needs to be expressly provided for in the event that entities fail to comply with the schedule of implementation of the early action BMPs.

On behalf of AOC, we thank the Board for the opportunity to comment on the Draft Permit and appreciate the consideration of our comments.

Sincerely,

Robert H. Sulnick

Huntington Oil Spill: Task Force Recommendations

By Bill Holmes

The Clean Coastal Waters Task Force was one of the few groups at the State Lands Commission hearings on March 7 to present tangible recommendations for reducing the impact of future oil spills. When Chairman Gray Davis asked for recommendations for the future, the representatives of the US Coast Guard, the Department of Fish and Game and the Clean Coastal Waters oil industry co-operative were unable to contribute anything. In contrast, our Task Force contended that until the Bush Administration and the US Congress establish a National Energy policy to reduce our dependency on non-renewable sources of energy, risks of tanker oil spills can be reduced in a number of ways:

PREVENTION

1) Establish five mile wide Shipping Safety Lanes along the coast of California as proposed by the US Coast Guard in 1982 and monitor the safety of these lanes.

2) Require all oil tankers entering the California 3 mile zone to be double hulled. This would have prevented the American Trader's anchor from penetrating the oil compartment.

3) Stop the issuance and renewal of Offshore Spread Mooring permits. Harbors are a much safer place for unloading oil.

4) Drastically tighten up regulations pertaining to the operation of an Offshore Spread Mooring by:

a) Setting minimum clearance standards from the bottom of the tanker to the sea floor in the vicinity of a mooring. The American Trader was over 800 feet long with an "average" depth beneath it's hull of less than 15 feet.

b) Prohibiting the unloading of oil in weather conditions that would prevent containment of the oil if a spill was to occur.

c) Approving the stalled legislation granting the State Lands Commission authority to inspect moorings to enforce regulations.

CONTAINMENT

1) Require all tankers to carry sufficient containment booms to hold in place a spill of at least 25% of cargo. Only 2250 feet of containment boom was set in place around the American Trader, not nearly enough to contain a spill of 400,000 gallons (less than 2% of total cargo).

2) Fund research into containment boom technology that will contain oil spills even in high swells. Currently booms are next to useless in anything above a two foot swell (occurring 90% of the time in Southern California).

CLEAN UP

1) Require sufficient skimmers on hand at each Oil Spill Response Center to be capable of cleaning up 100,000

Spill, *continued on page five*

What's Inside:

In it's mysterious past [the ocean] encompasses all the dim origins of life and receives in the end, after, it may be, many transmutations, the dead husks of that same life. For all at last returns to the sea—to Oceanus, the ocean river, like the ever-flowing stream of time, the beginning and the end.

---Rachel Louise Carson, 1907-1964

Rainstorms & Ocean Pollution

Rainstorms in Los Angeles bring much needed water to the LA basin but unfortunately the storm water rushing through drains carries pollution from all over the county to the ocean. A heavy rain often leaves the Los Angeles River and Ballona Creek, two of LA County's principal drainages, carpeted with floating plastic debris washed from streets and roadsides. Storm water scours the paved surfaces and erodible soil at construction sites and carries oil, grease and suspended solids contaminated with heavy metals to wetlands, beaches and the ocean. During heavy storms the total flow and pollutant loading of surface runoff is typically comparable with daily municipal waste water discharges from county sewage treatment facilities.

Storm water is only part of the story since it accounts for about 70% of total annual surface runoff. Outside of the rainy season, a "dry flow," comprised of pavement runoff from irrigation and domestic washdown, permitted commercial and industrial discharges, treated municipal wastewater, and illicit discharges, empties into the ocean. Storm drain effluent is probably the second largest source of pollution to the coast after municipal wastewater discharges. Improvements in contamination levels of sewage effluents from Los Angeles County treatment plants has proportionally increased the contribution of total contaminants to the coast from storm drain effluent. Oil, grease, pesticides, trace metals and coliform bacteria are all contaminants of concern found in storm water. Since storm channels discharge on or near the coast, their impact on surf zone and intertidal ecosystems are probably greater than that of municipal wastewater which is released miles offshore through outfalls.

The full impact of contaminated stormwater on marine resources is very difficult to assess since the sources of pollution are so diverse. Contaminant concentrations during storms vary with the flow level. Consequently, adequate measurements of pollutant flow require extensive sampling throughout the duration of the storm at multiple drainages. Harder still than accurately measuring the amount of contaminants is determination of a particular source's share of the impacts upon marine resources.

Partially because of the difficulty in gathering data on non-point source pollution, the EPA has largely ignored surface runoff contamination while regulating municipal waste water discharges. Soon this situation will change. Late this summer, EPA will issue final Federal Storm Water Regulations requiring permits for the discharge of surface runoff into "the waters of the United States." To facilitate earlier compliance and greater flexibility the EPA has encouraged the L.A. basin to seek an "early permit" prior to EPA's issuance of final regulations. By drafting an early permit - which still would need to be approved by the EPA - the County and all other municipalities would be able to join in the drafting of a plan tailored to LA's needs. The alternative is to seek permits under the evolving complex regulatory structure covering the entire country. Drafting an early permit is a good faith approach to expeditiously begin controlling surface runoff contamination.

The Santa Monica Bay Restoration Project has taken a leading role in encouraging and facilitating the drafting of a storm water permit in Los Angeles since it can provide the forum for all interested parties to participate. A tentative draft has been completed and public hearings are expected to be held in April at the California Regional Water Quality Control Board.

The draft stipulates phased implementation broken down by watershed in Los Angeles County. The Santa Monica Bay watershed would come under regulation first on July 1, 1990 to be followed by the upper San Gabriel River and upper Los Angeles River drainage basins on July 1, 1992. Finally on July 1, 1993, the lower Los Angeles and San Gabriel River basins plus the Santa Clarita Valley would enter compliance.

Provisions of the permit require permittees to survey and document existing knowledge about water flow patterns, water quality and precipitation. Documentation of existing procedures for the control of stormwater runoff at construction sites and the detection of illegal disposal practices is also required in the first year. Under the permit, best management practices (BMP's) for the prevention or reduction of stormwater pollution would be identified and implemented. Monitoring programs for the detection of illegal discharges would also be implemented. The permittee is required to demonstrate that adequate public input has been obtained prior to gaining approval of required workplans from the Executive Officer of the State Regional Water Resources Quality Control Board.

Although change will not be immediate, good faith efforts from all parties will bring us improvements in storm drain effluent quality much faster under the early permit than we might expect under the emerging EPA regulations. The permit should be modified to require the approval of the entire Water Resources Quality Control Board rather than just the Executive Officer. With this modification, the requirements for demonstration of adequate public input concerning implementation of the permit will provide public interest environmental organizations like the Sierra Club and Heal the Bay the opportunity to monitor and influence measures to clean up stormwater effluent in Los Angeles County.

Santa Monica BAY Restoration PROJECT

101 Centre Plaza Drive
Monterey Park, CA 91754
213/266-7500
Fax 213/266-7600

Dear Dr. Ghirelli:

At its May 24th, 1990 meeting, the Santa Monica Bay Restoration Project Management Committee voted its unanimous support for the Los Angeles County Stormwater/Urban Runoff permit before the Board on June 18th.

The forty-eight member Management Committee is composed of key organizations and individuals embodying the many constituencies of the Bay including environmental groups; dischargers; recreational interest groups; elected officials representing the Bay watershed at the local, state, and federal level; and regulatory agency leaders at the local, state and federal level.

A major objective of the Santa Monica Bay Restoration Project is to reduce stormwater pollution to the Bay. In meeting this objective, the Project was pleased to play a key role in assessing the feasibility of a stormwater management permit, and in negotiating the substance of the permit.

The permit represents a significant commitment on the part of Los Angeles County and the cities within the County to manage stormwater and urban runoff problems that affect not only Santa Monica Bay, but also other valuable water bodies in the County.

Thank you again for your leadership on this important issue! We look forward to the permit's issuance and the beginning of an effective stormwater management program in Los Angeles County.

Sincerely,

Catherine Tyrrell for

TED FINSTER, Co-Chair
Santa Monica Bay Restoration Project
and Member, State Water Resources Control Board

Robert Ghirelli
Executive Officer
California Regional Water Quality
Control Board, Los Angeles Region
101 Centre Plaza Drive
Monterey Park, CA 91754-2156

Dear Mr. Ghirelli:

The purpose of this letter is to summarize Region 9's position with respect to your current efforts to issue an NPDES permit for municipal stormwater discharges in the Los Angeles area prior to promulgation of EPA's permit application regulations.

As you will recall, an initial draft permit for stormwater was prepared by Regional Board staff in November, 1989 and Region 9 expressed certain concerns regarding this permitting activity in a letter from Harry Seraydarian to you dated November 16, 1989. Subsequently, a series of meetings was held to discuss stormwater permitting which involved the City and County of Los Angeles, representatives of the State Board, the Los Angeles Regional Board and Region 9. The initial draft permit was revised several times as a result of the discussions.

We believe that with some relatively minor modifications, the latest draft (Revision #6 dated February 8, 1990) is approvable by Region 9. Two of our major concerns with previous drafts have been the timetable for implementation of the permit requirements and the provisions for public participation in the decision-making.

The latest draft permit adequately addresses our concern regarding the timetable for implementation of the permit requirements. In the implementation schedule for each geographic area, the latest draft permit requires submittal within 2 years (rather than 3) of the plan to reduce pollutant discharges to the "maximum extent practicable." This is now similar to EPA's proposed regulations which would require submittal of a stormwater management plan within 2 years. Of course, we are still concerned that implementation would be delayed for certain areas of the County. However, given the size of the area being

17434

permitted, we believe that the implementation timetable is acceptable.

With regards to public participation, we would prefer that the Board (rather than the County as proposed) provide for the necessary public participation in the development of the various plans which are required by the permit. However, we could concur with your proposal if certain minimum requirements are specified regarding an adequate demonstration of public participation by the County. In its submittal to the Board, the County should demonstrate for each plan that:

1) a public meeting was held to discuss the plan,
2) notice of the meeting was widely disseminated to the public at large, environmental groups, Federal, State and local officials and other interested parties, and
3) the concerns expressed by the public were addressed by the County. If concerns were raised which were not addressed, the County should provide reasons why these concerns were not addressed.

In addition, the permit should include a statement which requires implementation of the plans after approval/modification by the Regional Board.

In a separate letter to Catherine Tyrrell dated February 9, 1990, we also suggested some minor editorial changes to the permit.

Let me emphasize in closing that Region 9 supports your efforts to issue an NPDES permit for stormwater runoff in the Los Angeles area as soon as possible. We believe that this action will expedite the overall efforts to address existing water quality degradation in the Los Angeles area (and particularly in the sensitive Santa Monica Bay area) which is caused at least in part by pollutants in stormwater runoff.

Should you have any questions, please call me at (415) 705-2079 or refer your staff to Eugene Bromley of the Sludge, Pretreatment and Stormwater Section at (415) 705-2160.

Sincerely,

Keith Takata

STATE WATER RESOURCES CONTROL BOARD
RESOLUTION NO. 90-27

APPROVAL OF AMENDMENT TO THE
WATER QUALITY CONTROL PLAN FOR OCEAN WATERS OF CALIFORNIA
(CALIFORNIA OCEAN PLAN)

WHEREAS:

1. The State Water Resources Control (State Board) adopted the Ocean Plan on July 6, 1972 and revised the plan in 1978, 1983, and 1988.
2. The State Board may adopt water quality control plans for waters for which water quality standards are required by the Federal Clean Water Act in accordance with California Water Code Section 13170.
3. The State Board is responsible for reviewing Ocean Plan water quality standards and for modifying and adopting standards in accordance with Section 303(c)(1) of the Federal Clean Water Act and Section 13170.2(b) of the California Water Code.
4. The State Board has considered relevant management agency agreements in accordance with Section 13170.1 of the California Water Code.
5. Additional information pertinent to water quality objectives for dioxin and related compounds is being developed and reviewed by the scientific community.
6. The State Board prepared and circulated a draft Function Equivalent Document in accordance with the provisions of the California Environmental Quality Act and Title 14, California Code of Regulations 15251(g).
7. The State Board conducted a public hearing in Torrance on August 29, 1989 to solicit comments regarding the proposed amendments of the Ocean Plan and has reviewed and considered carefully all comments and testimony received. The State Board considered the information contained in the Functional Equivalent Document prior to approval of the California Ocean Plan.
8. The California Ocean Plan as approved will not have a significant adverse effect on the environment.

THEREFORE BE IT RESOLVED:

1. That the State Board approves the Functional Equivalent Document for the amendment of the Water Quality Control Plan for Ocean Waters of California.
2. That the State Board hereby adopts amendments to the California Ocean Plan (attached).

3. That the State Board authorizes the Executive Director, or his designee, to transmit the Plan to the U.S. Environmental Protection Agency, Region 9 in compliance with Section 303(c)(1) of the Clean Water Act.

4. That the State Board directs its staff to review the water quality objective for dioxin and related compounds as soon as possible within the next triennial review period.

5. That the State Board declares its intent to require continual monitoring of the marine environment to assure that the Plan reflects the latest available data and that the water quality objectives are adequate to fully protect indigenous marine species and to protect human health.

CERTIFICATION

The undersigned Administrative Assistant to the Board, does hereby certify that the foregoing is a full, true, and correct copy of a resolution duly and regularly adopted at a meeting of the State Water Resources Control Board held on March 22, 1990.

VOL 12

CALIFORNIA OCEAN PLAN

WATER QUALITY CONTROL PLAN FOR OCEAN WATERS OF CALIFORNIA

INTRODUCTION

In furtherance of legislative policy set forth in Section 13000 of Division 7 of the California Water Code (Stats. 1969, Chap. 482) pursuant to the authority contained in Section 13170 and 13170.2 (Stats. 1971, Chap. 1288) the State Water Resources Control Board hereby finds and declares that protection of the quality of the ocean* waters for use and enjoyment by the people of the State requires control of the discharge of waste* to ocean* waters in accordance with the provisions contained herein. The Board finds further that this plan shall be reviewed at least every three years to guarantee that the current standards are adequate and are not allowing degradation* to marine species or posing a threat to public health.

This plan is applicable, it its entirety, to point source discharges to the ocean*. Nonpoint sources of waste* discharges to the ocean* are subject to Chapter I Beneficial Uses, Chapter II - Water Quality Objectives, Chapter III -General Requirements, Chapter IV - Table B (wherein compliance with water quality objectives shall, in all cases, be determined by direct measurements in the receiving waters) and Chapter V - Discharge Prohibitions.

This plan is not applicable to discharges to enclosed* bays and estuaries* or inland waters nor is it applicable to vessel wastes, or the control of dredging spoil.

Provisions regulating the thermal aspects of waste* discharged to the ocean* are set forth in the Water Quality Control Plan for the Control of Temperature in the Coastal and Interstate Waters and Enclosed* Bays and Estuaries* of California.

Chapter I
BENEFICIAL USES

The beneficial uses of the ocean* waters of the State that shall be protected include industrial water supply, water contact and non-contact recreation, including aesthetic enjoyment, navigation, commercial and sport fishing, mariculture*, preservation and enhancement of Areas of Special Biological Significance, rare and endangered species, marine habitat, fish migration, fish spawning and shellfish* harvesting.

Chapter II
WATER QUALITY OBJECTIVES

This chapter sets forth limits or levels of water quality characteristics for ocean* waters to ensure the reasonable protection of beneficial uses and the prevention of nuisance. The discharge of waste* shall not cause violation of these objectives.

The Water Quality Objectives and Effluent Quality Requirements are defined by a statistical distribution when appropriate. This method recognizes the normally occurring variations in treatment efficiency and sampling and analytical techniques and does not condone poor operating practices.

1 7442

---

* See Appendix I for definition of terms.

Compliance with the water quality objectives of this chapter shall be determined from samples collected at stations representative of the area within the waste field where initial* dilution is completed.

A. Bacterial Characteristics

1. Water-Contact Standards

Within a zone bounded by the shoreline and a distance of 1,000 feet from the shoreline or the 30-foot depth contour, whichever is further from the shoreline, and in areas outside this zone used for water contact sports, as determined by the Regional Board, but including all kelp* beds, the following bacterial objectives shall be maintained throughout the water column:

a. Samples of water from each sampling station shall have a density of total coliform organisms less than 1,000 per 100 ml (10 per ml); provided that not more than 20 percent of the samples at any sampling station, in any 30-day period, may exceed 1,000 per 100 ml (10 per ml), and provided further that no single sample when verified by a repeat sample taken within 48 hours shall exceed 10,000 per 100 ml (100 per ml).

b. The fecal coliform density based on a minimum of not less than five samples for any 30-day period, shall not exceed a geometric mean of 200 per 100 ml nor shall more than 10 percent of the total samples during any 60-day period exceed 400 per 100 ml.

The "Initial* Dilution Zone" of wastewater outfalls shall be excluded from designation as "kelp* beds" for purposes of bacterial standards, and Regional Boards should recommend extension of such exclusion zone where warranted to the State Board (for consideration under Chapter VI.F.). Adventitious assemblages of kelp plants on waste discharge structures (e.g., outfall pipes and diffusers) do not constitute kelp* beds for purposes of bacterial standards.

2. Shellfish* Harvesting Standards

At all areas where shellfish* may be harvested for human consumption, as determined by the Regional Board, the following bacterial objectives shall be maintained throughout the water column:

The median total coliform density shall not exceed 70 per 100 ml, and not more than 10 percent of the samples shall exceed 230 per 100 ml.

B. Bacterial Assessment and Remedial Action Requirements

The requirements listed below shall be used to 1) determine the occurrence and extent of any impairment of a beneficial use due to bacterial contamination; 2) generate information which can be used in the development of an enterococcus standard; and 3) provide the basis for remedial actions necessary to minimize or eliminate any impairment of a beneficial use.

---

* See Appendix I for definition of terms.

VOL 12

1743

R0050748

Measurement of enterococcus density shall be conducted at all stations where measurement of total and fecal coliforms are required. In addition to the requirements of Section II.A.1., if a shore station consistently exceeds a coliform objective or exceeds a geometric mean enterococcus density of 24 organisms per 100 ml for a 30-day period or 12 organisms per 100 ml for a six-month period, the Regional Board shall require the appropriate agency to conduct a survey to determine if that agency's discharge is the source of the contamination. The geometric mean shall be a moving average based on no less than five samples per month, spaced evenly over the time interval. When a sanitary survey identifies a controllable source of indicator organisms associated with a discharge of sewage, the Regional Board shall take action to control the source.

Waste discharge requirements shall require the discharger to conduct sanitary surveys when so directed by the Regional Board. Waste discharge requirements shall contain provisions requiring the discharger to control any controllable discharges identified in a sanitary survey.

C. <u>Physical Characteristics</u>

1. Floating particulates and grease and oil shall not be visible.
2. The discharge of waste* shall not cause aesthetically undesirable discoloration of the ocean* surface.
3. Natural* light shall not be significantly* reduced at any point outside the initial* dilution zone as the result of the discharge of waste*.
4. The rate of deposition of inert solids and the characteristics of inert solids in ocean* sediments shall not be changed such that benthic communities are degraded*.

D. <u>Chemical Characteristics</u>

1. The dissolved oxygen concentration shall not at any time be depressed more than 10 percent from that which occurs naturally, as the result of the discharge of oxygen demanding waste* materials.
2. The pH shall not be changed at any time more than 0.2 units from that which occurs naturally.
3. The dissolved sulfide concentration of waters in and near sediments shall not be significantly* increased above that present under natural conditions.
4. The concentration of substances set forth in Chapter IV, Table B, in marine sediments shall not be increased to levels which would degrade* indigenous biota.
5. The concentration of organic materials in marine sediments shall not be increased to levels which would degrade* marine life.
6. Nutrient materials shall not cause objectionable aquatic growths or degrade* indigenous biota.

---

* See Appendix I for definition of terms.

VOL 12

17444

E. Biological Characteristics

1. Marine communities, including vertebrate, invertebrate, and plant species, shall not be degraded*.

2. The natural taste, odor, and color of fish, shellfish*, or other marine resources used for human consumption shall not be altered.

3. The concentration of organic materials in fish, shellfish* or other marine resources used for human consumption shall not bioaccumulate to levels that are harmful to human health.

F. Radioactivity

1. Discharge of radioactive waste* shall not degrade* marine life.

Chapter III
GENERAL REQUIREMENTS FOR MANAGEMENT OF
WASTE* DISCHARGE TO THE OCEAN*

A. Waste* management systems that discharge to the ocean* must be designed and operated in a manner that will maintain the indigenous marine life and a healthy and diverse marine community.

B. Waste discharged* to the ocean* must be essentially free of:

1. Material that is floatable or will become floatable upon discharge.

2. Settleable material or substances that may form sediments which will degrade* benthic communities or other aquatic life.

3. Substances which will accumulate to toxic levels in marine waters, sediments or biota.

4. Substances that significantly* decrease the natural* light to benthic communities and other marine life.

5. Materials that result in aesthetically undesirable discoloration of the ocean* surface.

C. Waste* effluents shall be discharged in a manner which provides sufficient initial* dilution to minimize the concentrations of substances not removed in the treatment.

D. Location of waste* discharges must be determined after a detailed assessment of the oceanographic characteristics and current patterns to assure that:

1. Pathogenic organisms and viruses are not present in areas where shellfish* are harvested for human consumption or in areas used for swimming or other body-contact sports.

* See Appendix I for definition of terms.

VOL 12

1745

2. Natural water quality conditions are not altered in areas designated as being of special biological significance or areas that existing marine laboratories use as a source of seawater.

3. Maximum protection is provided to the marine environment.

Waste* that contains pathogenic organisms or viruses should be discharged a sufficient distance from shellfishing* and water-contact sports areas to maintain applicable bacterial standards without disinfection. Where conditions are such that an adequate distance cannot be attained, reliable disinfection in conjunction with a reasonable separation of the discharge point from the area of use must be provided. Disinfection procedures that do not increase effluent toxicity and that constitute the least environmental and human hazard should be used.

Chapter IV
QUALITY REQUIREMENTS FOR WASTE* DISCHARGES (EFFLUENT QUALITY REQUIREMENTS)

This chapter sets forth the quality requirements for waste* discharge to the ocean*.

Table A limitations apply only to publicly owned treatment works and industrial discharges for which Effluent Limitations Guidelines have not been established pursuant to Sections 301, 302, 304, or 306 of the Federal Clean Water Act.

Table B limitations apply to all discharges within the jurisdiction of this plan.

Table A limitations, and effluent concentrations calculated from Table B limitations, shall apply to a discharger's total effluent, of whatever origin (i.e. gross, not net, discharge), except where otherwise specified in this Plan.

The State Board is authorized to administer and enforce effluent requirements established pursuant to the Federal Clean Water Act. Effluent limitations established under Sections 301, 302, 306, 307, 316, 403, and 405 of the aforementioned Federal Act and administrative procedures pertaining thereto, are included in this plan by reference. Compliance with Table A limitations, or Environmental Protection Agency Effluent Limitations Guidelines for industrial discharges, based on Best Practicable Control Technology, shall be the minimum level of treatment acceptable under this plan, and shall define reasonable treatment and waste control technology.

* See Appendix I for definition of terms.

VOL 12

17446

TABLE A
MAJOR WASTEWATER CONSTITUENTS AND PROPERTIES

	Unit of measurement	Limiting Concentrations: Monthly (30 day Average)	Weekly (7 day Average)	Maximum at any time
Grease and Oil	mg/l	25	40	75
Suspended Solids			see below+	
Settleable Solids	ml/l	1.0	1.5	3.0
Turbidity	NTU	75	100	225
pH	units		within limits of 6.0 to 9.0 at all times	
Acute* Toxicity	TUa	1.5	2.0	2.5

+Suspended Solids: Dischargers shall, as a 30-day average, remove 75% of suspended solids from the influent stream before discharging wastewaters to the ocean*, except that the effluent limitation to be met shall not be lower than 60 mg/l. Regional Boards may recommend that the State Board (Chapter VI.F.), with the concurrence of the Environmental Protection Agency, adjust the lower effluent concentration limit (the 60 mg/l above) to suit the environmental and effluent characteristics of the discharge. As a further consideration in making such recommendation for adjustment, Regional Boards should evaluate effects on existing and potential water* reclamation projects.

If the lower effluent concentration limit is adjusted, the discharger shall remove 75% of suspended solids from the influent stream at any time the influent concentration exceeds four times such adjusted effluent limit.

Effluent limitations shall be imposed in a manner prescribed by the State Board such that the concentrations set forth below as water quality objectives shall not be exceeded in the receiving water upon completion of initial* dilution, except that limitations indicated for radioactivity shall apply directly to the undiluted waste* effluent.

* See Appendix I for definition of terms.

TABLE B
TOXIC MATERIALS LIMITATIONS

	Units of Measurement	Limiting Concentrations: 6-Month Median	Daily Maximum	Instantaneous Maximum
OBJECTIVES FOR PROTECTION OF MARINE AQUATIC LIFE				
Arsenic	ug/l	8	32	80
Cadmium	ug/l	1	4	10
Chromium (Hexavalent) (see below, a)	ug/l	2	8	20
Copper	ug/l	3	12	30
Lead	ug/l	2	8	20
Mercury	ug/l	0.04	0.16	0.4
Nickel	ug/l	5	20	50
Selenium	ug/l	15	60	150
Silver	ug/l	0.7	2.8	7
Zinc	ug/l	20	80	200
Cyanide (see below, b)	ug/l	1	4	10
Total Chlorine Residual (For intermittent chlorine sources, see below, c)	ug/l	2	8	60
Ammonia (expressed as nitrogen)	ug/l	600	2400	6000
Chronic* Toxicity	TUc		1	
Phenolic Compounds (non-chlorinated)	ug/l	30	120	300
Chlorinated Phenolics	ug/l	1	4	10
Endosulfan	ng/l	9	18	27
Endrin	ng/l	2	4	6
HCH*	ng/l	4	8	12
Radioactivity	Not to exceed limits specified in Title 22, Chapter 15, Article 4, Section 64443 of the California Code of Regulations.			

* See Appendix I for definition of terms.

Table B Continued

Chemical	Units of Measurement	30-day Average
OBJECTIVES FOR PROTECTION OF HUMAN HEALTH -- NONCARCINOGENS

tetrachloroethylene	ug/l	99
toxaphene	ng/l	0.21
trichloroethylene	ug/l	27
2,4,6-trichlorophenol	ug/l	0.29
vinyl chloride	ug/l	36

a) Dischargers may at their option meet this limitation as a total chromium limitation.

b) If a discharger can demonstrate to the satisfaction of the Regional Board (subject to EPA approval) that an analytical method is available to reliably distinguish between strongly and weakly complexed cyanide, effluent limitations for cyanide may be met by the combined measurement of free cyanide, simple alkali metal cyanides, and weakly complexed organometallic cyanide complexes. In order for the analytical method to be acceptable, the recovery of free cyanide from metal complexes must be comparable to that achieved by Standard Methods 412F, G, and H (Standard Methods for the Examination of Water and Wastewater. Joint Editorial Board, American Public Health Association, American Water Works Association, and Water Pollution Control Federation. Most recent edition.).

c) Water quality objectives for total chlorine residual applying to intermittent discharges not exceeding two hours, shall be determined through the use of the following equation:

$$\log y = -0.43 (\log x) + 1.8$$

where: y = the water quality objective (in ug/l) to apply when chlorine is being discharged;
x = the duration of uninterrupted chlorine discharge in minutes.

---

* See Appendix I for definition of terms.

Implementation Provisions for Table B

A. Calculation of Effluent Limitations

Effluent limitations for parameters identified in Table B with the exception of Radioactivity, shall be determined through the use of the following equation:

$$Ce = Co + Dm\,(Co - Cs) \quad (1)$$

where:

Ce = the effluent concentration limit,
Co = the concentration to be met at the completion of initial* dilution,
Cs = background seawater concentration (see Table C below),
Dm = minimum probable initial* dilution expressed as parts seawater per part wastewater.

For the purpose of this Plan, minimum initial dilution is the lowest average initial dilution within any single month of the year. Dilution estimates shall be based on observed waste flow characteristics, observed receiving water density structure, and the assumption that no currents, of sufficient strength to influence the initial dilution process, flow across the discharge structure.

The Executive Director of the State Board shall identify standard dilution models for use in determining Dm, and shall assist the Regional Board in evaluating Dm for specific waste discharger. Dischargers may propose alternative methods of calculating Dm, and the Regional Board may accept such method upon verification of its accuracy and applicability.

TABLE C
BACKGROUND SEAWATER CONCENTRATIONS (Cs)

Waste Constituent	Cs (ug/l)
Arsenic	3
Copper	2
Mercury	0.0005
Silver	0.16
Zinc	8

For all other Table B parameters, Cs = 0.

The six-month median effluent concentration limit shall apply as a moving median of daily values for any 180 day period in which daily values represent flow weighted

* See Appendix I for definition of terms.

VOL 12

17451

average concentrations within a 24-hour period. For intermittent discharges, the daily value shall be considered to equal zero for days on which no discharge occurred.

The daily maximum effluent concentration limit shall apply to flow weighted 24 hour composite samples.

The instantaneous maximum shall apply to grab sample determinations.

If only one sample is collected during the time period associated with the water quality objective (e.g., 30-day average or 6-month median), the single measurement shall be used to determine compliance with the effluent limitation for the entire time period.

Discharge requirements shall also specify effluent requirements in terms of mass emission rate limits utilizing the general formula:

$$lbs/day = 8.34 \times Ce \times Q \quad (2)$$

The six-month median limit on daily mass emissions shall be determined using the six-month median effluent concentration as Ce and the observed flow rate Q in millions of gallons per day. The daily maximum mass emission shall be determined using the daily maximum effluent concentration limit as Ce and the observed flow rate Q in millions of gallons per day.

Any significant change in waste* flow shall be cause for reevaluating effluent quality requirements.

B. Compliance Determination

All analytical data shall be reported uncensored with detection limits and quantitation limits identified. For any effluent limitation, compliance shall be determined using appropriate statistical methods to evaluate multiple samples. Compliance based on a single sample analysis should be determined where appropriate as described below.

When a calculated effluent limitation is greater than or equal to the PQL*, compliance shall be determined based on the calculated effluent limitation and either single or multiple sample analyses.

When the calculated effluent limitation is below the PQL*, compliance determinations based on analysis of a single sample shall only be undertaken if the concentration of the constituent of concern in the sample is greater than or equal to the PQL*.

When the calculated effluent limitation is below the PQL* and recurrent analytical responses between the PQL* and the calculated limit occur, compliance shall be determined by statistical analysis of multiple samples. Sufficient sampling and analysis shall be required to determine compliance.

Published values for MDL*s and PQL*s should be used except where revised MDL*s and PQL*s are available from recent laboratory performance evaluations, in which case the

* See Appendix I for definition of terms.

VOL 12

1 7452

R0050757

revised MDL*s and PQL*s should be used. Where published values are not available the Regional Boards should determine appropriate values based on available information.

If a discharger believes the sample matrix under consideration in the waste discharge requirements is sufficiently different from that used for an established MDL* value, the discharger may demonstrate to the satisfaction of the Regional Board what the appropriate MDL* should be for the discharger's matrix. In this case the PQL* shall be established at the limit of quantitation (equal to 10 standard deviations above the average measured blank used for development of the MDL* in the discharger's matrix).

When determining compliance based on a single sample, with a single effluent limitation which applies to a group of chemicals (e.g., PCBs) concentrations of individual members of the group may be considered to be zero if the analytical response for individual chemicals falls below the MDL* for that parameter.

Due to the large total volume of powerplant and other heat exchange discharges, special procedures must be applied for determining compliance with Table B limitations on a routine basis. Effluent concentration values (Ce) shall be determined through the use of equation 1 considering the minimal probable initial* dilution of the combined effluent (in-plant waste streams plus cooling water flow). These concentration values shall then be converted to mass emission limitations as indicated in equation 2. The mass emission limits will then serve as requirements applied to all inplant waste* streams taken together which discharge into the cooling water flow, except that limitations on total chlorine residual, chronic* toxicity and instantaneous maximum limitations on Table B toxic materials shall apply to, and be measured in, the combined final effluent, as adjusted for dilution with ocean water. The Table B limitation on radioactivity shall apply to the undiluted combined final effluent.

C. **Toxicity Reduction Requirements**

If a discharge consistently exceeds an effluent limitation based on a toxicity objective in Table B, a toxicity reduction evaluation (TRE) is required. The TRE shall include all reasonable steps to identify the source of toxicity. Once the source(s) of toxicity is identified, the discharger shall take all reasonable steps necessary to reduce toxicity to the required level.

The following shall be incorporated into waste discharge requirements: (1) a requirement to conduct a TRE if the discharge consistently exceeds its toxicity effluent limitation, and (2) a provision requiring a discharger to take all reasonable steps to reduce toxicity once the source of toxicity is identified.

---

* See Appendix I for definition of terms.

VOL 12

17453

R0050758

Chapter V
DISCHARGE PROHIBITIONS

A. Hazardous Substances

The discharge of any radiological, chemical, or biological warfare agent or high-level radioactive waste* into the ocean* is prohibited.

B. Areas of Special Biological Significance

Waste* shall not be discharged to areas designated as being of special biological significance. Discharges shall be located a sufficient distance from such designated areas to assure maintenance of natural water quality conditions in these areas.

C. Sludge

Pipeline discharge of sludge to the ocean* is prohibited by federal law; the discharge of municipal and industrial waste* sludge directly to the ocean*, or into a waste* stream that discharges to the ocean*, is prohibited by this Plan. The discharge of sludge digester supernatant directly to the ocean*, or to a waste* stream that discharges to the ocean* without further treatment, is prohibited.

It is the policy of the State Board that the treatment, use and disposal of sewage sludge shall be carried out in the manner found to have the least adverse impact on the total natural and human environment. Therefore, if federal law is amended to permit such discharge, which could affect California waters, the State Board may consider requests for exceptions to this section under Chapter VI, F. of this Plan, provided further that an Environmental Impact Report on the proposed project shows clearly that any available alternative disposal method will have a greater adverse environmental impact than the proposed project.

D. By-Passing

The by-passing of untreated wastes* containing concentrations of pollutants in excess of those of Table A or Table B to the ocean* is prohibited.

Chapter VI
GENERAL PROVISIONS

A. Effective Date

This Plan is in effect as of the date of adoption by the State Water Resources Control Board.

* See Appendix I for definition of terms.

B. Waste Discharge Requirements

The Regional Boards may establish more restrictive water quality objectives and effluent quality requirements than those set forth in this Plan as necessary for the protection of beneficial uses of ocean* waters.

Regional Boards may impose alternative less restrictive provisions than those contained within Table B of the Plan, provided an applicant can demonstrate that:

Reasonable control technologies (including source control, material substitution, treatment and dispersion) will not provide for complete compliance; or

Any less stringent provisions would encourage water* reclamation;

Provided further that:

a) Any alternative water quality objectives shall be below the conservative estimate of chronic toxicity, as given in Table D below, and such alternative will provide for adequate protection of the marine environment;

b) A receiving water toxicity* objective of 1 TUc is not exceeded; and

c) The State Board grants an exception (Chapter VI.F.) to the Table B limits as established in the Regional Board findings and alternative limits.

TABLE D
CONSERVATIVE ESTIMATES OF CHRONIC TOXICITY

Constituent	Estimate of Chronic Toxicity (ug/l)
Arsenic	19
Cadmium	8
Hexavalent Chromium	18
Copper	5
Lead	22
Mercury	0.4
Nickel	48
Silver	3
Zinc	51
Cyanide	10
Total Chlorine Residual	10.0
Ammonia	4,000.0
Phenolic Compounds (non-chlorinated)	a)(see below)
Chlorinated Phenolics	a)
Chlorinated Pesticides and PCB's	b)

* See Appendix I for definition of terms.

VOL 12 17455

a. There is insufficient data for phenolics to estimate chronic toxicity levels. Requests for modification of water quality objectives for these waste* constituents must be supported by chronic toxicity data for representative sensitive species. In such cases, applicants seeking modification of water quality objectives should consult the Regional Water Quality Control Board to determine the species and test conditions necessary to evaluate chronic effects.

b. Limitations on chlorinated pesticides and PCB's shall not be modified so that the total of these compounds is increased above the limitations in Table B (6-Month Median = 31 ng/l, Daily Maximum = 62 ng/l, and Instantaneous Maximum = 93 ng/l).

C. Revision of Waste* Discharge Requirements

The Regional Board shall revise the waste* discharge requirements for existing discharges as necessary to achieve compliance with this Plan and shall also establish a time schedule for such compliance.

D. Monitoring Program

The Regional Boards shall require dischargers to conduct self-monitoring programs and submit reports necessary to determine compliance with the waste* discharge requirements, and may require dischargers to contract with agencies or persons acceptable to the Regional Board to provide monitoring reports. Monitoring provisions contained in waste discharge requirements shall be in accordance with the Monitoring Procedures provided in Appendix II.

Where the Regional Board is satisfied that any substance(s) of Table B will not significantly occur in a discharger's effluent, the Regional Board may elect not to require monitoring for such substance(s), provided the discharger submits periodic certification that such substance(s) are not added to the waste* stream, and that no change has occurred in activities that could cause such substance(s) to be present in the waste* stream. Such election does not relieve the discharger from the requirement to meet the limitations of Table B.

The Regional Board may require monitoring of bioaccumulation of toxicants in the discharge zone. Organisms and techniques for such monitoring shall be chosen by the Regional Board on the basis of demonstrated value in waste* discharge monitoring.

E. Areas of Special Biological Significance

Areas of special biological significance shall be designated by the State Board after a public hearing by the Regional Board and review of its recommendations.

F. State Board Exceptions to Plan Requirements

The State Board may, in compliance with the California Environmental Quality Act, subsequent to a public hearing, and with the concurrence of the Environmental Protection Agency, grant exceptions where the Board determines:

* See Appendix I for definition of terms.

VOL 12

1 7456

1. The exception will not compromise protection of ocean* waters for beneficial uses, and

2. The public interest will be served.

* See Appendix 1 for definition of terms.

VOL 12

1 7457

APPENDIX I

DEFINITION OF TERMS

ACUTE TOXICITY

a. Acute Toxicity (TUa)

Expressed in Toxic Units Acute (TUa)

TUa = 100/96-hr LC 50%

b. Lethal Concentration 50% (LC 50)

LC 50 (percent waste giving 50% survival of test organisms) shall be determined by static or continuous flow bioassay techniques using standard test species. If specific identifiable substances in wastewater can be demonstrated by the discharger as being rapidly rendered harmless upon discharge to the marine environment, but not as a result of dilution, the LC 50 may be determined after the test samples are adjusted to remove the influence of those substances.

When it is not possible to measure the 96-hour LC 50 due to greater than 50 percent survival of the test species in 100 percent waste, the toxicity concentration shall be calculated by the expression:

$$TUa = \frac{\log(100 - S)}{1.7}$$

S = percentage survival in 100% waste. If S > 99, TUa shall be reported as zero.

CHLORDANE shall mean the sum of chlordane-alpha, chlordane-gamma, chlordene-alpha, chlordene-gamma, nonachlor-alpha, nonachlor-gamma, and oxychlordane.

CHRONIC TOXICITY: This parameter shall be used to measure the acceptability of for waters supporting a healthy marine biota until improved methods are developed to evaluate biological response.

a. Chronic Toxicity (TUc)

Expressed as Toxic Units Chronic (TUc)

TUc = 100/NOEL

b. No Observed Effect Level (NOEL)

The NOEL is expressed as the maximum percent effluent or receiving water that causes no observable effect on a test organism, as determined by the result of a critical life stage toxicity test listed in Appendix II.

---

* See Appendix I for definition of terms.

VOL 12

17458

DDT shall mean the sum of 4,4'DDT, 2,4'DDT, 4,4'DDE, 2,4'DDE, 4,4'DDD, and 2,4'DDD.

DEGRADE: Degradation shall be determined by comparison of the waste field and reference site(s) for characteristics species diversity, population density, contamination, growth anomalies, debility, or supplanting of normal species by undesirable plant and animal species. Degradation occurs if there are significant differences in any of three major biotic groups, namely, demersal fish, benthic invertebrates, or attached algae. Other groups may be evaluated where benthic species are not affected, or are not the only ones affected.

DICHLOROBENZENES shall mean the sum of 1,2- and 1,3-dichlorobenzene.

ENCLOSED BAYS are indentations along the coast which enclose an area of oceanic water within distinct headlands or harbor works. Enclosed bays include all bays where the narrowest distance between headlands or outermost harbor works is less than 75 percent of the greatest dimension of the enclosed portion of the bay. This definition includes but is not limited to: Humboldt Bay, Bodega Harbor, Tomales Bay, Drakes Estero, San Francisco Bay, Morro Bay, Los Angeles Harbor, Upper and Lower Newport Bay, Mission Bay, and San Diego Bay.

ENDOSULFAN shall mean the sum of endosulfan-alpha and -beta and endosulfan sulfate.

ESTUARIES AND COASTAL LAGOONS are waters at the mouths of streams which serve as mixing zones for fresh and ocean waters during a major portion of the year. Mouths of streams which are temporarily separated from the ocean by sandbars shall be considered as estuaries. Estuarine waters will generally be considered to extend from a bay or the open ocean to the upstream limit of tidal action but may be considered to extend seaward if significant mixing of fresh and salt water occurs in the open coastal waters. The waters described by this definition include but are not limited to the Sacramento-San Joaquin Delta as defined by Section 12220 of the California Water Code, Suisun Bay, Carquinez Strait downstream to Carquinez Bridge, and appropriate areas of the Smith, Klamath, Mad, Eel, Noyo, and Russian Rivers.

HALOMETHANES shall mean the sum of bromoform, bromomethane (methyl bromide), chloromethane (methyl chloride), chlorodibromomethane, and dichloro-bromomethane.

HEPTACHLOR shall mean the sum of heptachlor and heptachlor epoxide.

HCH shall mean the sum of the alpha, beta, gamma (lindane) and delta isomers of hexachlorocyclohexane.

INITIAL DILUTION is the process which results in the rapid and irreversible turbulent mixing of wastewater with ocean water around the point of discharge.

For a submerged buoyant discharge, characteristic of most municipal and industrial wastes that are released from the submarine outfalls, the momentum of the discharge and its initial buoyancy act together to produce turbulent mixing. Initial

* See Appendix I for definition of terms.

VOL 12

1 7 4 5 9

dilution in this case is completed when the diluting wastewater ceases to rise in the water column and first begins to spread horizontally.

For shallow water submerged discharges, surface discharges, and nonbuoyant discharges, characteristic of cooling water wastes and some individual discharges, turbulent mixing results primarily from the momentum of discharge. Initial dilution, in these cases, is considered to be completed when the momentum induced velocity of the discharge ceases to produce significant mixing of the waste, or the diluting plume reaches a fixed distance from the discharge to be specified by the Regional Board, whichever results in the lower estimate for initial dilution.

KELP BEDS, for purposes of the bacteriological standards of this plan, are significant aggregations of marine algae of the genera *Macrocystis* and *Nereocystis*. Kelp beds include the total foliage canopy of *Macrocystis* and *Nereocystis* plants throughout the water column.

MARICULTURE is the culture of plants and animals in marine waters independent of any pollution source.

MDL (Method Detection Limit) is the minimum concentration of a substance that can be measured and reported with 99% confidence that the analyte concentration is greater than zero, as defined in 40 CFR 136 Appendix B.

NATURAL LIGHT: Reduction of natural light may be determined by the Regional Board by measurement of light transmissivity or total irradiance, or both, according to the monitoring needs of the Regional Board.

OCEAN WATERS are the territorial marine waters of the State as defined by California law to the extent these waters are outside of enclosed bays, estuaries, and coastal lagoons. If a discharge outside the territorial waters of the State could affect the quality of the waters of the State, the discharge may be regulated to assure no violation of the Ocean Plan will occur in ocean waters.

PAHs (polynuclear aromatic hydrocarbons) shall mean the sum of acenaphthylene, anthracene, 1,2-benzanthracene, 3,4-benzofluoranthene, benzo[k]fluoranthene, 1,12-benzoperylene, benzo[a]pyrene, chrysene, dibenzo[ah]anthracene, fluorene, indeno[1,2,3-cd]pyrene, phenanthrene and pyrene.

PCBs (polychlorinated biphenyls) shall mean the sum of chlorinated biphenyls whose analytical characteristics resemble those of Aroclor-1016, Aroclor-1221, Aroclor-1232, Aroclor-1242, Aroclor-1248, Aroclor-1254 and Aroclor-1260.

PQL (Practical Quantitation Level) is the lowest concentration of a substance which can be consistently determined within +/- 20% of the true concentration by 75% of the labs tested in a performance evaluation study. Alternatively, if performance data are not available, the PQL* for carcinogens is the MDL* x 5, and for noncarcinogens is the MDL* x 10.

SHELLFISH are organisms identified by the California Department of Health Services as shellfish for public health purposes (i.e., mussels, clams and oysters).

---

* See Appendix I for definition of terms.

VOL 12 1 7460

SIGNIFICANT difference is defined as a statistically significant difference in the means of two distributions of sampling results at the 95 percent confidence level.

TCDD EQUIVALENTS shall mean the sum of the concentrations of chlorinated dibenzodioxins (2,3,7,8-CDDs) and chlorinated dibenzofurans (2,3,7,8-CDFs) multiplied by their respective toxicity factors, as shown in the table below.

Isomer Group	Toxicity Equivalence Factor
2,3,7,8-tetra CDD	1.0
2,3,7,8-penta CDD	0.5
2,3,7,8-hexa CDDs	0.1
2,3,7,8-hepta CDD	0.01
octa CDD	0.001
2,3,7,8 tetra CDF	0.1
1,2,3,7,8 penta CDF	0.05
2,3,4,7,8 penta CDF	0.5
2,3,7,8 hexa CDFs	0.1

WASTE: As used in this Plan, waste includes a discharger's total discharge, of whatever origin, i.e., gross, not net, discharge.

WATER RECLAMATION: The treatment of wastewater to render it suitable for reuse, the transportation of treated wastewater to the place of use, and the actual use of treated wastewater for a direct beneficial use or controlled use that would not otherwise occur.

APPENDIX II

STANDARD MONITORING PROCEDURES

The purpose of this appendix is to provide direction to the Regional Boards on the implementation of the California Ocean Plan and to ensure the reporting of useful information. It is not feasible to cover all circumstances and conditions that could be encountered by all dischargers. Therefore, this appendix should be considered as the basic components of any discharger monitoring program. Regional Boards can deviate from the procedures required in the appendix only with the approval of the State Water Resources Control Board unless the Ocean Plan allows for the selection of alternate protocols by the Regional Boards. If no direction is given in this appendix for a specific provision of the Ocean Plan, it is within the discretion of the Regional Board to establish the monitoring requirements for the provision.

The appendix is organized in the same manner as the Ocean Plan.

Chapter II. A. Bacterial Standards:

For all bacterial analyses, sample dilutions should be performed so the range of values extends from 2 to 16,000. The detection methods used for each analysis shall be reported with the results of the analysis.

Detection methods used for coliforms (total and fecal) shall be those presented in the most recent edition of Standard Methods for the Examination of Water and Wastewater or any improved method determined by the Regional Board (and approved by EPA) to be appropriate.

Detection methods used for enterococcus shall be those presented in EPA publication EPA 600/4-85/076, Test Methods for Escherichia coli and Enterococci in Water By Membrane Filter Procedure or any improved method determined by the Regional Board to be appropriate.

Chapter IV. Table B. Compliance with Table B objectives:

Procedures, calibration techniques, and instrument/reagent specifications used to determine compliance with Table B shall conform to the requirements of federal regulations (40 CFR 136). All methods shall be specified in the monitoring requirement section of waste discharge requirements.

Where methods are not available in 40 CFR 136, the Regional Boards shall specify suitable analytical methods in waste discharge requirements. Acceptance of data should be predicated on demonstrated laboratory performance.

The State or Regional Board may, subject to EPA approval, specify test methods which are more sensitive than those specified in 40 CFR 136. Total chlorine residual is likely to be a method detection limit effluent requirement in many cases. The limit of detection of total chlorine residual in standard test methods is less than or equal to 20 ug/L.

---

* See Appendix I for definition of terms.

VOL 12

1 7 4 6 2

Monitoring for the substances in Table B shall be required periodically. For discharges less than 1 MGD (million gallons per day), the monitoring of all the Table B parameters should consist of at least one complete scan of the Table B constituents one time in the life of the waste discharge requirements. For discharges between 1 and 10 MGD, the monitoring frequency shall be at least one complete scan of the Table B substances annually. Discharges greater than 10 MGD shall be required to monitor at least semiannually.

Chapter IV. Compliance with Toxicity Objectives:

Compliance with the acute toxicity objective (TUa) in Table A shall be determined using an established protocol, e.g., American Society for Testing Materials (ASTM), EPA, American Public Health Association, or State Board.

The Regional Board shall require the use of critical life stage toxicity tests specified in this Appendix to measure TUc. Other species or protocols will be added to the list after State Board review and approval. A minimum of three test species with approved test protocols shall be used to measure compliance with the toxicity objective. If possible, the test species shall include a fish, an invertebrate, and an aquatic plant. After a screening period, monitoring can be reduced to the most sensitive species. Dilution and control water should be obtained from an unaffected area of the receiving waters. The sensitivity of the test organisms to a reference toxicant shall be determined concurrently with each bioassay test and reported with the test results.

Use of critical life stage bioassay testing shall be included in waste discharge requirements as a monitoring requirement for all discharges greater than 100 MGD by January 1, 1991 at the latest. For other major dischargers, critical life stage bioassay testing shall be included as a monitoring requirement one year before the waste discharge requirement is scheduled for renewal. For major dischargers scheduled for waste discharge requirements renewal less than one year after the adoption of the toxicity objective, critical life stage bioassay testing shall be included as a monitoring requirement at the same time as the chronic toxicity effluent limits is established in the waste discharge requirements.

The following tests shall be used to measure TUc. Other tests may be added to the list when approved by the State Board.

Species	Effect	Test Duration	Reference
red alga, Champia parvula	number of cystocarps	7-9 days	1
giant kelp, Macrocystis pyrifera	percent germination; germ tube length	48 hours	2

Discussion of Dr. Osborne's Paper

Question:

Were the data you discussed measured dynamically?

Answer:

Yes--two years, around the clock.

Question:

Were the major impacts you noticed attributable to point or nonpoint sources?

Answer:

In some cases, even in agricultural areas, the biggest phosphorous impact is caused by point sources from urban areas, exacerbated by urban nonpoint sources.

Question:

Diurnal variations at the point of interest you define for yourself appear to be insufficient characterizations. Spatial variations along the stream are important as well. Determinations of K-rates and the effects of resuspension and sediment oxygen demand appear to have been left out of the relationships you described.

Answer:

The terms you mention do not appear to have been so big a problem. The respiration term I discussed tends to include the net effects of all those things. The more complex unresolved matters appear to be in the hydraulic context--particle flows versus water flows and the like.

State Perspectives on Water Quality Criteria

Eric H. Livingston[1]

ABSTRACT

The Federal Clean Water Act framework for water quality regulation is reviewed. The role of water quality standards in the regulation of stormwater discharges and the protection of beneficial uses is discussed. The relationship between the implementation of best management practices (BMPs) and water quality criteria is explored with emphasis on how Florida's stormwater regulatory program was established. Florida's BMP design and performance standards for stormwater discharges from new developments are summarized. A conceptual program to address the modification of existing stormwater discharges to reduce their pollution loading to receiving waters is proposed.

INTRODUCTION

The Federal Clean Water Act establishes the framework for the nation's water quality management regulations and programs by setting forth a national objective to "restore and maintain the chemical, physical and biological integrity of the nation's waters". Furthermore, the Act sets forth several goals to help achieve this objective including:

- Wherever attainable, water quality shall provide for the protection and propagation of fish, shellfish and wildlife and provide for recreation in and on the water.
- Programs to control nonpoint sources of pollution shall be developed and implemented expeditiously.

To carry out the purposes of the Act, the Environmental Protection Agency and the states have adopted water quality criteria and standards. The word "criterion" should not be used interchangeably with the word "standard" (EPA, 1976). Criterion represent a constituent concentration or level associated with a degree of environmental effect upon which scientific judgement may be based. Within the context of the water environment, criterion has come to mean a designated concentration of a

[1]Environmental Administrator, Nonpoint Source Management Section, Florida Department of Environmental Regulation, 2600 Blair Stone Road, Tallahassee, Florida 32399-2400

constituent that, when not exceeded, will protect an organism, or organism community or a prescribed water use or quality with an adequate degree of safety. Water quality criteria, therefore, reflect a knowledge of the capacity for environmental accumulation, persistence or effects of specific pollutants in specific aquatic systems. In some cases, a criterion may be a narrative statement instead of a constituent concentration.

A water quality standard includes designated beneficial uses (e.g., potable waters, fishable/swimmable waters), the water quality criteria to protect those uses as well as an antidegradation policy. A standard may use a water quality criterion as a basis for regulation or enforcement, but the standard may differ from a criterion because of prevailing local natural conditions or because of the importance of a particular waterway, economic considerations or the degree of safety to a particular ecosystem that may be desired.

Water quality criteria traditionally have been based on acute and chronic toxicity bioassay tests that were derived for continuous pollutant sources. Unfortunately, urban runoff is an intermittent pollutant source which represents a shock loading of relatively short duration with a longer time between exposures. In addition, urban stormwater impacts on receiving waters are highly variable depending on numerous factors such as rainfall and runoff characteristics, water body type, land use, soils, geology, chemistry and topography. Therefore, the validity of applying traditional water quality criteria to urban stormwater pollution sources is highly debatable.

Stormwater also exerts long term impacts on receiving waters thereby raising further questions about the applicability of current water quality criteria. Stormwater carries relatively high levels of suspended solids which alone can cause severe impacts on receiving water biota. Suspended solids also carry many other contaminants (e.g., metals, phosphorus) which accumulate as bottom sediments (a pollutant sink). Exposure to these sediment bound toxicants can pose threats to the aquatic biota and environment and can also impose a sediment oxygen demand. If the pH falls or bottom conditions become anaerobic, these contaminants can also release from the sediments and enter the water (Harper, 1985).

