Under the Phase II rule, a storm water discharge control program that meets the requirements of six minimum control measures would be administered within the jurisdiction of all regulated small MS4s. Small MS4 operators would design and administer the program, or would arrange with other government entities (including operators of nearby larger MS4s) to do so. These minimum control measures would consist of: public education and outreach on storm water impacts, public involvement/ participation, illicit discharge detection and elimination, construction site storm water runoff control, post-construction storm water management in new development and redevelopment, and pollution prevention/good housekeeping for municipal operations. The Agency provides an analysis of the costs to local governments of implementing the six municipal minimum control measures in Section B below.

Municipal Construction:

The 1990 Phase I rule required all operators of construction activity disturbing five or more acres of land surface to apply for an NPDES permit for any resulting point source discharges of storm water.[1] The construction provisions of the Phase II rule would extend similar requirements to construction projects that disturb between one and five acres of land. This provision would impose additional requirements on small construction projects of local governments, regardless of whether the local government is urban, suburban or rural. The rule excludes routine road maintenance from the definition of construction, thereby excluding many municipal public works projects. EPA expects that most new one to five acre road construction projects are likely to be built in conjunction with either larger development projects or State and Federal transportation programs and at least partially funded by these other sources. The Phase II rule would also provide waivers from coverage based on the potential to discharge storm water and cause a significant impact to water quality. EPA's analysis of construction starts concluded that the additional requirement for municipally constructed projects should not have a significant impact on a substantial number of the local governments subject to the regulation. EPA reports on its analysis of the costs to local governments of implementing the soil erosion control provisions for their construction sites between one and five acres in Section C below.

Regulatory Flexibility:

In promulgating Storm Water Phase II, EPA examined regulatory flexibility issues and potential cost impacts on small entities, including small local governments. In order to solicit input from potentially regulated small entities, EPA convened a Small Business Regulatory

[1] On December 18, 1991, Congress enacted the Intermodal Surface Transportation Efficiency Act (ISTEA), which postponed NPDES permit application deadlines for most storm water discharges associated with industrial activity at facilities that are owned or operated by small municipalities, including construction activity over five acres.

Enforcement Flexibility Act (SBREFA) Panel which included small local government representatives as well as other stakeholders. EPA conducted an analysis and determined that the rule was expected not to have a significant impact on a substantial number of small local governments or other small entities. However, in order to provide additional flexibility for small local governments, EPA included several programmatic options and potential waivers for small governments.

The rule would allow for a great deal of flexibility by providing various options for obtaining permit coverage and satisfying the required minimum control measures. For example, the NPDES permitting authority would be able to incorporate by reference qualifying State, Tribal, or local programs in a NPDES general permit and recognize existing responsibilities among different governmental entities for the implementation of minimum control measures. In addition, a regulated small MS4 could participate in the storm water management program of an adjoining regulated MS4 and could arrange to have another governmental entity implement a minimum control measure for them. The rule also provides potential waivers for MS4s serving a population less than 10,000 and also for construction projects not expected to significantly impair water quality. Therefore, Storm Water Phase II is not expected to have a significant impact on a substantial number of small local governments, and offers significant flexibility to those local governments in implementing provisions of the rule which may result in compliance cost impacts.

B. Impacts of the Municipal Minimum Control Measures on Local Governments

EPA estimated that the overall annual cost to local governments of implementing a storm water program based on the six minimum measures would be $297 million. EPA developed this estimate using actual program cost information from Phase II communities with existing storm water programs. The estimate assumes that all of the 5,040 Phase II designated municipalities would incur program costs and that costs are related to the size of the community served. Therefore, the Agency probably overestimates national costs because permitting authorities can waive permitting requirements for MS4s serving up to 10,000 people.

EPA conducted an in-depth analysis of the potential cost of complying with the six minimum measures on local governments in urbanized areas. These local governments are primarily urban and suburban, although a few rural governments may be designated by States to be included in the program based on potential water quality impacts. While the total regulatory costs associated with Phase II include all sizes of local government, EPA specifically considered the impacts to small local governments as required under the Regulatory Flexibility Act, as amended by the Small Business Regulatory and Enforcement Fairness Act. In preparing the analysis, EPA compared estimated annual compliance costs with annual municipal revenues for 4,455 small local governments (municipalities with fewer than 50,000 people) and evaluated cost-to-revenue ratios for indication of significant economic impacts. The results, which are reported in the economic analyses prepared for the proposed and final rules, led EPA to conclude that there would not be a substantial economic impact on a significant number of small governments; EPA expects even less of an impact on larger governments. Below is a summary of EPA's analysis.

Cost Analysis:

EPA estimated annual costs for the municipal programs based on a fixed cost component and a variable cost component. The fixed cost component included costs for the municipal application, record keeping, and reporting activities. On average, EPA estimated annual costs of $1,525 per municipality. Variable costs include the costs associated with annual operations for the six minimum measures. EPA reviewed cost data from existing Phase I storm water programs and cost data gathered from Phase II communities by the National Association of Flood and Storm Water Management Agencies (NAFSMA). These costs reflect the actual operating costs of program elements that are comparable to the six minimum measures for municipalities representing a wide range of population sizes. EPA estimated costs on a per household basis from both data sets. Annual mean costs per household are comparable across the data sets: $8.93 (NASFMA) and $8.85 (Phase I).

Total annual cost for each of the 4,455 municipalities was calculated as the sum of the $1,525 fixed cost and the urbanized area household estimate multiplied by the per household cost based on the NAFSMA data.[2] For example, a municipality with 5,000 households would have a total program cost of:

$$\$46,175 = \$1,525 + (5,000 * \$8.93).$$

Small Local Governments:

EPA estimated municipality revenues based on state-level revenue data collected by the U.S. Bureau of the Census 1992 Census of Governments. The Bureau of the Census reports municipal government revenues by population size for eight size categories including three used by EPA: less than 10,000, 10,000 to 24,999, and 25,000 to 49,999. For every state, EPA gathered the aggregate municipal revenue data and aggregate municipal population data reported by the Bureau of the Census for these three size categories.[3] EPA then divided revenue by population to obtain revenue per capita for each size category within each state. EPA merged this data set with the Phase II municipality population data set and multiplied the appropriate per capita revenue estimates by the Phase II urbanized area populations to obtain 4,455 estimates of annual municipal revenues.

---

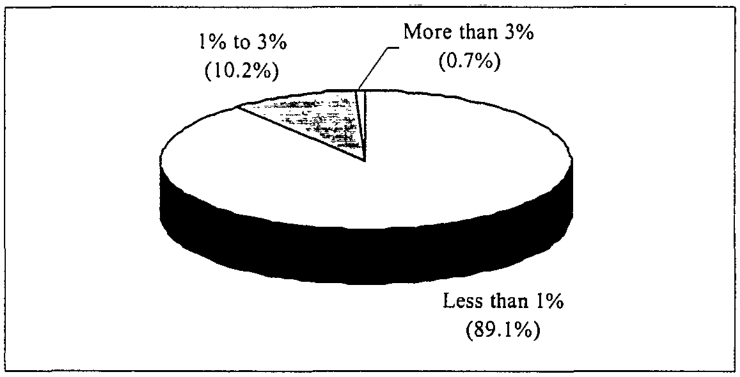
[2] Based on Census data, EPA used a conversion factor of 2.62 people per household to obtain household estimates for the Phase II communities.

[3] EPA did not adjust municipal revenue from their 1991 values to 1998 values, which is the unit of measure EPA used for costs. There is no standard adjustment factor for municipal revenues. Thus, the cost-to-revenue ratio probably overstates the cost impact.

Finally, EPA divided the 4,455 cost estimates by the 4,455 revenue estimates to obtain cost-to-revenue ratios. EPA categorized these ratios according to whether they were less than 1% (i.e., cost is less than 1% of revenue), between 1% and 3%, and greater than 3%. Figure A summarizes the results, showing that the cost-to-revenue ratios were less than 1% for 89% of the Phase II municipalities and greater than 3% for less than 1% of municipalities.

Under, the Phase II rule, the permitting authority could waive permitting requirements for systems serving less than 1,000 people. All of the municipalities with cost-to-revenue ratios that are greater than 3% have populations less than 1,000 people, and may qualify for a waiver. Consequently, the flexibility of the rule addresses any potentially significant adverse cost impacts. Because no Phase II municipality with a population of more than 6,000 had a cost-to-revenue ratio of more than 1%, EPA does not expect this provision will have significant economic impacts on the 585 municipalities with populations larger than 50,000.

Figure A. Summary of Cost-to-Revenue Ratios for 4,455 Phase II Municipalities with Populations Less than 50,000



C. Costs of the Soil Erosion Control Provision on Local Governments

EPA's cost analysis for the soil erosion control provision multiplies cost estimates per construction site for soil erosion control measures and administrative costs by the number of construction sites potentially affected by the rule. EPA estimates that the rule would apply to approximately 110,223 currently unregulated construction starts per year (using 1998 estimates) out of a total of 528,499 construction starts. Annual costs associated with installing the soil erosion controls and completing permitting activities is estimated as $505 million. Less than 0.5% (< $500,000) is expected to accrue from local governments.

Cost Analysis:

Most soil erosion control costs would accrue to the private sector, primarily to dischargers in the construction industry. However, local governments may also incur soil erosion control costs for discharges from public works projects that disturb between one and five acres (costs borne either directly by the local government or indirectly through a contractor). Since routine road maintenance is excluded from coverage under Storm Water Phase II, those public works starts are excluded from analysis. EPA used the site-based estimates of soil erosion control costs that it developed for the economic analysis of the final rule and Bureau of Census construction start data to estimate the expected annual impact on local governments. Table A summarizes the two types of costs by site size that a construction company or public works department may incur.

Table A. Summary of Site-Based Soil Erosion Control Costs

Cost	1 Acre Site	3 Acre Site	5 Acre Site
Administrative [a]	$937	$937	$937
Soil Erosion Control BMPs [b]	$1,206	$4,598	$8,709
Total Cost	$2,143	$5,535	$9,646
Annualized Cost (7%)[c]	$202	$522	$910

Notes:
a. These activities would include costs to submit a notice of intent to be covered by a general permit, to notify the municipality, to develop a storm water pollution prevention plan, to retain records, and to file a notice of termination from a general permit.
b. BMPs (best management practices) costs are based on combinations of the following that differ across sites with different sizes, slopes, and soil types: silt fence, mulch, seed/mulch, stabilized entrance, stone check dam, earth dike, and sediment traps.
c. Annualized cost assumes a 20-year period and a 7% cost of capital. The capitalization factor is 0.09439.

Small Local Governments:

There are four categories of local governments which may experience costs of compliance associated with the Phase II rule. These are:

1) Phase I jurisdictions (subject to Phase II requirements for construction between one and five acres; already required to have a municipal storm water program),
2) Phase II jurisdiction above 50,000 population (subject to Phase II municipal and construction requirements),
3) Phase II jurisdictions below 50,000 population (subject to Phase II municipal and construction requirements; subject to SBREFA review), and
4) Jurisdictions that are not required to have a municipal storm water program under

Phase I or Phase II (subject to Phase II requirements for construction).

The greatest potential economic impact of the soil erosion control provision is expected to be on the third category, because they would incur soil and erosion control costs in addition to annual program costs for the six minimum measures, and because of their smaller size. Therefore, the analysis below focuses on the impacts on these small local governments.

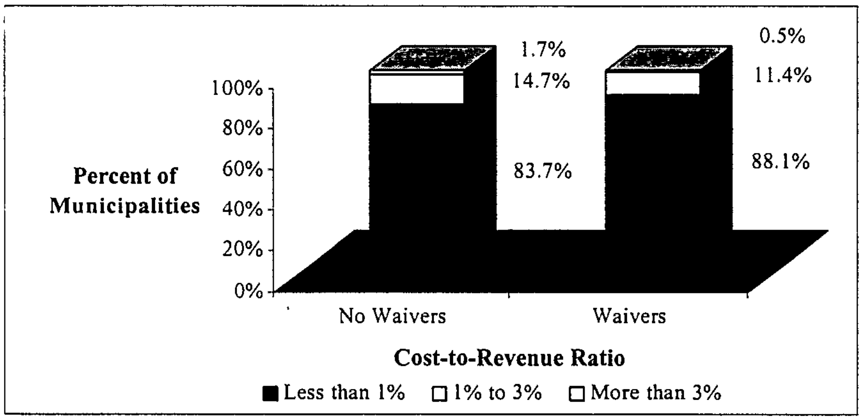
To evaluate the severity of potential impact, EPA used the Bureau of the Census construction start database to estimate the annual number of construction starts in Phase II municipalities that are classified by the Bureau of the Census as a "public works" start, excluding routine road maintenance. The data showed that 2% of municipalities are expected to have a 1-acre start, 2% are expected to have a 3-acre start and 1% are expected to have a 5-acre start. These results indicate that local governments would not incur soil and erosion control costs on an annual basis, because they would not necessarily have Phase II construction starts in any given year. As a conservative assumption (i.e., tending to overstate costs), EPA annualized the costs over a 20-year period, assuming a 7% cost of capital (see Table A). The 20-year assumption is conservative because it implies higher construction rates than the data suggest [i.e., 1-acre site (5%), 3-acre site (5%), and 5-acre site (5%)]. EPA then added the annualized values to obtain an annual cost of $1,634 per municipality for the soil erosion control provision.

Because the soil erosion control provision of the Phase II rule would apply to discharges from construction sites between one and five acres regardless of location, local governments other than Phase II designated municipalities could incur costs. EPA compared the annualized value across all site sizes of $1,634 to the national mean estimate of local government revenues. For the smallest municipality size category, the mean annual revenue was $1.4 million (1991 dollars; 1992 Census of Governments). The cost-to-revenue ratio for the smallest size category is well below 1%.

Finally, EPA then added the cost of complying with the Phase II soil erosion program for small construction to the cost-to-revenue ratios for the MS4 program discussed above to evaluate the combined impact on Phase II municipalities of the municipal minimum measures and soil erosion control costs that may be borne directly or indirectly (passed through from construction companies). Based on this revised cost-to-revenue analysis, the combined costs are not expected to have a significant economic impact on a substantial number of designated Phase II municipalities.

Figure B summarizes the cost-to-revenue impacts for all 4,455 Phase II municipalities with populations less than 50,000 (bar on left). Figure B also summarizes impacts for these Phase II municipalities assuming that the municipalities with populations below 1,000 are granted waivers so they incur soil erosion control costs as regulated small construction site dischargers but no program costs as small MS4 dischargers (bar on right). In either case, a vast majority of municipalities would not incur annual costs that are greater than 1% of revenues and fewer than 2% of municipalities would incur costs that are greater than 3% of revenues. Therefore, EPA concluded that the Phase II rule would not have a significant impact on potentially regulated small local governments.

Figure B. Summary of Cost-to-Revenue Ratios Revised to Include Soil Erosion Control Costs for 4,455 Phase II Municipalities with Populations under 50,000



* "No Waivers" estimates costs assuming (for the purpose of this analysis) that no small local governments with populations below 1,000 receive a waiver and, therefore, are subject to both the municipal and the soil erosion provisions of Phase II. Even if this were to occur, the potential impacts are not significant.

III. RATIONALE FOR THE ONE ACRE CONSTRUCTION THRESHOLD

This section responds to the Appropriations Act's direction to provide a report containing:

"(2) an explanation of the rationale of the Administrator for lowering the construction site threshold from 5 acres to 1 acre, including --
(A) an explanation, in light of recent court decisions, of why a 1-acre measure is any less arbitrarily determined than a 5-acre measure; and
(B) all qualitative information used in determining an acre threshold for a construction site;"

BACKGROUND

In 1990, EPA promulgated the first phase of the NPDES permit application rules for storm water. (*National Pollutant Discharge Elimination System Permit Application Requirements for Storm Water Discharges*, 55 Fed. Reg. 47990 (Nov. 16, 1990), referred to as the "Phase I" rule). As directed under CWA section 402(p)(4)(A), the Phase I rule set forth the permit application requirements for storm water discharges "associated with industrial activity," including, applicability provisions defining the term "storm water discharge associated with industrial activity." Under CWA section 402(p)(2)(B), storm water discharges associated with industrial activity were excluded from the moratorium against permitting discharges composed entirely of storm water.

Among other things, the Phase I rule defined storm water discharge associated with industrial activity to include discharges from "construction activity including clearing, grading and excavation activities except: operations that result in the disturbance of less than five acres of total land area which are not part of a larger common plan of development or sale." 40 C.F.R. 122.26(b)(14)(x). In 1992, a court ruled that the five acre threshold used for defining construction activity as "industrial activity" was improper because EPA had failed to identify information to support its position that construction activities on less than five acres are non-industrial in nature.

The Phase II rule would regulate storm water discharges from additional smaller construction activities. The rule would regulate these construction-related storm water sources under CWA section 402(p)(6) to protect water quality rather than under CWA section 402(p)(2). Designation under 402(p)(6) gives States and EPA the flexibility to waive the permit requirement for construction activity that is not likely to impair water quality, and to designate additional sources below one acre that are likely to cause water quality impairment. Thus, the one acre threshold under the Phase II rule would not be an absolute threshold like the five acre threshold that applies under the Phase I rule. The one acre threshold is reasonable for accomplishing the water quality goals of CWA section 402(p)(6) because it results in 97.5% of the total acreage disturbed by construction being designated for coverage by the NPDES storm water program, while excluding from automatic coverage the numerous smaller sites that represent 24.7% of the total number of construction sites.

Rationale for Five Acre Threshold in the Phase I Rule

In the preamble to the Phase I rule, which regulates storm water discharges from construction activity disturbing five acres or more as "storm water discharges associated with industrial activity," EPA had explained that the construction industry should be subject to storm water permitting because at a high level of intensity, construction is equivalent to other regulated industrial activities. 55 Fed. Reg. 48033. The Phase I rule regulates storm water "associated with industrial activity." EPA had proposed that the Phase I regulations apply to construction site discharges from sites disturbing down to one acre. EPA increased the size threshold to five acres for the final rule.

After a judicial challenge to the Phase I regulations, the Ninth Circuit remanded the regulation to EPA for further proceedings. NRDC v. EPA, 966 F.2d 1292, 1306 (9th Cir. 1992). To support the increased threshold (from one to five acres), the Agency had explained that larger sites typically involve heavier equipment for removing vegetation and bedrock than smaller sites. 55 Fed. Reg. 48036. The court found that EPA's rationale for increasing the limit was inadequate because the Agency cited no information to support its perception that construction activities on less than five acres are non-industrial in nature. 966 F.2d at 1306. Thus, the Court focused on the relationship between the size threshold and the statutory reference to "industrial."

Rationale for One Acre Threshold in the Phase II Rule

In lowering the threshold to one acre in the Phase II rule, the Phase II rule would not regulate discharges from small construction site as "industrial activity." Instead, EPA interprets the text of CWA section 402(p)(6) as a basis to designate small construction site discharges as sources "to be regulated to protect water quality." EPA interprets this language as less restrictive than the terms "associated with industrial activity" for the purpose of establishing an applicability threshold that is based on size alone but which may be modified by permitting authorities to account for higher and lower threat sources. In addition to water quality considerations, the text of CWA section 402(p)(6) allows for designations based on considerations of administrative feasibility by specifying that the Agency has discretion to identify sources "to be regulated."

Though the Phase II rule would not regulate a discharge from a construction site below the five acre threshold as a "discharge associated with industrial activity," the Phase II rule nonetheless responds to the Ninth Circuit's direction to conduct further rulemaking on the matter of discharges from sites disturbing more than one acre (from the Phase I proposed rule) and from sites disturbing less than five acres (from the Phase I final rule). For discharges from sources in this category, which the Agency still believes present water quality concerns based on the potential for water quality impairment due to gross sediment runoff (among other pollutants), CWA section 402(p)(6) rather than CWA section 402(p)(2)(B) and (3) provides a more sensible basis to address the sources that threaten water quality. In light of the Agency's decision to regulate these sources down to one acre to protect water quality with controls similar to those applied to Phase I sources, EPA believes it is unnecessary to examine further whether sites below five acres are "associated with industrial activity."

EPA is regulating storm water discharges from construction activity disturbing between 1 and 5 acres because the cumulative impact of many sources, and not just a single identified source, is typically the cause for water quality impairments, particularly in relation to sedimentation-related water quality standards.

The one acre threshold provides an administrative tool for more easily identifying those sites that are identified for coverage by the rule (but may receive a waiver) and those that are not automatically covered (but may be designated for inclusion). Although all construction sites less than five acres could have a significant water quality impact cumulatively, EPA is automatically designating for permit coverage only those storm water discharges from construction sites that disturb land equal to or greater than one acre. Categorical regulation of discharges from construction below this one acre threshold would overwhelm the resources of permitting authorities and might not yield corresponding water quality benefits. Construction activities that disturb less than one acre make up, in total, a very small percentage of the total land disturbance from construction nationwide (about 2.5%).

In addition to the diminishing water quality benefits of regulating all sites below one acre, the Agency relies on practical considerations in establishing a one acre threshold and not setting a lower threshold. Regardless of the threshold established by EPA, a NPDES permit can only be required if a construction site has a point source discharge. A point source discharge means that pollutants are added to waters of the United States through a discernible, confined, discrete conveyance. "Sheet flow" runoff from a small construction site would not result in a point source discharge unless and until it channelized. As the amount of disturbed land surface decreases, precipitation is less likely to channelize and create a "point source" discharge (assuming the absence of steep slopes or other factors that lead to increased channelization). Categorical designation of very small sites may create confusion about applicability of the NPDES permitting program to those sites. EPA's one acre threshold reflects, in part, the need to recognize that smaller sites are less likely to result in point source discharges. Of course, the NPDES permitting authority could designate smaller sites (below one acre, assuming point source discharges occur from the smaller designated sites) for regulation if a watershed or other local assessment indicated the need to do so. The Phase II rule would include this designation authority at 40 CFR 122.26(a)(9)(i)(D) and (b)(15)(ii).

Though location-specific water quality studies would provide the ideal information base from which to make regulatory decisions, the Phase II rule establishes one acre as a default standard for regulation in the absence of location-specific studies. The rule does account for location-specific water quality information, however, for any deviation from the default standard through additional designations and waivers. The rule codifies the ability of permitting authorities to provide waivers for sites greater than or equal to one acre and designate additional discharges from small sites below one acre when location-specific information suggests that the default one acre standard is either unnecessary (waivers) or too limited (designations) to protect water quality.

<u>OTHER QUALITATIVE AND QUANTITATIVE INFORMATION ON SIZE THRESHOLDS</u>

EPA had difficulty evaluating the water quality consequences of designating specific size thresholds because, while generally proportional to the size of the disturbed site, the water quality threat posed by discharges from construction sites of differing sizes varies nationwide, depending on the local climatological, geological, geographical, and hydrological influences. In order to ensure improvements in water quality nationwide, however, the Phase II rule does not allow various permitting authorities to establish different size thresholds except based on the waiver and designation provisions of the rule. EPA believes that a national one acre threshold for automatic designation, coupled with procedures for waiving sites above one acre and for designating sites below one acre based on local water quality considerations, ensures protection against adverse water quality impacts from storm water discharges from small construction sites while not overburdening the resources of permitting authorities and the construction industry.

EPA believes that the water quality impact from small construction sites is as high as or higher than the impact from larger sites on a per acre basis. The concentration of pollutants in the runoff from smaller sites is similar to the concentrations in the runoff from larger sites. The proportion of sediment that makes it from the construction site to surface waters is likely the same for larger and smaller construction sites in urban areas because the runoff from either site is usually delivered directly to the storm drain network where there is no opportunity for the sediment to be filtered out.

The expected contribution of total sediment yields from small sites depends, in part, on the extent to which erosion and sedimentation controls are being applied. Because current storm water regulations are more likely to require erosion and sedimentation controls on larger sites in urban areas, smaller construction sites that lack such programs are likely to contribute a disproportionate amount of the total sediment from construction activities (MacDonald, L.H. 1997. <u>Technical Justification for Regulating Construction Sites 1-5 Acres in Size</u>. Unpublished report submitted to the U.S. Environmental Protection Agency, Washington). Smaller construction sites are less likely to have an effective plan to control erosion and sedimentation, are less likely to properly implement and maintain their plans, and are less likely to be inspected (Brown, W. and D. Caraco. 1997. <u>Controlling Storm Water Runoff Discharges from Small Construction Sites: A National Review</u>. Submitted to the U.S. Environmental Protection Agency, Office of Wastewater Management, Washington, DC. by the Center for Watershed Protection, Silver Spring, MD).

To confirm its belief that sediment yields from small sites are as high as or higher than the 20 to 150 tons/acre/year measured from larger sites, EPA gave a grant to the Dane County, Wisconsin Land Conservation Department, in cooperation with the USGS, to evaluate sediment runoff from two small construction sites. The first was a 0.34 acre residential lot and the second was a 1.72 acre commercial office development. Runoff from the sites was channeled to a single discharge point for monitoring. Each site was monitored before, during, and after construction.

The Dane County study found that total solids concentrations from these small sites are similar to total solids concentrations from larger construction sites. Results show that for both of the study sites, total solids and suspended solids concentrations were significantly higher during construction than either before or after construction. For example, preconstruction total solids concentrations averaged 642 mg/L during the period when ryegrass was established, active construction total solids concentrations averaged 2,788 mg/L, and post-construction total solids concentrations averaged 132 mg/L (on a pollutant load basis, this equaled 7.4 lbs preconstruction, 35 lbs during construction, and 0.6 lbs post-construction for total solids). While this site was not properly stabilized before construction, after construction was complete and the site was stabilized, post-construction concentrations were more than 20 times less than during construction. The results were even more dramatic for the commercial site. The commercial site had one preconstruction event, which resulted in total solids concentrations of 138 mg/L, while active construction averaged more than 15,000 mg/L and post-construction averaged only 200 mg/L (on a pollutant load basis, this equaled 0.3 lbs preconstruction, 490 lbs during construction, and 13.4 lbs post-construction for total solids). The active construction period resulted in more than 75 times more sediment than either before or after construction (Owens, D.W., P. Jopke, D.W. Hall, J. Balousek and A. Roa. 1997. "Soil Erosion from Small Construction Sites in Dane County, Wisconsin." Draft Report. USGS and Dane County Land Conservation Department, WI).

Construction start data indicates that excluding construction sites below one acre from coverage under the Phase II rule would exclude a significant percentage of sites from automatic coverage while only excluding a small percentage of the total acreage. As is indicated in Table B, by choosing a nationwide threshold of one acre, the Phase I and Phase II rules will together address 97.5% of the national disturbed acreage yet will only regulate 75.3% of the construction starts. The remaining construction starts (24.7% or 130,435 starts) each occur on less than one acre of disturbed land and together constitute only 2.5% of total acreage disturbed by construction.

Table B. Percentage of national disturbed acreage and construction starts addressed by regulating all construction above different thresholds

	percentage of national disturbed area controlled by regulating all sites:	number of construction starts addressed (percent of national total)
all sites	100 %	527,774 (100 %)
greater than 1.0 acres	97.5 %	397,309 (75.3 %)
greater than 2.0 acres	92.3 %	301,941 (57.2 %)
greater than 3.0 acres	87.8 %	253,224 (48.0%)
greater than 4.0 acres	83.7 %	221,471 (42.0 %)
greater than 5.0 acres	78.1 %	188,425 (35.7 %)

* Table includes all construction starts. It does not exclude starts already regulated by Phase I, equivalent State programs, or potential Phase II waivers.

A two acre threshold would have tripled the total number acres that would not be designated for permit coverage. A threshold below one acre would have significantly increased the number of sites regulated without significantly increasing the number of acres for which storm water controls would be required. Thus, the additional increment in water quality protection that would be achieved by a lower size threshold would have resulted in a disproportionately higher burden on the regulated community.

Conclusion On One Acre Threshold

The Ninth Circuit concluded that EPA arbitrarily defined discharges "associated with industrial activity" when the Agency established the five acre size threshold, particularly in light of the Agency's proposal to establish the threshold at one acre. The Phase II one acre threshold is not arbitrary because (1) sediment loads from disturbed land surface cause adverse impacts on water quality, (2) as site size decreases, the likelihood that precipitation will create "discernible, confined, discrete conveyances" through channelization decreases, (3) the one acre threshold is not an absolute threshold because NPDES authorities can waive the threshold for sites (and during seasons) when there is a lower potential for a discharge that would impair water quality and can designate sources below the threshold where necessary to protect water quality on a localized basis, and (4) the number of additional sites that would be regulated by a threshold below one acre is disproportionately high relative to the total number of acres disturbed by those sites.

EPA recognizes that the size criterion alone may not be a perfect predictor of the need for regulation, but effective protection of water quality depends as much on simplicity in implementation as it does on the scientific information underlying the regulatory criteria. The default size criterion of one acre will ensure protection against adverse water quality impacts from storm water discharges from small construction sites while not overburdening the resources of permitting authorities and the construction industry to implement the program to protect water quality in the first place. Further, as noted above, NPDES permit authorities can designate sources below one acre where necessary to protect water quality in a particular area, or waive sites above one acre where NPDES permit coverage under the Phase II rule is not necessary to protect water quality.

IV. STORM WATER PROBLEMS IN CENSUS DESIGNATED URBANIZED AREAS

This section responds to the Appropriations Act's direction to provide a report containing:

"(3) documentation demonstrating that storm water runoff is generally a problem in communities with populations of 50,000 to 100,000 (including an explanation of why the coverage of the regulation is based on a census-determined population instead of a water quality threshold);

BACKGROUND

In 1990, EPA promulgated the first phase of the NPDES permit application rules for storm water ("Phase I"). Phase I required NPDES permits for storm water discharges from large and medium municipal separate storm sewer systems generally serving populations of 100,000 or more. Areas with a combined sewer were not included in the total population served for Phase I.

This definition of large and medium MS4s for Phase I created so-called "donut holes." Donut holes are unregulated MS4s located within those urbanized areas that include systems covered by the Phase I storm water program, but are not currently addressed by the storm water program because the Phase I regulations specify applicability based on political jurisdiction. In other words, donut holes are geographic gaps in the existing NPDES storm water program's regulatory scheme. Storm water discharges from donut hole areas present a problem due to their adverse impacts on local waters, as well as by frustrating the attainment of water quality goals of neighboring regulated communities.

The storm water Phase II rule designates discharges from small MS4s located in urbanized areas for NPDES permit coverage. EPA adopted the Bureau of the Census definition of an urbanized area as comprising a place and the adjacent densely settled surrounding territory that together have a minimum population of 50,000 people. A permitting authority may designate additional small MS4s after the authority develops designation criteria and applies those criteria to small MS4s located outside of an urbanized area, in particular those with a population of 10,000 or more and a population density of at least 1,000 per square mile. The permitting authority may waive the requirement for a permit for any small MS4 serving a jurisdiction with a population of less than 1,000 unless storm water controls are needed because the MS4 is contributing to a water quality impairment. The permitting authority may also waive permit coverage for MS4s serving a jurisdiction with a population of less than 10,000 if all waters that receive a discharge from the MS4 have been evaluated and discharges from the MS4 do not significantly contribute to a water quality impairment or have the potential to cause an impairment. The Phase II rule also allows States with a watershed permitting approach to phase in coverage for MS4s in jurisdictions with populations under 10,000.

EPA'S RATIONALE FOR BASING REGULATION ON CENSUS-DETERMINED POPULATION RATHER THAN A WATER QUALITY THRESHOLD

EPA adopted the Bureau of the Census definition of "urbanized area" for the purposes of the Phase II rule. The existing storm water Phase I rule already covers discharges from MS4s with more than 100,000 population. Phase II would address the remaining MS4s in urbanized areas.

The Bureau of the Census defines an urbanized area as comprising a place and the adjacent densely settled surrounding territory that together have a minimum population of 50,000 people. The densely settled surrounding territory generally has at least 1,000 people per square mile. The Bureau of the Census definition of "urbanized area," adopted by EPA for the purposes of the Phase II rule, was published in the Federal Register (55 FR 42592, October 22, 1990).

EPA is using urbanized areas to automatically designate regulated small MS4s on a nationwide basis for several reasons:

(1) Water Quality Impacts from Urban Runoff

Studies and data show a high correlation between degree of development/ urbanization and adverse impacts on receiving waters due to storm water. See section A below for a full discussion of storm water impacts due to urban development.

(2) Addresses gaps in coverage

The blanket coverage within the urbanized area encourages the watershed approach and addresses the problem of "donut-holes," where unregulated areas are surrounded by areas regulated under Phase I.

(3) Pollution Prevention

This approach targets present and future growth areas as a preventative measure to help ensure water quality protection. Urbanized areas have experienced significant growth over the past 50 years. According to EPA calculations based on Census data from 1980 to 1990, the national average rate of growth in the United States during that 10-year period was more than 4 percent. For the same period, the average rate of growth within urbanized areas was 15.7 percent and the average for outside of urbanized areas was just more than 1 percent. Table C below illustrates the growth of urbanized areas for the past five Census (EPA, 1995). The new development occurring in these growing areas can provide some of the best opportunities for implementing cost-effective storm water management controls.

Table C. Growth of Urbanized Areas in the United States Between 1950 and 1990

Year	Number of Urbanized Areas	Population in Urbanized Areas (millions)			Land Area (sq. mi.)
		Total	Central Cities	Urban Fringe	
1950	157	69.2	48.4	20.9	19,728
1960	213	95.8	57.9	37.8	25,544
1970	273	120.7	65.1	55.6	35,081
1980	366	139.2	67.0	72.1	52,017
1990	405	160.4	79.7	80.7	61,520

(4) Simplified Designation and Coverage

The determination of urbanized areas by the Bureau of the Census allows operators of small MS4s to quickly determine whether they are included in the NPDES storm water program as a regulated small MS4.

Using urbanized areas as a basis for designation effectively targets resources to the most densely developed territory. The 405 urbanized areas in the United States cover only 2 percent of the total U.S. land areas yet contain approximately 63 percent of the nation's population.

DOCUMENTATION OF WATER QUALITY PROBLEMS DUE TO STORM WATER RUNOFF FROM URBANIZED AREAS

EPA has compiled a number of studies demonstrating that storm water runoff is generally a problem in urbanized areas. This information is divided into storm water impacts due to urban development (section A below) and other discharges to municipal storm sewers (section B below). The Appropriations Act specifically requested that this report provide "documentation demonstrating that storm water runoff is generally a problem in communities with populations of 50,000 to 100,000." While 50,000 is the population threshold used by the Bureau of the Census for defining urbanized areas and EPA adopted the Census definition for the purpose of automatic designation in the Phase II rule, the studies below indicate that water quality impacts will occur in these areas and potentially in areas with lower population densities as well. The Phase II rule would allow the lower population density areas to be designated on a case by case basis.

A. Storm Water Impacts Due to Urban Development

EPA's 1995 Storm Water Phase II Report to Congress (EPA, 1995) and the Coastal Zone Management Measures Guidance (EPA, 1992) describe the impacts from urbanization. Urbanization impacts water quality principally through changes in hydrology and increases in pollutant loadings. Increases in population density and imperviousness due to urbanization can result in significant changes to stream hydrology including:

- increased peak discharges compared to predevelopment levels;
- increased volume of urban runoff produced by each storm in comparison to predevelopment conditions;
- decreased time needed for runoff to reach the stream, particularly if extensive drainage improvements are made;
- increased frequency and severity of flooding;
- reduced streamflow during prolonged periods of dry weather due to reduced level of infiltration in the watershed;
- greater runoff velocity during storms due to the combined effects of higher peak discharges, rapid time of concentration, and the smoother hydraulic surfaces that occur as a result of development.

An increase in imperviousness can also significantly decrease the amount of water infiltration, reducing groundwater recharge.

The types of pollutants found in urban runoff include sediment, nutrients, oxygen-demanding substances, pathogens, road salts, hydrocarbons, heavy metals, and toxics. In addition, thermal impacts from increased temperature of urban runoff and loss of riparian habitat can severely impair aquatic organisms that have finely tuned temperature limits.

1. Urbanization and Imperviousness

Urbanization alters the natural infiltration capability of the land and generates a host of pollutants that are associated with the activities of dense populations, thus causing an increase in storm water runoff volumes and pollutant loadings in storm water discharged to receiving waterbodies (U.S. EPA, 1992). Urban development increases the amount of impervious surface in a watershed as farmland, forests, and meadowlands with natural infiltration characteristics are converted into buildings with rooftops, driveways, sidewalks, roads, and parking lots with virtually no ability to absorb storm water. Storm water and snow-melt runoff wash over these impervious areas, picking up pollutants along the way while gaining speed and volume because of their inability to disperse and filter into the ground. What results are storm water flows that are higher in volume, pollutants, and temperature than the flows in less impervious areas, which have more natural vegetation and soil to filter the runoff (U.S. EPA, 1997. Urbanization and Streams: Studies of Hydrologic Impacts. EPA 841-R-97-009. Office of Water. Washington, DC).

Studies reveal that the level of imperviousness in an area strongly correlates with the quality of the nearby receiving waters. For example, a study in the Puget Sound lowland ecoregion found that when the level of basin development exceeded 5 percent of the total impervious area, the biological integrity and physical habitat conditions that are necessary to support natural biological diversity and complexity declined precipitously (May, C.W., E.B. Welch, R.R. Horner, J.R. Karr, and B.W. May. 1997. Quality Indices for Urbanization Effects in Puget Sound Lowland Streams, Technical Report No. 154. University of Washington Water Resources Series). Research conducted in numerous geographical areas, concentrating on various variables and employing widely different methods, has revealed a similar conclusion: stream degradation occurs at relatively low levels of imperviousness, such as 10 to 20 percent (even as low as 5 to 10 percent according to the findings of the Washington study referenced above) (Schueler, T.R. 1994. "The Importance of Imperviousness." Watershed Protection Techniques 1(3); May, C., R.R. Horner, J.R. Karr, B.W. Mar, and E.B. Welch. 1997. "Effects Of Urbanization On Small Streams In The Puget Sound Lowland Ecoregion." Watershed Protection Techniques 2(4); Yoder, C.O., R.J. Miltner, and D. White. 1999. "Assessing the Status of Aquatic Life Designated Uses in Urban and Suburban Watersheds." In Proceedings: National Conference on Retrofits Opportunities in Urban Environments. EPA 625-R-99-002, Washington, DC; Yoder, C.O and R.J. Miltner. 1999. "Assessing Biological Quality and Limitations to Biological Potential in Urban and Suburban Watersheds in Ohio." In Comprehensive Stormwater & Aquatic Ecosystem Management Conference Papers, Auckland, New Zealand). Furthermore, research has indicated that few, if any, urban streams can support diverse benthic communities at imperviousness levels of 25 percent or more. An area of medium density single family homes can be anywhere from 25 percent to nearly 60 percent impervious, depending on the design of the streets and parking (Schueler, 1994).

In addition to impervious areas, urban development creates new pollution sources as population density increases and brings with it proportionately higher levels of car emissions, car maintenance wastes, pet waste, litter, pesticides, and household hazardous wastes, which may be washed into receiving waters by storm water or dumped directly into storm drains designed to discharge to receiving waters. More people in less space results in a greater concentration of pollutants that can be mobilized by, or disposed into, storm water discharges from municipal separate storm sewer systems. A modeling system developed for the Chesapeake Bay indicated that contamination of the Bay and its tributaries from runoff is comparable to, if not greater than, contamination from industrial and sewage sources (Cohn-Lee, R. and D. Cameron. 1992. "Urban Stormwater Runoff Contamination of the Chesapeake Bay: Sources and Mitigation." The Environmental Professional, Vol. 14).

2. Large-Scale Studies and Assessments

In support of Phase II's regulatory designation of MS4s in urbanized areas, the Agency relied on broad-based assessments of urban storm water runoff and related water quality impacts, as well as more site-specific studies. The first national assessment of urban runoff characteristics was completed for the Nationwide Urban Runoff Program (NURP) study (U.S. EPA. 1983.

Results of the Nationwide Urban Runoff Program, Volume 1 - Final Report. Office of Water. Washington, D.C.). The NURP study is the largest nationwide evaluation of storm water discharges, which includes adverse impacts and sources, undertaken to date.

EPA conducted the NURP study to facilitate understanding of the nature of urban runoff from residential, commercial, and industrial areas. One objective of the study was to characterize the water quality of discharges from separate storm sewer systems that drain residential, commercial, and light industrial (industrial parks) sites. Storm water samples from 81 residential and commercial properties in 22 urban/suburban areas nationwide were collected and analyzed during the 5-year period between 1978 and 1983. The majority of samples collected in the study were analyzed for eight conventional pollutants and three heavy metals.

Data collected under the NURP study indicated that discharges from separate storm sewer systems draining runoff from residential, commercial, and light industrial areas carried more than 10 times the annual loadings of total suspended solids (TSS) than discharges from municipal sewage treatment plants that provide secondary treatment. The NURP study also indicated that runoff from residential and commercial areas carried somewhat higher annual loadings of chemical oxygen demand (COD), total lead, and total copper than effluent from secondary treatment plants. Study findings showed that fecal coliform counts in urban runoff typically range from tens to hundreds of thousands per hundred milliliters of runoff during warm weather conditions, with the median for all sites being around 21,000/100 ml. This is generally consistent with studies that found that fecal coliform mean values range from 1,600 coliform fecal units (CFU)/100 ml to 250,000 cfu/100 ml (Makepeace, D.K., D.W. Smith, and S.J. Stanley. 1995. "Urban Storm Water Quality: Summary of Contaminant Data." Critical Reviews in Environmental Science and Technology 25(2):93-139). Makepeace, et al., summarized ranges of contaminants from storm water, including physical contaminants such as total solids (76 - 36,200 mg/L) and copper (up to 1.41 mg/L); organic chemicals; organic compounds, such as oil and grease (up to 110 mg/L); and microorganisms.

Monitoring data summarized in the NURP study provided important information about urban runoff from residential, commercial, and light industrial areas. The study concluded that the quality of urban runoff can be affected adversely by several sources of pollution that were not directly evaluated in the study, including illicit discharges, construction site runoff, and illegal dumping. Data from the NURP study were analyzed further in the U.S. Geological Survey (USGS) Urban Storm Water Data Base for 22 Metropolitan Areas Throughout the United States study (Driver, N.E., M.H. Mustard, R.B. Rhinesmith, and R.F. Middleburg. 1985. U.S. Geological Survey Urban Storm Water Data Base for 22 Metropolitan Areas Throughout the United States. Report No. 85-337 USGS. Lakewood, CO). The USGS report summarized additional monitoring data compiled during the mid-1980s, covering 717 storm events at 99 sites in 22 metropolitan areas and documented problems associated with metals and sediment concentrations in urban storm water runoff. More recent reports have confirmed the pollutant concentration data collected in the NURP study (Marsalek, J. 1990. "Evaluation of Pollutant Loads from Urban Nonpoint Sources." Wat. Sci. Tech. 22(10/11):23-30; Makepeace, et al., 1995).[4]

America's Clean Water - the States' Nonpoint Source Assessment (Association of State and Interstate Water Pollution Control Administrators (ASIWPCA). 1985. America's Clean Water - The States' Nonpoint Source Assessment. Prepared in cooperation with the U.S. EPA, Office of Water, Washington, DC), a comprehensive study of diffuse pollution sources conducted under the sponsorship of the Association of State and Interstate Water Pollution Control Administrators (ASIWPCA) and EPA revealed that 38 States reported urban runoff as a major cause of designated beneficial use impairment and 21 States reported storm water runoff from construction sites as a major cause of beneficial use impairment. In addition, the 1996 305(b) Report (U.S. EPA. 1998. The National Water Quality Inventory, 1996 Report to Congress. EPA 841-R-97-008. Office of Water. Washington, DC), provides a national assessment of water quality based on biennial reports submitted by the States as required under CWA section 305(b) of the CWA. In the CWA 305(b) reports, States, Tribes, and Territories assess their individual water quality control programs by examining the attainment or nonattainment of the designated uses assigned to their rivers, lakes, estuaries, wetlands, and ocean shores. A designated use is the legally applicable use specified in a water quality standard for a watershed, waterbody, or segment of a waterbody. The designated use is the desirable use that the water quality should support. Examples of designated uses include drinking water supply, primary contact recreation (swimming), and aquatic life support. Each CWA 305(b) report indicates the assessed fraction of a State's waters that are fully supporting, partially supporting, or not supporting designated beneficial uses.

In their reports, States, Tribes, and Territories first identified and then assigned the sources of water quality impairment for each impaired waterbody using the following categories: industrial, municipal sewage, combined sewer overflows, urban runoff/storm sewers, agricultural, silvicultural, construction, resource extraction, land disposal, hydrologic modification, and habitat modification. The 1996 Inventory, based on a compilation of 60 individual 305(b) reports submitted by States, Tribes, and Territories, assessed the following percentages of total waters nationwide: 19 percent of river and stream miles; 40 percent of lake, pond, and reservoir acres; 72 percent of estuary square miles; and 6 percent of ocean shoreline waters. The 1996 Inventory indicated that approximately 40 percent of the Nation's assessed rivers, lakes, and estuaries are impaired. Waterbodies deemed as "impaired" are either partially supporting designated uses or not supporting designated uses.

The 1996 Inventory also found urban runoff/discharges from storm sewers to be a major source of water quality impairment nationwide. Urban runoff/storm sewers were found to be a source of pollution in 13 percent of impaired rivers; 21 percent of impaired lakes, ponds, and

---

[4] EPA notes that it is not relying solely on the NURP study to describe current water quality impairment. Rather, EPA is citing NURP as a source of data on typical pollutant concentrations in urban runoff. Recent studies have not found significantly different pollutant concentrations in urban runoff compared to the original NURP data (see Makepeace, et al., 1995; Marsalek, 1990; and Pitt, et al., 1995).

reservoirs; and 45 percent of impaired estuaries (second only to industrial discharges). In addition, urban runoff was found to be the leading cause of ocean impairment for those ocean miles surveyed.

In addition, a recent USGS study of urban watersheds across the United States has revealed a link between urban development and contamination of local waterbodies. The study found the highest levels of organic contaminants, known as polycyclic aromatic hydrocarbons (PAHs) (products of combustion of wood, grass, and fossil fuels), in the reservoirs of urbanized watersheds (U.S. Geological Survey (USGS). 1998. Research Reveals Link Between Development and Contamination in Urban Watersheds. USGS news release. USGS National Water-Quality Assessment Program).

Urban storm water also can contribute significant amounts of toxicants to receiving waters. Pitt, et. al. (1993), found heavy metal concentrations in the majority of samples analyzed. Industrial or commercial areas were likely to be the most significant pollutant source areas (Pitt, R., R. Field, M. Lalor, M. Brown 1993. "Urban stormwater toxic pollutants: assessment, sources, and treatability" Water Environment Research, 67(3):260-75).

3. Local and Watershed-Based Studies

In addition to the large-scale nationwide studies and assessments, a number of local and watershed-based studies from across the country have documented the detrimental effects of urban storm water runoff on water quality. A study of urban streams in Milwaukee County, Wisconsin, found local streams to be highly degraded due primarily to urban runoff, while three studies in the Atlanta, Georgia, region were characterized as being "the first documentation in the Southeast of the strong negative relationship between urbanization and stream quality that has been observed in other ecoregions" (Masterson, J. and R. Bannerman. 1994. "Impacts of Storm Water Runoff on Urban Streams in Milwaukee County, Wisconsin." Paper presented at National Symposium on Water Quality: American Water Resources Association; Schueler, T.R. 1997. "Fish Dynamics in Urban Streams Near Atlanta, Georgia." Technical Note 94. Watershed Protection Techniques 2(4)). Several other studies, including those performed in Arizona (Maricopa County), California (San Jose's Coyote Creek), Massachusetts (Green River), Virginia (Tuckahoe Creek), and Washington (Puget Sound lowland ecoregion), all had the same finding: runoff from urban areas greatly impair stream ecology and the health of aquatic life; the more heavily developed the area, the more detrimental the effects (Lopes, T. and K. Fossum. 1995. "Selected Chemical Characteristics and Acute Toxicity of Urban Stormwater, Streamflow, and Bed Material, Maricopa County, Arizona." Water Resources Investigations Report 95-4074. USGS; Pitt, R. 1995. "Effects of Urban Runoff on Aquatic Biota." In Handbook of Ecotoxicology; Pratt, J. and R. Coler. 1979. "Ecological Effects of Urban Stormwater Runoff on Benthic Macroinvertebrates Inhabiting the Green River, Massachusetts." Completion Report Project No. A-094. Water Resources Research Center. University of Massachusetts at Amherst.; Schueler, T.R. 1997. "Historical Change in a Warmwater Fish Community in an Urbanizing Watershed." Technical Note 93. Watershed Protection Techniques 2(4); May, C., R. Horner, J.

Karr, B. Mar, and E. Welch. 1997. "Effects Of Urbanization On Small Streams In The Puget Sound Lowland Ecoregion." Watershed Protection Techniques 2(4)).

Pitt and others also described the receiving water effects on aquatic organisms associated with urban runoff (Pitt, R.E. 1995. "Biological Effects of Urban Runoff Discharges" In Stormwater Runoff and Receiving Systems: Impact, Monitoring, and Assessment, ed. E.E Herricks, Lewis Publishers; Crunkilton, R., J. Kleist, D. Bierman, J. Ramcheck, and W. DeVita. 1999. "Importance of Toxicity as a Factor Controlling the Distribution of Aquatic Organisms in an Urban Stream." In Comprehensive Stormwater & Aquatic Ecosystem Management Conference Papers. Auckland, New Zealand).

In Wisconsin, runoff samples were collected from streets, parking lots, roofs, driveways, and lawns. Source areas were broken up into residential, commercial, and industrial. Geometric mean concentration data for residential areas included total solids of about 500-800 mg/L from streets and 600 mg/L from lawns. Fecal coliform data from residential areas ranged from 34,000 to 92,000 cfu/100 mL for streets and driveways. Contaminant concentration data from commercial and industrial source areas were lower for total solids and fecal coliform, but higher for total zinc (Bannerman, R.T., D.W. Owens, R.B. Dods, and N.J. Hornewer. 1993. "Sources of Pollutants in Wisconsin Stormwater." Wat. Sci. Tech. 28(3-5):241-59).

Bannerman, et al. also found that streets contribute higher loads of pollutants to urban storm water than any other residential development source. Two small urban residential watersheds were evaluated to determine that lawns and streets are the largest sources of total and dissolved phosphorus in the basins (Waschbusch, R.J., W.R. Selbig, and R.T. Bannerman. 1999. "Sources of Phosphorus in Stormwater and Street Dirt from Two Urban Residential Basins In Madison, Wisconsin, 1994-95." Water Resources Investigations Report 99-4021. U.S. Geological Survey). A number of other studies have indicated that urban roadways often contain significant quantities of metal elements and solids (Sansalone, J.J. and S.G. Buchberger. 1997. "Partitioning and First Flush of Metals in Urban Roadway Storm Water." ASCE Journal of Environmental Engineering 123(2); Sansalone, J.J., J.M. Koran, J.A. Smithson, and S.G. Buchberger. 1998. "Physical Characteristics of Urban Roadway Solids Transported During Rain Events" ASCE Journal of Environmental Engineering 124(5); Klein, L.A., M. Lang, N. Nash, and S.L. Kirschner. 1974. "Sources of Metals in New York City Wastewater" J. Water Pollution Control Federation 46(12):2653-62; Barrett, M.E, R.D. Zuber, E.R. Collins, J.F. Malina, R.J. Charbeneau, and G.H Ward., 1993. "A Review and Evaluation of Literature Pertaining to the Quantity and Control of Pollution from Highway Runoff and Construction." Research Report 1943-1. Center for Transportation Research, University of Texas, Austin).

4. Beach Closings/Advisories

Urban wet weather flows have been recognized as the primary sources of estuarine pollution in coastal communities. Urban storm water runoff, sanitary sewer overflows, and combined sewer overflows have become the largest causes of beach closings in the United States in the past three years. Storm water discharges from urban areas not only pose a threat to the ecological environment, they also can substantially affect human health. A survey of coastal and Great Lakes communities found that more than 1,500 beach closings and advisories where attributable to storm water runoff in 1998 (Natural Resources Defense Council. 1998. "Testing the Waters Volume VIII-Has Your Vacation Beach Cleaned Up Its Act?" New York, NY). Other reports also document public health, shellfish bed, and habitat impacts from storm water runoff, including more than 823 beach closings/advisories issued in 1995 and more than 407 beach closing/advisories issued in 1996 due to urban runoff (Natural Resources Defense Council. 1996. Testing the Waters Volume VI: Who Knows What You're Getting Into. New York, NY; NRDC. 1997. Testing the Waters Volume VII: How Does Your Vacation Beach Rate. New York, NY; Morton, T. 1997. Draining to the Ocean: The Effects of Stormwater Pollution on Coastal Waters. American Oceans Campaign, Santa Monica, CA). The Epidemiological Study of Possible Adverse Health Effects of Swimming in Santa Monica Bay (Haile, R.W., et. al. 1996. "An Epidemiological Study of Possible Adverse Health Effects of Swimming in Santa Monica Bay." Final Report prepared for the Santa Monica Bay Restoration Project) concluded that there is a 57 percent higher rate of illness in swimmers who swim adjacent to storm drains than in swimmers who swim more than 400 yards away from storm drains. This and other studies document a relationship between gastrointestinal illness in swimmers and water quality, the latter of which can be heavily compromised by polluted storm water discharges.

B. Other Discharges to Municipal Storm Sewers

In addition to runoff from storm events, municipal separate storm sewer systems may receive and ultimately discharge other materials introduced into the system. Non-storm water discharges to storm sewers come from a variety of sources, including:

- illicit connections and cross connections from industrial, commercial, and sanitary sewage sources
- leaking sanitary sewage systems
- malfunctioning on-site disposal systems (septic systems)
- improper disposal of wastes such as used oil, wastewater and litter
- spills
- infiltration of ground water contaminated by a variety of sources, including leaking underground storage tanks
- wash waters, lawn irrigation, and other drainage sources.

Studies have shown that discharges from MS4s often include wastes and wastewater from non-storm water sources. Federal regulations (§ 122.26(b)(2)) define an illicit discharge as "...any discharge to an MS4 that is not composed entirely of storm water...," with some exceptions. These discharges are "illicit" because municipal storm sewer systems are not designed to accept, process, or discharge such wastes. Sources of illicit discharges include, but are not limited to,: sanitary wastewater; effluent from septic tanks; car wash, laundry, and other industrial wastewaters; improper disposal of auto and household toxics, such as used motor oil and pesticides; and spills from roadway and other accidents.

Illicit discharges enter the system through either direct connections (e.g., wastewater piping either mistakenly or deliberately connected to the storm drains) or indirect connections (e.g., infiltration into the MS4 from cracked sanitary systems, spills collected by drain outlets, and paint or used oil dumped directly into a drain). The result is untreated discharges that contribute high levels of pollutants, including heavy metals, toxics, oil and grease, solvents, nutrients, viruses and bacteria into receiving waterbodies. The NURP study, discussed earlier, found that pollutant levels from illicit discharges were high enough to significantly degrade receiving water quality and threaten aquatic, wildlife, and human health. The study noted particular problems with illicit discharges of sanitary wastes, which can be directly linked to high bacterial counts in receiving waters and can be dangerous to public health.

Because illicit discharges to MS4s can create severe widespread contamination and water quality problems, several municipalities and urban counties performed studies to identify and eliminate such discharges. In Michigan, the Ann Arbor and Ypsilanti water quality projects inspected 660 businesses, homes, and other buildings and identified 14 percent of the buildings as having improper storm sewer drain connections. The program assessment revealed that, on average, 60 percent of automobile-related businesses, including service stations, automobile dealerships, car washes, body shops, and light industrial facilities, had illicit connections to storm sewer drains. The program assessment also showed that a majority of the illicit discharges to the storm sewer system resulted from improper plumbing and connections, which had been approved by the municipality when installed (Washtenaw County Statutory Drainage Board. 1987. Huron River Pollution Abatement Program).

In addition, an inspection of urban storm water outfalls draining into Inner Grays, Washington, indicated that 32 percent of these outfalls had dry weather flows. Of these flows, 21 percent were determined to have pollutant levels higher than the pollutant levels expected in typical urban storm water runoff characterized in the NURP study (U.S. EPA. 1993. Investigation of Inappropriate Pollutant Entries Into Storm Drainage Systems -- A User's Guide. EPA 600/R-92/238. Office of Research and Development. Washington, DC). That same document reports a study in Toronto, Canada, that found that 59 percent of outfalls from the MS4 had dry-weather flows. Chemical tests revealed that 14 percent of these dry-weather flows were determined to be grossly polluted.

Inflows from aging sanitary sewer collection systems are one of the most serious illicit discharge-related problems. Sanitary sewer systems frequently develop leaks and cracks, resulting in discharges of pollutants to receiving waters through separate storm sewers. These pollutants include sanitary waste and materials from sewer main construction (e.g., asbestos cement, brick, cast iron, vitrified clay). Municipalities have long recognized the reverse problem of storm water infiltration into sanitary sewer collection systems; this type of infiltration often disrupts the operation of the municipal sewage treatment plant.

The improper disposal of materials is another illicit discharge-related problem that can result in contaminated discharges from separate storm sewer systems in two ways. First, materials may be disposed of directly in a catch basin or other storm water conveyance. Second, materials disposed of on the ground may either drain directly to a storm sewer or be washed into a storm sewer during a storm event. Improper disposal of materials to street catch basins and other storm sewer inlets often occurs when people mistakenly believe that disposal to such areas is an environmentally sound practice. Part of the confusion may occur because some areas are served by combined sewer systems, which are part of the sanitary sewer collection system, and people assume that materials discharged to a catch basin will reach a municipal sewage treatment plant. Materials that are commonly disposed of improperly include used motor oil; household toxic materials; radiator fluids; and litter, such as disposable cups, cans, and fast-food packages. EPA believes that there has been increasing success in addressing these problems through initiatives such as storm drain stenciling and recycling programs, including household hazardous waste special collection days.

Programs that reduce illicit discharges to separate storm sewers have improved water quality in several municipalities. For example, Michigan's Huron River Pollution Abatement Program found the elimination of illicit connections caused a measurable improvement in the water quality of the Washtenaw County storm sewers and the Huron River (Washtenaw County Statutory Drainage Board, 1987). In addition, an illicit detection and remediation program in Houston, Texas, has significantly improved the water quality of Buffalo Bayou. Houston estimated that illicit flows from 132 sources had a flow rate as high as 500 gal/min. Sources of the illicit discharges included broken and plugged sanitary sewer lines, illicit connections from sanitary lines to storm sewer lines, and floor drain connections (Glanton, T., M.T. Garrett, and B. Goloby. 1992. The Illicit Connection: Is It the Problem? Wat. Env. Tech. 4(9):63-8).

V. Rationale for Using a NPDES Approach

This section responds to the Appropriations Act's direction to provide a report containing:

"(4) information that supports the position of the Administrator that the Phase II stormwater program should be administered as part of the National Pollutant Discharge Elimination System under section 402 of the Federal Water Pollution Control Act (33 U.S.C. 1342)"

EPA interprets Clean Water Act section 402(p)(6) as authorizing the Agency to develop a storm water program for Phase II sources either as part of the existing NPDES permit program or as a stand alone non-NPDES program such as a self-implementing rule. Although EPA believes that it has the discretion to not require sources regulated under CWA section 402(p)(6) to be covered by NPDES permits, the Agency has determined, for the reasons discussed below, that it is most appropriate to use NPDES permits in implementing the program to address the sources designated for regulation in Phase II. EPA believes that the NPDES program best achieves the goals of the Phase II rule for the following reasons:

- Applying an NPDES permit approach to Phase II sources allows for consistent regulation between larger MS4s and construction sites regulated under Phase I and smaller sources regulated under Phase II.
- Use of NPDES permits to regulate Phase II municipalities will allow co-permitting of small regulated MS4s with larger MS4s regulated under the existing Phase I storm water program.
- The use of NPDES permits is a familiar regulatory implementation vehicle that is well understood by State regulators and potential permittees.
- NPDES permits provide the flexibility to allow the use of general permits on a watershed basis, while also allowing site-specific controls to be developed on a case-by-case basis.
- NPDES permits allow incorporation by reference of existing State, Tribal and local programs.
- NPDES permit applications and NOIs provide important information to regulatory authorities and the public.
- NPDES permit procedures include beneficial processes for citizen participation and enforcement.
- NPDES permits are federally enforceable under the CWA.

- NPDES permit coverage provides "permit as a shield" legal protection to the permittee.

- NPDES permit coverage provides an established and predictable regulatory regime to avoid duplicative regulation under the Resource Conservation and Recovery Act and the Comprehensive Emergency Response, Compensation, and Liability Act, due to exclusions from regulation for facilities subject to NPDES permits.

In developing an approach for the Phase II rule, individual members of both the FACA Committee and the Storm Water Phase II FACA Subcommittee encouraged EPA to seek opportunities to integrate, where possible, the proposed Phase II requirements with existing Phase I requirements, thus facilitating a unified and "seamless" storm water discharge control program. EPA believes that using the NPDES framework is the best means of integrating the regulation of Phase II sources with the existing storm water program. The NPDES framework is already applied to regulated storm water sources and can be extended to the sources to be regulated in Phase II. This approach facilitates program consistency, public access to information, and program oversight.

Requiring Phase II sources to be covered by NPDES permits would help address the consistency problems currently caused by municipal "donut holes." Donut holes are gaps in program coverage where a small unregulated MS4 is located next to or within a regulated larger MS4 that is subject to an NPDES permit under the existing NPDES storm water program. The existence of such "donut holes" creates an equity problem because similar discharges may remain unregulated even though they cause or contribute to the same adverse water quality impacts. Using NPDES permits to regulate the unregulated discharges in these areas is intended to facilitate the development of a seamless regulatory program for the mitigation and control of contaminated storm water discharges in an urbanized area. For example, the Phase II rule would allow a newly regulated MS4 to join as a "limited" co-permittee with a regulated MS4 by referencing a common storm water management program. Such cooperation should be further encouraged by the fact that the minimum control measures to be required in the Phase II rule for regulated small MS4s are very similar to a number of the permit requirements for medium and large MS4s under the existing storm water program. The minimum control measures applicable to discharges from smaller MS4s under Phase II are described with slightly more generality than under the Phase I permit application regulations for larger MS4s, thus enabling maximum flexibility for operators of smaller MS4s to optimize efforts to protect water quality.

The Phase II rule would also apply NPDES permit requirements to construction sites below 5 acres that are similar to the existing requirements for those 5 acres and above. In addition, the rule would allow compliance with qualifying local, Tribal, or State erosion and sediment controls to meet the erosion and sediment control requirements of the general permits for storm water discharges associated with construction, both above and below 5 acres.

Incorporating the CWA section 402(p)(6) program into the NPDES program capitalizes upon the existing governmental infrastructure for administration of the NPDES program.

Moreover, much of the regulated community already understands the NPDES program and the way it works.

Another goal of the NPDES program approach is to provide flexibility in order to facilitate and promote watershed planning and sensitivity to local conditions. The following are some of the more significant examples of the flexibility provided by the NPDES approach:

- NPDES general permits may be used to cover a category of regulated sources on a watershed basis or within political boundaries.
- The NPDES permitting process provides a mechanism for storm water controls tailored on a case-by-case basis, where necessary.
- The NPDES permit requirements of a permittee may be satisfied by another cooperating entity.
- NPDES permits may incorporate the requirements of existing State, Tribal and local programs, thereby accommodating State and Tribes seeking to coordinate the storm water program with other programs, including those that focus on watershed-based nonpoint source regulation.

NPDES permits generally require an application or a notice of intent to trigger coverage. This information exchange assures communication between the permitting authority and the regulated community. This communication is critical in ensuring that the regulated community is aware of the requirements and the permitting authority is aware of the potential for adverse impacts to water quality from identifiable locations. The NPDES permitting process includes the public as a valuable stakeholder and ensures that the public is included and information is made publicly available.

Another concern for EPA and several of the individual FACA Subcommittee members was that the program ensure citizen participation. The NPDES approach ensures opportunities for citizen participation throughout the permit issuance process, as well as in enforcement actions. NPDES permits are also federally enforceable under the CWA.

EPA believes that the use of NPDES permits makes a significant difference in the degree of compliance with regulations in the storm water program. The Agency does not anticipate that a self-implementing rule would ensure the degree of public participation needed for the development, enforcement and revision of the storm water management program. Citizen suit enforcement has assisted in focusing attention on adverse water quality impacts on a localized, public priority basis. Citizens frequently rely on the NPDES permitting process and the availability of NOIs to track program implementation and help them enforce regulatory requirements.

NPDES permits are also advantageous to the permittee. The NPDES permit informs the permittee about the scope of what it is expected do to be in compliance with the Clean Water Act. As explained more fully in EPA's April 1995 guidance, Policy Statement on Scope of Discharge Authorization and Shield Associated with NPDES Permits, compliance with an NPDES permit constitutes compliance with the Clean Water Act (see CWA section 402(k)). In addition, NPDES permittees are excluded from duplicative regulatory regimes under the Resource Conservation and Recovery Act and the Comprehensive Emergency Response, Compensation and Liability Act under RCRA's exclusions to the definition of "solid waste" and CERCLA's exemption for "federally permitted releases."

Throughout development of the rule, State representatives sought alternatives to the NPDES approach for State implementation of the storm water program for Phase II sources. Discussions focused on an approach whereby States could develop an alternative program that EPA would approve or disapprove based on identified criteria, including that the alternative non-NPDES program would result in "equivalent or better protection of water quality." The State representatives, however, were unable to propose or recommend criteria for gauging whether a program would provide equivalent protection. EPA also did not receive any suggestions for objective, workable criteria in response to the Agency's explicit request for specific criteria (by which EPA could objectively judge such programs) in the preamble to the proposed rule.

EPA also considered suggestions that the Agency authorize Phase II to be implemented as a self-implementing rule, which would be a regulation promulgated at the Federal, State, or Tribal level to control some or all of the storm water dischargers regulated under the Phase II rule. Under this approach, a rule would spell out the specific requirements for dischargers and impose the restrictions and conditions that would otherwise be contained in an NPDES permit. It would be effective until modified by EPA, a State, or a Tribe, unlike an NPDES permit which cannot exceed a duration of five years. Some stakeholders believed that this approach would reduce the burden on the regulated community (e.g., by not requiring permit applications), and considerably reduce the amount of additional paperwork, staff time and accounting required to administer the proposed permit requirements.

EPA is sensitive to the interest of some stakeholders in having a streamlined program that minimizes the burden associated with permit administration and maximizes opportunities for field time spent by regulatory authorities. Key provisions in the Phase II rule would address some of these concerns by promoting a streamlined approach to permit issuance by, for example, using general permits for coverage of Phase II permittees and allowing the incorporation of existing programs. By adopting the NPDES approach rather than a self-implementing rule, the Phase II rule also allows for consistent regulation between larger MS4s and construction sites regulated under the Phase I rule and smaller sources regulated under Phase II.

EPA believes that it is most appropriate to use NPDES permits to implement a program to address Phase II sources. In addition to the reasons discussed above, NPDES permits provide a better mechanism than would a self-implementing rule for tailoring storm water controls on a case-by-case basis, where necessary. A self-implementing rule would not ensure the degree of public participation that the NPDES permit process provides for the development, enforcement and revision of the storm water management program. A self-implementing rule also might not have provided the regulated community the "permit shield" under CWA section 402(k) that is provided by an NPDES permit. Based on all these considerations, EPA declined to adopt a self-implementing rule approach and adopted the NPDES approach for Phase II sources.

Dennis Dickerson
Executive Officer
Los Angeles Regional Water Quality Control Board
320 W. 4th St., Suite 200
Los Angeles, CA 90013

Dear Mr. Nahai and Mr. Dickerson:

I'm pleased to provide you with the final report of EPA Region 9's review of the Los Angeles Regional Water Quality Control Board's National Pollution Discharge Elimination System (NPDES) program, conducted on June 3-5, 1998. In the 1970s and 1980s, EPA regularly reviewed delegated state environmental programs to ensure compliance with all requirements. After conducting a number of these reviews during those years, EPA Region 9 increasingly found that delegated programs in our states had few if any problems, so by the early 1990s, we had markedly reduced our state oversight activities. Last year, we resumed conducting reviews of state administered National Pollution Discharge Elimination System (NPDES) programs for several reasons. First, it had been at least five years since Region 9 had conducted reviews of state-administered NPDES programs. In part, the reviews were initiated to respond to national concerns highlighted by EPA's Office of Inspector General regarding the quality of state programs nationally. Consistency of state enforcement programs across the country - the "level playing field" concept - remains on the Inspector General's top ten list of significant issues facing EPA, and the Office of Management and Budget has expressed concern about backlogs of expired NPDES permits. For all these reasons, we re-initiated NPDES program reviews in our Region, working with the state agencies to be reviewed, to ensure effective state administration of the NPDES program.

In planning its review of the State of California, EPA focused on the Regional Boards with the largest NPDES programs–Sacramento, Los Angeles, and San Diego--and conducted its first review at the Los Angeles Regional Board. During our review of the Los Angeles Regional Board, EPA was aware of the 1997 Heal the Bay report criticizing its administration of the

Printed on Recycled Paper

R0018020

NPDES program. However, EPA's review of the Los Angeles Board is an independent, objective evaluation, based upon EPA's requirements for the NPDES program and applicable written agreements between EPA and the State of California. While our review didn't confirm or deny the specifics of Heal the Bay's review, we did note a comparable past history of weak NPDES enforcement by the Los Angeles Board. However, we also noted significant improvement by the Board over the past 2-3 years in both eliminating expired permit backlogs and in taking enforcement action. For example, since the EPA review, the Board assessed a record $2.3 million penalty against the City of Thousand Oaks for an 86 million gallon sewage spill. Also, in the past year, the Board has achieved an impressive record of enforcement actions and penalty assessments, a marked improvement over past performance, due largely to the leadership of the Regional Board, its Executive Officer, and the establishment of a separate Enforcement Unit. We commend these achievements.