From the foregoing discussion it seems evident that evaluating stormwater impacts on receiving waters, and consequently the design of control programs, cannot be based solely on traditional water quality criteria. Mancini (1983) proposes a methodology for the development of wet weather criteria while Mancini and Plummer (1986) further discuss this concept. While wet weather criteria may be applicable, their development and implementation

would be difficult and impractical. Especially since there is so little information on the toxicity of urban runoff thereby precluding the development of whole effluent information that would be needed for permitting stormwater discharges (EPA, 1983a). Sediment criteria is also essential with different criteria for fresh and marine environments (FDER, 1988). Finally, the basic foundation of any stormwater program should be the protection of beneficial uses.

REGULATORY FRAMEWORK OF FLORIDA'S STORMWATER PROGRAM

Section 208 of the Federal Clean Water Act required the development of areawide water quality management plans to control point and nonpoint sources of pollution. As part of Florida's program conducted during the late 1970's and early 1980's, many investigations were undertaken to assess the impacts of stormwater and the effectiveness of various best management practices (Livingston, 1984). These studies demonstrated that stormwater, whether from agriculture, forestry or urban lands, was the primary source of pollutant loading to Florida's receiving waters. Subsequently, it was concluded that the ability to meet the Clean Water Act objective of fishable and swimmable waters would require the implementation of stormwater programs to reduce the delivery of pollutants from stormwater discharges.

Recognition of this problem, along with the availability of Federal funds, led Florida to draft regulations to control stormwater in the late 1970's. The first official State regulation specifically addressing stormwater was adopted in 1979 as part of Chapter 17-4, Florida Administrative Code (F.A.C.). Chapter 17-4.248 was the first attempt to regulate this source of pollution that, at the time, was not very well understood. Under Chapter 17-4.248 the Department based its decision to order a permit on a determination of the "insignificance" or "significance" of the stormwater discharge. This determination seems reasonable in concept; however, in practice, such a decision can be as variable as the personalities involved. What may appear insignificant to the owner of a shopping center may actually be a significant pollutant load into an already overloaded stream.

In adopting Chapter 17-4.248, the Department intended that the rule would be revised when more detailed information on nonpoint source management became available. About one year after adoption, the Department began reviewing the results of research being conducted under the 208 program. The Department also established a stormwater task force with membership from all segments of the regulated and environmental communities. A revised stormwater rule, Chapter 17-25, F.A.C., was developed after two years, more than 100 meetings between department staff and the regulatory interests, and the dissemination of 29 official rule drafts for review and comment. The adopted rule required a stormwater permit for all new stormwater discharges and for modifications to existing discharges that were modified to increase flow or pollutant loading.

The Stormwater Rule had to be implemented within the framework of the federal Clean Water Act. The Act establishes two types of regulatory requirements to control pollutant discharges--technology-based effluent limitations which reflect the best controls available considering the technical and economic achievability of those controls; and water quality-based effluent limitations which reflect the water quality standards and allowable pollutant loadings set up by state permit (EPA, 1983). The latter approach can be developed and implemented through a biomonitoring approach based on whole effluent toxicity making it very applicable to stormwater. However, Florida's tremendous growth and the accompanying creation of tens of thousands of new stormwater discharges together with our lack of data on stormwater loading toxicity made this approach unimplementable.

Guidance on the development of stormwater regulatory programs and the role of water quality criteria has been issued by the Environmental Protection Agency (1987). The guidance recognizes that BMPs are the primary mechanism to enable the achievement of water quality standards. For the purposes of this paper, a BMP is a control technique that is used for a given set of site conditions to achieve stormwater quality and quantity enhancement at a minimum cost. Further, the guidance recommends that state programs should include the following steps:

1. design of BMPs based on site specific conditions; technical, institutional and economic feasibility; and the water quality standards of the receiving waters.

2. monitoring to ensure that practices are correctly designed and applied.

3. monitoring to determine
   a) the effectiveness of BMPs in meeting water quality standards
   b) the appropriateness of water quality criteria in reasonably assuring protection of beneficial uses.

4. adjustment of BMPs when it is found that water quality standards are not being protected to a designed level and/or evaluation and possible adjustment of water quality standards.

It is intended that proper installation and operation of state approved BMPs will achieve water quality standards. While water quality standards are to be used to measure the effectiveness of BMPs, EPA recognizes that there should be flexibility in water quality standards to address the impact of time and space components of stormwater as well as naturally occurring events. If water quality standards are not met, then the BMPs should be modified, or the discharge cease or, in some cases, reassessment of the water quality standards be undertaken.

RATIONALE FOR STORMWATER RULE STANDARDS

The overriding standards of the Stormwater Rule are the water quality standards and appropriate regulations established in other Department rules. Therefore, an applicant for a stormwater discharge permit must provide reasonable assurance that stormwater discharges will not violate state water quality standards. Because of the potential number of discharge facilities and the difficulties of determining the impact of any facility on a waterbody or the latter's assimilative capacity, the Department decided that the Stormwater Rule should be based on design and performance standards.

The performance standards established a technology-based effluent limitation against which an applicant can measure the proposed treatment system. If an applicant can demonstrate treatment equivalent to the description in the performance standard systems, then the applicant should be able to meet applicable water quality standards. The actual design and performance standards are based on a number of factors which will subsequently be discussed.

Stormwater Management Goals - Stormwater management has multiple objectives including water quality protection, flood protection (volume, peak discharge rate), erosion and sediment control, water conservation and reuse, aesthetics and recreation. The basic goal for new development is to assure that the post-development peak discharge rate, volume, timing and pollutant load does not exceed predevelopment levels. However, BMPs are not 100% effective in removing stormwater pollutants while site variations can also make this goal unachievable at times. Therefore, for the purposes of stormwater regulatory programs, the Department (water quality) and the Water Management Districts (flood control) have established performance standards based on risk analysis and implementation feasibility.

Rainfall Characteristics - An analysis of long term rainfall records was undertaken to determine statistical distribution of various rainfall characteristics such as storm intensity and duration, precipitation volume, time between storms, etc. It was found that nearly 90% of a year's storm events occurring anywhere in Florida produce a total of 2.54 cm (1 inch) of rainfall or less (Anderson, 1982). Also, 75% of the total annual volume of rain falls in storms of 2.54 cm or less.

Runoff Pollutant Loads - The first flush of pollutants refers to the higher concentrations of stormwater pollutants that characteristically occur during the early part of the storm with concentrations decaying as the runoff continues. Concentration peaks and decay functions vary from site to site depending on land use, the pollutants of interest, and the characteristics of the drainage basin. Florida studies (Wanielista and Shannon, 1977; Miller, 1985) indicated that for a variety of land uses the first 1.27 cm (.5 inch) of runoff contained 80-95 percent of the total annual loading of most stormwater pollutants. However, first flush effects generally diminish as the size of the drainage basin increases and the percent impervious area decreases because of the unequal distribution of rainfall over the watershed and the additive phasing of inflows from numerous small drainages in the larger watershed. In fact, as the drainage area increases in size above 40 ha (100 ac) the annual pollutant load carried in the first flush drops below 80% because of the diminishing first flush effect.

BMP Efficiency and Cost Data - Numerous studies conducted in Florida during the Section 208 program generated information about the pollutant removal effectiveness of various BMPs and the costs of BMP construction and operation. Analysis of this information revealed that the cost of treatment increased exponentially after "secondary treatment" (removal of 80% of the annual load) (Wanielista, et al., 1982).

Selection of Minimum Treatment Levels - After review and analysis of the above information, and after extensive public participation, the Department set a stormwater treatment objective of removing at least 80% of the average annual pollutant load for stormwater discharges to Class III (fishable/swimmable) waters. A 95% removal level was set for stormwater discharges to sensitive waters such as potable supply waters (Class I), shellfish harvesting waters (Class II) and Outstanding Florida Waters. The Department believed that these treatment levels would protect beneficial uses and thereby establish a relationship between the rule's BMP performance standards and water quality standards. The actual stormwater treatment volumes for various BMPs are set forth in Table 1.

ADMINISTRATION OF THE STORMWATER RULE

Under the Florida Water Resources Act of 1972, the

between storms, etc. It was found that nearly 90% of a year's storm events occurring anywhere in Florida produce a total of 2.54 cm (1 inch) of rainfall or less (Anderson, 1982). Also, 75% of the total annual volume of rain falls in storms of 2.54 cm or less.

Runoff Pollutant Loads - The first flush of pollutants refers to the higher concentrations of stormwater pollutants that characteristically occur during the early part of the storm with concentrations decaying as the runoff continues. Concentration peaks and decay functions vary from site to site depending on land use, the pollutants of interest, and the characteristics of the drainage basin. Florida studies (Wanielista and Shannon, 1977; Miller, 1985) indicated that for a variety of land uses the first 1.27 cm (.5 inch) of runoff contained 80-95 percent of the total annual loading of most stormwater pollutants. However, first flush effects generally diminish as the size of the drainage basin increases and the percent impervious area decreases because of the unequal distribution of rainfall over the watershed and the additive phasing of inflows from numerous small drainages in the larger watershed. In fact, as the drainage area increases in size above 40 ha (100 ac) the annual pollutant load carried in the first flush drops below 80% because of the diminishing first flush effect.

BMP Efficiency and Cost Data - Numerous studies conducted in Florida during the Section 208 program generated information about the pollutant removal effectiveness of various BMPs and the costs of BMP construction and operation. Analysis of this information revealed that the cost of treatment increased exponentially after "secondary treatment" (removal of 80% of the annual load) (Wanielista, et al., 1982).

Selection of Minimum Treatment Levels - After review and analysis of the above information, and after extensive public participation, the Department set a stormwater treatment objective of removing at least 80% of the average annual pollutant load for stormwater discharges to Class III (fishable/swimmable) waters. A 95% removal level was set for stormwater discharges to sensitive waters such as potable supply waters (Class I), shellfish harvesting waters (Class II) and Outstanding Florida Waters. The Department believed that these treatment levels would protect beneficial uses and thereby establish a relationship between the rule's BMP performance standards and water quality standards. The actual stormwater treatment volumes for various BMPs are set forth in Table 1.

ADMINISTRATION OF THE STORMWATER RULE

Under the Florida Water Resources Act of 1972, the

Department of Environmental Regulation, a water quality agency, serves as the umbrella administering agency delegating authority to five regional water management districts whose primary functions historically have been related to water quantity management. Therefore, a second objective in developing the Stormwater Rule was to coordinate the water quality considerations of the Department's stormwater permits with the water quantity aspects of the Districts' surface water management permits.

Table 1. BMP Treatment Volumes for Stormwater Discharges to Class III Waters

SWALES - Infiltrate 80% of the runoff generated by a 3 yr-1 hr storm (typically about 2 inches of runoff)

RETENTION - Off-line infiltration of the first 0.5 inch runoff (DA <100 acres) or the runoff from the first 1 inch of rainfall, whichever is greater (DA >100 acres)

DETENTION WITH FILTRATION - Filtration of retention volume

WET DETENTION - Detention of the first 1 inch of runoff or volume calculated by 2.5 times % impervious, whichever is greater
- Commercial, industrial land uses must pretreat up to 0.5 inch runoff by infiltration BMPs

WETLANDS - Detention and assimilation of retention volume

NOTES:
1. Discharges to sensitive waters must treat 50% more stormwater volume and may require infiltration pretreatment
2. Discharges to sinkhole watersheds must treat first two inches of runoff (SRWMD criterion)

In addition, the delegation of the stormwater permitting program allows for minor adjustments to the Stormwater Rule design and performance standards to better reflect local conditions. Florida is a very diverse state with major differences throughout in soils, geology, topography, rainfall, etc., which can directly affect the usability and treatment effectiveness of a BMP. Such problems can be minimized by adoption by the Districts of slightly different design and performance standards which are approved by the Department prior to implementation. Both the Department's and Districts' stormwater rules essentially require a new development to include a comprehensive stormwater management system. The system should be viewed as a "BMP treatment train" in which a number of different BMPs are integrated into a

comprehensive system that provides aesthetic and recreational amenities in addition to the traditional stormwater management objectives.

BMP GUIDELINES

In addition to the stormwater treatment volumes, other design and performance standards have been set to assure that BMPs function optimally to attain the stormwater treatment goal and other management objectives (Livingston, et al., 1988). These guidelines will be discussed for each of the BMPs currently being used extensively in Florida.

Swales - are defined by Chapter 403, Florida Statutes, as manmade trenches that:

- have a top width-to-depth ratio of the cross section equal to or greater than 6:1, or side slopes equal to or greater than 3 feet horizontal to 1 foot vertical.
- contains contiguous areas of standing or flowing water only following a rainfall event.
- is planted with or has stabilized vegetation suitable for soil stabilization, stormwater treatment and nutrient uptake.
- is designed to take into account the soil erodibility, soil percolation, slope, slope length and drainage area so as to prevent erosion and reduce pollutant concentration of any discharge.

Swale treatment of stormwater is accomplished primarily by infiltration of runoff and secondarily by adsorption and vegetative filtration and uptake (Yousef, et al., 1985). Recent investigations have concluded that Florida soil, slope and water table conditions essentially preclude the use of swales as the sole BMP to treat stormwater (Wanielista, et al., 1985). Therefore, the greatest utility of swales is as a pretreatment BMP within a BMP treatment train stormwater system. Infiltration pretreatment can be easily accomplished by using raised storm sewer inlets within the swale, or by elevating driveway culverts or using swale blocks to create mini-retention areas.

Retention - Off-line retention areas which receive the first flush volume only while the later runoff is diverted to a flood control BMP are the most effective stormwater treatment practice. Treatment is achieved through diversion and infiltration of the first flush thereby providing total pollutant removal for all stormwater that is retained on-site. To reduce operation needs, increase aesthetics and reduce the land area needed for stormwater treatment, retention areas should be incorporated into a site's landscaping and open space areas. Effectiveness of retention areas can be increased and groundwater impacts decreased by:

VOL 12

1. Infiltrating the stormwater treatment volume within 72 hours or within 24 hours if the retention area is grassed.
2. Grassing the retention area bottom and side slopes--reduces maintenance and maintains soil infiltration properties.
3. Maintaining at least three feet between the bottom of the retention area and seasonal high water tables or limerock.
4. In Karst sensitive areas, using several small, shallow infiltration areas to prevent formation of solution pipe sinkholes within the system.

Exfiltration trenches typically are used in highly urbanized areas where land is unavailable for retention basins. They consist of a rock filled trench, surrounded by filter fabric, in which a perforated pipe is placed. The stormwater treatment volume is stored within the pipe and exfiltrates out of the perforations into the gravel envelope and into the surrounding soil. Pretreatment with catch basins to remove sediments and other debris is essential to prevent clogging.

Detention with Filtration - systems were proposed as an alternative to retention for those areas of Florida where local conditions, especially flat topography and high water tables, prevent infiltrating the stormwater treatment volume. The filters must consist of two feet of natural soil or other suitable fine textured granular media which meets certain specifications including:

- Filters must have pore spaces large enough to provide sufficient flow capacity so that the filter permeability is equal to or greater than the permeability of the surrounding soil.
- The design shall assure that particles within the filter do not move.
- When sand or other fine textured material other than natural soil are used for filtration, the filter material will meet the following criteria:
  a) Be washed (less than 1 percent silt, clay or organic matter) unless filter cloth is used to retain such materials within the filter
  b) Have a uniformity coefficient between 1.5 and 4.0
  c) Have an effective gain size of 0.20 to 0.55 mm in diameter.
- Be designed with a safety factor of at least two.
- Will recover the treatment volume (bleed down) within 72 hours.

Filters are placed in the bottom or sides of detention areas where the filtered stormwater is collected in an underdrain pipe and then discharged. Experience has shown that these filters are very difficult to design and construct. Operation is also difficult because of low hydraulic head and maintenance is nearly impossible. It

is not a question of if a filter will clog, only when it will clog. In addition, filters are designed to remove particulate pollutants and do not remove dissolved pollutants such as phosphorus or zinc. Therefore, filtration systems are no longer recommended for use except under very special conditions and where a full time maintenance entity such as a local government will assume such responsibilities.

Wet Detention - systems consist of a permanent water pool, an overlying zone in which the stormwater treatment volume temporarily increases the depth while it is stored and slowly released and a shallow littoral zone (biological filter). In addition to their high pollutant removal efficiencies (EPA, 1983b), wet detention systems can also provide aesthetic and recreational amenities, a source of fill for the developer and even "lake front" property which brings a premium price.

Wet detention criteria are listed in Table 2. These have been developed to take full advantage of the biological, physical and chemical assimilation processes occurring within the wet detention system. If the system is designed as a development amenity, the use of pretreatment BMPs integrated into the overall stormwater management system is highly recommended to prevent algal blooms or other perturbations that would reduce the aesthetic value. Placing raised storm sewers in grassed areas such as parking lot landscape islands, using swale conveyances, or a perimeter swale/berm system along the detention lake shoreline are techniques that have been used frequently.

Table 2. Wet Detention Guidelines

- Treatment volume as per Table 1.
- Treatment volume slowly recovered in no less than 120 hours with no more than half of the volume discharged within the first 60 hours following the storm.
- Volume in the permanent pool should provide a residence time of at least 14 days.
- At least 30% of the surface area shall consist of littoral area with slopes of 6:1 or flatter that is established with appropriate native aquatic plants selected to maximize pollutant uptake and aesthetic value.
- Littoral zone plants shall have a minimum 80% survival rate and coverage after two years. Cattails and other undesirable plants shall be removed.
- Littoral zone is concentrated near the outfall or in a series of shallow benches ending at the outfall.
- Side slopes no steeper than 4:1 out to a depth of two feet below the level of the permanent pool.
- Maximum depth of 8-10 feet below the invert of the discharge structure is recommended. Maximum depth

VOL 12

1 F-H-F-E

shall not create aerobic conditions in bottom sediments and waters.

- Maximize flow length possible between inlets and outlet; a length to width ratio of at least 3:1 is recommended. Diversion barriers such as baffles, islands or a peninsula should be used if necessary to increase flow length and length to width ratio.
- An oil and grease skimmer shall be designed into the outlet structure.
- If the system is planned as a "real estate lake", pretreatment by infiltration is recommended.
- Inlet areas should include a sediment sump.

Wetland Treatment - was authorized by the 1984 Henderson Wetlands Protection Act which allows stormwater treatment in wetlands that are connected by an intermittent water course which flows in direct response to rainfall thereby causing the water table to rise above ground surface. Not only does this take advantage of natural treatment mechanisms but it gives another economic value to wetlands, an incentive to the developer to use not destroy the wetland, and it revitalizes ditched and drained wetlands by providing water.

Wetlands may be viewed as nature's kidneys--they store stormwater, dampen floodwaters, and also transform pollutants and even retain them thereby providing natural stormwater treatment (Richardson, 1988). However, care must be taken to protect the numerous assimilation mechanisms within the wetland plants and sediments. In addition, the wetland hydroperiod--the duration that water stays at various levels--must be protected or restored since it determines the form, function and nature of the wetland. Therefore, pretreatment practices to attenuate stormwater volume and peak rate and to reduce oil, grease and especially sediment are essential. Normally, a pretreatment lake is constructed adjacent to the wetland.

The following guidelines are presented for incorporating wetlands into a stormwater management system:

- Treatment volume as per Table 1.
- Treatment volume slowly recovered in no less than 120 hours with no more than half of the volume discharged within the first 60 hours following the storm.
- Stormwater must sheet flow evenly through the wetland to maximize contact with the wetland plants, sediments and microorganisms. Spreader swales, distribution systems or a level spreader between the pretreatment lake and the wetland have been used extensively.
- Swales should be used for stormwater conveyance throughout the development.
- The hydroperiod must be protected or restored. Treatment capacity of the wetland is determined by the storage volume available between the normal low and

high elevations. These elevations are determined by site specific indicators such as lichen and moss lines, water stain lines, adventitious root formation, plant community zonation, hydric soils distribution and rack/debris lines.

- Erosion and sediment control during construction is essential since only a few inches of sediment deposited in the wetland will destroy the wetland filter.
- Inflow/outflow monitoring, sediment metal levels and vegetative transect monitoring is required to help evaluate the effectiveness of these systems and the impacts of stormwater additions to wetlands.

THE CHALLENGE AHEAD

Probably the biggest stormwater management problem facing Florida is how to reduce pollutant loadings discharged by older systems, especially local government master systems, constructed before the Stormwater Rule. These systems were designed solely for flood protection and rapidly deliver untreated stormwater directly to rivers, lakes, estuaries and sinkholes. Retrofitting urban stormwater discharges will become a national priority because of the recently enacted Section 402 of the 1987 Federal Clean Water Act. This section requires the establishment of a NPDES permitting program for stormwater discharges as described elsewhere in these proceedings (Gallop, et al.). The Act requires that these stormwater pollutant discharges be reduced to "the maximum extent practicable". Interpretation, implementation and enforcement of this standard could prove extremely difficult similar to the problems Florida encountered in implementing its first stormwater regulations (17-4.248)

Establishing a stormwater program to retrofit existing systems presents many technical, institutional and financial dilemmas. The unavailability and cost of land in urbanized areas make the use of conventional BMPs infeasible in most instances. Current state laws and institutional arrangements promote piecemeal, crises solving approaches aimed at managing stormwater within political boundaries yet stormwater follows watershed boundaries. Land use planning and management must be fully integrated into the stormwater management scheme. Retrofitting is also prohibitively expensive and many local governments are already short of funds. Therefore, solving our existing urban stormwater problems will require imaginative, innovative approaches.

STORMWATER LEGISLATION

During the next year, stormwater legislation will be proposed in Florida to enhance the state's current program and initiate a long term effort to reduce pollutant

R0050778

loadings from older stormwater systems. Following is a brief discussion of some of the essential elements of such a program

Watershed Management - A watershed approach which integrates land use planning with the development of stormwater infrastructure is essential. After all, it is the intensification of land use and the increase in impervious surfaces within a watershed that creates the stormwater and water resources management problems. Consequently, a "watershed management team" effort involving state and local governments together with the private sector is necessary. In fact, local governments are the primary team member since they determine zoning and land use, they issue building permits and inspect projects, and they have code enforcement powers that can help to assure that stormwater systems are properly operated and maintained.

Local governments need to identify and map the existing natural stormwater system--the creeks, wetlands, flood plains, drainageways and natural depressional areas. Once mapped, these areas need to be zoned for conservation or low intensity uses compatible with the functions provided by the natural system. The existing manmade stormwater system must also be mapped and essential characteristics such as pipe size, drainage areas, invert elevations, etc., be determined. This information should then be fully integrated with the existing and future land use plan for the watershed and a master stormwater management plan developed and implemented. The Growth Management Act of 1985, which requires all local governments to adopt comprehensive plans addressing current and future land use with infrastructure needs, establishes a base structure that could promote a watershed management approach.

Treatment Requirements for Older Systems - Numerous problems inherent in a highly urbanized area prevent the application of new development stormwater treatment standards from being imposed on older systems. Instead a "watershed loading" concept is proposed which considers the beneficial uses of the receiving waters, the total stormwater load that can be assimilated by the receiving waters, a hierarchy of treatment levels based on BMP feasibility and local public perceptions about receiving water quality. For example, treatment standards would progressively increase as one moves from the downtown central business district to the suburbs to rural areas. However, the actual treatment level would depend on the watershed s total allowable loading which is based on citizen desires for certain beneficial uses of the receiving water.

Selective Targeting - The extremely high cost of retrofitting older urban stormwater systems also implies a

need for careful evaluation of pollutant reduction goals. A long term (25 years) plan based on prioritization of watersheds such that existing systems are selectively targeted for modification is needed to assure that citizens receive the greatest benefit (pollutant load reduction, flood protection) for the dollar. The upgrading of older systems must also be coordinated with other already planned infrastructure improvements such as road widenings. An excellent example of this approach is the Orlando Streetscape Project. While downtown streets were torn up for this downtown renovation, the existing stormwater system was modified by the addition of off-line exfiltration systems to reduce pollution loads to downtown lakes.

Education - Education programs for the general public and for professionals involved in stormwater management are vital. Citizens must understand how their everyday activities contribute to stormwater pollution. For example, citizens should not discard leaves, grass clippings, used motor oil or other material into swales or storm sewers. Even more importantly, comprehensive training and certification programs are needed for those in the private and public sectors who design, construct, inspect, operate or maintain stormwater management systems.

Funding - The cost of providing needed stormwater infrastructure improvements to address current and future flooding and water quality problems is gigantic. Yet local governments are already struggling financially and traditional revenue sources such as property taxes cannot be relied upon to pay for stormwater management. Instead a dedicated source of revenue based on contributions to the stormwater problem is needed. The stormwater utility can provide this. The City of Tallahassee implemented Florida's first stormwater utility in October 1986 and many other local governments have or are following this example.

Innovative BMPs - The infeasibility of using traditional BMPs to reduce stormwater pollutant loads in highly urbanized areas means that creative and innovative BMPs will be needed such as those discussed in this section.

Alum injection within storm sewers was used in Tallahassee to reduce stormwater loadings to Lake Ella (Harper, et al., 1986). A sonic flow meter measures storm sewer flow causing a flow proportional dose of aluminum sulfate to be injected and mix with the polluted stormwater. As the alum mixes with the stormwater, a small floc is produced which attracts suspended and dissolved pollutants by adsorption and enmeshment into and onto the floc particles. The floc then settles to the lakes bottom sediments, gradually blanketing and incorporating into the sediments thereby reducing internal recycling of nutrients and metals. Other advantages of alum injection include excellent pollutant reduction (>85%) and relatively low construction and operations costs, especially for the highly urbanized areas.

Pervious concrete consists of specially formulated mixtures of Portland cement, uniform open graded coarse aggregate and water. When properly mixed and installed pervious concrete surfaces have a high percentage of void space which allows rapid percolation of rainfall and runoff. Pervious concrete is being used widely in Florida, especially for parking lots, and could be an important BMP to reduce stormwater loadings in highly urbanized areas. Recent field investigations of pervious concrete parking areas that have been in place for up to 12 years, revealed that the infiltration capacity of the concrete has not decreased significantly, a major concern. Further information about the use, design and construction of pervious concrete surfaces is available (FCPA, 1988).

Improved street sweepers that will pick up the small particles (<60 microns) that contain high concentrations of metals and other pollutants could also prove valuable in reducing stormwater loadings, especially from downtown business districts where other BMPs will usually be infeasible. Initial evaluation of an innovative sweeper design indicates that this sweeper can remove these small particles (Stidger, 1988). However, extensive watershed tests to evaluate the machine's cost-effectiveness, pollution removal effectiveness and other advantages or disadvantages will not be undertaken until later this year.

Regional stormwater systems which manage stormwater from several developments or an entire drainage basin offer many advantages over the piecemeal approach that relies upon small, individual on-site systems. They provide economies of scale in construction, operation and maintenance. Regional systems can also help manage stormwater from existing and future land uses and will be a central part of any retrofitting program. Another reason for a watershed management approach that fully integrates land use and stormwater management.

The Southeast Lakes Program--A Model - Many of the above elements of a watershed-wide master stormwater planning approach are being implemented by the City of Orlando. The city has adopted an excellent local stormwater ordinance, developed a fine community education program and a prioritized urban lake management program (Zeno and Palmer, 1986). One of the most innovative programs is the Southeast Lakes Project which is designed to correct flooding problems and to reduce stormwater pollutant loads to 15 urban lakes and 58 drainage wells which currently convey untreated stormwater to an aquifer. A corrective

watershed management plan was cooperatively developed by the city, its consultants, the Department of Environmental Regulation and the St. Johns River Water Management District. The project was initiated not because of enforcement of water quality standards but because of a loss of beneficial uses and local citizen desires and perceptions. Modifications to the existing stormwater systems will be made over a ten-year period with treatment requirements based on "net environmental improvement" and total watershed load.

One of the most important aspects of the project is the use of innovative BMP designs which promote multiple objectives and take advantage of city-owned properties. At Al Coith Park a spreader swale will be built on the park's perimeter. When it rains, runoff will enter and fill the swale, overtopping the sidewalk berm and sheet flow across the grassed parkland where it will percolate into the ground. At Lake Greenwood, the surrounding city-owned land is being converted into an urban wetland and expanded lake. The wetland and lake is a complex treatment train which incorporates many BMPs into a very aesthetically pleasing stormwater system and park. In addition to improved stormwater management, the citizens are receiving added benefits of recreation and open space. In addition, the retrofitting project has stimulated redevelopment and renovation of existing properties thereby providing citizens with economic benefits as property values rise.

Discussion of Mr. Livingston's Paper

Question:

Have you considered ground water impacts?

Answer:

Yes, in two studies. But I admit there isn't much information for criteria developed yet.

Question:

Do you have a data base for developing sediment-related criteria?

Answer:

Some, in salt water. We're getting an excellent data base on heavy metals on sediments.

WATER QUALITY CONTROL PLAN FOR INLAND SURFACE WATERS OF CALIFORNIA

DRAFT

11747 9

Adopted and Effective

R0050784

In developing site-specific objectives, all the requirements for of the Porter-Cologne Water Quality Control Act and the federal Clean Water Act must be are met.

Alternate site-specific water quality objectives as established by the Regional Board are not effective until approved by the State Board with the concurrence of EPA.

Chapter III. PROGRAM OF IMPLEMENTATION PROVISIONS

A. Effective Date

This Plan plan is in effect as of the date of adoption by the State Water Resources Control Board.

BC. Mixing Zones, Effluent Limitations, and Monitoring Requirements, and Compliance Determination

The State Board is authorized to issue and enforce NPDES permits and waste discharge requirements established pursuant to the Federal Clean Water Act and the Porter-Cologne Act.

Effluent limitations in WDRs shall be imposed such that the water quality objectives established by this plan in Tables 1, 2, and 3 shall not be exceeded in the receiving water outside any designated mixing* zone. Effluent limitations shall not cause receiving water concentrations of pollutants to exceed levels that existed on the date of adoption of this plan. Where the Regional Board is satisfied that any substance(s) in Tables 1, and 2, and 3 does not occur, or is not likely to occur, in a discharger's effluent, the Regional Board may elect not to establish effluent limitations for such substance(s), provided the discharger conducts periodic monitoring for all pollutants in Tables 1, and 2, and 3 and certifies that such substance(s) are not in the waste* stream, and that no change has occurred that could cause such substance(s) to be present in the waste* stream. Such a determination shall be based on the discharger's certification that the substance is not in the waste* stream and that no source has been identified which would likely result in the presence of such substance in the waste* stream. This certification shall be accompanied, at a minimum, by laboratory analysis of the discharge for substances listed in Tables 1 and 2, and by process and treatment description which demonstrate the absence of such substances in the waste* stream. At a minimum, this monitoring and certification shall be required prior to issue or and reissue of NPDES permits or waste discharge requirements WDRs. The Regional Boards may choose to shall have the discretion to not require periodic monitoring and certification for these pollutants in de minimus low volume discharges determined to be of little threat to water quality.

B1. Application of Mixing* Zones

A mixing* zone is a volume of a receiving water that is allocated for mixing with a wastewater discharge. Mixing* zones will be

* See Appendix I for definition of terms.

VOL 12 1780

granted or denied by the Regional Boards after consideration of site-specific factors and according to the provisions of this section. ~~If a mixing zone is allowed, numerical water quality objectives must be met at the edge of the mixing zone. Numerical~~ Water quality objectives are to be met throughout a waterbody except within any mixing* zones granted by a Regional Board. A mixing* zone is not a source* of drinking water. To the extent of any conflict between this determination and the Sources of Drinking Water Policy (State Board Resolution No. 88-63), this determination supersedes the provisions of the policy.

All Inland Surface Waters

~~1.~~ o Mixing* zones can only be applied to point source discharges, and nonpoint source discharges with a physically identifiable point of discharge, ~~to surface waters~~ regulated through ~~NPDES permits, waste discharge requirements, or reclamation requirements~~ WDRs issued or waived by the Regional Boards. A mixing* zone shall apply only in the calculation of water* quality-based permit limits and shall not be used to meet technology*-based permit limits.

~~2.~~ o The primary goals when designating a mixing* zone are to ~~limit~~ define areas where ~~numerical~~ water quality objectives need ~~are~~ not be met and to avoid unreasonable wastewater treatment. The Regional Boards must balance these goals before granting a mixing* zone. If a Regional Board allows a mixing* zone, the WDR ~~NPDES permit, waste discharge requirements, or reclamation requirement~~ shall specify the method by which the mixing* zone was derived and either the dilution ratio granted to the discharge or the point in the receiving water at which water quality objectives must be met.

~~3.~~ o The Regional Boards shall deny a mixing* zone if necessary to protect beneficial uses. Careful consideration shall be given to the appropriateness of a mixing* zone where the discharge contains pollutants that are carcinogenic, mutagenic, or teratogenic to humans, and for pollutants that are attractive to aquatic organisms, persistent*, or subject to bioaccumulation*.

~~4.~~ o A mixing* zone shall be as small as practical ~~possible~~. A mixing* zone shall not restrict passage of aquatic life. Pollutants in a mixing* zone shall not create objectionable* bottom deposits. Acute* toxicity shall not occur in a mixing zone.

~~5. A Regional Board may specify more stringent mixing zone provisions than those contained in this plan. Less stringent mixing zone provisions than those contained herein may be allowed by a Regional Board with State Board and EPA concurrence, as indicated under "Exceptions to Plan Requirements".~~

* See Appendix 1 for definition of terms.

VOL 12

DRAFT

17481

Lakes and Reservoirs

Mixing* zones for discharges to lakes and reservoirs shall extend no greater than 25 feet from the point of discharge. No more than 5 percent of the volume of a lake or reservoir can be allocated for the sum of mixing* zones in that waterbody. Where a Regional Board has identified a site-specific concern with a particular pollutant in a lake or reservoir environment, a maximum* dilution credit may be applied.

Rivers and Streams

Mixing* zones for discharges to rivers and streams shall be based on a designated volume or percentage of stream flow, as determined by the Regional Board. If a Regional Board ~~determines a dilution ratio by~~ allocates~~ing~~ a percentage of the stream flow for mixing, the outfall must be designed for rapid mixing in the receiving waterbody. Regardless of the method used, the mixing* zone shall not extend more than 250 feet from the point of discharge, to ensure rapid mixing, or be located less than 500 feet from an adjacent mixing* zone. A zone* of passage for aquatic life should be provided if, in doing so, adverse impacts on sensitive aquatic species would be minimized. ~~Design flows~~ Dilution ratios for ~~permit~~ effluent limitation derivation can be based on either steady-state* or dynamic* considerations.

2. Calculation of Effluent Limitations

Where a wasteload allocation has not been completed, water quality-based effluent limitations shall be developed using one of the following methods, (a) or (b):

(a) $Ce = Co + D(Co - Cb)$, when $Co > Cb$, and
$Ce = Co$, when $Co < Cb$.

~~Effluent limitations (Ce) for substances identified in Table I shall be determined through the use of the following equation:~~

~~$Ce = Co + D(Co - Cb)$~~

where Ce = the effluent concentration limit for the substance,
Co = the ~~concentration~~ (water quality objective) for the substance to be met in the receiving waterbody ~~at the edge of any designated mixing* zone (Table I objectives)~~
Cb = the ambient background concentration of the substance in the receiving waterbody, and
D = the allocated dilution ratio, expressed as parts receiving water per part wastewater, based on mixing* zone provisions.

* See Appendix I for definition of terms.

Ambient background concentration (Cb) means the median concentration of a substance, in the vicinity of a discharge, which is not influenced by the discharge. Ambient concentrations should be determined using analytical methods at least as sensitive as those used to determine compliance with effluent limitations.

(b) Regional Boards may elect to apply the statistically-based approach to the calculation of effluent limits, as described in EPA's Technical Support Document for Water Quality-Based Toxics Control (EPA-440/4-85-032, September 1985) where sufficient information exists to adequately characterize effluent and receiving water. ~~In situations where a Regional Board determines that the statistically-based approach to calculation of effluent limitations, as described in EPA's Technical Support Document for Water Quality-Based Toxics Control (U.S. EPA, 1985), may appropriately be applied,~~

For discharges to waterbodies which support aquatic habitat beneficial uses solely as a result of the discharge of wastewater, effluent limitations in WDRs for substances for which the aquatic life objectives are limiting shall be applied as follows:

(1) Initial effluent limitations shall be based on the aquatic life objectives in Tables 1 or 2 and calculated by the methods described above.

(2) Within 5 years, revised effluent limitations based on effluent quality may be established for substances other than selenium and endrin, provided the chronic toxicity limitation is consistently met.

(3) Any increase in an effluent limitation as a result of this process shall not constitute backsliding.

DRAFT

The four-day average shall apply as the mean concentration from samples collected over a four-day period.

The daily average shall apply as the mean concentration from samples collected during a 24-hour period.

The one-hour average shall apply as the mean concentration from samples collected during a one-hour period.

The instantaneous maximum shall apply to any single grab sample.

The 30-day average shall apply as the mean concentration from samples collected over a 30-day period.

The six-month median shall apply as a moving median of daily values for any 180-day period in which daily values represent flow-weighted average concentrations within a 24-hour period. For intermittent discharges, the daily value shall be considered to equal zero for days on which no discharge occurred.

See Appendix I for definition of terms.

recalculation of the objective using measured site-specific bioconcentration factors, fish consumption, body weight, and/or other relevant factors; and

f) the ~~alternate~~ site-specific objectives will provide for the attainment and maintenance of the water quality objectives of downstream waters; ~~and~~ or

g) if the full potential of designated beneficial uses ~~aquatic life~~ is not protected, a use attainability analysis has been conducted.

In developing site-specific objectives, ~~the~~ requirements ~~for~~ of the Porter-Cologne Water Quality Control Act and the federal Clean Water Act must be ~~are~~ met.

~~Alternate site-specific water quality objectives as established by the Regional Board are not effective until approved by the State Board with the concurrence of EPA.~~

DRAFT

Chapter III. PROGRAM OF IMPLEMENTATION ~~PROVISIONS~~

A. Effective Date

This ~~Plan~~ plan is in effect as of the date of adoption by the State ~~Water Resources Control~~ Board.

B. Mixing Zones, Effluent Limitations, ~~and~~ Monitoring Requirements, and Compliance Determination

~~The State Board is authorized to issue and enforce NPDES permits and waste discharge requirements established pursuant to the federal Clean Water Act and the Porter-Cologne Act.~~

Effluent limitations in WDRs shall be imposed such that the water quality objectives established by this plan ~~in Tables 1, 2, and 3~~ shall not be exceeded in the receiving water outside any designated mixing* zone. ~~Effluent limitations shall not cause receiving water concentrations of pollutants to exceed levels that existed on the date of adoption of this plan.~~ Where the Regional Board is satisfied that any substance(s) in Tables 1~~,~~ and 2~~, and 3~~ does not occur, or is not likely to occur, in a discharger's effluent, the Regional Board may elect not to establish effluent limitations for such substance(s), provided the discharger conducts periodic monitoring for all pollutants in Tables 1~~,~~ and 2, ~~and 3~~ and certifies that such substance(s) are not in the waste* stream~~.~~ and that no change has occurred that could cause such substance(s) to be present in the waste* stream. Such a determination shall be based on the discharger's certification that the substance is not in the waste* stream and that no source has been identified which would likely result in the presence of such substance in the waste* stream. This certification shall be accompanied, at a minimum, by laboratory analysis of the discharge for substances listed in Tables 1 and 2, and by process and treatmentdescription which demonstrate the absence of such substances in the waste* stream. At a minimum, this monitoring and certification shall

* See Appendix 1 for definition of terms.

VOL 12

1 7485

be required prior to issue ~~or~~ and reissue of ~~NPDES permits or waste discharge requirements~~ WDRs. The Regional Boards may choose to ~~shall have the discretion to~~ not require periodic monitoring and certification for these pollutants in ~~de minimus~~ low volume discharges determined to be of little threat to water quality.

11. Application of Mixing* Zones

A mixing* zone is a volume of a receiving water that is allocated for mixing with a wastewater discharge. Mixing* zones will be granted or denied by the Regional Boards after consideration of site-specific factors and according to the provisions of this section. ~~If a mixing zone is allowed, numerical water quality objectives must be met at the edge of the mixing zone. Numerical~~ Water quality objectives are to be met throughout a waterbody except within any mixing* zones granted by a Regional Board. A mixing* zone is not a source* of drinking water. To the extent of any conflict between this determination and the Sources of Drinking Water Policy (State Board Resolution No. 88-63), this determination supersedes the provisions of the policy.

All Enclosed Bays and Estuaries

~~1.~~ a Mixing* zones can only be applied to point source discharges, and nonpoint source discharges with a physically identifiable point of discharge, ~~to surface waters~~ regulated through ~~NPDES permits, waste discharge requirements, or reclamation requirements~~ WDRs issued or waived by the Regional Boards. A mixing* zone shall apply only in the calculation of water* quality-based permit limits and shall not be used to meet technology*-based permit limits.

~~2.~~ b The primary goals when designating a mixing* zone are to ~~limit~~ define areas where ~~numerical~~ water quality objectives need ~~are~~ not be met and to avoid unreasonable wastewater treatment. The Regional Boards must balance these goals before granting a mixing* zone. If a Regional Board allows a mixing* zone, the WDR ~~NPDES permit, waste discharge requirements, or reclamation requirement~~ shall specify the method by which the mixing* zone was derived and either the dilution ratio granted to the discharge or the point in the receiving water at which water quality objectives must be met.

~~3.~~ c The Regional Boards shall deny a mixing* zone if necessary to protect beneficial uses. Careful consideration shall be given to the appropriateness of a mixing* zone where the discharge contains pollutants that are carcinogenic, mutagenic, or teratogenic to humans, and for pollutants that are attractive to aquatic organisms, persistent*, or subject to bioaccumulation*.

* See Appendix I for definition of terms.

VOL 12 17486

VOL 12

~~4~~/o A mixing* zone shall be as small as practical ~~possible~~. A mixing* zone shall not restrict passage of aquatic life. Pollutants in a mixing* zone shall not create objectionable* bottom deposits. Acute* toxicity shall not occur in a mixing zone.

~~5. A Regional Board may specify more stringent mixing zone provisions than those contained in this plan. Less stringent mixing zone provisions than those contained herein may be allowed by a Regional Board with State Board and EPA concurrence, as indicated under "Exceptions to Plan Requirements".~~

Enclosed Bays

Mixing zones for discharges with a high-rate diffuser to enclosed* bays shall not extend beyond the zone* of initial dilution. For discharges without a high-rate diffuser, or where a Regional Board has identified a site-specific concern with a particular pollutant in a bay ~~or estuarine~~ environment, a maximum* dilution credit may be applied.

DRAFT

Estuarine Rivers and Streams

Mixing* zones for discharges to estuarine rivers and streams shall be based on a designated volume or percentage of stream flow, as determined by the Regional Board. If a Regional Board ~~determines a dilution ratio by~~ allocates~~ing~~ a ~~percentage of the stream flow for~~ mixing* zone, the outfall must be designed for rapid mixing in the receiving waterbody. Regardless of the method used, the mixing* zone shall not extend more than 250 feet from the point of discharge, to ensure rapid mixing, or be located less than 500 feet from an adjacent mixing* zone. A zone* of passage for aquatic life should be provided if, in doing so, adverse impacts on sensitive aquatic species would be minimized. ~~Design flows~~ Dilution ratios for effluent ~~permit~~ limitation derivation can be based on either steady-state* or dynamic* considerations.

1 7487

2. Calculation of Effluent Limitations

Where a wasteload allocation has not been completed, water quality-based effluent limitations shall be developed using one of the following methods, (a) or (b):

(a) $Ce = Co + D(Co - Cb)$, when $Co > Cb$, and
$Ce = Co$, when $Co \leq Cb$.

~~Effluent limitations (Ce) for substances identified in Table 1 shall be determined through the use of the following equation:~~

*See Appendix I for definition of terms.

R0050792

~~Ce = Co + D(Co - Cb)~~

where Ce = the effluent concentration limit for the substance,
Co = the ~~concentration~~ (water quality objective) for the substance to be met in the receiving waterbody ~~at the edge of any designated mixing zone (Table 1 objectives),~~
Cb = the ambient background concentration of the substance in the receiving waterbody, and
D = the allocated dilution ratio, expressed as parts receiving water per part wastewater, based on mixing* zone provisions.

Ambient background concentration (Cb) means the median concentration of a substance, in the vicinity of a discharge, which is not influenced by the discharge. Ambient concentrations should be determined using analytical methods at least as sensitive as those used to determine compliance with effluent limitations.

(b) Regional Boards may elect to apply the statistically-based approach to the calculation of effluent limits, as described in EPA's Technical Support Document for Water Quality-Based Toxics Control (EPA-440/4-85-032, September 1985) where sufficient information exists to adequately characterize effluent and receiving water. ~~In situations where a Regional Board determines that the statistically-based approach to calculation of effluent limitations, as described in EPA's Technical Support Document for Water Quality-Based Toxics Control (U.S. EPA, 1985), may appropriately be applied.~~

For discharges to waterbodies which support aquatic habitat beneficial uses solely as a result of the discharge of wastewater, effluent limitations in WDRs for substances for which the aquatic life objectives are limiting shall be applied as follows:

(1) Initial effluent limitations shall be based on the aquatic life objectives in Tables 1 or 2 and calculated by the methods described above.

(2) Within 5 years, revised effluent limitations based on effluent quality may be established for substances other than selenium and endrin, provided the chronic toxicity limitation is consistently met.

(3) Any increase in an effluent limitation as a result of this process shall not constitute backsliding.

The four-day average shall apply as the mean concentration from samples collected over a four-day period.

The daily average shall apply as the mean concentration from samples collected during a 24-hour period.

The one-hour average shall apply as the mean concentration from samples collected during a one-hour period.

* See Appendix 1 for definition of terms.

CALIFORNIA REGIONAL WATER QUALITY CONTROL BOARD

Resolution No. 89-002

Regional Board Acceptance of Storm Runoff Report

WHEREAS:

1. The Los Angeles Regional Water Quality Control Board and the Southern California Coastal Water Research Project conducted a cooperative study of storm runoff in Los Angeles and Ventura Counties.

2. Pursuant to terms of the cooperative agreement, the Southern California Water Research Project has completed and submitted a final report entitled Storm Runoff in Los Angeles and Ventura Counties.

3. The study provides new information on the contaminant load that enters the coastal waters off Los Angeles and Ventura Counties.

4. A significant reduction in pollutant discharge to coastal waters can be achieved through better management and control of urban runoff.

NOW, THEREFORE, BE IT RESOLVED:

1. That the Regional Board accepts the report, Storm Runoff in Los Angeles and Ventura Counties; and

2. That the report be distributed to all affected agencies and interested parties; and

3. That staff be directed to work with all appropriate agencies to develop an urban runoff management strategy to control pollutant discharges to coastal waters.

I, Robert P. Ghirelli, Executive Officer, do hereby certify that the foregoing is a full, true and correct copy of a resolution adopted by the California Regional Water Quality Control Board, Los Angeles Region, on February 27, 1989.

SUMMARY

Forty-nine samples of runoff were collected from eight sites in Los Angeles and Ventura Counties on September 23-25, 1986, during the first rain after the dry season. Six sites were near the mouths of major storm channels and three were spread along the Los Angeles River, the largest source of gaged runoff in Southern California. Suspended solids, oil and grease, total extractable organics (TEO), trace metals, DDT, polychlorinated biphenyl compounds (PCBs), polycyclic aromatic hydrocarbons (PAHs), and n alkanes were measured. Fifteen-minute flow data were obtained for most sites from the county flood control districts. Because the storm was unpredicted and so early in the rain season, samples were not taken as regularly as planned, but low-flow, high-flow, and post high-flow samples were taken at each site.

In general the highest contaminant concentrations occurred near the peak flows and not at the first increase in flow. With few exceptions the highest concentrations appeared at the channels with the greatest flows also making them the greatest sources of contaminant mass emissions.

The two Ventura sites showed minimal increases in flows, probably due to a limited amount of impermeable surface area and the dry status of the soils. The Santa Clara River samples had the highest suspended solids concentrations and DDT levels of any site, but the low volumes produced very low mass emissions.

Accurate flow measurements at the four Los Angeles County sites were obtained only for Ballona Creek and the three sites on the Los Angeles River. There was no gage on the Dominguez Channel and one of two gages required to determine the total flow for the San Gabriel River failed during the storm.

Flows from the Los Angeles River, Ballona Creek and the San Gabriel River were large; each exceeded the daily flow of the largest municipal wastewater treatment plant in the county. The runoff of the Los Angeles River at Willow Street and Ballona Creek had the highest mean concentrations of almost all contaminants. Concentrations of oil and grease, cadmium, chromium, copper, and nickel were similar to Hyperion 1985 five-mile effluent values, while lead, zinc, DDT, and PCB concentrations were higher.

Within the Los Angeles River system, runoff contaminant concentrations increased from the headwaters at Tujunga Wash through the mid-river site at the San Fernando Valley to the mouth near Long Beach. Most contaminants were below detectable limits at Tujunga Wash above any land development.

Downtown Los Angeles and the commercial and industrial area of south Los Angeles County added less than one-half the flow of the upstream drainage but three to five times the mass of contaminants.

Petroleum hydrocarbon characteristics in runoff were not very consistent within or between channels. However gas chromatograms for most samples contained unresolved complex mixtures (UCMs) humps characteristic of crankcase oil inputs. The relative abundances of polycyclic aromatic hydrocarbons (PAHs) in runoff samples at several sites indicated the input of unweathered petroleum and combustion by-products with the latter in greater amounts.

VOL 12

17495

Previous studies found that the mean concentrations of contaminants in the Los Angeles River did not change much between 1971/72 and 1979/80, except for lead and PCBs. Our preliminary results for the Los Angeles River do not indicate much change since 1979 with the exception of a fourfold decrease in DDT concentrations.

INTRODUCTION

This report is the result of a cooperative study with the Los Angeles Regional Water Quality Control Board to measure runoff contaminant concentrations and to estimate mass emissions during storm flow conditions at several important channels in Los Angeles and Ventura Counties. Three to ten samples were taken at each of seven sites (49 samples total) during a 48-h period in order to sample peak and decreasing flow stages. We measured concentrations of suspended solids, percent volatile solids, oil and grease, TEO, cadmium, chromium, copper, nickel, lead, zinc, DDT, DDD, DDE, PCBs, n-alkanes and PAHs in whole water samples. A subset of samples was analyzed for triterpanes and steranes by UCLA. Rainfall and flow data were obtained from the County Flood Control Districts.

Results from a second storm sampled in January 1987 at these sites are not included in this report but will be reported when complete data become available. This study is part of a long-term Southern California Coastal Water Research Project (SCCWRP) program to update and improve past estimates of contaminant inputs to the Southern California Bight. By the summer of 1988 we will have sampled storm runoff from the largest storm channels in four of the coastal counties of Southern California.

Background Studies

Southern California Bight

Beach closures, pelican reproduction failures, fin rot, contaminated fish seizures, and kelp bed disappearances off the Southern California coast have stimulated interest in anthropogenic inputs of contaminants to Southern California coastal waters since the 1960's. Extensive monitoring of trace metals and chlorinated organics in municipal wastewater effluents, the principal source of most anthropogenic contaminants to the Southern California Bight (20, 26), began around 1970 and has expanded through the 1970's and 1980's. By 1985, source control, improved sludge handling, and increased treatment (additional advanced primary and secondary treatment) combined to reduce wastewater emissions significantly. Silver, cadmium, chromium, copper, mercury, nickel, lead, and zinc discharges were an average of 65% lower than peak (mid-1970's) emissions. DDT and PCB discharges were 99 and 90% lower, respectively. These reductions occurred despite increases in population and effluent flows (21). Recently, completed and planned municipal wastewater effluent improvements should continue to reduce outfall inputs while continued population growth and land development have made and will continue to make runoff a more important pollutant source of contaminants than it was 10 years ago.

Studies of contaminants in Southern California runoff are scarce compared with those available for municipal wastewater outfalls. Among possible reasons are (1) no agency has been responsible for storm drain water quality; (2) storm flow (which is responsible for most runoff volume and contaminant emissions) is unpredictable, highly variable and limited to a few months of the year; and (3) representative samples of storm flow are not easily obtained.

One of the first studies to measure runoff impacts in Southern California was conducted by Chen in the early 1970's at Marina del Rey (4). Water and sediment samples were taken from the marina near two storm drains and Ballona Creek over several stormy periods. It was determined that storm runoff had little direct effect on trace metal and pesticide levels in the water column within the marina. In contrast, sediments near the runoff channels were highly contaminated; sediments near the storm drains with DDE levels up to 5.5 mg/dry kg were 60 times more contaminated than sediments near the Hyperion five-mile outfall.

The most detailed and complete study of runoff emissions was conducted by SCCWRP during 1971/72, an unusually dry year (43% of average annual runoff). Wet and dry weather flows were sampled at four major rivers, and dry flow was sampled at an additional 11 streams in Southern California (20). Based on this limited survey it was concluded that the contribution of contaminants via runoff was less than 10% of that discharged by municipal outfalls in southern California. Exceptions to this generalization included suspended solids, nitrate, nitrogen, iron, manganese, lead, and cobalt. Two contaminants of note were suspended solids (274,000 metric tons, 99% of effluent emissions) and lead (90 metric tons, 43% of effluent emissions). DDT (0.12 metric tons) and PCB (0.25 metric tons) emissions were about 1 and 3%, respectively, of the combined outfall values.

Using the same sampling technique, Young et al. (25) repeated a similar study of three storms at the largest source of runoff in Southern California, the Los Angeles River (30% of the total average annual gaged flow from Southern California) in 1979/80. In that year low flow was responsible for only 5% of the annual discharge, and low-flow contaminant concentrations were approximately one-half of the storm concentrations. This indicates that storm runoff was by far the most important source of mass emissions. The 1979/80 study and the 1971/72 study also showed that with the exception of nickel, 88-99% of the trace metal and chlorinated hydrocarbons were associated with particulates (>0.4 m). A comparison of flow-proportioned mean concentrations of 10 trace metals, DDT, and PCBs between two storms in 1971/72 and three storms in 1979/80 showed that the standard error of 10 of the 12 contaminants was less than 50% (six of the twelve were less than 20%). This suggests that there was not a large difference in mean concentration values between years. Differences in lead and PCB concentrations were much larger than those of the other contaminants, and mean concentrations (between 1971/72 and 1979/80) showed a six- and eightfold reduction, respectively. These reductions were most likely due to legal restrictions on the industrial use of both compounds.

The Los Angeles County Flood Control District (now called the Department of Public Works) has conducted detailed monitoring of storm channel contaminants since the late 1960's. Monthly samples from 30 channel sites were collected from 1967 through 1984 (5). Biochemical oxygen demand (BOD) and levels of oil and grease, nutrients, trace metals, pesticides, and bacteria were measured (5). In 1985, the monthly monitoring program was reduced to 7 stations plus 14 additional stations monitored bimonthly or quarterly and 15 stations sampled twice annually during storm flows (6). Although this is the largest storm channel data base for Southern California and may reveal trends in low flow concentrations, it was not designed for the estimation of mass emissions because corresponding flows have not been recorded. In addition, runoff was rarely sampled during peak flows when

VOL 12

17497

concentrations are most variable and emissions are most significant. Despite limitations of this data set, Garber (12) has made some preliminary estimates of long-term emissions rates to Santa Monica Bay. He used the annual average concentrations from Flood Control contaminant data and annual flow measurements from four gaged channels and assumed individual storm drains contribute about 40% of the gaged runoff. The single greatest cause of variation in annual emissions is variation in annual water discharge volume.

Figures 1 and 2 show the annual flow and lead emissions between 1967 and 1982 for the Los Angeles River, the total runoff to Santa Monica Bay, and the Hyperion combined outfalls. From the available data, Garber (12) estimated that Santa Monica Bay runoff inputs (1967-1982) of lead, selenium, nickel, copper, mercury, chromium, and total identifiable hydrocarbons to be 40%, 17%, 14%, 6%, 52%, 9%, and 7%, respectively, of the 1987 emissions from Hyperion's two outfalls. These estimates are probably low because storm conditions (which normally lead to much higher contaminant concentrations) were not proportionally sampled. As of the end of 1987 the sludge outfall discharges have been terminated reducing many outfall contaminant inputs by 50% and further increasing the importance of runoff as a source of contaminants.

The Pico-Kenter storm drain in Santa Monica delivered a small but regular flow that accumulated on the beach. This site has been the focus of attention because of petroleum-like discharges that have closed the beach and because of high incidences of cancer in lifeguards who have worked in the area (7). The linkage of storm drain constituents to the incidences of cancer has been investigated (and discounted) and chemical values (nutrients, BOD, chemical oxygen demand (COD), oil and grease, phenols, cyanide, and 14 metals) have been reported (7). Estimates of mass emissions have been made by using Pico-Kenter contaminant data and County Flood Control flow data for all of Santa Monica Bay (18). These calculations estimate that runoff to the bay is responsible for 10% of the oil and grease and 10-50% of the trace metals that the seven-mile sludge line discharged in 1981.

Studies of water and sediment quality in Marina del Rey, the adjacent mouth of Ballona Creek, and storm drains entering the harbor (13) have shown higher levels of contaminants at sites near the storm drains and creek mouth than in the harbor. Elevated contaminant concentrations and reduced dissolved oxygen were detected at most stations after storm runoff. Interestingly, measurements of oil and grease in runoff to Marina del Rey showed no decrease in the concentration ranges through three consecutive storms indicating a large reserve.

Eganhouse and Kaplan (9-11) characterized organics in Los Angeles River water from an early season storm in 1978 and compared constituents and masses of runoff inputs with municipal emissions. They found that 60% of the extractables were petroleum derived, whereas the non-hydrocarbons were mostly biogenic. Although runoff inputs of hydrocarbons were estimated to be one-half of municipal outfall inputs to Southern California, they were estimated to represent 2% of the global inputs from all sources to the ocean.

In 1986 Anderson and Gossett (1) reported on PAHs in marine sediments from the outfall and harbor areas between San Diego and Los Angeles. They found some of the highest levels near the mouths of the Los Angeles River, and the Dominguez Channel and near storm drains in San Diego Bay.

Background Outside Southern California

In comparison to Southern California runoff, the east coast of the United States has been extensively studied (2, 15, 16, 17, 23). There is also considerably more information about sources of contaminants. However, these studies were carried out in areas that receive much more frequent rain than Southern California does, and in most cases rainfall occurs throughout the year with short intervals between runoff events.

In a three-year study of contaminant sources and mass emissions to Narragansett Bay, Hoffman and Quinn (15) determined that runoff was the largest source of petroleum hydrocarbons, high molecular weight PAHs, lead, and zinc to the bay. Municipal outfalls were the major source of low-molecular-weight PAHs. Although highways and industrial areas occupied a relatively small portion of the drainage basin they were important sources because of their very high concentrations. Highways and industrial runoff contained, respectively, 40 and 80 times the petroleum hydrocarbons, 40 and 12 times the copper, 100 and 7 times the lead, and 160 and 15 times the zinc as residential runoff concentrations.

In Richmond, California, Stenstrom et al. (22) measured oil and grease emissions from five different land use areas in a basin that drains into San Francisco Bay. The authors concluded that runoff emissions were an important and growing problem and that 50% of the oil and grease emissions from the studied basin could be eliminated if emissions from industrial and parking facilities (11% of land in the basin) were controlled.

Ebbert and Wagner (8) examined 35 collection sites from eight urban areas throughout the United States, compared rain concentrations of contaminants with runoff concentrations, and found that rain could be a significant source of contaminants. The mean contributions of rain to runoff emissions were 74% for nitrate plus nitrite, 12% for COD, 12% for copper, 6% for lead, and 2% for suspended solids.

Richards and Holloway (19) used Monte Carlo techniques to evaluate the accuracy and precision of tributary load estimates using a 4000 data point sampling set. Hypothetical annual sampling programs with 12 to 600 samples were examined. The results showed that the bias and precision of loading estimates were influenced not only by the frequency and pattern of the sampling plan but also by the size of the drainage basin (smaller channels need more frequent sampling) and the behavior of the constituent measured. Stratified sampling with the bulk of the samples taken during the highest flow will produce the most accurate estimates. Estimates within 20% accuracy are suggested with only a few low flow measurements and careful concentrated sampling during the 2 or 3 greatest flows of the year (24).

OBJECTIVES

The primary objective of this study was to determine the concentrations of contaminants from major runoff sources and to estimate their mass emission rates to the ocean. These data are compared to past estimates of runoff emissions as well as other sources of contamination to the Southern California Bight.

VOL 12 1799

We also determined how the concentration and mass of contaminants varied throughout the storm events to see if significant portions of the mass emissions were concentrated in a small part of the flow. We sampled sites to see how contaminant levels varied with land use. In addition, we measured polycyclic aromatic hydrocarbons (PAH) concentrations for the first time for several channels to determine which compounds were present in Southern California runoff.

METHODS

Six large runoff sources in Ventura and Los Angeles Counties were sampled (Figure 3). Each channel has a unique drainage basin, and most of the channels (Santa Clara River, Calleguas Creek, Los Angeles River, and San Gabriel River) receive wastewater effluent from one or more municipal wastewater treatment plants. This contributes significantly to dry weather flows.

Sampling locations on each channel were selected for the following reasons: (1) to provide safe sampling; (2) to be used under adverse weather conditions; (3) to provide access to the center channel of the flow; and (4) to be downstream from the major sources of runoff contaminants. In an attempt to sample downstream from potential major sources we located three of our stations (Calleguas Creek, Dominguez Channel, and San Gabriel River) in the upper reaches of the tidal prism.

Santa Clara River

The Santa Clara River drains the second largest basin in Southern California (4,200 km^2) and has produced some of the largest peak flows (165,000 cfs) in Southern California's history. However, the flow near the mouth is poorly correlated with natural weather conditions because water is imported from the California Water Project and flow in the upper and middle river is regulated by releases from the dams at Lake Piru, Lake Pyramid, and Lake Casitas. Diversions and groundwater recharge prevent upstream flows from reaching the ocean except during large storms. Even below the last water diversion the dry sandy riverbed is capable of absorbing most of the flow from early season and small storms.

We sampled on the north side of the channel where Highway 101 crosses the river (H on Figure 3). This site is located about 8 km above the mouth of the river, which is at McGrath State Beach. Our site is the last accessible, safe location to sample moderate or high flow conditions. The channel is over 300 ft wide, and the bed is unlined.

Calleguas Creek

Calleguas Creek drains 650 km^2, including the southern part of the Hueneme Plain, and receives secondary effluent discharge from several treatment plants. This sampling site on Highway 1 is in the middle of the tidal prism and above Mugu Lagoon (I on Figure 3). We decided to sample here because it would allow us to obtain runoff from Calleguas Creek as well as Revlon Slough, which also drains a large portion of the Hueneme Plain that is used intensively to grow vegetables and other cash crops. Unfortunately, between the time we selected this site and when it was sampled, the channels were separated and the junction point moved below our site location. Therefore we collected separate samples from only

Calleguas Creek. Flow data were obtained from the Ventura Department of Public Works from their station at Camarillo, which is about 6 km above the sampling site.

Ballona Creek

Ballona Creek drains 232 km^2 of highly urbanized land in West Los Angeles. The main channel is concrete lined. Oil and tar lines on the banks of the channel are evidence of the occasional discharge of petroleum from freeway tanker spills and other sources. Our sampling station (D on Figure 3) is located 4 km above the mouth of the creek, between the entrance to Marina del Rey and the beach at Playa del Rey. The station on the Inglewood Avenue bridge is above tidal influence except during the highest tides; however, we saw no visual or chemical evidence of saltwater intrusion during any sampling period. Flow data were obtained from the Los Angeles County Department of Public Works recording gauge F 38C-R, which is located near Sawtelle Avenue about 1 km above the sampling site.

Dominguez Channel

The Dominguez Channel drains about 100 km^2 of industrial and urban land in south Los Angeles. In the past, the upper reaches received runoff from the Montrose Chemical Plant. This plant was the source of most of the DDT discharged from municipal outfalls or dumped into Southern California marine waters between the late 1940's and mid-1970's (3). The sides of the Dominguez Channel are covered with riprap, and the lower 10 miles are within the tidal prism and continuously filled with water. There is no recording flow gage in the lower reaches of the channel. The sampling site (C on Figure 3) is located on the railroad bridge just south of Anaheim Street, which was as close to the channel's termination in Los Angeles/Long Beach Harbor as possible. Although this sampling site lacked adequate flow data and was in the lowest section of the tidal prism, we decided to sample here because the 5-6 km of channel immediately above this site is lined with oil refineries. In addition, the harbor sediment just below our sampling site has been shown to have very high levels of petroleum hydrocarbons and pesticides (1). Justification for selecting this site comes from its high potential for producing environmentally significant concentrations of contaminants under rapid flow conditions.

Los Angeles River

The Los Angeles river was sampled because it is responsible for about 30% of the total annual gaged runoff from Southern California and it has been studied twice before by using similar techniques. Three sites were selected in an attempt to separate sources of contaminants to the river. The upper river basin is slightly developed, the middle portion drains the San Fernando Valley and is largely residential, while the lower half of the river drainage is more commercial and industrial. The three sites sampled were Big Tujunga Wash (F on Figure 3), Fletcher Avenue Bridge (E on Figure 3), and the Willow Street Bridge (B on Figure 3).

Big Tujunga Wash is one of three major tributaries draining the foothills above Los Angeles. Our sampling site was located below the Big Tujunga Dam which collects runoff from undeveloped steep-sloped hills. Although the flow in this area is small, we decided to sample here because anthropogenic contaminants in this area could only have been deposited by aerial fallout.

VOL 12

1750 1

The Fletcher Avenue Bridge crosses the Los Angeles River about halfway between the headwaters and the mouth. Drainage above this site is mostly from the suburban San Fernando Valley and the less developed foothills. The Los Angeles County Public Works Department maintains a recording gage that records flow at 15-min intervals at this site.

The Willow Street sampling site is located in Long Beach at the end of the concrete-lined channel about 2 km above the river mouth in Long Beach Harbor. The total area drained above this site is about 3200 km^2. Past flows at this site have reached over 100,000 cfs. This section of the channel receives runoff from downtown Los Angeles and the commercial/industrial developments of east and southeast Los Angeles. The Rio Hondo Channel is approximately 16 km above this site and is capable of transferring water from the San Gabriel River to the Los Angeles River at the discretion of the Public Works Department.

Flow data for the three sites were obtained from the Los Angeles County Department of Public Works for stations F168-R, F57C-R, and F319-R (Figure 3). These are within 1 km of their respective sampling sites.

San Gabriel River

The San Gabriel River drains approximately 1600 km^2, but its discharge to the ocean is relatively small. During low flow and small storm flows much of the upper river water is retained for groundwater recharge. Most of the dry weather flow in the lower river is from advanced wastewater effluents.

We intended to sample two sites on the San Gabriel River; however, the first storm occurred so early in the season that we missed sampling the upper station at San Gabriel Parkway.

The lower San Gabriel River was sampled at College Park, (A on Figure 3), which is about 3 km above the river mouth in Long Beach Harbor. Unfortunately, this site was also located about 1 km below the upper end of the tidal prism. The site was selected because it was the nearest point of access below the confluence of the San Gabriel River and Coyote Creek. Storm flows from Coyote Creek to the San Gabriel River can constitute more than one-half of the total flow. We selected this site under the assumption that any significant flow would flush saltwater out even at the highest tides. However, salinity measurements of a few low flow samples taken at high tide indicated the presence of marine water. Consequently, trace metals were not measured for those samples nor were they included in emission estimates. Two Los Angeles County Department of Public Works flow gages were required to measure the total flow from both channels for our site. Gage F428-R on the San Gabriel River malfunctioned during the storm and no data were collected. Gage F354-R, below Spring Street, measured Coyote Creek flow about 3 km above the sampling site. Mass emission estimates are based only on the Coyote Creek flow.

Samples were collected from the center of flow for each channel by lowering an acid-washed kilned 1-gallon bottle in an epoxy covered metal sampler that was equipped with a horizontal and vertical tail stabilizer that kept the bottle opening facing upstream. The bottles passed through the surface layer uncapped. The sampler was submerged about 0.5 meter below the surface, and was filled in about 90 seconds. The sampler was deployed twice for each sampling period, and the sample was proportionally divided into the sample containers for organics (4 liters),

VOL 12 17502

trace metals (1 liter), suspended solids (1 liter), oil and grease (1 liter), and toxicity (20 ml).

Cumulative rainfall data from 17 sites (Table 1) located within the drainage basins that we were studying were collected from Los Angeles County Department of Public Works files.

River Flow Data

Figure 3 shows gaging stations for Los Angeles County. The gages on Ballona Creek, the Los Angeles River, the San Gabriel River, and Coyote Creek can provide flow data at 15-min intervals. Continuous flow data for Calleguas Creek were provided by the Ventura County Department of Public Works. Data for the Santa Clara River flow are based on field crews observations, which we believe to be acceptable since the flow was low and did not change much during the storm.

RESULTS AND DISCUSSION

A complete listing of flow rates, flow volume, interval volume, contaminant concentrations, and mass emissions for each sample is listed in Appendix A.

Differences Between Sites

Mean concentrations

Flow-proportioned mean contaminant concentrations and ranges for eight sites are summarized in Table 2. Histograms of mean concentrations at the sampling sites are shown in Figure 4, A-N.

Suspended solids mean concentrations for seven sites are shown in Figure 4, C. The highest (1250 mg/liter at the Santa Clara River) and lowest (30 mg/liter at Calleguas Creek) concentrations were found in Ventura County. The sites in Los Angeles County ranged between 200 and 750 mg/liter.

The Los Angeles River at the Willow Street site (Figure 4; B, D-H). generally had the highest concentrations of hydrophobic (oil and grease, total extractable organics, PAH, n-alkanes, PCBs, and DDT) contaminants. Exceptions occurred at Ballona Creek, which had 50% more oil and grease and a DDT concentration 4 times that of the Willow Street site, and Santa Clara, which had a DDT concentration 11 times that of the Willow Street site.

The trace metals concentrations (cadmium, chromium, copper, nickel, lead, and zinc) were all highest at Ballona Creek followed by the LA River at Willow (Figure 4, I-N). Concentrations at Tujunga Wash were consistently below detection, while the other sites had roughly equal levels.

Within the LA River system contaminants increased between upper and lower stations. The Willow runoff had about twice the amount of suspended solids as the upper two stations did. Oil and grease and TEO concentrations quadrupled between Tujunga and Fletcher and again between Fletcher and Willow. Metal concentrations were below detection limits at Tujunga, but metal concentrations at Willow were two to four times higher than those at Fletcher (Figure 4, I-N).

VOL 12

17503

VOL 12

Mean concentrations per gram of suspended solid

Past studies have shown that most of the contaminants are associated with suspended particulates (9, 21). We have calculated contaminant concentrations per gram of suspended solid in Table 3 assuming that all of the contaminants are particulate bound. This could be a misleading supposition if contaminant levels are very low and dissolved contaminants constitute a significant percent of the total concentration. However, with this caution in mind Table 3 (and Figure 5, A-L) gives an indication of quality of particulates that may accumulate in sediments or be spread in near-shore waters.

Oil and grease measurements at Tujunga and Santa Clara were an order of magnitude less than at the other sites (Figure 5, A). The four sites with moderate to high flows (Willow, Fletcher, Ballona, and San Gabriel) had similar values between 10.5 and 23.6 mg/g. The very high concentrations at Calleguas Creek were a result of the very low concentrations of suspended solids.

DDT and PCBs had two different patterns (Figure 5, E-F). Santa Clara River and Ballona Creek particulates were more contaminated with DDT than were particulates at the other sites, while PCBs were more uniformly distributed at all sites except Tujunga Wash.

The Los Angeles River and Ballona Creek had much higher concentrations of PAHs and n-alkanes than the other sites.

The trace metals concentrations on suspended solids (Figure 5, G-L) were reasonably uniform at four stations (Willow, Fletcher, Ballona, and San Gabriel), while concentrations of metals at Tujunga and the Santa Clara River were much lower.

Los Angeles River System

Within the Los Angeles River stations, the Tujunga samples had the lowest contaminant concentrations but moderately high suspended solids levels. This resulted in very low concentrations per gram of suspended solid. The trace metals, pesticides, PCBs and PAHs were below detection limits while oil and grease and n-alkanes were 4 and 9 times higher than at mid-river. Concentrations of metals, pesticides and PCB on suspended solids are similar for samples from mid-river (Fletcher) and lower river (Willow). However, the lower river samples are 2 to 9 times high in TEO, PAHs and n-alkanes.

Mass Emissions

Calculated flow-proportioned mass emissions are listed in Table 4 and shown in Figure 6, A-N.

The Los Angeles River is the largest source of runoff to the Southern California Bight. The highest flows combined with the high concentrations caused the Willow Street site to have the highest mass emissions of all constituents except DDT.

For all constituents except DDT there is a consistent pattern of greatest emissions coming from the Los Angeles River, then Ballona Creek followed by Fletcher and San Gabriel. The remaining stations have minimal inputs.

1 7504

Within the LA River stations, Tujunga emits a miniscule volume of runoff and contaminants. The flow at the Willow site is about 30% greater than that at Fletcher, but contaminant emissions are 3 to 10 times greater, indicating a much greater source, in the lower basin.

The Ballona Creek drainage is only about 10% of the Los Angeles drainage basin, but during this storm its flow was about 40% of the LA River flow. The emissions of most contaminants were approximately 40% of the LA River emissions. Exceptions were lead and zinc, which were about equal to Willow emissions, and DDT and n-alkanes which were twice and one-sixth of the Willow emissions.

We have underestimated the emissions from the San Gabriel River because we only have flow data from Coyote Creek, so our estimates could be low by a factor of 2 or more. The measured flow is three-fourths the size of the Ballona Creek flow, but emissions of oil and suspended solids, oil and grease, TEO, trace metals, and chlorinated hydrocarbons are between 3 and 20% of Ballona's emissions, while PAH and n-alkane emissions are 1 and 3%, respectively.

Trends in flow and contaminant concentrations with time

Figure 7, A-H, shows the flow and concentrations of suspended solids, oil and grease, TEO, lead, total PAHs, total PCBs, and volatile solids for the Los Angeles River during the 48-h of sampling.

There were two peaks in flow about 6 h apart; the first peak exceeded 10,000 cfs, whereas the second peak returned to 9,000 cfs after dropping to 5,000 cfs.

The peak contaminant concentrations (except percent volatile solids) occurred in either sample 6 or 7 before the first peak in flow. Although sample 8 had the highest flow, the concentrations of all contaminants dropped. This may be due to a washout of contaminants.

Trends in Cumulative Emissions

As an example of when contaminant emissions occur, Figure 8, A-D, shows the cumulative percent flow with cumulative percent emissions of suspended solids, oil and grease, combined trace metals, and chlorinated hydrocarbons for the Willow station, and Figure 9, A-D, shows that approximately 80% of the flow and suspended solids were discharged within a 10-h period. Contaminant emissions lagged during the first 5% of flow but rapidly increased after 10% of the flow occurred. In general the first 25% of flow produced 50% of the contaminant emissions, and when 50% of the flow had occurred, 75% of the contaminant emissions had occurred. This pattern is representative of the other sites studied.

Petroleum hydrocarbon characterization

Aliphatic hydrocarbons

Figure 10a represents a typical chromatogram of the aliphatic fraction from our stormwater runoff samples. Generally, most of the samples contained a single hump of varying size (known as the unresolved complex mixture-UCM) and numerous resolved peaks which represent simple alkanes containing from 10 to 30

VOL 12 17505

carbons. The presence of a UCM maximizing at n-C21-C35 is indicative of crankcase oil in the runoff. The n-alkanes, which are the resolved peaks labelled with their respective number of carbons, showed maxima at n-C17 as well as the higher molecular weight n-alkanes with odd numbers of carbons (i.e., n-C27, C29 and C31). The odd-even carbon chain length predominance of these higher molecular weight species indicates the presence of waxes characteristically associated with the cuticles of higher plants.

There were two notable exceptions to the pattern illustrated in Figure 10a. First, samples taken from Ballona Creek at 6 and 47 hours contained two UCM humps, the first hump being larger and maximizing at n-C18 (Figure 10b). It has been suggested by some researchers that this pattern may be representative of bacterial degradation products. Second, the 31 hour sample taken from the Los Angeles River at Willow Street contained no UCM at all. It did, however, exhibit the highest concentrations of n-alkanes (mostly from the C23-C39 range) with little apparent odd-even predominance. This sample was taken during the second peak in flow at approximately 8500 cubic feet/second (Figure 7a). The distribution we observed is not consistent with a recent biogenic origin, but may be related to dewaxing of petroleum. Similar distributions were not observed in samples taken before or after this one. Therefore, it is unclear whether these results are anomalous, representing the inclusion of a small particle of pure wax, or an indication of a short-term input to the river.

Aromatic hydrocarbons

Figure 11 presents a relative abundance plot for the 26 PAHs measured in this study (see Appendix A for a list of the compounds and their individual concentrations). This sample was taken from the Los Angeles River at Willow Street after 30.8 hours and is indicative of the most common distributional pattern. Most of the samples contained some naphthalenes (compounds 1-4) and phenanthrenes (compounds 9-12) which are the dominant PAHs in unweathered petroleum. However, the compounds with four or more rings (fluoranthene through benzo[g,hi,i]perylene; compound 14-26), which are combustion products, were frequently present at higher concentrations. Therefore, results of this study showed a mixture of both types of hydrocarbons being discharged during this storm with a larger amount of combustion products present.

The PAH composition was variable throughout the storm at a single point on the channel and in samples taken contemporaneously during a storm at different sites in the channel. However, the plot from the Los Angeles River station at Willow Street (Figure 8) is comparable to those obtained by Anderson and Gossett (1) for bottom sediments collected at the mouth of the Los Angeles River as well as those for sediments from the vicinity of Los Angeles County's outfall, suggesting that stormwater runoff and municipal effluent may contain PAHs of similar composition.

CONCLUSION

As the emissions of contaminants from outfalls continue to decrease, runoff emissions become a more important source of marine inputs. Outfall emissions have been steadily reduced over the last 10 years (21), but little has been done to reduce contaminants. Young et al. (25) concluded that variations in runoff concentrations were not significantly different in the Los Angeles River between 1971 and 1979 except for lead and PCBs, which were reduced by factors of 6 and 8, respectively. There do not appear to be many major changes in concentration since

1979. Table 5 shows concentrations for the five storms measured in 1971 and 1979 and the present 1986 results. Between 1979 and 1986 copper and lead concentrations increased by about a factor of 2, while suspended solids and chromium were reduced by two-thirds and one-half, respectively. The rest of the trace metals and PCBs varied by less than one-third. DDT had the largest change and was reduced by a factor of 4.

How the volume of runoff affects contaminant emissions is not clear. Los Angeles River runoff in 1971/72 was about one-half of normal runoff, while 1979/80 produced runoff five times the 15-year average; yet Young and his co-workers found most contaminant concentrations to be similar. Five of the twelve highest concentrations in the year did not occur in the first storm of 1979, and the third storm had cadmium and lead concentrations higher than those of the first storm. Data from the storm we sampled in January 1987 should allow us to determine the changes between storms within a year.

We did have some indication of a washout of contaminants in the Los Angeles River in this year's study because almost all of the contaminant concentrations peaked before our highest flow sample was taken. If the distribution of rain on land use areas did not change significantly there may have been a reduction in available contaminants. Hoffman et al. (14) found that residential, highway, commercial, and industrial areas had different rates of washout during a storm with residential concentrations of petroleum hydrocarbon approaching zero after less than 2 cm of rain, while industrial sites showed no reductions in concentrations after 2 cm of rain.

Large flows from Ballona Creek, Los Angeles River Willow, Los Angeles River Fletcher, and the San Gabriel River exceeded 3.5×10^9 liters (920 million gallons) during the storm, while flows of less than 0.32×10^9 liters (84 million gallons) occurred at the Santa Clara, Tujunga, and Calleguas sites.

During the storm, flows changed very little at Big Tujunga Wash, the Santa Clara River, and Dominguez Channel, while at Ballona Creek, Los Angeles River Willow, and San Gabriel flows varied by about 100x.

The highest concentrations of contaminants are associated with peak flows. Because we sampled the two Ventura sites while they had relatively low flow, this data may be less representative annual emissions of contaminants.

The two channels with the highest flows, Los Angeles River Willow and Ballona Creek, had the highest mean contaminant concentrations and consequently had the highest emissions of oil and grease, TEOs, cadmium, chromium, copper, nickel, lead, zinc, PCBs, PAHs, resolved hydrocarbons, and n-alkanes.

Annual estimate of runoff should be viewed with the awareness of certain limitations, some relevant to all runoff studies and others relevant only to this study. Factors that need further examination include annual variations in total rainfall within a drainage basin, the intentional retention of runoff for groundwater recharge, and diversions between drainage basins. The factors can combine to make each storm and year difficult to compare with other storms and years.

ACKNOWLEDGMENTS

We appreciate the financial and field support that was provided by the Los Angeles Regional Water Quality Control Board, especially Allen Chartrand and Michael Sowby. The Hyperion Laboratory kindly allowed us to use their facilities to measure oil and grease. We thank our fellow staff members who interrupted their work and sleep patterns to make this study possible.

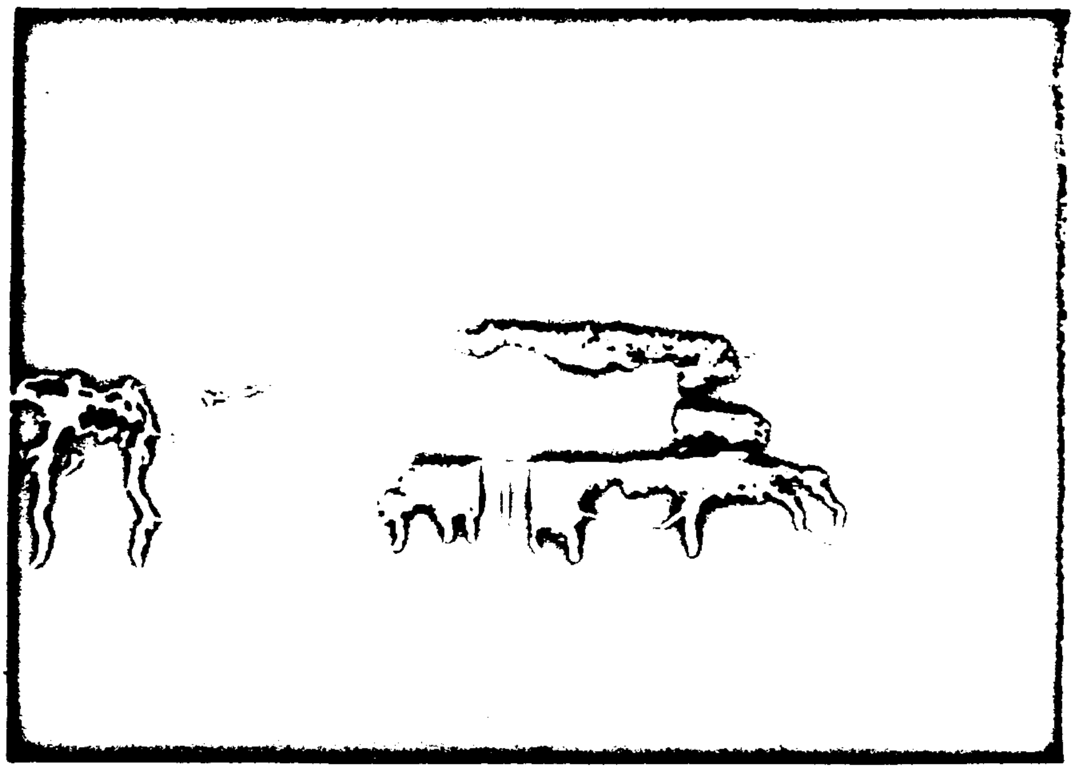
FINAL REPORT

OF THE

NATIONWIDE URBAN RUNOFF PROGRAM



17586

WATER PLANNING DIVISION
U.S. ENVIRONMENTAL PROTECTION AGENCY
WASHINGTON, D.C. 20460

The significant impact of urban runoff on shellfish harvesting has been well documented by the Long Island, New York NURP project. In this project, stormwater runoff was identified as the major source of bacterial loading to marine waters and, thus, the indirect cause of the denial of certification by the New York State Department of Conservation for about one-fourth of the shellfishing area. Much of this area is along the south shore, where the annual commercial shellfish harvest is valued at approximately $17.5 million.

The Myrtle Beach, South Carolina NURP project found that stormwater discharges from the City of Myrtle Beach directly onto the beach showed high bacterial counts for short durations immediately after storm events. In many instances these counts violated EPA water quality criteria for aquatic life and contact recreation. The high bacteria counts, however, were associated with standing pools formed at the end of collectors for brief periods following the cessation of rainfall and before the runoff percolated into the sand. Consequently, the threat to public health was not considered great enough to warrant closure of the beach.

Groundwater Aquifers

1. Groundwater aquifers that receive deliberate recharge of urban runoff do not appear to be imminently threatened by this practice at the two locations where it was investigated.

   Two NURP projects (Long Island and Fresno) are situated over sole source acquifers. They have been practicing recharge with urban runoff for two decades or more at some sites, and extensively investigated the impact of this practice on the quality of their groundwater. They both found that soil processes are efficient in retaining urban runoff pollutants quite close to the land surface, and concluded that no change in the use of recharge basins is warranted.

   Despite the fact that some of these basins have been in service for relatively long periods of time and pollutant breakthrough of the upper soil layers has not occurred, the ability of the soil to continue to retain pollutants is unknown. Further attention to this issue is recommended.

CONTROL EFFECTIVENESS

General

A limited number of techniques for the control of urban runoff quality were evaluated by the NURP program. The set is considerably smaller than previously published lists of potential management practices. Since the control approaches that were investigated were selected at the local level, the choices may be taken as an initial indication of local perceptions regarding practicality and feasibility from the standpoint of implementation.

Conclusions

1. Control measures selected at the local level for detailed investigation reflected a strong preference for detention devices, street sweeping, and recharge devices. Interest was also shown in grass swales and wetlands.

   Six NURP projects monitored the performance of a total of 14 detention devices. Five separate projects conducted in-depth studies of the effectiveness of street sweeping on the control of urban runoff quality. A total of 17 separate study catchments were involved in this effort. Three NURP projects examined either the potential of recharge devices to reduce discharges of urban runoff to surface waters or the potential of the practice to contaminate groundwaters. A total of 12 separate sites were covered by this effort.

   Grass swales were studied by two NURP projects. Two swales in existing residential areas, and one experimental swale constructed to serve a commercial parking lot were studied.

   A number of NURP projects indicated interest in wetlands for improving urban runoff quality at early stages of the program. Only one allocated monitoring activity to this control measure, however.

   Various other management practices were identified as having local interest by individual NURP projects, but none of them was allocated the necessary resources to be pursued to a point which allowed an evaluation of their ability to control pollution from urban runoff. Management practices in this category included urban housekeeping (e.g., litter programs, catch basin cleaning, pet ordinances) and public information programs.

2. Detention basins are capable of providing very effective removal of pollutants in urban runoff. Both the design concept and the size of the basin in relation to the urban area served have a critical influence on performance capability.

   Wet basins (designs which maintain a permanent water pool) have the greatest performance capabilities. Observed pollutant reductions varied from excellent to very poor in the basins which were monitored. However, when basins are adequately sized, particulate removals in excess of 90 percent (TSS, lead) can be obtained. Pollutants with significant soluble fractions in urban runoff show lower reductions; on the order of 65 percent for total P and approximately 50 percent for BOD, COD, TKN, Copper, and Zinc. Results indicate that biological processes which are operative in the permanent pool produce significant reductions (50 percent or more) in soluble nutrients, nitrate and soluble phosphorus. These performance characteristics are indicated by both the NURP analysis results and conclusions reached by individual projects.

   Dry basins, (conventional stormwater management basins), which are designed to attenuate peak runoff rates and hence only very briefly detain portions of flow from the larger storms, are indicated by NURP data to be essentially ineffective for reducing pollutant loads.

VOL 12

1 7 5 8 8

Dual-purpose basins (conventional dry basins with modified outlet structures which significantly extend detention time) are suggested by limited NURP data to provide effective reductions in urban runoff loads. Performance may approach that of wet ponds; however, the additional processes which reduce soluble nutrient forms do not appear to be operative in these basins. This design concept is particularly promising because it represents a cost effective approach to combining flood control and runoff quality control and because of the potential for converting existing conventional stormwater management ponds.

Approximate costs of wet pond designs are estimated to be in the order of $500 to $1500 per acre of urban area served, for on-site applications serving relatively small urban areas, and about $100 to $250 per acre of urban area for off-site applications serving relatively large urban areas. The costs reflect present value amounts which include both capital and operating costs. The difference is due to an economy of scale associated with large basin volumes. The range reflects differences in size required to produce particulate removals in the order of 50 percent or 90 percent. Annual costs are estimated at $60 to $175, and $10 to $25 respectively.

3. Recharge Devices are capable of providing very effective control of urban runoff pollutant discharges to surface waters. Although continued attention is warranted, present evidence does not indicate that significant groundwater contamination will result from this practice.

Both individual project results and NURP screening analyses indicate that adequately sized recharge devices are capable of providing high levels of reduction in direct discharges of urban runoff to surface waters. The level of performance will depend on both the size of the unit and the soil permeability.

Application will be restricted to areas where conditions are favorable. Soil type, depth to groundwater, land slopes, and proximity of water supply wells will all influence the appropriateness of this control technique.

Surface accumulations which result from the high efficiency of soils to retain pollutants, suggest further attention in applications where dual purpose recharge areas also serve as recreational fields or playground areas.

4. Street sweeping is generally ineffective as a technique for improving the quality of urban runoff.

Five NURP projects evaluated street sweeping as a management practice to control pollutants in urban runoff. Four of these projects concluded that street sweeping was not effective for this purpose. The fifth, which had pronounced wet and dry seasons, believed that sweeping just prior to the rainy season could produce some benefit in terms of reduced pollution in urban runoff.

A large data base on the quality of urban runoff from street sweeping test sites was obtained. At 10 study sites selected for detailed analysis, a total of 381 storm events were monitored under control conditions, and an additional 277 events during periods when street sweeping operations were in effect. Analysis of these data indicated that no significant reductions in pollutant concentrations in urban runoff were produced by street sweeping.

There may be special cases in which street cleaning applied at restricted locations or times of year could provide improvements in urban runoff quality. Some examples that have been suggested, though not demonstrated by the NURP program, include periods following snow melt or leaf fall, or urban neighborhoods where the general level of cleanliness could be significantly improved.

5. Grass swales can provide moderate improvements in urban runoff quality. Design conditions are important. Additional study could significantly enhance the performance capabilities of swales.

Concentration reductions of about 50 percent for heavy metals, and 25 percent for COD, nitrate, and ammonia were observed in one of the swales studied. However the swale was ineffective in reducing concentrations of organic nitrogen, phosphorus, or bacterial species. Two other swales studied failed to demonstrate any quality improvements in the urban runoff passing through them.

Evaluations by the NURP projects involved concluded, however, that this was an attractive control technique whose performance could be improved substantially by application of appropriate design considerations. Additional study to develop such information was recommended.

Design considerations cited included slope, vegetation type and maintenance, control of flow velocity and residence time, and enhancement of infiltration. The latter factor could produce load reductions greater than those inferred from concentration changes and effect reductions in those pollutant species which are not attenuated by flow through the swale.

6. Wetlands are considered to be a promising technique for control of urban runoff quality. However, neither performance characteristics nor design characteristics in relation to performance were developed by NURP.

Although a number of projects indicated interest, only one assigned NURP monitoring activity to a wetland. This was a natural wetland, and flows passing though it were uncontrolled. Results suggest its potential to improve quality, but the investigation was not adequate to associate necessary design factors to performance capability. Additional attention to this control technique would be useful, and should include factors such as the need for maintenance harvesting to prevent constituent recycling.

quite high indeed. The opportunities for control in central business districts are quite limited, however, and the only practicable option in many cases may be to route this portion of a locality's urban runoff to a treatment plant via the sanitary sewers. More study is required before such a recommendation can be made, however, because this practice could either create a combined sewer overflow situation or aggrevate one which already exists.

Socio-Economic Effects

Although the NURP data in this area are quite limited, they strongly suggest that the runoff from disadvantaged neighborhoods contains dramatically higher levels of pollutants than does the runoff from more affluent parts of an urban area. Unique control opportunities may exist in such situations, but further study will be required before this issue can be dealt with in an adequate fashion.

Physical Effects

Several projects concluded that the physical impacts of urban runoff upon receiving waters have received too little attention and, in some cases, are more important determinants of beneficial use attainment than chemical pollutants. This contention requires much more detailed documentation.

Synergy

NURP did not evaluate the synergistic effects that might result from pollutant concentrations experienced in stormwater runoff, in association with pH and temperature ranges that occur in the receiving waters. This type of investigation might reveal that control of a specific parameter, such as pH, would adequately reduce an adverse synergistic effect caused by the presence of other pollutants in combination and be the most cost effective solution. Further investigations should include this issue.

Opportunities for Control

Based upon the results of NURP's evaluation of the performance of urban runoff controls, opportunities for significant control of urban runoff quality are much greater for newly developing areas. Institutional considerations and availability of space are the key factors. Guidance on this issue in a form useful to States and urban planning authorities should be prepared and issued.

Wet Weather Water Quality Standards

The NURP experience suggests the desirability of EPA supporting efforts to develop "wet weather" standards, criteria, or modifications to ambient criteria to reflect differences in impact due to the intermittent, short duration exposures characteristic of urban runoff and other nonpoint source discharges.

Coliform Bacteria

The appropriateness of using coliform bacteria as indicator organisms for human health risk where the source is exclusively urban runoff warrants further investigation.

Wetlands

The use of wetlands as a control measure is of great interest in many areas, but the necessary information on design performance relationships required before cost effective applications can be considered has not been adequately documented. The environmental impacts of such use upon wetlands is a critical issue which, at present, has been addressed marginally, if at all.

Swales

The use of grass swales was suggested by two NURP projects to represent a very promising control opportunity. However, their performance is very dependent upon design features about which information is lacking. Further work to address this deficiency and appropriate maintenance practices appears warranted.

Illicit Connections

A number of the NURP projects identified what appeared to be illicit connections of sanitary discharges to stormwater sewer systems, resulting in high bacterial counts and dangers to public health. The costs and complications of locating and eliminating such connections may pose a substantial problem in urban areas, but the opportunities for dramatic improvement in the quality of urban stormwater discharges certainly exist where this can be accomplished. Although not emphasized in the NURP effort, other than to assure that the selected monitoring sites were free from sanitary sewage contamination, this BMP is clearly a desirable one to pursue.

Erosion Controls

NURP did not consider conventional erosion control measures because the information base concerning them was considered to be adequate. They are effective, and their use should be encouraged.

Combined Sewer Overflows

In order to address urban runoff from separate storm sewers, NURP avoided any sites where combined sewers existed. However, in view of their relative levels of contamination, priority should be given to control of combined sewer overflows.

Implementation Guidance

The NURP studies have greatly increased our knowledge of the characteristics of urban runoff, its effects upon designated uses, and of the performance efficiencies of selected control measures. They have also confirmed earlier

VOL 12

impressions that some States and local communities have actually begun to develop and implement stormwater management programs incorporating water quality objectives. However, such management initiatives are, at present, scattered and localized. The experience gained from such efforts is both needed and sought after by many other States and localities. Documentation, evaluation, refinement and transfer of management and financing mechanisms/arrangements, of simple and reliable problem assessment methcdologies, and of implementation guidance which can be used by planners and officials at the State and local level are urgently needed as is a forum for the sharing of experiences by those already involved, both among themselves and with those who are about to address nonpoint source issues.

CHAPTER 1
INTRODUCTION

There is general agreement as indicated in State 305(b) reports, nonpoint source (NPS) Assessment Reports, and in the proposed Stormwater NPDES permitting requirements that urban runoff can be a significant contributor to degraded water quality in receiving waters. It may therefore be necessary to implement controls to prevent any further deterioration or to improve receiving water quality. Moreover, the focus on implementation is at the local level as federal legislation and state stormwater management planning efforts stipulate that a municipality is responsible for the quality and quantity of runoff within its jurisdiction.

In some cases, sufficient resources may not be available to implement all of the controls that may be required. In other cases, a staged approach to the implementation of a comprehensive management program may be appropriate. For either of these possibilities, there is a need to target the available resources and to prioritize the control program based on site specific conditions, so that the greatest water quality benefit is realized for the resources expended.

However, much of the available information (data and procedures) that would facilitate the required effort are currently not available in an appropriately organized and consolidated format, and hence are not conveniently accessible by State and local personnel involved in addressing NPS issues.

To assist State and local agency personnel in targeting areas within their jurisdiction, this manual consolidates existing information and develops a methodology for targeting urban areas for control. This manual addresses the following aspects related to NPS pollutant discharges from urban areas:

1. The nature and characteristics of urban runoff, and the types of water quality problems that are most likely to occur. (Chapter 2)
2. The types of best management practices (BMP's) that are appropriate for control of NPS pollutant loads from urban and developing areas, and guidance for their selection. (Chapter 3)
3. A procedure for prioritizing urban areas for control. (Chapter 4)

This manual has a technical orientation with a level of detail appropriate for local and state agency use. The information and procedures presented are expected to be suitable for developing local planning strategies for controlling the quality of urban runoff and associated receiving water effects. It does not provide comprehensive and exhaustive treatment of technical aspects. For more detailed information, selected references are provided.

CHAPTER 2
URBAN NONPOINT SOURCE POLLUTANTS

In this manual, urban runoff is defined as any discharge from a pipe, channel, or other conveyance that removes stormwater from an urban area. Combined sewers, which convey sanitary sewage as well as stormwater, are specifically excluded from consideration here.

Urban runoff quantity and quality are significantly affected by watershed development and, in particular, drainage systems that are constructed for human safety, health, and convenience. Urbanization alters the natural vegetation and natural infiltration characteristics of the watershed, causing runoff from an urban area to have a much higher surface flow component, a much smaller interflow component, and a somewhat reduced baseflow component. Urbanization also can cause water quality problems because activities associated with urbanization create sources of pollutants (e.g., automobile emissions) for surface runoff. Thus urbanization tends to increase runoff and pollutant loadings to the receiving water body. Specifically, some effects of urbanization are to:

- increase peak discharges (typically by about two to five times)
- increase runoff volume from a given storm (volume increases of 50% or more are common)
- decrease the watershed response time (the time of concentration)
- reduce streamflow in dry weather periods (especially during prolonged dry spells; urbanization can actually cause small headwater perennial streams to become ephemeral)
- increase runoff velocity during storms
- increase the discharge of pollutants
- significantly modify the type and nature of pollutants

The following sections discuss these effects and provide methods of estimating those effects (runoff volume and water quality) that are required for the targeting methodology presented in Chapter 4.

2.1 URBAN RUNOFF HYDROLOGY

2.1.1 Regional Precipitation Characteristics

Precipitation causes runoff which in turn mobilizes and transports pollutants from the urban area to the receiving water. Storm event characteristics and patterns vary considerably in different regions of the country, and can influence the nature and extent of the receiving water impacts. For example, in the East and Southeast, short duration - high intensity summer thunderstorms tend to increase the erosion potential compared to the Pacific Northwest, where the prevailing rainfall pattern is one of longer duration - low intensity events. Receiving water impacts are also affected by the characteristics of the receiving water body. In streams and rivers, water quality effects are associated with the individual storm events; whereas in the case of lakes and impoundments, the impact produced is usually the result of the cumulative effect of NPS discharges over an extended period of time. Regions with greater annual precipitation amounts will contribute higher pollutant loadings to these waterbodies, than areas with low annual precipitation.

A recent EPA study characterizes storm event properties that are useful for preliminary planning assessments (Driscoll, et al, 1989). Table 2-1 tabulates the statistics of a set of storm event properties for various rain zones shown in Figure 2-1, and are based on the analysis of rain gage data for the locations shown on the map. Specific information on the individual sites is provided in the referenced document. The data presented is based on those storm events that produce storm volumes greater than 0.1 inch, because experience indicates that very small storms do not produce runoff. As a result, the statistics shown are for runoff-producing storm events. For these events the annual statistics show the average and year-to-year variability (expressed as the coefficient of variation) of the number of storms per year and the annual precipitation volume. The "event" statistics show the average and variability of the characteristics of individual storms. These data indicate significant regional differences which must be taken into account in NPS assessments. For example, as discussed earlier, note the four-fold difference in average storm intensity between the Pacific Northwest (0.035 in/hr) and the Southeast (0.122 in/hr).

2.1.2 Estimating Runoff Volume

<u>Percent Imperviousness</u>

An important element in targeting watersheds for control is the runoff volume from the respective watersheds within a jurisdiction. The following describes various simplified methods that may be used for estimating runoff volume.

The single most important factor in determining the quant[illegible] of runoff that will result from a given storm event is the percent imperviousness of the [illegible]nd cover. Other factors include soil infiltration properties, topography (which defines [illegible]atershed slopes and depression storage capacity), vegetative cover , and anteceden[illegible] conditions.

Impervious areas include paved streets, sidewalks, driveways, parking areas, rooftops, patios, decks, and similar man-made structures. Obviously, the extent of imperviousness is a function of local development customs and zoning requirements such as lot sizes, single- or multiple-level construction, preferences for garages, use of alleyways, curb and gutter versus swale drainage, and similar factors. Such customs vary widely across the country due to climate, land cost, and a host of other reasons. Even within a given region or municipality, they are typically not uniform and may vary by land use and, even within a given land use, by the age of the development or its location within the city.

Given the importance of percent imperviousness in NPS assessments, it is strongly recommended that the percent imperviousness for a given study area be determined from site specific information. For example, the impervious area can be estimated from site plans, maps, and aerial photographs. This method does involve some degree of uncertainty (for example, rooftops may or may not drain to other impervious areas). An alternative or complimentary method would treat the percent imperviousness as a "calibration factor" to be determined utilizing a simple runoff model and rainfall and runoff records.

For preliminary screening purposes, prior to obtaining detailed site specific information, initial estimates of percent imperviousness can be made based upon land use category. While useful for larger urban areas where things tend to "average out," caution is

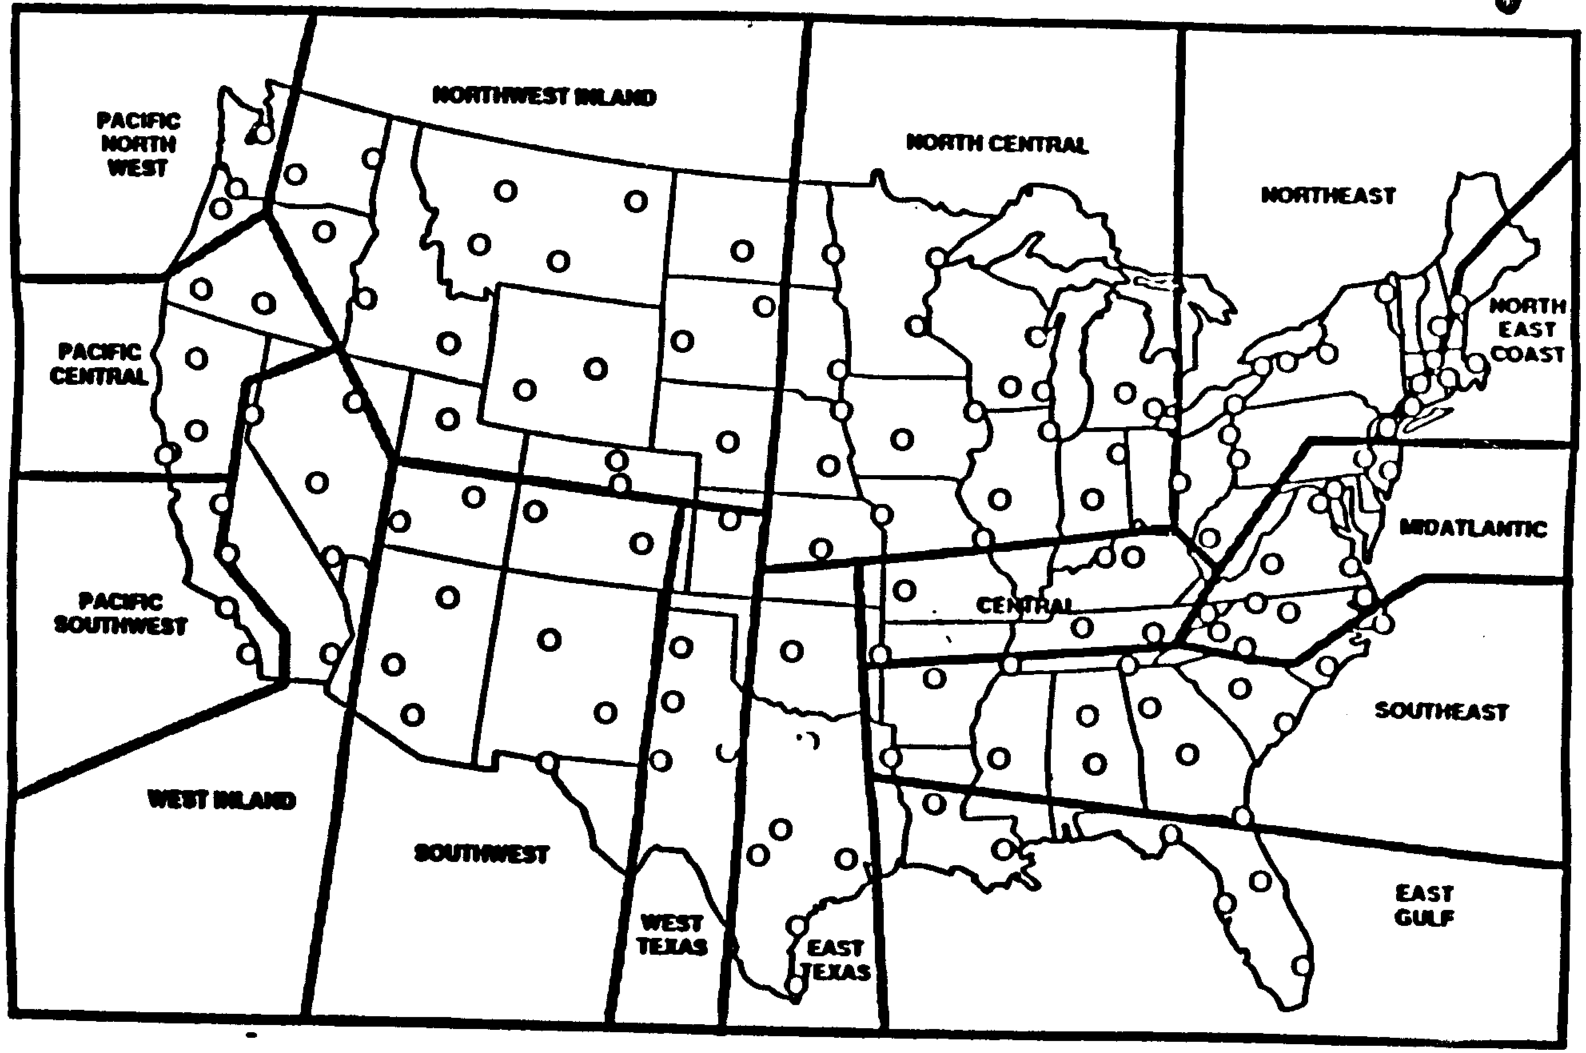

FIGURE 2-1. RAIN ZONES OF THE UNITED STATES.

called for in inferring such values for small specific sites. Use local data where there is any question.