Our review of the Los Angeles Board's NPDES program encompassed five main NPDES activities: permitting, compliance, pretreatment, storm water, and enforcement, over the time period from 1995 through June 1998. The enclosed Executive Summary includes commentary regarding the strengths of the Los Angeles Board's administration of the NPDES program, discussion of issues arising State-wide that require change at all the Regional Boards, the changes that are required at the Los Angeles Board, and other suggestions that EPA offers for the Los Angeles Board's consideration. In brief, the strengths in the Los Angeles Board's NPDES program include:

- Between 1995 and 1998, the Board eliminated their backlog of 70 percent-expired NPDES permits.
- The Board has an excellent review, tracking, and inspection program to assess permit compliance of major and minor NPDES permittees.
- The Board has shown leadership by developing a new data system that will replace California's current data system for dischargers.
- In the storm water program, though much more needs to be done, the Board's small staff is doing what they can to address the huge universe of regulated facilities.
- There has been significant increase in both the number of enforcement actions taken and penalties assessed, as discussed above.

Changes that need to be made by all the Regional Water Quality Control Boards in California, including the Los Angeles Board, to fully comply with all NPDES program requirements include:

- The current lack of State-wide water quality standards for toxic pollutants results in NPDES water quality permit limit problems at all the Regional Boards. Until EPA's promulgation of the California Toxics Rule and the State's adoption of the Inland Surface Waters and Enclosed Bays and Estuaries Plan's Implementation Policy, all the Regional

Water Boards should refer to EPA's *Technical Support Document for Water Quality-based Toxics Control*, and to examples of fact sheets and permits that will be provided by the State Board.

- Penalty actions need to comply with State penalty policies.
- Greater inspection presence is needed in the storm water program, which is significantly under funded State-wide.
- Pretreatment program expertise needs to be strengthened and industrial user regulation is needed.

Changes needing to be made that are specific to the Los Angeles Board to fully comply with all NPDES program requirements include:

- NPDES permits must ensure that aquatic life is protected from toxics by establishing appropriate, protective effluent limits consistent with Basin Plan objectives.
- The Los Angeles Board must carefully observe all procedural requirements in issuing NPDES permits in order to avoid potential permit challenges based on procedural grounds.
- For storm water, the Board needs to review and comment on the Los Angeles County storm water permit model program submittals, since successful implementation of this permit depends on these reviews.
- In pretreatment, the Board must complete the review and approval process for local limits programs as well as one overall pretreatment program.
- All formal enforcement actions taken by the Board must require compliance by a date certain, and contain appropriate interim effluent limits and schedule milestone dates.
- The Board's current emphasis on enforcement is commended, and needs to be continued.

Based on this review, once the required changes are made, EPA believes that the Los Angeles Board will be administering an NPDES program that meets all applicable requirements, though limited by available resources.

EPA's review provides us all with a great opportunity to ensu e that our mission, to protect public health and the environment, is successfully achieved. The enclosed evaluation focuses on the legal and policy requirements of the NPDES program, but doesn't address other perhaps less tangible aspects of our shared responsibilities, such as opportunities for leadership in environmental and public health protection. The Board's enforcement action on the Thousand Oaks spill, and the Board's record of enforcement since the Thousand Oaks action, demonstrate the kind of leadership and profile that stimulates compliance and a cleaner environment. We commend the Los Angeles Board for this record of recent action, and urge you to continue this vigorous enforcement program.

Alexis Strauss and Mike Schulz of our Water Division will be pleased to discuss this review in more detail with you if you wish. We sincerely appreciate the participation and cooperation of you and your staff, as well as that of the State Water Resources Control Board, in our shared endeavors to better manage water resources in California.

Yours,

Felicia Marcus
Regional Administrator

NPDES PROGRAM IMPLEMENTATION REVIEW
LOS ANGELES REGIONAL WATER QUALITY CONTROL BOARD

EXECUTIVE SUMMARY

On June 3 through 5, 1998, the U.S. Environmental Protection Agency, Region 9 (EPA), conducted a review of the Los Angeles Regional Water Quality Control Board's (the L. A. Board, or Board) approved National Pollution Discharge Elimination System (NPDES) program. The review was conducted by EPA to assess the L. A. Board's implementation of the NPDES program, generally covered the time period from 1995 through 1998, and focused on five main NPDES activities: permitting, compliance, pretreatment, storm water, and enforcement. EPA conducted its review by evaluating a representative sample of the L. A. Board's NPDES program files, documents, quarterly and other reports, and by conducting interviews of the L. A. Board's NPDES program managers and staff. This report presents the results of EPA's review, summarized below.

The L. A. Board's jurisdiction covers nearly 4,000 square miles, services more than 10 million people, and includes approximately 390 surface water body segments, of which 40 percent are recognized as having impaired beneficial uses, including Santa Monica Bay, the Los Angeles River, and Malibu Creek. In addition, 11 Publicly Owned Treatment Works (POTWs) in the L. A. Board's jurisdiction receive discharges from industries comprising half of the total industries in California, accounting for a significant component of the toxics control accomplished in the State under the Clean Water Act. The L. A. Board regulates 44 major and 260 minor NPDES permitted facilities, regulates 345 enrollees under six different general permits, is responsible for 2,600 industrial facilities and 600 construction sites that are subject to storm water regulations, and regulates Ventura and Los Angeles Counties with municipal storm water permits, with 11 and 86 co-permittees, respectively.

EPA's NPDES program reviews conducted in California to date at the Los Angeles, San Diego, and Sacramento Regional Water Quality Control Boards have revealed issues which are applicable throughout the State of California. These issues, as agreed upon by the State Water Resources Control Board (SWRCB), all nine Regional Water Quality Control Boards (RWQCBs), and EPA, are listed below. EPA is working with the SWRCB and the RWQCBs to identify and implement solutions to these State-wide NPDES program needs, as discussed in more detail in Appendix A of this report.

- The current lack of State-wide water quality standards for toxic pollutants results in NPDES permit issuance problems at the RWQCBs.
- Adoption of NPDES permits containing compliance schedules for water quality based effluent limitations is not allowable, unless an authorizing provision is contained in the

applicable water quality control plan. This issue is not applicable to the Oakland and Sacramento RWQCBs, which have the necessary authorizing provisions.

- Appropriate receiving water limitations language, for which acceptable model language has been developed by EPA, the SWRCB, and the California Storm Water Quality Task Force, needs to be included in all forthcoming municipal storm water permits.
- Permit fact sheets/statements of basis need to clearly establish that permits are consistent with applicable statutes, regulations, and policy.
- Copies of inspection reports of major permittees, as well as copies of responses from permittees about violation follow-up, must be sent by all RWQCBs to EPA.
- Compliance review of Discharge Monitoring Reports (DMRs) is often not timely.
- Quarterly Non-Compliance Reports (QNCRs) need improvement in quality and content.
- Field presence/compliance assessment at NPDES major/minor facilities is not adequate.
- A greater inspection presence in the storm water program for both industrial and construction sites needs to be established by all RWQCBs.
- Pretreatment program expertise needs to be increased, industrial user regulation by the State is needed, and industrial user compliance problems must be addressed by the State.
- All RWQCB penalty actions need to comply with State penalty policies.

EPA's review conducted at the L. A. Board identified both specific NPDES program strengths and areas for improvement, as discussed below, applicable to their implementation of the NPDES program.

PERMITS

Strengths

In Fiscal Year (FY) 1994/1995, the L. A. Board had a NPDES permit backlog (individual permits including storm water) with nearly 70 percent of their permits requiring reissuance. In 1995, the L. A. Board implemented a watershed permitting approach, whereby priorities for permit issuance are being established consistent with emphasis on priority watersheds. At the end of FY 1997/1998, the L. A. Board was reissuing all permits in accordance with its workplan schedule for permit issuance, with only a few minor permits remaining backlogged. This permit backlog reduction is a significant accomplishment. In addition, the L. A. Board is coordinating the setting of water quality standards with NPDES permitting using a priority watershed approach, which results in better permits. The L. A. Board is establishing water quality based effluent limitations for toxic chemicals in NPDES permits based on "reasonable potential," when a pollutant causes, or has the reasonable potential to cause or contribute to an exceedance of narrative or numeric water quality standards. Also, where "reasonable potential" is established and numeric water quality objectives for toxic chemicals are lacking, the L. A. Board is using the Basin Plan narrative toxicity objective in conjunction with numeric criteria for toxic chemicals to establish water quality based effluent limitations which, in most cases, ensures protection of beneficial uses.

Required Changes

Though the L. A. Board is implementing an NPDES permitting program which is effective overall, the following changes must be made in order to fully comply with all requirements.

State-wide Issues

The current lack of State-wide water quality standards for toxic pollutants, and the absence of a plan of implementation for establishing water quality based effluent limits for toxics and whole effluent toxicity, results in NPDES permit issuance problems at all the RWQCBs, including the L. A. Board. EPA promulgation of the California Toxics Rule (CTR) and the State's adoption of the Inland Surface Waters and Enclosed Bays and Estuaries Plan's Implementation Policy are expected to address this issue for most constituents. In the interim, to ensure permits are issued as required, all the RWQCBs should refer to EPA's *Technical Support Document for Water Quality-based Toxics Control* (*Technical Support Document, or TSD*), and to fact sheets and permits that will be provided as examples by the SWRCB.

During the period prior to adoption of the CTR and the State's Implementation Policy, all RWQCBs should develop a permitting process to ensure consistent establishment of water quality based effluent limits using Basin Plan objectives and other protective numeric criteria. In addition, during the period prior to adoption and implementation of Total Maximum Daily Loads (TMDLs) for 303(d) listed waters, all RWQCBs should develop a permitting process which ensures consistent establishment of water quality based effluent limits for discharges to 303(d) listed waters without TMDLs, where discharges are found to contain pollutants causing or contributing to non-attainment of water quality standards.

Adoption of NPDES permits by the RWQCBs containing compliance schedules for water quality based effluent limitations is not allowable unless an authorizing provision is contained in applicable water quality control plans, an issue applicable to all RWQCBs except Oakland and Sacramento which have the necessary authorizing provisions. Several of the L. A. Board's tentative permits that were reviewed contained unauthorized compliance schedules for water quality based effluent limitations. These concerns, however, have been fully addressed, and Time Schedule Orders (TSOs) for these facilities were issued by the L. A. Board to meet this requirement.

All RWQCBs including the L. A. Board need to ensure that permit fact sheets/statements of basis clearly establish that permits are consistent with applicable statutes, regulations, and policy (e.g., reasonable potential, antibacksliding, establishing mixing zones, determining dilution credits, etc.). Along with summary explanations, fact sheets/statements of basis need to provide additional explanation detailing the basis for requiring water quality based effluent limitations, including reasonable potential procedures and the method used to implement water quality objectives/criteria as effluent limits.

Appropriate receiving water limitations language, for which acceptable model language has been developed by EPA, the SWRCB, and the California Storm Water Quality Task Force, needs to be included in all forthcoming municipal storm water permits from the RWQCBs, including the L. A. Board. EPA notes the June 17, 1999, adoption by the SWRCB of a policy requiring all RWQCBs to include this model language in permits.

Issues Specific to the L. A. Board

The L. A. Board must establish metals effluent limits in the "total recoverable" form rather than the "dissolved" form. When recent toxic chemical effluent data indicate the "reasonable potential" to exceed the Basin Plan narrative toxicity objective protecting aquatic life beneficial uses, the L. A. Board must establish water quality based effluent limits for that toxic chemical using numeric Basin Plan objectives (or other protective numeric criteria when numeric objectives are lacking) that will protect aquatic life beneficial uses. When recent chronic Whole Effluent Toxicity (WET) data indicate the "reasonable potential" to exceed the Basin Plan narrative toxicity objective, the L. A. Board must establish water quality based effluent limitations for either chronic toxicity or for the pollutant(s) causing the toxicity.

The L. A. Board must conduct a second public notice when changes to tentative permits are "substantial," or when permit changes cannot reasonably be considered a "logical outgrowth" of public comments received during the comment period. The L. A. Board's major permit modifications must be public noticed and subject to appeal procedures. This includes changes to permit monitoring programs which result in less stringent permit conditions. Also, in accordance with case law, the L. A. Board's expired permits may not be modified. These issues may be of State-wide concern in addition to those State-wide issues discussed in Appendix A.

Two of the six permits reviewed in depth by EPA that were issued by the L. A. Board with pollutant effluent limits did not require monitoring for those pollutants; the L.A. Board must ensure that all permit effluent limits require monitoring. NPDES permits and related information need to be submitted by the L. A. Board to EPA.

COMPLIANCE

Strengths

The L. A. Board has an excellent review and tracking program to assess compliance of its 44 major and 260 minor NPDES permittees. The overall inspection and sampling coverage of NPDES permitted facilities is good, and generally meets EPA requirements. The L. A. Board's quarterly violations summary report, which includes a listing of all violations (not just NPDES) and is prepared for submittal to its Board, is useful, and the L. A. Board is commended for including this report on its internet site, an excellent way to convey compliance information to the public. The new data system (SWIM, formerly know as ERIS) that the L. A. Board developed to replace the State-wide data system (the Waste Discharger System) is outstanding,

R0018030

and is expected to be a major step forward in data management for the entire State. The L. A. Board is to be commended for its leadership in data management in support of the State-wide program. The L. A. Board's tracking, follow-up, and review process of Discharge Monitoring Reports (DMRs) is excellent, and staff is very knowledgeable of the compliance status of the permittees. EPA's review of selected field notes indicate that staff are knowledgeable about inspection techniques and the inspections are thorough.

Required Changes

State-wide Issues

The L. A. Board's inspection coverage generally meets EPA requirements. However, State-wide, compliance assessment at NPDES major and minor facilities is not adequate. State-wide issues include use of appropriate sampling methods, adequacy of field inspection notes, and depth of on-site review. Notes taken during inspections must be retained by inspectors at all the RWQCBs for at least three years. Copies of inspection reports of major permittees, as well as copies of responses from permittees about violation follow-up, must be sent by all RWQCBs to EPA.

The QNCRs submitted by the RWQCBs need improvement in quality and content. The L. A. Board must report all appropriate violations on the QNCR, including violations of non-monthly averages.

Issues Specific to the L. A. Board

The L. A. Board needs to implement a solution to the BKK Corporation technical noncompliance problem. Since the review, EPA notes that the L. A. Board rescinded BKK's permit and enrolled it under the General Industrial Storm Water Permit.

The L. A. Board needs to implement proper compliance evaluation of report submittals. At a minimum, the language in all future permits needs to be reflective of the way reports will be tracked for compliance. The L. A. Board is now implementing practices to ensure that permittees are notified of their respective "date certain" report due dates, and the ERIS/SWIM system is now being used to track report receipt.

The SWRCB needs to be notified by the L. A. Board of changes in inspection schedules if they will result in less than 100 percent inspection coverage of majors for the inspection year, to afford EPA the opportunity to conduct remaining inspections if so desired.

STORM WATER COMPLIANCE AND ENFORCEMENT

Strengths

The L. A. Board has knowledgeable and dedicated staff that are accomplishing an admirable level of work in spite of a large universe of regulated facilities and a severely limited resource base. The Ventura County permit implementation and compliance program is well implemented, with an adequate level of Board oversight; the L. A. Board nominated this permit for an EPA national award. The L. A. Board staff inspected 100 percent of active construction sites within the Ventura watershed at least once prior to the onset of the 1997-98 rainy season, and re-inspected approximately 80 percent during the rainy season. The L. A. Board is to be commended for this pre/post rainy season inspection protocol. Los Angeles Coastal Watershed Unit staff have started to perform in-depth audits of individual co-permittees under the Los Angeles County MS4 program. The L. A. Board is to be commended for developing and implementing an improved storm water inspection tracking system in September 1998.

Required Changes

State-wide Issues

A greater inspection presence in the storm water program for both industrial and construction sites needs to be established by all RWQCBs, including the L. A. Board. Activities conducted by the L. A. Board during 1997-98 in the Ventura watershed construction program are a good model for the L. A. Board's other watershed units to strive for. Within the industrial program, the L. A. Board needs to continue and more actively seek out non-filing facilities. EPA recognizes that increased efforts are underway.

Issues Specific to the L. A. Board

The L. A. Board must review and comment upon the Los Angeles County MS4 model program submittals. Without timely Board action, implementation of this MS4 permit is not possible.

PRETREATMENT

Strengths

The L. A. Board is responsible for the regulatory oversight of 11 pretreatment programs. The Board's Pretreatment Compliance Inspections (PCIs), audits, and accompanying reports appear to be complete, including appropriate findings, requirements, and recommendations. The *Self-Monitoring Program Summary Review Sheet* is a comprehensive log which is used by some staff to record pretreatment program reviews, status, and activities. This *Review Sheet* is excellent and recommended for use by all staff.

Required Changes

State-wide Issues

The SWRCB, the L. A. Board, or some combination of RWQCBs must develop the necessary program expertise in industrial wastewater treatment, the Federal categorical standards and pretreatment regulations, and industrial user permitting and oversight, in order to effectively implement the pretreatment program. State-wide, pretreatment priority and work commitments need to be addressed. The L. A. Board needs to establish procedures to ensure that audits and pretreatment compliance inspections (PCIs) are appropriately scheduled, and that EPA and the SWRCB are notified quarterly of schedule revisions and shortfalls, as required by the Clean Water Act Section 106 annual workplan. State-wide, lack of pretreatment enforcement is of concern, especially where water quality problems exist due to pretreatment noncompliance; the L. A. Board must ensure that pretreatment enforcement activities are conducted, and are timely.

Issues Specific to the L. A. Board

The L. A. Board needs to review quarterly and annual pretreatment reports, in preparation for PCIs and audits, and for submittal of Water Enforcement National Data Base (WENDB) data elements. The L. A. Board needs to ensure that all PCI and audit reports are issued and timely; that adequate and timely PCI and audit follow-up investigation is conducted; and that PCI reports, audit reports, and WENDB data elements are submitted to EPA.

The L. A. Board needs to complete the review of the Burbank local limits and formally approve the limits, as modified if necessary. In response to EPA's formal reviews of the City of Los Angeles local limits, the Board needs to approve these local limits. Also, the Board needs to complete the pretreatment program review and approval process for the Ventura Waterworks District No. 1 (Moorpark facility).

ENFORCEMENT

Strengths

Since the time this review was conducted, EPA notes a significant improvement in both the number of enforcement actions taken and the penalties assessed by the L. A. Board. This is based on the Board's intention to issue 140 ACLs and to assess over $1.5 million in fines this year.

The L. A. Board's establishment of the Water Quality Standards and Enforcement Unit in August 1997 is commended. This Unit increases and improves the Board's focus and efforts on enforcement case development. The L. A. Board generally initiates formal enforcement actions to address NPDES violations when warranted, largely in conformance with SWRCB/RWQCB policy, and imposes and collects some civil penalties. Since the time of this review, EPA notes that the L. A. Board assessed a record $2.3 million penalty against the City of Thousand Oaks for an 86 million gallon sewage spill, recovering economic benefit. The L. A. Board has adopted a "progressive enforcement approach" in which enforcement actions are generally escalated according to a discharger's response to a previous Board action. Consistent with EPA policy and the Clean Water Action Plan, the L. A. Board is emphasizing enforcement actions for violations due to sewage spills. The L. A. Board has established a sound citizen complaint tracking system, and has also established a binder that contains all enforcement actions available for public review.

Required Changes

State-wide Issues

Penalty actions at all RWQCBs need to comply with applicable State penalty policies. Economic benefit amounts must not be reduced or rescinded as an incentive toward achieving compliance or as an off-set for supplemental environmental projects.

All RWQCBs need to place more emphasis on initiating formal enforcement actions within the storm water program. In particular, industries that are subject to, but that have not yet filed for coverage under, the General Industrial Storm Water Permit should be targeted. EPA acknowledges the L. A. Board's efforts which have resulted in an annual report submittal rate of 90 percent. For the remaining non-submitting facilities, the L. A. Board has been implementing a progressive enforcement strategy that has been effective in bringing facilities into compliance.

Issues Specific to the L. A. Board

The L.A. Board should ensure that all applicable violations are included in the "Report of Violations and Enforcement Actions" so that it complies with the SWRCB Enforcement Policy that all applicable violations are brought to the attention of the Regional Boards. EPA's review determined that staff exercise discretion when determining what violations to include in this report. Board staff should ensure that they send to EPA copies of all relevant enforcement documents related to NPDES major facilities, including Notices of Violation, formal enforcement actions, civil penalty settlement correspondence, civil penalty agreements, referrals for judicial action, and case closures.

OTHER NPDES PROGRAM SUGGESTIONS

During the conduct of this review of the L. A. Board's NPDES program, EPA identified a number of suggestions for improving their administration of the program. These suggestions are based upon both EPA's experience in implementing the NPDES program and national program perspective. EPA believes these suggestions will result in a more effective program at the L. A. Board. Though not explicitly required by law, regulation, or national policy, EPA urges the L. A. Board to implement the following:

Permits

The L. A. Board should consider encouraging public agencies that develop general public education programs on reduction of discharge of toxic materials to include pesticides in their programs. This could be accomplished by specifically mentioning pesticides in both the *residential public education* and *public agency activities* sections of the MS 4 permits. This would be expected to result in lessening the adverse impact on water quality stemming from routine household use of pesticides. Also, in addition to procedures for evaluating exfiltration from the sanitary sewer, the L. A. Board is encouraged to persuade permittees to include procedures for evaluating malfunctioning septic systems in their programs, as EPA's Part 2 MS4 guidance recommends. The L. A. Board should include each of the annual reporting requirements, as listed in the regulations, in MS4 permits so that permittees will not mistakenly only respond to the specific requirements as set forth in the permit.

To protect beneficial uses: (1) NPDES permits issued by the L. A. Board should contain toxicity conditions which require sensitivity screening for acute toxicity using a vertebrate and an invertebrate test species, and (2) NPDES permits issued by the L. A. Board should contain toxicity conditions which require increased effluent monitoring for toxicity following the measurement of effluent toxicity at critical levels, as denoted by the exceedance of an effluent limit or benchmark where no effluent limit has been established. This approach is similar to existing permit conditions which specifically require increased monitoring when a monthly average effluent limit is exceeded.

To protect beneficial uses and to facilitate water quality based permitting, the L. A. Board should develop an implementation procedure for the chronic mixing zone provision contained in Chapter 4 of the Basin Plan.

Compliance

The L. A. Board should consider establishing an automated system to track its follow-up on citizen complaints and spills. EPA notes that the data system called SWIMS, when implemented, will accommodate this tracking activity.

The L. A. Board should consider having all inspectors use bound notebooks for note-taking during inspections as contemporaneous, bound notes are potentially of more value in civil and criminal enforcement proceedings.

Pretreatment

All L. A. Board pretreatment program oversight staff should use the *Self-Monitoring Program Summary Review Sheet.*

Enforcement

The L. A. Board's Watershed Units that are responsible for the day-to-day oversight of regulated facilities and the new Enforcement Unit should develop and implement procedures to further improve on-going communication. This will ensure that a facility's total compliance history is considered when developing enforcement cases, and will also ensure that any enforcement strategies are not hindered by lack of other information regarding a facility. All compliance information is relevant and needs to be considered in the development of an enforcement action.

INTRODUCTION

On June 3 through 5, 1998, the U.S. Environmental Protection Agency, Region 9 (EPA), conducted a review of the Los Angeles Regional Water Quality Control Board's (RWQCB 4) approved National Pollution Discharge Elimination System (NPDES) program. The review was conducted by EPA to assess RWQCB 4's implementation of the NPDES program, in accordance with Federal laws, regulations, and policies, as agreed upon by EPA and California, and described in the following documents:

1. NPDES Memorandum of Agreement between the U. S. Environmental Protection Agency and the California State Water Resources Control Board (September 1989), and
2. Final FY 1995/1996, FY 1996/1997, and FY 1997/1998 Section 106 Workplans.

The EPA review focused on five main NPDES activities: permitting, compliance, pretreatment, storm water, and enforcement, and generally covered the time period from 1995 to 1998. EPA conducted its review by evaluating a representative sample of RWQCB 4's NPDES program files, documents, quarterly and other reports, and by conducting interviews of RWQCB 4's NPDES program managers and staff. The EPA evaluation of RWQCB 4's NPDES program took place both at EPA's offices in San Francisco (document review) and at RWQCB 4's offices in Monterey Park. The EPA review is documented on checklists which correlate with the requirements of the above-listed documents. This report presents the results of EPA's review of RWQCB 4 regarding the approved California NPDES program.

EPA's review participants included the following Region 9 Water Division staff:

Mike Schulz, Associate Director
Robyn Stuber, Environmental Scientist, Permitting Review
Robert Wills, Environmental Engineer, Compliance and Pretreatment Program Review
Jeremy Johnstone, Environmental Engineer, Enforcement and Storm Water Review
Jenée Gavette, Environmental Protection Specialist, Pretreatment Compliance and Enforcement Review
Dyi-You Shieh, Environmental Engineer, Compliance/Enforcement Review
Eugene Bromley, Environmental Engineer, Storm Water Permitting Review
Laurie Kermish, Attorney, from Region 9's Office of Regional Counsel

A draft review report was issued in September 1998, with comments received from the SWRCB on October 30, 1998, from RWQCB 4 dated November 6, and from RWQCB 4 staff on December 1, 1998. All comments have been discussed with the SWRCB and RWQCB 4, and the results of these discussions are incorporated into this final report. We wish to extend our thanks to the staff and managers at RWQCB 4 for their hospitality and cooperation in the conduct of this NPDES review.

OVERVIEW OF THE STATE WATER RESOURCES CONTROL BOARD AND THE REGIONAL WATER QUALITY CONTROL BOARDS

The California State Water Resources Control Board (SWRCB) and the nine Regional Water Quality Control Boards (RWQCBs) exercise the regulatory and adjudicatory powers of the State of California in the field of water resources. To implement the State's water quality program, a regional or watershed approach to water issues was created in 1949 and greatly expanded in 1969 when the Porter-Cologne Water Quality Control Act was signed into law. Through this regional approach, the State has been divided into nine major watershed areas with the establishment of a RWQCB in each area. The RWQCBs have primary authority and responsibility for implementing four major functions to protect water quality by ensuring the adoption and implementation of water quality control plans--planning, permitting, monitoring, and enforcement.

The SWRCB was created in 1967 to combine into one agency regulatory powers covering both water rights and water quality issues, thus complementing the authority of the RWQCBs. The SWRCB may issue water quality control plans in areas of State-wide significance (i.e., an Ocean Plan, a Bay Delta Plan, a Tahoe Plan) and also ensures consistency through the adoption of State-wide policies. The SWRCB also administers key elements of the Federal Clean Water Act, such as storm water general permitting and the non-point source pollution control program, and conducts oversight of the RWQCBs, including approval of water quality control plans. The SWRCB is authorized to review most actions (or inaction) by the RWQCBs, and to adopt water quality orders when appropriate.

The SWRCB and each of the RWQCBs are headed by Boards consisting of members appointed by the Governor to four-year terms. Each Board is made up of nine volunteers from diverse backgrounds (i.e., wastewater, law, public-at-large, engineering, etc.) to ensure equal representation of each RWQCB's regulated community who are appointed by the Governor to their positions as Board members. The RWQCBs and their appointed Boards each have discrete approval or issuance authorities, as set forth in the attached Table 1.

During the last half of 1997, the SWRCB and RWQCBs added 18 new positions State-wide for enforcement activities. In addition, the SWRCB created the Compliance Assurance and Enforcement (CA&E) Unit to coordinate and evaluate enforcement activities taken State-wide. Key staff were assigned and an organizational structure was identified in each of the nine RWQCBs to assure that enforcement and compliance actions are increased. The CA&E Unit had three major tasks: (1) improve management reporting of compliance assurance and enforcement activities, (2) track the use of the special enforcement staff resources, and (3) develop a strategy to direct State compliance assurance and enforcement activities in the coming years. These three tasks have been completed, and the Compliance Assurance and Enforcement Strategy was issued in June of 1998, about the same time as EPA's review was conducted. The Strategy contains many recommendations for improving compliance and enforcement activities, many of which are expected to address issues identified in this review.

BACKGROUND AND REVIEW OBJECTIVES

The State of California and EPA have entered into the Memorandum of Agreement (MOA) and annual Clean Water Act Section 106 Workplans to ensure an effective and well-coordinated program of water quality control in California. These agreements delineate the respective responsibilities of California and of EPA for the operation of a cooperative State-Federal NPDES program, including permitting, compliance, and enforcement in accordance with the Federal Water Pollution Control Act (P.L. 92-500) as amended by the Clean Water Act (CWA) of 1987 (P.L. 100-4).

These agreements recognize that the issuance of NPDES permits, conduct of inspections, and issuance of enforcement actions necessary for the protection and enhancement of waters in California are the primary responsibility of RWQCBs, and require that RWQCBs issue permits which are consistent and compatible with the CWA and its regulations and policies. The agreements recognize EPA's substantial interest and oversight role in the issuance of NPDES permits and related enforcement matters, and describe EPA's primary role in providing financial and technical assistance, including policy guidance, to RWQCBs. The agreements also require EPA's and the RWQCB 's full cooperation to promote and conduct an enforcement program capable of providing maximum effectiveness in achieving Federal and State objectives for the regulation of water quality as follows:

1. regulating all discharges subject to the NPDES and pretreatment programs, except those reserved to EPA, in conformance with Federal and State law, regulations, and policy;
2. maintaining technical expertise, administrative procedures, and management control, such that implementation of the NPDES and pretreatment programs consistently conforms to State laws, regulations, and policies;
3. implementing federal program revisions;
4. providing technical assistance to the regulated community to encourage voluntary compliance with program requirements;
5. assuring that no person or entity realizes an economic benefit from non-compliance;
6. maintaining an adequate public file at the appropriate RWQCB Office for each permittee. Such files must, at a minimum, include copies of: the permit application, issued permit, public notice and fact sheet, discharge monitoring reports, all actions, and other pertinent information and correspondence;
7. comprehensively evaluating and assessing compliance with schedules, effluent limitations, and other conditions in permits;
8. taking timely and appropriate enforcement actions in accordance with the CWA, applicable Federal regulations, and State law; and
9. implementing pretreatment program responsibilities.

The agreements also recognize that the SWRCB is responsible for supporting and overseeing the RWQCBs' management of the NPDES and pretreatment programs in California, as follows:

1. evaluating RWQCB performance in the areas of permit content, procedure, compliance, monitoring and surveillance, quality assurance of sample analyses, and program enforcement;
2. providing that the SWRCB shall act on its own as necessary to assure that the program is administered in conformance with Federal and State legislation, regulations, policy, the MOA, and the State annual 106 workplan;
3. providing technical assistance to the RWQCBs;
4. developing and implementing regulations, policies, and guidelines as needed to maintain consistency between State and Federal policy and program operations, and to maintain consistency of program implementation throughout all nine RWQCBs and over time;
5. reviewing decisions of the RWQCBs upon petition from aggrieved persons or upon its own motion;
6. assisting the RWQCBs in the implementation of federal program revisions through the development of policies and procedures;
7. performing any of the functions and responsibilities ascribed to the RWQCBs, and
8. implementing pretreatment program responsibilities.

U.S. EPA and the State of California have been cooperatively engaged in the operation of the approved California NPDES program since 1973. During this time, formal and informal reviews and various EPA oversight activities have been conducted to determine the effectiveness of RWQCB NPDES programs. Though it has been at least five years since EPA has conducted an NPDES program review of a RWQCB, EPA is ultimately responsible to the U.S. Congress and the American public. Thus, EPA needs first-hand knowledge that EPA-approved programs are effective and compliant with all applicable laws, regulations, and policies. This review was conducted to achieve this objective.

This report consists of several components. First is an overview of the RWQCB 4 NPDES program, which briefly describes RWQCB 4's organizational structure relevant to NPDES administration. The results of EPA's review are then presented for each of five areas of the NPDES program: permits, compliance, storm water, pretreatment, and enforcement. Each of these five sections discusses EPA's evaluation of RWQCB 4's NPDES activities, including which actions were reviewed by EPA, and provides EPA's conclusions (strengths and changes required by law, regulation, and/or national policy) for improving administration of RWQCB 4's approved NPDES program, including discussion of program issues of State-wide concern. The sixth section of the report includes EPA's suggestions for improving RWQCB 4's NPDES program.

NPDES PROGRAM OVERVIEW FOR RWQCB 4

The Surface Water Division (SWD), one of three divisions/program offices of RWQCB 4, is responsible for the implementation and operation of RWQCB 4's NPDES program, including permitting, compliance, and enforcement activities for all of its NPDES-permitted facilities. The SWD's Assistant Executive Officer reports to the RWQCB 4 Executive Officer (EO). At the time of the review, the SWD was divided into two sections, Watershed Regulatory and Regional Programs, as illustrated in the attached Table 2. The Watershed Regulatory section was divided into four units, including a data and information management unit and three watershed units--Los Angeles Coastal, Ventura Coastal, and Los Angeles Inland. Watershed Unit staff were individually responsible for all permitting, compliance, and informal enforcement activities related to each NPDES facility to which they are assigned. The Regional Programs Section's Standards and Enforcement Unit was responsible for all formal enforcement actions related to NPDES facilities. The attached Tables 3 and 4 lists RWQCB 4 NPDES-permitted facilities. The attached Table 5 lists the numbers of Notices of Violation (NOVs), Time Schedule Orders (TSOs), Cease and Desist Orders (CDOs), Clean-up and Abatement Orders (CAOs), Administrative Civil Liability Complaints (ACLCs), and penalty amounts proposed, assessed, and collected by RWQCB 4 for Fiscal Years 1995 through 1998.

The SWRCB has developed NPDES program cost factors to serve as the basis for determining NPDES program needs in California; these cost factors should be used in determining RWQCB 4's resource needs in administering all aspects of its NPDES program. It should be noted that California's NPDES program has been historically underfunded, resulting in insufficient resources at all the RWQCBs, including RWQCB 4. Therefore, the RWQCBs shifted priorities and redirected resources, in RWQCB 4's case, through implementation of a watershed management approach (see RWQCB 4 Staffing for the NPDES Permitting Program section of this report). In 1999, the California state legislature recognized that there were inadequate resources to support the NPDES program and provided additional resources state-wide, including RWQCB 4.

RWQCB 4's jurisdiction covers nearly 4,000 square miles, services more than 10 million people and includes approximately 390 surface water body segments, of which 40 percent are recognized as having impaired beneficial uses, including Santa Monica Bay, Los Angeles River, and Malibu Creek. In addition, 11 Publicly Owned Treatment Works (POTWs) in RWQCB 4 receive discharges from industries comprising 50 percent of the total industries in California, accounting for the vast majority of toxics control accomplished in California under the Clean Water Act. RWQCB 4 regulates 44 major and 260 minor NPDES permitted facilities, regulates 345 enrollees under six different general permits, is responsible for 2,600 industrial facilities and 600 construction sites that are subject to storm water regulations, and regulates Ventura and Los Angeles Counties with municipal storm water permits, with 11 and 86 co-permittees, respectively.