The largest single land use in most metropolitan areas is residential, which typically accounts for between 50% and 70% of the total area. Lacking any other information, it is suggested that an initial estimate of 60% be used. If population data is available, an estimate of the percent imperviousness can be obtained using the following expression (Shelley, 1988):

$$PI = 9(PD)^{0.5} \qquad (2\text{-}1)$$

where

PI = percent impervíuosness [%]
PD = population density [persons/acre]

Note the population density can be estimated by first determining the population from census data or other sources and dividing this by the area of the residential land use. Equation (2-1) is based upon extensive examination of all residential land use sites in the NURP and USGS runoff data bases.

Commercial land use typically represents from 5% to 15% of the total urban area; a value of 10% is suitable as a first approximation. The imperviousness of commercial areas varies considerably, from around 50% for shopping malls with considerable landscaping and associated undeveloped space to over 90% for central business districts. In the absence of specific information, the use of 75% to 80% impervious area is suggested for commercial land use.

Industrial land use will vary considerably with the region of the country and the nature of the community, being rather high for older heavily industrialized communities. Typical values range from 10% to 20% of the total urban area; with 15% recommended for use as a first approximation. Here also, the percent imperviousness varies considerable, but often is between 40% and 70%. A preliminary estimate of 55% to 60% impervious area is suggested for use in lieu of site specific data.

The land use for the remaining portions of the urban area consists largely of open areas such as parks, golf courses, cemeteries, and undeveloped land. Typically, this land use category is around 15%, and this value is suggested as a preliminary estimate. Here also, the percent imperviousness can vary widely (from 5% to over 40%); a value between 10% to 20% is a reasonable first estimate.

The foregoing procedure can be used to arrive at a composite estimate of overall percent inperviousness for an urban area, by developing a weighted average based upon allocating the total urban area to the four major land uses just discussed and using the preliminary percent imperviousness estimates as suggested. To illustrate, consider a medium sized urban area with a population density of 9 persons per acre.

Land Use	% of Total Area	% Impervious	Net Impervious Fraction
Residential	60%	27%	0.162
Commercial	10%	75%	0.075
Industrial	15%	55%	0.0825
Open/Other	15%	15%	0.0225
TOTAL IMPERVIOUSNESS			0.342

This value of 34.2% imperviousness is in the typical range of 30% to 35% for moderate sized urban areas and is a reasonable first approximation.

Runoff Coefficient

The runoff coefficient is the measure of the watershed response to rainfall events. It is a dimensionless number obtained by dividing the total storm runoff by the total rainfall volume.

Thus,

$$Rv = Qs / I \quad (2\text{-}2)$$

where
Rv = the runoff coefficient [dimensionless]
Qs = runoff [inches]
I = rainfall [inches]

For a given site, the value for Rv will vary from event to event depending upon the characteristics of the rainfall event (intensity, duration, etc.) as well as the antecedent conditions. However, the variability can be statistically characterized from which mean seasonal or annual values can be estimated. From site to site, the variability in Rv can largely be attributed to differences in the percent imperviousness. Thus, a method is needed for estimating Rv based upon the percent imperviousness. As a very simplistic first approximation, the percent imperviousness can be used as the estimate of the runoff coefficient, with a lower bound of around 0.1 and an upper bound of around 0.95. Thus, in the example just cited, the runoff coefficient would be taken to be 0.342.

An alternative and preferred method for estimating the runoff coefficient from the percent imperviousness utilizes the following regression equation (Shelley, 1988):

$$Rv = 0.050 + 0.009\,(PI) \quad (2\text{-}3)$$

where PI is estimated from land use information (as in the above table) or from population density (Equation 2-1). The correlation coefficient for the regression is 0.71, indicating that over 70% of the variance between Rv and percent impervious is explained by the regression. For the example just discussed, the refined estimate of the runoff coefficient would be 0.358 [= 0.050 + (0.009)(34.2)].

Given a rainfall event of a certain size, Rv is used to estimate the runoff volume that will result. This is the general approach used to estimate runoff quantity. It must be emphasized again that this approach only provides an estimate for the wet weather runoff portion of the urban runoff flow. Dry weather and base flow contributions, to the extent that they are present, must be determined from site-specific information.

VOL 12

2.2 URBAN RUNOFF WATER QUALITY

2.2.1 Pollutants in Urban Runoff

The net effect of urbanization is to increase pollutant runoff loads by at least an order of magnitude over pre-development levels. The impact is felt not only on adjacent streams and lakes, but also on downstream receiving waters. The following discussion identifies the principal types of pollutants found in urban runoff and describes their potential adverse effects on receiving waters.

Sediment: Suspended sediment concentrations and mass loads are the highest of any of the pollutant types discharged by urban runoff. Sediment has both short- and long-term impacts on receiving waters. Among the immediate adverse impacts of high concentrations of sediment are increased turbidity, reduced light penetration, reduced prey capture for sight feeding predators, clogging of gills/filters of fish and aquatic invertebrates, reduced spawning and juvenile fish survival, and reduced angling success. Additional impacts result after sediment is deposited in slower moving receiving waters and include smothering of the benthic community, changes in the composition of the bottom substrate, more rapid filling of small impoundments (necessitating more frequent dredging), and reduction in aesthetic values. Sediment having a high organic or clay content is also an efficient carrier of trace metals and toxicants. Once deposited, pollutants in these enriched sediments can be remobilized under suitable environmental conditions, posing a risk to benthic and other aquatic life.

Oxygen Demanding Substances: Decomposition of organic matter by microorganisms depletes dissolved oxygen (DO) levels in receiving waters, especially slower moving streams and lakes and estuaries. There are several measures of the degree of potential DO depletion, the most common of which are the Biochemical Oxygen Demand (BOD) test and the Chemical Oxygen Demand (COD) test. Both of these tests have problems associated with their use in urban runoff, but it is clear that urban runoff can severly depress DO levels after large storms.

Nutrients: The levels of phosphorus and nitrogen in urban runoff can lead to accelerated eutrophication in downstream receiving waters. Generally, phosphorus is the controlling nutrient in freshwater systems. The greatest risk of eutrophication is in urban lakes and impoundments with long detention times (say two weeks or greater). Surface algal scums, water discoloration, strong odors, depressed oxygen levels (as the bloom decomposes), release of toxins, and reduced palatability to aquatic consumers are among the problems encountered. High nutrient levels can also promote the growth of dense mats of green algae that attach to rocks and cobbles in shallow, unshaded headwater streams.

Heavy metals: Heavy metals are of concern because of their toxic effects on aquatic life and their potential to contaminate drinking water supplies. The heavy metals having the highest concentrations in urban runoff are copper, lead, and zinc with cadmium a distant fourth. Howver, when inappropriate connections between sanitary and storm sewers are present, other heavy metals such as arsenic, beryllium, chromium, mercury, nickel, selenium, and thallium can be found. A large fraction of the heavy metals in urban runoff are adsorbed to particulates and thus are not readily available for biological uptake and subsequent bioaccumulation. Also, the typical periods of exposure are those of urban runoff events (typically under 8 hours), which are much shorter than the exposure periods used in bioassay tests (typically 24 to 96 hours for toxicity testing). Nonetheless, it is likely that the heavy metals in urban runoff are toxic to aquatic life in certain situations,

1 7506

R0050911

particularly for the more soluble metals such as copper and zinc. Compared to risks to aquatic life, human health risks appear to be more remote.

Bacteria : Fecal coliform levels in urban runoff usually will exceed public health standards for water contact recreation and shellfish harvesting. Furthermore, because bacteria multiply faster during warm weather, it is not uncommon to find a twenty-fold difference in bacterial levels between summer and winter in colder climates. The substantial seasonal differences do not correspond with comparable variations in urban activities, which suggests that in addition to temperature effects, sources of coliform unrelated to those traditionally associated with human health risk may be significant. Thus, despite the high numbers of coliforms found in urban runoff, in the absence of contamination from sanitary sewage, the health implications are unclear. The current literature suggests that fecal coliform may not be useful in identifying health risks from urban runoff pollution.

Oil and Grease : Oil and grease contain a wide variety of hydrocarbon compounds, some of which (e.g., polynuclear aromatic hydrocarbons) are known to be toxic to aquatic life at low concentrations. Hydrocarbons are often initially found as a rainbow colored film or sheen on the water's surface. Other hydrocarbons, especially weathered crankcase oil, appear in solution or in emulsion and have no sheen. However, hydrocarbons have a strong affinity for sediment, and much of the hydrocarbon load eventually adsorbs to particles and settles out. Hydrocarbons tend to accumulate rapidly in the bottom sediments of lakes and estuaries, where they may persist for long periods of time and exert adverse impacts on benthic organisms. The precise impacts of hydrocarbons on the aquatic environment are not well understood. Bioassay data which do exist are largely confined to laboratory exposure tests for specific hydrocarbon compounds. Remarkably few toxicity tests have been performed to examine the effect of urban runoff hydrocarbon loads on aquatic communities under the typical exposure conditions fou . in urban streams.

Other Pollutants : Other toxic chemicals are rarely found .n urban runoff from residential and commercial land use areas in concentrations that exceed current water quality criteria. Pesticide concentrations in runoff from such areas, wh.n they are found at all, tend to be near their detection limits. However, it should be noted that there has been relatively little sampling of runoff from industrial areas, where toxic compounds might be expected to be more prevalent.

2.2.2 Characterizing Urban Runoff Water Quality

Pollutant concentrations in urban runoff vary considerably, both during the course of a storm event as well as from event to event at a given site, from site to site within a given city, and from city to city across the country. This variability is the natural result of high variations in rainfall characteristics, differing watershed features that affect runoff quantity and quality, and variable antecedent conditions. In many situations, where interevent variability is not important and the focus is on urban runoff loads, the event mean concentration (defined as the total constituent mass discharge divided by the total runoff volume) is frequently used as the representative measure of pollutant concentration. The event mean concentation values at a given site tend to be well represented by the lognormal probability distribution, which means that two parameters can be used to characterize a given pollutant at a given site. These parameters are the site median (a measure of central tendency or location for which half of the values are higher and half are lower) and the coefficient of variation (a dimensionless measure of variability computed by dividing the standard deviation by the mean). Because the underlying distributions are lognormal, the appropriate statistic to employ for comparisons between individual sites or groups of sites is the median value. This is because the median is less influenced by the small number of large values typical of lognormal distributions and, hence is a more robust measure of central tendency. However, for comparisons with published data where average values are reported and for certain computations and analyses (such as annual mass loads), the mean value is more appropriate. For a lognormal distribution, the mean is calculated by multiplying the median by the square root of one plus the square of the coefficient of variation, i.e.,

$$\text{Mean} = \text{Median} * [1+CV*CV]^{0.5} \qquad (2\text{-}4)$$

Utilizing the lognormal distribution to characterize water quality has a number of important benefits (WCC, 1989), including:

- Concise summaries of highly variable data can be developed and the variability can be quantified and dealt with appropriately.
- Comparisons of results from different sites, events, etc. are convenient and more easily understood.
- Statements can be made about frequency of occurrence, i.e., one can express how often values will exceed various magnitudes of interest.
- A more useful and informative method of reporting data than the use of ranges is provided; one that is less subject to misinterpretation.
- A framework is provided for examining the transferrability of data in a quantitative manner.

Based upon the results of considerable analysis of the NURP data, it was determined that geographic location, land use category, rainfall characteristics, and other factors did not adequately explain the site-to-site variability of EMCs. Therefore, the EMC data for all urban sites were pooled and examined statistically. It was found that the lognormal distribution was an adequate representation of this pooled data set also. The results, given in Table 2-2, provide an initial basis for estimating pollutant concentrations in urban runoff. The median EMC values are given for the median urban site in the NURP data set, along with the median values for the 90th percentile site (i.e., median values that would be exceeded by only 10% of the urban sites). The event to event variability (not site to site variability) in the EMCs is given as an expected range in the coefficient of variation. For planning level purposes, these values are believed to provide the best description of the quality characteristics of urban runoff. For constituents that do not appear in Table 2-2, the NURP data base was too sparse to allow the analytical treatment just described, and local estimates must be provided.

2.2.3 Sources of Urban Runoff Pollutants

Erosion : Soil erosion can be an important source of pollutants in runoff from urban areas, either because of stream bank erosion or as a result of the disturbance of land surfaces. For example, initial clearing and grading operations during construction expose much of the surface soils. Unless adequate erosion controls are installed and maintained at the site, large quantities of sediment can be delivered to the stream channel, along with attached soil nutrients, organic matter, and other adsorbed pollutants. Uncontrolled construction site sediment loads on the order of 40 tons/acre/year and higher have been reported (Novotny and Chesters, 1981; Wolman and Schick, 1967; Yorke and Herb, 1976

TABLE 2-2. WATER QUALITY CHARACTERISTICS OF URBAN RUNOFF

Constituent		Event to Event Variability in EMCs (Coef. of Variation)	Site Median EMC	
			For Median Urban Site	For 90th Precentile Urban Site
TSS	(mg/l)	1 - 2	100	300
BOD	(mg/l)	0.5 - 1.0	9	15
COD	(mg/l)	0.5 - 1.0	65	140
Tot. P	(mg/l)	0.5 - 1.0	0.33	0.70
Sol. P	(mg/l)	0.5 - 1.0	0.12	0.21
TKN	(mg/l)	0.5 - 1.0	1.5	3.30
NO2+3-N	(mg/l)	0.5 - 1.0	0.6	1.75
Tot. Cu	(µg/l)	0.5 - 1.0	34	83
Tot. Pb	(µg/l)	0.5 - 1.0	144	350
Tot. Zn	(µg/l)	0.5 - 1.0	160	500

and 1978). Such loads are one to two orders of magnitude higher than from agricultural or stabilized urban land uses respectively.

Atmospheric Deposition : A significant source of pollutants in urban areas is atmospheric deposition in the form of both as wetfall and dryfall. In almost all cases, some of the pollutants from atmospheric sources are trapped and remain on the land surface, rather than washing off in ordinary storm events. If source control of atmospheric deposition is desired, control stategies based on automobile and industrial emission controls are required.

Construction Materials : The various surfaces of the urban landscape are another major source of pollutants. Metals, for example, are a common element in many urban structures, such as flashing and shingles, gutters and downspouts, galvanized pipes, metal plating, paints, wood preservatives, etc. Over time, these surfaces corrode, flake, dissolve, decay, or are subject to leaching thereby allowing metals to be carried away in urban runoff. The process is often exacerbated by the acidity of the rainfall.

Manufactured Products : The use of a variety of manufactured products represents a source of some pollutants in urban runoff. For example, most copper found in urban runoff originate from various anthropogenic sources including oxides and sulfates of copper used for insecticides, algicides, and fungicides. Copper is frequently incorporated into paints and wood preservatives to inhibit growth of algae and invertebrate organisms. Copper salts are used in water supply systems for controlling biological growths. Primary sources of copper in industrial wastewater are metal process pickling and plating baths. Other sources include mine drainage, pulp and paper mills, fertilizer manufacturing, petroleum refining, and certain rayon processes. Copper is used in the automobile industry in brake linings, clutch facings, and certain tire compounds. Smelters may release copper to the atmosphere which is eventually returned to surface wate The variety of potential sources for copper explains why it is almost invariably found : urban runoff at levels of concern.

Many pollutants which derive from manufactured produc: are toxic or hazardous materials. The more significant potential sources of some of these substances are given in Table 2-3. Note that automobile use contributes significantly to many of these constituents. Polycyclic aromatic hydrocarbons (PAHs), the most commonly detected toxic organic compounds found in urban runoff (EPA, 1982), originate from oil and combustion products. Phthalate esters, a relatively common toxic organic compounds, are derived primarily from plastics. Pentachlorophenol, also frequently found, comes from wood preservatives.

Plants and Animals : Other sources of pollutants that accumulate and subsequently wash off urban surfaces include plant debris (leaves,etc.) and animal excrement which in natural systems are recyled. For example, trees and shrubs deposit pollen and leaves which, no longer able to be converted to humus on the forest floor, enter into urban runoff. During the growing season, nutrients leach from tree leaves and stems during storms and are quickly conveyed to the stream if the ground is saturated or the tree's drip line extends over an impervious area.

Non-Stormwater Connections : An important potential source of toxic and other pollutants in urban runoff is through non-stormwater discharges to stormwater drainage systems. Inadvertent or deliberate discharges of sanitary sewage and industrial waters to storm drains has been identified as a widespread and serious occurence. The detection and elimination of such discharges is a major focus of the NPDES Stormwater Permit program.

TABLE 2-3. POTENTIAL SOURCES OF TOXIC AND HAZARDOUS SUBSTANCES IN URBAN RUNOFF

	AUTOMOBILE USE	PESTICIDE USE	INDUSTRIAL/OTHER USE
Heavy Metals			
Copper	metal corrosion	algicide	paint, wood preservative electroplating
Lead	gasoline, batteries		paint
Zinc	metal corrosion tires, road salt	wood preservative	paint, metal corrosion
Chromium	metal corrosion		paint, metal corrosion electroplating
Halogenated Aliphatics			
Methylene chloride		fumigant	plastics, paint remover solvent
Methyl chloride	gasoline	fumigant	refrigerant, solvent
Phthalate Esters			
Bis (2-ethyhexyl) phthalate			plasticizer
Butylbenzyl phthalate			plasticizer
Di-N-butyl phthalate		insecticide	plasticizer, printing inks paper, stain, adhesive
Polycylic Aromatic Hydrocarbons			
Chrysene	gasoline, oil, grease		
Phenanthrene	gasoline		wood/coal combustion
Pyrene	gasoline, oil, asphalt	wood preservative	wood/coal combustion
Other Volatiles			
Benzene	gasoline		solvent
Chloroform	formed from salt, gasoline & asphalt	insecticide	solvent, formed from chlorination
Toluene	gasoline, asphalt		solvent
Pesticides and Phenols			
Lindane (gamma-BHC)		mosquito control seed pretreatment	
Chlordane		termite control	
Dieldrin		insecticide	
Pentachlorophenol		wood preservative	wood processing paint
PCBs			electrical, insulation

VOL 12

1761

As an illustrative example of how heavy metals can enter flows from industrial areas, consider the use of heat exchangers in plating tanks at metal finishing and electro-plating shops. It is not uncommon to have condensate return lines discharge directly to storm drains. As long as the heat exchangers are intact, this operating condition has no impact on discharge water quality. However, heat exchangers used in such applications typically develop pin-hole leaks, and as a result, plating solutions with high heavy metal concentrations can leak into the storm sewer system. In other instances, what is believed by a manufacturing firm to be non-contact cooling water, and appropriate to discharge to a storm drain, may in reality be a process cooling water with a significant concentration of heavy metals and other pollutants.

Cross-connections delivering sanitary sewage to storm drains can, like industrial contamination, occur in many different ways. There was a case reported where the sanitary lines from a high rise building were tied into the storm drain rather than the sanitary sewer. Locations with hyraulically overloaded sewage treatment plants or undersized sewers may provide relief points that transfer excess flow into storm drains. This type of situation is more likely in areas with aging sewer systems with excessive infiltration/inflow.

Accidental Spills: Another source of pollutants in urban runoff is accidental spills. Here, virtually any pollutant can be found, depending upon the nature of the spill. Deliberate dumping into storm sewers and catch basins (used crankcase oil is especially common) is yet another common source. Leaking underground storage tanks, leachate from sanitary landfills and hazardous waste treatment, storage, and disposal sites can also contribute to pollutants in storm sewers.

This discussion of sources of urban runoff pollutants indicates the types of activities that are believed to be the principal generators of urban runoff pollution. Once a particular receiving water body or segment of concern has been identified, there is an obvious need to identify the areas that contribute to it. As a rule of thumb, greater concentrations of pollutants will be found in urban runoff from industrial areas and older parts of the city. Given the role of the automobile in generating pollutants within the urban landscape, areas of high automobile density can be expected to have increased levels of pollution. The need to look for cross-connections and other illegal or inappropriate connections to separate storm drains cannot be overemphasized.

2.3 RECEIVING WATER PROBLEMS

2.3.1 Water Quantity Problems.

The two principal concerns relating to the quantity of stormwater runoff are the total volume of runoff discharged, and the peak rates of flow that are produced. Problems associated with runoff quantity include flooding and erosion/sedimentation impacts. Historically, drainage has been the principal local-level concern regarding urban runoff. Flooding concerns can be divided into two basic categories; nuisance flooding and major flooding. Nuisance flooding (e.g., temporary ponding of water on streets, road closings, minor basement flooding), rarely affects the entire urban populace and is seldom life-threatening. Nonetheless, the concerns of affected citizens commonly requires that local action be taken to minimize the recurrence of such events. Such mitigation activities are usually locally determined, funded, and implemented because the affected public and government decision makers perceive and concur that such flooding constitutes a problem. Catastrophic flood events, on the other hand, have to be thought about differently for several reasons:

- They typically affect the majority of the urban populace.

- Mitigation measures often involve engineering improvements extending well beyond local jurisdictions.

- Mitigation measures often cost more than the local community can afford. In such cases, water quantity problems are readily observable, the degree of damage as well as the benefits of alternative flood control projects can be estimated. Thus, decision makers face a relatively low risk in prescribing courses of action and justifying the associated costs in light of the benefits. As will be discussed later, decision making in the case of water quality concerns is less straightforward.

Erosion concerns may be the result of a relatively short-term condition produced by disturbance of the land surface during construction activity, or a longer term condition of stream bank erosion and scour and deposition of the stream bed produced by peak flow rates. Although erosion and sedimentation are storm-event related, their resultant problems are not exclusively either water "quantity" problems or water "quality" problems. When sediment loads from undeveloped areas are discharged into receiving waters, the effects are primarily physical and only secondarily chemical, because the mineral constituents which make up the primary sediment load are relatively benign in most cases. Among the physical problems in receiving waters subjected to increased sediment loads are:

- Excess turbidity reduces light penetration, thereby interfering with sight feeding and photosynthesis.

- Particulate matter clogs gills and filter systems in aquatic organisms, resulting, for example, in retarded growth, systemic disfunction, or asphyxiation in extreme cases.

- Benthal deposition can bury bottom dwelling organisms, reduce habitat for juveniles, and interefere with egg deposition and hatching.

- degradation of general habitat.

Urbanization accelerates erosion through alteration of the land surface. Disturbing the land cover, altering natural drainage patterns, and increasing imperviousness all increase the quantity and rate of runoff, thereby increasing both flooding and erosion potential. Furthermore, the sedimentation products that result from urban activities are generally not as benign as the natural mineral sediments which result from soil erosion from undeveloped areas. Atmospheric deposition (associated with industrial and energy production activities) and added surface particulates (resulting from tire wear, automobile exhaust, road surface decomposition, and the like) are incorporated in the sediments discharged from urbanized areas. Their effects on receiving waters tend to be more chemical than physical. This is also true of natural mineral sediments that become contaminated by the adsorption of toxics and other chemicals present in the urban environment.

2.3.2 Water Quality Problems

The following are three considerations in evaluating water quality problems in surface waters subjected to urban runoff.

- the nature of the designated <u>beneficial uses</u>, e.g., drinking water supply, recreation, fisheries, wildlife and associated <u>water quality objectives</u>.

- water quality characteristics, i.e., the physical, chemical, and biological data resulting from analytical determinations made in the field or laboratory.

- ecological effects associated with a discharge, e.g., toxicity, carcinogenicity, disease, eutrophication, altered vegetation and succession, reproductive disorders, etc.

Water quality is what is typically measured, although laboratory and in situ toxicity testing using representative aquatic species is a tool for addressing ecological effects. Ecological effects determine how well a designated beneficial use is met. Although Congress has established fishable and swimmable waters as a goal, water quality planning activities will be more cost effective when the specific beneficial uses are supported by the local community. This is because the determination of the most appropriate beneficial use is strongly influenced by local attitudes, beliefs, needs and expectations. Unlike water quantity problems, water quality problems tend to be elusive because their definition involves subjective considerations. Also water quality problems are often not immediately obvious and are less dramatic than floods. They also tend to vary markedly with locality and geographic regions within the country.

For evaluating urban runoff impacts, three possible approaches for identifying the presence of a problem can be considered.

1. Actual impairment or denial of a designated beneficial use;
2. Violation of a water quality criterion;
3. Local public perception and concern.

The first type of problem would be where a determination has been made that some specific use, such as shellfishing, should be attained but that present aquatic tissue contamination is such harvesting and eating the organisms poses a health risk causing shellfishing ito be banned for part or all of the year.

The second type of problem refers to violations of an applicable water quality criterion. An example would be a case where some measure of water quality characteristics (e.g., trace metal concentration) exceeds recommended or mandatory levels for the receiving water classification (e.g., EPA toxic criteria for aquatic life). This problem definition is less exact than the preceeding problem definition in that the receiving water classification may not be appropriate, the beneficial use may not be impaired or denied, and the water quality criteria associated with that classification may or may not be overly conservative or directly related to the desired use.

The third basis for problem identification involves public perception. This may be expressed in a number of ways, such as telephone calls to public officials complaining about receiving water color, odor, or general aesthetic appearance. Public perception of receiving water problems is highly variable, further complicating this level of problem definition.

The foregoing approaches provide a framework which permits water quality problems associated with urban runoff to be defined in a way that will assist in the formulation of a management plan, the implementation of an effective control strategy, and establishing a means of assessing its effectiveness.

2.3.3 Examples of Urban Runoff Receiving Water Impacts

Stormwater discharges into urban streams can dramatically change the character of a stream as it passes through an urban area. Some examples of the nature of the problems that can be produced, based on actual cases reported in the literature, are described below. These cases provide background on the types of things to look for in a local assessment of the significance of urban NPS discharges.

In-stream monitoring of Village Creek in Birmingham, Alabama (Water Quality Engineers, 1981) provides a classic example of stream degradation due to intense urban development. At the stream's origin at Roebuck Springs, the creek has excellent physical and chemical characterictics, supporting watercress and other vegetation. By the time the stream passes under Vanderbilt Road it has turned grey-green and has an oily sheen and significant debris. Further downstream at the western limits of Birmingham, the creek is dark green, has a putrid odor and contains considerable oil and grease. At this point the creek is often anaerobic and contains no fish or other biological life. This study found that, on an annual basis, more than 90 percent of the copper loadings, more than 75 percent of the chromium and zinc loadings, and about 40 percent of the lead loadings originated from urban runoff.

A study (Dong et al., 1979, and Southeastern Wisconsin Planning Commission, 1976) of the Menomonee River near Milwaukee, Wisconsin indicated that the upper, more rural reaches of the river had an average of 40 times more fish than the lower, urbanized reach. The urban segments of the river supported a significantly reduced and scattered fish population and some segments were virtually devoid of even very pollution tolerant species. These conditions are the combined result of higher concentrations of toxic pollutants and poorer habitat conditions resulting from increased flow velocities and channelization. Further, the watershed benthic community is i· "poor" condition in the urban area. The Menomonee study concluded that a relatively nall degree of urbanization, less than 20 percent, is sufficient to cause significant receiving ᴧater degradation.

Studies at other locations have produced results similar to :hose cited above. Interestingly, toxic pollutants or long-term oxygen depletion has been found to cause more serious receiving water problems than short-term, event-related oxygen depletion or other concentration excursions. The accumulation of toxics in sediments and their subsequent movement through the food chain is especially pronounced in urban receiving waters. Studies on the Saddle River near Lodi, New Jersey (Wilber and Hunter, 1980) found significant enrichment of heavy metals (two to seven times) in lower Saddle River sediments (affected by urbanization) as compared to upper rural reaches. Similar results were found in a stream near Champaign-Urbana, Illinois (Rolfe anf Reinhold, 1977), where the upper two inches of sediment in an urban stream reach had much higher lead concentrations (almost 400 ug/g) than sediments in the rural stream reaches. Species diversity of plants and animals were found to be lower in urban streams as compared to streams in rural areas. This impact is likely to be influenced by habitat and temperature changes, as well as pollutant levels.

Long-term biological, chemical, and physical investigations of Coyote Creek near San Jose, California (Pitt and Bozeman, 1982) revealed distinctive urban-rural differences in the composition and relative abundance of aquatic biota. A comparison of urban Kelsey Creek to rural Bear Creek near Bellevue, Washington (Pitt and Bissonette, 1984; Perkins, 1982; Scott et al. 1982) indicated significant interrelationships among the physical, biological, and chemical characteristics. The urban creek was significantly degraded when compared to the rural creek, but it still supported a limited and unhealthy salmon fishery. Most fish in the urban creek had respiratory anomalies attributed to carcinogens in the water

VOL 12 1765

associated with urban runoff. Although Kelsey Creek did not appear to be as polluted as some of the urban creeks cited earlier, flooding caused by increased runoff from urban development increased dramatically, with the result that the large amounts of toxic pollutants discharged to the stream during wet weather, were diluted to very low concentrations by the increased runoff volumes. The large flows that produced habitat problems diverted attention away from the long-term toxic accumulation potential and to the physical effects of accelerated runoff. The dilemma here is that if the flows were to be reduced in order to improve habitat conditions, the stream's assimilative capacity would decline, and the effects of toxic pollutants could become even more pronounced.

As the foregoing examples indicate, urban runoff can produce both water quantity and water quality problems, and the two are often interrelated. The water quantity problems include but are not limited to flooding, streambank erosion, habitat impairment and altered salinity. The water quality problems depend on (i) the type of receiving water involved (stream, lake, etc.) and its characteristics, (ii) the beneficial use or uses to be protected, and (iii) the specific pollutants involved. These in turn depend upon the intensity and the nature of the activities in the urbanized watershed.

CHAPTER 3
BMPs FOR CONTROL OF URBAN NPS

The term BMP, or Best Management Practice, has gained wide acceptance as a general term designating any method for controlling the quantity and quality of stormwater runoff. For the purposes of this manual, a "best management practice" (BMP) is considered to be either (1) a practice (routine procedure) that reduces the pollutants available for transport by the normal rainfall-runoff process, or (2) a device that reduces the amount of pollutants in the runoff before it is discharged to a surface water body.

It is almost impossible technically and economically to completely eliminate NPS pollutant discharges to a receiving water body. Realistic objectives of an urban NPS management program are either (1) to sufficiently reduce pollutant levels to eliminate or mitigate an existing water quality problem, or (2) to avoid the creation of a future problem where none exists now.

This chapter identifies and presents an overview of the different types of BMPs that may be considered in the development of urban NPS management plans. Sufficient information is provided to support a planning level assessment of control options, but other appropriate studies and reports should be reviewed for additional detail on design, installation and operating aspects of specific BMPs. The chapter organization is structured to address BMP types individually, but in practice, BMPs can and should be considered in combination. Some examples include vegetated filter strips for pretreatment of inflows to infiltration systems, and detention basins to reduce sediment loads to a wetland. The specific characteristics of the site will determine the BMP types and combinations that are most appropriate in each case.

Institutional aspects of the development of an effective urban NPS management program are not emphasized in this manual, but planning activities must include a recognition of the need to develop an understanding of the issues at several levels of local government, and provide support for the resolution of institutional issues. This may involve the identification of the relationships between NPS management plan features and existing programs, plans and activities of City Managers, Planning Directors, and Public Works Directors, whose departments and responsibilities will provide the institutional framework for implementation of many of the important elements of a NPS management plan.

3.1 TYPES OF URBAN BMPs

Effective techniques for the control of nonpoint runoff pollutant discharges from urban areas, are identified below. These techniques are grouped into four categories, based on the operating principle or the physical mechanism that reduces the amount of runoff pollutants discharged to surface waters.

- **Detention basins** - The term "detention" applies when the runoff is temporarily stored and, apart from relatively minor incidental losses due to evaporation or percolation, is subsequently discharged to a surface water. Control results from a reduction in pollutant concentrations due to settling during the period the runoff is detained.

- **Retention devices** - The term "retention" applies when runoff is permanently captured so that it never discharges directly to a surface water. The usual mechanism by which stormwater controls permanently "capture" surface runoff is by infiltration. These techniques are often referred to as infiltration BMPs.

- **Vegetative controls** - Vegetative controls provide contact between stormwater runoff and vegetated areas and accomplish pollutant removal by a combination of filtration, sedimentation and biological uptake that reduce pollutant concentrations, and/or by a reduction in runoff volume due to infiltration or evapo-transpiration. Figure 3-1 provides a schematic illustration of various types of vegetative BMPs that can be considered in urban areas.

- **Source controls** - Source Control techniques include any practice that either (1) reduces the amounts of accumulated pollutants on the land surface available for washoff by rainfall, or (2) regulates the amount of impervious area to reduce the portion of rainfall that will appear as runoff, or (3) excludes inappropriate discharges to storm drains.

There is no generic method by which these different control techniques can be ranked either qualitatively or quantitatively. Site-specific conditions determine which practices are best, and even whether a particular approach is appropriate. Key factors that influence the suitability of a particular BMP include the following.

- **Drainage area served** - The feasibility of a particular control measure depends on the drainage area. There tend to be upper and/or lower bounds of the urban drainage area that can be served with a particular control practice. These bounds are based on design features, size requirements, as well as the operating characteristics of the BMP. Figure 3-2 presents a number of BMPs and the associated range of feasible drainage areas.

- **Soil permeability** - The soil type, that effectively governs the long-term percolation rate, is an important feature, which can limit the applicability of a technique at a site. Figure 3-3 illustrates typical ranges of infiltration rates associated with different soil types and their impact on the feasibility of different BMPs.

- **Local acceptance** - The acceptability of particular types of BMPs in different urban areas may vary considerably and will influence selection.

- **Other restricting factors** - In addition to the factors discussed above, Figure 3-4 summarizes several other factors that typically limit the applicability of a control practice.

Consideration of the factors discussed above will usually permit a planner to significantly reduce the choice of control practices appropriate for a detailed evaluation.

The following sections discuss each of the BMP categories identified above. The level of detail is limited to that considered appropriate for a planning-level assessment of the general features of a NPS urban pollutant control program. An annotated list of selected references is provided for a detailed evaluation. Key design features of the different control techniques are identified, but it should be recognized that other variations are possible. The discussion is limited to the size of a device and the density or intensity of application of a source control practice, because these factors are most important at the planning or assessment stage. Many of the detailed design and implementation features are critical to the ultimate success of a program, but are generally beyond the scope of a planning level assessment. Similarly, the discussion of performance is limited to the range in removal

FIGURE 3-4. OTHER COMMON RESTRICTIONS FOR BMPs efficiency that can be achieved by a BMP type. Finally general benefits and common limitations or constraints of the particular practice are discussed briefly.

3.2 DETENTION BASINS

The dominant treatment mechanism is the reduction of pollutant concentrations by sedimentation, so that this practice is most effective for suspended solids and the fraction of a pollutant associated with particulate matter. For example, most of the lead that is present in urban stormwater is present in particulate form. The soluble fraction of total lead is typically on the order of only about 10 percent, and as a result the removal efficiency for lead in comparable to that for sediment. In contrast, as much as 40 or 50 percent of a pollutant such as copper in runoff may be present in a dissolved form, and not susceptible to removal by sedimentation.

Although the main benefit results from the reduction of pollutants concentrations in the runoff, water quality impacts may also be reduced by the delayed release of stormwater runoff volumes. The resulting reduction in peak discharge flows will tend to reduce stream bank erosion and place less stress on the physical habitat. A slower release of stormwater to a flowing stream may also result in lower concentrations of runoff pollutants in the stream because of higher dilution in the stream.

Depending on the design of the inlet and outlet structures, detention basins can be classified into the following three catgories.

Dry ponds - These are basins with the outlet located at the bottom. They are almost always dry, except infrequently and for relatively short periods following larger storm events. The outlet size is restricted to limit the maximum flow rate. Dry ponds are used for flood and erosion control and are not effective for water quality control purposes. They may often be retrofitted to achieve water quality control.

Wet ponds - These basins employ outlet structures designed to maintain a permanent pool of water. They can provide high removal efficiencies for particulates, and have also been observed to be effective in significantly reducing soluble nitrogen and phosphorus concentrations by means of biological activity such as algal growth in the pool of water.

Extended detention dry ponds - These basins employ an outlet structure that will cause most storms to pond in the basin. Following a storm these basins drain in about 24 to 40 hour and will be dry at all other times. The outlet structures may be either perforated risers or subsurface drains. They provide a practical technique for retrofitting dry ponds to obtain water quality benefits, and can provide particulate (and the associated pollutant) removal efficiency equivalent to that for wet ponds.

3.2.1 Design Features

Pollutant removal efficiency of an otherwise properly designed and maintained detention basin may be influenced by seasonal factors such as algal growth, shoreline vegetation, and ice formation. However, overall efficiency is determined principally by the size of the basin (the available storage volume provided) relative to the amount of runoff it receives during storm events. For any storm event, the volume of runoff will depend primarily on the size of the contributing drainage area, and the proportion of impervious area. The latter is influenced by land use. Since performance of a basin will vary with storm size, pollutant removal estimates reflect the long-term average removal efficiency over all storms.

VOL 12

1 7 6 2 3

A variety of basin sizing rules are in current use, depending on the experience and/or preference of the jurisdiction. In some of the agencies that have been active in the implementation of urban stormwater controls for a number of years, the sizing rules have changed over time, or alternate rules have been adopted for different situations. There is no generally accepted rule or standard for the size of a detention basin. Four commonly used basin sizing rules are discussed below.

Design storm basis - Basin volume is set equal to the runoff produced by a specified design storm. For example, the 1 year or the 2 year, 24 hour duration storm event is sometimes used to specify the size of an extended detention basin where a reduction of flooding and peak flow are important. The volume of rainfall must be converted to the amount of runoff it will produce, and this will vary with the land use distribution (percent impervious area) of the watershed.

First flush basis - Basin volume is designed to store 1/2 inch of runoff per impervious acre of the contributing watershed. This is the most common rule, but the same rule, using 1 inch, is sometimes used. This rule is attractive, because it is simple to use and apply.

Mean storm volume basis - Basin volume is specified as a multiple of the mean runoff volume of all storms. The value of mean runoff is determined by a statistical analysis of the rainfall records. This method has the advantages of being able to base the size on the desired level of performance, and to account for regional rainfall characteristics. For example, the storm that produces 1/2 inch of runoff per impervious acre is a more frequent event in the southeast, than it is in the midwest, and there would be corresponding differences in the long-term pollutant removal efficiencies for otherwise similarly sized basins in the two regions. For some jurisdictions, this approach has been used (with local rainfall characteristics) to determine the storage volume required to produce a particular performance level (e.g., 70% TSS (Total Suspended Solids) reduction), and then translated to a simple-to-apply sizing rule for everyday use.

Residence time basis - Basin volume is designed to provide a specified residence time. Where this is used, long residence times (typically 14 days) are used. This rule generally results in larger basins that provide higher levels of reduction of most pollutants. However the principal objective is to enhance the removal of soluble nutrients by improving conditions favorable for growth of algae and aquatic plants.

A comparative evaluation of the above four approaches to determine basin size can be obtained by the approximate ratio of the basin volume (VB) and the mean runoff volume (VR). This requires an appropriate analysis of the rainfall record and the characteristics of the contributing drainage area. For different regions of the country, the rainfall volume for the mean storm event ranges from about 0.2 to 0.5 inches. This can be taken as an approximation of the runoff volume if we consider only the impervious acres. On this basis, a basin with a VB/VR ratio of 1.0 would provide between 700 and 1800 cubic feet of storage per impervious acre in the watershed. Note that the design volume of a basin is directly proportional to the value of VB/VR. Approximate values of VB/VR for different basin sizing rules are presented in Table 3-1.

Note in general the larger the basin volume, the greater the removal efficiency. However basins with VB/VR ratios larger than 2.5 or 3 yield diminishing returns.

VOL 12

11

7625

TABLE 3-1

RATIO OF BASIN VOLUME TO THE MEAN RUNOFF VOLUME FOR DIFFERENT DESIGN RULES

RULE	CHARACTERISTIC VALUE	VOLUME RATIO (VB/VR)
First flush	1/2 inch per impervious acre	1 to 2
Mean storm volume	1 inch per impervious acre	2 to 4
Residence time	14 day residence time	4 to 5
Design storm	1 year storm	7 to 8
Design storm	2 year storm	8 to 9

3.2.2 Performance

Depending on the size selected, wet ponds and extended detention ponds can reduce suspended solid concentrations in stormwater runoff by 50 to 95 percent. Removal efficiency for other pollutants is generally proportional to the pollutant fraction associated with (adsorbed on to) the particulates. For screening level analysis, approximate removal ranges that can be expected for detention basins are shown in Table 3-2. The performance levels shown are estimates of the approximate order of the removal efficiency for different pollutant types and basin sizes. Note that there is very limited data available on the removal of bacteria. The high removal efficiencies shown in Table 3-2 may be deceptive, because the water quality criteria levels are very low relative to the concentrations usually present in stormwater.

3.2.3 Advantages and Limitations

Advantages:

- Detention basins are effective runoff control devices, and there is an appreciable body of experience that attests to their performance capabilities, and provides a source of guidance for many important design details.
- They are suitable for relatively large drainage areas, and can be readily incorporated into the overall plans for new developments.
- Properly designed detention basins can enhance the value of the surrounding property.
- Existing dry ponds, previously installed for flow control, can often be economically converted to serve as extended dete· :on basins and provide water quality control.

Limitations:

- It is important to note that detention basins can become unsightly if routine maintenance is not performed.
- Removal of accumulated sediments will be required after 10 to 20 years of service, and can be quite expensive.
- The availability of sufficient land area at an appropriate location in the watershed can be a problem.
- Finally, it is usually difficult and often impossible to construct detention ponds in an existing built-up area.

3.3 RETENTION DEVICES

Retention or infiltration devices enable a fraction of the runoff volume to percolate into the ground, and hence reduce the discharge to a surface water body. Consequently, the removal efficiency is the same for all pollutants, and is proportional to the percentage of the total runoff volume that infiltrates. Many of the pollutants in urban runoff are effectively trapped in the upper soil layers, and do not reach the subsurface aquifer. This filtration or adsorption mechanism is particularly effective in the case of suspended solids, bacteria, heavy metals and phosphorus. Note that some of the percolating runoff may reach the surface water body, usually after a considerable delay, and after being "treated" by contact with the soil. Retention devices can be classified into the following three catgories.

TABLE 3-2

TYPICAL PERCENT POLLUTANT REMOVED FOR DIFFERENT RATIOS OF BASIN VOLUME TO MEAN RUNOFF VOLUME

POLLUTANT	PERCENT REMOVAL FOR INDICATED VB/VR 1	2.5	5	7.5
Suspended solids	50-60	70-80	85-90	90-95
Organics (BOD, COD)	25-30	35-40	40-45	45-50
Total N and total P	30-40	40-50	50-60	60-70
Lead	45-50	60-70	70-80	80-90
Other heavy metals	30-35	40-45	40-50	45-60
Bacteria	about 90 percent to about 99 percent			

Infiltration basins - These are relatively large open depressions, produced by either natural site topography or by excavation, in which runoff is temporarily stored while percolation occurs through the bottom or the sides. Outlet devices to allow overflow of excess inflows are generally provided but are elevated so to maximize the storage volume. Infiltration basins are normally designed so that any stored runoff will percolate in no more than a day or two. Thus such basins are generally dry.

Infiltration trenches and dry wells - The design of infiltration trenches and dry wells is similar. The major difference is in the size and the configuration. These are essentially excavated holes filled with coarse aggregate and then covered. Drywells are used primarily for roof drainage from residential and commercial sites. Trenches or modifications of trenches serve larger drainage areas, and are particularly applicable for streets and parking lots in commercial areas.

Porous pavement - The main practical application is for parking lots. Heavy traffic and heavy loads that would tend to occur in most streets would compact the surface and reduce the infiltration rate over time. Also, the vacuum sweeping to remove fine sediments from the pavement, that is an important recommended maintenance procedure, is most realistic for parking lot areas.

3.3.1 Design Features

Key design factors that determine performance are the hydraulic conductivity of the underlying soil and the size of the device relative to the contributing drainage area. In this case, the size refers to the surface area available for percolation, and to the storage volume. Examples of typical sizing rules that have been applied include the following:

- Storage volume for 1/2 inch of runoff per impervious acre, or storage volume for 1 inch of runoff from the entire watershed. These rules are usually applied for infiltration trenches. Generally, trenches are made relatively wide and shallow, and percolation rates range from 0.5 to 1 inches per hour.
- Storage volume equal to the volume of runoff from a 2 year storm. This sizing rule is usually limited to infiltration basins, and makes assumptions comparable to the preceeding rule.
- Percolating area and storage volume may be determined by analyzing the rainfall records and soil percolation rates for the site or area.

3.3.2 Performance

For retention basins, "treatment rate" can be thought of as the product of the percolation rate and the available percolating area. Performance improves as the treatment rate increases and efficiency can be enhanced by the amount of storage volume provided. If large runoff volumes do not have time to drain between storms, basin performance may decrease because the soil column does not dry out during the period between storms.

Depending on the size and the soil characteristics, infiltration devices are capable of achieving removal efficiencies up to 99 percent. The removal of pollutants for different sizes and designs in the Maryland-Northern Virginia area are listed in Table 3-3. Note that the indicated performance can be expected to differ for areas with different rainfall and soil types, but the indicated efficiencies are typical of infiltration BMPs.

TABLE 3-3

TYPICAL PERCENT POLLUTANT REMOVAL FOR RETENTION DEVICES

POLLUTANT	PERCENT REMOVAL FOR INDICATED SIZE		
	1/2 inch per impervious acre	1 inch from total area	2 yr runoff vol
Suspended solids	75	90	99
Organics (BOD, COD)	70	80	90
Total N and total P	45-55	55-70	60-75
Heavy metals	75-80	85-90	95-99
Bacteria	75	90	98

VOL 12 1 7629

3.3.3 Advantages and Limitations

Advantages:

- Infiltration devices are capable of very high pollutant removals.
- In many cases they can be built in developed areas.
- In addition to water quality control, they also reduce stormwater runoff to surface water bodies during and after storm events and provide desirable subsurface recharge resulting in an increase in low, dry-weather stream flows. This has the desirable effect of reducing flow variations in streams.

Limitations:

- A variety of site specific factors (impermeable soils, high water table, bedrock, etc) restrict the applicability of this type of BMPs.
- Care during installation is necessary to prevent compaction of soil by construction machinery, or the sealing of infiltration surfaces by sediment generated during construction activities.
- Even during normal operating conditions, infiltration devices require pretreatment (e.g., grass filter strips, geo-textile cloth) to reduce the amount of coarse sediment reaching the infiltration surface.

3.4 VEGETATIVE CONTROLS

Vegetative BMPs include a variety of landscaping arrangements that serve to increase the contact of rainfall and stormwater runoff with appropriate types of vegetation. Vegetative control practices have the ability to reduce pollutant discharges by reducing the quantity of runoff through enhanced infiltration, and to reduce concentrations through a combination of filtration, sedimentation and biological uptake. The major types of vegetative BMPs include the following.

Basin landscaping - Basin landscaping can be addressed during early development of a watershed and can have a significant effect on the control of NPS pollutants. The objectives of basin landscaping include but are not limited to minimization of impervious surface area; protection and utilization of existing wetlands; provision for green-belt buffers along stream banks; routing of runoff flow through vegetated areas and away from erosion-prone steep slopes. Careful selection of vegetation most suitable for site conditions has an important bearing on physical appearance and the long-term performance of basin landscaping.

Wetlands - As part of site landscaping, it is possible to create new shallow marsh wetlands specifically designed to operate as an urban runoff control measure. In rare cases, there may be an existing wetland of appropriate type, size and location, to warrant its consideration as a BMP for urban runoff. However, in such cases, issues that will be difficult to resolve with current knowledge, such as the potential of urban runoff flows or pollutants to damage the existing wetland ecosystem need to be addressed.

Grassed swales - Grassed swales are a shallow grass covered channel, rather than a buried storm drain, that is used to convey stormwater. Grass channels are mostly applicable in residential areas. They require shallow slopes, and soils that drain well.

Often grassed swales are used to provide "pretreatment" of runoff to other controls, particularly infiltration devices.

Filter strips - These are similar in concept to grass swales, but are designed to distribute runoff across the entire width and result in an overland sheet flow. These strips should have relatively low slopes, adequate length, and should be planted with erosion resistant plant species. They are often used as pretreatment for other BMPs, for example, by being placed in the flow path between a parking lot and an infiltration trench.

3.4.1 Design Features

Performance of vegetative controls is strongly influenced by the depth and velocity of flow through or across the device (determined by slope and flow distribution), and by contact time (determined by the length of the flow path). Soil with higher infiltration rates, and the use of small check dams to produce temporary ponding of runoff improves performance by enhancing the infiltration rates. Care in selecting plant species appropriate for site specific conditions, and routine maintenance to maintain optimum height are important maintenance requirements.

3.4.2 Performance

The pollutant reduction capabilities of vegetative controls are not documented as well for the other types of BMPs. Available information suggests that under favorable conditions, vegetative controls can achieve moderate removals of particulates such as sediment and heavy metals. They are generally not effective in reducing nutrients.

Many of the important design features are determined by physical characteristics of the site, over which the planner or designer has little or no control. Thus, both the applicability and the degree of performance that can be expected are highly site-specific.

3.4.3 Advantages and Limitations

Advantages:

- The costs for vegetative controls tend to be lower than those for detention and infiltration practices.
- With appropriate planning and design, they can enhance the visual attractiveness of a site.
- Vegetative controls are usually most appropriate to provide pretreatment of runoff in order to improve the operation and maintenance of other BMPs.

Limitations:

- Vegetative controls are usually not adequate to serve as the only runoff control practice for a site.
- The overall pollutant reduction that can be obtained from vegetative practices is usually limited, and depends to a substantial degree on the physical characteristics of individual sites.
- Seasonal differences in performance can be important. Removal effectiveness for some pollutants can be markedly different during growing and dormant periods.

• Information on removal efficiencies for the range of conditions that might be encountered is relatively limited.

3.5 SOURCE CONTROLS

This category of BMPs includes any practice that (a) reduces the amounts of accumulated pollutants on the land surface available for washoff by rainfall, or (b) regulates the amount of impervious area to reduce the amount of runoff, or (c) excludes inappropriate discharges from storm drains.

Source controls address one or more of the above objectives. Depending on the basic nature of a practice, it may apply at a local level or on an areawide basis. In most cases, a management plan will incorporate an array of different source controls that are applicable for the area. All source controls involve each of the following "implementation" aspects, to a greater or lesser degree.

Education - Since many source control practices require either active public participation, or general public acceptance, public education elements are an important feature. Developing a public understanding of the need for an action, the benefit it can produce, and the pertinent details of its implementation, will be critical to success, and wil require a specific program element that addresses this requirement.

Regulation - In many cases appropriate legal authority will have to be developed and assigned to an appropriate agency. There may be a need for redefining roles or establishing new agencies or departments. For example, an appropriate regulation against a particular form of pollutant discharge and legal enforcement authority may exist. If however, the enforcement authority resides in the Police Department, the situation may fall so far down on the priorities dictated by the general mission of a police agency, as to preclude any realistic expectation of active enforcement. This is an example of one of the variety of issues that will have to be resolved, that may not be apparent in a simple listing of the elements of a particular NPS control action.

Guidance - For some source controls, specific formal technical guidance may have to be developed and distributed to assure effective implementation. Examples include details of erosion control practices, oil separators that may be required for service stations, or detention facilities for new residential developments.

3.5.1 Design Features

There is no consistent way to characterize the salient design features of the variety of different types of practices that can be included in the source control BMP category. An important factor is the "application density". This generally (depending on the nature of the particular practice) addresses how actively, frequently and/or thoroughly the practice is pursued, and over how much of the total urban area it is applied. For example, the frequency at which each catch basins is cleaned; the number of streets or parking areas that are swept and how often the sweeper returns to a particular location are examples of application density, and ultimately of how effective a source control practice will be in reducing NPS pollutant loads from an overall urban area.

Source controls that have broad general applicability are identified below, with examples of some of the more important elements that are necessary for effective implementation. The list is not exhaustive; local situations can be expected to suggest other

VOL 12

17632

practices that are not included in this discussion. In addition, some of those that have been included in the list may not be applicable in all areas.

A. **Exclude Inappropriate Discharges to Storm Drains**

- **Eliminate illicit connections** - This is one of the more important source controls. The NPS stormwater permit regulations emphasize the detection and elimination of non-stormwater discharges to storm drainage systems. Elements of such a measure include the following:

  - Research, strengthen (if necessary), and enforce existing regulations which give local jurisdictions the legal authority to eliminate cross-connections that result in sanitary sewage or industrial wastewater entering the storm drainage systems.

  - Develop and implement an aggressive field program to search for, detect and control domestic, commercial or industrial cross-connections and illegal dumping.

  - Develop and implement an aggressive field program to search for, detect, and control sanitary sewer leaks and areas where surcharging or overflows would be most likely to occur.

- **Prevent rainfall and runoff from contacting potential contaminants** - This is a well established standard practice that has obvious benefit. It applies primarily to industrial or commercial sites.

  - Educate regarding the need to keep rainfall and runoff from contacting potential contaminants. Describe typical examples of the problem and practical solutions.

  - Develop and implement regulations to require covers for outdoor storage areas that contain contaminants. Keep runoff from passing over areas that contain contaminants. Emphasize good housekeeping for open loading-unloading areas.

  - Develop and implement an aggressive field program to search for, detect and correct situations where rainfall or runoff presently contact potential contaminants.

- **Encourage Proper use and disposal of materials by homeowners** - The contaminants addressed by this control activity include materials such as fertilizers, pesticides and herbicides, oil and antifreeze, paints, and solvents. Specific actions for preventing the discharge of household contaminants include the following.

  - Educate regarding the proper storage and use of fertilizers, herbicides and pesticides; application methods, rates and frequency appropriate for the area; and the potential environmental damage that can be caused by these materials. Identify alternative methods for controlling insects and weeds (e.g., physical controls, biological controls, less toxic chemicals).

  - Educate regarding the need to keep oils, paints and similar contaminants out of storm drains; the potential environmental damage that can be caused by these materials; and acceptable disposal methods.

  - Develop and implement programs and set up receiving facilities and procedures for specific pollutants such as crankcase oil, pesticide or paint containers, and other potentially harmful chemicals. Recycle if possible. The success of such a practice depends on the number and location (convenience) of stations and the awareness of the community about the effect of pollutants on the environment.

- Research, strengthen (if necessary), and enforce existing regulations which give local jurisdictions the legal authority to prevent improper disposal of pollutants into storm drainage systems.

- Label storm drain inlets and provide signs along the banks of drainage channels and creeks explaining the environmental impacts of dumping wastes.
- Develop and implement an agressive field program to search for, detect and prevent dumping or routinely discharging pollutants into storm sewers, drainage channels and urban streams. This should involve reevaluating previous decisions to allow certain relatively clean waters to be discharged to the stormwater system.

B. Reduce Street and Land Surface Sources of Pollutants -

- **Control littering and improper waste disposal practices -** In addition to its pollution control benefits, an effective litter control program will improve the general aesthetic appearance of the area. Because such programs have easily achieved public acceptance, with visibile effects, they can assist in developing interest and acceptance of other BMPs where the relation between practice and benefit may be less obvious. Specific actions might include the following.

  - Educate regarding the NPS pollution impacts that result from littering and improper waste disposal practices.

  - Research, strengthen (if necessary), and enforce existing regulations which give local jurisdictions the legal authority to control littering and the improper disposal of potentially harmful or aesthetically objectionable materials.

  - Provide litter bags for use in cars. Work with citizen action programs to facilitate efforts to report littering incidents and illegal dumping.

  - Develop and implement regularly scheduled cleanup days and corresponding curbside collection of trash and household debris.

  - Provide, collect and maintain an adequate number of litter recepticles in strategic public areas, and during major public events.

  - Coordinate with efforts (by others) to establish practical controls regarding potentially harmful packaging of consumer products.

- **Control animal wastes -** The specific practices considered should consider both household pets and where appropriate, suburban livestock such as horses and chickens.

  - Educate regarding the need to clean up and properly dispose of pet wastes, and where appropriate, the need for proper management of wastes from suburban livestock and agricultural operations in the watershed.

  - Provide informational signs and dispense doggie litter bags in parks and other selected areas.

VOL 12

17634

- implement and enforce leash laws and pet waste cleanup ordinances in selected public-use areas.

- **Improve the maintenance of major paved areas** - Activities in this category include both physical repairs to maintain pavement surfaces in good condition so that pavement debris and degradation products are not washed into storm drains, and street cleaning practices that remove litter and externally generated dust and associated pollutants that accumulate on paved surfaces.
  - Improve pavement repair and maintenance programs on streets and parking areas (e.g., fill potholes, seal cracks, apply surface treatments).
  - Develop and implement sufficiently intensive street sweeping programs for strategic locations. For example, paved surfaces in central business districts, shopping malls, major parking lots and industrial areas tend to produce more concentrated surface sources of heavy metals, oil and similar contaminants.
  - Implement street parking regulations (e.g., alternate side parking days) where necessary for effectiveness of street sweeping programs.

- **Institute programs to remove accumulations of litter and debris** - Floatables and accumulations of debris represent an important aesthetic problem for urban streams in many areas.
  - Sponsor periodic stream bank cleanup programs to remove accumulations of litter and debris in urban streams or on their banks. Floatable materials often accumulate behind roadway culverts. Encourage participation by suitable community groups (e.g., Boy Scouts, etc.). Coordinate with Public Works Departments for hauling and disposal of removed materials.
  - Provide for routine sweeping of streets that border urban stream courses.
  - Provide surveillance and enforce regulations against dumping.

- **Control airborne pollutants** - A significant source of many of the pollutants present in urban stormwater runoff is the deposition of atmospheric particles that originate from a variety of sources, on land surfaces in the urban area. Source control activities that can address this situation include the following.
  - Educate regarding the relationship between air pollution and NPS water quality problems, and the need to coordinate with programs (by others) that seek to reduce particulate atmospheric emissions of pollutants from individual, public, commercial and industrial sources.
  - Educate regarding the potential benefits of reduced automobile use by various means (e.g., ride sharing, carpooling, public transportation), and the importance of frequent vehicle inspection and maintenance efforts to reduce atmospheric emissions.
  - Educate regarding the proper operation of fireplaces and wood burning stoves to minimize the emissions of particulate matter.

VOL 12

17635

- Cooperate with public transportation agencies, public agency motorpools, and public works departments to provide effective air pollution controls on publically owned vehicles and motorized equipment, and, where practical, on the use of alternative clean-burning fuels.

C. **Control Erosion** -

- **Control erosion at construction sites** - These actions suggested here are directed at the control of erosion from land disturbed during construction, or the prevention of eroded materials from leaving the site.
  - Educate architects, engineers, contractors, and public works personnel about the need for and practical methods for erosion control, sediment control, groundwater disposal, and site waste management and disposal.
  - Develop and implement effective erosion and sediment control regulations, and requirements for corresponding construction inspection programs. These should apply to public-sector as well as private-sector construction programs.
  - Develop and implement improved erosion and sediment control policies in the environmental elements of all general Plans (develop and adopt General Plan ammendments, when needed).
  - Adopt policies that require all CEQA compliance documents and all site development plans to explicitly address the topics of erosion potential, proposed erosion and sediment control plans, and enforceable mitigation measures to minimize environmental impacts.
  - Require contractors to post bonds to cover potential damages from erosion or sediment deposition.
- **Control erosion of undeveloped land and park land** - These efforts are directed at the control of erosion from essentially undisturbed urban land areas, to reduce potential adverse impacts on urban water bodies.
  - Educate public works personnel and managers of parks and open-space lands about the need for and practical methods for erosion control and sediment control.
  - Develop and implement programs to actively search for, identify, evaluate, and prioritize erosion problems on undeveloped land, park land or open-space urban land use areas.
  - Develop and implement programs to work with landowners, tenants, and public agencies to apply practical erosion and sediment control practices.
  - Develop and implement practical programs for revegetating and otherwise restoring eroding areas (e.g., areas damaged by fires, off-road vehicle use).
  - Educate managers and users of park lands and open-space lands concerning the need to restrict off-trail activities. Establish and enforce practical, site specific regulations to control harmful off-trail activities.

VOL 12

17636

D. **Implement Land Use Planning -**

- **Implement Zoning regulations** - Appropriate zoning ordinances may be used in sensitive areas to provide for development patterns that are compatible with control of NPS discharges and the protection of receiving waters.
  - Zone to limit dwelling unit density and control the amount of on-site pollutants generated and control the amount of runoff by limiting the impervious surface area created.
  - Restrict development adjacent to streambanks. Require vegetated buffer strips along streambanks.
  - Restrict development on sites with soils and slopes that are susceptible to serious erosion.
- **Limit the directly connected impervious area -**
  - Develop planning guidelines illustrating favorable development techniques.
  - Use grass swales for drainage in preference to curbs and gutters and piped drains, where feasible
  - Encourage use of cluster housing, buffer strips, open space, or other patterns that reduce the quantity of runoff from the site.
  - Avoid direct connection of roof leaders to drain pipes or paved surfaces.
- **Require physical controls for new developments -**
  - Require the installation of detention basins or infiltration devices as BMPs for the control of the quality and/or quantity of runoff and for control of peak flows on all new development sites.
  - Develop specific guidelines for design and construction of these devices.
  - Provide for the necessary supervision, inspection and enforcement of regulations to insure compliance.

E. **Other Control Measures -**

- **Control oil and grease** - Automobile operation and maintenance is the principal source of oil and grease that can result in objectionable films and sheens on the surface of receiving waters. Fractions that remain in solution may contribute toxic contaminants. Food service facilities may contribute animal fats and greases (vs hydrocarbon based) to runoff.
  - Educate regarding the effective use of "housekeeping" practices, oil and grease traps, the use of adsorbents and cleaning compounds for controlling oil and grease at gas stations, automotive repair shops, parking areas, commercial and industrial facilities, and food service facilities.

- Educate regarding the need to provide adequate and sufficiently frequent vehicle inspection, and to maintain efforts to reduce leakage of oil, antifreeze, hydraulic fluid, etc.

- Research, strengthen (if necessary), and enforce regulations which give local jurisdictions the legal authority to require oil and grease controls in areas that are significant sources (e.g., gas stations, automotive repair shops, parking areas, commercial and industrial facilities, and food service facilities).

- Develop technical guidance that will facilitate efforts by responsible parties to comply with regulations requiring oil and grease controls (e.g., oil traps, plate separators, synthetic adsorbent material, grassed swales).

• **Control leaks from gasoline, fuel oil, and chemical storage tanks** - The actions listed can help to control pollutant contributions from leaking storage tanks.

- Educate regarding the environmental impacts that result from leaks and spills from gasoline, fuel oil, and chemical tanks, above and below ground.

- Coordinate with efforts (by others) to intensify the implementation of existing regulations which call for improved design of new tanks,(e.g., double walls, monitoring facilities); replacement of tanks over a specified age; self-monitoring programs; and implementation of a strategically focused spot-check program to search for, identify, test, and control leaking storage tanks.

• **Intensify the maintenance and repair of stormwater drainage systems** - These actions are directed at removing the pollutants that tend to be retained, and accumulate at specific locations in the stormwater drainage system.

- Determine the effectiveness of increasing the frequency of cleaning out storm sewer inlets, catchbasins, storm sewer pipes and drainage channels in areas where sediments, debris, or floatable materials tend to accumulate. Develop and implement improved programs where appropriate.

- Develop and implement an aggressive field program to search for, test, remove, and properly dispose of sediment deposits in drainage channels and streams, which contain relatively high concentrations of pollutants.

- Develop and implement a program which provides a means of recording the observations of field inspection and maintenance personnel, so that this information can be used to help locate the sources of pollutants.

3.5.2 Performance

There is no realistic way to accurately estimate the effect such practices may have on area-wide pollutant loads or to problems in specific water bodies. There is a high degree of uncertainty associated with the ability to define what these practices really do in terms of load reduction. In addition, even assuming performance levels could be defined, the extent to which the public at large would be faithful in applying a practice will generally be uncertain.

3.5.3 Advantages and Limitations

Advantages:

- Some source control actions will be very visible and will involve high level of public awareness and involvement. They can help to generate a sense of active community participation in an overall NPS control program, and may help secure the implementation of other, less obvious, elements of a management plan.
- In addition to reducing pollutant discharges to water bodies, many will have attendant aesthetic or cosmetic benefits.

Limitations:

- Adoption (with or without enforcement) of the necessary ordinances may create negative public reactions that may have an adverse effect on other areas of the program.
- In most cases, there is no reliable way to estimate the effect of a particular source control measure on the urban NPS pollutant loads.
- Effectiveness of a practice depends on the degree to which it is applied and the geographical extent of the application. Even with appropriate regulations in place, there is no positive assurance of compliance to the extent desired.
- Developing and assigning the necessary legal authority, and adding new responsibilities to established public agencies whose budget, experience, and priorities may not relate directly to NPS control may be difficult to resolve.

CHAPTER 4
TARGETING TO PRIORITIZE URBAN AREAS FOR CONTROL

4.1 INTRODUCTION

This chapter presents a ranking procedure for identifying the area (or areas) within an urban jurisdiction where it is most appropriate to focus initial NPS pollutant control efforts. While the ultimate goal may be fishable and swimmable quality for all surface waters, technical, economic and timing considerations usually require a staged management effort. The methodology ranks areas relative to the other areas in the jurisdiction and is not intended to imply that areas receiving lower ranking do not require controls.

A large urban jurisdiction will commonly involve a network of streams differing in size, use and sensitivity to urban runoff, and which receive discharges from different parts of the jurisdiction. A few of these may have greater local importance than others because of the nature and visibility of the resource, or the type or level of the its use. In addition some urban NPS control practices will generally apply to the entire jurisdiction (e.g., an anti-litter ordinance), but in many cases the control choices will tend to be either site-specific or land use-specific. For example appropriate pollutant control practices for industrial areas will usually be quite different than those suitable for residential areas. Further, factors such as topography, soil conditions, land availability and cost will often influence the selection of controls even for similar land uses in different parts of the jurisdiction.

For large urban areas it is necessary to develop a targeting procedure for implementing NPS controls for the following reasons:

- Implementation of NPS controls over the entire urban jurisdiction at once is not usually possible . Thus a phased approach will generally be necessary.
- Development of a rational basis for ranking different areas within the jurisdiction will be desireable.
- Accounting for relevant site-specific attributes and documenting the decision process is necessary. This will be particularly useful for describing the specific targeting decisions to the public
- Assist the urban jurisdiction in meeting the requirements of Sections 319 and 402 of the Clean Water Act.

4.2 ELEMENTS OF THE TARGETING PROCEDURE

The procedure described in this chapter provides a way to prioritize urban watersheds so that an NPS program can be sequentially implemented based on general and site-specific considerations. The approach consists of the following elements:

1. Identify discrete watersheds within the overall urban area, and the corresponding receiving stream segment. The necessary information could be developed from topographic or drainage system maps.
2. Determine relevant physical characteristics and other attributes of each watershed, and of the receiving stream segment.
3. Tabulate pertinent data in summary form.

4. Complete a "targeting table" by assigning a relative ranking value to each attribute. Assign weights to the attributes to reflect their relative importance in the local decision process.

5. Prioritize urban drainage areas in accordance with the resulting weighted sum of ranks.

There is no standard or generally accepted set of attributes that are used for establishing priorities for NPS control programs. A few attributes which are generally important are presented in Section 4.3. Note that any additional attributes that may be appropriate to consider for the local situation should be added to the procedure. The relative importance of each factor is accounted for by assigning different weights to each factor.

4.3 FACTORS USED FOR PRIORITIZATION

The factors in the ranking process are discussed below.

Waterbody Importance - This factor describes the general importance, and the ability of the waterbody to support a variety of beneficial uses. Since aquatic life populations and diversity as well as citizen use are likely to be greater for large streams (or lakes) with appreciable amounts of water, than for very small water bodies with low flows and small surface areas, flow or watershed size can be used as a surrogate for waterbody importance. Since measured flow data is not likely to be available at all points of interest, total drainage area of the watershed upstream of the location of interest can be used for comparison purposes. Absolute values of drainage area are thus assigned an appropriate rank in the 1 to 9 range. Note the larger the stream size is, the larger is the rank.

Type of Use - In order to provide a comparative measure of the importance of the type of use of the waterbody, the following types of primary beneficial uses are suggested.

RANK	LOW		--------------------------->	HIGH
USE	urban drainage	aquatic life	recreation - aesthetic	recreation - contact

Status of Use - This factor accounts for the present status of beneficial uses of the water body. In assigning a ranking to this factor, it is assumed that an EXISTING use in fairly good condition (or a threatened water), should have a lower priority than one for which the use is present but IMPAIRED. The highest rank would be assigned to a use whose degree of impairment is so great that it is effectively DENIED. While the foregoing is suggested as the recommended way to rank in terms of use status, it may be reasonable in some cases to assign a higher rank to an IMPAIRED use than to a DENIED use. The relative ease and cost of reclaiming the IMPAIRED use might be such that demonstrable control program benefits would be achieved more rapidly, and there might be a greater impact on health and safety (if there is,in fact, no actual use of the denied resource).

Level of Use - Although the stream size factor affects the level of use, this independent factor is included to make an important additional distinction that recognizes local factors. There will be cases where even a stream that would otherwise be considered quite small, will have a disproportionately high level of use, e.g., a small stream that flows through a park or recreational area and is popular with children for wading. The assigned rank for this factor should be based on whether the level of use is low, moderate or high - relative to the other waterbodies in the target area.

Pollutant Loads - The difference in annual pollutant load contributed by runoff from the different watersheds can be used as a surrogate for the potential to cause water quality problems that result in the impairment of a beneficial use. The procedure described below for estimating these loads, is useful for a comparative evaluation of pollutant sources for a screening type analysis. It is not designed to estimate actual loads for the area. Considerable site-specific refinements would be required to estimate the loads accurately.

The pollutant mass load in urban runoff is determined by (i) the amount of rainfall (ii) the total area of the watershed, and (iii) the distribution of land use types in the watershed. The rainfall should be assumed to be the same in all parts of the urban jurisdiction. The land use type influences the typical fraction of impervious surface area, which determines how much of the rain is converted to surface runoff. Land use also influences the average concentration of a pollutant in the runoff.

The annual rainfall typical for the urban jurisdiction will normally be known. However the exact value assigned will not be important because the comparison to be made is one of relative differences between different watersheds in the jurisdiction. The total area and the distribution of land use categories for each urban watershed being considered, must be extracted from local maps. For selected land use categories Table 4-1 provides typical values for impervious fraction and pollutant concentration in urban runoff (in milligrams per liter). It also lists values for runoff coefficient (Rv), which is computed from the impervious fraction, and represents the fraction of the rainfall that becomes surface runoff.

Impervious percent values are presented in Table 4-1 based on data from EPA's NURP program, and are suitable for a screening type analysis. However, they should be modified as appropriate if local information is available or if site-specific factors are likely to modify them. Note that the NURP study was not designed to provide definitive information on the differences between land use types, and provided no information on industrial runoff. The variation in concentration with land use shown in Table 4-1, is based on judgement concerning the relative differences that are likely to be associated with the general differences in the land uses. The values shown are considered appropriate for an analysis designed to estimate a relative comparision of mass loads. In particular, the values shown for industrial land use should be used with caution, because they are very sensitive to the type of industrial activity.

In Table 4-1, runoff concentrations for only four pollutants are presented. However, these can be used as surrogates for other pollutants for which data may not be readily available. For example, total suspended solids (TSS) can serve as a general surrogate for sediment deposition and siltation in streams and lakes. Oil and grease can be used as a surrogate for the potential for problems associated with degraded aesthetic values. The heavy metal copper (Cu) can be used as a surrogate for potential toxic impacts on aquatic life.

The mass load (pounds) of a pollutant from runoff is computed by :

$$M = RainV * Rv * Area * Conc * 0.227 \quad (4.1)$$

where:

M	= mass load [pounds]
RainV	= rainfall amount [inches]
Rv	= runoff coefficient [unitless]
Area	= drainage area [acres]
Conc	= average concentration in runoff [mg/l]
0.227	= unit conversion factor

VOL 12

17642

R0050947

TABLE 4-1

TYPICAL VALUES OF PERCENT IMPERVIOUS AREA AND POLLUTANT CONCENTRATIONS

LAND USE	% IMP	Rv	POLLUTANT CONCENTRATION (mg/l)			
			TSS	TP	O&G	Cu
Open -Developing	5	0.1	150	0.800	0	0.010
Open- Park	5	0.1	50	0.800	0	0.010
Resid - LOW DENS	20	0.2	100	0.600	5	0.030
Resid - HIGH DENS	50	0.4	90	0.400	10	0.040
Commercial	90	0.8	80	0.200	15	0.050
Industrial	70	0.6	120	0.200	20	0.050

If the rainfall amount used is the annual rainfall, the load computed would be pounds per year. However, since the analysis requires only comparative loads, a rainfall amount of 1 inch may be used for convenience. Loads should be computed for each land use within a watershed, and then combined to provide the total watershed pollutant mass load to be used for comparison. Rank values would be assigned to each watershed based on the range of mass values computed.

Implementability of Controls - This factor is designed to reflect the fact that an effective management program may be easier to implement for certain watersheds than for others. The prioritization scheme takes this into account. Differences may be based on institutional factors, existing ordinances, or technical factors. For example, it will usually be much easier to implement effective runoff controls for a newly developing area, than to retrofit controls in an existing central business district. Similarly, control requirements may be institutionally easier to implement for an industrial area than for scattered residential areas.

4.4 DESCRIPTION OF TARGETING PROCEDURE

A rank between 1 and 9 is assigned to each of the above factors to reflect increasing value or importance of the selected factor. It is emphasized that in each case, the rank is not an absolute measure of importance, but rather a comparative measure. Rank values are assigned so that the higher the value, the higher will be the priority for action. Scale ranges other than 1 to 9 could obviously be used as well. Very high ranges (e.g., 0 to 100) imply an ability to make fine distinctions and gradations that will not usually be possible. A very small range (e.g., 1 to 3) may represent the realistic level at which distinctions can be made in a screening analysis of this type, but constrains the sensitivity of the comparisons. The range of 1 to 9 is suggested as a reasonable compromise.

It is recognized that some factors will be more important than others. The relative importance of different factors is accounted for by assigning different weights to each factor. This helps to avoid the choice of factors from forcing the results in a particular direction. The assignment of weights also permits the emphasis of locally important considerations. For example, if the planning body determined that it was most important to get an implementation program started at an early stage, the "ability to implement" factor could be given a high weight. In a case where the main concern is the violation of water quality standards for fishable, swimmable waters, the relative weights would emphasize the "use status" and "pollutant load" factors. It is important that the sum of the weights add up to 100. This would help in balancing the assignment of relative importance to the different targeting factors.

It is important to bear in mind that there is considerable subjective element involved in the selection of factors, the assignment of ranks and relative weights. Presumably these will be developed as a result of group discussions involving interested parties. The methodology presented here provides a useful framework for balancing priorities and forming a collective judgement.

The targeting procedure is best illustrated by an example. Figure 4-1 presents a schematic illustration of a hypothetical urban jurisdiction. Watersheds and land use types are delineated and their spatial relationship to important use locations are shown. Table 4-2 presents a summary of the information that describes the urban area and is used to compute the runoff pollutant loads from the different watersheds in the urban area. This table also contains data to calculate the mass loads, which are computed using Equation 4.1. The runoff coefficient (Rv) is computed from the percentage of impervious area as described in Chapter 2. The percent impervious area must be estimated from appropriate local maps or inspections, or from the approximate relationship described in Chapter 2. Mass loading results for total suspended solids are presented in Table 4-3.

WATERSHED RANK VALUE	1.7	4.1	3.2		9.0

The information on comparative loads and comparative stream size is converted to a set of rank values and are presented in Table 4-4. Rank values are also assigned and entered for the additional targeting factors as shown in the table.

To illustrate the use of the prioritization scheme, and the rank values assigned for this hypothetical case, the following considerations are assumed to have been the concensus reached in planning discussions.

- Ranks for the stream size factor are assigned in proportion to the total drainage area (urban and upstream) providing flow to the stream.

- Beneficial use "type" ranks are based on providing a mid-range value to stream A, whose actual use is a habitat for aquatic life, with little or no direct human contact. Stream B has a low rank because, although water quality is the poorest, the stream is viewed primarily as an urban drain. Stream C (as well as the combination of the urban streams) are assigned a high rank because of the recreational use (actual or potential) at the city park or the downstream recreational area.

- Use "status" ranks are based on the following. Streams A's use is still a viable one, but is somewhat impaired, and it is felt that it can be improved and protected by control of the runoff loads. It is assigned a high rank compared to the others. B and C receive low ranks for two different reasons. Stream B has had poor quality water for so long that the denial of any use other than conveyance of drainage water has long been accepted. There is no current biota or human contact to be protected. The part flowing through the city park is in a buried culvert. Stream C is given a low rank because the quality is still good. The combined flow below town is higher than C because it is affected by the loads coming from A and B.

- Use "level" ranks are a reflection of the relative number of people using or affected by the different stream segments.

- Pollutant load ranks are assigned in proportion to the loads from each area that were developed on Table 4-1. For illustrative purposes, TSS is used as the general indicator of runoff pollutants. The analysis could be repeated using the other pollutants to determine whether the targeting decision is affected.

- Ability to implement ranks assume that control would be easiest to apply in watershed B, because a major part of the area is industrial. Watershed C, and the total urban watershed are given lower ranks than A because there is a greater area to control. In practice, physical factors such as steep slopes, high groundwater, rock, etc. - would also influence the rank value assigned.

For this analysis, equal weights are assigned to the four factors. Since beneficial use has three sub-categories, weights are assigned so that they total to 25 to be consistent with the others.

On the basis of the site data and the series of value judgements discussed above, the prioritization results shown by Table 4-4 suggests that pollutant controls be applied first to watershed C, then to A, and finally to B. Although the "total urban area" has the second highest score, it implies control of the entire urban area.

TABLE 4-4. PRIORITIZATION ANALYSIS FOR URBAN AREA TARGETING

URBAN WATERSHED	STREAM SIZE	BENEFICIAL USE			POLLUTANT LOAD TSS	ABILITY TO IMPLEMENT	TARGET SCORE
		TYPE	STATUS	LEVEL			
WEIGHTS	25	10	10	5	25	25	100
WATERSHED A	4	5	7	4	1.7	5	4.08
WATERSHED B	2	2	2	1	4.1	7	3.73
WATERSHED C	8	8	2	6	3.2	3	4.85
TOTAL URBAN WATERSHEDSHED	8	8	5	8	9.0	2	8.45

TARGET SCORE = WEIGHTED AVERAGE OF RANK POINTS = SUM (RANK SCORE * WEIGHT) / SUM (WEIGHTS)

VOL 12

17649

R0050954

Using this targeting methodology sensitivity analyses are easy to perform, and are recommended. In addition to repeating the analysis with other pollutants as mentioned earlier, the ranks (or weights) can be modified to determine the sensitivity of the targeting decision.

If all uses were considered equally important, and in about the same condition (good or poor) then zero weights could be assigned to everything but pollutant loads. In this case, the higher loads from watershed B would put it at the top of the targeting list.

4.5 DISCUSSION

There is no "magic formula" that can be applied that will "decide" for a user, the most appropriate priority to assign for a general implementation program. The degree of subjectivity in assigning both rank values and weights will be apparent as the targeting procedure is applied. The principal value of a formal procedure for an analysis with this unavoidable degree of subjectivity, is that it provides a way to document the decision process. Equally useful is the fact that it provides a framework to organize the thought process and provides a structure to the intermediate decision elements that determine the relative importance of different factors in the local situation.

Some urban jurisdictions will have relatively unique features that cannot be realistically reflected in a generalized procedure. In such a case, additional factors may be added to the assessment.

Similarly, the procedure could be made more complex in terms of the estimation of loads and relating them to the nature and severity or the water quality impact they cause. This consideration was rejected in the interest of keeping the procedure simple, and because value judgements on elements that are not subject to formal computation are also important in the targeting process.

Some judgement is required in the interpretation of the computed pollutant loads. They should not be used to infer either the presence or absence of an actual problem,which will also depend on a number of other factors. The loads computed are based on an arbitrary one inch of rainfall in an attempt to emphasize that they reflect only the comparative pollution potential of the different areas.

CHAPTER 2: CHOOSING THE BEST BMP OPTION FOR A SITE

This chapter outlines factors that planners and engineers need to consider when choosing an urban best management practice (BMP) for a particular development site. It begins with a brief discussion of the minimum objectives that a BMP plan for a site should meet. The next section provides a series of screening tools that can be used to select the most appropriate BMP for a particular development site. These screening tools can be used to evaluate the following:

- BMP options that are suitable for a site, given its physical condition and development status.
- Stormwater control benefits provided by each BMP option.
- The expected pollutant removal capability for each BMP option, under several different design scenarios.
- Environmental and human amenity values associated with the BMP option selected.

The screening tools can be used in any order, or may be used as an overall summary of BMP performance. Several examples of how the screening tools can be used for a particular development site are presented. The chapter concludes with a summary index that shows where more information on the design, cost and maintenance of a BMP option can be found elsewhere in the manual.

OBJECTIVES IN BMP PLANNING

Over the past two decades, a number of urban BMPs have been developed and refined to mitigate some of the adverse impacts associated with development activity. Experience has shown that each BMP option has both unique capabilities and persistent limitations. These, in turn, must be balanced with both the physical constraints imposed by the development site and the overall management objectives for the watershed. In practice, this balance is achieved through a negotiating process between the engineering consultant and the local planner. Typically, the engineering consultant is responsible for developing the initial BMP plan, and represents the interests of the developer. The planner reviews the plan to ensure that it conforms with local policies and design standards, and represents the interests of the community.

During the BMP review process, it is important to identify the ultimate objectives for managing runoff from the site. The objectives in nonpoint source pollution and stormwater management have gradually evolved over the years, and may vary considerably among jurisdictions. However, the local planner and engineering consultant often do recognize several common and general goals which should be incorporated into a BMP plan. At a minimum, the BMP plan jointly developed for a site should accomplish the following goals:

- Reproduce, as nearly as possible, the hydrological conditions in the stream prior to development.
- Provide a moderate level of removal for most urban pollutants.
- Be appropriate for the site, given physical constraints.
- Be reasonably cost-effective in comparison with other BMPs.
- Have an acceptable future maintenance burden.
- Have a neutral impact on the natural and human environment.

Reproduce Pre-development Hydrological Conditions

The historical concern in stormwater management has been to reduce the frequency and severity of downstream floods. In most areas, this goal is achieved by controlling the peak discharge computed for a specific design storm to pre-development levels. In reality, however, floods are but one of a series of hydrological changes brought about by watershed development. Other hydrological changes can have equally profound impacts on the quality of downstream aquatic habitat and/or the severity of streambank erosion. Some BMP options are capable of mitigating these impacts through artificial groundwater recharge or the control of small to intermediate storm events. Both the planner and the engineer should check the condition of stream channels downstream to determine if such options should be required.

Provide Moderate Pollutant Removal Capability

In recent years, BMP designs have been adapted to enhance pollutant removal during storms, and thereby, improve the quality of stormwater runoff delivered to receiving waters. BMPs differ markedly in the pollutant removal mechanisms they employ, and consequently, their performance in removing different pollutants can vary significantly. However, the engineer has some ability to enhance removal rates by increasing the volume of runoff effectively treated by the BMP, or by adding extra design features. The planner's responsibility is to provide specific guidance to the engineer on which urban pollutants are to be targeted for removal in the watershed.

Feasibility for the Site

A surprisingly high number of BMPs are constructed on sites for which they are not suitable. As a consequence, some BMPs are often plagued with chronic maintenance problems or nuisance conditions, and in extreme cases, may no longer function as designed. To prevent these sorts of problems from occurring, both the planner and engineer should clearly understand the physical restrictions associated with each BMP. In addition, the engineer should perform field tests to verify the physical condition of the site. Depending on the results, the engineer may have to modify the BMP plan or incorporate preventative design features.

Cost-effectiveness

The construction costs for different BMP options can vary substantially, even on similar sites. This is due to inherent differences in the methods and materials used for BMPs, as well as certain economies-of-scale. Since BMP costs are eventually passed on to the consumer, cost-minimization should

VOL 12

1756

- Reproduce, as nearly as possible, the hydrological conditions in the stream prior to development.
- Provide a moderate level of removal for most urban pollutants.
- Be appropriate for the site, given physical constraints.
- Be reasonably cost-effective in comparison with other BMPs.
- Have an acceptable future maintenance burden.
- Have a neutral impact on the natural and human environment.

Reproduce Pre-development Hydrological Conditions

The historical concern in stormwater management has been to reduce the frequency and severity of downstream floods. In most areas, this goal is achieved by controlling the peak discharge computed for a specific design storm to pre-development levels. In reality, however, floods are but one of a series of hydrological changes brought about by watershed development. Other hydrological changes can have equally profound impacts on the quality of downstream aquatic habitat and/or the severity of streambank erosion. Some BMP options are capable of mitigating these impacts through artificial groundwater recharge or the control of small to intermediate storm events. Both the planner and the engineer should check the condition of stream channels downstream to determine if such options should be required.

Provide Moderate Pollutant Removal Capability

In recent years, BMP designs have been adapted to enhance pollutant removal during storms, and thereby, improve the quality of stormwater runoff delivered to receiving waters. BMPs differ markedly in the pollutant removal mechanisms they employ, and consequently, their performance in removing different pollutants can vary significantly. However, the engineer has some ability to enhance removal rates by increasing the volume of runoff effectively treated by the BMP, or by adding extra design features. The planner's responsibility is to provide specific guidance to the engineer on which urban pollutants are to be targeted for removal in the watershed.

Feasibility for the Site

A surprisingly high number of BMPs are constructed on sites for which they are not suitable. As a consequence, some BMPs are often plagued with chronic maintenance problems or nuisance conditions, and in extreme cases, may no longer function as designed. To prevent these sorts of problems from occurring, both the planner and engineer should clearly understand the physical restrictions associated with each BMP. In addition, the engineer should perform field tests to verify the physical condition of the site. Depending on the results, the engineer may have to modify the BMP plan or incorporate preventative design features.

Cost-effectiveness

The construction costs for different BMP options can vary substantially, even on similar sites. This is due to inherent differences in the methods and materials used for BMPs, as well as certain economies-of-scale. Since BMP costs are eventually passed on to the consumer, cost-minimization should

VOL 12

1757

be a priority for both the engineering consultant and the planner. Generally, the engineering consultant, who has a legitimate interest in developing the least cost plan for his or her client, will perform the needed cost analyses.

Acceptable Future Maintenance Burden

Like any other pollution control device, BMPs can only continue to be effective if they are regularly inspected and maintained. Maintenance tasks for most BMPs include both low cost routine tasks and more expensive non-routine tasks, such as rehabilitation or sediment removal. Maintenance costs for BMPs are significant. Over a twenty year interval they will often equal or exceed the initial construction cost. However, the cost and responsibility for maintenance is normally passed on to future residents or the public sector, and not the original developer.

Consequently, the planner must clearly vest responsibility for maintenance: How and when tasks will be performed, how it is to be financed, and who will inspect the BMP. In most cases, the maintenance burden of a BMP is ultimately rooted in the initial design and construction of the facility. Planners and engineers should work together in this phase to anticipate future maintenance problems at the site and develop designs that can alleviate them. If maintenance requirements are addressed during the design and construction phases, both the scope and cost of future maintenance activities can be sharply reduced.

Neutral Impact on the Environment

Urban BMPs nearly always represent a significant modification to both the natural environment and the adjacent community. As such, BMPs can either enhance or degrade the amenity values that both provide. Comparatively small investments in design, landscaping and maintenance can make a BMP an attractive feature of a community, or at least an unobtrusive one. Without such efforts, many BMPs become "dead space" in a development; that is, they appear unsightly or discordant, provide no habitat or recreational opportunities, and are plagued by nuisance problems. The importance of enhancing the amenity values of a BMP cannot be overemphasized, as resident perceptions about a BMP are generally formed by the amenities they do or do not provide. These perceptions, in turn, strongly influence their acceptance of and support for BMPs, which is critical if the same residents are expected to pay for maintenance.

BMP SCREENING TOOLS

To aid the planner or engineer in choosing the best BMP for a site, a series of screening tools have been developed to compare the capabilities and limitations of each BMP. The first screening tool can be used to identify which BMP options are physically feasible for the site (Figures 2.1 and 2.2). These help the designer to shorten the list of BMP options that need be considered at a site. The second screening tool (Figure 2.3) summarizes the stormwater benefits which are provided by each BMP option. The third screening tool (Figure 2.4) provides rapid guidance on the relative pollutant removal capability of BMPs for a number of urban pollutants of concern. Finally, the fourth screening tool (Figure 2.5) indicates what natural or human amenities, if any, can be provided by the BMP.

Assuming that one or more BMP option has been selected, final design can then begin. More detailed information on the specific design methods, maintenance requirements and cost estimating techniques for the BMP option can be found using the summary index (Table 2.1). The reader is also encouraged to refer to each individual BMP chapter during all phases of the design.

SCREENING BMPs BASED ON PHYSICAL SUITABILITY

The first step in choosing a BMP is to identify which BMPs are actually suitable for physical conditions of the site. The two most important physical factors to consider in this assessment are the total contributing watershed area, and the infiltration rate of the soils of the site. Most BMPs can only be applied within relatively narrow ranges of watershed area and soil types. Figure 2.1 shows these ranges in schematic fashion. Solid black bars indicate when these two factors do not pose a problem, and the absence of a bar denotes that the BMP probably should not be applied under the specified condition. In cases where the bar becomes narrow, the BMP may or may not be feasible for the site depending on local design standards, development intensity, or the expected level of future maintenance.

Figure 2.2 presents a matrix that shows whether a BMP is also subject to other physical restrictions. In these cases, a solid dot indicates that the factor is not normally a restriction, whereas an open dot suggests that it is a restriction. In most cases, these restrictions do not necessarily prevent the use of a BMP option, but may affect where a BMP is located on a site, or how it is designed. As a general rule, pond BMPs normally face fewer of these site restrictions than infiltration BMPs.

The nature of each of the physical factors outlined in these screening tools are described below.

Watershed Area Served

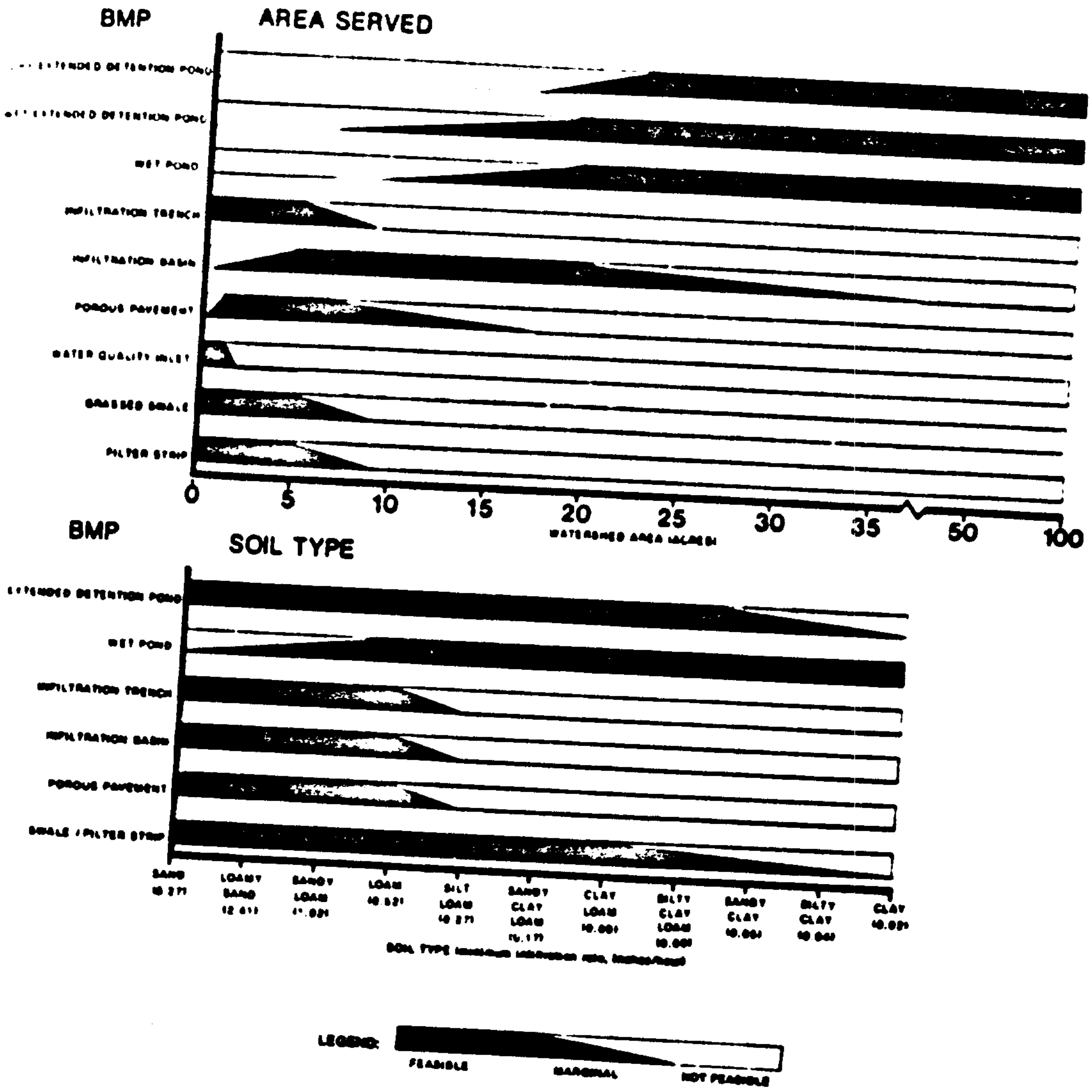
Pond BMPs normally require a significant contributing watershed area (greater than ten acres) to ensure proper operation. The lower range of suitability for ponds is set by the minimum orifice size for dry extended detention ponds, or the capacity to maintain water levels in wet ponds and wet extended detention ponds. By way of contrast, infiltration and vegetative BMPs are generally only applicable on sites less than ten acres, due to space, economic or flow velocity constraints.

It should be noted that the contributing area of a site does not always have to be fixed. By creatively using local topography and drainage, site area can be increased or decreased to better accommodate a particular BMP. For example, additional runoff generated away from the site (off-site runoff) can be routed to the BMP, thereby increasing total site area and making pond options more feasible. Conversely, various portions of the total runoff from a site can be routed to individual BMPs (decreasing site area, and making infiltration and vegetative BMPs more practical).

VOL 12

1 7659

Figure 2.1: Watershed Area and Soil Permeability Restrictions for BMPs



VOL 12

17660

Soil Type

The permeability of the soil underlying a BMP has a profound influence on its effectiveness. This is particularly true for infiltration BMPs, which cannot be applied on sites with soils that have infiltration rates (fc) less than 0.27 inches/hour, as defined by the least permeable layer in the soil profile. This excludes most "C" and "D" soils which cannot exfiltrate enough runoff through the subsoil.

Pond BMPs tolerate a much broader range of soil conditions. Extremely permeable sandy soils may make it difficult to maintain water levels in wet ponds, and clayey soils may cause standing water problems in dry extended detention ponds.

○ MAY PRECLUDE THE USE OF A BMP
◐ CAN BE OVERCOME w/ CAREFUL SITE DESIGN
● GENERALLY NOT A RESTRICTION

Slope

Steep slopes restrict the use of several BMPs. For example, porous pavement and grassed swales must be situated in sites with slopes of 5% or less. Also, infiltration trenches and filter strips are not practical when slopes exceed 20%.

High Water Table

The water table acts as an effective barrier to exfiltration and can sharply reduce the ability of an infiltration BMP to drain properly. If the height of the seasonally high water table extends to within four feet of the bottom of an infiltration BMP, the site is seldom considered suitable.

Close to Bedrock

The downward exfiltration of storm runoff is also impeded if the bedrock layer lies too close to the soil surface. As with a high water table, a close bedrock layer prevents an infiltration BMP from draining properly. Therefore, if the bedrock layer extends to within 2 to 4 feet of the bottom of an infiltration BMP, the site is not feasible. Similarly, pond BMPs are often not feasible if bedrock lies within the area that must be excavated to provide stormwater storage.

Proximity to Foundations and Wells

Since infiltration BMPs divert runoff back into the soil, some sites may experience problems with local seepage. This can be a real problem if the BMP is located too close to a building foundation. Another risk is that the runoff and pollutants diverted into the groundwater may contaminate water supplies. While relatively little research has been performed to evaluate this risk, it is advisable to keep infiltration BMPs located at least 100 feet away from drinking water wells.

Land Consumption

Some sites are so small or so intensively developed that no room is available for BMP options that consume a large amount of space. Pond BMPs and porous pavement both require a large surface area and a generous buffer, and consequently may not fit into extremely tight sites.

Maximum Depth

To preserve storage capacity and provide optimal pollutant removal conditions, infiltration BMPs must be designed to completely drain within 2 to 3 days after a storm. If the infiltration rates of the underlying soils are marginal, the depth of the infiltration facility may be limited. These restrictions vary depending on whether the facility is a trench, basin or porous pavement facility.

Wet ponds are also subject to a maximum depth limit as well. Extremely deep ponds (greater than 8 feet deep) may stratify during the summer and create low oxygen conditions near the bottom of the pond. This in turn, creates the potential for the release of pollutants from the sediments back into the water column.

Restricted Land Uses

Certain BMPs can only be applied to particular land uses, and are not broadly applicable for all development sites. Porous pavement, for example, can only be used for sites with parking lots not expected to receive heavy car or truck traffic. Similarly, grassed swales can only be used in conjunction with low density residential areas or roads.

High Sediment Input

Most BMPs are unable to handle the large loads of sediment eroded during the construction phase of development. Infiltration BMPs are particularly susceptible to rapid clogging and subsequent failure if significant sediment loads are allowed to enter the structure. As a general rule, these BMPs should not be installed until all of the land disturbed by construction in the contributing watershed is effectively stabilized. Contractors must often take unusual steps during the actual installation of the infiltration BMPs to prevent soil compaction or sediment contamination. Although sediment loads drop sharply after the construction phase, gradual clogging of infiltration BMPs can still occur, so many designs call for the use of a pre-treatment device to filter out sediment and other coarse particles before they reach the facility.

Pond BMPs can be used for sediment control during the construction phase of development, with proper conversion, clean-out and regrading. After the site is stabilized, significant amounts of pond storage capacity can still be lost due to the gradual accumulation of deposited sediments. After 5 to 20 years, the sediment deposits are large enough to impair the function of a pond, and must be removed. The cost and scope of sediment removal can be reduced by preventative design, extra storage and/or sediment forebays.

Thermal Enhancement

Shallow marshes and wet ponds warm up rapidly during the summer months. Under certain circumstances, runoff leaving these BMPs can be 5 to 10 degrees warmer than the runoff entering the structure. Such warm water release can be a lethal thermal shock to aquatic organisms that are adapted to coldwater conditions. Thus, the use of wet ponds and shallow marshes should be avoided in watersheds with sensitive coldwater streams.

SCREENING BMPs BASED ON STORMWATER BENEFITS PROVIDED

The objective of stormwater management is to attempt to reproduce the pre-development hydrology of the site. As noted earlier, this can be done through a combination of peak discharge control, volume control, groundwater recharge and streambank erosion control. Figure 2.3 shows the extent to which common BMP designs provide these benefits. A solid dot indicates that the BMP normally provides the benefit; an open dot indicates that it does not; and a half dot suggests that the benefit might be provided in certain sites or with special design modifications. As can be seen, very few BMP options can achieve the full spectrum of desirable stormwater benefits. This is because a different flow condition and/or frequency must be controlled to provide each benefit. As an example, the designer needs to control very large, infrequent storms to attain peak discharge control, yet must concentrate on much smaller and more frequent storms to provide groundwater recharge.

The design variations for infiltration BMPs shown in Figure 2.3 deserve some additional explanation. The term "exfiltration" refers to the amount of runoff that is effectively infiltrated through the soil profile. Full exfiltration occurs when all of the runoff delivered to an infiltration BMP is completely exfiltrated back into the soil. As one might imagine, full exfiltration BMPs need to be very large in volume. Partial exfiltration BMPs only divert a fixed volume of runoff into the soil (the remaining runoff is conveyed through the BMP, but may be detained long enough to provide some peak discharge control). In water quality exfiltration BMPs, a small, fixed runoff volume is diverted into the soil. The remaining runoff is conveyed away, and is not detained long enough to provide any peak discharge control.

Peak Discharge Control

As shown in Figure 2.3, peak discharge control is often required for one or more design storms under local regulations. The most common design storm used is the 2 year storm, which is a flood that occurs, on average, every two years. In natural watersheds, the two year storm produces a flood that fills a stream to the top of its banks (i.e., the bankfull flood). Some jurisdictions also require control of the 10 or 100 year design storms, particularly if there is unprotected development further downstream on the floodplain. Even if a BMP does not control these larger design storms, they must still be designed to safely pass them through (e.g., using an emergency spillway or an overflow pipe).

Peak discharge control is accomplished in pond BMPs by temporarily detaining a large portion of the runoff volume for the design storm, and then releasing it at the lower pre-development rate. This is done by using a vertical riser with a control orifice or weir. A single pond can control a series of design storms by using a series of orifices and weirs at progressively higher elevations. In general, pond BMPs are an excellent means of providing peak discharge control.

Infiltration BMPs have a more limited capacity to control peak discharges. Full exfiltration systems are normally only capable of controlling peak discharges for the 2 year storm (and in rare cases, the 10 year storm). Most partial exfiltration systems can control the 2 and 10 year storm, and pass the 100 year storm. Water quality exfiltration systems, water quality inlets, swales, and filter strips normally have little or no capacity to control peak discharges.

Volume Control

Infiltration BMPs can help to reduce the increased runoff volumes generated from small and intermediate storms, since they divert a significant fraction of storm runoff volume back into the soil. Pond BMPs, on the other hand, are ineffective in reducing runoff volume. Ponds only detain or retain runoff for a short period of time before releasing it downstream.

Groundwater Recharge

Infiltration BMPs are an excellent means of providing for groundwater recharge, which is often lost as a consequence of watershed development. "Natural" levels of groundwater recharge can be duplicated by diverting a significant fraction of the runoff from frequent small and moderate storms back into the soils. Most exfiltration designs recharge the groundwater sufficiently to sustain normal low flows in headwater streams during the critical summer months. Vegetative BMPs, such as grassed swales and filter strips have a more limited capability, and pond BMPs generally have little or none.

Streambank Erosion Control

All BMPs that control peak discharges for the 2 year storm provide some degree of streambank erosion control. However, the 2 year storm creates an erosive condition in natural channels (i.e., a bankfull discharge). To adequately protect downstream channels, it is necessary to control both the post-development increase in the 2 year bankfull flood and the increased frequency with which it occurs. This normally entails the control of storm events of intermediate size (less than the 2 year storm and greater than the mean storm). Some preliminary design suggestions for minimizing the increased frequency of bankfull flooding are provided in Appendix B. Based on this analysis, it appears that extended detention ponds and some infiltration BMPs can effectively reduce the frequency with which bankfull flooding occurs, if sized properly. Wet ponds (without extended detention), vegetative BMPs, and water quality inlets show little capability in this regard.

SCREENING BMPs BASED ON POLLUTANT REMOVAL BENEFITS

The pollutant removal capability of a BMP is primarily governed by three interrelated factors: 1) the removal mechanisms used, 2) the fraction of the annual runoff volume that is effectively treated, and 3) the nature of the urban pollutant being removed. The designer has a limited ability to control the first two factors, but has no influence on the third.

Figure 2.4 illustrates the comparative pollutant removal capabilities of BMP options. The removal rates shown are inferred from field performance monitoring, laboratory experiments, modeling analyses and theoretical considerations. Due to the inherent uncertainties involved, removal rates are expressed in 20 percent increments. A removal rate has been estimated for several design variations of each BMP. The design variations for each BMP are arrayed in order of increasing fractions of annual runoff volume treated.

As noted earlier, the nature of the pollutant being removed often sets an upper limit on the potential removal rate that can be achieved. From an operational standpoint, pollutants can be said to exist in either particulate or soluble forms, or more commonly, as a mix of both forms (MWCOG, 1987). Particulate pollutants, such as sediment and lead, are relatively easy to remove by common BMP removal mechanisms, including settling and filtering. Soluble pollutants, such as nitrate, phosphate, and some trace metals, are much more difficult to remove. Settling and filtering removal mechanisms have little or no effect, and biological mechanisms, such as uptake by bacteria, algae, rooted aquatic plants or terrestrial vegetation, must be used.

VOL 12

17656

The importance of pollutant form can clearly be seen in Figure 2.4. Most BMPs can achieve an extremely high removal rate for suspended sediment and trace metals that exist largely in particulate forms. Much lower removal rates are generally obtained for total phosphorus, oxygen-demanding materials and total nitrogen, since they typically exist as a mix of particulate and soluble forms.

The following sections summarize the pollutant removal capability of BMPs, with an emphasis on their major removal mechanisms, and design enhancements which can be used to improve their performance.

Extended Detention Ponds

Dry extended detention ponds rely primarily on settling to remove pollutants. Depending on how much and how long runoff is detained, it is possible to achieve moderate or high removal rates for particulate pollutants that are relatively easy to settle. However, removal rates for most soluble pollutants are quite low for dry extended detention ponds, although it is possible to enhance rates by incorporating biological removal mechanisms into the design of the pond (e.g., by establishing a shallow marsh in the bottom stage of a dry extended detention pond, or by using extended detention in combination with a wet pond).

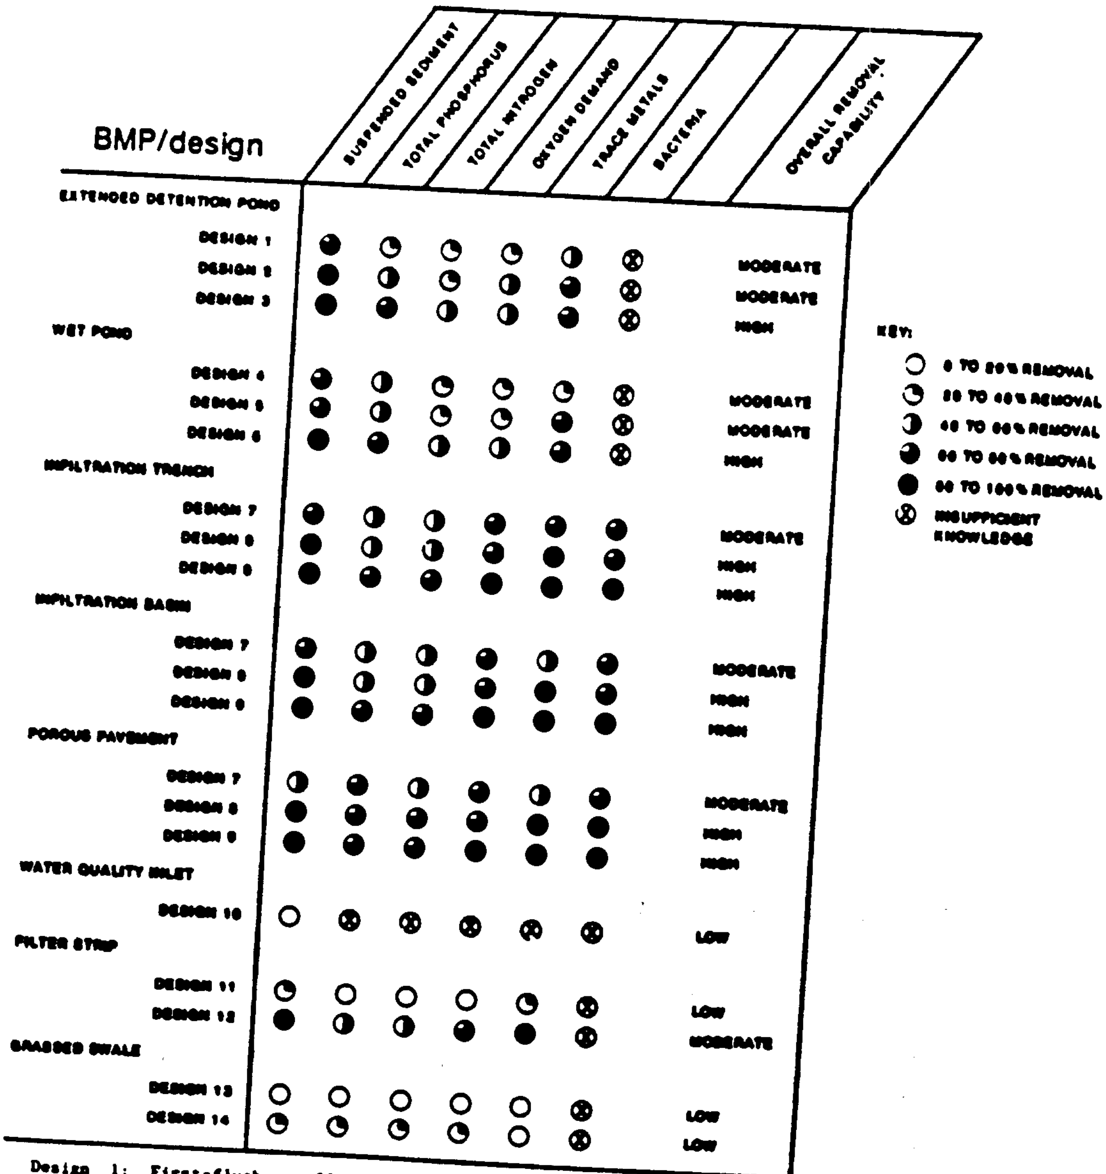
Wet Ponds

Wet ponds have a moderate to high capability of removing most urban pollutants, depending on how large the volume of the permanent pool is in relation to the runoff produced from the surrounding watershed. Wet ponds utilize both settling and biological uptake, and are capable of removing both particulate and soluble pollutants. In addition to increasing the volume of the permanent pool, wet pond removal rates can be enhanced by establishing marshes around the perimeter, and by adjusting the geometry of the pond.