STATE-WIDE NPDES PROGRAM NEEDS

EPA's NPDES program reviews conducted to date at RWQCBs 4 (Los Angeles), 5 (Sacramento), and 9 (San Diego) have revealed issues which are applicable throughout the State of California. These issues, as agreed upon by the SWRCB, all nine RWQCBs, and EPA during meetings held in January and February 1999 in Sacramento, are listed below, and discussed in more detail in Appendix A of this report. EPA is working with the SWRCB and the RWQCBs to identify and implement solutions to these State-wide NPDES program needs. These issues are:

- The current lack of State-wide water quality standards for toxic pollutants, and the absence of a plan of implementation for establishing water quality based effluent limits for toxics and whole effluent toxicity, results in NPDES permit issuance problems at the RWQCBs.
- Adoption of NPDES permits containing compliance schedules for water quality based effluent limitations is not allowable, unless an authorizing provision is contained in the applicable water quality control plan.
- Permit fact sheets/statements of basis need to clearly establish that permits are consistent with applicable statutes, regulations, and policy (e.g., reasonable potential, antibacksliding, establishing mixing zones, determining dilution credits, etc.).
- Appropriate receiving water limitations language, for which acceptable model language was recently developed by EPA, the SWRCB, and the California Storm Water Quality Task Force, needs to be included in all forthcoming municipal storm water permits.
- Copies of inspection reports of major permittees, as well as copies of responses from permittees about violation follow-up, must be sent by all RWQCBs to EPA, in accordance with the Memorandum of Agreement (MOA) between EPA and State of California.
- Compliance review of Discharge Monitoring Reports (DMRs) is often not timely, especially for minors.
- The Quarterly Non-Compliance Reports (QNCRs) submitted by the RWQCBs need improvement in quality and content.
- Field presence/compliance assessment at NPDES major and minor facilities is not adequate. Issues include use of appropriate sampling methods, adequacy of field inspection notes, and depth of on-site review.
- A greater inspection presence in the storm water program for both industrial and construction sites needs to be established by all RWQCBs; this program element is significantly under-funded State-wide.
- Pretreatment program expertise, in general, needs to be strengthened State-wide. Industrial user regulation by the State is needed. Industrial user compliance problems, especially when the pretreatment authority is for whatever reason unable to exert authority over the industrial user, must be addressed by the State.

- All RWQCB penalty actions need to comply with EPA and State policies which call for recovery of economic benefit resulting from noncompliance.

PERMITS

RWQCB 4's scope of responsibility for NPDES permit issuance encompasses the following:

• Individual Permits:	44 majors[1] 260 minors
• General Permits (non-storm water):	six categories (345 enrollees)
• Municipal Storm Water Permits:	Ventura County (11 co-permittees) Los Angeles County (86 co-permittees)
• Industrial/commercial storm water Notices of Intent (NOIs):	2,600 industrial/600 construction

EPA Evaluation Procedures

EPA's NPDES permit review consisted of four parts:

1. An in-depth review of a subset of RWQCB 4-issued permits--City of Los Angeles, Donald C. Tillman Water Reclamation Plant (WRP) (tentative permit); City of Simi Valley Water Quality Control Facility (WQCF); Las Virgenes Municipal Water District's Tapia Water Reclamation Facility (WRF); Chevron U.S.A., Inc.'s El Segundo Refinery; and the Los Angeles County Municipal Separate Storm Sewer System (MS4) permit--and a spot check of other individual permits to verify that permits are written in accordance with applicable law, regulations, and policy.
2. A review of the Memorandum of Agreement (MOA) to ensure that requirements are followed and that the MOA accurately reflects the needs of California's approved NPDES program.
3. An on-site review of RWQCB 4's permit files to ensure that administrative records are complete and contain required information.
4. A general review of overall program effectiveness in terms of permit backlog, staffing, training, etc.

---

1 Major municipal discharges have a design flow greater than one million gallons per day (mgd) or an EPA/State-approved industrial pretreatment program. Major industrial discharges are determined based on specific ratings criteria that have been developed by EPA and the State. Minor discharges are all remaining discharges.

The NPDES ~~permits selected for in-depth review~~ or that were ~~spot checked~~ were for facilities located in Ventura or Los Angeles Counties. These two counties contain some of the largest concentrations of population and commercial activity in the world. The permits selected for in-depth review were chosen because the facilities are significant major dischargers representing different discharge categories. Also, the permits selected for in-depth review or that were spot-checked reflect water quality-based permitting practices subsequent to the 1994 invalidation of California's Inland Surface Water Quality Control Plan and Enclosed Bays and Estuaries Water Quality Control Plan, and the initiation of RWQCB 4's watershed permitting approach. Tillman WRP and several spot-checked permits were tentative permits under consideration for adoption by the RWQCB 4's Board during its June 1998 meeting. Therefore, any EPA comments on these tentative permits would have been timely for permit reissuance. Subsequent to the exit briefing, EPA objected to provisions of three tentative permits, the Donald C. Tillman WRP; the City of Los Angeles/Los Angeles-Glendale Water Reclamation Plant; and the City of Burbank Public Works Department/Burbank Water Reclamation Plant and Steam Power Plant. In response to EPA's objections, the RWQCB's Board adopted these permits with all required revisions, fully addressing EPA's concerns.

The purpose of the on-site permit file review was to view the administrative records for Tillman WRP, Simi Valley WQCF, Tapia WRF, and El Segundo Refinery. The NPDES permit files that EPA reviewed were current, orderly, and readily available for review.

RWQCB 4 Staffing for the NPDES Permitting Program

While in previous years RWQCB 4 has had an appreciable backlog of expired permits, under the watershed permitting approach (and Watershed Management Initiative, or WMI), permit issuance has been prioritized using a rotating watershed approach. RWQCB 4 has established 11 watershed management areas which are scheduled for permitting activities on a seven-year cycle. This cycle began in 1995, with the Ventura River and Calleguas Creek Watersheds, and will be completed in 2002, with the Los Angeles/Long Beach Harbors and Dominguez Channel Watersheds. The focus of permitting activities by RWQCB 4 during FY 1997/1998 and FY 1998/1999 is the Los Angeles River Watershed.

In the Watershed Regulatory Section (WRS), 12 staff and four supervisors are responsible for all surface water core regulatory activities in 11 watershed management areas, including NPDES permit reissuance. WRS priority activities for FY 1998/1999 include:

- permit reissuance and processing new individual permit applications;
- conducting inspections, tracking violations, and recommending enforcement (as appropriate);
- working with stakeholder groups in "off-year" watersheds on development and implementation of watershed management plans and monitoring programs;

- working with municipal storm water permittees on implementation of MS4 permits; and
- outreach to industrial/construction general storm water permit non-filers, etc.

While most WRS staff are experienced at writing NPDES permits, EPA encourages WRS staff to attend relevant training courses to update and broaden their expertise as training funds become available. At the request of RWQCB 4, Region 9 will be pleased to conduct a one-day whole effluent toxicity (WET) training course at the RWQCB 4 offices during FY 1999.

NPDES Permits--EPA Conclusions

Watershed Management Initiative (WMI) Schedule for Permit Issuance

In FY 1994/1995, RWQCB 4 had a NPDES permit backlog (individual permits including storm water) with nearly 70 percent of their permits requiring reissuance. In 1995, RWQCB 4 implemented its watershed permitting approach in accordance with the WMI, whereby priorities for permit issuance have been established consistent with emphasis on priority watersheds. At the completion of FY 1997/1998, RWQCB 4 is reissuing all permits in accordance with their WMI schedule for permit issuance, with only a few minor permits remaining backlogged. This is a significant accomplishment.

Storm Water Permitting

The Los Angeles County storm water permit (MS4) was reissued in July 1996. EPA was heavily involved in developing the draft permit and endorsed its reissuance. This review utilizes storm water permitting guidance available in 1996, which EPA used at that time to evaluate the reissued permit. The most important component of an MS4 permit is the storm water management program (SWMP). This permit specifies highly detailed and well thought-out requirements for the SWMP. RWQCB 4 is commended for its efforts in the development of these requirements, and for its extensive outreach to interested parties in the development of the SWMP and other permit requirements.

EPA suggests that RWQCB 4 include each of the requirements for an annual report as specified at 40 CFR 122.42(c) in its MS4 permits. Although the Los Angles County MS4 permit requires compliance with 40 CFR 122.42(c), the list of annual reporting components which is included in the permit omits any reference to budget information. A permittee may mistakenly only respond to the specific requirements as set forth in the permit. The suggested change would reduce the chance for such an omission.

EPA suggests that RWQCB 4 consider encouraging public agencies that develop general public education programs on reduction of discharge of toxic materials to include pesticides in their programs - this would be expected to result in lessening the adverse impact on water quality stemming from routine household use of pesticides. Part 2.V.C.1.b.i.aa of the Los Angeles

County MS4 permit omits mention of pesticides in its outline of the residential public education program. EPA recommends that pesticides be specifically mentioned as they are in Part 2.IV.C.4.a for public agency activities.

Also, in addition to procedures for evaluating exfiltration from the sanitary sewer, RWQCB 4 should persuade permittees to include procedures for evaluating malfunctioning septic systems in their programs. EPA's Part 2 MS4 guidance manual recommends that failing septic systems be investigated as a potential source of pollutants in storm water runoff. The Santa Monica Bay EPI study also cited failing septic systems as potential sources of the pathogens which have generated concerns in Santa Monica Bay recreational waters.

In addition, the reissued Los Angeles County MS4 permit provides that the County is to propose "model" programs which, upon approval by the Executive Officer or RWQCB 4's Board, are then to be adopted by the co-permittees. In light of the current problems hindering implementation of the terms of the reissued permit (see discussion on pages 28-30 of this report, Storm Water Compliance Activities), neither EPA nor RWQCB 4 should endorse this type of permit in the future. Any permits which rely on action by the regulatory agency before requirements are triggered may experience similar implementation problems due to the uncertainties of future resources and changing priorities.

Finally, EPA has objected to "precedential" receiving water limits which were adopted by the SWRCB in January 1998, and incorporated into recent MS4 permits (the RWQCB 2 Vallejo and the RWQCB 9 Riverside County MS4 permits). The "precedential" language requires that storm water management plans be designed, implemented, and, if necessary, upgraded to prevent only those exceedances which "cause or substantially (in more than a de minimus amount) contribute to a continuing or recurring exceedance of any applicable water quality standard." EPA believes that receiving water limitations must address all exceedances of water quality standards--not just those that are substantial, continuing, or recurring. The Los Angeles County MS4 permit contains its own unique receiving water limits language which provides that implementation of Best Management Practices (BMPs) required by the permit constitute compliance with receiving water limits. EPA accepted this language when the permit was reissued and has not reconsidered its acceptability since that time. However, the revised receiving water limitation language, which EPA developed with the SWRCB and the California Storm Water Quality Task Force, needs to be included in all forthcoming MS4 permits issued in the State, including those in RWQCB 4.

Application of Secondary Treatment Standards

In response to CWA requirements, EPA has established performance standards for secondary treatment at 40 CFR 133.102 which describe national minimum levels of effluent quality required for five-day Biochemical Oxygen Demand (BOD_5) and Suspended Solids (SS) (both effluent concentration and percent removal from influent) as well as pH. All publicly owned treatment works with permits reviewed or spot checked by EPA contained appropriate secondary treatment standards, including some which were more stringent than the Federal minimums in order to fully protect beneficial uses. In some of these permits, while EPA found that secondary treatment standards for effluent pH were not contained in the permit's "Discharge Limitations" section, they were found in the "Standard Provisions, General Monitoring, and Reporting Requirements" section ("Attachment N" to these permits).

Application of Effluent Limitations Guidelines

National effluent limitations guidelines set forth effluent limits for industrial categories (i.e., refineries, foundries, etc.). The guidelines, as developed by EPA, represent a reasonable level of wastewater treatment which is within the economic means of specific categories of industrial facilities. The industrial permit reviewed by EPA (El Segundo Refinery) included all effluent limits required by applicable effluent limitations guidelines. WRS staff are commended on their implementation of the guidelines given the complex circumstances surrounding the discharge of process and non-process wastewaters by this facility (described in the fact sheet and permit findings).

Implementation of Water Quality Standards

EPA recognizes that a number of the RWQCB 4 water quality standard permitting problems that are discussed below are partially attributable to the lack of State-wide water quality standards for toxic pollutants. EPA's promulgation of the California Toxics Rule (CTR) and the State's adoption of the Inland Surface Waters and Enclosed Bays and Estuaries Plan's Implementation Policy are expected to address this issue for most constituents. In the interim, to ensure permits are issued as required, all RWQCBs should refer to EPA's *Technical Support Document* and to fact sheets and permits that will be provided as examples by the SWRCB, as discussed in Appendix A, State-wide issues.

The regulations at 40 CFR 122.44(d) require that numeric water quality based effluent limitations be established for discharged pollutants which cause, have the reasonable potential to cause, or contribute to an exceedance of narrative or numeric water quality standards. In the permits reviewed in-depth or spot checked, fact sheets/permit findings indicate that "reasonable potential" served as the basis for many of the water quality based effluent limitations. Fact sheets/statements of basis need to clearly detail: (1) the procedure by which reasonable potential was determined for the discharge (e.g., the statistical approach from EPA's *Technical Support Document for Water Quality-based Toxics Control (Technical Support Document*; TSD) for water quality-based toxics control, percent of objective approach, detected in effluent approach, etc.); (2) which effluent pollutants were evaluated for reasonable potential; and (3) other important characteristics of effluent pollutant data sets evaluated for reasonable potential (e.g., operational time period which data represent, size of data set, etc.). In addition, EPA recommends that the WRS use a consistent approach for determining reasonable potential.

In some of the ~~permits reviewed in depth,~~ EPA found ~~that some~~ water quality based effluent limitations were not based on appropriate numeric criteria, for example: (1) for protection of an "aquatic life" beneficial use, effluent limits were established based on less stringent Maximum Contaminant (MCL) objectives, rather than on more stringent protective aquatic life criteria; and (2) while daily maximum limits were established based on available <u>acute</u> aquatic life criteria, no monthly average limits were established based on available <u>chronic</u> aquatic life criteria. EPA also found that the averaging period for a given numeric objective/criterion was not consistently applied to permits. For example, the averaging period for the same objective should not be "daily maximum" in one permit and "monthly average" in another permit. EPA suggests that the WRS develop procedures to ensure consistent implementation of objectives/criteria with respect to beneficial use protection, reasonable potential determinations and effluent limit averaging period (see also EPA's *Technical Support Document*, Chapter 3, Effluent Characterization, and Chapter 5, Permit Requirements).

In all inland surface water discharge permits reviewed in depth or spot checked, the metals effluent limits were not properly developed. The "form" required for most metals effluent limits in these permits was the "dissolved" form rather than the "total recoverable" form, as defined in 40 CFR 136. Expressing water quality objectives/criteria for metals in the dissolved form poses the need to "translate" between dissolved and total recoverable metal forms for the purpose of NPDES permits, so that total recoverable effluent limits for metals can be established as required by 40 CFR 122.45(c). This translation is necessary because chemical conditions in ambient waters frequently differ substantially from those in effluents, and there is no assurance that effluent particulate metal will not dissolve after discharge.

A "translator" is the ratio of dissolved to total recoverable metal concentrations as an effluent mixes with the receiving water, and is used to estimate the concentration of total recoverable metal in an effluent (i.e., the wasteload allocation based on a TMDL or estimated using a water quality objective/criterion) that equates to a dissolved instream concentration equal to the dissolved objective/criterion[2]. This "total recoverable" wasteload allocation represents the maximum release that will still allow attainment of the "dissolved" objective/criterion. Total recoverable metal effluent limits are established based on this wasteload allocation. Where site-specific "translators" have not been developed, EPA recommends using criteria conversion factors as default translators. EPA notes that Water Effect Ratios (WERs) should be used to

---

2

$$WLA_t = \frac{[C_t(Q_u+Q_e)-Q_uC_u]}{Q_e}, \text{ where}$$

WLA_t	=	total recoverable wasteload allocation
C	=	concentration
C_t	=	total recoverable instream concentration equal to the dissolved criterion (i.e., "dissolved" criterion + translator)
Q	=	flow
u	=	upstream
e	=	effluent

develop site-specific objectives/criteria, not "dissolved" effluent limits, as allowed in RWQCB 4 permit conditions. Also, in some permits, EPA found that hardness values for the "effluent" rather than the "ambient water body" were used to determine applicable water quality criteria for some metals. EPA recommends that ambient hardness values be used to determine applicable water quality criteria for metals.

Implementation of Whole Effluent Toxicity

EPA recognizes that a number of the whole effluent toxicity (WET) permitting problems discussed below are partially attributable to the lack of a State-wide implementation policy for toxicity. Progress in addressing these issues is expected once the State adopts its Implementation Policy for toxics standards for inland surface waters, enclosed bays, and estuaries of California.

EPA recommends that permits require sensitivity screening using a vertebrate and an invertebrate for acute toxicity test species, as recommended in the *Technical Support Document.* Most permits reviewed in depth or spot checked required both acute and chronic WET monitoring, and most inland surface water discharge permits required chronic toxicity monitoring in the receiving water. While these permits required sensitivity screening using a vertebrate, invertebrate, and alga for chronic toxicity test species, they did not require sensitivity screening using a vertebrate and an invertebrate for acute toxicity test species. In addition, permits should require that all WET and receiving water testing be conducted using the most current acute and chronic toxicity test methods manuals approved under 40 CFR 136.

In all inland surface water discharge permits reviewed or spot checked, EPA found that chronic toxicity limits (using the Basin Plan's narrative objective for toxicity) are applied to the "receiving water" rather than the "effluent." Subsequent to the EPA review exit briefing, further analyses indicated that for at least one of these facilities where there had been chronic toxicity problems with the effluent (Tillman WRP; see Enforcement Case Studies section of this report), the permit was reissued with receiving water limits for chronic toxicity rather than effluent limits. EPA wishes to emphasize that receiving water limits for chronic toxicity may be used to complement, but cannot substitute for water quality-based effluent limits for chronic toxicity when required by "reasonable potential" regulations at 40 CFR 122.44(d)[3]. Where effluent data for chronic toxicity demonstrate the "reasonable potential" to exceed the Basin Plan's narrative objective for toxicity, regulations at 40 CFR 122.44(d) require water quality based effluent limits for chronic toxicity or for the pollutant(s) causing the toxicity. Where receiving water limits for chronic toxicity are warranted, EPA recommends that the permit clearly establish the distance downstream of the effluent discharge within which chronic toxicity may occur, consistent with Basin Plan chronic toxicity mixing zone provisions (<250 feet).

3 While this statement is made in the context of our review of implementation of whole effluent toxicity in permits, it also applies to any pollutant discharged under the NPDES.

Several ~~permits reviewed in depth contained~~ "Toxicity Identification Evaluation (TIE) trigger" conditions following exceedances of 1 TUc in the receiving water; EPA supports using the magnitude of 1 TUc as a benchmark for triggering investigation into the causes of toxicity and as the basis for establishing water quality-based limits for chronic toxicity when reasonable potential is demonstrated.

All permits reviewed in depth contained "TIE trigger" conditions based on the observance of "consistent toxicity," or toxicity observed over "n" consecutive months; however, these permits did not require accelerated effluent monitoring for toxicity following the exceedance of an effluent limit or benchmark where no effluent limit has been established. Where accelerated effluent monitoring is not required following such an exceedance, EPA is concerned that critical levels of effluent toxicity may continue for an unacceptably long period of time before any action to reduce effluent toxicity is required by the permit. This is of special concern where effluent monitoring requirements for toxicity are infrequent in relation to the frequency of exceedances that trigger action by the permittee to reduce or identify the cause(s) of toxicity. Region 9's recommendations for accelerated effluent monitoring following the measurement of effluent toxicity at critical levels may be found in the *Regions 9 and 10 Guidance for Implementing Whole Effluent Toxicity Testing Programs* (Denton and Nerves, 1996).

Finally, understanding that ammonia, in conjunction with other toxicants, may be responsible for toxicity at critical levels, EPA recommends that standard permit language specifying the conditions under which ammonia can be removed during a toxicity test be updated. When the suspected toxicant is ammonia, recommended procedures for identifying and evaluating the cause(s) of toxicity are outlined in pages 5-7 through 5-9 of *Regions 9 and 10 Guidance for Implementing Whole Effluent Toxicity Testing Programs.*

Other Permitting and Documentation Requirements

In two of the six permits reviewed in depth (Simi Valley WQCF and Tapia WRF), effluent or receiving water monitoring requirements for some pollutants with effluent limits or receiving water limits (e.g., chronic toxicity) were omitted from the monitoring and reporting program. This should not be allowed. Despite these two cases, EPA believes that only on occasion do these types of omissions occur and that it is routine procedure for RWQCB 4 to include monitoring requirements for all pollutants with effluent limits and for ambient toxicity when a permit contains a toxicity "receiving water limit" or "receiving water objective".

The fact sheet (or statement of basis) and supporting documentation serve as the primary basis for defending a permit in an administrative appeal and, ultimately, in the courts. Regulations at 40 CFR 124.8 require that fact sheets contain the following information:

- the type and ~~quantity of pollutants treated and discharged;~~
- a summary of the basis for the tentative permit conditions including reference to applicable statutory or regulatory provisions and appropriate supporting references to the administrative record; and
- any calculations or other necessary explanations of the derivation of specific effluent limits and conditions.

The fact sheets prepared by the WRS provide summary explanations for permit requirements, and special attention is given to the source document for water quality based effluent limitations. Additional explanation detailing the basis for requiring water quality based effluent limitations needs to be provided in the fact sheet, including reasonable potential procedures and the methodology used to implement water quality objectives/criteria as effluent limits.

For some permits reviewed in depth, fact sheets/permit findings did not indicate whether antibacksliding requirements at Section 402(o) of the CWA (see also 40 CFR 122.44(l)) and Section 303(d) of the CWA have been met. Permit fact sheets/statements of basis need to clearly document whether antibacksliding requirements are met.

In general, fact sheets/permit findings for the reviewed and spot checked permits did not appear to establish whether the permit is consistent with State and federal antidegradation policies. The fact sheet/statement of basis needs to document whether the permitted discharge is consistent with State and federal antidegradation policies.

As discussed above, the need for greater specificity in fact sheets is a State-wide issue. To ensure permits are issued as required, all RWQCBs should refer to EPA's *Technical Support Document* and to fact sheets and permits that will be provided as examples by the SWRCB, as discussed in Appendix A, State-wide issues.

Standard Permit Conditions

Standard permit conditions in 40 CFR 122.41 and 122.42 delineate the legal, administrative, and procedural requirements for all NPDES permits. Standard conditions may be incorporated into the permit verbatim, or by specific reference to the regulations. The use of standard conditions helps ensure uniformity and consistency of all NPDES permits issued by authorized States or EPA. NPDES permits adopted by RWQCB 4 contain these standard permit conditions in the "Standard Provisions, General Monitoring, and Reporting Requirements" section (NPDES permit "Attachment N"). EPA reviewed "Attachment N" dated April 21, 1997, and concluded that it should be updated with respect to violation penalties, sludge conditions, and reporting requirements. EPA also noted that at least two different versions of "Attachment N" (i.e., April 21, 1997 and May 14, 1997) are being used by the WRS. Because attachments may change ~~over time; EPA requests that signed major permits~~ sent by RWQCB 4 to EPA include all attachments, including "Attachment N."

Memorandum of Agreement (MOA)

The MOA requirements are generally followed by RWQCB 4. While tentative permits seem to be provided to EPA for review within time frames specified under the MOA, all permit attachments and fact sheets/statements of basis do not accompany these submittals. EPA requests that the practice of sending to EPA all permit attachments and fact sheets for major permits be reinstated.

EPA has noted that during the public comment period, as RWQCB 4 enters into negotiations with the permittee and other interested parties, substantial changes may be made to the noticed tentative permit prior to adoption by the RWQCB's Board. In accordance with 40 CFR 124.10 and case law which establishes the standard for re-initiating public notice, a second public notice may be required when RWQCB 4 changes to tentative permits are "substantial" or when the changes can not reasonably be considered a "logical outgrowth" of the public comments received during the public comment period. While this can be a fact-specific judgment call, re-noticing may avoid procedural challenges and bring out any lingering substantive concerns. This issue may be of State-wide concern, in addition to those State-wide issues discussed in Appendix A.

Permit Modification Procedures

In its review, EPA noted that permit modifications, especially modifications to monitoring and reporting programs which result in less stringent permit conditions, are frequently made by the Executive Officer. Many of these modifications are major modifications as defined by regulations at 40 CFR 122.62, and must be properly public noticed and subject to appeal procedures (see also the MOA). During the in-depth review of major permits, EPA found that RWQCB 4 improperly modified one of the permits subsequent to its expiration date (Tillman, Order No. 91-102 issued 9/9/91, as modified in 1998). Improper modifications undermine permit enforceability, therefore, EPA requires that all permit modifications be conducted in accordance with applicable regulations. This issue may be of State-wide concern, in addition to those State-wide issues discussed in Appendix A.

Compliance Schedules

As established by 40 CFR 122.47 and applicable case law, NPDES permits cannot contain compliance schedules for achieving water quality based effluent limitations unless an authorizing provision is included in a State's water quality standards. The primary water quality standards document in the Los Angeles Region is the Basin Plan. The Basin Plan contains an authorizing compliance schedule provision for ammonia objectives, but not for other effluent pollutants routinely regulated in NPDES permits. Several permits reviewed in depth or spot checked by EPA contained unauthorized compliance schedules for water quality based effluent limitations without an authorizing provision in the applicable water quality control plan. EPA requires that when an authorizing compliance schedule provision is not included in the applicable water quality control plan, the permit must be issued with a companion enforcement order containing appropriate compliance schedule conditions. This was one of the bases for EPA's subsequent objections to the reissuance of permits for Tillman WRP, Glendale WRP, and Burbank WRP and SPP. EPA's concerns were fully addressed by RWQCB 4, and Time Schedule Orders (TSOs) for these facilities have been issued. This issue is of State-wide concern, as discussed in Appendix A.

EPA CONCLUSIONS SUMMARY--PERMITS

Strengths

1. In FY 1994/1995, RWQCB 4 had a NPDES permit backlog (individual permits including storm water) with nearly 70 percent of their permits requiring reissuance. At the completion of FY 1997/1998, RWQCB 4 was reissuing all permits in accordance with its workplan schedule for permit issuance, with only a few minor permits remaining backlogged. This is a significant accomplishment.
2. RWQCB 4 is coordinating the setting of water quality standards with NPDES permitting using a rotating priority watershed approach.
3. RWQCB 4 is establishing water quality based effluent limitations for toxic chemicals in NPDES permits when the RWQCB finds that a discharge causes, has the reasonable potential to cause, or contribute to an exceedance of narrative or numeric water quality objectives (i.e., has "reasonable potential").
4. Where reasonable potential is established and numeric water quality objectives for toxic chemicals are lacking, RWQCB 4 is using the Basin Plan narrative toxicity objective in conjunction with protective numeric criteria for toxic chemicals (e.g., NTR criteria, Gold Book criteria, etc.) to establish water quality based effluent limitations which in most cases ensure protection of beneficial uses. Lack of State-wide water quality standards for toxic pollutants is a State-wide issue, discussed below.
5. RWQCB 4's NPDES permit files were orderly, current, and readily available for review.

Required Changes--State-wide Issues

1. The current lack of State-wide water quality standards for toxic pollutants, and the absence of a plan of implementation for establishing water quality based effluent limits for toxics and whole effluent toxicity, results in NPDES permit issuance problems at all the RWQCBs, including RWQCB 4. EPA Promulgation of the California Toxics Rule (CTR) and the State's adoption of the Inland Surface Waters and Enclosed Bays and Estuaries Plan's Implementation Policy are expected to address this issue for most

constituents. In ~~the interim, to ensure permits~~ are issued as ~~required,~~ all RWQCBs should refer to EPA's *Technical Support Document* and to fact sheets and permits that will be provided as examples by the SWRCB. During the period prior to adoption and implementation of the CTR and the toxic standards for inland surface waters, enclosed bays, and estuaries, all RWQCBs should develop a permitting process to ensure consistent establishment of water quality based effluent limits using Basin Plan objectives and other protective numeric criteria. In addition, during the period prior to adoption and implementation of Total Maximum Daily Loads (TMDLs) for 303(d) listed waters, all RWQCBs should develop a permitting process which ensures consistent establishment of water quality based effluent limits for discharges to 303(d) listed waters without TMDLs where discharges are found to contain pollutants causing or contributing to non-attainment.

2. Adoption of NPDES permits by the RWQCBs containing compliance schedules for water quality based effluent limitations is not allowable (in accordance with 40 CFR 122.47 and applicable case law [i.e., Star-Kist Caribe, Inc., NPDES Appeal No. 88-5]) unless an authorizing provision is contained in the applicable water quality control plan (e.g., Basin Plan, Ocean Plan, etc.) EPA requires that when an authorizing compliance schedule provision is not included in the applicable water quality control plan, the permit must be issued with a companion enforcement order containing appropriate compliance schedule conditions. RWQCB 4's Basin Plan contains an authorizing compliance schedule provision for ammonia objectives, but not for other effluent pollutants routinely regulated in NPDES permits. Several RWQCB 4 tentative permits reviewed in depth or spot checked by EPA contained unauthorized compliance schedules for water quality based effluent limitations without an authorizing provision in the applicable water quality control plan. EPA's concerns were fully addressed and Time Schedule Orders (TSOs) for these facilities were issued by RWQCB 4 to meet this requirement.
3. All RWQCBs including RWQCB 4 need to ensure that permit fact sheets/statements of basis clearly establish that permits are consistent with applicable statutes, regulations, and policy (e.g., reasonable potential, antibacksliding, establishing mixing zones, determining dilution credits, etc.). Along with summary explanations, RWQCB 4's fact sheets need to provide additional explanation detailing the basis for requiring water quality based effluent limitations, including reasonable potential procedures and the methodology used to implement water quality objectives/criteria as effluent limits.
4. Appropriate receiving water limitations language, for which acceptable model language was developed by EPA, SWRCB, and the California Storm Water Quality Task Force, needs to be included in all forthcoming municipal storm water permits from all the RWQCBs, including RWQCB 4.

Required Changes--RWQCB 4

1. In accordance with 40 CFR 122.45(c), RWQCB 4 must establish metals effluent limits in the "total recoverable" form rather than the "dissolved" form.

2. In accordance with 40 CFR 122.44(d), where recent toxic chemical effluent data indicate the "reasonable potential" to exceed the Basin Plan narrative toxicity objective protecting aquatic life beneficial uses, RWQCB 4 must establish water quality based effluent limits for that toxic chemical using numeric Basin Plan objectives (or other protective numeric criteria when numeric objectives are lacking) that will protect aquatic life beneficial uses. For example, a MCL objective should not be used to protect aquatic life beneficial uses where aquatic life criteria are available and more stringent than the MCL.
3. In accordance with 40 CFR 122.44(d), when recent chronic WET data indicate the "reasonable potential" to exceed the Basin Plan narrative toxicity objective, RWQCB 4 must establish water quality based effluent limitations for either chronic toxicity or for the pollutant(s) causing the toxicity.
4. In accordance with 40 CFR 124.10 and case law which establishes the standard for re-initiating public notice, RWQCB 4 must conduct a second public notice when RWQCB 4 changes to tentative permits are "substantial" or when permit changes can not reasonably be considered a "logical outgrowth" of the public comments received during the comment period. This issue may be of State-wide concern, in addition to those State-wide issues discussed in Appendix A.
5. In accordance with 40 CFR 122.62, RWQCB 4's major permit modifications must be public noticed and subject to appeal procedures. This includes changes to permit monitoring programs which result in less stringent permit conditions. EPA notes that this issue may be of State-wide concern, in addition to those State-wide issues discussed in Appendix A.
6. In accordance with applicable case law, RWQCB 4's expired permits may not be modified (Tillman). EPA notes that this issue may be of State-wide concern, in addition to those State-wide issues discussed in Appendix A.
7. In accordance with 40 CFR 122.44(i), permits issued by RWQCB 4 with pollutant effluent limits must require monitoring for those pollutants.
8. NPDES permits and related information need to be submitted by RWQCB 4 to EPA in accordance with the MOA.

COMPLIANCE

EPA Evaluation Procedures

Activities conducted at EPA prior to the June 1998 RWQCB 4 office visit included the review of data (obtained quarterly from the State's Waste Discharger System (WDS) data system) in EPA's Permits Compliance System (PCS) data system, review of the quarterly non-compliance reports (QNCRs) submitted by RWQCB 4 from FY 1995 through 2nd quarter FY 1998, and review of the self-monitoring reports (SMRs) for the same period.

Field activities at the RWQCB 4 office included interviews with the unit chiefs (also referred to as "seniors") in the Watershed Regulatory Section (WRS) and 11 other staff of the WRS, review of files maintained by the staff, and review of staff inspection notebooks. Subsequent to the field review, supplemental information was gathered from telephone conversations with one of the above and two additional staff members.

WRS staff are responsible for all activities from permitting through compliance and informal (and occasionally formal) enforcement. Therefore, it was not possible to estimate the resources utilized in individual program activities such as inspections or SMR review.

Compliance Tracking--Procedures

RWQCB 4 has developed and is piloting a new data system, the Environmental Reporting Information System (ERIS, now known as SWIM), to replace the existing State-wide WDS. ERIS/SWIM has expanded capability as compared to WDS in terms of programs it can handle, ease of use, and ready expansion of data fields. ERIS/SWIM is also designed to receive electronic data submission from dischargers and automatically compare submitted data to requirements, thus eventually relieving staff from doing manual compliance determinations.

SMRs and other reports required by NPDES permits are received and date-stamped at a central location. The receipt date is entered into ERIS/SWIM and the report is routed to the appropriate senior; the senior then routes it to the staff responsible for the facility. The staff reviews the reports and, exercising discretion, prepares a Level 1 letter (signed by a senior) if the report is inadequate. The staff will also generate a Level 1 letter in the case of non-receipt of a due report; it is expected that ERIS/SWIM will generate non-receipt letters in the future after due dates are coded. See the Enforcement Procedures section of this report for discussion of "Levels".

Monitoring files are kept at the individual staff person's office. The staff reviews the SMRs using the actual permit or a summary sheet as a compliance reference, and enters information about the review (date, violations, etc.) onto a SMR summary review sheet (orange sheet kept on top of the SMRs in the monitoring file). For violations which warrant action other than a telephone call, a Level 1 or Level 2 letter (EO signature level, similar to a Notice of Violation) is prepared and routed up to a senior for review and transmittal to the facility, or a recommendation for Level 3 action (formal enforcement, which includes clean-up and abatement orders (CAOs), cease and desist orders (CDOs), administrative civil liability complaints (ACLCs), and civil and criminal litigation) is routed up to a senior for review/transmittal to the Standards and Enforcement Unit for action. On occasion, depending upon workload, WRS staff will prepare the Level 3 action.

All outgoing correspondence, regardless of signature level, is accompanied by a green mail checklist sheet which serves as the route slip/concurrence sheet for the document and is routed to/through the unit and section chiefs. The mail checklist is stored in a central location for approximately three months after the document is signed. If no problems occur with the document, the mail checklist is recycled.

Telephone conversations with permittees are recorded on a Record of Communication form and are filed in the facility correspondence file. This includes "dings" for minor violations when the staff person decides that a Level 1 letter is not warranted. Phone complaints received from the public are normally handled by staff responsible for the facility and the complaints are written up on a Spill/Complaint Report form. Follow-up is documented on the form which is then filed in the correspondence file. If the complaint is about a storm water problem which normally would be handled by a municipal separate storm sewer system (MS4) program, the complaint is forwarded to the MS4 agency for follow-up. Currently, RWQCB 4 is entering records of spills and complaints into its violation and enforcement tracking system and are included in the EO's report to RWQCB 4's Board. However, the current system does not accommodate automated tracking to ensure that follow-up is accomplished. EPA notes that the State-Wide Information Management System (SWIMS), when implemented, can accommodate automated tracking of follow-up

Monthly, WRS staff members give information to the unit chiefs on SMRs received and reviewed, with highlights of problems noted. The unit chief includes this information in a monthly report to the WRS section chief. Quarterly, WRS staff also prepares a form regarding all violations noted (all programs, not just NPDES), actions taken, and other information. The completed forms are given to the permit coordinator who is responsible for a number of tracking systems and reports for violations, spills, enforcement actions, and public information requests. The permit coordinator consolidates the violations information into a quarterly violations summary report which is sent to the EO as an attachment to the quarterly report. This report is made available to the public on the RWQCB 4 web site (http://www.swrcb.ca.gov/~rwqcb4).

Quarterly, WRS staff prepares the Quarterly Non-Compliance Report (QNCR) for each of their assigned facilities, as necessary. The permit coordinator compiles each individual QNCR into one report and sends it to EPA. Questions from EPA regarding content are referred to the appropriate staff person.

Compliance Tracking--Conclusions

The monitoring files reviewed by EPA were complete, well organized, and the summary review sheets were completed promptly. The WRS staff interviewed by EPA had a good knowledge of the compliance status of the facilities for which they were responsible. There is little chance that non-reporting can occur without action or that noncompliance will be unobserved. There are some problems, however, which need correction in the reporting of noncompliance.

Some of the staff are not entering certain violations on the forms which comprise RWQCB 4's quarterly violations summary report, the QNCR, or both. In some cases, staff may be using discretion in deciding that the violations are not important enough to report. This is counter to the intent of the report. Discretion can be factored in at the actions part of the report, but all violations should be reported. In one case, BKK Corporation, staff was making compliance determinations based on an interpretation of the permit rather than the permit itself. The metals limits in the 1991 permit did not state what form (total, total recoverable, dissolved) the limits took. Without such delimitation, the plain meaning is total metals. It is not proper to factor in discretion when determining compliance. RWQCB 4 needs to implement a solution to the BKK Corporation technical noncompliance problem. Since the review, EPA notes that RWQCB 4 rescinded BKK's permit and enrolled it under the General Industrial Storm Water Permit.

In another case, Ventura RCSD-Santa Paula, no information was provided on the QNCR for this facility even though it was in significant noncompliance (SNC) with BOD limits for the October 1997 through March 1998 period. The staff person said that it was not included because the information regarding noncompliance had been forwarded to the Standards and Enforcement Unit for action. The facility still should have been reported as SNC on the QNCR.

A potential problem observed was the way in which reports from the permittees are being tracked. The date that a report is physically received at the RWQCB 4 office is the official logged date for compliance purposes. However, a review of RWQCB 4 permits indicates that most, if not all, reporting requirements are phrased as "transmitted" or "submitted" without definitions being provided for these terms. The plain meaning of these terms is "sent." Thus, rather than track by receipt date, the WRS should be tracking against "sent" or postmarked date. This is hard to do, as few reports are sent certified mail and postmarks are often illegible or missing. However, enforcement could be compromised by using the wrong triggering date. RWQCB 4 has implemented procedures to ensure that permittees are notified of their respective "date certain" report due dates. The ERIS/SWIM system is now being used to track report due dates and receipt.

The WRS has experienced some difficulties in the preparation of the QNCR, especially since 1996, when EPA added non-monthly averages to the coverage. Neither the permit coordinator responsible for the QNCR nor staff have had training on preparation of the QNCR and none were familiar with the 1996 coverage expansion. Adequate preparation of the QNCR (quality and content) is of State-wide concern, as discussed in Appendix A, State-wide issues.

Inspections--Procedures

Each WRS inspector provides the WDS coordinator with a schedule of inspections to be accomplished during the upcoming inspection year (July 1 through June 30). The scheduled dates are entered into WDS and serve as a reference for future accomplishment reports.

Inspections are generally conducted without notice or with a one-day notice to all facilities, except for Department of Defense facilities (which require additional pre-notice) and power plants (which need enough notice to arrange for an environmental representative to be at the facility). Almost all of the annual inspections of major facilities are sampling inspections.

The inspector sets up the automatic sampler for the effluent sample on the first day of the inspection, conducts the inspection, and retrieves the 24-hour composite sample on the second day. A sample of the influent, when needed, is obtained by splitting a sample taken by the permittee. Samples are delivered, using chain-of-custody procedures, to the State laboratory in Los Angeles for analysis. The State lab provides the sample bottles (with preservatives, if necessary, already in the containers) and cleans the automatic samplers after use.

Inspection findings are recorded either in a bound notebook or on loose-leaf paper during the inspection. The inspectors check the standard items during the inspection, including facility site review, operations and maintenance, records, and reporting and compliance schedules. Laboratory analytical procedures are not evaluated as part of the inspection as the permits require the use of State-certified labs for self monitoring and analysis. Compliance with EPA sludge regulations is also not normally evaluated, with the exception of the Tapia wastewater treatment plant where sludge problems have been observed.

Once back at the office, the inspector completes the Facilities Inspection Report (SWRCB Form 001). The report usually does not contain any narrative description of the findings of the inspection unless non-compliance was observed; an exception to this may be if it was the inspector's first visit to the facility. The inspector may wait for the sampling results to come back from the State lab (usually one month) or may indicate "pending" on Form 001. A copy of Form 001 is then sent to RWQCB 4's WDS coordinator for data entry. After data input, the WDS coordinator indicates by a check mark on Form 001 that the data has been entered and keeps the form in a file. When the lab results are received, information about compliance or non-compliance is written on the form and the form is filed by the inspector in the facility inspection file. The lab results are also filed in the inspection file. It is left to staff discretion whether or not this information is submitted to the WDS Coordinator for entry into a "comment" field of the WDS system. The notes from the inspection may or may not be retained, depending upon the inspector and whether notes were taken on bound or loose-leaf paper.

When non-compliance is noted, either during the inspection or as a result of sample analysis, a narrative report is added to Form 001 and the report is sent to the permittee by cover letter (usually Level 1; see the Enforcement Procedures section of this report for discussion of Levels) requiring that the permittee explain the reasons for noncompliance and the actions taken to prevent recurrence. Depending upon the response, the inspector may recommend escalated action.

The APM, in Chapter 4, states that inspections conducted to fulfill EPA requirements will be documented using both Form 001 and EPA Form 3560-3, and that for majors the latter EPA Form will be sent to EPA. The inspectors do not complete the EPA Inspection Report Form 3560-3 for any inspections as EPA told the State that Forms 001 and 3560-3 contain basically the same information, so completion of the latter is not necessary. Copies of inspection reports have not been sent to EPA since 1992 when inspection data started being entered into WDS. The APM also states that copies of inspection reports will be sent to the facilities inspected, whereas RWQCB 4 only sends a report to facilities if violations are noted during the inspection. As of the time of this review, RWQCB 4 had not sent copies of inspection reports to the SWRCB for approximately two years.

Quarterly, the WDS coordinator prepares a report for each inspector which compares the inspection schedule in WDS with accomplishments. Copies of the quarterly reports are sent to the seniors and the section chief. This serves as a reminder to staff regarding remaining workload and also as a reminder to submit Forms 001 for data entry.

Inspections–EPA Conclusions

RWQCB 4 is doing a good job in conducting NPDES inspections. During inspection years (IYs) 1995 through 1997, 126 of 132 scheduled inspections of major facilities were conducted, for a 95 percent completion rate. This is very close to the regulatory requirement of 100 percent coverage [40 CFR 123.26(e)(5)]. Of these 126 inspections, 80 percent were sampling inspections which significantly exceeds the minimum requirement. One inspection was missed during IY 1995, none were missed during IY 1996, and five were missed during IY 1997. Of the latter IY, four were missed because of increased emphasis on permitting in that particular watershed, and the other facility was inspected the first month in the following inspection year. However, even though it was known that the inspections would not be conducted, no information regarding commitment changes was provided to the SWRCB and, therefore, to EPA. This eliminated EPA's opportunity to increase the coverage to 100 percent if it chose to do so, by conducting the inspections with EPA staff or contractors.

With regard to minor facilities, RWQCB 4 inspected over 97 percent of the facilities during the five-year period IY 1993 through IY 1997, which meets the EPA policy requirement of inspecting minor facilities at least once during the five year life of each permit.

Although detailed inspection reports are not routinely prepared, a review of selected field notes indicates that staff are knowledgeable about inspection techniques and the inspections are thorough. On-the-job inspector training is supplemented by formal training, such as training by sampler manufacturers, when available. Having ready access to a State lab for sample containers and cleaned samplers is a considerable asset in lessening the workload involved in sampling inspections.

Inspection reports of major facilities are not being sent to EPA as required by the MOA. For EPA to maintain its oversight role, general knowledge is needed of on-going violations and of the State and permittee actions regarding those violations. Thus, receiving copies of inspection reports which note violations is important. Also important is receiving copies of report transmittal letters which detail the action needed by the permittee as well as copies of the responses from the permittees. For inspections where no violations were noted, there is no additional information about the inspection other than what is contained in Form 001 which is entered into WDS. As this WDS data is subsequently transferred to PCS where it is available to EPA, EPA considers the inspection report to have been "sent" to EPA, and the requirement of the MOA is satisfied. This issue is of State-wide concern, as discussed in Appendix A, State-wide issues.

EPA has no requirement that reports for inspections with no violations observed should be sent to the permittee. While all EPA guidance indicates that inspection reports are normally sent to the permittees, RWQCB 4 may choose to do otherwise. The primary purpose served by sending such a report, other than courtesy, is to provide the permittee with an official record that an inspection was conducted and that no violations were found. Balanced against this would be the time involved for the additional replies and whether sufficient information may have been provided to the permittee by the inspector during the closeout interview. Regardless, inspectors should be careful to complete the portion of Form 001 which indicates which compliance areas were observed/evaluated during the inspection, and note which areas were not evaluated. This minimizes the possibility of a permittee claiming, should violations be found later, that the inspector had observed and determined facility compliance with all compliance areas.

Inspectors' use of loose-leaf paper rather than bound notebooks to record field observations is of some concern, but more troubling is that some inspectors do not keep field notes of inspections conducted where no violations are found. 40 CFR 123.26 requires that "Investigatory inspections shall be conducted, samples shall be taken and other information shall be gathered in a manner that will produce evidence admissible in an enforcement proceeding or in court". Reasonable implementation of this regulation calls for records retention for at least three years. The field notes will support findings in an inspection report as well as oral testimony because these records are the actual record of the inspection and contemporaneous recordings of observations. The notes also serve as the primary evidence in any action that may be taken. For example, a permittee may request inspector's notes of inspection findings to defend itself against an enforcement action. This issue is of State-wide concern, as discussed in Appendix A, State-wide issues. Common practice for inspectors is to keep their notebooks for their entire career. Using bound notebooks with numbered pages, with care taken so that all pages are accounted for (including, where appropriate, marking pages or portions of pages "deliberately left blank"), is the "gold standard" of note taking for field inspectors, and is strongly encouraged.

EPA CONCLUSIONS SUMMARY--COMPLIANCE

Strengths

1. RWQCB 4 has an excellent review and tracking program to assess compliance of its 44 major and 260 minor NPDES permittees. Inspection coverage of both major and minor permits is good and generally meets EPA requirements. Inspections of majors almost always includes sampling which exceeds EPA's requirements. The system developed for scheduling and reporting inspections provides a good tool for tracking accomplishments/work to be done.
2. The tracking, follow-up, and review process of SMRs is excellent, and staff is very knowledgeable of the compliance status of the permittees. The files are complete and easy to access, even though being kept at individual work stations. RWQCB 4's quarterly violation summary report is an excellent means for keeping management up-to-date on compliance, and making it available on the Internet is an excellent way to convey compliance information to the public.
3. The new ERIS/SWIM data system will be a great step forward in data management for the State of California. RWQCB 4 is to be commended for its leadership in data management in support of the State-wide program.
4. EPA's review of selected field notes indicate that staff are knowledgeable about inspection techniques and the inspections are thorough.

Required Changes--State-wide Issues

1. RWQCB 4's inspection coverage is generally adequate. However, State-wide, field presence/compliance assessment at NPDES major and minor facilities is not adequate. Issues include use of appropriate sampling methods, adequacy of field inspection notes, and depth of on-site review. Notes taken during inspections must be retained by inspectors at all the RWQCBs for at least three years, as required by 40 CFR 123.26.
2. Copies of inspection reports of major permittees, as well as copies of responses from permittees about violation follow-up, must be sent by all RWQCBs to EPA, in accordance with the Memorandum of Agreement (MOA) between EPA and the State.
3. The QNCRs submitted by the RWQCBs need improvement in quality and content. RWQCB 4 must report all appropriate violations on the QNCR, including violations of non-monthly averages, in accordance with 40 CFR 123.45 and EPA guidance.

Required Changes--RWQCB 4

1. RWQCB 4 needs to implement a solution to the BKK Corporation technical noncompliance problem, per 40 CFR 122.45(c) and 40 CFR 123.45. Since the review, EPA notes that RWQCB 4 rescinded BKK's permit and enrolled it under the General Industrial Storm Water Permit.

2. RWQCB 4 needs to implement proper compliance evaluation of report submittals, as required by 40 CFR 123.45(a)(2)(ii)(D). At a minimum, the language in all future permits needs to be reflective of the way reports will be tracked for compliance. RWQCB 4 is now implementing practices to ensure that permittees are notified of their respective "date certain" report due dates, and the ERIS/SWIM system is now being used to track report receipt.
3. The SWRCB needs to be notified by RWQCB 4 of changes in inspection schedules if they will result in less than 100 percent inspection coverage of majors for the inspection year (July 1 through June 30), in accordance with the MOA, to afford EPA the opportunity to conduct remaining inspections if so desired.

STORM WATER COMPLIANCE AND ENFORCEMENT

EPA Storm Water Evaluation Procedures

EPA's storm water compliance review consisted of two parts: (1) interviews and discussions with RWQCB 4 staff and management to discuss activities, priorities, resources issues, and other challenges, and (2) a review of selected files at RWQCB 4's offices. In particular, the Los Angeles County and Ventura County MS4 program files were spot checked for purposes of completeness, and for RWQCB 4 action on permittee submittals.

Storm Water Staffing

RWQCB 4 staff are responsible for tracking dischargers' compliance with the following storm water permits: two municipal storm water program permits covering the Counties of Los Angeles (with 86 co-permittees, including Los Angeles County) and Ventura (with 11 co-permittees, including Ventura County), both issued by RWQCB 4, and two General Permits, issued by the SWRCB, one each regulating storm water discharges from industrial and construction sites. Regarding these latter two permits, there are approximately 2,600 and 600 facilities/sites, respectively, that are subject to these two permits within RWQCB 4's jurisdiction.

As of the time of this review, RWQCB 4 received five person years from the SWRCB to implement the storm water program, including oversight of municipal, industrial, and construction permit compliance. Storm water compliance resources are distributed within each of the WRS's watershed units, as well as in the Standards and Enforcement Unit. At the time of this review, 1.5 person years were allocated within the Los Angeles Coastal Unit for oversight of the Los Angeles County MS4 program alone. This allocation includes an estimated 0.75 person years expended in support of on-going litigation with the City of Long Beach, which filed suit against RWQCB 4 in connection with issuance of the Los Angeles County MS4 permit. RWQCB 4 estimates that they require significantly more resources to properly implement their responsibilities in regard to the storm water program, and have submitted requests to the

SWRCB for the additional resources. Storm water staffing levels is a State-wide concern, as discussed in Appendix A, State-wide issues.

Storm Water Compliance Activities

WRS compliance activities in the municipal storm water program include review, comment, and approval, as appropriate, of submittals made pursuant to permit requirements. WRS staff also spend a significant portion of their time involved in periodic outreach and management meetings with co-permittees and other regulated entities (industrial facilities). In 1997-98, the WRS committed to evaluate 10 co-permittees program submittals for compliance with the Los Angeles MS4 permit conditions[4]. However, there was a significant lack of overall progress in implementing the terms and conditions of this storm water permit (as re-issued in July 1996) because the WRS had not reviewed and approved the model program components submitted by Los Angeles County, the lead permittee. The MS4 permit was structured such that a number of storm water management program components (e.g., illicit connections/illegal discharges, industrial/commercial best management practices (BMPs), etc.) are to be proposed by the County as "model" programs. Only after Executive Officer/Board approval of individual model programs are the other co-permittee cities required to adopt the model program within their own jurisdiction. As of the time of the EPA review, five major model programs submitted by the County had not yet been reviewed and/or approved by the WRS, thus hindering overall progress towards achieving permit objectives.

Compliance activities in the industrial storm water program include annual report tracking, review, and referral for enforcement (generally informal) for annual report non-submittal. Staff also responds to telephone and written inquiries from the public, and inspects sites to verify Notices of Termination and Notices on Non-Applicability, to investigate possible non-filers or to determine permit compliance status of permittee facilities. According to RWQCB 4's records, during State FY 1996/1997 (the last complete year that such records were available), WRS staff accomplished, among other things, review of 671 annual reports, issuance of 676 letters for non-submittal of annual reports, inspection of 50 industrial sites, processing of 154 Notices of Termination, and response to 1,113 phone inquiries.

Compliance activities in the construction storm water program largely consist of conducting inspections of construction sites and engaging in occasional outreach activities. For State FY 1997/1998, the Ventura Coastal Watershed Unit established and accomplished the goal of conducting pre-rainy season inspections at each active site within the watershed (approximately 40). Staff also performed follow-up inspections during the rainy season at approximately 80 percent of the active sites.

---

4 Co-permittees are required to comply with the requirements of the last (1990) permit until such time as individual elements under the re-issued (1996) permit go into effect.

Storm Water Compliance--EPA Conclusions

RWQCB 4 storm water program staff are both very knowledgeable and dedicated. They accomplish a great deal in spite of a resource base that is both severely underbudgeted and diverted from compliance activities due to the litigation brought by the City of Long Beach. Oversight of the Los Angeles County MS4 program has been adversely affected by this diversion of staff. Oversight of the Ventura County MS4 program appears to be adequate. Staff working in the Ventura Coastal Unit admirably conducted a significant number of inspections of construction sites prior to and during the past rainy season.

Going into the review, EPA was particularly concerned about the lack of compliance oversight of the Los Angeles County MS4 program. Overall progress under the terms and conditions of the storm water permit had been severely hindered due to the inability of RWQCB 4 to review/approve model program components submitted by the County as the lead permittee. Since the NPDES permit is structured such that compliance with permit requirements is dependant upon this RWQCB 4 action, EPA believed that it was important that RWQCB 4 find the means to provide a prompt and thorough review of model program components as submitted. Since the time of the review, EPA was able to assist by providing contractor resources to RWQCB 4 to help in the review of some of the outstanding model program component submittals. Also, to its credit, RWQCB 4 staff have conducted audits of certain individual co-permittee city storm water management programs.

Within the industrial and construction program areas, RWQCB 4 needs to establish a greater field presence, both to provide an appropriate level of compliance oversight of permitted facilities and sites, and to identify entities that are operating without having filed for appropriate permit coverage. This latter point is important both as an equity issue and also as a possible source of future budgetary resources for RWQCB 4's storm water staff, as a portion of permit filing fees are returned to the RWQCB from the SWRCB in the form of storm water program person years. EPA remains concerned about the lack of resources for implementation of the storm water program State-wide, as discussed in Appendix A, State-wide issues.

Finally, RWQCB 4's storm water files are generally both voluminous and very well organized. At the time of this review, the inspections tracking system was limited to gross reporting of statistics, such as the total number of inspections of industrial facilities in a given time period. However, RWQCB 4 has since developed a tracking system to account for individual inspections and dates which was activated on September 1, 1998.

See also the conclusions summaries for permitting and enforcement for additional information on the RWQCB 4 storm water program.

EPA CONCLUSIONS SUMMARY--STORM WATER

Strengths

1. RWQCB 4 is fortunate to have such knowledgeable and dedicated staff working in its storm water program. Staff is accomplishing an admirable level of work given its severely limited resource base.
2. The Ventura County municipal program is well implemented, with an adequate level of oversight by RWQCB 4 staff; RWQCB 4 nominated this permit for an EPA national award.
3. RWQCB 4 staff inspected 100 percent of active construction sites within the Ventura watershed at least once prior to the onset of the 1997-98 rainy season, and re-inspected approximately 80 percent during the rainy season. RWQCB 4 is to be commended for this pre/post rainy season inspection protocol.
4. Los Angeles Coastal watershed unit staff have started to perform in-depth audits of individual co-permittees under the Los Angeles County MS4 program.
5. During the review, the need was identified for a better inspection tracking system, to account for individual inspections and dates rather than just total number of inspections. RWQCB 4 is to be commended for developing and implementing such a tracking system in September 1998.
6. The storm water program's files are voluminous, but well organized.

Required Changes--State-wide Issues

1. A greater inspection presence in the storm water program for both industrial and construction sites needs to be established by all RWQCBs, including RWQCB 4. Activities conducted by RWQCB 4 during 1997-98 in the Ventura watershed construction program are a good model for the other RWQCB 4 watershed units to strive for.
2. Within the industrial program, RWQCB 4 needs to continue and more actively seek out non-filing facilities. EPA recognizes that increased efforts are underway.

Required Changes--RWQCB 4

1. RWQCB 4 must review and comment on the Los Angeles County MS4 permit model program submittals. Without timely RWQCB 4 action, implementation of this MS4 permit is not possible.

PRETREATMENT

EPA Pretreatment Evaluation Procedures

The review conducted at EPA of FY 1995 through FY 1998 records included Discharge Monitoring Reports (DMRs) from all RWQCB 4 approved pretreatment programs. Field activities at RWQCB 4 included review of selected records, including RWQCB 4 and SWRCB quarterly activity reports, RWQCB 4's Watershed Management Initiative (WMI) information, Pretreatment Compliance Inspection Reports (PCIs) and audits, pretreatment-related records for nine of the 11 pretreatment programs as indicated in the attached Table 4, and an interview with the Watershed Regulatory Supervisor.

Pretreatment Staffing

RWQCB 4 is responsible for the regulatory oversight of 11 approved pretreatment programs as listed in the attached Table 4. Pretreatment program oversight is assigned to six WRS staff members according to the watershed and associated permittees for which they are responsible. Each staff member is responsible for overall oversight of one to three pretreatment programs. RWQCB 4's WMI chapter identifies pretreatment inspections and audits as a Category I core activity.

In RWQCB 4, and throughout California, nearly all industrial wastewaters discharge into POTWs under the regulation of pretreatment programs. The 11 pretreatment programs in RWQCB 4 regulate over 50 percent of all significant industrial users (IUs) in California, including mostly large and old facilities, most of which must comply with complicated Federal standards. These programs account for a significant component of the toxics control accomplished in California under the Clean Water Act.

The complexity of the pretreatment program and its importance to RWQCB 4 requires in-depth experience and expertise. Implementation and oversight of the pretreatment program requires a working knowledge of the Federal pretreatment implementation regulations as well as the nearly 30 categories of Federally-regulated industries. For each regulated industry, an understanding is required of Federal rules, development documents which support the rules, industrial processes and methods, and technologies for wastewater treatment and handling. The SWRCB, RWQCB 4, or some combination of RWQCBs must develop the necessary pretreatment program expertise described above, as well as in industrial user permitting and oversight, in order to fulfill the requirements of the APM and to effectively implement the pretreatment program. This issue is of State-wide concern, as discussed in Appendix A.

Pretreatment Compliance Tracking

Quarterly and annual pretreatment reports submitted by the permittees are not consistently tracked (receipt) or reviewed by RWQCB 4. Of the nine pretreatment programs reviewed by EPA, only two pretreatment programs' annual and quarterly reports were tracked and reviewed, as indicated by the inclusion of a *Self-Monitoring Program Summary Review Sheet* in the files.

RWQCB 4's report tracking and review process requires change in order to comply with the SWRCB's Pretreatment Program Administrative Procedures Manual (APM). The APM calls for review of quarterly and annual reports, especially for submittal of Water Enforcement National Data Base (WENDB) data elements (see discussion below) and in preparation for PCIs and audits. Consistent tracking and review will ensure report receipt as required by the NPDES permit, as well as indicate Industrial User (IU) compliance status and adequate/inadequate program response and implementation. The *Self-Monitoring Program Summary Review Sheet* is a comprehensive log which is used to record program reviews, status, and activities, and is recommended for use by all RWQCB 4 pretreatment program oversight staff.

Pretreatment PCIs and Audits

The schedule for conducting PCIs and audits is included each year in California's annual CWA Section 106 grant workplan. The WMI documents set forth the following standard for pretreatment audits and inspections: all pretreatment facilities will be audited once during a 5-year period, and for years when an audit is not conducted, a PCI will be conducted. This is compatible with EPA guidance. During FY 1994/1995, four PCIs/audits were scheduled and conducted, but only two reports were issued; during FY 1995/1996, eight PCIs/audits were scheduled, but only two were conducted and had reports issued; during FY 1996/1997, eight PCIs/audits were scheduled, but only three were conducted and had reports issued. RWQCB 4 did not formally revise its PCI/audit schedule, which is required on a quarterly basis by the CWA Section 106 workplan, so that the SWRCB could notify EPA when PCI/audit commitments were not going to be met.

EPA reviewed five PCI/audit reports. This review indicated that the PCI/audits were thorough, including findings from the last PCI/audit, and review and evaluation of legal authority, local limits, IU characterization, control mechanism, compliance monitoring, enforcement program, and program resources. EPA's file review indicated that in only three cases were PCI/audit checklists used to conduct the inspections. While checklist use is not required by the APM, regular use will ensure ongoing consistency and thoroughness in the manner in which PCI/audits are conducted.

PCI/audit reports are complete, including findings, recommendations, and requirements. Of the seven reports issued by RWQCB 4, PCI reports were issued approximately three months after each PCI was conducted; audit reports were issued approximately four months after each audit was conducted, with the exception of one which was issued three years after the audit. This delay was attributed to RWQCB 4's backlogged permit reissuance activities. The APM and 106 workplan require that PCI reports be completed within 60 days from the inspection, and that audit reports be completed within 90 days from the audit. Three reports were not issued for two audits and one PCI conducted by RWQCB 4 during FY 1994/1995. However, they were reported to EPA as conducted/complete. According to EPA policy, a PCI or audit is not considered "complete" or "conducted" unless a report is issued.

The PCI/audit reports were transmitted to the pretreatment program permittees by letters signed by the watershed unit chiefs. In most cases, a 45-day response from the permittee was requested. There was some follow-up to some reports in the form of correspondence, submittals, and further RWQCB 4 review and evaluation, but this was not the case for all reports. It is also noted that RWQCB 4 has not taken any pretreatment-related enforcement actions (formal or informal) during the three-year review period, even though PCI/audit reports included findings along with "requirements" which the pretreatment permittee needed to implement in order to be in full compliance with pretreatment regulations and requirements. The APM requires that in the event of non-compliance by a discharger, the RWQCB should issued a Notice of Violation (NOV, an informal action) and conduct follow-up investigations.

Copies of PCI reports, audit reports, and completed WENDB forms (for entry into PCS) for PCIs, audits, and annual report reviews are not consistently submitted to EPA in accordance with the 106 workplan.

RWQCB 4 maintains formal files for approximately half of its approved pretreatment program permittees. Of these, most were in good order and current, but in some cases PCI and audit reports were missing and had to be located. Some files included the *Self-Monitoring Program Summary Review Sheet* as described above. RWQCB 4 must establish and maintain complete and current public files for each NPDES permittee's approved pretreatment program.

Pretreatment PCIs and Audits--EPA Conclusions

PCI and Audit Scheduling

RWQCB 4 does not formally revise its PCI/audit schedule on a quarterly basis, as required by the CWA Section 106 workplan, so that the SWRCB can notify EPA when PCI/audit commitments cannot be met. RWQCB 4 needs to establish procedures to ensure that audits and PCIs are scheduled in accordance with WMI principles and that the EPA/SWRCB is notified quarterly of schedule revisions and shortfalls.

R0018069

PCIs, Audits, Reports, and Follow-up

PCIs, audits, and their reports appear to be complete and include findings, requirements, and recommendations. Most PCI and audit reports are issued three to four months after the inspection, instead of the required two and three month interval. Three reports were not issued for two audits and one PCI conducted by RWQCB 4 during FY 1994/1995, though they were reported to EPA as conducted/complete. PCI and audit reports are transmitted by letter. RWQCB 4 needs to ensure that all PCI and audit reports are issued and timely, that adequate and timely PCI and audit follow-up investigation and enforcement is conducted, and that PCI reports, audit reports, and WENDB data elements are submitted to EPA. Lack of pretreatment enforcement is of State-wide concern, as discussed in Appendix A, State-wide issues.

Pretreatment Files

RWQCB 4 maintains formal files for approximately half of its permittees with approved pretreatment programs for which it has oversight responsibility. Of these, most were in good order and current, though RWQCB 4 needs to establish and maintain complete and current public files for all of its approved pretreatment programs, either in the permittee's facility file or in a separate pretreatment file. The *Self-Monitoring Program Summary Review Sheet* should be completed and included in all pretreatment files.

Pretreatment Program Approvals and Modifications

Program approvals and modifications generally have a lower priority than other RWQCB 4 NPDES activities, and thus have lagged in recent years. No formal approvals/modifications, including approvals of local limits, had been done during the three-year time period covered by this review. Thus, there was a backlog of actions needed (approval of local limits for the City of Los Angeles, and Burbank programs, and approval of a full-level program for Ventura Waterworks District No.1--Moorpark).

PRETREATMENT CONCLUSIONS SUMMARY

Strengths

1. PCIs, audits, and their reports are complete, including appropriate findings, requirements, and recommendations.
2. The *Self-Monitoring Program Summary Review Sheet* is a comprehensive log which is used by some staff to record program reviews, status, and activities. This *Review Sheet* is excellent and recommended for use by all staff.

Required Changes--State-wide Issues

1. The SWRCB, RWQCB 4, or some combination of RWQCBs must develop the necessary program expertise in industrial wastewater treatment, the Federal categorical standards and pretreatment regulations, and industrial user permitting and oversight, in order to fulfill the requirements of the APM and to effectively implement the pretreatment program.
2. State-wide, pretreatment priority and work commitments need to be addressed. RWQCB 4 needs to establish procedures to ensure that audits and PCIs are scheduled in accordance with WMI principles, and that EPA and the SWRCB are notified quarterly of schedule revisions and shortfalls, as required by the annual 106 workplan.
3. Lack of pretreatment enforcement State-wide is of concern, especially where water quality problems exist due to pretreatment noncompliance. RWQCB 4 must ensure that pretreatment enforcement activities are conducted, as described above, and are timely.

Required Changes--RWQCB 4

1. RWQCB 4 needs to review quarterly and annual pretreatment reports, in preparation for PCIs and audits, and for submittal of WENDB data elements as required by the MOA.
2. RWQCB 4 needs to ensure that all PCI and audit reports are issued and timely; that adequate and timely PCI and audit follow-up investigation is conducted;.and that PCI reports, audit reports, and WENDB data elements are submitted to EPA, in accordance with the MOA and the APM.
3. RWQCB 4 needs to complete the review of the Burbank local limits and formally approve the limits, as modified if necessary. In response to EPA's now completed formal reviews of the City of Los Angeles local limits, RWQCB 4 needs to approve these local limits. Also, RWQCB 4 needs to complete the pretreatment program review and approval process for the Ventura Waterworks District No. 1 (Moorpark facility).
4. RWQCB 4 needs to ensure that all records for all of its approved pretreatment programs are filed as required by the MOA.

ENFORCEMENT

EPA Evaluation Procedures

EPA's NPDES enforcement review consisted of three parts:

1. A review of the Memorandum of Agreement (MOA), applicable portions of the SWRCB's Administrative Procedures Manual [Water Quality Enforcement Policy (Resolution No. 96-030, as amended by Resolution 97-085) and "Guidance to Implement the Water Quality Enforcement Policy"], the Regional Board's Enforcement Strategy

(Order No. 97-005) and implementing guidance, and applicable portions of recent CWA Section 106 Workplans.
2. A review of case files on a subset of recent enforcement actions to verify that appropriate procedures are being adhered to.
3. A review of a selection of other NPDES permitted facility files based upon a screening of discharger self monitoring reports (SMRs) to determine how the WRS responds to violations.

Enforcement Procedures

RWQCB 4's enforcement process to ensure discharger compliance is provided in the SWRCB's Administrative Procedures Manual (APM), Water Quality, Chapter 6, which consists of the SWRCB's Water Quality Enforcement Policy (Resolution No. 96-030, as amended by Resolution No. 97-085) and "Guidance to Implement the Water Quality Enforcement Policy," dated April 1996 and amended September 1997. In March 1997, RWQCB 4 adopted Order No. 97-005, which formally adopted the SWRCB enforcement policy as its own.

According to the SWRCB's "Guidance to Implement the Water Quality Enforcement Policy," enforcement cases may be initiated from any of the following means: (1) review of SMRs, (2) compliance inspections, (3) direct facility reporting, (4) complaints, (5) file review, and/or (6) interagency notifications.

The Water Quality Enforcement Policy sets forth specific types of violations that are to be considered for possible enforcement action by the RWQCBs:

1. major NPDES facilities in Significant Non-Compliance (SNC) with Technical Review Criteria (TRC) per 40 CFR 123.45;
2. major NPDES facilities in SNC of monthly average effluent limitations in any four months in a six month period per 40 CFR 123.45;
3. any incidence of acute toxicity which violates Waste Discharge Requirements (WDRs), Basin Plans, or other provisions of law;
4. violations of narrative toxicity standards contained in WDRs or Basin Plans due to chronic toxicity;
5. violations of prohibitions contained in WDRs, Basin Plans, or enforcement orders;
6. spills (unauthorized discharges);
7. failure to submit reports;
8. violations of compliance schedule milestones;
9. failure of a POTW to implement its approved pretreatment program, and/or
10. failure to comply with terms and conditions of a storm water permit.

In taking an enforcement action, the SWRCB's Guidance to Implement the Water Quality Enforcement Policy specifies that the following types of actions are available:

1. Informal Enforcement
   - Telephone contact/follow-up letter
   - Notice of Non-Compliance Letter
2. Time Schedule Orders (TSO)
3. Notices to Comply
4. Cease and Desist Order (CDO)
5. Cleanup & Abatement Orders (CAO)
6. Modification or Rescission of WDR
7. Administrative Civil Liability (ACL)
8. Referrals for Judicial Action
   - Attorney General
   - District Attorney

In establishing its own enforcement strategy to implement the requirements of Resolution 96-030, RWQCB 4 has developed what it refers to as a "progressive enforcement policy" in which enforcement actions are generally escalated according to a discharger's response to a previous RWQCB 4 action. RWQCB 4 reserves its ability to bypass lower threshold actions if the nature of a particular set of violations so warrants. Under its progressive enforcement policy, RWQCB 4 has identified the following levels of enforcement:

Level 1:	warning letters (Notices of Non-Compliance letters), issued by the section/unit chief;
Level 2:	formal Notice of Violation, issued by the EO;
Level 3:	administrative enforcement actions, issued by the EO (CAOs) or pursuant to Board Order;
Level 4:	referrals for judicial enforcement made pursuant to Board Order

Enforcement matters had been handled within each of the respective programmatic or watershed units. However, in August 1997, the Executive Officer (EO) established a new Standards and Enforcement Unit (SEU) within the Surface Water Division, which, among other things, is responsible for the development and pursuit of all of the formal enforcement actions that are recommended to the EO or to RWQCB 4's Board for issuance. Originally a team of two plus a supervisor, the SEU had six staff at the time of this review, including a supervisor and one staff person who is dedicated to matters relating to the industrial storm water program. "Informal" enforcement--the drafting of violation letters and Notices of Violation--is still largely left to the individual WRS project officer for a given facility.