Infiltration Practices (trenches, basins, porous pavement)

From a pollutant removal standpoint, infiltration trenches, basins, and porous pavement behave in a similar manner, and can be treated as a group. Infiltration practices filter runoff through the soil layer, where a number of physical, chemical and biological removal processes occur. Infiltration practices have a moderate to high removal capability for both particulate and soluble urban pollutants, depending how much of the annual runoff volume is effectively exfiltrated through the soil layer. Removal rates can be further enhanced by increasing the surface area reserved for exfiltration and adjusting the geometry of the practice to achieve a draining time of less than 3 days. It should be noted that infiltration practices should not be relied on to achieve high levels of particulate pollutant removal (particularly sediments), since these particles can rapidly clog the device. Rather, particulate pollutants should be removed before they enter the structure by means of a filter strip, sediment trap or other pretreatment device.

Figure 2.4: Comparative Pollutant Removal Of Urban BMP Designs



Design 1: First-flush runoff volume detained for 6-12 hours.
Design 2: Runoff volume produced by 1.0 inch, detained 24 hours.
Design 3: As in Design 2, but with shallow marsh in bottom stage.
Design 4: Permanent pool equal to 0.5 inch storage per impervious acre.
Design 5: Permanent pool equal to 2.5 (Vr); where Vr=mean storm runoff.
Design 6: Permanent pool equal to 4.0 (Vr); approx. 2 weeks retention.
Design 7: Facility exfiltrates first-flush; 0.5 inch runoff/imper. acre.
Design 8: Facility exfiltrates one inch runoff volume per imper. acre.
Design 9: Facility exfiltrates all runoff, up to the 2 year design storm.
Design 10: 400 cubic feet wet storage per impervious acre.
Design 11: 20 foot wide turf strip.
Design 12: 100 foot wide forested strip, with level spreader.
Design 13: High slope swales, with no check dams.
Design 14: Low gradient swales with check dams.

VOL 12

1 7658

Water Quality Inlets

Current designs of water quality inlets appear to have low to moderate removal rates for particulate pollutants, and low to zero rates for soluble pollutants. Water quality inlets rely primarily on settling for removal, and given their small storage capacity and brief residence times, it is likely that only coarse grit, sand, and some silts will be trapped. Inlets do show some promise in removing hydrocarbons, such as oil, gas and grease, from runoff. Due to resuspension problems, however, pollutant removal can only be attained in water quality inlets if they are cleaned regularly.

Filter Strips

Filter strips have a low to moderate capability of removing pollutants in urban runoff, and exhibit higher removal rates for particulate rather than soluble pollutants. Removal mechanisms include filtering (through vegetation and/or soil), settling/deposition and uptake by vegetation. Forested buffer strips appear to have a higher removal capability than grass buffer strips. However, length, slope and soil permeability are critical factors which influence the effectiveness of any strip. Another practical design problem is how to prevent runoff from concentrating and thereby "short-circuiting" the strip. Special design modifications and regular maintenance are needed to provide optimal removal rates in the field.

Grassed Swales

Grassed swales have a low capability of removing urban pollutants, except under site conditions which are unusual in the Washington metropolitan area (e.g., extremely gentle slopes, permeable and uncompacted soils, installation of check dams and maintenance of a dense grass turf). If constructed under these conditions, pollutants can be removed through the filtering action of the grass, by deposition in low velocity areas, and by exfiltration through the soil layer. Moderate removal of particulate pollutants, and low removal of soluble pollutants can be expected under these optimal conditions.

SCREENING BMPs FOR ENVIRONMENTAL AMENITIES

Figure 2.5 is a screening tool that shows the environmental and human amenities which can be provided by a particular BMP. In most cases, these amenities are not automatically provided when a BMP is built. Rather, they are a result of thoughtful design, regular maintenance, and creative landscape planting. In this matrix, a solid dot indicates that there is a strong potential for a BMP to provide the amenity; an open dot indicates the BMP has little or no potential; and a half dots suggests that a BMP might provide the amenity with some design modifications or as a result of unusual site conditions.

The first five headings in Figure 2.5 refer to amenities related to the improvement of the natural environment, while the last five headings pertain to amenities which are provided to the adjacent community. As might be expected, community amenities are quite subjective, and often adjacent residents hold widely divergent opinions as to their value. However, based on opinion surveys and less formal surveys of complaints to public works officials, some generalities have been made.

VOL 12

1761

Low Flow Maintenance

Downstream aquatic life can be jeopardized when the natural low flow levels experienced during the summer months decline even further because of reduced infiltration in urbanized watersheds. Infiltration BMPs contribute significantly to groundwater recharge and appear to be capable of sustaining low flows during the critical summer months if widely applied in a watershed. Vegetative BMPs, such as swales and filter strips, appear to have modest potential in this regard, and pond BMPs have little effect in maintaining low flows.

Streambank Erosion Control

Streambank erosion not only contributes large sediment loads to receiving waters, but also has an adverse impact on the habitat quality for downstream aquatic life. Some BMPs, such as extended detention ponds and full exfiltration BMPs, can control erosive stormflows enough to keep downstream channels and banks relatively stable, whereas most other BMPs have only marginal capabilities.

Aquatic Habitat Creation

Some BMP options are attractive in that they can create wetland or open water areas utilized by waterfowl, marsh birds, and other wildlife. Shallow marshes and wet ponds are particularly well suited for this role, if relatively small investments are made in landscaping design and plant selection. "Volunteer" wetland plants may also colonize these BMPs (and poorly drained extended detention ponds) without intentional planting efforts, but may not provide high quality habitat. Tips for enhancing aquatic habitat are presented in the Chapter 4 and the Basin Landscaping Guide (Chapter 9).

Wildlife Habitat Creation

BMPs with generous buffers (wet ponds, extended detention ponds, infiltration basins and filter strips) present good opportunities for creating terrestrial wildlife habitat. The buffer areas (and sometimes the basin floors) can be managed as wet meadows, thus reducing mowing costs for the facility. Relatively diverse biological communities can be further enhanced through judicious planting of trees, shrubs and grasses that provide food and cover for wildlife (see Chapter 9). These communities have added value because of the general scarcity of wildlife habitat in urbanized areas.

No Thermal Enhancement

As noted earlier, wet ponds can be detrimental in some watersheds as they heat water passing through the structure during the summer months. Their use is often restricted in watersheds that contain sensitive coldwater fisheries, such as those that support native trout populations.

Landscape Enhancement

Few BMPs will be an attractive feature of a community unless serious efforts are directed toward natural grading, landscaping and regular maintenance. If properly designed, pond options probably have the most potential to enhance the urban landscape. Wet ponds are frequently used to create a waterfront effect in residential developments, and may actually increase the value of adjacent property. Vegetative BMPs have a less dramatic effect on landscape values, and most infiltration BMPs and dry extended detention ponds have a neutral or negative effect.

Recreational Benefits

With the exception of large wet ponds, few BMPs provide active recreational opportunities (e.g., fishing, swimming, or skating). In fact most jurisdictions generally do not encourage such activities, as they may invite vandalism or liability problems. However, if properly landscaped, pond BMP options can provide passive recreation opportunities for adjacent residents, such as walking, birdwatching, or nature enjoyment, particularly when combined with bike or jogging paths, picnic areas, and tot-lots situated in nearby open space. In rare instances, the floors of extended detention ponds can even be used for ballfields and play areas.

Hazard Reduction

Careful design of pond BMPs is needed to reduce potential safety hazards. Plans should be analyzed to eliminate obvious hazards, such as steep side-slopes, deep water, sudden drop-offs from the shore, or dangerous outlet/pipe configurations. Most infiltration BMPs entail little if any safety risks, and some (porous pavement) are thought to reduce certain traffic safety problems.

Aesthetic Value

As shown in Figure 2.5, most pond options have the potential to be either an attractive or an unattractive feature of a community, depending on the attention paid to their design, landscaping ,and maintenance. Artificial contours should be avoided, and control structures (risers, low flow channels, outlets and riprap) should be concealed in the embankment, or by vegetation where feasible. Infiltration BMPs generally have little potential to be attractive, but can at least be designed to be unobtrusive.

Community Acceptance

Surveys of resident perceptions about adjacent BMPs have revealed that most BMPs are acceptable if regular cosmetic maintenance is performed. Residents often indicate a preference for wet ponds over dry ponds. Their response to infiltration BMPs is not well documented. Residents' primary concerns often center around perceived nuisance conditions (algae blooms, odors, mosquitos, weeds, trash, turbidity, etc.), most of which are temporary conditions which should seldom occur if the BMP is properly designed and maintained.

VOL 12

17672

HOW TO USE THE SCREENING TOOLS

The following examples provide illustrations of how the screening tools provided in this Chapter are best used.

EXAMPLE 2-1: USE OF THE SCREENING TOOLS

A developer has a 5 acre parcel which will be converted into an office complex and parking lot. The site has low slopes and permeable, sandy loam soils. The management objectives for the site are; 1) 2 year peak discharge control, 2) groundwater recharge, and 3) moderate to high removal of all urban pollutants.

Step 1. Using Figure 2.1 the following BMPs are suitable, given the area and soil characteristics of the site:

1. Infiltration Trench
2. Infiltration Basin
3. Porous Pavement
4. Grassed Swale
5. Filter Strip

After checking the other site restrictions contained in Figure 2.2, and the accompanying text, it is apparent that grassed swales and filter strips are not appropriate, given the proposed high land-use intensity. The remaining BMP options appear feasible, but must have some kind of pretreatment device to protect them from high sediment inputs.

Step 2. Full or partial exfiltration designs of the infiltration BMP options can provide the desired 2 year peak discharge control and groundwater recharge benefits:

1. Infiltration trench
2. Infiltration basin
3. Porous pavement

Step 3. If the infiltration BMPs are sized according to design rules 8 or 9, high levels of pollutant removal can be expected for all of the remaining options (see Figure 2.4).

Step 4. All of the remaining BMP options provide a similar level of environmental amenities (Figure 2.5).

Step 5. A final BMP option can now be selected on the basis of costs or maintenance requirements. Estimation of both can be found elsewhere in the text using Table 2.1.

VOL 12

1 7673

EXAMPLE 2-2: USE OF THE SCREENING TOOLS

A developer is planning to build a residential subdivision on a 40 acre parcel of land, with moderate slopes (5%) and sandy clay loam soils. Local ordinances require peak discharge control for the 2 and 10 year design storm. In addition, the planning review agency has specified that the BMP should provide a high level of streambank erosion control, and provide a moderate to high level of nutrient removal. Because of the intended character of the residential area, the developer would like the BMP to provide environmental amenities. Using the screening tools, identify the BMP option(s) which are physically suitable for the site, and determine whether they can provide the desired benefits.

Step 1. From Figure 2.1, it is evident that most infiltration BMPs are not feasible because of watershed area and soil permeability restrictions. The remaining options are:

1. Dry extended detention pond
2. Wet extended detention pond
3. Wet pond

Based on Figure 2.2, which shows other common site restrictions for BMPs, it appears that no other insurmountable limitations exist for the use of the BMPs listed above.

Step 2. Using Figure 2.3, it is evident that all these BMPs can control peak discharges from the 2 and 10 year storm. However, only dry and wet extended detention ponds can provide the desired level of streambank erosion control.

Step 3. From a nutrient removal standpoint, dry extended detention (design 3, with marsh) and wet extended detention (design 6) both have the potential to provide high levels of removal (Figure 2.4).

Step 4. As shown in Figure 2.5, both dry extended detention with marsh, and wet extended detention ponds provide several natural environmental amenities, with proper landscaping and maintenance. These include streambank erosion control, and wildlife and aquatic habitat creation. From the standpoint of community amenities, wet extended detention appears to be preferable, as it gets higher marks for landscaping, recreation, and resident acceptance.

Based on the screening tool, and the stated management objectives for the site, the most appropriate BMP would be a wet extended detention pond. Methods for estimating construction costs and maintenance requirements for the BMP can be found by referring to the appropriate section of this manual, as outlined in Table 2.1.

VOL 12

1 7 6 7 4

FINAL DESIGN CONSIDERATIONS

Once a BMP has been selected for the site, more detailed design of the facility can begin. As noted earlier, the designer should consider a number of design features that can enhance pollutant removal, reduce maintenance needs and costs, reduce construction costs, and provide desired environmental and community amenities. Table 2.1 provides a summary index on where such design information can be found within this manual.

Tips for Enhancing Pollutant Removal

Each BMP chapter in this manual contains a section that provides a series of design tips to maximize the pollutant removal capability of a BMP. These guidelines include: ways of adjusting the size and geometry of a BMP to create ideal removal conditions; how vegetation can be effectively used to promote biological removal; how optimum detention/draining times can be achieved; and other means of achieving high pollutant removal requirements.

Table 2.1: Summary Index for BMP Design

	TIPS FOR ENHANCING POLLUTANT REMOVAL	MAINTENANCE REQUIREMENTS FOR THE BMP	TIPS FOR REDUCING MAINTENANCE NEEDS	PROJECTING BMP CONSTRUCTION COSTS	DESIGN VARIATIONS FOR THE BMP	DETAILED DESIGN METHODS FOR THE BMP	DESIGN SUMMARIES

VOL 12

Common Maintenance Requirements

Both the regular and non-routine maintenance requirements for each BMP are described in detail elsewhere in this manual. Where data is available, estimates of the costs associated with maintenance are provided, as are inspection schedules and methods. Where construction methods are critical to the successful operation of the BMP, recent specifications on materials and workmanship are also provided.

Tips For Reducing Maintenance Needs

Engineers should make maintenance reduction a major element of every BMP design. A significant amount of future maintenance activities and costs can be eliminated through preventative design. Each BMP chapter includes a series of tips which should be carefully reviewed. These include suggestions on how to reduce maintenance needs by providing access, using long-lasting construction materials, trapping sediment inputs, creative use of the geometry of the BMP to make routine maintenance easier, providing backup drainage systems, and proper stabilization of erosion-prone areas.

Projecting BMP Construction Costs

Each BMP chapter presents a method for computing a rapid planning estimate of the construction costs of a BMP. Unit costs for major construction components are provided for infiltration and pond BMPs (see Table 7.4). Cost equations are also provided for a number of BMPs. The cost-effectiveness of each BMP, in relation to watershed size, development intensity, and other BMP options, is also discussed (see also MWCOG, 1983a; Wiegand et al, 1986).

Design Variations

Each BMP chapter begins with a section that describes several variations in the basic design of a BMP. These designs, drawn from applications around the Washington, D.C. area, illustrate innovative ways to fit a BMP into a particular development site and combine BMPs together to improve performance or minimize maintenance needs.

Design Methods

This manual does not provide step-by-step methods for the hydrological design of BMPs, nor does it give specific models or equations that can be used to accurately determine the necessary storage requirements, geometry and configuration of a BMP at a particular site. These technical aids, used for the final BMP design, are provided by reference at the end of each chapter.

Design Summary

Each chapter concludes with a brief design summary that highlights some of the recommended BMP design features that should be included in every site plan. Both the engineering consultant and the site-plan reviewer can use these summaries as a checklist to ensure that the BMP plan for the site will be effective.

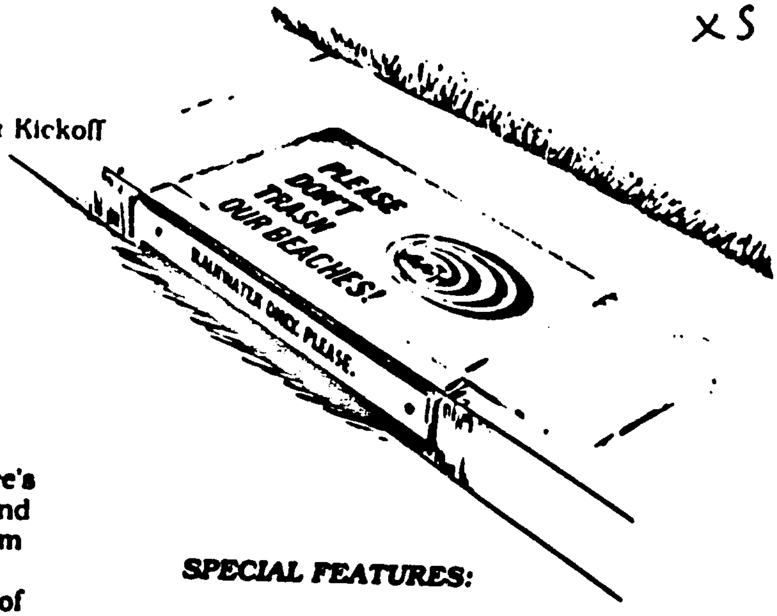
PRESS CONFERENCE ANNOUNCEMENT: CITY OF SANTA MONICA'S STORM DRAIN COVER AND SIGNAGE PROGRAM, SEPTEMBER 21, 1990

1 7677

R0050982

¯RESS CONFERENCE:

City of Santa Monica
Dept. of General Services
Storm Drain Inlet Cover and
Signage Program Unveiling & Kickoff



DATE: September 21, 1990

TIME: 10:00 AM

PLACE: Colorado Blvd. South Side between 4th & Main (in front of Sears), Santa Monica

EVENT: Unveiling and kick-off of the Department of General Service's new storm drain inlet cover and signage program. The program is a comprehensive effort intended to reduce the amount of waste dumped into Santa Monica's storm drain system – waste that ends up in the Santa Monica Bay and beaches.

New designs for storm drain inlets with signs and decals will be unveiled. These signs and decals will be painted on storm drains throughout the City. The signage dramatically appeals to pedestrians and motorists not to throw waste into the drain system.

SPECIAL FEATURES:

- Speech by Mayor Dennis Zane.
- Video tour of Santa Monica's storm drains made by the City's unique "Tunnel-Kam" camera system.
- Santa Monica and L.A. City Council members, State Representatives, DWP and MWD Representatives in attendance.
- Sign and decal unveiling.

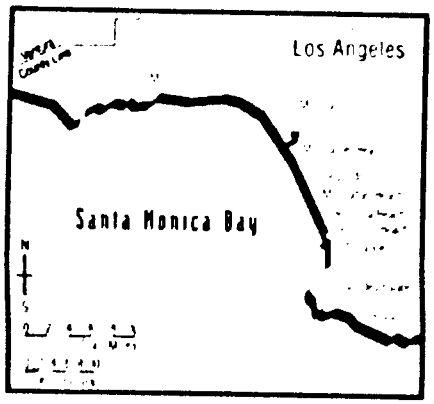
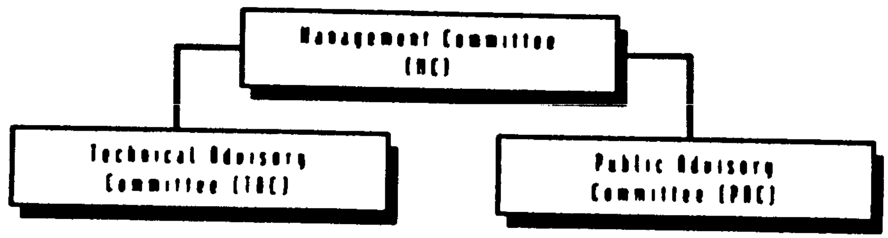
AN INTRODUCTION TO THE SANTA MONICA BAY RESTORATION PROJECT

Santa Monica Bay adjoins one of the most densely populated coastlines and popular playgrounds in America. In areas once inhabited by the Gabrieleno and Chumash Indians, today we find an urban and industrial landscape that is home to nearly 9 million people. Not surprisingly, the demands from recreational, municipal and industrial uses have resulted in an environmentally troubled Santa Monica Bay.

In 1988, Santa Monica Bay was recognized by the Environmental Protection Agency and the State of California as a natural resource that must be protected and preserved. The Santa Monica Bay Restoration Project (SMBRP) was formed under the National Estuary Program (NEP) to assess the pollution problems and develop solutions for restoring and protecting the Bay. The SMBRP, whose boundaries stretch from the Ventura County line to Point Fermin in Palos Verdes,



Santa Monica Bay



Santa Monica Bay Restoration Project Management Conference

will address the questions that so many of us have about Santa Monica Bay:

- Is it safe to swim in Santa Monica Bay?
- Is it safe to eat fish caught in the waters of Santa Monica Bay?
- Are the fish and wildlife protected?
- What is the future of Santa Monica Bay?

The SMBRP's **Management Conference** is organized into three primary committees. The **Management Committee (MC)**, composed of more than 50 members, is the decision-making body responsible for finding the solutions to the Bay's problems which will be detailed in a document called the **Comprehensive Conservation and Management Plan (CCMP)**. The MC's membership includes elected and appointed policy-making officials from the federal, state and local levels of government, government agencies, environmental groups, industry and the general public. The **Technical Advisory Committee (TAC)** is made up of scientists. Its role is to ensure that the Management Conference has the appropriate scientific and technical basis for decision making. **The Public Advisory Committee (PAC)** includes interested members of the public and provides guidance on educating, informing, and involving the public in SMBRP activities.

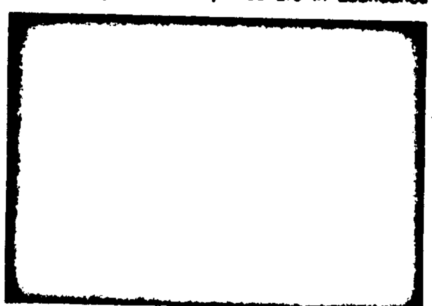
The CCMP, to be developed by 1994, will determine how Santa Monica Bay will be restored and protected. It will be based on scientific and technical information, as well as an assessment of the present regulatory programs designed to protect the Bay. Included in this document will be a series of Action Plans that will identify who should be responsible for implementing these programs and how they should be financed.

USES OF THE BAY

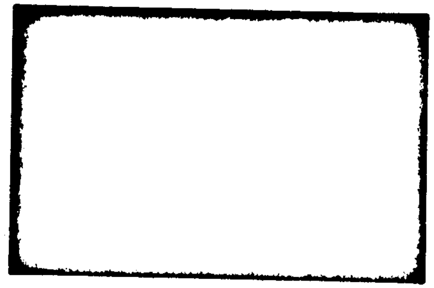
We are fortunate to live alongside one of America's greatest natural resources, the California coastline. The beaches are vast and the scenery is spectacular. In addition to the people who inhabit Los Angeles County, millions of tourists come from all over the world to enjoy this rich coastal area. While Santa Monica Bay is intensely utilized by the surrounding human population, it also supports a wide variety of marine life. All too often, these multiple uses have created conflict.

Habitats of the Bay

Santa Monica Bay is home to many types of fish and wildlife that live in the Bay's various habitats. The **pelagic**, or open-ocean community, is inhabited by marine life living in the water column such as schools of fish, plankton, whales migrating through the Bay and dolphins cruising up and down the coastline. Bird populations at Santa Monica Bay include shore birds such as willets and spotted sandpipers, and water birds such as the California brown pelican, least terns and gulls. Many of these species are in abundance



California brown pelican

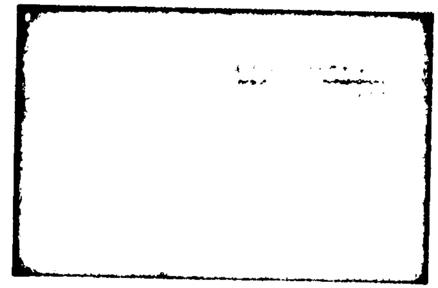


throughout the fall and winter when they arrive during their migrations, and scarce during the summer as they continue on their way. The **benthic**, or bottom-dwelling community, is made up of hundreds of plant, fish and invertebrate species such as crabs, clams, mussels, mollusks, sea urchins and sand dollars.

The remaining natural wetlands in Los Angeles County are salt and brackish marshes. These areas provide an essential natural habitat for migratory and resident birds. Fish and invertebrates use the wetlands for feeding, and many fish use the calm shallow waters as nurseries. The wetlands host a variety of vegetation, and the mudflats support many species of clams, snails and crabs.

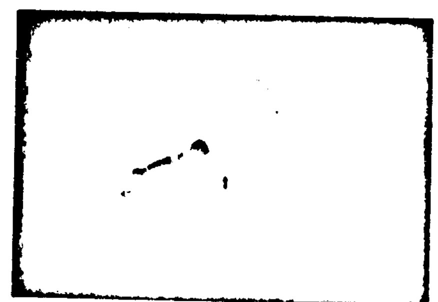
Recreational Activities

Santa Monica Bay is a playground for residents and tourists alike. At the beach, generations of surfers have skillfully maneuvered their surfboards on the swelling waves. People visit the beach to read, swim,



or ride their bicycles along the 21 miles of bike paths. Professional beach volleyball games are now world famous, and athletic competitions between lifeguards are an annual event. The marinas are busy with weekend sailors gently gliding across the Bay, mingling with the dolphins and sea birds. Santa Monica Bay finds many sport fishermen catching their evening meals off boats or from one of the six piers located on the Bay.

Santa Monica Bay offers a rare combination of outdoor excitement and relaxation, and millions each year crowd the beaches to take advantage.

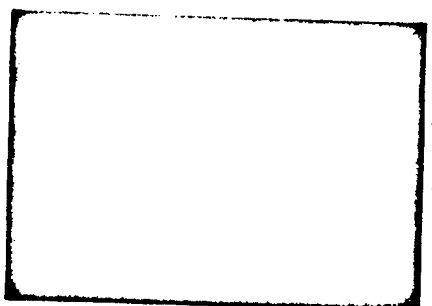


SOURCES OF POLLUTION

In addition to supporting an abundant marine life and providing a recreational wonderland, Santa Monica Bay has been used for other purposes which have led to its current degraded state. Numerous substances enter the waters of Santa Monica Bay. Some are harmless, but many damage the Bay's environment.

Municipal and Industrial Discharges

Six point sources directly discharge contaminants into Santa Monica Bay. Each day, two municipal sewage treatment plants discharge nearly 800 million gallons of treated wastewater from domestic, commercial and industrial sources into the Bay. This amount would fill the Los Angeles Coliseum almost twice each day. In the past, these treatment plants have contributed the greatest amounts of contaminants to the Bay. However, as source control, treatment technology and monitoring of discharges have improved, the concentration and amount of contaminants from these facilities have decreased substantially.



Sewage treatment facility

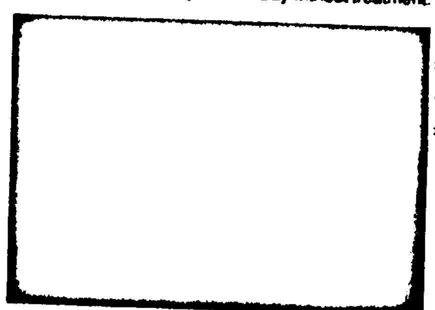
Hyperion Treatment Plant

Before their use was banned in the 1970s, the organic chemicals DDT and PCB were regularly discharged off the Palos Verdes Peninsula through the sewage system. These chemicals have caused extensive damage to the marine life, and we are still seeing the effects today.

Industrial sources of discharge include three electric power generating stations that use seawater to cool condensers and an oil refinery that discharges treated water from its manufacturing process into the Bay.

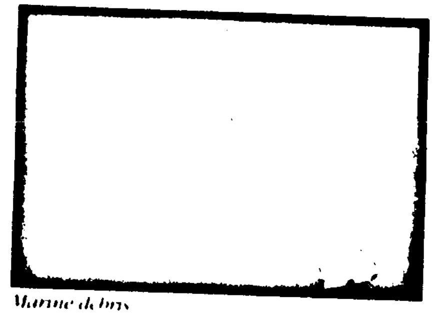
Storm Drain Runoff

With better control of municipal and industrial sewage treatment discharges, runoff from storm drains is now the pollution source of greatest concern. The storm drain system is separate from the sewer system. Although storm drains were created to prevent flooding, they also collect excess fertilizer, pesticides, litter, car washing water, animal and human waste, anti-freeze and motor oil. Approximately 60 storm drains carry these pollutants directly into the Bay without treatment.



Storm drain catch basin

Mary Sue Maurer



Marine debris

Center For Marine Conservation

During a major storm, the volume of untreated discharge can increase by up to 1000 times. These chemical pollutants and bacterial contaminants from storm drain runoff are of particular concern because they empty near the shoreline where swimmers and surfers gather.

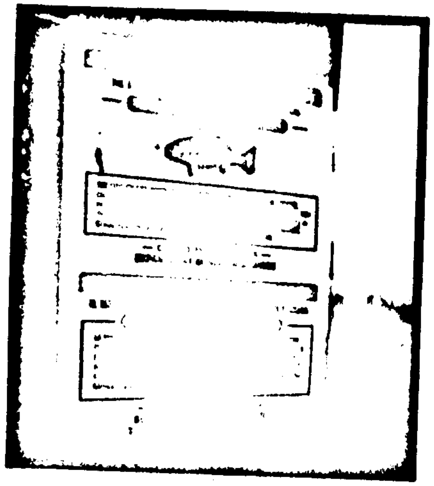
Non-point Sources

Other sources of pollution aside from municipal and industrial discharges and storm drains are called non-point sources. These include air pollution, legal and illegal ocean dumping, operation and maintenance of recreational and commercial vessels, natural crude oil seeps, marine debris and materials carried by ocean currents. Oil spills from nearby shipping lanes are another potential source of pollution.

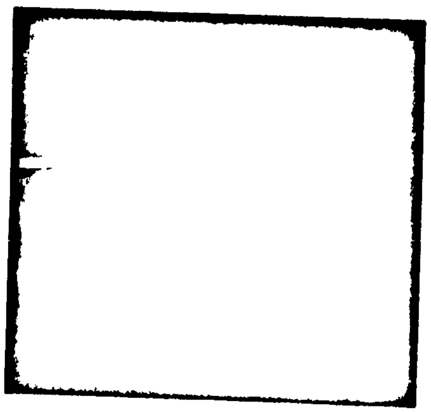
All of these different point and non-point sources of pollution have contributed to complex problems that the members of the Santa Monica Bay Restoration Project are working to solve.

AREAS OF CONCERN

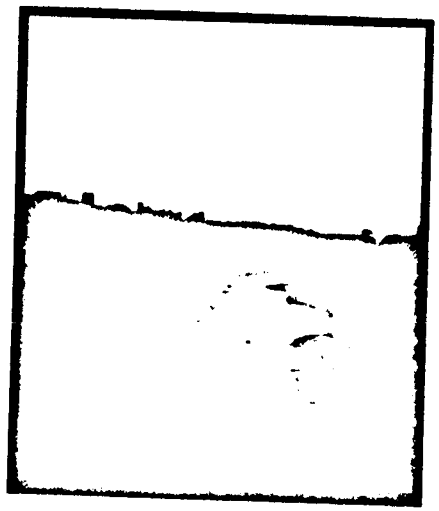
Pollution is impacting [illegible] in numerous ways. The [illegible] concentrations of DDT and PCB [illegible] ments, reports of [illegible] contaminated [illegible] and polluted storm drain runoff [illegible] to concern about human health [illegible] threats posed to the Bay's [illegible]. To address these problems, the SMBRP [illegible] the following areas of [illegible] Early Action Plan [illegible]. These areas include:



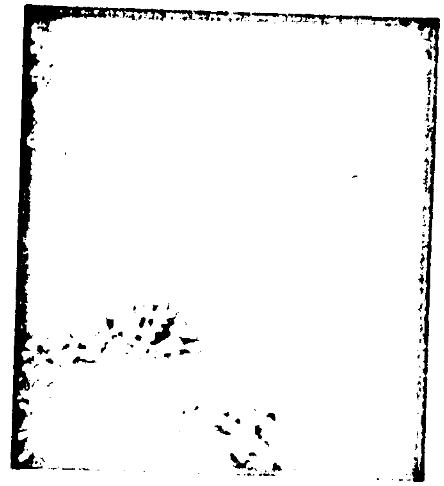
HUMAN HEALTH RISKS ASSOCIATED WITH EATING CONTAMINATED SEAFOOD



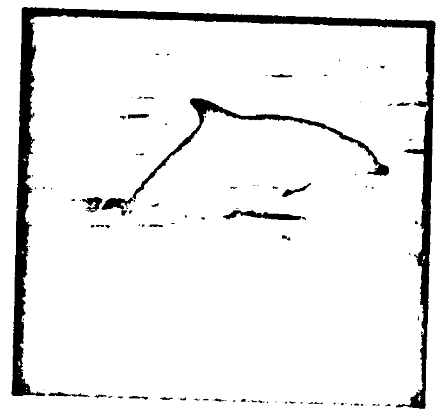
HUMAN HEALTH RISKS ASSOCIATED WITH DISEASE - CAUSING VIRUSES IN THE SURFZONE



LOSS AND DEGRADATION OF WETLANDS



IMPACT OF POLLUTION ON THE BENTHIC (BOTTOM-DWELLING) COMMUNITY



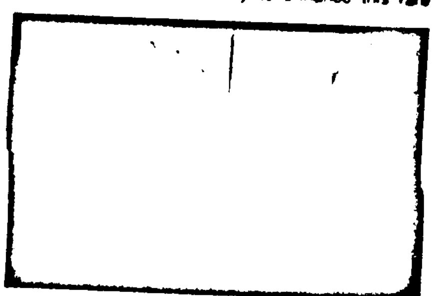
IMPACT OF POLLUTION ON THE PELAGIC (OPEN-OCEAN) COMMUNITY

EARLY ACTION PROJECTS

When completed the CCMP will include Action Plans that define a specific problem identify the cause or source and recommend possible solutions In the meantime the SMBRP has already taken a number of steps called **Early Action Projects** to address some of the areas of concern

Wetlands Restoration

One project involves revitalizing the 16-acre Ballona Lagoon wetlands. Ballona Lagoon is a natural tidal lagoon situated in the midst of an urban area. It lies parallel to the coastline of the Santa Monica Bay, forming a connection between the Marina del Rey boat channel and the Venice canals. In addition to providing habitat for many species of wildlife, the lagoon offers the public valuable opportunity for aesthetic, educational and recreational activities. Unfortunately, this rare aquatic ecosystem has suffered environmental harm with extensive damage to the native vegetation, the marine life of the mudflats, and the quality of its water. Plans are underway to enhance this rare remaining wetland, and the SMBRP is helping to implement those plans.



Sea hare at Ballona Lagoon

Urban Runoff – Early NPDES Permit Program

A milestone for the Project has been the development of a landmark storm water program tailored to the distinct structure and conditions of L.A. County and its 86 cities. After lengthy negotiations initiated by the SMBRP, L.A. County and cities were issued an unprecedented storm water discharge permit in June 1990. The County and 16 of 18 Santa Monica Bay watershed cities are included in the first phase of the program set forth in the National Pollutant Discharge Elimination System (NPDES) permit that requires local governments to begin controlling water pollution discharged from storm drains. The effort represents a significant accomplishment by regulatory and implementation agencies to address urban runoff.

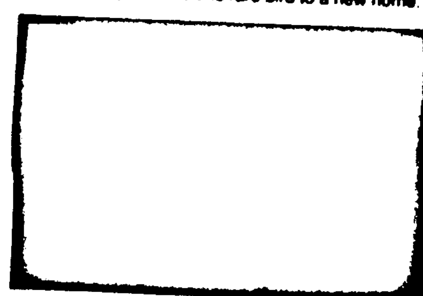
Urban Runoff – Ozonation Treatment Program

A pilot program being tested in the City of Santa Monica involves treatment of urban runoff from storm drains. The City has been treating the water with varying doses of ozone, a gas used to disinfect drinking water. Hopes are high that if the process is successful, a plant to treat the storm drain water will be constructed and the reclaimed water will be used to irrigate freeway landscapes.

Banding a newly hatched least tern chick

Least Tern Colony Project

A project to bring an endangered species back to the beaches is also in development. The least tern is an endangered water bird that once appeared in great numbers. Their nests were found in the white sandy beaches and dunes. Increased beach use destroyed the least terns' nesting grounds, and their population declined. Today, there is a breeding colony on Venice Beach, and a new site in Playa del Rey has been set aside by SMBRP to allow for expansion of the least tern population. With decoys and recorded mating calls, scientists hope to lure this rare bird to a new home.



Ozonation treatment facility

TECHNICAL STUDIES

The SMBRP continues to conduct studies to assess the Bay's pollution problems. This information will assist the SMBRP in developing programs that form the groundwork for the CCMP.

Environmental Monitoring and Data Management

Because there are as many as fourteen different governmental and private agencies conducting research in the Santa Monica Bay area, the SMBRP is designing a system to better monitor the marine environment in the Bay. This Monitoring and Data Management System will ultimately ensure that all information collected is beneficially used by all organizations involved in helping the Bay.

Sediment Dynamics

Historical deposits of DDT and PCBs off the Palos Verdes Peninsula are a cause for concern because of their potential effects on the ecosystem, marine food web, and humans (through consumption of contaminated seafood). However, cleaning up sediment contamination is extremely expensive, and considerable information is needed to develop viable and effective options for clean up.

In a first step, the SMBRP began studies aimed toward gaining a better understanding of sediment dynamics -- past and present levels of sediment contamination, patterns of sediment movement, and natural rates of burial and removal. In addition, a workshop was held with ten of the foremost experts in the field of sediment resuspension who recommended additional studies that would be necessary to develop restoration programs.

Mackerel, a popular sport fish

Human Health Risks Associated With Eating Seafood

High levels of DDT and PCBs still continue to work their way into the food chain. A Seafood Consumption Survey will identify the number and types of fish and shellfish being caught, and profile who is eating them. Combined with the Seafood Contamination Survey, these two studies will enable an assessment of health risks associated with eating contaminated seafood from the Bay.

Human Health Risks Associated With Pathogens

The goal of this long term study is to determine the relationship between storm drain runoff and illnesses in swimmers and surfers. The first phase of the study unexpectedly found disease-causing viruses (pathogens) in Santa Monica's Pico-Kenter storm drain. The second phase of the study will develop techniques for locating the sources of the viruses.

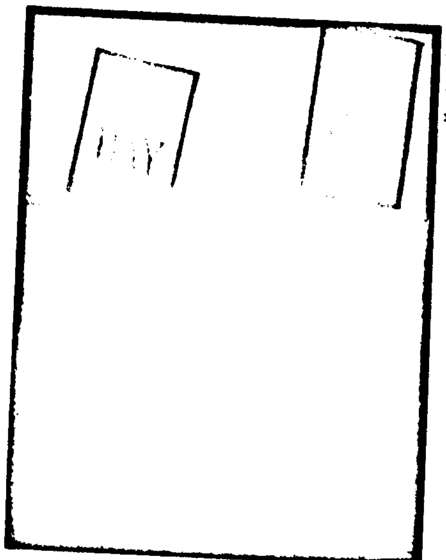
Posted signs warn swimmers when there are unhealthy conditions in the water near storm drains. The County Department of Health advises against ocean swimming for two days after a rainstorm due to the heavily polluted runoff that flows through storm drains into the Bay.

PUBLIC INVOLVEMENT ACTIVITIES

Informing the public of the Bay's problems and encouraging community involvement in possible solutions are crucial if we are to successfully restore and protect this prized natural resource for future generations. During 1990, SMBRP planned special activities to inform, educate and involve the public in the progress being made to clean up the Bay.

Earth Day 1990

On Earth Day 1990, SMBRP, with the help of the Teenage Mutant Ninja Turtles, kicked off a campaign to educate the public about storm drain misuse. The creators of the Turtles designed an original, eight-page "Storm Drain Savers" comic book exclusively for the SMBRP. The comic books, along with a special appearance by the Turtles, generated an incredible amount of excitement at Los Angeles County Earth Day events, where more than 40,000 copies of the booklet were distributed.



Teenage Mutant Ninja Turtles support storm drain education

Storm Drain Savers

Coastal Cleanup Day

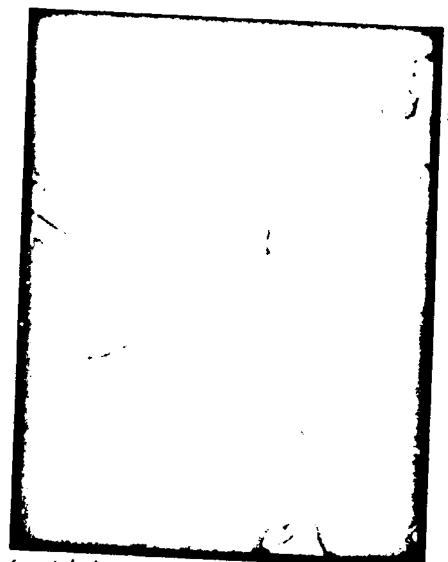
Thousands of Los Angeles County residents flocked to the beaches in September to pick up debris and learn about marine pollution. This statewide program was sponsored locally by SMBRP in conjunction with Los Angeles County Department of Beaches and Harbors and Heal the Bay. The cleanup resulted in the collection of 12,000 pounds of trash and 3,000 pounds of recyclable material! The debris collected was documented on data cards so that the origin of the pollution could be determined and stopped.

Health Risks Study Release

When a SMBRP study unexpectedly found disease-causing viruses (pathogens) in the Pico-Kenter storm drain in Santa Monica, the information was quickly released to the public. The SMBRP will release new information about its studies to keep the public as informed as possible about developments related to the Bay.

Public Advisory Committee Meetings

People who are interested in learning more about SMBRP's agenda or want to get involved in finding solutions to Santa Monica Bay's environmental problems are invited to attend the monthly meetings of the Public Advisory Committee.



Coastal Cleanup volunteer documenting collected trash

WHAT'S NEXT?

The Santa Monica Bay Restoration Project has many things to accomplish in the near future. As this report makes clear, the Project's major focus for the coming year is the development of the Comprehensive Conservation and Management Plan (CCMP).

To develop a successful plan, however, requires the involvement and support of those who will be responsible for carrying out the CCMP's various Action Plans — the members of the Management Committee, Technical Advisory Committee, Public Advisory Committee and the general public. To more actively involve these crucial players, the Project will be entering a new phase, focusing its efforts on the newly formed CCMP subcommittees and on an expanded public involvement program.

The job of the subcommittees will be to focus on specific components of the CCMP. They will examine the management and policy issues relevant to those components and recommend options for action. In this way the SMBRP will be able to channel the activity into the hands of those who possess the particular expertise and who, eventually, will be responsible for implementation. To date, subcommittees have been established to address point sources, non-point sources, wetlands, marine habitats and watershed management issues.

In expanding its public involvement and information activities, the SMBRP will endeavor to generate greater public awareness and support for the CCMP and other Project activities.

A recent development that promises future benefits is the establishment of the Santa Monica Bay Restoration Foundation. The Foundation, a non-profit corporation, is an independent fund-raising vehicle that allows the Project to accept and distribute funds received from cities, counties, special districts, private foundations and industry. These funds are for use in research projects, planning, and implementation activities that complement CCMP development.

Although the Santa Monica Bay Restoration Project has made progress in identifying solutions for Santa Monica Bay's environmental problems, its success in protecting this coastal area and its living resources will be realized in the future. Accompanying the full implementation of the CCMP will be a revitalized, thriving Santa Monica Bay. This area, around which we and so many other creatures make our homes, will once again be a safe and beautiful place.

Heal the Bay: Who We are

Heal the Bay is a non-profit environmental organization working through a variety of research, education, public outreach, and advocacy programs to make Santa Monica Bay and Southern California beaches safe and healthy again for people and marine life. We do this by educating the media, the public and our elected officials about sources of pollution and possible remedies; monitoring government to ensure that the law is enforced; intervening legally when necessary; and helping set the standards for the future of our Bay. Our goals include: reducing the flow and toxicity of storm drain waters; pressuring the County of Los Angeles to meet the sewage treatment standards of the Clean Water Act; helping to develop permanent household hazardous waste dropoff sites; and initiating an innovative environmental education program throughout Southern California schools.

The State of the Marina
Marina del Rey

I. Introduction

Urban Los Angeles is home to the largest man-made marina in the world, Marina del Rey (MDR), which has over 6,000 boat slips, over 30 restaurants and is home to nearly 11,000 residents. Marina del Rey is a valuable resource to the variety of recreational boaters, bathers and tourists who visit each year. It is also an important source of revenue for Los Angeles County and many local businesses as the Marina generates an estimated $1.4 billion per year (Rabin, 1992). In addition, MDR is an important habitat for marine life as it functions as a shallow water habitat for fish eggs, larvae and young adults. The Marina's value as a nursery is especially important because over ninety percent of the coastal wetlands in the Los Angeles area have been lost because of urban development (Soule et al. 1992).

The area's large commercial and recreational use, along with the continual input of urban runoff from adjacent storm drains, has impacted the Marina's ecological health. The extent of the Marina's pollution goes far beyond the trash and oily sheen commonly seen floating on the water's surface. Toxic sediments from Ballona Creek have accumulated (shoaled) at the mouth of MDR, creating navigational problems and reducing tidal flushing. Divers responsible for boat maintenance complain about severe water pollution caused by illegal discharges from vessel holding tanks (Butler per. comm. 1993) and from input from the Oxford Street flood control basin. Equally disturbing are the strikingly high indicator bacteria counts found in parts of the marina which have been responsible for historic closures of the popular bathing area, Mother's Beach.

Because the public is unaware of the Marina's pollution problems, and the lack of public attention focused on them, Heal the Bay's State of the Marina report was produced to raise awareness of environmental problems at the Marina and provide the public and County decision makers with recommendations on pollution prevention and disposal. The report is intended to augment the momentum created by the recent Santa Monica Bay Restoration Project/Center for Marine Conservation "Boaters for the Bay" conference to clean up pollution problems in the Marina. Heal the Bay's position is that, with the proper attention and action, the condition of Marina del Rey can be improved so that it is not one of the most polluted areas in the southern California Bight. The National Oceanic and Atmospheric Administration has stated that "the most contaminated sites for sediment, mussels, and fish [in the southern California Bight] have occurred in bays and harbors." (Mearns et al. 1991)

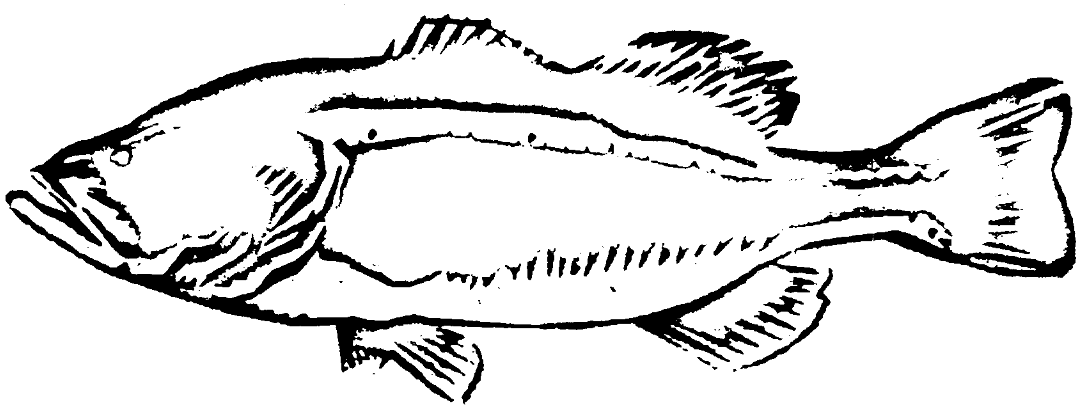
VOL 12

II. BACKGROUND

The Marina was constructed between 1960 and 1962 on the site of the degraded Ballona Wetlands. Prior to the 1920's, runoff from most of the Los Angeles basin flowed into the Ballona wetlands through Ballona Creek. The wetlands served as flood control and water purification for runoff until Ballona Creek was concreted and channeled for stormwater control along with the other major rivers in southern California in the 1930's. The wetlands were gradually degraded as they were filled and drained for use as farmland, oil and gas fields, and industrial development.

In 1954, construction of MDR became an authorized federal project. The $40 million cost of construction (Fawcett per comm. 1993) was split between the federal government and the County of Los Angeles. Local funds were raised through a statewide bond issue. Today it is maintained and funded primarily by the Los Angeles County Department of Beaches and Harbors, although periodic dredging is performed by the Army Corps of Engineers. The Department of Beaches and Harbors and Army Corps must comply with the dredge disposal requirements of various regulatory agencies including the Environmental Protection Agency (EPA), California Coastal Commission and the Regional Water Quality Control Board.

17696



III. Pollution Problems

The ecology, and water and sediment quality of Marina del Rey have been studied since the mid 1970's by marine scientists at the University of Southern California (USC). Since 1985, the Department of Beaches and Harbors has spent an average of $158,000 per year on a monitoring program to determine the pollution levels and marine organism toxicity of the water and sediments. This program has been conducted by USC's Hancock Institute for Marine Studies by Drs. Dorothy Soule, Mikihiko Oguri and Burton H. Jones. Key findings from the Hancock Institute's studies are discussed below. The National Oceanic and Atmospheric Administration (NOAA) has also compiled data on the entire southern California Bight, including Marina del Rey (Mearns et. al. 1991).

Sediment Quality

The Soule-Oguri studies indicate that there have been high levels of a variety of toxic contaminants in the Marina over the past several years. These contaminants include heavy metals such as copper, lead, zinc, and mercury, as well as organic compounds including chlordane, PCB's and DDT. Although specific guidelines regulating sediment contamination have not yet been established by the U.S. Environmental Protection Agency (EPA) or the State Water Resources Control Board, NOAA suggests using certain general sediment quality criteria: low and medium effects level guidelines (ER-L and ER-M respectively). These criteria are based on the levels of contaminants that are high enough to cause detrimental effects in marine life. Soule and Oguri have found that the most chronically contaminated sediments in the Marina are located in its inner recesses, specifically basins D, E and F and the area near Oxford Basin (see figures). Although no tests have been completed that demonstrate a direct linkage between any particular metal or contaminant and its effects on the Marina's benthic (bottom dwelling) population of marine animals, laboratory sediment tests have shown that these contaminants above ER-L and ER-M levels have chronic (but not lethal) inhibitory effects on certain species (Soule et al. 1992).

Chlordane and DDT are highly toxic pesticides that have been banned from manufacture; however, chlordane has not been banned from use. Levels of DDT exceeded the NOAA ER-L of 1 ppb (parts per billion) at most stations in the 1991 - 1992 study period. Chlordane levels exceeded NOAA ER-L and ER-M throughout the entire Marina with the highest concentrations at the entrance to the Marina and at the Oxford Basin. In 1991, the range of levels of contamination ranged from less than 10 ppb to 360 ppb. The ER-L and ER-M for chlordane are 0.5 and 6 ppb respectively (see figures in this report).

In 1991, levels of PCBs were considerably higher than in past years of sampling, but they returned to background levels in 1992. The most probable reason for this sudden PCB spike was runoff from a large construction site located just east of MDR and adjacent to the Oxford flood control basin. There were also high concentrations of PCBs near the mouth of the main channel. The source of these PCBs in the main channel is uncertain because levels of PCBs in Ballona Creek, a large source of contaminated sediments, were not as elevated as the sediments at the Marina's entrance. PCB concentrations are now below the level of detection for most of the Marina (see figures).

Marina sediments also are contaminated with various heavy metals. The most significant contamination problem is with lead. All stations within the Marina, except in the main channel, were above the NOAA ER-L of 35 ppm for lead. Levels of lead, 1040 ppm, found by Army Corps consultants near the terminus of Ballona Creek were above levels considered hazardous waste (1000 ppm, State of California, Code of Regulations, Title 22). Levels of lead in Oxford basin were the highest within the Marina at 487 ppm in 1991 (Soule et al. 1993) (see figures).

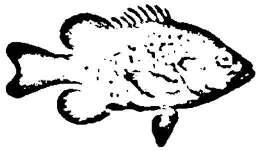
Zinc has remained high throughout the study period which began in 1978, with an upward trend in contaminant level. The entire Marina is above the NOAA ER-L level with approximately 1/3 of the sampling locations above the ER-M of 270 ppm (Soule et al. 1992). High levels of lead and zinc in sediments are often found near areas of high automobile use. The probable source of lead and zinc in the Marina's sediments is the storm drain system (see figures).

Tributyltin (TBT) was used in anti-fouling paints to prevent biological growth on boat hulls until 1988 when it was banned for use on most boats. Since then, TBT in MDR sediments has decreased by three orders of magnitude from a peak of 1070 ppm in 1987 to between 0.4 and 0.53 ppm (Soule, p. vi). The active ingredient now commonly used in anti-fouling paints is copper. Copper levels in the 1991-1992 survey increased to the highest levels of the past seven years. The rise in copper levels has probably occurred because of the ban on TBT as an anti-fouling agent. Approximately 1/2 of the sampling locations were above the NOAA ER-L level of 70 ppm (Soule et al. 1992) (see figures).