Enforcement Action Case Studies

Enforcement case files of six major NPDES permitted facilities were reviewed by EPA, in accordance with the NPDES program review checklists developed for this review and the APM. The files were selected from among the 18 actions forwarded to EPA in May 1998, and were selected so as to review one each of several different types of formal actions. EPA also reviewed facility files for three NPDES major facilities, for which enforcement had not been taken but which appeared to merit consideration due to the nature of violations reported in SMRs. The results are summarized below.

Order 95-020, Administrative Civil Liability Complaint (ACLC), Village Properties Co.

RWQCB 4 issued an ACLC on April 21, 1995, for violations of the California General Construction Activities Storm Water NPDES Permit (NPDES Permit No. CAS000002). Specifically, the ACLC alleged failure to develop and implement a Storm Water Pollution Prevention Plan (SWPPP), failure to develop and implement a monitoring program, and discharge in a manner which caused, or threatened to cause, a condition of pollution, contamination, or nuisance on at least 19 days. The ACLC cited a total maximum civil liability of $17,824,000, and recommended that RWQCB 4's Board impose an administrative civil liability in the amount of $226,200, with $26,200 ($15,000 penalty plus $11,200 staff costs) to be made due and payable, and the remaining $200,000 to be suspended, conditioned upon the discharger's compliance with the terms and conditions of the General Permit. The ACLC estimated an economic benefit of non-compliance (cost savings) in excess of $105,000, although the recommended cash penalty of $15,000 would not recover it. Village Properties (Baldwin Co.) filed for bankruptcy protection sometime after issuance of the ACLC. In subsequent discussions, RWQCB 4 agreed to settle for $35,000. There was nothing in the files dated later than February 1996 which indicated whether or not the penalty was paid. Discussions with RWQCB 4 and SWRCB staff indicated that a decision was made to not pursue the penalty through the bankruptcy process.

Order No. 95-115, Cease and Desist Order, Ojai Valley Sanitary District

RWQCB 4's Board adopted this CDO on August 21, 1995. The purpose of the Order was to extend the final date for compliance with effluent limits from July 1, 1996, to January 1, 1998. The discharger had been under a CDO establishing a final compliance date since May 21, 1990 (Order No. 90-063). The original July 1, 1996, date was the result of a previous CDO (Order No. 90-063, amended in 1992 to extend the original compliance date from July 1993 to July 1996). Order No. 95-115 also required compliance with interim milestone dates. A review of the file indicated that all interim milestone dates were complied with as reported by the discharger, and that final compliance was achieved with dedication of a new treatment facility in October 1997. When RWQCB 4 adopted the renewal order (Order No. 96-04) for Ojai Valley, that Order had a provision rescinding the CDO Order No. 90-063 which had been amended by Orders No. 92-093 and No. 95-115.

Order No. 97-136, Time Schedule Order (TSO), Las Virgenes Municipal Water District (MWD), Tapia Water Reclamation Facility (WRF)

This TSO was issued at the time of the reissuance of the facility's NPDES Permit (No. CA0056014) on November 3, 1997, because the facility was unable to immediately comply with new effluent limits established for nitrate (as N) or dichlorobromomethane. The TSO set interim effluent limits for these constituents, and also established a time schedule that required the discharger to investigate measures to reduce concentrations of these two constituents in its effluent. The TSO also set a final compliance date of October 10, 2002, for compliance with the permitted effluent limit for nitrate. However, there was no final date for compliance with the effluent limit established for dichlorobromomethane, instead stating that the interim limit "is in effect until such time as the Discharger has completed the study required in this Order and has implemented the necessary measures to reduce the pollutant in the discharge, and the Executive Order (sic) has determined that the constituent limit is achievable." Las Virgenes MWD has complied with milestone dates that had passed as of the time of the EPA review. WRS committed to the discharger that it would review the December 1997 workplans by the end of January 1998; there was no record in the file that the WRS review had been done.

Order No. 98-016, Cleanup and Abatement Order (CAO), City of Thousand Oaks, Unit W Sewer Interceptor

RWQCB 4's EO issued this CAO on February 9, 1998, to address a February 3, 1998 washout of the City's Unit W sewer interceptor during a storm event and the resulting discharge of raw sewage into the South Fork of Arroyo Conejo. The Order required an assessment of the extent of contamination resulting from the spill; implementation of a cleanup and abatement program; submittal of a written report on the February 3, 1998 event; submittal of a long term corrective action plan; and monthly status reports. According to the EO's Report of April 13, 1998 (prepared for the RWQCB's Board meeting), the discharger had complied with all of the requirements of the CAO to that date. RWQCB 4 also issued an ACLC seeking payment of penalties for the February 3, 1998 event. (EPA is aware of the results of the Board hearing on this ACLC, which occurred after this review was completed.)

City of Los Angeles, Tillman Water Reclamation Plant (WRP)

This facility's file was selected for review based upon a review of Discharge Monitoring Reports (DMRs) at EPA's office that indicated a recent history of violations of the chronic toxicity limit. The facility violated the limit for chronic toxicity during the following months: January through March, May through July, September, and November 1997; and January and March 1998. A review of this facility's files at RWQCB 4's offices revealed that the facility had acknowledged each monthly violation in submitting applicable DMRs. Further, the facility completed a toxicity identification evaluation and toxicity reduction evaluation (TIE/TRE) in February 1998, identifying "seasonal diazanon" as the likely causative agent. A review of staff reports dated 1998 to RWQCB 4's Board did not indicate that the Board had been kept informed of the continuing toxicity violations, but that is perhaps attributable to a clause in the facility's permit stating that if the discharger is implementing a TIE it shall not be considered in violation of the chronic toxicity effluent limit. The discharger requested an alternate, narrative effluent limit. The permit was re-issued in June 1998, and the chronic toxicity effluent limit was replaced with chronic toxicity "receiving water limits" for chronic toxicity, rather than effluent limits (see discussion in this report at NPDES Permitting, Other Permitting and Documentation Requirements). A review of the files also indicated several (approximately five instances during 1995 through 1997) violations of the effluent limit established for residual chlorine. There was no record that violations were reported by staff to RWQCB 4's Board in accordance with required procedures (the SWRCB's Water Quality Enforcement Policy (Resolution No. 96-030, as amended by Resolution No. 97-085). However, the WRS area engineer assigned to this facility was aware of the violations and stated that the facility was presently undergoing a rehabilitation of its chlorination/dechlorination control system, which is due to be completed in 1999.

Shell Oil Los Angeles Refinery/Carson Plant

This facility's file was also selected for review based upon a review of DMRs at EPA's office that indicated a recent history of violations of the chronic toxicity limit. In July 1997, the facility completed a Phase I TIE Report to address previously recurring toxicity in the bioassay test organism *Selanastrum*. The report identified the ionic nature of the discharge as the root cause of the observed toxicity, and recommended a change in test species to the Fathead minnow. However, the discharger reported violations of the toxicity limit in December 1997 and from January through April 1998 even with the change in test species. Additionally, the facility also reported violations of effluent limits for the following parameters: zinc (February 1998), silver (April 1998), and xylene and toluene (March 1998). There was no record that the violations were reported by staff to RWQCB 4's Board (only the toxicity violations were required to be reported per policy). The WRS staff assigned to this facility were familiar with the violations, and stated that the facility had ceased operating as a petroleum refinery, had changed to use as a bulk distribution plant, and thus now only discharged storm water, no longer having any process wastewater. The facility had, therefore, requested that its NPDES permit be terminated, and that it be placed under coverage of the California General Industrial Activities Storm Water NPDES Permit.

Texaco Refining/Marketing Inc. Los Angeles Plant

This facility's file was selected for review based upon a review of DMRs at EPA's office that indicated a recent history of violations of several effluent limits in 1997 and 1998. The facility had also been identified in a report by a local environmental group[5] as having had a significant number of spills (this assertion was not independently verified in the course of the EPA program review). A review of the facility file indicated that RWQCB 4 had in the past sent a number of informal and formal notices of violation (Levels 1 and 2) for the above-referenced effluent limit violations. Discussions with RWQCB 4 staff indicated that an enforcement action was being developed against this facility for the above-noted effluent limit violations, demonstrating a good example of RWQCB 4's progressive enforcement approach. However, the SEU indicated that they were not considering the facility's spills history in their assessment, and were unaware of the extent of this history, stating that this information had not been provided to

5 Omission Accomplished: The Lack of a Regional Water Board Enforcement Program, 1992-1997, Heal the Bay, January 1998.

them. Additionally, during the EPA site review, a draft renewal NPDES permit was mailed by the WRS without the knowledge of the SEU.

Enforcement--EPA Conclusions

EPA's review found that RWQCB 4 enforcement activities largely meet the requirements of the approved NPDES program. RWQCB 4 has adopted a "progressive enforcement approach" in implementing the SWRCB's Enforcement Policy, although not always followed in the past, in particular regarding the issuance of Level 1 and 2 non-compliance notices. At the time of this review, RWQCB 4 had taken a few formal enforcement actions in the past, and had collected some civil penalties. In August 1997, the EO created the Standards and Enforcement Unit, primarily responsible for initiating and undertaking formal enforcement actions. The number of formal actions has increased significantly since the creation of this unit. Since the time this review was conducted, EPA notes a significant improvement in both the number of enforcement actions taken and the penalties assessed by RWQCB 4, i.e., RWQCB 4 expects to issue 140 ACLs and assess over $1.5 million in fines this year. A summary of formal enforcement actions may be found in the attached Table 5. Also, enforcement files were generally complete and well organized, although most enforcement-related documentation is not being forwarded to EPA, as required by the MOA.

EPA's review found that the following RWQCB 4 enforcement activities require change to comply with applicable regulations and national policy.

Civil Penalties and Economic Benefit

During the review, EPA found that, while RWQCB 4 imposes and collects some penalties, it rarely included an assessment of, nor attempted to recover, the economic benefit of non-compliance in its penalty actions. The need for State enforcement actions to comply with State penalty policies including recovery of economic benefit through penalties is of State-wide concern, as discussed in Appendix A.

However, EPA notes that, since the time of the review, RWQCB 4 assessed a record $2.3 million penalty, which did recover economic benefit, against the City of Thousand Oaks for an 86 million gallon sewage spill. During 1999, RWQCB 4 has also initiated several ACL actions with complaints which appear to include assessment of the economic benefit of non-compliance. RWQCB 4 staff have also attended EPA's training class in BEN, the Agency's computer model for estimating economic benefit, thus providing them with the ability to determine, calculate, justify, and recover economic benefit in a consistent, fair, and equitable manner in accordance with the SWRCB's and RWQCB 4's enforcement and penalty policies and EPA national policy requirements.

EPA also noted during the review that RWQCB 4 has a history of supporting the use of supplemental environmental projects (SEPs) as a major part of its penalty actions. EPA also supports the use of SEPs, to the extent that they are consistent with EPA's "Interim Revised Supplemental Environmental Projects Policy," dated May 3, 1995. In general, EPA's policy states that SEPs may be used as a supplement to a cash penalty, which in turn "should recover, at a minimum, the economic benefit of non-compliance, plus 10 percent of the gravity component, or 25 percent of the gravity component only, whichever is greater" (Revised SEP Policy, Section E.1., page 11).

Also, although ACLCs adequately document the discharger's liability and the justification for the proposed penalty assessment, case files themselves do not appear to contain record of final payment of the ACLC penalty by the violator. This information must be retrieved from a SWRCB database. It would be advisable for the case officer to track the discharger's compliance with requirements to pay the penalty and, where appropriate, compliance with other requirements established as a condition of suspending a portion of the ACLC. These tracking activities should be documented in the files.

Violations Reporting

The SWRCB enforcement policy requires that specific types of violations be reported by RWQCB 4 to its Board. RWQCB 4 accomplishes this requirement with a quarterly "Report of Violations and Enforcement Actions." However, as noted in the case file reviews above, not all of the applicable violations are being brought to the attention of the Board as required. This may be attributable to the fact that the forwarding of violations to the compiler of the quarterly report has largely been left to individual staff's discretion. It is anticipated that this problem will be corrected with the implementation of the new automated database that is under development by RWQCB 4 (ERIS/SWIM), discussed in the Compliance Section of this report, from which the quarterly reports will be compiled in the future.

Final Compliance Dates

In the matter of the Las Virgenes Tapia WRP, one of the six case files reviewed by EPA, the adopted TSO did not contain a final compliance date for the effluent limit set for dichlorobromomethane. RWQCB 4 must ensure that all TSOs, CAOs, and CDOs require compliance with the applicable NPDES permit, establish a final compliance date, and set appropriate interim effluent limits and schedule milestones.

EPA CONCLUSIONS SUMMARY–ENFORCEMENT

Strengths

1. RWQCB 4's creation of and resource commitment to the new Standards and Enforcement Unit is commended, as is the significant improvement in both the number of enforcement actions taken and the penalties assessed by RWQCB 4 this year.
2. RWQCB 4 generally initiates formal enforcement actions (TSOs, CAOs, CDOs) to address NPDES violations when warranted, largely in conformance with SWRCB and RWQCB 4 policy.
3. RWQCB 4 imposes and collects some civil penalties through issuance of ACLCs. Since the time of this review, EPA notes that RWQCB 4 assessed a record $2.3 million penalty, which recovered economic benefit, against the City of Thousand Oaks for an 86 million gallon sewage spill.
4. RWQCB 4 has adopted a "progressive enforcement approach."
5. RWQCB 4 is currently emphasizing enforcement actions for violations due to raw sewage spills. This is consistent with EPA policy and the Federal government's Clean Water Action Plan.
6. RWQCB 4 has established a sound citizen complaint tracking system.
7. RWQCB 4 has established a binder that contains all enforcement actions available for public review.

Required Changes--State-wide Issues

1. Penalty actions at all RWQCBs need to comply with applicable State penalty policies, including recovery of economic benefit resulting from noncompliance. Economic benefit amounts must not be reduced or rescinded as an incentive toward achieving compliance or as an off-set for supplemental environmental projects.
2. All RWQCBs including RWQCB 4 need to place more emphasis on initiating formal enforcement actions in the storm water program. In particular, industries that are subject to, but that have not yet filed for coverage under, the General Industrial Storm Water Permit should be targeted. EPA acknowledges RWQCB 4's efforts which have resulted in an annual report submittal rate of 90 percent. For the remaining non-submitting facilities, RWQCB 4 has been implementing a progressive enforcement strategy that has been effective in bringing facilities into compliance. (See also the Storm Water section of this report.)

Required Changes--RWQCB 4

1. In one instance, an adopted Time Schedule Order did not contain a final compliance date. All formal enforcement actions taken by RWQCB 4 must require compliance by a date certain, and contain appropriate interim effluent limits and schedule milestone dates.
2. RWQCB 4 should ensure that all applicable violations are included in the "Report of Violations and Enforcement Actions" so that it complies with the SWRCB Enforcement Policy that all applicable violations are brought to the attention of the RWQCB 4's Board.
3. RWQCB 4 staff should ensure that they send to EPA copies of all relevant enforcement documents related to NPDES majors, including NOVs, formal actions (TSOs, CAOs, CDOs, and ACLCs), civil penalty settlement correspondence, civil penalty agreements, referrals for judicial action, and case closures.

OTHER NPDES PROGRAM SUGGESTIONS

During the conduct of this review of RWQCB 4's NPDES program, EPA identified a number of suggestions for improving RWQCB 4's administration of the program. These suggestions are based upon both EPA's experience in implementing the NPDES program and national program perspective. EPA believes these suggestions will result in a more effective program at RWQCB 4. Though not explicitly required by law, regulation, or national policy, EPA urges RWQCB 4 to implement the following:

Permits

1. RWQCB 4 should consider encouraging public agencies that develop general public education programs on reduction of discharge of toxic materials to include pesticides in their programs (i.e., pesticides should be specifically mentioned in Section V of the MS4 permit, in addition to Section IV). This would be expected to result in lessening the adverse impact on water quality stemming from routine household use of pesticides. (See page 9.)
2. In addition to procedures for evaluating exfiltration from the sanitary sewer, RWQCB 4 is encouraged to persuade permittees to include procedures for evaluating malfunctioning septic systems in their programs. (See page 10.)
3. The L. A. Board should include each of the annual reporting requirements, as listed in 40 CFR 122.42(c), in MS4 permits so that permittees will not mistakenly only respond to the specific requirements as set forth in the permit. (See page 10.)
4. The WRS should develop procedures to ensure consistent implementation of objectives/criteria with respect to beneficial use protection, reasonable potential determinations and effluent limit averaging period (see also EPA's *Technical Support*

Document, Chapter 3, Effluent Characterization, and Chapter 5, Permit Requirements). (See page 11.)

5. To protect beneficial uses, NPDES permits issued by RWQCB 4 should contain toxicity conditions which require sensitivity screening for acute toxicity using a vertebrate and an invertebrate test species. (See pages 11-12.)
6. To protect beneficial uses, NPDES permits issued by RWQCB 4 should contain toxicity conditions which require accelerated effluent monitoring for toxicity following the measurement of effluent toxicity at critical levels, as denoted by the exceedance of an effluent limit or benchmark where no effluent limit has been established. This approach is similar to existing permit conditions which specifically require accelerated monitoring when a monthly average effluent limit is exceeded. (See pages 14.)
7. To protect beneficial uses and to facilitate water quality based permitting, RWQCB 4 should develop an implementation procedure for the chronic mixing zone provision contained in Chapter 4 of the Basin Plan. (See page 13.)

Compliance

1. RWQCB 4 should consider establishing an automated system to track its follow-up on citizen complaints and spills. EPA notes that SWIMS, when implemented, will accommodate this tracking activity. (See page 21.)
2. RWQCB 4 should consider having all inspectors use bound notebooks for note-taking during inspections as contemporaneous, bound notes are of more value in civil and criminal enforcement proceedings. (See pages 23, 25.)

Pretreatment

1. All RWQCB 4 pretreatment program oversight staff should use the *Self-Monitoring Program Summary Review Sheet*. (See pages 32, 33.)

Enforcement

1. The Watershed Units that are responsible for the day-to-day oversight of regulated facilities and the new Enforcement Unit should develop and implement procedures to further improve on-going communication. This will ensure that a facility's total compliance history is considered when developing enforcement cases, and will also ensure that any enforcement issuance strategies are not hindered by lack of other information regarding a facility. As discussed above, in the context of the pending case against Texaco, all compliance information is relevant and needs to be considered in the development of an enforcement action. (See page 40-41.)

Attachment–Table 5 INVENTORY OF RWQCB 4 MAJOR NPDES ACTIONS BY YEAR								
					ACLCs			
Year	NOVs[1]	TSOs	CAOs	CDOs	No. Issued	$ Proposed by RWQCB	$ Assessed by Board	$ Collected
1995	NR[2]	0	7	1	1	$211,200	$ 11,200	0
1996	NR	0	4	2	4	$196,805	$195,805	$ 51,250
1997	360[3]	2	10	1	1	$20,000	$ 20,000	$ 15,000
1998 (as of 6/1)	568[4,7]	4	16	2	21[5]	$3,471,740[6]	3,524,140	$230,520
Total				-		$ 2,482,780[6]		

Figures on this Table may vary slightly due to conversion of tracking systems (WDS to ERIS to SWIMS). Also, collected penalty amounts do not include amounts that have/are funding supplemental environmental projects.

<u>Notes Key</u>

1) "NOVs" include informal letters, for all RWQCB programs, not just NPDES majors
2) "NR" indicates not reviewed.
3) 1997 NOV data for 7-12/97 only
4) 1998 NOV data thru 3/31 only
5) 4 of these ACLCs relate to violations of storm water permit requirements
6) $2,300,000 of this amount is attributable to a single assessment against the City of Thousand Oaks
7) This amount includes the hundreds of letters sent to industrial facilities as part of a statewide initiative to identify non-filers that are potentially subject to storm water permit requirements.

APR 0 5 1999

Mr. John Norton, Chief
Compliance Assurance and Enforcement Unit
California State Water Resources Control Board
P.O. Box 100
Sacramento, CA 95812-0100

Dear Mr. Norton:

As we discussed during our February 11, 1999, meeting with representatives from the Regional Water Quality Control Boards (RWQCBs) and the State Water Resources Control Board (SWRCB), enclosed is the list of issues in the NPDES program which all agreed are applicable throughout the State of California. These issues were identified during our NPDES reviews conducted last year at RWQCBs 4, 5, and 9. Each issue statement on the enclosed includes the actions we all agreed were needed to resolve each issue. Please distribute the enclosed list to the appropriate individuals at the SWRCB and RWQCBs.

I want to thank you for facilitating our meeting of February 11 - it greatly contributed to our being able to reach agreement on these issues and the actions needed to address them. If there are any questions on the enclosed information, please do not hesitate to contact me at (415) 744-1817 or Ms. Jenée Gavette at (415) 744-1942.

Sincerely,

Original signed by:

Mike Schulz
Associate Director
Water Division

Enclosure

EPA's NPDES program reviews conducted to date at Regional Water Quality Control Boards (RWQCBs) 4, 5, and 9 have revealed issues which are applicable throughout the State of California. These State-wide issues, discussed and ~~agreed upon by the~~ RWQCBs, State Water Resources Control Board (SWRCB), and EPA during meetings held in January and February of 1999, are listed below, along with the agreed-upon actions that address each one.

- The current lack of State-wide water quality standards for toxic pollutants, and the absence of a plan of implementation for establishing water quality based effluent limits for toxics and whole effluent toxicity, result in NPDES permit issuance problems at the RWQCBs.
  - Identified as an on-going problem, it was agreed that promulgation of the California Toxics Rule (CTR) and the State's adoption of the Inland Surface Waters and Enclosed Bays and Estuaries Plan's Implementation Policy would address this issue for most constituents.
  - In the interim, before the CTR becomes final and the State Implementation Policy is adopted, RWQCBs should refer to EPA's national guidance, *Technical Support Document for Water Quality-Based Toxics Control (EPA/505/2-90-001, March 1991).* This guidance is also summarized in *Guidance for NPDES Permit Issuance (EPA, Region 9, February 1994).* RWQCBs should also refer to the fact sheets and permits that the SWRCB will provide on the Internet (see discussion below).
  - EPA's national Permit Writers Training Course, to be given in San Francisco the week of March 22, 1999, will provide detailed instructions on the development of water quality based effluent limits in NPDES permits, giving permit writers at the RWQCBs some guidance on how to write permits addressing these issues, until the CTR and the State's Implementation Policy are completed.

- Adoption of NPDES permits containing compliance schedules for water quality based effluent limitations is not allowable, unless an authorizing provision is contained in the applicable water quality control plan.
  - Sheila Vassey, SWRCB Counsel, will address this issue by writing a memorandum to be sent to the RWQCBs and EPA.

- Permit fact sheets/statements of basis need to clearly establish that permits are consistent with applicable statutes, regulations, and policy (e.g., reasonable potential, antibacksliding, establishing mixing zones, determining dilution credits, etc.).
  - Good examples of fact sheets that defend permitting decisions will be provided in EPA's national Permit Writers Course, to be given in San Francisco beginning on March 22, 1999. EPA has requested that an additional course be given in California later this calendar year.

- These examples, along with the permits they defend, will be provided on the Internet by the SWRCB for reference by the RWQCBs.
- This issue will be referred to California's NPDES Roundtable for further discussion, and EPA will participate.
- The recommended method for reasonable potential analysis is provided in EPA's national guidance, *Technical Support Document for Water Quality-Based Toxics Control (EPA/505/2-90-001, March 1991)*. This guidance is also summarized in *Guidance for NPDES Permit Issuance (EPA, Region 9, February 1994)*. Both documents are available to the RWQCBs and SWRCB.

- Appropriate receiving water limitations language, for which acceptable model language was recently developed by EPA, the State Water Resources Control Board (SWRCB), and the California Storm Water Quality Task Force, needs to be included in all forthcoming municipal storm water permits.

  - EPA, the SWRCB, and the RWQCBs all agree to use this new language in all future municipal storm water permits.
  - As EPA issues MS4 permits, EPA will send copies to the SWRCB for distribution to all RWQCBs.

- Copies of inspection reports of major permittees, as well as copies of responses from permittees about violation follow-up, must be sent by all RWQCBs to EPA, in accordance with the Memorandum of Agreement (MOA) between EPA and State of California.

  - This issue will be discussed and resolved at California's NPDES Roundtable meeting on March 23, 1999. Bob Wills from EPA will participate.

- Compliance review of Discharge Monitoring Reports (DMRs) is often not timely, especially for minors.

  - This issue will be referred to California's NPDES Roundtable for resolution; the SWRCB will develop procedures by May 1999 for use by all RWQCBs.

- The Quarterly Non-Compliance Reports (QNCRs) submitted by the RWQCBs need improvement in quality and content.

  - Jose Angel of the State and Bob Wills of EPA will provide procedures and training for the RWQCBs this calendar year.

- Field presence/compliance assessment at NPDES major and minor facilities is not adequate. *Issues include use of appropriate sampling methods, adequacy of field inspection notes, and depth of on-site review.*

    - The SWRCB's Compliance Assurance and Enforcement Unit is developing procedures to address this issue, targeted for completion in June 1999, with State-wide implementation thereafter. EPA will assist the SWRCB in this effort.

- A greater inspection presence in the storm water program for both industrial and construction sites needs to be established by all RWQCBs; this program element is significantly under funded State-wide.

    - The identification of non-filers is a high priority and should be emphasized.
    - Expected level of inspection presence needs to be defined, as well as procedures for targeting inspections (geographic or otherwise). The State Urban Runoff Task Force will address this issue. The "floor" of a credible state-wide storm water compliance program needs to be defined. EPA compliance staff will assist in this effort.
    - EPA will work with the State to decide what activities will be funded in the coming year, e.g., identification of non-filers, development of the "floor" for a credible inspection program, and a given number of storm water inspections (SWRCB notes that $100,000 = 100 inspections).

- Pretreatment program expertise, in general, needs to be strengthened State-wide. Industrial user regulation by the State is needed. Industrial user compliance problems, especially when the pretreatment authority is for whatever reason unable to exert authority over the industrial user, must be addressed by the State.

    - Instances where EPA has identified water quality problems due to pretreatment noncompliance need to be addressed promptly by the State.
    - Pretreatment priority an work commitments need to be addressed in next year's Clean Water Act Section 106 workplan.
    - Sheila Vassey, SWRCB Counsel, will write a memorandum regarding the State's industrial user enforcement authority, to be furnished to EPA, the SWRCB, and the RWQCBs.
    - Development and availability of State-wide pretreatment expertise will be addressed by the State's NPDES roundtable, i.e., how and where to provide this expertise (at the RWQCBs or SWRCB).
    - SWRCB will identify significant unregulated industrial users.

- All RWQCB penalty actions need to recover economic benefit resulting from noncompliance, ~~in accordance with EPA policy, the MOA, the State's Administrative~~ Procedures Manual (APM), and the State Enforcement Policy.

    - The State economist has evaluated BEN (EPA's model for determining economic benefit) and determined that it's a useful tool to determine economic benefit.
    - RWQCBs will attend BEN training, to be scheduled this calendar year by EPA.
    - The State Compliance and Enforcement Roundtable is developing both penalty assessment and settlement procedures. EPA will participate in these Roundtable discussions.

National Pollutant Discharge Elimination System—Regulations for Revision of the Water Pollution Control Program Addressing Storm Water Discharges

AGENCY: Environmental Protection Agency (EPA).

ACTION: Final rule.

SUMMARY: Today's regulations (Phase II) expand the existing National Pollutant Discharge Elimination System (NPDES) storm water program (Phase I) to address storm water discharges from small municipal separate storm sewer systems (MS4s) (those serving less than 100,000 persons) and construction sites that disturb one to five acres. Although these sources are automatically designated by today's rule, the rule allows for the exclusion of certain sources from the national program based on a demonstration of the lack of impact on water quality, as well as the inclusion of others based on a higher likelihood of localized adverse impact on water quality. Today's regulations also exclude from the NPDES program storm water discharges from industrial facilities that have "no exposure" of industrial activities or materials to storm water. Finally, today's rule extends from August 7, 2001 until March 10, 2003 the deadline by which certain industrial facilities owned by small MS4s must obtain coverage under an NPDES permit. This rule establishes a cost-effective, flexible approach for reducing environmental harm by storm water discharges from many point sources of storm water that are currently unregulated.

EPA believes that the implementation of the six minimum measures identified for small MS4s should significantly reduce pollutants in urban storm water compared to existing levels in a cost-effective manner. Similarly, EPA believes that implementation of Best Management Practices (BMP) controls at small construction sites will also result in a significant reduction in pollutant discharges and an improvement in surface water quality. EPA believes this rule will result in monetized financial, recreational and health benefits, as well as benefits that EPA has been unable to monetize. Expected benefits include reduced scouring and erosion of streambeds, improved aesthetic quality of waters, reduced eutrophication of aquatic systems, benefit to wildlife and endangered and threatened species, tourism benefits, biodiversity benefits and reduced costs for siting reservoirs. In addition, the costs of industrial storm water controls will decrease due to the exclusion of storm water discharges from facilities where there is "no exposure" of storm water to industrial activities and materials.

DATES: This regulation is effective on February 7, 2000. The incorporation by reference of the rainfall erosivity factor publication listed in the rule is approved by the Director of the Federal Register as of February 7, 2000. For judicial review purposes, this final rule is promulgated as of 1:00 p.m. Eastern Standard Time, on December 22, 1999 as provided in 40 CFR 23.2.

ADDRESSES: The complete administrative record for the final rule and the ICR have been established under docket numbers W–97–12 (rule) and W–97–15 (ICR), and includes supporting documentation as well as printed, paper versions of electronic comments. Copies of information in the record are available upon request. A reasonable fee may be charged for copying. The record is available for inspection and copying from 9 a.m. to 4 p.m., Monday through Friday, excluding legal holidays, at the Water Docket, EPA, East Tower Basement, 401 M Street, SW, Washington, DC. For access to docket materials, please call 202/260–3027 to schedule an appointment.

FOR FURTHER INFORMATION CONTACT: George Utting, Office of Wastewater Management, Environmental Protection Agency, Mail Code 4203, 401 M Street, SW, Washington, DC 20460; (202) 260–5816; sw2@epa.gov.

SUPPLEMENTARY INFORMATION: Entities potentially regulated by this action include:

Category	Examples of regulated entities
Federal, State, Tribal, and Local Governments.	Operators of small separate storm sewer systems, industrial facilities that discharge storm water associated with industrial activity or construction activity disturbing 1 to 5 acres.
Industry	Operators of industrial facilities that discharge storm water associated with industrial activity.
Construction Activity.	Operators of construction activity disturbing 1 to 5 acres.

This table is not intended to be exhaustive, but rather provides a guide for readers regarding entities likely to be regulated by this action. This table lists the types of entities that EPA is now aware could potentially be regulated by this action. Other types of entities not listed in the table could also be regulated. To determine whether your facility or company is regulated by this action, you should carefully examine the applicability criteria in §§ 122.26(b), 122.31, 122.32, and 123.35 of the final rule. If you have questions regarding the applicability of this action to a particular entity, consult the person listed in the preceding **FOR FURTHER INFORMATION CONTACT** section.

I. Background

A. Proposed Rule and Pre-Proposal Outreach

On January 9, 1998 (63 FR 1536), EPA proposed to expand the National Pollutant Discharge Elimination System (NPDES) storm water program to include storm water discharges from municipal separate storm sewer systems (MS4s) and construction sites that were smaller than those previously included in the program. The proposal also addressed industrial sources that have "no exposure" of industrial activities and materials to storm water. Today, EPA is promulgating a final rule to implement most of the proposed revisions with minor changes based on public comments received on the proposal. Today's final rule also extends the deadline by which certain industrial facilities operated by municipalities of less than 100,000 population must be covered by a NPDES permit; the deadline is changed from August 7, 2001 until March 10, 2003.

In 1972, Congress amended the Federal Water Pollution Control Act (commonly referred to as the Clean Water Act (CWA)) to prohibit the discharge of any pollutant to waters of the United States from a point source unless the discharge is authorized by an NPDES permit. The NPDES program is a program designed to track point sources and require the implementation of the controls necessary to minimize the discharge of pollutants. Initial efforts to improve water quality under the NPDES program primarily focused on reducing pollutants in industrial process wastewater and municipal sewage. These discharge sources were easily identified as responsible for poor, often drastically degraded, water quality conditions.

As pollution control measures for industrial process wastewater and municipal sewage were implemented and refined, it became increasingly evident that more diffuse sources of water pollution were also significant causes of water quality impairment. Specifically, storm water runoff draining large surface areas, such as agricultural and urban land, was found to be a major cause of water quality impairment, including the nonattainment of designated beneficial uses.

In 1987, Congress amended the CWA to require implementation, in two phases, of a comprehensive national program for addressing storm water discharges. The first phase of the program, commonly referred to as "Phase I," was promulgated on November 16, 1990 (55 FR 47990). Phase I requires NPDES permits for storm water discharge from a large number of priority sources including municipal separate storm sewer systems ("MS4s") generally serving populations of 100,000 or more and several categories of industrial activity, including construction sites that disturb five or more acres of land.

Today's rule, which is the second phase of the storm water program, expands the existing program to include discharges of storm water from smaller municipalities in urbanized areas and from construction sites that disturb between one and five acres of land. Today's rule allows certain sources to be excluded from the national program based on a demonstrable lack of impact on water quality. The rule also allows other sources not automatically regulated on a national basis to be designated for inclusion based on increased likelihood for localized adverse impact on water quality.

Today's rule also conditionally excludes storm water discharges from industrial facilities that have "no exposure" of industrial activities or materials to storm water. Today's rule and the effort that led to its development are commonly referred to as "Phase II." On August 7, 1995, EPA promulgated a final rule that required facilities to be regulated under Phase II to apply for a NPDES permit by August 7, 2001, unless the NPDES permitting authority designates them as requiring a permit by an earlier date. (60 FR 40230). That rule is referred to as "the Interim Phase II Rule." Today's rule replaces the Interim Phase II rule.

EPA performed extensive outreach and worked with a variety of stakeholders prior to proposing today's rule. On September 9, 1992, EPA published a notice requesting information and public comment on how to prepare regulations under CWA section 402(p)(6) (see 57 FR 41344). The notice identified three sets of issues associated with developing new NPDES storm water regulations: (1) How should EPA identify unregulated sources of storm water to protect water quality, (2) what types of control strategies should EPA develop for these sources, and (3) what are appropriate deadlines for implementing new requirements. The notice recognized that potential sources for coverage under the section 402(p)(6) regulations would fall into two main categories: municipal separate storm sewer systems and individual (commercial and residential) sources. EPA received more than 130 comments on the September 9, 1992, notice. For further discussion of the comments received, see *Storm Water Discharges Potentially Addressed by Phase II of the National Pollutant Discharge Elimination System: Report to Congress* (EPA, 1995a), pp. 1–21 to 1–22, and Appendix J (which provides a detailed summary of the comments received as they relate to the specific issues raised in the notice).