Mercury and nickel have not shown any trend toward reduction or increase. They do persist in concentrations that have low range effects at some sampling locations.

The other metals of concern, chromium, cadmium and arsenic, are not in sufficient concentrations to pose any low range effects on marine organisms throughout the Marina.

Impacts on Marine Life



MDR is an important marine resource because it serves as a habitat for several wetland fish species and as a nursery for several juvenile fish species, such as halibut. The swimming beach in Basin D, also know as Mother's Beach, has a gentle, sloping, soft substrate that is otherwise not present in Marina del Rey or in other local recreational harbors. Basin D used to be home to sea grass beds that offered a refuge for species such as the California killifish, the staghorn sculpin, and the brown smoothhound. The most probable cause of the recent disappearing grass beds was an influx of pollutants or smothering caused by fine sediments washed in from storm water (Soule per. comm. 1993). Studies currently underway suggest that the grass beds are recovering because the fine sediments have recently washed away (Soule per. comm. 1993). Other wetland species fish in the Marina include the yellowfin goby, the deepbody anchovy and the California needlefish (Stephans et al. 1991). The number of fish species and total abundance of fish have remained relatively unchanged over the last fifteen years.

Although studies have shown that fish muscle tissue caught in this area is safe for human consumption, they have also shown that the concentrations of chlorinated organic contaminants in liver and gonads are high enough to impair liver and reproductive functions in these fish species (Soule et al. 1992).

Studies of the marine benthic (bottom dwelling) population demonstrate that the Marina's pollution problems are having adverse effects on the marine invertebrates, as both the species diversity and the total abundance were lower in 1989-1991 than the long-term mean from 1976 to 1992. In 1991, the benthic population density was at an all time low at Station 6, and was fifty percent below the lowest previous records at Station 8 and Station 10. The loss of sea grass beds and the influx of pollutants has had detrimental effects on populations of both benthic and fish species. The primary benthic species found in the Marina is a type of nematode worm (round worm), which can tolerate contaminants, while other groups of organisms which are commonly found locally in healthy benthic communities, such as crustaceans and molluscs, are scarce. Although the abundances of molluscs and crustaceans still remain low, their appearance in new areas is a sign that the bans on TBT and the cessation of the PCB contamination are having beneficial effects on benthic populations (Soule et al. 1992).

Water Quality

Several indicators useful in assessing the quality of water for recreational contact and for adequate marine life survival are discussed below.

1. Dissolved Oxygen

The amount of dissolved oxygen (DO) in water is an indication of the suitability of the water to support aquatic life. Because DO is used to decompose organic material, low levels of DO, below five parts per million (ppm), suggest the presence of large amounts of organic matter and poor tidal circulation in the Marina. Organic matter can come from dead sea life (plants and animals), vessel holding tanks, or outside sources, such as storm drains.

The levels of DO along California's coast range from 6.0 to 8.5 parts per million (ppm). However, levels of DO often fall below the regulatory agencies' minimum level of five ppm for survival of fish species at some stations in the Marina (Soule et al. 1992). The most recent data demonstrates that DO levels were higher in 1992. There are many species of invertebrates that can survive very low levels of DO down to the point of anoxia (without oxygen). DO levels are typically higher in the fall and winter and lower in the spring and summer. The areas of the Marina most prone to low DO are the inner recesses, which do not have adequate flushing and are subject to input from storm drains. Specifically, E basin, where the Oxford Street flood control basin discharges, and the mouth of Ballona Creek have had DO problems. Soule and Oguri also found that biological oxygen demand (BOD), an indicator of the amount of organic degradable material in the water, was highest in the inner recesses of the Marina.

2. Nutrients

The amount of ammonia nitrogen and phosphorus are other indicators of water quality. High levels of ammonia-N and phosphorus can lead to algal blooms, eutrophication (high nutrient levels leading to algal overgrowth), and low DO levels in both fresh and marine waters.

Areas of high nutrient levels correspond with areas of low DO and high BOD. These areas are located at the terminus of each basin, near storm drain outlets and at the furthest distances from the main channel. Levels of ammonia-N in the main channel were not significantly higher than levels commonly found in the open ocean (Soule et al. 1992).

VOL 12

3. Bacteriology

Certain types of bacteria, called indicator bacteria, are useful in assessing the presence of pathogenic microbes which can cause infection and disease. According to the Soule-Oguri studies, there have been numerous violations of State Ocean Plan standards for indicator bacteria in the Marina over the last several years. Also, the Los Angeles County Department of Health Services weekly indicator monitoring program demonstrates that the most significant source of bacterial contamination appears to be from stormwater runoff as the entire Marina exceeds their Health Warning and Beach Closure Protocol bacterial objectives for beach closures during wet weather. The area known as Mother's Beach received a "D" grade in 1989, an "F" grade in 1990 and an "F" grade in 1991 during wet weather, according to Heal the Bay's Annual Beach Pollution Report Cards. Mother's Beach "improved" to a F, C & C, during dry weather in 1989, 1990, and 1991 respectively. The data used for these reports was data obtained directly from the Department of Health Services. Despite the history of bacterial contamination, the Department of Health Services and the Los Angeles County Department of Beaches and Harbors have kept Mother's Beach open to swimmers. Another source of bacterial contamination may be illegal discharges of vessel holding tanks.

Although violations in 1992 were reduced from the 1990-1991 study period, the Oxford Street flood control basin was almost always contaminated with high bacteria counts. High bacteria counts primarily occurred during or after rainy weather, and stations near Ballona Creek and near the Oxford Street flood control channel continued to have the most violations (Soule-Oguri, 1992).

1770 1

IV. Dredging

Adequate tidal circulation is mandatory for the Marina's health because it mitigates the effects of pollution by continually washing out pollutants and washing in new oxygenated ocean water. When there is not adequate circulation, contaminants build up and water quality deteriorates within the Marina as demonstrated by the pollutant hot spots at the inner recesses of the Marina.

When the Marina was developed in the early sixties, engineers erred by constructing the Marina directly adjacent to Ballona Creek, the largest source of nearshore pollution to the Santa Monica Bay. The Creek has an average dry weather flow of over 15 million gallons per day. During wet weather, Ballona Creek's flow can exceed ten billion gallons per day. The sediments that are discharged by Ballona Creek accumulate (shoal) at the entrance to the Marina because the

VOL 12

1702

breakwater in front of both the main channel and the storm drain slows down stormwater flow enough to cause sediments to settle on the Marina floor. In addition to reducing tidal circulation, these sediments interfere with navigation. To reduce the buildup, regular maintenance dredging of MDR is necessary. The Army Corps is responsible for dredging the Marina to keep the channels of the marina navigable and to allow adequate tidal flushing.

Before dredging, the Army Corps must have the sediment tested for contaminant levels and toxicity. The results of these tests, along with suggested methods for sediment disposal, are then sent to the EPA for approval. If the sediments are considered 'safe,' they can be used for beach replenishment, or can be disposed of at an offshore dump site over six miles southwest of the Palos Verdes peninsula. If the EPA determines that the sediments are toxic, they must be treated as such and disposed of appropriately in an environmentally responsible manner.

The tests performed on Marina sediment from around the south jetty have caused a very high bioaccumulation of lead and chlordane in the tissues of two test animals (worms and clams), indicating high levels of biologically available contaminants in the sediment. The potential biological impacts of such contaminants raises the question of what should be done with the sediment after dredging. The typical methods of disposal, such as ocean disposal and beach replenishment, are not appropriate or environmentally responsible, but the treatment of the sediment and its responsible disposal is extremely costly. Because of the numerous advantages and disadvantages of the various options, the subject of dredging has become controversial, and long term management decisions regarding the fate of dredge spoils have been postponed.

As the sediment disposal controversy continued, the south entrance of the Marina approached 70 percent closure in 1992. The Department of Beaches and Harbors asked for and received permission to implement a temporary emergency "knockdown" in the summer. This meant that instead of removing the accumulated sediments, a contractor leveled the shoaled material from the south jetty to the terminus of Ballona Creek. Although a myriad of potential environmental problems associated with the knockdown (the possibility of increased turbidity, smothering of benthic organisms, a reduced visibility for visual feeders such as terns, and biological problems caused by resuspension of contaminated sediments) never materialized because of the use of an innovative, enclosed knockdown technique, the success was overshadowed by the practical problems of the operation. Within months after the knockdown was performed, a barrage of storms caused the reaccumulation of sediment and shoaling problems at the Marina entrance. The $400 thousand spent on the knockdown provided at best a three-month solution to tidal circulation and navigational problems. This expenditure demonstrates the great need for a long term solution to the shoaling problem at the mouth of MDR.

V. Los Angeles County Responsibilities

Marina del Rey is the largest source of non-tax income for all of Los Angeles County. The Marina generates an annual income of approximately $25 million dollars for the County, most of which comes from percentages of boat slip fees, office and apartment rentals, and restaurant receipts (Smith, per comm. 1991). Despite the large revenues the Marina generates, little money is reinvested in the Marina, and a very small fraction of that is spent on actual operations and maintenance costs. Only a little over two percent of the total revenues generated by the Marina, $600,000 is set aside for major maintenance; the rest goes to L.A. County's general fund.

With extensive contaminated sediment problems, poor tidal flushing, and frequently sighted marine floating debris, Heal the Bay contends that $600,000 is not sufficient to properly maintain the Marina, which has resulted in its degradation. For example, there is a question about claimed maintenance for which there is little visible evidence. The Department of Beaches and Harbors operates a debris skimming boat that is responsible for picking up any floating trash or debris in the main channels of the Marina. Heal the Bay has been informed that the Department of Beaches and Harbors performs debris skimming five days a week; however, sources from the boating community have repeatedly stated that they have rarely seen this boat functioning. Boating groups, such as the Pioneer Skippers are beginning to form coalitions that will retrieve trash that has accumulated in the inner recesses of each basin.

VI. RECOMMENDATIONS

Indisputably, there is a significant pollution problem in the Marina. Although part of the problem is caused by factors which are difficult to control, such as contaminants from the Oxford Street flood control channel and the Ballona Creek storm drain, an effort must be made to improve the water quality and restore the marine habitat of MDR. There are actions that the County and Marina users can take that will, if properly implemented and stringently followed, significantly reduce the pollution problem in the Marina. The recommendations below came from the Center for Marine Conservation, San Diego's Environmental Health Coalition, the EPA, local boating groups, Sound Watch: An Environmental Guide for Boaters, and Heal the Bay staff. In order to expedite the enhancement process, Heal the Bay makes the following recommendations:

General Recommendations:

The most significant sources of pollution to the Marina are the Oxford Street flood control basin, urban run-off from nearby streets and the Ballona Creek storm drain. These sources are responsible for many of the contaminants present in the Marina, including toxic sediments and organic matter. The pollution within the Marina will persist if there is not a long-term plan to reduce the influx of contaminants from these sources. Because of the high value of the Marina for commercial and recreational uses and the Marina's important biological function as a shallow water habitat, it should be targeted for an intensive, Marina specific, County stormwater management effort designed to reduce the amount of pollution in urban runoff. Plans should include full compliance by the County of Los Angeles and all other co-permittee cities in the Ballona Creek watershed under the National Pollutant Discharge Elimination System (NPDES) municipal stormwater permit. The NPDES permit is designed to reduce the flow and pollutant loads of stormwater urban runoff. The County has begun stenciling catch basins in the Marina area with the "No Dumping-This Drains to Ocean" logo. All recommendations of the County's Ballona Creek Task Force should be implemented as soon as possible.

Another possibility that needs serious long term consideration is the reconfiguration of the entrance to MDR or Ballona Creek. Reconfiguration is needed to reduce the deposition of contaminated sediments from Ballona Creek at the mouth of the Marina. A short term solution to the problem would be to implement a regular sediment removal program in Ballona Creek before the rainy season.

Strongly support Senate Bill 1084, (Calderon, Los Angeles). The bill will continue funding the State's Bay protection and Toxic Cleanup Act. SB 1084 will enable the State Water Board to identify, characterize, priority rank and develop remediation plans for toxic hot spots like Marina del Rey.

County:

The County should impose an Environmental Protection Fee that would pay for more pumpouts, hazardous waste facilities and maintenance of these facilities. This fee does not have to be onerous. A modest five dollars per month would raise approximately $350,000 for environmental protection within MDR. The five dollars could come from existing slips fees if the money was categorically designated or funds could come from a new environmental surcharge to existing slip fees.

Clearly labeled recycling containers with lids are needed at each dock to reduce the possibility of illegal trash disposal and to encourage recycling of at least plastics, aluminum and glass. Under the International Marine Pollution Treaty (MARPOL ANNEX V) and the U.S. legislation that implements this treaty in our waters, it is illegal to dispose of plastic anywhere in the waters of the United States. It is also illegal to dispose of any garbage from vessels within 3 miles of shore.

A program (permanent facility or periodic household hazardous waste roundups) for responsible disposal of the many hazardous materials used in boat maintenance (such as anti-fouling paint, motor oil, antifreeze and batteries) is desperately needed to reduce the temptation of illegal dumping and improper disposal. A permanent used motor oil disposal facility is needed to provide boaters and Marina workers a safe, convenient and inexpensive place for oil disposal. Some opposition has suggested that use of an underground tank as a disposal facility may result in a spill, but the possible advantages far outweigh the threat. Santa Barbara has a used motor oil tank that has been successfully and safely utilized for oil disposal since 1990.

The Department of Beaches and Harbors needs to publicize the recently installed public holding tank pump out facility, as illegal discharges may be a significant source of pollution to the Marina. Adequate pumpout facilities are not available in MDR. EPA recommends one pumpout facility for every 300 boats: equivalent to over 20 pumpouts in MDR. Disposal facilities for portable toilets are also needed.

Other businesses that operate in the Marina should be targeted for education on pollution problems. Although there has not been an inspection program, restaurants and charter boat services may contribute significant amounts of pollution to areas within MDR by improper food and septic waste disposal.

The Harbor Master should be given the authority to spot inspect any vessel for illegal discharges of holding tanks and adequate numbers of life preservers.

Heal the Bay believes Mother's Beach should be closed for recreational swimming. For years, this stretch of beach has repeatedly been in violation of the Department of Health Services beach closure and health warning objectives for indicator bacteria. A bathing beach in close proximity to so many sources of pollution puts swimmers at a potential health risk. At a minimum, the beach should be permanently posted with large health warning signs.

The Los Angeles County Department of Beaches and Harbors should reinstate their quarterly newsletter to educate and inform all slip lessees about using the Marina in an environmentally responsible manner. The Pioneer Skippers, a local association of boaters, have graciously offered to publish this newsletter which would provide regular public education to Marina users.

Each time a boater renews his or her slip lease, the boater should have to pass a simple test that is similar to a driver's license test. Any new lessee should take an education class consisting of lessons on general boater safety, Marina rules and regulations, and environmental concerns (especially advising boaters about the vessel holding tank pumpout and anti-fouling techniques).

Although there's never been a demonstrated significant problem, dye tablets should be placed in every vessel equipped with a holding tank as a precautionary measure to catch illegal dumpers. The dye tablets are a cost-effective way (seven and one-half cents per tablet) to identify any leaking holding tanks or illegal discharges. This technique is recommended in EPA's Guidance Specifying Management Measures for Sources of Nonpoint Pollution in Coastal Waters to deter illegal discharges and has been successfully used in Avalon harbor on Santa Catalina Island. Each dockmaster would be responsible for his or her own anchorage (responsibilities would include passing out dye tablets, periodic inspections, etc.), thereby reducing the staffing needs of the County.

Automatic shut-off valves should be placed on fuel pumps at fueling docks in the Marina. Boaters should be encouraged to install devices that would prevent overflows of their tanks and signal when the tank is full. Moreover, fueling should only be done by trained fuel dock employees. Over-filling and spillage are a common occurrence during boat refueling at the fuel docks as demonstrated by the often reported hydrocarbon sheen that extends from the fuel docks across the main channel.

VOL 12

17706

R0051011

VOL 12

Boaters

When scraping or preparing the hull of a boat for painting or varnishing occurs over water, a tarp should be affixed to the hull to trap any debris. The debris from the tarp should be collected and disposed of properly before the tarp is removed.

Oil absorbent towels should be placed under the engine to prevent oil from dripping into the bilge water. These towels are very inexpensive ($1.50) and will greatly reduce the amount of oil in bilge water. Any bilge water possessing a sheen should not be discharged into surface waters. Oil-absorbent materials should be placed in the bilge to soak up oily bilge water if there is any sign of an oil sheen on the bilge water surface. Oil, bilge and absorbent should either be placed in a shoreside bilge collection system or removed by a private bilge collection vendor. Keeping oil out of bilge water will also reduce the chance of an on board fire.

Boaters should minimize the use of toxic chemicals for cleaning their vessels and should use safe substitutes whenever possible.

A pamphlet on methods for keeping boats bottoms clean should be developed and distributed to each boater. The pamphlet should include information on the paints that are the most environmentally sensitive and it should offer methods of removing slime and barnacles from hulls. This type of information would be ideal for the reinstated quarterly newsletter.

1 7707

VII. Conclusion

Marina del Rey is more than just a recreational harbor. As a refuge and nursery for fish in Santa Monica Bay and a large source of income and jobs for Los Angeles County, more funds and Best Management Practices (proven management techniques for pollution reduction) are needed to enhance and protect this valuable resource. Soule and Oguri's yearly monitoring reports indicate that the quality of water in the Marina is vital to the survival of many aquatic species and is slowly beginning to improve. Although this is encouraging news, significant pollution problems still exist and need to be remedied. Successful Marina enhancement and protection only will occur with the help and cooperation of all stakeholders in the quality of the resource; the County, boaters, the Army Corps of Engineers, the local business community, and all those who value the Marina as a recreational and biological resource. Heal the Bay will push for rapid implementation of the report's recommendations in the coming months. Heal the Bay has offered solutions to the Marina's pollution problems. Now it is up to everyone in the region to make Marina del Rey clean and healthy for people and marine life.

EXECUTIVE SUMMARY

HISTORICAL BACKGROUND

Marina del Rey, the largest manmade marina in the world, has some 5,800 boat slips and a resident population of about 11,000 people, along with numerous shops, some 28 restaurants, four hotels, and two motels which draw people from the surrounding urban megalopolis as well as from international tourist groups.

Wetlands Function

Sited on a degraded wetlands, the marina replaced an area of mud and sand flats with small drainage channels, said to have been populated by molluscs, crustaceans, echinoderms and benthic worms, although no environmental inventory studies were ever performed there. The marina benthos is now dominated by worms, some of which provide food for fish larvae, juveniles and adults. The soft, unconsolidated bottom, straight sided concrete walls and low flushing rate make the area more optimal for a marina than for a marine habitat. The use of antifouling compounds and potential for spillage of oil and grease also detract from faunal diversity and production. In spite of this, the marina is productive and serves as a valuable refuge and nursery ground for some marine fish species, important factors in light of the severe reduction of more natural wetlands in the greater Los Angeles area.

NON-POINT SOURCE IMPACTS ON THE MARINA

By far the largest impact on the marina comes from the Oxford Street flood control channel, which drains into the marina through a tide gate in Basin E. The soil in some adjacent terrestrial areas is apparently highly contaminated with trace metals, pesticides and polychlorinated biphenyls (PCBs) accumulated from earlier dumping or from World War II industrial contamination, so that, when soils are excavated during construction and erode during rainstorms, pollutants are carried into the marina attached or complexed chemically with the suspended sediments. Runoff from storm drains carries a miscellaneous burden of organic and inorganic contaminants and coliform bacteria.

Ballona Creek flood control channel, although carrying a much larger volume of water from a larger area, seems to have less impact on the marina than Oxford Street basin flow. The creek receives a large amount of debris: yard clippings, Christmas trees, fast food plastic containers, waste motor oil, beer cans and the like. Street runoff carries the metal, rubber and oil residues from highways, and garden runoff carries pesticides. Heavy wet weather flow will carry much of the debris into Santa Monica Bay, but during dry weather low flow, debris will enter the marina on rising tides. Storms or extreme high tides carry material washed off the jetties, such as dog, bird and people feces, into the marina.

ENVIRONMENTAL STUDIES

Effects of El Niño on Water Quality

This report covers the period from 1 October 1991 to 30 June 1992 because of a change in the fiscal year for the contract. One of the principal physical factors influencing water quality during that period was a warm water influx in October and November and in the spring in March and April due to a moderate tropical El Niño-Southern Oscillation (ENSO) event. The ENSO events in the equatorial Pacific, with a pool of very warm tropical water moving eastward toward the Americas and a cessation of normal Trade winds, caused rainfall patterns to change, and produced more rainfall than in any year since the very strong ENSO of 1982-1983.

The impacts of rainfall on the marina were more obvious in 1990-1991, when only two storms occurred, each of which occurred just prior to a monthly cruise. The influences on dissolved oxygen, nutrients and bacterial contamination were quite apparent, in addition to the expected temperature, salinity, pH and turbidity effects.

Rainfall in 1991-1992 occurred over longer periods of time and thus impacts were more diffuse and not quite as dramatic as they were in the previous year, when almost all of the rainfall occurred in the two storms. It was very clear, however, that rainfall, with its associated runoff, has serious impacts on the marina.

VOL 12

The minima for dissolved oxygen due to chemical and biological oxygen demand (COD, BOD) during oxidation by bacteria and other microbial populations occurred most surveys in Oxford Street flood control basin. The exceptions were during spring rainy periods; in March, when bottom waters were below the regulatory 5.0 ppm in Basin D near the marina beach and in Basin E near the tide gate for Oxford Street basin, and in April when bottom waters were below 5.0 ppm at Stations 6, 8, 10, 18 and 20 as well as in Oxford Street basin. Bottom waters continued to have low DO values in May at Stations 6, 7, 10 and 20, and in June at Stations 6,7,8 and 10, as well as in Oxford Street basin. Los Angeles County Life Guards attributed the May and June problems to runoff and debris from the fires associated with the riots at the end of April, which could have stimulated blooms that had died off, to toxicity, or to COD and BOD.

Changes in nutrients were not quite as distinctive as in 1990-1991. For the most part the ranges in concentrations of ammonia-nitrogen, nitrate and nitrite, and phosphate were similar, as were the seasonal trends. Silicate showed a narrower range, however. Nutrients have a negative correlation with salinity, since they are primarily associated with the influx of fresh water into the marina from runoff. Ammonia showed a large increase in average levels and an extreme maximum in February, with a lesser peak in April; nitrate plus nitrite showed high maxima in January, February, April and June with the highest averages in January and April, while phosphate maxima occurred in February and April, with the highest average in February. Maxima occurred most often in Oxford Street basin. Normally it is expected that higher average values will occur in the winter when phytoplankton populations may be smaller, using less of the available supply.

<u>Sediment Contaminants</u>

Only one sediment survey could be performed in the period, in October 1991, due to budget reductions. Rainfall in the previous spring increased greatly the percentage of the finest sediments, to which a large proportion of contaminants are attached or complexed, causing increases in many trace metals and some other parameters. The finest grain size sediments continued to increase during dry weather, which may be indicative of the reduced flushing caused by partial occlusion of the mouth of the marina by accumulated sand and sediments trapped by that barrier.

In October 1991, there had been improvement in sediment content of immediate oxygen demand, phosphate, and sulfide, while volatile solids, chemical oxygen demand and organic nitrogen had worsened somewhat. Among trace metals, levels of arsenic, cadmium and chromium have not in the past reached levels of low environmental effects determined by the National Oceanographic and Atmospheric Administration (NOAA) and have decreased in recent surveys. Tributyl tin, banned in 1988 for most antifouling paint use except on aluminum hulls and on vessels longer than 25 meters, has shown a decrease of three orders of magnitude. Contamination with nickel have declined to where only Stations 9 and 10 are slightly over the NOAA level for low environmental effects range (ER-L). Copper, lead and zinc have fluctuated in the marina, but of these, lead and zinc show increases after heavy rainfall, indicating terrestrial sources. Copper seems to have increased over dry seasons as well as wet ones to the highest levels in the 1984-1991 surveys. This may represent increased use as an antifoulant since tributyl tin was banned. Control of copper, lead and zinc emissions would improve the marina biota greatly.

One of the most important changes was the reduction of polychlorinated biphenyls (PCBs) to below the limits of detection. Aroclor 1254 and 1260, highly toxic, long lasting substances used as lubricants in transformers and other electrical equipment, in printing and other industrial processes, first were detected in the marina in October 1989 in large amounts. Some Aroclor 1260 was still present in May 1991, but all had disappeared by October, 1991. The relatively sudden appearance of Aroclors in the marina may have been due to runoff from large scale excavation and grading at terrestrial sites near the marina or to some unidentified accidental spill, although no records of such an accident have been found. Its disappearance within two years is indicative of flushing because the material does not biodegrade well.

VOL 12

1774

Pesticides continue to be a problem in the marina. Chlordane has been banned since 1988, but appears to continue entering the marina. Levels exceeded the low (ER-L), medium (ER-M) and higher levels of environmental effects (apparent effects threshold, AET) indicated by NOAA at all stations. Chlordane was highest at Station 2, at the sand bar, possibly indicating that it is flushed from Ballona Lagoon where many wooden structures may have had Chlordane applied for termite control, and is high in Oxford Street basin as well.

The DDTs decreased from Oct ıer 1990 to October 1991, but had been lower in May 1991 than in October 1991, indicating a dry weather increase. The largest accumulation is at the sand bar at Station 2, as it was with Chlordane. DDTs exceed the NOAA low effects range at most stations, indicating the potential for continuing impact on the larval and juvenile organisms and for bioaccumulation in the food chain.

Fish Tissue Contamination

Levels of pesticides and PCBs in fish taken at the Fisherman's Village fishing docks are well below levels deemed to be a public health risk. Levels of pesticides vary greatly in fish, depending on the reproductive period since these fat soluble substances accumulate in muscle and liver but are mobilized into the liver and gonad prior to reproduction, much of it leaving the body in the egg yolks on spawning. This is of course harmful to liver function and reproductive capacity of the fish, but protects consumers of cleaned, gutted fish. Levels of pesticides can also vary between individuals of the same species at the same season, presumably influenced on the diet of the individual fish. The mean level of PCB Aroclor 1260 in fish tissues appeared to be increased but the liver/gonad level was much decreased, suggesting that reproduction had occurred in some of the fish sampled on 2 November 1991. A similar trend was seen for Chlordane contamination. Levels of p.p'DDT and p.p'DDD appear to be decreasing, but the amount p.p'DDE has fluctuated and o.p'DDE has increased greatly, suggesting that the metabolites of DDT are being recycled rather than new DDT being introduced into diets of the fish.

VOL 12

1 7725

VOL 12

Bacterial Contamination

Effects of rainfall on bacteria in marina waters were indicated by the rise in total coliforms, fecal coliforms and enterococcus bacteria during or after rains. Violations of Public Health standards occurred within the marina at several stations in the wet months of January, February, March and April, and only two violations of fecal coliform standards occurred in dry weather. The marina should be considered unsafe for body contact during storms and for a few days afterward, with risks of gastroenteritis and sometimes other infections.

There is little evidence of violations of sanitation regulations by vessels in the marina, other than an occasional unexplained peak during dry weather. Violations of Public Health standards were reduced in 1991-1992 as compared to the previous year.

Although Oxford Street flood control basin and Ballona Creek flood control channel are not body contact water areas, waters flow from these sources into the marina and present problems of contamination. Oxford Street basin almost always has high coliform counts. During the rainy periods, both the creek and the basin exceeded public health standards for total and fecal coliforms and for enterococcus.

Benthic Populations

The rains of the spring of 1991 may have cleared contamination from Ballona Creek and swept benthic organisms to sea, but the two stations in the creek responded differently. Station 12, near the footbridge, was recolonized by very large numbers of freshwater tolerant, opportunistic nematodes, while Station 1 at the mouth of Ballona Creek was apparently recolonized by polychaetes, and also by some molluscs and crustaceans not usually seen in marina surveys.

The mean number of individuals in the marina was a record high, but consisted mostly of nematodes at Stations 12 and 2; without the nematodes the mean was above that of the previous six years if Station 12 is excluded. At Station 2, at the sand bar where sediments contaminated with pollutants have accumulated, nematodes were dominant.

1 7 7 2 6

The sand bar may partially occlude circulation in the marina, reducing flushing in the main channel and inner marina basins. Populations were at an all time low at Station 6 in Basin B, and were 50 percent or more below the lowest previous records at Station 8 in Basin D and Station 10 in Basin E. No single contaminant is associated with these distributions, and it is probable that different parameters are affecting different locations. Stations 6 and 8 had large increases in the finest sediments, with their contaminant burdens, and Station 10 is very much influenced by the Oxford Street basin runoff, with its sediment and pollutant burden, coupled with the low levels of circulation in all th locations.

Fish Populations

The marina is an important habitat for fish eggs, larvae and young adults, serving as a warm water, low energy, high nutrient environment where turbidity shelters them from predation. Thus the marina fulfills functions of a wetlands. The mean number of fish species in the marina is stabilized at about 39, with slightly more species present in the spring (May) than in the fall (October), although there is considerable annual variation. This serves to indicate the need for long term surveys to determine actual trends. The total number of species, or higher taxa where identifications of eggs or larvae are not possible, is over 90 for the 16 surveys conducted since techniques were standardized in 1984.

Progress has been made in the ensuing years on identification of eggs and larvae so that some taxa that were found to be duplicated as adults were deleted from the master list of occurrences. Diver transect observations in the Entrance Channel and at the breakwater indicate that is the richest area for diverse fauna, although large schools of smelt in Basin D have in the past dominated the numbers.

Coincidentally, since the disappearance of the seagrass beds in Basin D at marina beach in 1991, no large numbers of smelt have been found in October 1991, May 1992, or October 1992. These are populations that move in and out of the marina rapidly, depending on food, predators, temperature and salinity, and therefore may not coincide with the infrequent surveys.

I. INTRODUCTION

HISTORICAL BACKGROUND

The site of Marina del Rey, the largest manmade marina in the world, was a degraded wetlands that once extended through the communities of Venice on the north, southwest through La Ballona, eastward almost to the site of the San Diego Freeway and south of the present Culver Boulevard to the Westchester Bluffs. In earlier years, the Ballona wetlands joined the wetlands leading to the Los Angeles River, inland of th Palos Verdes Peninsula, which was once an island. The Los Angeles River sometimes di·erged from its course, exiting where the Port of Los Angeles is now, to flow through the Ballona estuary (Bancroft, 1884; Beecher, 1915).

Ballona wetlands had numerous small, meandering channels, with a large pond where Basin D beach is now located, and waters exited into what is now the remains of Ballona Lagoon and Del Rey Lagoon, behind a large barrier beach. Historically, river flow there had helped to cut Santa Monica Canyon into the alluvial shelf of Santa Monica Bay (Figure I.1). Major rivers in southern California were concrete lined in the 1920s and 1930s to control disastrous flooding and loss of life that occurred during heavy winter rains in some years.

By the time the marina was built in 1960-1962, large areas of the wetlands were degraded, having been filled or drained to provide industrial development, access to oil and gas fields, salt pannes, disposal areas, and a measure of control over mosquito and black fly infestations. Construction of the marina began with the building of dry walls and dredging of basins followed. Land between the Entrance Channel and Basin A and between Fiji Way and Ballona Creek were used to dewater the hydraulically dredged soils. When the basins were completed the coast highway road was closed, leaving the bridge over Ballona Creek as a footbridge, the roadway embankment was breached and the opening eroded tidally to form the Entrance Channel. Soule and Oguri (1990) showed a series of aerial photographs

VOL 12

1773 5

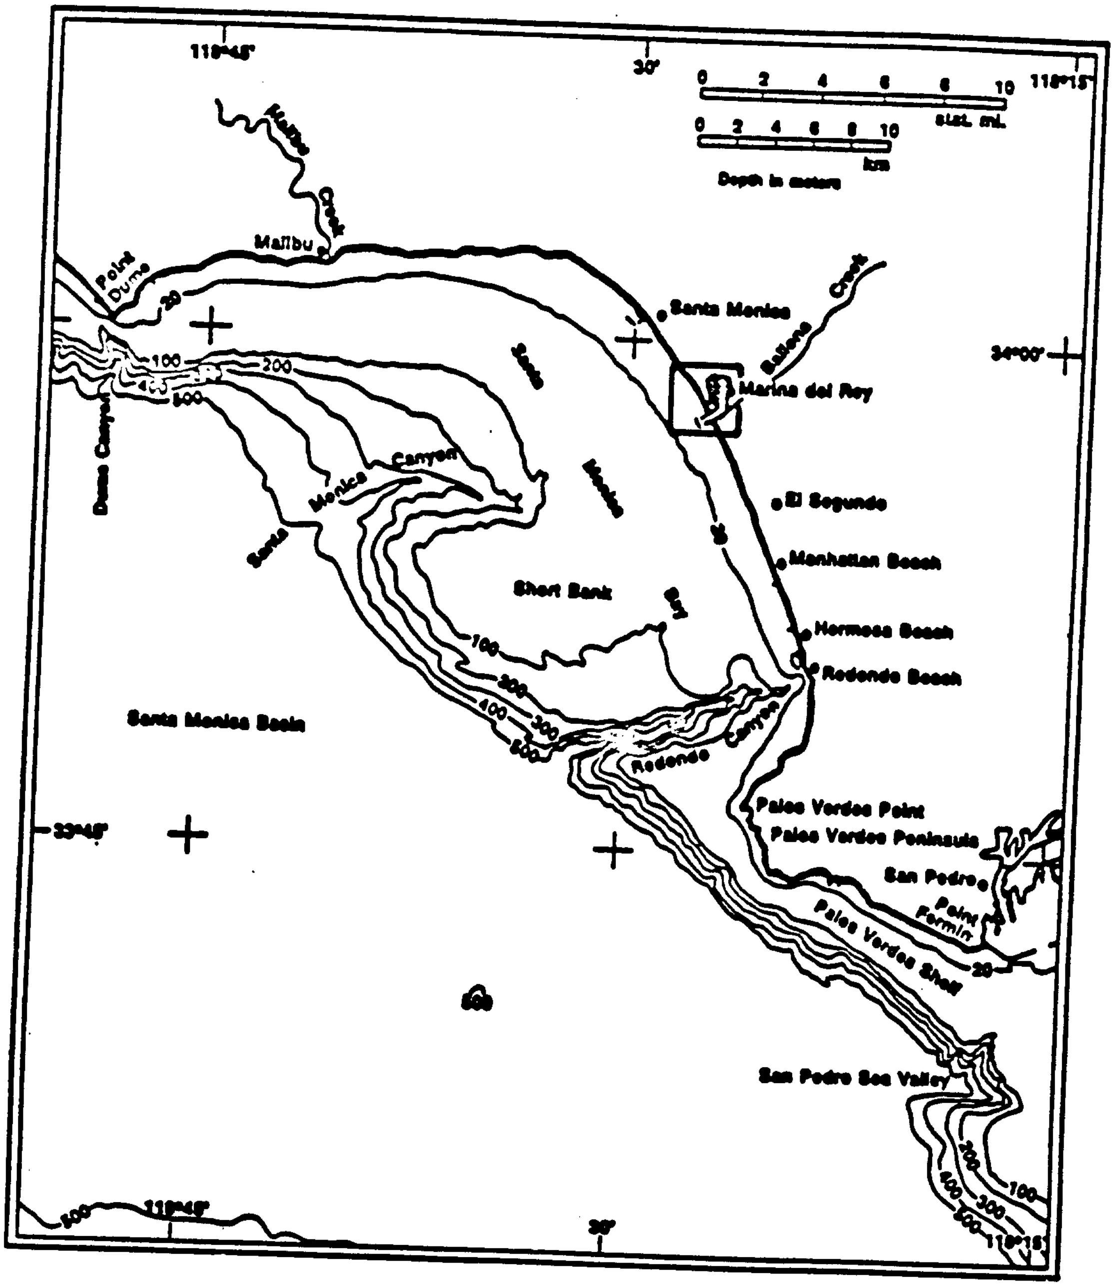

Figure I.1. Location of Marina del Rey within Santa Monica Bay.

of the sequence of construction. The residential areas along the Westchester bluffs and inland in Culver City developed greatly after World War II, making the marina a truly urban development (Figure 1.2).

ENVIRONMENTAL STUDIES

Although the U.S. Army Corps of Engineers modeled various configurations for the marina at the Waterways Experiment Station in Vicksburg, Mississippi, no environmental studies were performed to evaluate the impact on existing biota in the wetlands in the dec: 'e prior to passage of the National Environmental Policy Act in 1970. The con. . .ration selected was supposed to prevent storm damage from the prevailing wave and surge patterns, but the first year when Basin A was opened, storm surge came up the Entrance Channel, reflected off the walls in the area of the present Administration docks and caused great damage to boats in Basin A, across the Main Channel.

Environmental baseline studies in the marina were not undertaken until 14 years after its construction. From July 1976 to June 1979, an extensive program of physical, chemical and biological surveys at 13 stations was performed by the University of Southern California (USC) Harbors Environmental Projects with funding from the federal Sea Grant Program at USC (NOAA, Department of Commerce) and the Los Angeles County Department of Small Craft Harbors, now the Department of Beaches and Harbors (Soule and Oguri, 1977, 1980). This provided the first detailed information on the marina as an important biological resource in addition to its recreational function.

Limited surveys were resumed in 1984 in the spring and fall, with a reduced scope which included monthly measurements of water quality, biannual surveys of benthic organisms and fish, and annual analyses of sediment chemistry. Surveys were then reduced to one period a year, In October, November and December (Soule and Oguri, 1985, 1986, 1987, 1988).

In October 1988, year round monthly surveys were resumed and four more stations added (Figure I.3), Stations 18, 19, 20 and 22. In 1989, Station 25 was added between the

fishing docks and the Administration docks where the entrance to the future Playa Vista marina may be. Special projects have also been performed which include bioassay/toxicity studies of the effects of contaminated bottom sediments on local species, effects of tributyltin in antifouling paints, body burden of PCBs and DDTs in fish caught at the local docks and the incidence of coliform organisms at the marina beach, as well as at other marina sites.

Station locations are shown in Figure I.3 and descriptions are listed below. Depths vary according to tide stage and i· egularities in the bottom that develop due to storm deposition or erosion, runoff, tidal . . w and to propeller wash.

STATION LOCATIONS AND DESCRIPTIONS

MDR-1. Located midway between the breakwater at the east entrance to the Marina and the beach, at the mouth of Ballona Creek flood control channel. The area is subjected to discharges from the creek, to severe impacts from storm water flow and to deposition or erosion from storm wave action. Depth irregular, 2-6 meters.

MDR-2. At the entrance of the Marina, midway between the two Marina jetties. The area is protected from most storm waves but subject to weak coastal currents. Sands have been deposited from storms and blown from the adjacent beach resulting in severe, irregular deposition. Heavy flow in Ballona Creek flood control channel also carries sediment and debris into the mouth of the Marina. Dredging was undertaken in February 1987 to reestablish the channel and is scheduled for "knockdown" again in October 1992. Depths 4-6 meters.

MDR-3. On the north (west) side of the entrance channel, in front of the tide gates to Ballona Lagoon and the Venice Canal system. Protected from all but severe storm waves, the site is subjected to discharge of waters from the canal system. Shell mounds present during the 1976-1979 surveys disappeared, replaced first with fine sediment and then sand. Depths 3-6 meters.

MDR-4. Seaward of the Administration/ Coast Guard dock on the south (east) side of the entrance channel at junction with main channel. Subject to heavy boat use. Protected from most surge, the area was heavily damaged by 1983 storms and docks were rebuilt in 1985. Depths 3-6 meters.

MDR-5. In the center of the Main Channel, subject to heavy boat traffic. Sediment from the basins accumulates there . Depth 3-6 meters.

MDR-6. At the innermost end of Basin B; protected from westerly winds by seawall, circulation reduced. Depth 3-5 meters.

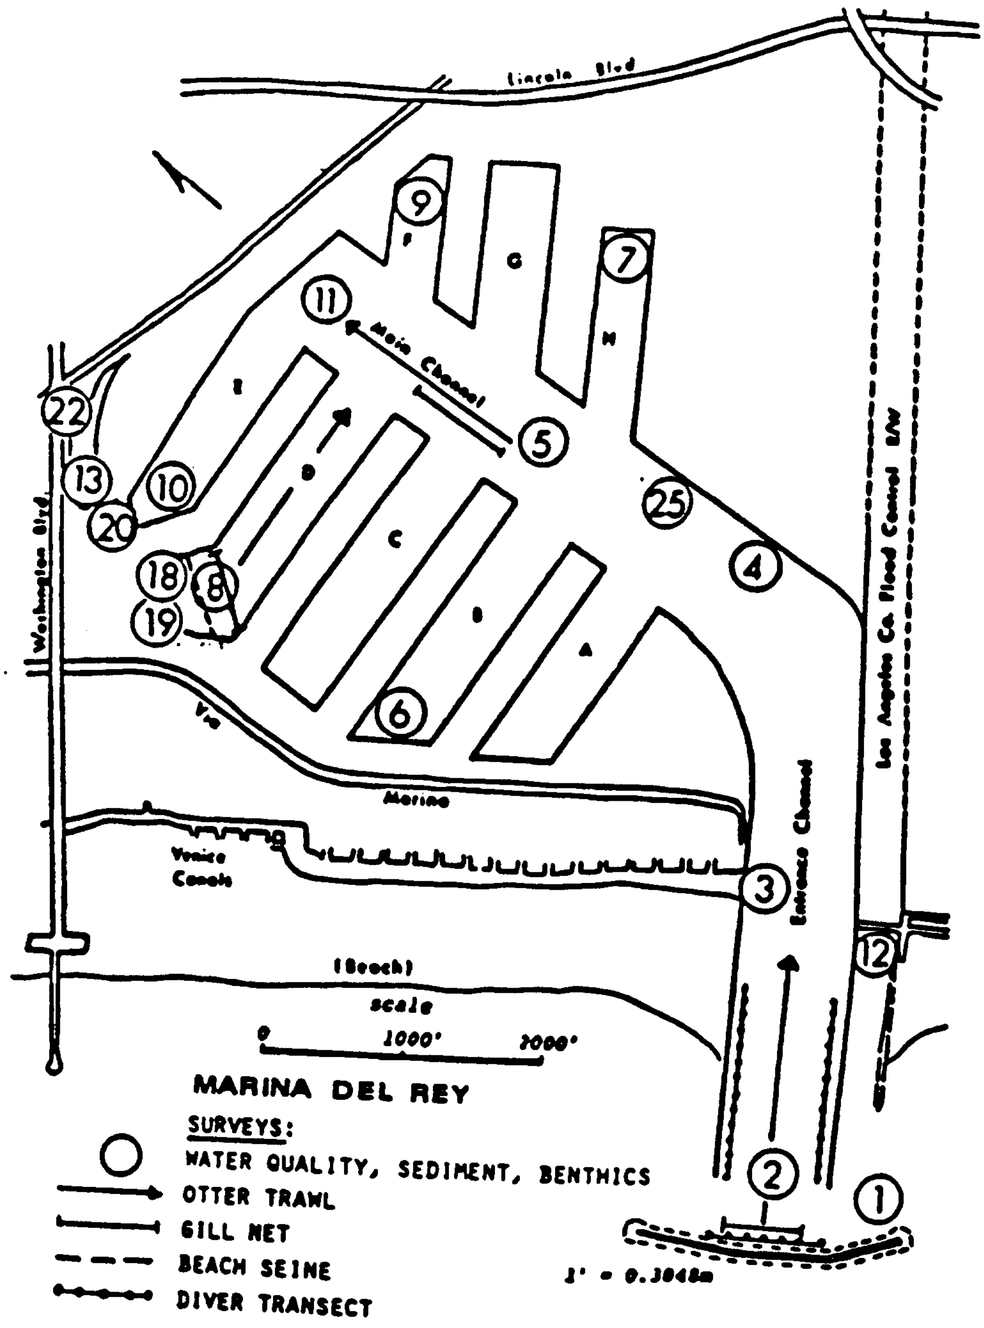

Figure I.3. Survey stations in Marina del Rey.

VOL 12

1 77 40

VOL 12 17741

MDR-7. At the end of Basin H near the work yard dock. Large storm drain present; exposed to afternoon westerly winds. Depth 3-4 meters.

MDR-8. Off the swimming beach in Basin D near first slips. Exposed to afternoon winds. Depth 3-4 meters.

MDR-9. At the innermost end of Basin F. Large storm drain present; protected by slips and sea wall. Depth 2-4 meters.

MDR-10. Innermost end of Basin E; subject to daily flushing from the Oxford Street flood control basin through tide gates and to storm water runoff. Depth 3-4 meters.

MDR-11. At end of Main Channel; subjected to storm drain flow and to influx from Station 10; impacted by reduced flushing due to .creased slip capacity. Depth 3-5 meters.

MDR-12. Ballona Creek, sampled from beneath the Pacific Avenue foot bridge. Subject to tidal flushing and continuing freshwater discharge into the flood control channel; also subjected to illegal dumping of trash upstream and to sewage overflow. Depths 1-4 meters.

MDR-13. Inside tide gates of Oxford Street flood control basin; subject to minimal daily tidal flushing, storm water runoff and drainage, surface only. Inaccessible at times.

MDR-18. Twenty meters off wheelchair ramp in basin D perimeter of swimming area. Depths 1-3 meters

MDR-19. At end of wheel chair ramp, surface only.

MDR-20. At innermost end of Basin E where Oxford Street basin flow enters Marina. Depths 1-4 meters; flow partially obstructed by large vessel docked there.

MDR-22. Inner end of Oxford Basin at Washington Street culvert, surface only.

MDR-25 Between the Administration - Life Guard docks and the public fishing dock.

II. PHYSICAL WATER QUALITY

INTRODUCTION

The water quality of Marina del Rey is influenced by a number of factors including both point source and non-point source discharges which enter either the marina or adjacent and contiguous waters. These waterways include Ballona Creek, Ballona Lagoon and the Oxford Flood Control Basin, which serve as collectors of runoff from non-marina urban areas. Waters from these collectors enter the marina either as a result of tidal exchange or, during and after rainfall, as a result of drainage from adjacent surfaces or from the storm drains. During the period covered by this report, the long-standing drought was broken by rainfall during or shortly prior to the January through April sampling periods. The May survey may have been influenced by terrestrial runoff from the Los Angeles area in late April. The runoff may have decreased dissolved oxygen and increased BOD in certain stations in the marina survey, as discussed in the following pages.

PROCEDURES

The data discussed in this report cover the period from October 1991 through June 1992. Sampling and data collection for water quality assessment were carried out at monthly intervals. The monthly dates were selected, when possible, to permit the early part of the sampling to occur during or near peak tides to permit boat access in shallow areas such as Station 12 in Ballona Creek.

Temperature, conductivity, later converted to salinity, dissolved oxygen and pH were measured at one meter intervals through the water column using a Martek Mark XVII water quality monitor. Beam transmittance was measured at the same depths using a modified HydroProducts transmissometer with a 0.1 meter light path. Both instruments were calibrated immediately prior to each field excursion and, if any data were considered questionable, immediately after the instruments were returned to the laboratory. Visual observations of ambient light penetration and water color were measured using a Secchi disk and comparing the water color to a Forel-Ule water color scale. The field log is presented in Appendix A and complete water quality data tables are contained in Appendix B.

TEMPERATURE

1991-1992 Ranges

The temperatures encountered in surface waters of Marina del Rey during this sampling period ranged from a high of 23.7° C to a low of 11.0° C. The highest water temperature, 23.7° C, was found at Station 22 in April 1992. The temperature at Station 13 during that monthly sampling period was 22.7° C. In six of the nine months during this monitoring period Station 22 or Station 13 had the highest temperature and both were usually warmer than all other stations. The lowest temperature encountered during this period, 11.0°C, also occurred Station 13 in January 1992, following a period of heavy rains. The temperature at Station 22 was 12.9°C, the next lowest at that time.

The monthly averages of near surface water temperatures at all stations in Marina del Rey during the period ranged from winter low temperatures of 13.8°C in December 1991 and 13.3°C in January 1992 to a high of 21.4°C in October 1991. Average temperatures for April, May and June were 19.3° C, 21.6°C and 22.1°C. These temperatures, particularly for April, are higher than in immediately preceding years, indicating the El Niño conditions prevailing in the area at that time.

Historical Quarterly Ranges

Seasonal ranges in temperatures from 1976 to 1979 and 1984 to 1992 are shown in Table II.1. The data indicate that the temperature range for the autumn months of 1991 does not depart from the pattern of previous years. The range noted for the winter of 1991-1992, however, was slightly cooler than preceding winters. The temperatures reported for the spring months showed a warmer range than in years 1989-1991, possibly reflecting the mild El Niño that occurred then. The temperature range in June 1992, the only summer month included in this report, was similar to the ranges reported for previous years.

Historical Monthly Records

Figures II.1 through II.3 present the near surface average temperature data for

Table II.1. Temperature Ranges (°C) by season and year*

	Spring Mar, Apr, May	Summer Jun, Jul, Aug	Autumn Sep, Oct, Nov	Winter Dec, Jan, Feb
1976		20.3-23.0	19.2-20.9	16.0-18.3

October of 1989 through 1991, 1984 though 1988 and 1976 through 1978, respectively. Temperatures during this month are among the highest in the years reported here. The range was narrowest in the 1976-1978 period. Temperatures are also among the most uniformly distributed throughout the pattern of stations. The expected pattern of warmer temperatures as distance of the station from the breakwater increases is clear in the gentle upward slope from lows in the 18° C to 20° C nearest the breakwater to the typical 20°-23° C range at the stations farthest from the breakwater. This is due to insolation of the shallow waters within the marina and the relatively slow exchange rate with the waters of Santa Monica Bay. October of 1991, although showing warmer than usual temperatures in Ballona Creek, is otherwise typical.

The pattern of temperature distribution through the marina in November, as seen in Figures II.4 through II.6 for the years 1989-1991, 1984-1988 and 1976-1978, respectively, shows a wider divergence in temperature ranges for 1976-1978, with a narrower range in 1984-1988 and the narrowest range in 1989-1991. There was a lowering of the ranges of about 2° C to 3°C. As in October the pattern of temperature increasing with distance from the breakwater is apparent. In November 1991, temperatures encountered, as shown in Figure II.4, were more uniform throughout the marina, compared to the years 1989 and 1990, exceeding the range of 16.5° C to 17.6° C only at stations in, and immediately adjacent to, the Oxford Street flood control basin.

December of 1991, the first of the winter months, had cooler temperatures and as expected, the relatively even temperature distribution at all stations during the period of 1989-1991 and 1985-1988, as shown in Figures II.7 and II.8. The temperatures encountered in 1976 through 1978, Figure II.9, indicate that the 1976 period was warmer by about 2° to 4°. In contrast to the pattern for October and November, in December the temperature of surface waters tended to be cooler in Ballona Creek, Station 12, than that at other locations in Marina del Rey during the years 1985, 1987, 1988, 1990 and 1991. This may reflect the effects of seasonal lowering of temperature of Santa Monica Bay and/or lower air temperatures affecting temperatures in runoff from the area drained by Ballona Creek.

The data for January temperatures, shown for 1989-1992 and 1977-1979 in Figures II.10 and II.11, respectively, continue the pattern of relative uniformity of temperatures throughout the marina that was noted for December, with generally lower temperatures than in December. The major departure from the pattern of uniform temperatures occurred in the relatively impounded waters of the Oxford Street flood control basin, where increased seasonal runoff and atmospheric temperatures would have the most pronounced effect.

The February data, particularly for 1977, indicate that 1977-1978 were warmer than 1989-1992 (Figures II.12 and II.13). A mild El Niño (El Niño-Southern Oscillation or ENSO) event occurred in 1977-1978, with the intrusion of warm equatorial waters carried north as a countercurrent, exhibiting variations as to the strength and extent northward. It is normal for the countercurrent to surface somewhere in southern California in winter, but the extent of northern flow, sometimes as far as British Columbia, the strength of linkage with the equatorial Pacific countercurrent and the intrusion of warm equatorial waters into South America determine whether it will be considered an El niño event. A strong El Niño occurred in 1984, lingering into 1985 as a pool of warmer water in the southern California bight and a milder El Niño extended intermittently into southern California in 1991-1992. In February 1992, data for Stations 8, 10, 20, 13, and 22 were incomplete due to probe malfunction in the rain, and Stations 7, 9, and 11 were not sampled when the Life Guard vessel being used was called on an emergency.

March temperatures in Marina del Rey, during the years for which we have data, show a warming trend. The data are presented in Figure II.14 for the years 1989-1992 and in Figure II.15 for 1977-1979. The higher ranք ıoted for February 1977 and 1978 and March of 1978, 1979 and 1992 were indicative of El Niño conditions. However the relatively warm temperatures of February 1977 were succeeded in March of that year by the coolest range of the March 1977 through 1979 annual series of measurements.

April temperatures, as shown in Figure II.16 for 1989-1992 and Figure II.17 for 1977-1979, displayed the seasonal warming that appears in all the years for which data are presented, except in 1978, when waters were warmer in March than in April. The differences in range from year to year are due to the differences from year to year in seasonal patterns in atmospheric and oceanic temperatures. Temperatures for April 1992 are probably due to the El Niño condition, although it was weakening in the tropics at that time. The upward slope of the temperatures according to distance from the breakwater that may be seen in these figures, as compared to those for earlier months, suggests that reduced flushing caused by the seasonally lower tidal range also increases solar heating of the shallow resident water in the marina. The effect of the insolation is most notable on waters within the Oxford Street flood control basin, Stations 13 and 22, where residence time of the contained waters is higher than elsewhere in the marina itself.