In early 1993, the Rensselaerville Institute and EPA held public and expert meetings to assist in developing and analyzing options for identifying unregulated sources and possible controls. The report on the 1993 meetings identified two options that were favored by the various groups that participated. One option was a program that allowed States to select sources to be controlled in a manner consistent with criteria developed by EPA. A second option was a tiered approach under which EPA would select high priority sources for control by NPDES permits and States would select other sources for control under a State water quality program other than the NPDES program. For additional details see the "Report on the EPA Storm Water Management Program (Rensselaerville Study)," Appendix I of *Storm Water Discharges Potentially Addressed by Phase II of the National Pollutant Discharge Elimination System: Report to Congress* (EPA, 1995a).

EPA also conducted outreach with representatives of small entities in conjunction with the convening of a Small Business Advocacy Review Panel under the Small Business Regulatory Enforcement Fairness Act (SBREFA). This process is discussed in section IV.E of today's preamble. For additional background see the discussion in the preamble to the proposal for today's rule.

To assist EPA by providing advice and recommendations regarding the urban municipal wet weather water pollution control program, EPA established the Urban Wet Weather Flows Federal Advisory Committee (hereinafter, "FACA Committee") under the Federal Advisory Committee Act (FACA). The Office of Management and Budget approved the charter for the FACA Committee on March 10, 1995. The FACA Committee provided a forum for identifying and addressing issues associated with water quality impacts from storm water sources.

The FACA Committee established two subcommittees: the Storm Water Phase II FACA Subcommittee and the Sanitary Sewer Overflows (SSOs) FACA Subcommittee. Consistent with the requirements of FACA, the membership of both the FACA Committee and the subcommittees was balanced among EPA's various outside stakeholder interests, including representatives from municipalities, States, Indian Tribes, EPA, industrial and commercial sectors, agriculture, and environmental and public interest groups.

The Storm Water Phase II FACA Subcommittee ("Subcommittee") met fourteen times between September 1995 and June 1998. The 32 Subcommittee members discussed possible regulatory frameworks at these meetings as well as during numerous other meetings and conference calls. Members of the FACA Committee provided views regarding the development of the "no exposure" provision and other provisions in drafts of the Phase II rule. EPA provided Subcommittee members with four successive drafts of the proposed rule and preamble, outlines of the rule, summaries of the written comments received on each draft, and documents identifying the changes made to each draft. In the course of providing input to the Committee, individual Subcommittee members provided significant input and advice that EPA considered in the context of public comments received. Ultimately, the Subcommittee did not provide a written report back to the FACA Committee, and the FACA Committee did not provide written advice and recommendations to EPA. The Agency, therefore, did not rely on group recommendations in developing today's rule, but does consider the process to have resulted in important public outreach.

B. Water Quality Concerns/Environmental Impact Studies and Assessments

Storm water runoff from lands modified by human activities can harm surface water resources and, in turn, cause or contribute to an exceedance of water quality standards by changing natural hydrologic patterns, accelerating stream flows, destroying aquatic habitat, and elevating pollutant concentrations and loadings. Such runoff may contain or mobilize high levels of contaminants, such as sediment, suspended solids, nutrients (phosphorous and nitrogen), heavy metals and other toxic pollutants, pathogens, toxins, oxygen-demanding substances (organic material), and floatables (U.S. EPA. 1992. *Environmental Impacts of Storm Water Discharges: A National Profile.* EPA 841–R–92–001. Office of Water. Washington, DC). After a rain, storm water runoff carries these pollutants into nearby streams, rivers, lakes, estuaries, wetlands, and oceans. The highest concentrations of these contaminants often are contained in "first flush" discharges, which occur during the first major storm after an extended dry period (Schueler, T.R. 1994. "First Flush of Stormwater Pollutants Investigated in Texas." Note 28. *Watershed Protection Techniques* 1(2)). Individually and combined, these pollutants impair water quality, threatening designated beneficial uses and causing habitat alteration or destruction.

Uncontrolled storm water discharges from areas of urban development and construction activity negatively impact receiving waters by changing the physical, biological, and chemical composition of the water, resulting in an unhealthy environment for aquatic organisms, wildlife, and humans. The following sections discuss the studies and data that address and support this finding.

Although water quality problems also can occur from agricultural storm water discharges and return flows from irrigated agriculture, this area of concern is statutorily exempted from regulation as a point source under the Clean Water Act and is not discussed here. (See CWA section 502(14)). Other storm water sources not specifically identified in the regulations may be of concern in certain areas and can be addressed on a case-by-case (or category-by-category) basis through the NPDES designation authority preserved by CWA section 402(p)(2)(6), as well as today's rule.

1. Urban Development

Urbanization alters the natural infiltration capability of the land and generates a host of pollutants that are associated with the activities of dense populations, thus causing an increase in storm water runoff volumes and pollutant loadings in storm water discharged to receiving waterbodies (U.S. EPA, 1992). Urban development increases the amount of impervious surface in a watershed as farmland, forests, and meadowlands with natural infiltration characteristics are converted into buildings with rooftops, driveways, sidewalks, roads, and parking lots with virtually no ability to absorb storm water. Storm water and snow-melt runoff wash over these impervious areas, picking up pollutants along the way while gaining speed and volume because of their inability to disperse and filter into the ground. What results are storm water flows that are higher in volume, pollutants, and temperature than the flows in less impervious areas, which have more natural vegetation and soil to filter the runoff (U.S. EPA, 1997. *Urbanization and Streams: Studies of Hydrologic Impacts*. EPA 841–R–97-009. Office of Water. Washington, DC).

Studies reveal that the level of imperviousness in an area strongly correlates with the quality of the nearby receiving waters. For example, a study in the Puget Sound lowland ecoregion found that when the level of basin development exceeded 5 percent of the total impervious area, the biological integrity and physical habitat conditions that are necessary to support natural biological diversity and complexity declined precipitously (May, C.W., E.B. Welch, R.R. Horner, J.R. Karr, and B.W. May. 1997. *Quality Indices for Urbanization Effects in Puget Sound Lowland Streams*, Technical Report No. 154. University of Washington Water Resources Series). Research conducted in numerous geographical areas, concentrating on various variables and employing widely different methods, has revealed a similar conclusion: stream degradation occurs at relatively low levels of imperviousness, such as 10 to 20 percent (even as low as 5 to 10 percent according to the findings of the Washington study referenced above) (Schueler, T.R. 1994. "The Importance of Imperviousness." *Watershed Protection Techniques* 1(3); May, C., R.R. Horner, J.R. Karr, B.W. Mar, and E.B. Welch. 1997. "Effects Of Urbanization On Small Streams In The Puget Sound Lowland Ecoregion." *Watershed Protection Techniques* 2(4); Yoder, C.O., R.J. Miltner, and D. White. 1999. "Assessing the Status of Aquatic Life Designated Uses in Urban and Suburban Watersheds." In *Proceedings: National Conference on Retrofits Opportunities in Urban Environments*. EPA 625–R–99–002, Washington, DC; Yoder, C.O and R.J. Miltner. 1999. "Assessing Biological Quality and Limitations to Biological Potential in Urban and Suburban Watersheds in Ohio." In *Comprehensive Stormwater & Aquatic Ecosystem Management Conference Papers*, Auckland, New Zealand). Furthermore, research has indicated that few, if any, urban streams can support diverse benthic communities at imperviousness levels of 25 percent or more. An area of medium density single family homes can be anywhere from 25 percent to nearly 60 percent impervious, depending on the design of the streets and parking (Schueler, 1994).

In addition to impervious areas, urban development creates new pollution sources as population density increases and brings with it proportionately higher levels of car emissions, car maintenance wastes, pet waste, litter, pesticides, and household hazardous wastes, which may be washed into receiving waters by storm water or dumped directly into storm drains designed to discharge to receiving waters. More people in less space results in a greater concentration of pollutants that can be mobilized by, or disposed into, storm water discharges from municipal separate storm sewer systems. A modeling system developed for the Chesapeake Bay indicated that contamination of the Bay and its tributaries from runoff is comparable to, if not greater than, contamination from industrial and sewage sources (Cohn-Lee, R. and D. Cameron. 1992. "Urban Stormwater Runoff Contamination of the Chesapeake Bay: Sources and Mitigation." *The Environmental Professional*, Vol. 14).

a. Large-Scale Studies and Assessments

In support of today's regulatory designation of MS4s in urbanized areas, the Agency relied on broad-based assessments of urban storm water runoff and related water quality impacts, as well as more site-specific studies. The first national assessment of urban runoff characteristics was completed for the *Nationwide Urban Runoff Program (NURP)* study (U.S. EPA. 1983. *Results of the Nationwide Urban Runoff Program, Volume 1—Final Report*. Office of Water. Washington, D.C.). The NURP study is the largest nationwide evaluation of storm water discharges, which includes adverse impacts and sources, undertaken to date.

EPA conducted the NURP study to facilitate understanding of the nature of urban runoff from residential, commercial, and industrial areas. One objective of the study was to characterize the water quality of discharges from separate storm sewer systems that drain residential, commercial, and light industrial (industrial parks) sites. Storm water samples from 81 residential and commercial properties in 22 urban/suburban areas nationwide were collected and analyzed during the 5-year period between 1978 and 1983. The majority of samples collected in the study were analyzed for eight conventional pollutants and three heavy metals.

Data collected under the NURP study indicated that discharges from separate storm sewer systems draining runoff from residential, commercial, and light industrial areas carried more than 10 times the annual loadings of total suspended solids (TSS) than discharges from municipal sewage treatment plants that provide secondary treatment. The NURP study also indicated that runoff from residential and commercial areas carried somewhat higher annual loadings of chemical oxygen demand (COD), total lead, and total copper than effluent from secondary treatment plants. Study findings showed that fecal coliform counts in urban runoff typically range from tens to hundreds of thousands per hundred milliliters of runoff during warm weather conditions, with the median for all sites being around 21,000/100 ml. This is generally consistent with studies that found that fecal coliform mean values range from 1,600 coliform fecal units (CFU)/100 ml to 250,000 cfu/100 ml (Makepeace, D.K., D.W. Smith, and S.J. Stanley. 1995. "Urban Storm Water Quality: Summary of Contaminant Data." *Critical Reviews in Environmental Science and Technology* 25(2):93-139). Makepeace, et al., summarized ranges of contaminants from storm water, including physical contaminants such as total solids (76—36,200 mg/L) and copper (up to 1.41 mg/L); organic chemicals; organic compounds, such as oil and grease (up to 110 mg/L); and microorganisms.

R0018097

Monitoring data summarized in the NURP study provided important information about urban runoff from residential, commercial, and light industrial areas. The study concluded that the quality of urban runoff can be affected adversely by several sources of pollution that were not directly evaluated in the study, including illicit discharges, construction site runoff, and illegal dumping. Data from the NURP study were analyzed further in the U.S. Geological Survey (USGS) Urban Storm Water Data Base for 22 Metropolitan Areas Throughout the United States study (Driver, N.E., M.H. Mustard, R.B. Rhinesmith, and R.F. Middleburg. 1985. *U.S. Geological Survey Urban Storm Water Data Base for 22 Metropolitan Areas Throughout the United States.* Report No. 85–337 USGS. Lakewood, CO). The USGS report summarized additional monitoring data compiled during the mid-1980s, covering 717 storm events at 99 sites in 22 metropolitan areas and documented problems associated with metals and sediment concentrations in urban storm water runoff. More recent reports have confirmed the pollutant concentration data collected in the NURP study (Marsalek, J. 1990. "Evaluation of Pollutant Loads from Urban Nonpoint Sources." *Wat. Sci. Tech.* 22(10/11):23–30; Makepeace, et al., 1995).

Commenters argued that the NURP study does not support EPA's contention that urban activities significantly jeopardize attainment of water quality standards. One commenter argued that the NURP study and the 1985 USGS study are seriously out of date. Because they were issued 10 years or more before the implementation of the current storm water permit program, the data in those reports do not reflect conditions that exist after implementation of permits issued by authorized States and EPA for storm water from construction sites, large municipalities, and industrial activities.

In response, EPA notes that it is not relying solely on the NURP study to describe current water quality impairment. Rather, EPA is citing NURP as a source of data on typical pollutant concentrations in urban runoff. Recent studies have not found significantly different pollutant concentrations in urban runoff when compared to the original NURP data (see Makepeace, et al., 1995; Marsalek, 1990; and Pitt, et al., 1995).

America's Clean Water—the States' Nonpoint Source Assessment (Association of State and Interstate Water Pollution Control Administrators (ASIWPCA). 1985. *America's Clean Water—The States' Nonpoint Source Assessment.* Prepared in cooperation with the U.S. EPA, Office of Water, Washington, DC), a comprehensive study of diffuse pollution sources conducted under the sponsorship of the Association of State and Interstate Water Pollution Control Administrators (ASIWPCA) and EPA revealed that 38 States reported urban runoff as a major cause of designated beneficial use impairment and 21 States reported storm water runoff from construction sites as a major cause of beneficial use impairment. In addition, the 1996 305(b) Report (U.S. EPA. 1998. *The National Water Quality Inventory, 1996 Report to Congress.* EPA 841–R–97–008. Office of Water. Washington, DC), provides a national assessment of water quality based on biennial reports submitted by the States as required under CWA section 305(b) of the CWA. In the CWA 305(b) reports, States, Tribes, and Territories assess their individual water quality control programs by examining the attainment or nonattainment of the designated uses assigned to their rivers, lakes, estuaries, wetlands, and ocean shores. A designated use is the legally applicable use specified in a water quality standard for a watershed, waterbody, or segment of a waterbody. The designated use is the desirable use that the water quality should support. Examples of designated uses include drinking water supply, primary contact recreation (swimming), and aquatic life support. Each CWA 305(b) report indicates the assessed fraction of a State's waters that are fully supporting, partially supporting, or not supporting designated beneficial uses.

In their reports, States, Tribes, and Territories first identified and then assigned the sources of water quality impairment for each impaired waterbody using the following categories: industrial, municipal sewage, combined sewer overflows, urban runoff/storm sewers, agricultural, silvicultural, construction, resource extraction, land disposal, hydrologic modification, and habitat modification. The 1996 Inventory, based on a compilation of 60 individual 305(b) reports submitted by States, Tribes, and Territories, assessed the following percentages of total waters nationwide: 19 percent of river and stream miles; 40 percent of lake, pond, and reservoir acres; 72 percent of estuary square miles; and 6 percent of ocean shoreline waters. The 1996 Inventory indicated that approximately 40 percent of the Nation's assessed rivers, lakes, and estuaries are impaired. Waterbodies deemed as "impaired" are either partially supporting designated uses or not supporting designated uses.

The 1996 Inventory also found urban runoff/discharges from storm sewers to be a major source of water quality impairment nationwide. Urban runoff/storm sewers were found to be a source of pollution in 13 percent of impaired rivers; 21 percent of impaired lakes, ponds, and reservoirs; and 45 percent of impaired estuaries (second only to industrial discharges). In addition, urban runoff was found to be the leading cause of ocean impairment for those ocean miles surveyed.

In addition, a recent USGS study of urban watersheds across the United States has revealed a link between urban development and contamination of local waterbodies. The study found the highest levels of organic contaminants, known as polycyclic aromatic hydrocarbons (PAHs) (products of combustion of wood, grass, and fossil fuels), in the reservoirs of urbanized watersheds (U.S. Geological Survey (USGS). 1998. *Research Reveals Link Between Development and Contamination in Urban Watersheds.* USGS news release. USGS National Water-Quality Assessment Program).

Urban storm water also can contribute significant amounts of toxicants to receiving waters. Pitt, et. al. (1993), found heavy metal concentrations in the majority of samples analyzed. Industrial or commercial areas were likely to be the most significant pollutant source areas (Pitt, R., R. Field, M. Lalor, M. Brown 1993. "Urban stormwater toxic pollutants: assessment, sources, and treatability" *Water Environment Research*, 67(3):260–75).

b. Local and Watershed-Based Studies

In addition to the large-scale nationwide studies and assessments, a number of local and watershed-based studies from across the country have documented the detrimental effects of urban storm water runoff on water quality. A study of urban streams in Milwaukee County, Wisconsin, found local streams to be highly degraded due primarily to urban runoff, while three studies in the Atlanta, Georgia, region were characterized as being "the first documentation in the Southeast of the strong negative relationship between urbanization and stream quality that has been observed in other ecoregions" (Masterson, J. and R. Bannerman. 1994. "Impacts of Storm Water Runoff on Urban Streams in Milwaukee County, Wisconsin." Paper presented at National Symposium on Water Quality: American Water Resources Association; Schueler, T.R. 1997. "Fish Dynamics in Urban Streams Near Atlanta, Georgia."

R0018098

Technical Note 94. *Watershed Protection Techniques* 2(4)). Several other studies, including those performed in Arizona (Maricopa County), California (San Jose's Coyote Creek), Massachusetts (Green River), Virginia (Tuckahoe Creek), and Washington (Puget Sound lowland ecoregion), all had the same finding: runoff from urban areas greatly impair stream ecology and the health of aquatic life; the more heavily developed the area, the more detrimental the effects (Lopes, T. and K. Fossum. 1995. "Selected Chemical Characteristics and Acute Toxicity of Urban Stormwater, Streamflow, and Bed Material, Maricopa County, Arizona." *Water Resources Investigations Report* 95-4074. USGS; Pitt, R. 1995. "Effects of Urban Runoff on Aquatic Biota." In *Handbook of Ecotoxicology;* Pratt, J. and R. Coler. 1979. "Ecological Effects of Urban Stormwater Runoff on Benthic Macroinvertebrates Inhabiting the Green River, Massachusetts." Completion Report Project No. A-094. Water Resources Research Center. University of Massachusetts at Amherst.; Schueler, T.R. 1997. "Historical Change in a Warmwater Fish Community in an Urbanizing Watershed." Technical Note 93. *Watershed Protection Techniques* 2(4); May, C., R. Horner, J. Karr, B. Mar, nd E. Welch. 1997. "Effects Of Jrbanization On Small Streams In The Puget Sound Lowland Ecoregion." *Watershed Protection Techniques* 2(4)).

Pitt and others also described the receiving water effects on aquatic organisms associated with urban runoff (Pitt, R.E. 1995. "Biological Effects of Urban Runoff Discharges" In *Stormwater Runoff and Receiving Systems: Impact, Monitoring, and Assessment*, ed. E.E Herricks, Lewis Publishers; Crunkilton, R., J. Kleist, D. Bierman, J. Ramcheck, and W. DeVita. 1999. "Importance of Toxicity as a Factor Controlling the Distribution of Aquatic Organisms in an Urban Stream." In *Comprehensive Stormwater & Aquatic Ecosystem Management Conference Papers*. Auckland, New Zealand).

In Wisconsin, runoff samples were collected from streets, parking lots, roofs, driveways, and lawns. Source areas were broken up into residential, commercial, and industrial. Geometric mean concentration data for residential areas included total solids of about 500-800 mg/L from streets and 600 mg/L from lawns. Fecal coliform data from residential areas ranged from 34,000 to ,000 cfu/100 mL for streets and ıveways. Contaminant concentration data from commercial and industrial source areas were lower for total solids and fecal coliform, but higher for total zinc (Bannerman, R.T., D.W. Owens, R.B. Dods, and N.J. Hornewer. 1993. "Sources of Pollutants in Wisconsin Stormwater." *Wat. Sci. Tech.* 28(3-5):241-59).

Bannerman, et al. also found that streets contribute higher loads of pollutants to urban storm water than any other residential development source. Two small urban residential watersheds were evaluated to determine that lawns and streets are the largest sources of total and dissolved phosphorus in the basins (Waschbusch, R.J., W.R. Selbig, and R.T. Bannerman. 1999. "Sources of Phosphorus in Stormwater and Street Dirt from Two Urban Residential Basins In Madison, Wisconsin, 1994-95." *Water Resources Investigations Report* 99-4021. U.S. Geological Survey). A number of other studies have indicated that urban roadways often contain significant quantities of metal elements and solids (Sansalone, J.J. and S.G. Buchberger. 1997. "Partitioning and First Flush of Metals in Urban Roadway Storm Water." *ASCE Journal of Environmental Engineering* 123(2); Sansalone, J.J., J.M. Koran, J.A. Smithson, and S.G. Buchberger. 1998. "Physical Characteristics of Urban Roadway Solids Transported During Rain Events" *ASCE Journal of Environmental Engineering* 124(5); Klein, L.A., M. Lang, N. Nash, and S.L. Kirschner. 1974. "Sources of Metals in New York City Wastewater" *J. Water Pollution Control Federation* 46(12):2653-62; Barrett, M.E, R.D. Zuber, E.R. Collins, J.F. Malina, R.J. Charbeneau, and G.H Ward., 1993. "A Review and Evaluation of Literature Pertaining to the Quantity and Control of Pollution from Highway Runoff and Construction." Research Report 1943-1. Center for Transportation Research, University of Texas, Austin).

c. Beach Closings/Advisories

Urban wet weather flows have been recognized as the primary sources of estuarine pollution in coastal communities. Urban storm water runoff, sanitary sewer overflows, and combined sewer overflows have become the largest causes of beach closings in the United States in the past three years. Storm water discharges from urban areas not only pose a threat to the ecological environment, they also can substantially affect human health. A survey of coastal and Great Lakes communities reports that in 1998, more than 1,500 beach closings and advisories were associated with storm water runoff (Natural Resources Defense Council. 1999. "A Guide to Water Quality at Vacation Beaches" New York, NY). Other reports also document public health, shellfish bed, and habitat impacts from storm water runoff, including more than 823 beach closings/advisories issued in 1995 and more than 407 beach closing/advisories issued in 1996 due to urban runoff (Natural Resources Defense Council. 1996. *Testing the Waters Volume VI: Who Knows What You're Getting Into.* New York, NY; NRDC. 1997. *Testing the Waters Volume VII: How Does Your Vacation Beach Rate.* New York, NY; Morton, T. 1997. *Draining to the Ocean: The Effects of Stormwater Pollution on Coastal Waters.* American Oceans Campaign, Santa Monica, CA). The Epidemiological Study of Possible Adverse Health Effects of Swimming in Santa Monica Bay (Haile, R.W., et. al. 1996. "An Epidemiological Study of Possible Adverse Health Effects of Swimming in Santa Monica Bay." *Final Report prepared for the Santa Monica Bay Restoration Project*) concluded that there is a 57 percent higher rate of illness in swimmers who swim adjacent to storm drains than in swimmers who swim more than 400 yards away from storm drains. This and other studies document a relationship between gastrointestinal illness in swimmers and water quality, the latter of which can be heavily compromised by polluted storm water discharges.

2. Non-Storm Water Discharges Through Municipal Storm Sewers

Studies have shown that discharges from MS4s often include wastes and wastewater from non-storm water sources. Federal regulations (§ 122.26(b)(2)) define an illicit discharge as "* * * any discharge to an MS4 that is not composed entirely of storm water * * *," with some exceptions. These discharges are "illicit" because municipal storm sewer systems are not designed to accept, process, or discharge such wastes. Sources of illicit discharges include, but are not limited to: sanitary wastewater; effluent from septic tanks; car wash, laundry, and other industrial wastewaters; improper disposal of auto and household toxics, such as used motor oil and pesticides; and spills from roadway and other accidents.

Illicit discharges enter the system through either direct connections (e.g., wastewater piping either mistakenly or deliberately connected to the storm drains) or indirect connections (e.g., infiltration into the MS4 from cracked sanitary systems, spills collected by drain outlets, and paint or used oil dumped directly into a drain). The result is untreated discharges that contribute high levels of pollutants, including heavy metals, toxics, oil and grease, solvents, nutrients, viruses and bacteria into receiving waterbodies. The NURP study, discussed earlier, found that pollutant levels from illicit discharges were high enough to significantly degrade receiving water quality and threaten aquatic, wildlife, and human health. The study noted particular problems with illicit discharges of sanitary wastes, which can be directly linked to high bacterial counts in receiving waters and can be dangerous to public health.

Because illicit discharges to MS4s can create severe widespread contamination and water quality problems, several municipalities and urban counties performed studies to identify and eliminate such discharges. In Michigan, the Ann Arbor and Ypsilanti water quality projects inspected 660 businesses, homes, and other buildings and identified 14 percent of the buildings as having improper storm sewer drain connections. The program assessment revealed that, on average, 60 percent of automobile-related businesses, including service stations, automobile dealerships, car washes, body shops, and light industrial facilities, had illicit connections to storm sewer drains. The program assessment also showed that a majority of the illicit discharges to the storm sewer system resulted from improper plumbing and connections, which had been approved by the municipality when installed (Washtenaw County Statutory Drainage Board. 1987. Huron River Pollution Abatement Program).

In addition, an inspection of urban storm water outfalls draining into Inner Grays, Washington, indicated that 32 percent of these outfalls had dry weather flows. Of these flows, 21 percent were determined to have pollutant levels higher than the pollutant levels expected in typical urban storm water runoff characterized in the NURP study (U.S. EPA. 1993. *Investigation of Inappropriate Pollutant Entries Into Storm Drainage Systems—A User's Guide*. EPA 600/R–92/238. Office of Research and Development. Washington, DC). That same document reports a study in Toronto, Canada, that found that 59 percent of outfalls from the MS4 had dry-weather flows. Chemical tests revealed that 14 percent of these dry-weather flows were determined to be grossly polluted.

Inflows from aging sanitary sewer collection systems are one of the most serious illicit discharge-related problems. Sanitary sewer systems frequently develop leaks and cracks, resulting in discharges of pollutants to receiving waters through separate storm sewers. These pollutants include sanitary waste and materials from sewer main construction (e.g., asbestos cement, brick, cast iron, vitrified clay). Municipalities have long recognized the reverse problem of storm water infiltration into sanitary sewer collection systems; this type of infiltration often disrupts the operation of the municipal sewage treatment plant.

The improper disposal of materials is another illicit discharge-related problem that can result in contaminated discharges from separate storm sewer systems in two ways. First, materials may be disposed of directly in a catch basin or other storm water conveyance. Second, materials disposed of on the ground may either drain directly to a storm sewer or be washed into a storm sewer during a storm event. Improper disposal of materials to street catch basins and other storm sewer inlets often occurs when people mistakenly believe that disposal to such areas is an environmentally sound practice. Part of the confusion may occur because some areas are served by combined sewer systems, which are part of the sanitary sewer collection system, and people assume that materials discharged to a catch basin will reach a municipal sewage treatment plant. Materials that are commonly disposed of improperly include used motor oil; household toxic materials; radiator fluids; and litter, such as disposable cups, cans, and fast-food packages. EPA believes that there has been increasing success in addressing these problems through initiatives such as storm drain stenciling and recycling programs, including household hazardous waste special collection days.

Programs that reduce illicit discharges to separate storm sewers have improved water quality in several municipalities. For example, Michigan's Huron River Pollution Abatement Program found the elimination of illicit connections caused a measurable improvement in the water quality of the Washtenaw County storm sewers and the Huron River (Washtenaw County Statutory Drainage Board, 1987). In addition, an illicit detection and remediation program in Houston, Texas, has significantly improved the water quality of Buffalo Bayou. Houston estimated that illicit flows from 132 sources had a flow rate as high as 500 gal/min. Sources of the illicit discharges included broken and plugged sanitary sewer lines, illicit connections from sanitary lines to storm sewer lines, and floor drain connections (Glanton, T., M.T. Garrett, and B. Goloby. 1992. The Illicit Connection: Is It the Problem? *Wat. Env. Tech.* 4(9):63–8).

3. Construction Site Runoff

Storm water discharges generated during construction activities can cause an array of physical, chemical, and biological water quality impacts. Specifically, the biological, chemical, and physical integrity of the waters may become severely compromised. Water quality impairment results, in part, because a number of pollutants are preferentially absorbed onto mineral or organic particles found in fine sediment. The interconnected process of erosion (detachment of the soil particles), sediment transport, and delivery is the primary pathway for introducing key pollutants, such as nutrients (particularly phosphorus), metals, and organic compounds into aquatic systems (Novotny, V. and G. Chesters. 1989. "Delivery of Sediment and Pollutants from Nonpoint Sources: A Water Quality Perspective." *Journal of Soil and Water Conservation*, 44(6):568–76). Estimates indicate that 80 percent of the phosphorus and 73 percent of the Kjeldahl nitrogen in streams is associated with eroded sediment (U.S. Department of Agriculture. 1989. "The Second RCA Appraisal, Soil, Water and Related Resources on Nonfederal Land in the United States, Analysis of Condition and Trends." Cited in Fennessey, L.A.J., and A.R. Jarrett. 1994. "The Dirt in a Hole: a Review of Sedimentation Basins for Urban Areas and Construction Sites." *Journal of Soil and Water Conservation*, 49(4):317–23).

In watersheds experiencing intensive construction activity, the localized impacts of water quality may be severe because of high pollutant loads, primarily sediments. Siltation is the largest cause of impaired water quality in rivers and the third largest cause of impaired water quality in lakes (U.S. EPA, 1998). The 1996 305(b) report also found that construction site discharges were a source of pollution in: 6 percent of impaired rivers; 11 percent of impaired lakes, ponds, and reservoirs; and 11 percent of impaired estuaries. Introduction of coarse sediment (coarse sand or larger) or a large amount of fine sediment is also a concern because of the potential of filling lakes and reservoirs (along with the associated remediation costs for dredging), as well as clogging stream channels (e.g., Paterson, R.G., M.I. Luger, E.J. Burby, E.J. Kaiser, H.R. Malcolm, and A.C. Beard. 1993. "Costs and Benefits of Urban Erosion and Sediment Control: North Carolina Experience." *Environmental Management* 17(2):167–78). Large inputs of coarse sediment into stream channels initially will reduce stream depth and minimize habitat complexity by filling in pools (U.S. EPA. 1991. *Monitoring Guidelines to Evaluate Effects of Forestry Activities on Streams in the Pacific Northwest and Alaska*. EPA 910/9–91–001. Seattle, WA). In addition, studies have shown that stream reaches affected by construction activities often extend well downstream of the construction site. For example, between 4.8 and 5.6 kilometers of stream below construction sites in the Patuxent River watershed were observed to be impacted by sediment inputs (Fox, H.L. 1974. "Effects of Urbanization on the Patuxent River, with Special Emphasis on Sediment Transport, Storage, and Migration." Ph.D. dissertation. Johns Hopkins University, Baltimore, MD. As Cited in Klein, R.D. 1979. "Urbanization and Stream Quality Impairment." *Water Resources Bulletin* 15(4): 948–63).

A primary concern at most construction sites is the erosion and transport process related to fine sediment because rain splash, rills (i.e., a channel small enough to be removed by normal agricultural practices and typically less than 1-foot deep), and sheetwash encourage the detachment and transport of this material to waterbodies (Storm Water Quality Task Force. 1993. *California Storm Water Best Management Practice Handbooks—Construction Activity*. Oakland, CA: Blue Print Service). Construction sites also can generate other pollutants associated with onsite wastes, such as sanitary wastes or concrete truck washout.

Although streams and rivers naturally carry sediment loads, erosion from construction sites and runoff from developed areas can elevate these loads to levels well above those in undisturbed watersheds. It is generally acknowledged that erosion rates from construction sites are much greater than from almost any other land use (Novotny, V. and H. Olem. 1994. *Water Quality: Prevention, Identification, and Management of Diffuse Pollution*. New York: Van Nostrand Reinhold). Results from both field studies and erosion models indicate that erosion rates from construction sites are typically an order of magnitude larger than row crops and several orders of magnitude greater than rates from well-vegetated areas, such as forests or pastures (USDA. 1970. "Controlling Erosion on Construction Sites." *Agriculture Information Bulletin*, Washington, DC; Meyer, L.D., W.H. Wischmeier, and W.H. Daniel. 1971. "Erosion, Runoff and Revegetation of Denuded Construction Sites." *Transactions of the ASAE* 14(1):138–41; Owen, O.S. 1975. *Natural Resource Conservation*. New York: MacMillan. As cited in Paterson, et al., 1993).

A recent review of the efficiency of sediment basins indicated that inflows from 12 construction sites had a mean TSS concentration of about 4,500 mg/L (Brown, W.E. 1997. "The Limits of Settling." Technical Note No. 83. *Watershed Protection Techniques* 2(3)). In Virginia, suspended sediment concentrations from housing construction sites were measured at 500–3,000 mg/L, or about 40 times larger than the concentrations from already-developed urban areas (Kuo, C.Y. 1976. "Evaluation of Sediment Yields Due to Urban Development." Bulletin No. 98. Virginia Water Resources Research Center, Virginia Polytechnic Institute and State University, Blacksburg, VA).

Similar impacts from storm water runoff have been reported in a number of other studies. For example, Daniel, et al., monitored three residential construction sites in southeastern Wisconsin and determined that annual sediment yields were more than 19 times the yields from agricultural areas (Daniel, T.C., D. McGuire, D. Stoffel, and B. Miller. 1979. "Sediment and Nutrient Yield from Residential Construction Sites" *Journal of Environmental Quality* 8(3):304–08). Daniel, et al., identified total storm runoff, followed by peak storm runoff, as the most influential factors controlling the sediment loadings from residential construction sites. Daniel, et al., also found that suspended sediment concentrations were 15,000–20,000 mg/L in moderate events and up to 60,000 mg/L in larger events.

Wolman and Schick (Wolman, M.G. and A.P. Schick. 1967. "Effects of Construction on Fluvial Sediment, Urban and Suburban Areas of Maryland." *Water Resources Research* 3(2): 451–64) studied the impacts of development on fluvial systems in Maryland and determined that sediment yields in areas undergoing construction were 1.5 to 75 times greater than detected in natural or agricultural catchments. The authors summarize the potential impacts of construction on sediment yields by stating that "the equivalent of many decades of natural or even agricultural erosion may take place during a single year from areas cleared for construction" (Wolman and Schick, 1967).

A number of studies have examined the effects of road construction on erosion rates and sediment yields. A highway construction project in West Virginia disturbed only 4.2 percent of a 4.72-square-mile basin, but resulted in a three-fold increase in suspended sediment yields (Downs, S.C. and D.H. Appel. 1986. *Progress Report on the Effects of Highway Construction on Suspended-Sediment Discharge in the Coal River and Trace Fork, West Virginia*, 1975–81. USGS Water Resources Investigations Report 84–4275. Charlestown, WV). During the largest storm event, it was estimated that 80 percent of the sediment in the stream originated from the construction site. As is often the case, the increase in suspended sediment load could not be detected further downstream, where the drainage area was more than 50 times larger (269 square miles).