The trends noted for April are also present in May, Figure II.18 for 1989-1992 and II.19 for 1977-1979, and in June, shown in Figures II.20 for 1989-1992 and II.21 for 1977 and 1978. Seasonal warming trends led to higher temperatures than in previous months, a slope upward is apparent as distance from the breakwater increases and the temperatures at

VOL 12

1 7747

the Oxford Street flood control basin were higher than in the adjacent waters of the marina. The warmer waters noted in Ballona Creek for the autumn months are also in evidence in April in 1977-1978, in May and June 1978 and to a lesser extent in June 1990. Cloud cover is usually heavy in May and June, sometimes leading to cooler temperatures in those months than in April in ocean waters, as can be seen in 1977. In the spring of 1991 there were lower air temperatures than normal in the United States due to high atmospheric particulates and associated clouds due to volcanic eruptions of Mt. Pinatubo in the Philippines.

Monthly Depth Profiles in 1991-1992

Figures II.22 through II.30 present the data for average temperature of surface to 2 meters and bottom temperatures. Convergence of the two lines indicates that the there is no vertical stratification of the water column that might impede mixing of the usually well aerated surface with the underlying waters. This is usually typical of the colder months, when higher seasonal tides, increased winds and reduced insolation tend to promote more rapid exchange of the marina waters with the adjacent deeper waters of Santa Monica Bay and greater mixing of the waters during their residence within the marina. This pattern is evident in November, December, February, and March.

A second pattern, more typical of warmer months, shows a divergence of the temperatures for the superficial waters of the marina from the temperatures of the bottom waters. This is caused by the reversal of the conditions that lead to the isothermal waters of the cooler months and is evident in the temperatures for October, April, May and June, respectively (Figures II.22, II.28, II.29 and II.30).

A third pattern is shown in Figure II.25, the temperatures for January of 1992 and at Station 12, Ballona Creek in December and February. In these cases a thermal inversion may be seen, with the cooler waters of 0-2 meters overlying the warmer deep waters.

The density of sea water is determined by the combination of salinity and temperature. Cooler water may be less dense than warm water if it is less saline and higher salinity waters may be less dense than fresher water if it is warmer. The thermal inversion noted for January is due to the runoff from the winter storms reaching and overlying the more saline deep waters of the marina. In December and February this is apparent only locally within Ballona Creek.

Temperature Extremes and Means

The extremes and means of temperature in October 1991 to June 1992 are shown in Table II.II.2. The lowest temperatures are generally nearest the bay except in November and December, and the highest are generally in Oxford Street basin except for December, January and February.

Table II.2. Monthly temperature minimum, maximum and mean (in °C).

Month	Minimum	Station	Maximum	Station	Mean	Tide Phase
October	18.2	2	22.7	22	20.8	falling
November	16.3	1	18.3	13	16.9	falling
December	13.3	8	14.3	1	13.7	falling
January	11.0	13	14.6	9	13.7	rising/falling
February*	14.4	12	14.9	5	14.7	rising/falling
March	15.8	1	17.6	13	16.4	high/falling
April	16.1	1	23.7	22	18.5	falling
May	18.0	1	21.6	13	20.0	falling
June	15.8	1	22.1	22	19.4	falling

* Incomplete data at Stations 8, 10, 13, 20, 22 due to probe malfunction during rain; Stations 7, 9, 11 not sampled due to emergency call for Life Guard vessel being used in survey.

Figure II.31 presents the maximum, mean and minimum temperatures averaged for all data for each month. The seasonal patterns are clear, of autumn warm waters cooling off to winter lows and then warming through the spring into summer. Also evident are the countercurrent El Niño warm water of March and April, where the maxima appear to be atypically high.

The extreme low minimum in January, despite more closely related average and maximum temperatures, highlights the thermal inversion noted throughout the marina during that month.

Figure II.32 shows the average for all depths at each location sampled during all months. The characteristic low points, reflecting the ambient temperatures of Santa Monica Bay, are at Stations 1 and 2. Station 12 would be included in this group were it not for the variability in runoff temperatures. Otherwise, distance from the breakwater appears to be the determinant for relative warmth of the water at the different stations, indicating that the shallower depths and increased residence time of waters in the basins, with the resultant increased insolation, are governing factors in distribution of temperature throughout the marina.

Comparison of Marina del Rey monthly averages with those from Catalina Island, Newport Bay and Pt. Dume indicate that the marina was the warmest of these in October 1991, and March through June 1992, while Catalina was warmest in December through February. The marina was colder in December and January than the other sites. In February there was little difference among the four sites.

SALINITY

Salinity in the marina is strongly influenced by the fresh water flow from drainage into Ballona creek and the Oxford Street flood control basin. If it were not for these two sources, the inner basins would have higher salinities due to evaporation from the longer residence time there during warm weather, while during cold weather higher salinities would be likely in Santa Monica Bay. During wet weather, storm drain runoff into the basins from parking lots and streets influences the distribution of high or low salinities as well. Tide phase also influences salinity distribution, since a rising or high tide in dry weather will cause bay waters to extend inland past Station 12 in Ballona Creek and also influence Stations 1 and 2 more extensively.

Salinity in the marina can be considered as marine, but the much of the fauna is probably euryhaline, tolerant of occasional fresh water intrusions. Fish that are not euryhaline probably move out of the marina as salinity decreases and there is positive flow seaward. Some benthic worm populations are apparently killed or washed out to sea by storms, but they recolonize rapidly from adjacent populations (see Chapter VII). Since fresh water tends to layer on the surface, deeper waters may not be affected unless there is mixing.

In Table II.3, the salinity means and extremes of the monthly data from October to June are presented, along with the predominant tidal phase during the surveys. While the maxima and means do not vary greatly the minima are quite striking in the months with (ensive rainfall and runoff, such as January, March and April, 1992. The Cruise Log (Appendix A) gives the rainfall preceding and during each cruise.

Table II.3. Monthly salinity minimum, maximum and mean (in parts per thousand, converted from conductivity).

Month	Minimum	Station	Maximum	Station	Mean	Tide Phase
October	30.1	22	33.4	7	33.0	falling
November	30.1	12	32.8	7,8,9,10	32.5	falling
December	31.0	12	33.5	1	33.3	falling
January	17.4	13	32.6	7	31.3	rising/falling
February*	22.3	22	32.5	5,25	31.8	rising/falling
March	1.4	22	32.3	1,2	31.7	high/falling
April	7.3	22	33.2	1	31.7	falling
May	31.5	12	32.3	2,3,4,25, 5,6,18,8	32.2	falling
June	25.5	22	33.1	1	32.6	falling

Figure II.33 illustrates the relatively narrow range of the maxima and means, while there is great deviation in the minima due to the influx of rainfall runoff. The average of at salinities at all depths and all months (Figure II.34) indicates the large influx of low salinity waters in Oxford Street basin at Station 22 and the smaller reduction at Station 12.

DISSOLVED OXYGEN

Dissolved oxygen (DO) is introduced into the water by plant metabolism, primarily by single celled algae, the phytoplankton, or by physical aeration due to turbulence in the surf zone and along rocky shorelines. Oxygen depletion occurs during respiration of marine plants and animals, or due to the bacterial degradation of dead biota, or to the oxidation of organic and inorganic chemicals introduced into the waters. When nutrient input is high, phytoplankton may increase exponentially, forming a bloom and causing DO first to rise well above theoretical saturation and then to plummet when the bloom dies off.

Dissolved oxygen along the coast usually ranges between 6.0 and 8.5 ppm, and regulatory agencies have specified 5.0 ppm as the minimum DO necessary for the sustenance of fish populations, although many invertebrates can survive on much lower levels, down almost to the point of anoxia. If DO is totally depleted, hydrogen sulfide (H_2S) is released from chemical reduction of sulfates in sediments and water; noxious odors result and H_2S is toxic to some organisms.

Monthly Depth Profiles in 1991-1992

Monthly profiles of the surface to 2 m depth average DO and the bottom meter DO are illustrated in Figures II.35 to II.43. Water depth varies with tide and location from 4 to 6 m at Stations 1 through 5 and from 3 to 4 m in the rest of the marina.

The monthly profiles figured indicate that the waters are generally well mixed. In the cool months of the year there are fairly uniform DO levels, as is seen in November and February, but rainfall can change this pattern. During the warmer months when a thermocline is apt to be present the DO tends to differ in surface and bottom waters. Also, bloom conditions can occur at almost any time, and sometimes in very limited areas, as indicated by high DO values (e.g., above 8.5 ppm). Low DO values may be indicative of death of a bloom, with oxygen being consumed in the breakdown of the cells by microbial action, or by an influx of chemicals or debris during rainfall runoff that are oxidized chemically or by microbials, or by insolation in shallow waters, when increasing temperature decreases solubility and drives oxygen from the water.

In October 1991, bloom conditions appeared to be in effect throughout much of the marina, with values exceeding 8.5 ppm except in Basin E and Oxford Street basin. In

November, DO values were again high in the entrance channel, declining slightly in the inner channels and basins; at a number of stations the bottom waters had higher DO levels than the surface, especially at Station 5 (Figure 36). A similar pattern occurred in December, with a deviation at Station 5, this time with the surface values higher than the bottom. Bloom conditions again seemed to be occurring in the entrance and main channels.

In January 1992, bottom DO values were higher at most stations, with a wider spread. This may have been due to rainfall prior to the survey, but blooms apparently continued in the outer marina. February, only Stations 12, 1 and 2 had excessive DO levels but this may have been due .. turbulence because of storms. Data were incomplete in that survey, since Stations 7, 9, and 11 had to be skipped when the Life Guard vessel from which the surveys are performed was called out on an emergency. In March 1992, there was a distinct change in the regime and bottom waters were below 5.0 ppm at Stations 8, 10 and 20 following substantial rains in the previous few days.

In April, bottom waters in the outer marina were again higher than those at the surface; it had rained the previous day. The lowest DO values of the survey, 2.0 ppm and 3.0 ppm, occurred in Oxford Street basin at Stations 13 and 22 respectively, indicating the impact of street runoff. May DO levels, when blooms might be expected to return to the marina, may have been lower than normal due to storm drain runoff from the Los Angeles area. There were low DO values in bottom waters at Stations 6, 7, 10, and 20 and at Station 22 (surface sample only). In June, bottom waters were near or below the minimum at Stations 6, 7, 8, 18, 10, 13 and 20. This is unusual, and may still represent chemical oxygen demand or toxicity from debris carried into the marina or the death of a phytoplankton bloom. Complete data are presented in Appendix B.

<u>Historical Monthly Records</u>

Comparative data from 1976-1979 and 1984 to 1991 are illustrated in Figures II.44 to II.61 for October, November and December, the months with the largest data base.

In comparing October 1991 DO data with that of previous years (Figures II.44-

II.49), the 1991 data have among the higher averages, exceeding most of the 1980s data. The exception is that of 1989, which was higher except at Stations 12 and 1. The 1977 averages were well above most of those in 1976 and 1978. Bloom conditions may thus have increased over the 1980s levels but low oxygen episodes do not approach those of the 1970s. Bottom water DO values in October 1991 were also better than those of the 1980s.

Comparison of November averages (Figures II.50-II.55) indicate that the DO values were higher in both surface and bottom waters in 1991 than they were in any other years surveyed except for 1977.

The year July 1977-June 1978 had the highest rainfall, 33.44 in, since 1889-1890. Whether algal blooms can be linked to rainfall and the accompanying nutrient input is open to question. Increased oxygen levels may be associated with storm related turbulence at the breakwater but the high oxygen demand from debris and chemicals in runoff may negate such increases.

In December 1991 surface DO levels were the highest in all surveys except for 1977, when data were incomplete. The 1990 data showed a higher level at Ballona Creek in surface waters and in bottom waters at almost all stations. In 1984-1988 data were much more similar to one another and more uniform throughout the marina, but in 1989 and 1990 the decline from outer to inner marina were more pronounced.

The minimum, maximum and mean DO in October 1991 through June 1992 are listed in Table II.4, along with the tide phase during the sampling period.

The averages of all stations for minimum, maximum and mean DO by month are illustrated in Figure II.62. The general trend in the mean is downward from October to April, after which it rises. None of the monthly means for all stations approached the regulatory minimum standard of 5.0 ppm, but minima in March, April, May and June were below it, as discussed above.

The average DO for all depths and all months by station (Figure II.63) illustrates the general trend of decreasing DO from the marina entrance to the innermost basins, with

Oxford Street basin being the lowest.

Table II.4. Monthly dissolved oxygen minimum, maximum and mean (in ppm).

Month	Minimum	Station	Maximum	Station	Mean	Tide Phase
October	5.6	22	10.2	1	8.5	falling
November	6.3	13	9.8	1	8.3	falling
December	7.3	13	10.1	1	8.8	falling
January	5.5	13	9.4	12	7.7	rising/falling
February	5.7	22	9.6	1	8.0	rising/falling
March	4.4	20	8.2	12	5.5	high/falling
April	2.0	13	8.8	1	6.1	falling

June	4.3	20	8.8	2	6.6	falling

FIVE DAY BIOCHEMICAL DEMAND (BOD_5)

Biochemical oxygen demand is a comparative measure of the amount of biological or chemical material in the water column that will use up dissolved oxygen during microbial degradation. Sample bottles must be filled completely so that only oxygen dissolved in the water will be measured. The BOD_5 is measured in an arbitrary five day incubation period at 20 °C, predicated on the laboratory work week rather than any scientific basis and is not considered to be a very dependable method, although it is a widely used, traditional public water quality method. Samples from areas such as sewage and industrial waste plumes or in harbors and estuaries where loadings are high must be diluted to be certain that the oxygen is not depleted before the incubation period is over, leading to calculation of a falsely low estimate of demand.

The minimum, maximum and mean BOD_5 are illustrated in Figure II.64 for all stations and depths from October to June, and the data are tabulated in Table II.5.

The minimum for the period of October 1991 through June 1992 was 0.4 mg/l, which occurred three times at Station 7. The minimum was 0.1 mg/l higher than in 1990-1991. The minimum for the month occurred at Station 7 five out of nine months surveyed,

VOL 12

17755

at Station 5 in three surveys, at Stations 11 and 25 in two surveys and at Station 6 in one survey. This is in contrast to the previous period when the minimum was at Station 6 in four surveys. The highest minima occurred during May and June.

Table II.5. Monthly biochemical oxygen demand minimum, maximum and mean (mg/l).

Month	Minimum	Station	Maximum	Station	Mean	Tide Phase
October	0.4	7	2.8	22	0.9	falling
November	0.6	7,11	6.1	19	1.3	falling
December	0.4	7	2.4	22	0.9	falling
January	0.4	7	5.9	13	1.3	rising/falling
February*	0.6	10	18.9	22	2.2	rising/falling
March	0.5	25,5,7	2.7	22	1.0	high/falling
April	0.5	5	6.0	22	1.4	falling
May	0.7	6	7.8	12	2.3	falling
June	0.7	25,5,11,9	4.6	22	1.5	falling

* survey not completed at Stations 7,9,11 due to Life Guard emergency call.

The maxima showed no seasonal trend; the highest value was 18.9 mg/l in February 1992 at Station 22 during rain and storm turbulence. The peak in 1990-1991 was also in February but not during a rainy period and was only 15.3 mg/l. The second highest in 1992 was 7.8 mg/l in May at Station 12 in Ballona Creek, when storm drains may have been carrying runoff and debris from the Los Angeles area. The maxima were at Station 22 at the inner end of Oxford Street basin in six of nine months, and once at Station 13, at the outer end of Oxford Street basin. The only true marina station with a maximum was at Station 19, the wheel chair ramp at the beach in Basin D in November. Coliform and enterococcus bacteria levels were elevated at that station at the time, but higher levels occurred at Station 22 so the BOD would not appear to be due to fecal material. The low mean for that month indicates that the other values are low. The February maximum is quite distinct and the mean was correspondingly higher in the marina.

In Figure II.65, the average for all depths and all months surveyed is presented by

Station in distance from the breakwater. The influence of Oxford Street basin at Station 22 is pronounced. There is a gradient from Stations 12 and 1 in Ballona Creek through stations in the entrance and main channels which probably indicates the influence of Ballona Creek loadings as they extend, declining, into the marina as far as Station 5.

Monthly profiles of BOD_5 that are illustrated in Figures II.66 through II.74 show the trends in the averages for the entire period surveyed, but the monthly plots do not show the declining values from Ballona Creek as distinctively. Individual deviations, such as those around the Administration dock at Stations 4 and 25 in December illustrate a localized event, perhaps drainage there from the storm drain or from bait boat activity at the fishing dock.

HYDROGEN ION CONCENTRATION (pH)

The pH of sea waters generally ranges from 7.3 to 8.4 on a scale based on the negative logarithm of the hydrogen ion in gram atoms per liter, measurable on a hydrogen electrode but usually expressed without units other than number; the lower numbers are acidic and the higher ones basic chemically. Sea water is in the basic range. In October 1990-September 1991 the range was from 6.8 to 8.4, with the lowest values occurring at Stations 13 or 22 in Oxford Street flood control basin. In October 1991-June 1992, the range was slightly narrower, from 7.3 to 8.3, and with few exceptions the lowest values were again in Oxford Street basin. The maxima are usually found at Stations 12, 1 and 2, nearest the bay, as can be seen in Table II.6, below.

In spite of the large volume of storm water runoff carried by Ballona Creek, the pH was much more lower in runoff in Oxford Street basin, regardless of the tide phase. Figure II.75 illustrates the monthly minimum, maximum and mean calculated without Ballona Creek and Oxford Street basin, showing a relatively uniform range throughout the period, while Figure II.76 illustrates the same values when Ballona Creek and Oxford Street basin are included. The fluctuations are largely due to the latter; absence of data at the Oxford Street stations in February no doubt produced an artificially high minimum.

Table II.6. Monthly minimum, maximum and mean pH values.

Month	Minimum	Station	Maximum	Station	Mean	Tide Phase
October	7.8	13	8.3	12,1-4	8.2	falling
November	8.0	17,13,22	8.3	12,1-3	8.2	falling
December	7.9	13	8.3	1,2	8.1	falling
January	7.5	13,22	8.2	12,1-5,25,7	8.1	rising/falling
February*	7.9	6	8.1	12,1-3,18	8.0	rising/falling
March	no data due to probe malfunction					
April	7.1	22	8.3	12,1,2	8.1	falling
May	7.9	22	8.2	1-5,25	8.1	falling
June	7.3	22	8.2	12,1-4	8.1	falling

* Data incomplete, Stations 8-22, due to probe failure in rain; Stations 7, 9, 11 not sampled due to Life Guard emergency call.

There were rains for several days prior to the surveys in January, March and April, while it was raining during the February cruise. The February cruise was aborted without sampling Stations 7, 9, and 11 because the Life Guard vessel that provides transport for the survey was called on an emergency, the first time that this has happened since the surveys were resumed in 1984. The supposedly waterproof electronic readout panel had shorted out in the rain after the survey of Stations 12 and 1-6 was completed. The equipment was repaired but failed again in March, necessitating replacement of some equipment.

WATER COLOR (FOREL-ULE SCALE)

Water color is indicative of physical factors such as depth, substrate and suspended particulates, chemical factors, and biological factors such as bacteria and other microbials, and phytoplankton densities. Suspended particulates in turn are influenced by tide phase, winds, surf, and terrestrial runoff.

Color is measured by the Forel-Ule (FU) scale, which consists of a series of small vials filled with various marine colors or shades that are compared to the seawater viewed above a white Secchi disk suspended beneath the surface. Numbers 1 to 3 are deep sea blue, numbers 4 to 5 are blue green, 5 to 11 are increasingly darker greens, 12 to 15 are greenish browns, and 16 to 22 are increasingly darker browns. Color is a very subjective measure and it is essential to have the same person perform the observations in all surveys. It is not appropriate to use the FU scale in the shallow, restricted waters of Oxford Street basin. The complete FU data are included in Appendix B, Physical Water Quality. The monthly minimum, maximum and means are presented in Table II.7, below.

The lowest values, 4 and 5, generally occurred nearest the bay, although they were by no means restricted to that area. The highest value was a 17 at Station 12 in April, following se[illegible] l days of rain. Red tides may have been responsible for the high values throughout m[illegible] of the marina in May; runoff in the flood control channels in the previous two weeks from the Los Angeles area may have stimulated a general bloom, or may have added to turbidity, causing further discoloration.

Table II.7. Monthly color, Forel-Ule scale, minimum, maximum and mean[1].

Month	Minimum	Station	Maximum	Station	Mean	Tide Phase
October	5	1	10	2-4,5,7-10,18	8.7	falling
November	6	1,5,7,11	12	8	7.4	falling
December	5	1,2,6,7,20	10	18	6.5	falling
January	7	5-7,9,11	14	12	8.5	rising/falling
February*	10	4,25,6,8,10	15	12	11.6	rising/falling
March	6	1,2	12	7,8,10,18,20	9.5	high/falling
April	7	5,6	17	12	9.9	falling
May	10	6	14	12	12.3	falling
June	4	12	12	18	7.8	falling

* Stations 7, 9, 11 not sampled due to Life Guard emergency call.
[1] Forel-Ule not done at Stations 13, 22; water too shallow to determine marine colors.

Figure II.77 presents the minimum, maximum and mean for all stations surveyed by month, excluding the Oxford Street basin stations. There was rainfall runoff prior to the surveys in January, March and April, and it was raining in February when the surveys could not be completed. Figure II.78 illustrates the FU data for all months by station, excluding Oxford Street stations. Higher values are found at Ballona Creek Station 12 and in the restricted waters of Basin D, Stations 8 and 18, and in Basin E, Stations 10 and 20. The reduced flushing of those areas is probably a factor in the genesis of blooms.

WATER TRANSPARENCY

Water transparency varies with the amount of particulate matter or density of microbial and phytoplankton organisms. It is evaluated in two ways: by electronic measurement of percent light transmittance and by visual observation with a Secchi disk. A modified HydroProducts transmissometer having a self contained, white light with a 0.1 meter path, a constant length. Secchi disk observations, made as a white disk is lowered through the water column to a depth where it disappears from sight, are dependent on ambient light and the visual acuity of the observer.

Percent Light Transmission

Tables II.8 and II.9, below, present the minimum, maximum and means for percent light transmittance (%T) and Secchi disk respectively. Complete data are in Appendix B. As in other electronically measured parameters, that for %T are incomplete in February, perhaps skewing the data.

The narrowest ranges for %T were in November and December when waters were cooler and were clearer prior to turbidity produced by the rains of January through April. The minima (most turbid water with reduced light penetration) occurred at Stations 7, 9, 10, or 11. High %T (clearest water) was most often observed at stations 12 and 1, where it would be influenced by the clearer bay waters.

Secchi Disk

Minimum Secchi disk depths occurred primarily in the inner basins, where phytoplankton blooms are likely to be concentrated, except during the rainy periods of February, March, and April, and the possible fire-related runoff in May, which may have stimulated a general bloom. The value of 8 percent in April at Station 9 is anomalous; one

April	0.5	12,1	3.0	4,25,5,7	2.2	falling
May	2.0	12,3,7,9,18	3.0	6	2.3	falling
June	1.5	18	4.5	1	2.9	falling

* Stations 7,9,11 not sampled due to Life Guard emergency call.

Rainfall preceded survey days in January, February, March and April.
Possibly influenced by runoff from Los Angeles area.

would conclude that the probe was fouled; the Secchi disk depth is more consistent with those of other stations. The maximum depths of visibility occurred at Station 1, at the entrance to the bay, in non-rainy months but the maximum depths were scattered through the marina during low runoff periods.

Figure II.79 illustrates the minimum, maximum and mean percent light transmittance values, while Figure II.80 illustrates the Secchi disk depths for comparison. While the maxima and minima seem to diverge considerably, due in part to the anomalous April %T reading at Station 9, the averages are very similar.

CONCLUSIONS

Water quality in the marina is most strongly influenced by drainage from Oxford Street flood control basin and less so by waters from Ballona Creek flood control channel. Rainfall and consequent drainage produces the most obvious impacts on all parameters measured. Bloom conditions, as evidenced by high dissolved oxygen levels, were more pronounced in 1991-1992. There were several episodes of low dissolved oxygen in bottom waters in Basin E in March through June, but averages were not below 5.0 ppm.

III. NUTRIENTS

SOURCES AND FATES

Inorganic nutrients are necessary for supporting the normal functioning of marine ecosystems by providing the necessary raw materials for plant growth. The plant nutrients that are most likely to limit or regulate phytoplankton growth include nitrogen sources (nitrate, nitrite, and ammonia), phosphate and silicate. Carbon is also essential but is usually in sufficient quantity that it is seldom found to limit or regulate ph· plankton growth in marine systems. When the concentrations of these nutrients become exc. ive, a major algal bloom may occur. While this bloom may have an initial positive effect on the local ecosystem by photosynthetically increasing oxygen concentration in the water column and providing food for herbivorous organisms, the die-off of a massive bloom may result in decomposition and microbial respiration that consumes far more oxygen than the bloom left dissolved in the water column. Thus high concentrations of nutrients could be considered as pollutants if they occur in sufficient concentrations to produce such a bloom. Additional effects of blooms can include the blooming of toxic phytoplankton species including some dinoflagellates, and providing food for other organisms that may not be desirable for the ecosystem.

The functioning of phytoplankton and other forms of algae in a marine ecosystem also depends on the availability of light. While the organisms themselves affect the light field by absorbing the available light, other factors such as high turbidity caused by detritus and inorganic particulate material will strongly attenuate the light and limit the growth of the algae (Kirk, 1983). Thus light availability could become a regulating factor of nutrient cycling within the ecosystem. Although turbidity and light penetration are not the focus of this section, they are important to the fate of the nutrients within a given ecosystem.

In estuarine and coastal systems, nutrient sources are likely to include fresh water sources, in contrast to open ocean systems where the nutrient supply derives primarily from natural recycling processes. Where recycling is the primary nutrient source animals and microorganisms break down the organic matter of the phytoplankton, often releasing the nitrogen as ammonia (NH_3). Ammonia nitrogen may be taken up directly by plants to synthesize new organic matter or it may be oxidized first to nitrite (NO_2), then to the more stable form of nitrate (NO_3). Plants may take up nitrogen in any of these forms, but ammonia may be more readily taken up than oxidized forms of nitrogen because it can be directly incorporated into amino acids. Organic phosphate (PO_4), which is used for energy transfer, for synthesis of proteins and for nucleic acids, is rapidly cycled within the water column since the form that it occurs as most frequently within organisms, ortho-phosphate, is also the most abundant form in seawater. Dissolved ortho-silicate comes from both recycling and river input.

METHODS

Water samples for nutrient analysis were obtained at all stations with a Nauman sampler, a PVC, self-closing sampler, at two meter intervals beginning at the surface. One subsample was immediately acidified in the field with concentrated hydrochloric acid and held for later laboratory analysis with an Orion ammonia electrode. A second subsample was immediately frozen in dry ice for later analysis in the laboratory. This sample was thawed and analyzed for silicate, phosphate, nitrate, and nitrite on an AlpKem Rapid Flow Analyzer (RFA) 300 automated analytical chemistry instrument using methods described by Sakomoto et al. (1990). Subsamples for BOD determinations and for microbiological counts were chilled for analysis upon return to the laboratory.

VOL 12

RESULTS AND DISCUSSION

Ammonia-Nitrogen

Ammonia nitrogen (NH_3) is formed by the breakdown of organic material and recycling into inorganic nitrogen. In most ocean waters, the concentration of ammonia nitrogen is very low, usually less than 1 µg-at/l (1 µg-at/l = 14 µg ammonia nitrogen per liter). In southern California higher concentrations of ammonia (up to 25-30 µg-at/l) may be observed in association with anthropogenic sources such as ocean outfalls (e.g. Eppley et al., 1979; Jones et al., 1990). Therefore, high ammonia concentrations are often indicative of sources of pollutants. When ammonia nitrogen is present, it may be more readily consumed by phytoplankton than other inorganic forms of nitrogen because it can be used directly in the synthesis of amino acids within the cells.

Ammonia-nitrogen concentrations within Marina Del Rey are always higher than concentrations typically observed in Santa Monica Bay and the adjacent ocean waters (0-0.5 µg-at/l; Eppley, et al., 1979; Jones, et al., 1990, 1991), except near the Hyperion and Whites Point sewage outfalls. Minimum concentrations within the marina during October 1991 to June 1992, occurred most often near the marina entrance (Stations 1 and 2; Figure 12) where the proportion of Santa Monica Bay water is likely to be the greatest. These monthly minima ranged from 1 to 4 µg-at/l. The highest concentrations during this nine month period consistently occurred within the Oxford Street basin (Stations 13 and 22; Figures III.1-9 and III.12). Ammonia concentrations within Ballona Creek were not predictably higher than within the marina, and on three occasions, December 5, March 5, and June 11, the concentrations at Station 12 in Ballona Creek were among the lowest observed for the entire Marina sampling. There is a consistent annual average spatial pattern through the last three years of sampling that shows

1799

slightly higher concentrations of ammonium at the end of the basins where tidal exchange is lowest (Stations 6, 7, 8, 9, 10, 11, 18, 19 and 20). However, the pattern is not apparent for every month. In November 1991, May and June 1992, the concentrations at these inner basin stations were actually lower than in the main channel. However, on average ammonia concentrations were generally lowest within the Main channel and at the marina entrance (Stations 1, 2, 3, 4, 5, and 25), regions where tidal exchange should be greatest. The accumulation of ammonia at these inner basin stages may simply be due to increased nutrient recycling in these areas coupled with weak tidal exchange.

The monthly average ammonia concentrations for the entire basin during the preceding two years have generally been higher during June through January, and lower during February through May. For the nine month period from October 1991 through June 1992 the pattern is not clear. The average ammonia concentration in the basin rose steadily from October through January, followed by a decrease in February (Table III.1; Figure III.10). However, the concentrations then rose again in March and April and fell again in May and June. The highest average concentration within the marina was observed in January 1992, similar to the seasonal maximum that has been observed in the previous two years. There was no apparent relationship between the concentrations within Oxford Street basin and the average concentrations within the marina. The highest ammonia concentration (200 μg-at/l) observed in recent years occurred in Oxford Street Basin in February at Station 22 (Figure 5), when average concentrations within the marina were the second lowest for the nine month period. It was raining during this cruise, and sampling was incomplete; Stations 7, 9, and 11 had to be omitted due to an emergency call for the Life Guard vessel in use.

In comparison to previous years (1984-1990), the October 1991 ammonia concentrations were on average the lowest observed; October 1990 had been the previously lowest value in this series. The November and December 1991 observations were slightly higher than the concentrations observed in November and December 1990.

Nitrate plus Nitrite - Nitrogen

Nitrate (NO_3) is usually the most abundant form of inorganic nitrogen in the ocean. However, in the surface mixed layer nitrate concentrations may often be less than 0.1 µg-at/l and nitrite may have a similar range. Below this layer, often separated by the seasonal thermocline, nitrate concentrations may reach 30-40 µg-at/l. In the San Pedro-Santa Monica Basin, NO_3 concentrations reach 35 µg-at/l at depths of 600 m (Williams, 1986). Low surface concentrations are due to phytoplankton utilization and a low rate of supply of nitrate from

VOL 12

17801

below. Surface concentrations may reach values of 5-30 μg-at/l in coastal upwelling regions that are common to much of the California coast. Coastal upwelling is not a dominant process within Santa Monica Bay, but it does predictably occur off of Point Dume and Point Fermin when winds are favorable for upwelling. Within Santa Monica Bay, concentrations of 10-20 μg-at/l may occur at depths as shallow as 20 meters and can be transported to the surface by either wind-induced mixing or by local upwelling. The concentrations of nitrate plus nitrite (N+N) in sewage wastewater and sludge are two to three orders of magnitude less than the concentration of ammonia (Morel and Schiff, 1983). Thus, the impact of ocean outfall effluents on the coastal ocean nitrate plus nitrite concentrations is much less than for ammonia (e.g. Jones et al., 1991).

The measurement technique for nitrate requires that nitrate first be converted to nitrite (NO_2) which is then measured colorimetrically (Whitledge et al., 1981). The NO_3 concentration is derived from this by correcting for the efficiency of converting NO_3 to NO_2 and correcting for the ambient NO_2 concentration. Since NO_2 concentrations are generally much less than 1μg-at/l the correction is generally not large. In the following text, nitrate will be used in place of nitrate plus nitrite for brevity.

The average spatial pattern of nitrate within the marina tends to remain similar year to year. As in the October 1990-September 1991 data set, the nitrate concentration was, on average, lowest at Station 2 near the breakwater and increased toward the inner Marina basin and into Ballona Creek (Figure 24). As with ammonia, the highest nitrate concentrations usually occurred in Oxford Street basin. The low values at Station 2, and sometimes Station 1, reflect the influence of Santa Monica Bay water where near-surface nitrate concentration is low except during strong mixing or coastal upwelling events. When the nitrate concentrations reached their minima in May and June 1992, concentrations within the central channel (Stations 3, 4, 5, and

25) were <1 μg-at/l. Higher concentrations of nitrate were often observed at the ends of the basins, similar to the patterns observed in ammonia.

The highest nitrate concentrations during October 1991 through June 1992 occurred in Oxford Street basin, in Basin E near the flood gate from Oxford Street basin, or in Ballona Creek (Table III.2; Figures III.22-23). Concentrations at Station 12 in Ballona Creek were higher than nitrate concentrations at stations within the main channel of the marina, except in June 1992. At station 12, the high concentrations were usually from the surface sample indicating that the high NO_3 was associated with the freshwater coming down Ballona Creek. As in previous years, the highest concentrations within the marina occurred concentrations at Station 10 or 20 in Basin E, where water enters the marina from Oxford Street basin. A large, live-aboard vessel has been docked adjacent to the flood gate from Oxford Street basin (Station 20) until June of this year, partially obstructing flow into Oxford Street basin.

• Excluding Oxford Street basin and Ballona Creek, Stations 12,13, and 22.
' Rainfall during or prior to survey

The seasonal pattern of nitrate concentration within the marina during October 1991 through June 1992, was similar to the pattern for the previous two years. As in previous years, the average concentrations within the basin were highest during the early winter period, November through January (Table III.2 and Figure III.22). The nitrate began to decrease from its winter maximum in February and reached its minimum in May and June 1992. This trend was interrupted only in April when there was an increase to about 4 μg-at/l.

The highest individual concentrations observed during this nine month period (58 and 99 μg-at/l) are comparable to the maximum concentrations observed during the previous two years. These high concentrations are significantly greater than concentrations observed in the deep open ocean. The 58 μg-at/l peak occurred in February, during a 2.2 in. rainfall. There had been about 6 in. of rain early in January as well (see Appendix A). The rains may have resulted in a significant increase in nutrients within the marina. As stated in previous reports, higher concentrations may also result, in part, from reduced phytoplankton growth and nutrient uptake rates resulting from lower temperatures and lower available light levels. The deeper average secchi depths and increased beam transmission in the winter months (see Physical Water Quality, Chapter II) are consistent with lower phytoplankton abundance during this period. However, direct measurements of phytoplankton growth and nutrient utilization would be required to verify this possibility. The lower average NO_3 concentrations observed during May and June may reflect the reduced inflow from storm drain sources and higher phytoplankton productivity within the marina as day length and, therefore, light availability increase and temperature increases which enables higher phytoplankton growth rates (Eppley, 1972). During

VOL 12

11804

this period the concentrations in both Ballona Creek and especially in Oxford Street basin were much lower than during winter.

In comparison to the previous several years of observations, the nitrate plus nitrite concentrations during October-December (Figures 13-15), the period for which there are several years of observations, were relatively characteristic for each of the three months. The extremely high values in Ballona Creek and Oxford Street basin did not appear until January, similar to the pattern that has existed in previous years.

The absolute value of nitrate concentrations was generally less than ammonia concentrations during the October 1991-June 1992 period. In addition, the average spatial pattern was somewhat different between the two nitrogen-based nutrients (see Figure III.12 for NH_3 and 24 for N+N). In general, nitrate increased by a larger proportion in the inner basins relative to the main channel than did the ammonia concentrations. Also, the ratio of nitrate concentration in Ballona Creek to the concentrations in the main channel was usually greater than the same ratio for ammonia concentration. While the average distributions for both nutrients indicate high concentrations in Oxford Street basin (Figures 12 and 24), comparison of the monthly patterns (Figures III.1-9 for ammonia, and Figures III.13-21 for nitrate) shows that ammonia was almost always significantly higher in Oxford Street basin, while there were several months (September, October, December, and May) when the nitrate in Oxford Street basin was only marginally higher than in the inner basins of the marina.

<u>Total Dissolved Inorganic Nitrogen</u>

Total dissolved inorganic nitrogen (DIN) is the sum of the three measured nitrogen based nutrients: nitrate, nitrite, and ammonia. While there may be other forms of inorganic nitrogen which may contribute to the DIN we have assumed that these additional contributions are minimal and that the overall DIN concentration can be characterized by these three nutrients. The DIN thus provides an estimate of the total nitrogen available to the phytoplankton and attached algae for their growth. The monthly spatial distributions of DIN are shown in Figures 25-33.

The monthly average DIN concentrations listed in Table III.3 indicate that the highest concentrations within the marina occurred during the winter months, especially November through January. The lowest concentrations, similar to the 1990-91 observations occurred in May and June. Based on previous years, we would expect the lower concentrations to persist through the summer. The overall range of values for the October 1991-June 1992 period is comparable to previous data from the marina.

Phosphate

Inorganic phosphate in the ocean of the Southern California Bight region ranges from more than 3.5 µg-at/l at depths of 800-900 meters in the basins to less than 0.5 µg-at/l in surface waters (Williams, 1986). As with the other nutrients, local variations may be mediated by ocean outfalls, coastal upwelling and turbulent mixing processes. Unlike nitrate, phosphate is seldom depleted in the surface waters of the ocean and few situations occur where phosphate is likely to regulate or limit the primary production of phytoplankton. Phosphates are readily used by the bacteria, as well as by phytoplankton. Phosphorous is important for proteins, nucleic acids and energy transfer within organisms.

The spatial distributions of phosphate (Figures III.34-42) are generally similar to the spatial patterns of nitrate. High phosphate concentrations were always observed in Oxford Street basin. Relatively high concentrations usually occurred in the surface sample at Station 12; March and June were exceptions to this pattern when Station 12 was among the stations lowest in phosphate. As with nitrate and ammonia, the lowest phosphate concentrations within the basin usually occurred at Station 1 or 2, near the breakwater (Table III.4; Figures III.34-42 and III.45). Phosphate concentrations usually increased at the inner basins (Stations 6, 7, 8, 9, 10, 18, 19, and 20) relative to the Main Channel. In most cases, the highest concentrations in the marina itself occurred at Stations 10 and 20 in Basin E, near the flood gate from Oxford Street basin.

The seasonal range of average phosphate concentrations within the marina during October 1991-June 1992 (0.8-1.4 µg-at/l; Table III.4 and Figure 43) was similar to the range for the same period during the previous year (0.7-1.4 µg-at/l; Soule, et al., 1992). The two highest average concentrations occurred during the winter months of December and January. This was much less than the relative range of the average concentrations for either nitrate or silicate. The minimum average concentration occurred in May 1992, when rainfall runoff was low.

The general range of concentrations for the October 1991- June 1992 period is similar to the range for the previous two years. The clearest pattern that emerges from these three years of observations is that the highest concentrations occur during the winter months, but the annual cycle of phosphate variation does not appear to be as clear and repeatable as does that annual cycle of average nitrate concentration within the marina.

Silicate

Silicate concentrations in the ocean surrounding Los Angeles are often relatively low at the surface, ranging from nearly unmeasurable concentrations to several microgram-atoms per liter. In the deep basins, silicate concentrations may approach 100 μg-at/l at depths of 800-900 meters (Williams, 1986). Low silicate concentrations in the upper layer result primarily from uptake by diatoms when nitrate and phosphate are sufficient to promote their growth (e.g. Broecker and Peng, 1982). It is not uncommon in the oceanic euphotic zone for residual silicate concentrations of 2-5 µg-at/l to occur after phytoplankton have reduced the available nitrogen to <0.1 µg-at/l. Silicate concentrations are often high in freshwater inflows into the coastal environment.

The spatial patterns for silicate were very similar to the patterns for phosphate and nitrate (nine month erage distribution is shown in Figure III.57 and monthly distributions in Figures III.46-54). . :latively high concentrations were usually observed in the Oxford Street basin and at the surface at Station 12 in Ballona Creek. Silicate concentrations within the marina were generally low at Stations 1 and 2, near the breakwater, and increased toward the inner basins.

The average silicate concentrations within the marina were highest in October 1991 and June 1992. The minimum average concentrations occurred in March and April (Table III.5 and Figures III.55-56), despite the heavy rainfall that occurred in the Los Angeles area in the months preceding both of these cruises. Similar patterns have been seen in previous years when the minimum appeared in the spring and, also when there were rains preceding the monthly sampling. However, the minimum monthly averages in 1992 were at least 50 percent greater than the minima observed in the past two years. In 1990 the spring minimum was about 4 µg-at/l and in 1991 the minimum was about 6 µg-at/l. While the minimum average concentrations were higher during October 1991-June 1992, the maximum average concentrations were lower than in the previous two years. The maximum concentrations for the basin were >13 µg-at/l in October 1991 and June 1992, but the maximum average concentration 1989 was >20 µg-at/l, and in June 1991 it was >17 µg-at/l. Although, the complete summer data

(July-September 1992) are not available, the trend that is apparent with high concentrations in October 1991, at the end of the 1991 summer period, and in June 1992 at the beginning of the 1992 summer period, is similar to the pattern of high concentrations in the summers of 1990 and 1991. We do not have a clear explanation of this seemingly repeatable annual cycle. Whether high summer concentrations are due to increased input of silicate into the marina from an unknown source, or to decreased uptake of silicate possibly due to a shift from a diatom dominated phytoplankton community that requires silicate for growth to a dinoflagellate community that does not require silicate, remains unknown to us.

Silicate concentrations and distributions during for the fall period, October-December, for which there is the greatest amount of historical data, compare well with observations from previous years. Both the general spatial patterns and the magnitude of concentrations are similar.

CORRELATIONS WITH OTHER VARIABLES

We have examined the interrelationships of nutrients with other variables in an attempt to understand the processes that may affect the variability of nutrients within Marina Del Rey, and hence the potential large phytoplankton blooms and their associated consequences. In the ocean there are usually predictable relationships of one nutrient with another and of nutrients with physical variables such as temperature and salinity. For example, nitrate concentrations can usually be correlated with temperature, particularl; low the euphotic zone (e.g. Zentara and Kamykowski, 1977).

The relationship between nutrients and temperature within the marina is not as direct as it is for coastal and open ocean situations. The clearest temperature/nutrient relationship for the October 1991-June 1992 data set is between temperature and phosphate. Phosphate decreased from a high value of about 1.5 µg-at/l at 14°C to 0.8-1.0 µg-at/l for temperatures 17°C and warmer. Other nutrients had a less clear pattern. However, the phosphate/temperature relationship was similar in pattern to the nitrate/temperature relationship in the October 1990-September 1991 data set.

Another relationship that would seem likely to provide insight into the nutrient variability is the relationship between salinity and nutrients. Over the past several years we have observed that nutrient concentrations within the marina often increase immediately after a substantial rainfall. This would suggest that nutrient concentrations within the marina would tend to increase with decreasing salinity. When the monthly average nutrient concentrations are correlated with the monthly average salinity concentrations for the basin, very little relationship seems to exists between salinity and the nutrient concentrations. However, if we consider the nine-month average of nutrients and salinity at each sampling point, which provides the nine-month average spatial distributions for the marina, then nutrient concentrations generally tend to increase with decreasing salinity. This suggests that a major portion of the nutrients within the marina comes from the inputs from Oxford Street basin and Ballona Creek. This is not an unexpected result.

Other relationships have been explored within the available data set. Nutrients have been compared with the physical variables of temperature and salinity, the chemical variables of dissolved oxygen and pH, and the microbiological and BOD measurements. At this time, we have not found any clear relationships between the monthly basin averages of these variables other than discussed above. This last nine month period, has coincided with a major El Nino event which resulted in warmer temperatures in Santa Monica Bay and changes in some of the fish populations observed in the local ocean. However, nutrient variability within the marina appears to be relatively uncoupled from Santa Monica Bay and therefore this large scale variation in the ocean does not have a strong effect on the nutrients within the marina.

When the nine month averages for each sampling point (location and depth) of the different variables are intercompared, then there are some definable relationships between nutrients and other variables. The most basic relationship is with salinity. There is generally a negative correlation between salinity and nutrients, i.e. higher nutrient concentrations are found in fresher water. In addition, the nutrients generally correlate well with each other in this spatial pattern. When compared with phosphate, the other nutrients increase relatively linearly with respect to phosphate concentration.

CONCLUSIONS

In most respects the nutrient variability within Marina Del Rey was similar during October 1991-June 1992, to observations from previous years. For most of the nutrients the ranges of nutrient concentration were similar. Silicate was the one nutrient that seemed to have a narrower range of average concentrations than in previous years. Seasonal patterns of nutrient variability were less well defined during this period than in previous years. Phosphate demonstrated the clearest seasonal pattern: concentrations were high during the winter months and were at a minimum of 0.8-1.0 μg-at/l during the warmer (T>17°C) months.

As we have concluded in previous reports, the primary input of nutrients into the marina is from freshwater sources, especially Oxford Street basin and Ballona Creek. The observation of increased nutrients immediately after episodes of measurable rainfall that has been seen in previous years was not as apparent in this year's data set. Perhaps, because there was significantly more rain during the winter (see cruise logs, Appendix A) the effect of any one rain event was not as large as it might have been in previous years where rain events were relatively infrequent. Nutrient measurements in the coastal ocean off of Palos Verdes during the February storms did not demonstrate large nutrient concentrations associated with the freshwater runoff layers, in contrast to what we had expected.

The nine month period of October 1991 through June 1992 was anomalous in comparison to the recent years. The seasonal patterns of nutrient variability were less pronounced, and the relationships between different variables were less clear. It is possible that the major El Nino that occurred during this period could have had an affect on these observations. However, as we stated above, the nutrient variability within the marina appears to be uncoupled from the coastal ocean where El Niño effects were very apparent.

IV. SEDIMENT COMPOSITION AND CONTAMINATION

INTRODUCTION

Sediments in the marina area before construction were a mixture of large grained barrier beach sands and fine grained sediments that had accumulated in the slowly draining wetlands. The marina benthos is largely composed of finer sediments due to seaward movement of heavier sands where flushing is relatively good and the settling of finer materials in the low energy basins and inner channels. No extensive deposition of sediment has occurred in the inner basins, but coastal sand transport has caused large sandbars to accumulate at the entrance of the marina trapping finer sediments behind them. This further reduces flushing in the marina and caused increased deposition of fine sediments. Since contaminants adhere to or complex with the finer grained sediments, the distribution of fines will, in large measure, affect the distribution of contaminants in the marina. The lack of substantial rainfall for several years further reduced flushing. Two major storms in the spring of 1991 may have flushed the marina but brought other sediments in to accumulate additional fine grained material and associated contaminants.

PROCEDURES

Sediment samples were taken at 15 stations on 17 October 1991 from the University of Southern California R.V *Golden West* by Campbell grab (modified Van Veen), which samples a 0.1 m^2 of surface. Budget cuts precluded performing a May 1992 survey for comparison. Aliquots of sediment samples were taken for determination of grain size, trace metals and nonmetallic contaminants, and pesticides and chlorinated hydrocarbons before screening for benthic fauna. Samples for chemical analysis were placed in clean plastic containers, frozen with dry ice on board and transported to Associated Laboratories in Orange, California where they were kept frozen until analyzed. Techniques used are those specified by the U.S. Environmental Protection Agency or Standard Methods (APHA, 1985).

GRAIN SIZE

Grain size is a relative measurement of sediment size determined by sieving sediments through a series of screens of graded mesh size. The larger the screen mesh number, the finer the sediments are that will pass through the screen, with the finest grain size determined as passing through a 200 mesh screen (<200). The size of sediment grains determines whether the benthos will consolidate and remain stable, or will be subject to disturbances and redistribution, whether chemicals will attach to particles in quantity, and what kinds of fauna will live in or on the substrate.

RESULTS: GRAIN SIZE

Comparison of the October 1991 results with those of October 1990 and May 1991 (Tables IV. 1-3) show that there were increases in the finest grained sediments, in May 1991 following spring storms at Stations 1, 3, 5, 7, 8, and 13; the increases were especially large at Stations 3, 8 and 13. Each station may be responding to combinations of different factors depending on the area drained into the marina.

Dry weather runoff, drainage flow and extremes in tidal action carry sediment laden waters into the marina where low flushing causes fine sediments to settle out. This is illustrated by results from the October 1991 survey, which showed increases in the finest component (<200) at every station over the May 1991 levels. Large increases occurred in Ballona Creek and the entrance channel, at Stations 12, 1, 2, and 4, in Basin B, at station 6, and in Oxford Street basin at Stations 13 and 22.

There was a loss of larger grained sediments and sand (25 mesh screen size). In October 1990 the only stations lacking the largest grain sizes were Stations 5 and 11, which had no sand. In May 1991, only Station 5 had no sand, but fines accumulated during dry weather so that by October 1991, Stations 4, 5, 7, 9 and 11 had no sand, while Stations 5, 7, 9, and 11 had no slightly smaller particles (mesh size 5) and Station 5 had no mesh size 60 particles (Table IV.3). Station 5, in mid-main channel, appears to accumulate fines moving out of the basins nearby, as is also indicated by sulfide buildup there. The only station to show a slight increase in sand was Station 1, at the mouth of Ballona Creek.

CONCLUSIONS: GRAIN SIZE

The accumulation of fine sediments during and following a period of heavy rainfall is not surprising. The larger accumulation during dry weather is indicative of reduced flow volume and velocity in the flood control channels; increased deposition in the marina may be caused by the occlusion of the entrance of the marina. The siltation of Basin D is of concern because it represents a considerable change in that valuable habitat which may be associated with the destabilizing effects of loss of the seagrass bed.

SEDIMENT CONTAMINANTS

INTRODUCTION

Sources of contaminants in the marina have been reviewed extensively in earlier reports (e.g., Soule et al., 1992), and range from the minor spillage of oil and grease associated with vessel fueling and operation, to coastal oil spills, marina storm drain runoff, sewage leaks or overflows and drainage from the flood control channels. These channels are recipients of street runoff and illegal dumping of trash, particularly plastic containers, yard debris including Christmas trees, and contaminants such as used motor oil, paint and pesticides.

Oxford Street flood control basin seems to carry a heavier load of contaminants which is quite out of proportion to the relatively small volume of drainage that enters the marina from that source, as compared with the very large volume of water carried by Ballona Creek, especially during wet weather flow. Drainage from the Oxford Street basin will be increased by the Los Angeles County Flood Control District to ameliorate surface street flooding adjacent to the basin, which may wash more contaminants into the marina, or could help to flush it, depending on the sources of the present contamination. Terrestrial sediments in adjacent properties sometimes carry a heavy burden of contaminants due to earlier industrial use or unregulated dumping in the area.

Contaminated sediments tend to be carried through the tide gate opening at a greater velocity near Station 13 than is found at either Station 22 at the inner end of the Oxford Street basin, or at Station 10 at the end of the slips in Basin E. Additional docks constructed recently to serve restaurants at the inner end of the basin seem to have become occupied docks, further reducing the already very poor rate of flow in Basin E. Sediments accumulate under the docks and slip facilities where water velocities are lowest.

Ballona Creek drains a large section of the northwestern Los Angeles basin. Overflow of partially treated (screened) sewage into Ballona Creek during dry weather seems to have been controlled in the last few years by construction of holding tanks; however, such waters are released during storms to prevent overwhelming the Los Angeles

City Hyperion waste treatment plant facilities. Chlorination is performed as a public health measure, which is given paramount importance over considerations of habitat, but if residual chlorine remains in the waters after treatment, it can be harmful to marine organisms exposed to it, particularly to sensitive larval and juvenile stages.

RESULTS: METALS AND NONMETALLIC CONTAMINANTS

Reported in this section are results from samples at 15 stations analyzed for 20 metals and nonmetallic indicators of pollution; analyses for pesticides and chlorinated hydrocarbons are discussed in the subsequent section. As has been done in previous reports, stations were ranked from 1, the cleanest, to 15, the most contaminated, for the 20 parameters. Rankings were then added up to develop scores for each station. The highest possible score would be 300 under this system.

In Table IV.4, rankings for October 1990, May 1991 and October 1991 are compared (in Soule et al., 1992, a typographical error led to a slightly different ranking of a few stations; this has been corrected in the present table).

Of particular importance is the large increase in contamination at Station 8 in Basin D, near the marina beach. Its score has risen from 137 in October 1990 to 178 in May 1991 and to 205 in October 1991. Another large increase occurred at Station 3, which rose from 46, the lowest, to 178, medium high and dropped a small amount to 164 over the three surveys. These scores can be compared with the Ballona Creek scores of 108, 97 and 87 at Station 12 and the scores of 147, 64 and 55 at Station 1 at the mouth of the Creek, over the same periods. There was a decrease at Station 2, at the sandbar, from 150 in May to 96 in October 1991, perhaps due to extreme low tides, up to -1.5 ft, in June and July.

As is usual, the most contaminated were Stations 10 and 9, followed by either Station 11 or 25. The three inner marina stations, 9, 10, and 11, receive extensive drainage and have the poorest circulation. Station 25 is probably the busiest location in the marina, with the U.S Coast Guard, Los Angeles County Sheriff's Patrol and Lifeguard *Bay Watch* vessels operating there, the day excursion fishing vessels and dock fishing adjacent, and drainage from parking lots.

NONMETALLIC CONTAMINANTS

Distribution and concentrations of nonmetallic contaminants are illustrated in Figures IV.1-9, and the data are presented in Table IV.5. Table IV.6 gives ranges of contaminants from 1985 through 1991. In general, there were higher mean levels in these parameters in October 1991 than there were in October 1990, but the larger increases had occurred in the spring prior to the May 1991 survey after rainstorms, indicating that some dry weather decrease occurred. Exceptions were in percent Volatile Solids, Total Organic Carbon and Immediate Oxygen Demand, where means increased from May to October 1991.

<u>Percent Moisture</u>

Among the nonmetallic contaminants listed, percent moisture is indicative of the