Another study evaluated the effect of 290 acres of highway construction on watersheds ranging in size from 5 to 38 square miles. Suspended sediment loads in the smallest watershed increased by 250 percent, and the estimated sediment yield from the construction area was 37 tons/acre during a 2-year period (Hainly, R.A. 1980. *The Effects of Highway Construction on Sediment Discharge into Blockhouse Creek and Stream Valley Run, Pennsylvania*. USGS Water Resources Investigations Report 80–68. Harrisburg, PA). A more recent study in Hawaii showed that highway construction increased suspended sediment loads by 56 to 76 percent in three small (1 to 4 square mile) basins (Hill, B.R. 1996. *Streamflow and Suspended-Sediment Loads Before and During Highway Construction, North Halawa, Haiku, and Kamooalii Drainage Basins, Oahu, Hawaii, 1983–91*. USGS Water Resources Investigations Report 96–4259. Honolulu, HI). A 1970 study determined that sediment yields from construction areas can be as much as 500 times the levels detected in rural areas (National Association of Counties Research Foundation. 1970. *Urban Soil Erosion and Sediment Control*. Water Pollution Control Research Series, Program #15030 DTL. Federal Water Quality Administration, U.S. Department of Interior. Washington, DC)

Yorke and Herb (Yorke, T.H., and W.J. Herb. 1978. *Effects of Urbanization on Streamflow and Sediment Transport in the Rock Creek and Anacostia River Basins, Montgomery County, Maryland, 1962–74*. USGS Professional Paper 1003, Washington, DC) evaluated nine subbasins in the Maryland portion of the Anacostia watershed for more than a decade in an effort to define the impacts of changing land use/land cover on sediment in runoff. Average annual suspended sediment yields for construction sites ranged from 7 to 100 tons/acre. Storm water discharges from construction sites that occur when the land area is disturbed (and prior to

R0018101

surface stabilization) can significantly impact designated uses. Examples of designated uses include public water supply, recreation, and propagation of fish and wildlife. The siltation process described previously can threaten all three designated uses by (1) depositing high concentrations of pollutants in public water supplies; (2) decreasing the depth of a waterbody, which can reduce the volume of a reservoir or result in limited use of a water body by boaters, swimmers, and other recreational enthusiasts; and (3) directly impairing the habitat of fish and other aquatic species, which can limit their ability to reproduce.

Excess sediment can cause a number of other problems for waterbodies. It is associated with increased turbidity and reduced light penetration in the water column, as well as more long-term effects associated with habitat destruction and increased difficulty in filtering drinking water. Numerous studies have examined the effect that excess sediment has on aquatic ecosystems. For example, sediment from road construction activity in Northern Virginia reduced aquatic insect and fish communities by up to 85 percent and 40 percent, respectively (Reed, J.R. 1997. "Stream Community Responses to Road Construction Sediments." Bulletin No. 97. Virginia Water Resources Research Center, Virginia Polytechnic Institute, Blacksburg, VA. As cited in Klein, R.D. 1990. *A Survey of Quality of Erosion and Sediment Control and Storm Water Management in the Chesapeake Bay Watershed*. Annapolis, MD: Chesapeake Bay Foundation). Other studies have shown that fine sediment (fine sand or smaller) adversely affects aquatic ecosystems by reducing light penetration, impeding sight-feeding, smothering benthic organisms, abrading gills and other sensitive structures, reducing habitat by clogging interstitial spaces within a streambed, and reducing the intergravel dissolved oxygen by reducing the permeability of the bed material (Everest, F.H., J.C. Beschta, K.V. Scrivener, J.R. Koski, J.R. Sedell, and C.J. Cederholm. 1987. "Fine Sediment and Salmonid Production: A Paradox." *Streamside Management: Forestry and Fishery Interactions*, Contract No. 57, Institute of Forest Resources, University of Washington, Seattle, WA). For example, 4.8 and 5.6 kilometers of stream below construction sites in the Patuxent River watershed in Maryland were found to have fine sediment amounts 15 times greater than normal (Fox, 1974. As cited in Klein, 1979). Benthic organisms in the streambed can be smothered by sediment deposits, causing changes in aquatic flora and fauna, such as fish species composition (Wolman and Schick, 1967). In addition, the primary cause of coral reef degradation in coastal areas is attributed to land disturbances and dredging activities due to urban development (Rogers, C.S. 1990. "Responses of Coral Reefs and Reef Organizations to Sedimentation." *Marine Ecology Progress Series*, 62:185–202).

EPA believes that the water quality impact from small construction sites is as high as or higher than the impact from larger sites on a per acre basis. The concentration of pollutants in the runoff from smaller sites is similar to the concentrations in the runoff from larger sites. The proportion of sediment that makes it from the construction site to surface waters is likely the same for larger and smaller construction sites in urban areas because the runoff from either site is usually delivered directly to the storm drain network where there is no opportunity for the sediment to be filtered out.

The expected contribution of total sediment yields from small sites depends, in part, on the extent to which erosion and sedimentation controls are being applied. Because current storm water regulations are more likely to require erosion and sedimentation controls on larger sites in urban areas, smaller construction sites that lack such programs are likely to contribute a disproportionate amount of the total sediment from construction activities (MacDonald, L.H. 1997. *Technical Justification for Regulating Construction Sites 1–5 Acres in Size*. Unpublished report submitted to U.S. EPA, Washington, DC). Smaller construction sites are less likely to have an effective plan to control erosion and sedimentation, are less likely to properly implement and maintain their plans, and are less likely to be inspected (Brown, W. and D. Caraco. 1997. *Controlling Storm Water Runoff Discharges from Small Construction Sites: A National Review*. Submitted to Office of Wastewater Management, U.S. EPA, Washington, DC., by the Center for Watershed Protection, Silver Spring, MD). The proportion of sediment that makes it from the construction site to surface waters is likely the same for larger and smaller construction sites in urban areas because the runoff from either site is usually delivered directly to the storm drain network, where there is no opportunity for the sediment to be filtered out.

To confirm its belief that sediment yields from small sites are as high as or higher than the 20 to 150 tons/acre/year measured from larger sites, EPA gave a grant to the Dane County, Wisconsin Land Conservation Department, in cooperation with the USGS, to evaluate sediment runoff from two small construction sites. The first was a 0.34 acre residential lot and the second was a 1.72 acre commercial office development. Runoff from the sites was channeled to a single discharge point for monitoring. Each site was monitored before, during, and after construction.

The Dane County study found that total solids concentrations from these small sites are similar to total solids concentrations from larger construction sites. Results show that for both of the study sites, total solids and suspended solids concentrations were significantly higher during construction than either before or after construction. For example, preconstruction total solids concentrations averaged 642 mg/L during the period when ryegrass was established, active construction total solids concentrations averaged 2,788 mg/L, and post-construction total solids concentrations averaged 132 mg/L (on a pollutant load basis, this equaled 7.4 lbs preconstruction, 35 lbs during construction, and 0.6 lbs post-construction for total solids). While this site was not properly stabilized before construction, after construction was complete and the site was stabilized, post-construction concentrations were more than 20 times less than during construction. The results were even more dramatic for the commercial site. The commercial site had one preconstruction event, which resulted in total solids concentrations of 138 mg/L, while active construction averaged more than 15,000 mg/L and post-construction averaged only 200 mg/L (on a pollutant load basis, this equaled 0.3 lbs preconstruction, 490 lbs during construction, and 13.4 lbs post-construction for total solids). The active construction period resulted in more than 75 times more sediment than either before or after construction (Owens, D.W., P. Jopke, D.W. Hall, J. Balousek and A. Roa. 1999. "Soil Erosion from Small Construction Sites." Draft USGS Fact Sheet. USGS and Dane County Land Conservation Department, WI). The total solids concentrations from these small sites in Wisconsin are similar to total solids concentrations from larger construction sites. For example, a study evaluating the effects of highway construction in West Virginia found that a small storm produced a sediment concentration of 7,520 mg/L (Downs and Appel, 1986).

One important aspect of small construction sites is the number of small sites relative to larger construction sites

R0018102

and total land area within the watershed. Brown and Caraco surveyed 219 local jurisdictions to assess erosion and sediment control (ESC) programs. Seventy respondents provided data on the number of ESC permits for construction sites smaller than 5 acres. In 27 cases (38 percent of the respondents), more than three-quarters of the permits were for sites smaller than 5 acres; in another 18 cases (26 percent), more than half of the permits were for sites smaller than 5 acres.

In addition, data on the total acreage disturbed by smaller construction sites have been collected recently in two States (MacDonald, 1997). The most recent and complete data set is the listing of the disturbed area for each of the 3,831 construction sites permitted in North Carolina for 1994–1995 and 1995–1996. Nearly 61 percent of the sites that were 1 acre or larger were between 1.0 and 4.9 acres in size. This proportion was consistent between years. Data showed that this range of sites accounted for 18 percent of the total area disturbed by construction. The values showed very little variation between the 2 years of data. The total disturbed area for all sites over this 2-year period was nearly 33,000 acres, or about 0.1 percent of the total area of North Carolina.

EPA estimates that construction sites disturbing greater than 5 acres disturb 2.1-million acres of land (78.1 percent of the total) while sites disturbing between 1 and 5 acres of land disturb 0.5-million acres of land (19.4 percent). The remaining sites on less than 1 acres of land disturb 0.07-million acres of land (only 2.5 percent of the total). Given the high erosion rates associated with most construction sites, small construction sites can be a significant source of water quality impairment, particularly in small watersheds that are undergoing rapid development. Exempting sites under 1 acre will exclude only about 2.5 percent of acreage from program coverage, but will exclude a far higher number of sites, approximately 25 percent.

Several studies have determined that the most effective construction runoff control programs rely on local plan review and field enforcement (Paterson, R. G. 1994. "Construction Practices: the Good, the Bad, and the Ugly." *Watershed Protection Techniques* 1(3)). In his review, Paterson suggests that, given the critical importance of field implementation of erosion and sediment control programs and the apparent shortcomings that exist, much more focus should be given to plan implementation.

Several commenters disputed the data presented in the proposed rule for storm water discharges from smaller construction sites. One commenter stated that EPA has not adequately explained the basis for permitting construction activity down to 1 disturbed acre. Another commenter stated that EPA did not present sufficient data on water quality impacts from construction sites disturbing less than 5 acres.

EPA believes that the data presented above sufficiently support nationwide designation of storm water discharges from construction activity disturbing more than 1 acre. Based on total disturbed land area within a watershed, the cumulative effects of numerous small construction sites can have impacts similar to those of larger sites in a particular area. In addition, waivers for storm water discharges from smaller construction activity will exclude sites not expected to impair water quality. EPA will continue to collect water quality data on construction site storm water runoff.

C. Statutory Background

In 1972, Congress enacted the CWA to prohibit the discharge of any pollutant to waters of the United States from a point source unless the discharge is authorized by an NPDES permit. Congress added CWA section 402(p) in 1987 to require implementation of a comprehensive program for addressing storm water discharges. Section 402(p)(1) required EPA or NPDES-authorized States or Tribes to issue NPDES permits for the following five classes of storm water discharges composed entirely of storm water ("storm water discharges") specifically listed under section 402(p)(2):

(A) a discharge subject to an NPDES permit before February 4, 1987

(B) a discharge associated with industrial activity

(C) a discharge from a municipal separate storm sewer system serving a population of 250,000 or more

(D) a discharge from a municipal separate storm sewer system serving a population of 100,000 or more but less than 250,000

(E) a discharge that an NPDES permitting authority determines to be contributing to a violation of a water quality standard or a significant contributor of pollutants to the waters of the United States.

Section 402(p)(3)(A) requires storm water discharges associated with industrial activity to meet all applicable provisions of section 402 and section 301 of the CWA, including technology-based requirements and any more stringent requirements necessary to meet water quality standards. Section 402(p)(3)(B) establishes NPDES permit standards for discharges from municipal separate storm sewer systems, or MS4s. NPDES permits for discharges from MS4s (1) may be issued on a system or jurisdiction-wide basis, (2) must include a requirement to effectively prohibit non-storm water discharges into the storm sewers, and (3) must require controls to reduce pollutant discharges to the maximum extent practicable, including best management practices, and other provisions as the Administrator or the States determine to be appropriate for the control of such pollutants. At this time, EPA determines that water quality-based controls, implemented through the iterative processes described today are appropriate for the control of such pollutants and will result in reasonable further progress towards attainment of water quality standards. See sections II.L and II.H.3 of the preamble.

In CWA section 402(p)(4), Congress established statutory deadlines for the initial steps in implementing the NPDES program for storm water discharges. This section required development of NPDES permit application regulations, submission of NPDES permit applications, issuance of NPDES permits for sources identified in section 402(p)(2), and compliance with NPDES permit conditions. In addition, this section required industrial facilities and large MS4s to submit NPDES permit applications for storm water discharges by February 4, 1990. Medium MS4s were to submit NPDES permit applications by February 4, 1992. EPA and authorized NPDES States were prohibited from requiring an NPDES permit for any other storm water discharges until October 1, 1994.

Section 402(p)(5) required EPA to conduct certain studies and submit a report to Congress. This requirement is discussed in the following section.

Section 402(p)(6) requires EPA, in consultation with States and local officials, to issue regulations for the designation of additional storm water discharges to be regulated to protect water quality. It also requires EPA to extend the existing storm water program to regulate newly designated sources. At a minimum, the extension must establish (1) priorities, (2) requirements for State storm water management programs, and (3) expeditious deadlines. Section 402(p)(6) specifies that the program may include performance standards, guidelines, guidance, and management practices and treatment requirements, as appropriate. Today's rule implements this section.

D. EPA's Reports to Congress

Under CWA section 402(p)(5), EPA, in consultation with the States, was required to conduct a study. The study was to identify unregulated sources of storm water discharges, determine the nature and extent of pollutants in such discharges, and establish procedures and methods to mitigate the impacts of such discharges on water quality. Section 402(p)(5) also required EPA to report the results of the first two components of that study to Congress by October 1, 1988, and the final report by October 1, 1989.

In March 1995, EPA submitted to Congress a report that reviewed and analyzed the nature of storm water discharges from municipal and industrialacilities that were not already regulated under the initial NPDES regulations for storm water (U.S. Environmental Protection Agency, Office of Water. 1995. *Storm Water Discharges Potentially Addressed by Phase II of the National Pollutant Discharge Elimination System Storm Water Program: Report to Congress.* Washington, D.C. EPA 833-K-94-002) ("Report"). The Report also analyzed associated pollutant loadings and water quality impacts from these unregulated sources. Based on identification of unregulated municipal sources and analysis of information on impacts of storm water discharges from municipal sources, the Report recommended that the NPDES program for storm water focus on the 405 "urbanized areas" identified by the Bureau of the Census. The Report further found that a number of discharges from unregulated industrial facilities warranted further investigation to determine the need for regulation. It classified these unregulated industrial discharges in two groups: Group A and Group B. Group A comprised sources that may be considered a high priority for inclusion in the NPDES program for storm water because discharges from these sources are similar or identical to already regulated sources. These "look alike" storm water discharge sources were not covered in the initial NPDES regulations for storm water due to the language used to define "associated with industrial activity." In the initial regulations for storm water, "industrial activity" is identified using Standard Industrial Classification (SIC) codes. The use of SIC codes led to incomplete categorization of industrial activities with discharges that needed to be regulated to protect water quality. Group B consisted of 18 industrial sectors, which included sources that EPA expected to contribute to storm water contamination due to the activities conducted and pollutants anticipated onsite (e.g., vehicle maintenance, machinery and electrical repair, and intensive agricultural activities).

EPA reported on the latter component of the section 402(p)(5) study via President Clinton's Clean Water Initiative, which was released on February 1, 1994 (U.S. Environmental Protection Agency, Office of Water. 1994. *President Clinton's Clean Water Initiative.* Washington, D.C. EPA 800-R-94-001) ("Initiative"). The Initiative addressed a number of issues associated with NPDES requirements for storm water discharges and proposed (1) establishing a phased compliance with a water quality standards approach for discharges from municipal separate storm sewer systems with priority on controlling discharges from municipal growth and development areas, (2) clarifying that the maximum extent practicable standard should be applied in a site-specific, flexible manner, taking into account cost considerations as well as water quality effects, (3) providing an exemption from the NPDES program for storm water discharges from industrial facilities with no activities or significant materials exposed to storm water, (4) providing extensions to the statutory deadlines to complete implementation of the NPDES program for the storm water program, (5) targeting urbanized areas for the requirements in the NPDES program for storm water, and (6) providing control of discharges from inactive and abandoned mines located on Federal lands in a more targeted, flexible manner. Additionally, prior to promulgation of today's rule, section 431 of the Agency's Appropriation Act for FY 2000 (Departments of Veterans Affairs and Housing and Urban Development and Independent Agencies Appropriations Act of 2000, Public Law 106-74, section 432 (1999)) directed EPA to report on certain matters to be covered in today's rule. That report supplements the study required by CWA Section 402(p)(5). EPA is publishing the availability of that report elsewhere in this issue of the **Federal Register.**

Several commenters asserted that the Report to Congress is an inadequate basis for the designation and regulation of sources covered under today's final rule, specifically the nationwide designation of small municipal separate storm sewer systems within urbanized areas and construction activities disturbing between one and five acres.

EPA believes that it has developed an adequate record for today's regulation both through the Report to Congress a. the Clean Water Initiative and through more recent activities, including the FACA Subcommittee process, regulatory notices and evaluation of comments, and recent research and analysis. EPA does not interpret the congressional reporting requirements of CWA section 402(p)(5) to be the sole basis for determining sources to be regulated under today's final rule.

EPA's decision to designate on a national basis small MS4s in urbanized areas is supported by studies that clearly show a direct correlation between urbanization and adverse water quality impacts from storm water discharges. (Schueler, T. 1987. *Controlling Urban Runoff: A Practical Manual for Planning & Designing Urban BMPs.* Metropolitan Washington Council of Governments). "Urbanized areas"—within which all small MS4s would be covered—represent the most intensely developed and dense areas of the Nation. They constitute only two percent of the land area but 63 percent of the total population. See section I.B.1, Urban Development, above, for studies and assessments of the link between urban development and storm water impacts on water resources.

Commenters argued that the Report to Congress does not address storm water discharges from construction sites. They further argued that the designation of small construction sites per today's final rule goes beyond the President's 1994 Initiative because the Initiative only recommends requiring municipalities to implement a storm water management program to control unregulated storm water sources, "including discharges from construction of less than 5 acres, which are part of growth, development and significant redevelopment activities." They point out that the Initiative provides that unregulated storm water discharges not addressed through a municipal program would not be covered by the NPDES program. Commenters assert that EPA has not developed a record independent of its section 402(p)(5) studies that demonstrates the necessity of regulating under a separate NPDES permit storm water discharges from smaller construction sites "to protect water quality." EPA disagrees.

EPA evaluated the nature and extent of pollutants from construction site sources in a process that was separate and distinct from the development of the Report to Congress. Today's decision to regulate certain storm water discharges from construction sites disturbing less than 5 acres arose in part

R0018104

out of the 9th Circuit remand in *NRDC v. EPA*, 966 F.2d 1292 (9th Cir. 1992). In that case, the court remanded portions of the Phase I storm water regulations related to discharges from construction sites. Those regulations define "storm water discharges associated with industrial activity" to include only those storm water discharges from construction sites disturbing 5 acres or more of total land area (see 40 CFR 122.26(b)(14)(x)). In its decision, the court concluded that the 5-acre threshold was improper because the Agency had failed to identify information "to support its perception that construction activities on less than 5 acres are non-industrial in nature" (966 F.2d at 1306). The court remanded the below 5 acre exemption to EPA for further proceedings (966 F.2d at 1310).

In a **Federal Register** notice issued on December 18, 1992, EPA noted that it did not believe that the Court's decision had the effect of automatically subjecting small construction sites to the existing application requirements and deadlines. EPA believed that additional notice and comment were necessary to clarify the status of these sites. The information received during the notice and comment process and additional research, as discussed in section I.B.3 Construction Site Runoff, formed the basis for the designation of construction activity disturbing between one and five acres on a nationwide basis. EPA's objectives in today's proposal include an effort to (1) address the 9th Circuit remand, (2) address water quality concerns associated with construction activities that disturb less than 5 acres of land, and (3) balance conflicting recommendations and concerns of stakeholders.

One commenter noted that EPA's proposal would fail to regulate industrial facilities identified as Group A and Group B in the March 1995 *Report to Congress*. EPA is relying on the analysis in the Report, which provided that the recommendation for coverage was meant as guidance and was not intended to be an identification of specific categories that must be regulated under Section 402(p)(6). *Report to Congress*, p. 4–1. The Report recognized the existence of limited data on which to base loadings estimates to support the nationwide designation of individual or categories of sources. *Report to Congress*, p. 4–44. Furthermore, during FACA Subcommittee discussion, EPA continued to urge stakeholders to provide further data relating to industrial and commercial storm water sources, which EPA did not receive. EPA concluded that, due to insufficient data, these sources were not appropriate for nationwide designation at this time.

E. Industrial Facilities Owned or Operated by Small Municipalities

Congress granted extensions to the NPDES permit application process for selected classes of storm water discharges associated with industrial activity. On December 18, 1991, Congress enacted the Intermodal Surface Transportation Efficiency Act (ISTEA), which postponed NPDES permit application deadlines for most storm water discharges associated with industrial activity at facilities that are owned or operated by small municipalities. EPA and States authorized to administer the NPDES program could not require any municipality with a population of less than 100,000 to apply for or obtain an NPDES permit for any storm water discharge associated with industrial activity prior to October 1, 1992, except for storm water discharges from airports, power plants, or uncontrolled sanitary landfills. See 40 CFR 122.26(e)(1); 57 FR 11524, April 2, 1992 (reservation of NPDES application deadlines for ISTEA facilities).

The facilities exempted by ISTEA discharge storm water in the same manner (and are expected to use identical processes and materials) as the industrial facilities regulated under the 1990 Phase I regulations. Accordingly, these facilities pose similar water quality problems. The extended moratorium for these facilities was necessary to allow municipalities additional time to comply with NPDES requirements. The proposal for today's rule would have maintained the existing deadline for seeking coverage under an NPDES permit (August 7, 2001).

Today's rule changes the permit application deadline for such municipally owned or operated facilities discharging industrial storm water to make it consistent with the application date for small regulated MS4s. Because EPA missed its March 1999 deadline for promulgating today's rule, and the deadline for MS4s to submit permit applications has been extended to three years and 90 days from the date of this notice, the deadline for permitting ISTEA sources has been similarly extended. The permitting of these sources is discussed below in section "II.I.3. ISTEA Sources."

F. Related Nonpoint Source Programs

Today's rule addresses point source discharges of storm water runoff and non-storm water discharges into MS4s. Many of these sources have been addressed by nonpoint source control programs, which are described briefly below.

In 1987, section 319 was added to the CWA to provide a framework for funding State and local efforts to address pollutants from nonpoint sources not addressed by the NPDES program. To obtain funding, States are required to submit Nonpoint Source Assessment Reports identifying State waters that, without additional control of nonpoint sources of pollution, could not reasonably be expected to attain or maintain applicable water quality standards or other goals and requirements of the CWA. States are also required to prepare and submit for EPA approval a statewide Nonpoint Source Management Program for controlling nonpoint source water pollution to navigable waters within the State and improving the quality of such waters. State program submittals must identify specific best management practices (BMPs) and measures that the State proposes to implement in the first four years after program submission to reduce pollutant loadings from identified nonpoint sources to levels required to achieve the stated water quality objectives.

State nonpoint source programs funded under section 319 can include both regulatory and nonregulatory State and local approaches. Section 319(b)(2)(B) specifies that a combination of "nonregulatory or regulatory programs for enforcement, technical assistance, financial assistance, education, training, technology transfer, and demonstration projects' may be used, as necessary, to achieve implementation of the BMPs or measures identified in the section 319 submittals.

Section 6217 of the Coastal Zone Act Reauthorization Amendments (CZARA) of 1990 provides that States with approved coastal zone management programs must develop coastal nonpoint pollution control programs and submit them to EPA and the National Oceanic and Atmospheric Administration (NOAA) for approval. Failure to submit an approvable program will result in a reduction of Federal grants under both the Coastal Zone Management Act and section 319 of the CWA.

State coastal nonpoint pollution control programs under CZARA must include enforceable policies and mechanisms that ensure implementation of the management measures throughout the coastal management area. *EPA issued Guidance Specifying Management Measures for Sources of Nonpoint Pollution in Coastal Waters* under section 6217(g) in

January 1993. The guidance identifies management measures for five major categories of nonpoint source pollution. The management measures reflect the greatest degree of pollutant reduction that is economically achievable for each of the listed sources. These management measures provide reference standards for the States to use in developing or refining their coastal nonpoint programs. A few management measures, however, contain quantitative standards that specify pollutant loading reductions. For example, the New Development Management Measure, which is applicable to construction in urban areas, requires (1) that by design or performance the average annual total suspended solid loadings be reduced by 80 percent and (2) to the extent practicable, that the pre-development peak runoff rate and average volume be maintained.

EPA and NOAA published *Coastal Nonpoint Pollution Control Program: Program Development and Approval Guidance* (1993). The document clarifies that States generally must implement management measures for each source category identified in the EPA guidance developed under section 6217(g). Coastal Nonpoint Pollution Control Programs are not required to address sources that are clearly regulated under the NPDES program as point source discharges. Specifically, such programs would not need to address small MS4s and construction sites covered under NPDES storm water permits (both general and individual).

II. Description of Program

A. Overview

1. Objectives EPA Seeks To Achieve in Today's Rule

EPA seeks to achieve several objectives in today's final rule. First, EPA is implementing the requirement under CWA section 402(p)(6) to provide a comprehensive storm water program that designates and controls additional sources of storm water discharges to protect water quality. Second, EPA is addressing storm water discharges from the activities exempted under the 1990 storm water permit application regulations that were remanded by the Ninth Circuit Court of Appeals in NRDC v. EPA, 966 F.2d 1292 (9th Circuit, 1992). These are construction activities disturbing less than 5 acres and so-called "light" industrial activities not exposed to storm water (see discussion of "no exposure" below). Third, EPA is providing coverage for the so-called "donut holes" created by the existing NPDES storm water program. Donut holes are geographic gaps in the NPDES storm water program's regulatory scheme. They are MS4s located within areas covered by the existing NPDES storm water program, but not currently addressed by the storm water program because it is based on political jurisdictions. Finally, EPA also is trying to promote watershed planning as a framework for implementing water quality programs where possible.

Although EPA had options for different approaches (see alternatives discussed in the January 9, 1998, proposed regulation), EPA believes it can best achieve its objectives through flexible innovations within the framework of the NPDES program. Unlike the interim section 402(p)(6) storm water regulations EPA promulgated in 1995, EPA no longer designates all of the unregulated storm water discharges for nationwide coverage under the NPDES program for storm water. The framework for today's final rule is one that balances automatic designation on a nationwide basis and locally-based designation and waivers. Nationwide designation applies to the classes or categories of storm water discharges that EPA believes present a high likelihood of having adverse water quality impacts, regardless of location. Specifically, today's rule designates discharges from small MS4s located in urbanized areas and storm water discharges from construction activities that result in land disturbance equal to or greater than one and less than five acres. As noted under Section I.B., Water Quality Concerns/Environmental Impact Studies and Assessments, these two categories of storm water sources, when unregulated, tend to cause significant adverse water quality impacts. Additional sources are not covered on a nationwide basis either because EPA currently lacks information indicating a consistent potential for adverse water quality impact or because EPA believes that the likelihood of adverse impacts on water quality is low, with some localized exceptions. Additional individual sources or categories of storm water discharges could, however, be covered under the program through a local designation process. A permitting authority may designate additional small MS4s after developing designation criteria and applying those criteria to small MS4s located outside of an urbanized area, in particular those with a population of 10,000 or more and a population density of at least 1,000. Exhibit 1 illustrates the designation framework for today's final rule.

BILLING CODE 6560-50-P

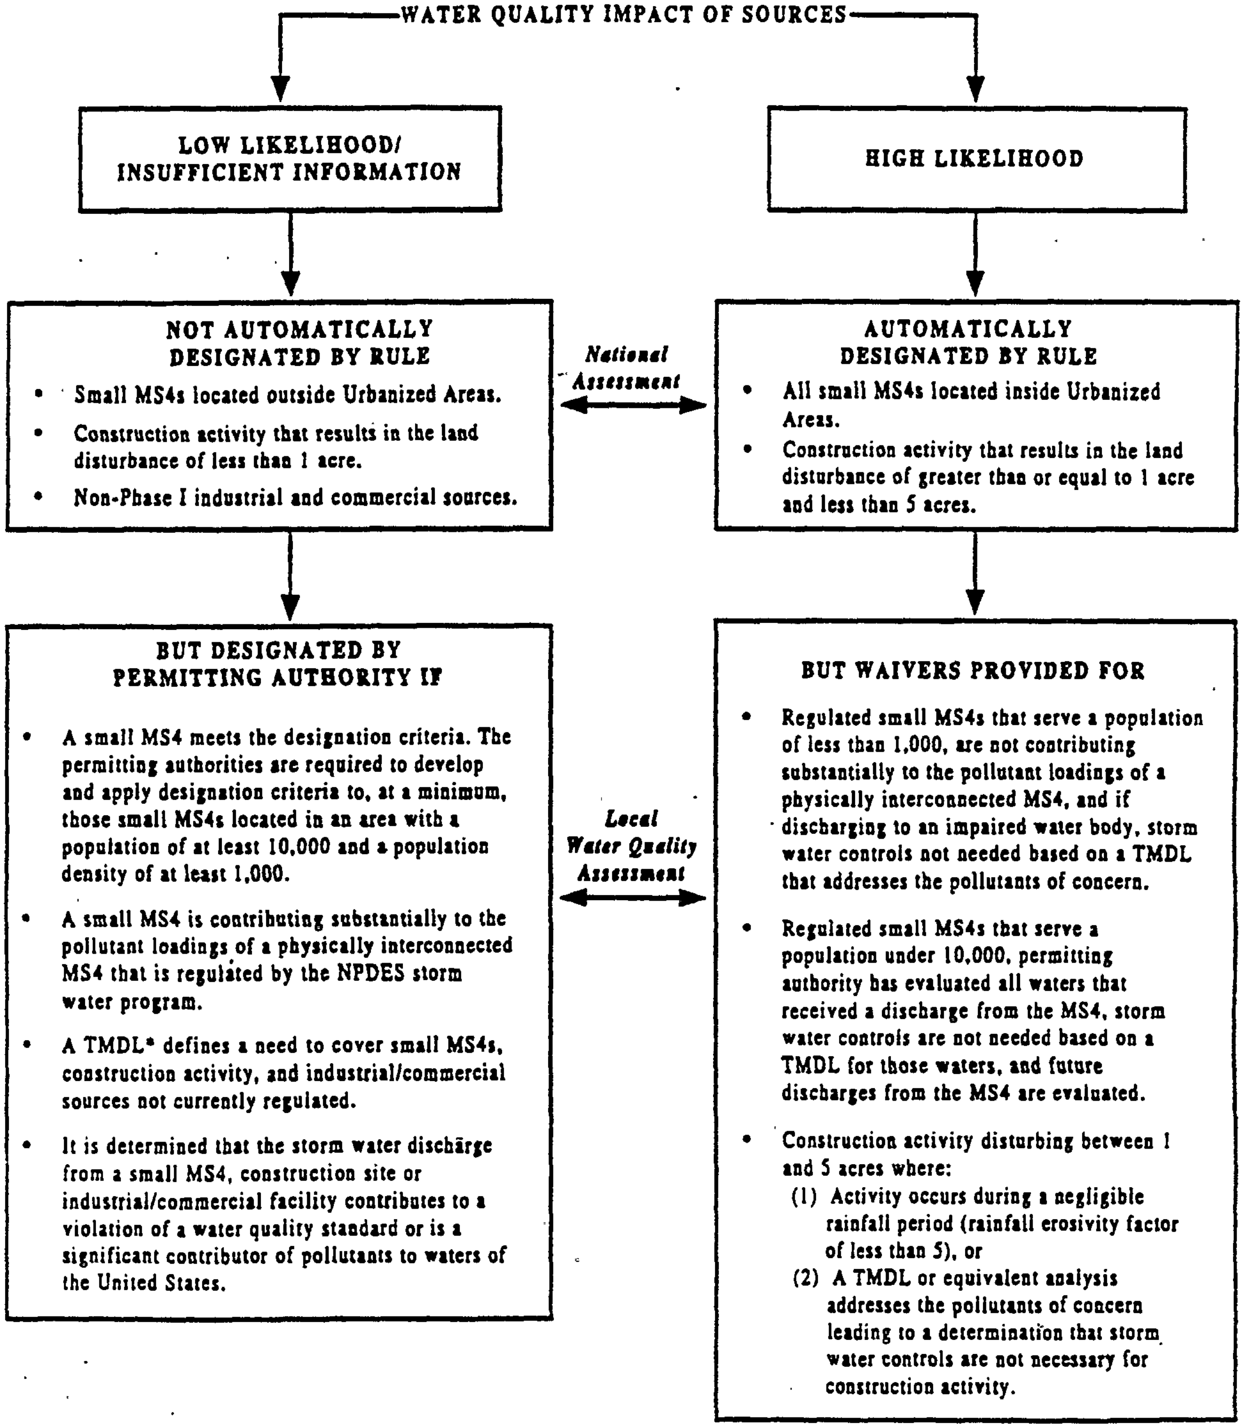
EXHIBIT 1.—PHASE II SOURCE DECISIONS



*EPA will continue to require States to comply with their Total Maximum Daily Load (TMDL) implementation schedules.

BILLING CODE 6560–50–C

R0018107

The designation framework for today's final rule provides a significant degree of flexibility. The proposed provisions for nationwide designation of storm water discharges from construction and from small MS4s in urbanized areas allowed for a waiver of applicable requirements based on appropriate water quality conditions. Today's final rule expands and simplifies those waivers.

The permitting authority may waive the requirement for a permit for any small MS4 serving a jurisdiction with a population of less than 1,000 unless storm water controls are needed because the MS4 is contributing to a water quality impairment. The permitting authority may also waive permit coverage for MS4s serving a jurisdiction with a population of less than 10,000 if all waters that receive a discharge from the MS4 have been evaluated and discharges from the MS4 do not significantly contribute to a water quality impairment or have the potential to cause an impairment. Today's rule also allows States with a watershed permitting approach to phase in coverage for MS4s in jurisdictions with populations under 10,000.

Water quality conditions are also the basis for a waiver of requirements for storm water discharges from construction activities disturbing between one and five acres. For these small construction sources, the rule provides significant flexibility for waiving otherwise applicable regulatory requirements where a permitting authority determines, based on water quality and watershed considerations, that storm water discharge controls are not needed.

Coverage can be extended to municipal and construction sources outside the nationwide designated classes or categories based on watershed and case-by-case assessments. For the municipal storm water program, today's rule provides broad discretion to NPDES permitting authorities to develop and implement criteria for designating storm water discharges from small MS4s outside of urbanized areas. Other storm water discharges from unregulated industrial, commercial, and residential sources will not be subject to the NPDES permit requirements unless a permitting authority determines on a case-by-case basis (or on a categorical basis within identified geographic areas such as a State or watershed) that regulatory controls are needed to protect water quality. EPA believes that the flexibility provided in today's rule facilitates watershed planning.

2. General Requirements for Regulated Entities Under Today's Rule

As previously noted, today's final rule defines additional classes and categories of storm water discharges for coverage under the NPDES program. These designated dischargers are required to seek coverage under an NPDES permit. Furthermore, all NPDES-authorized States and Tribes are required to implement these provisions and make any necessary amendments to current State and Tribal NPDES regulations to ensure consistency with today's final rule. EPA remains the NPDES permitting authority for jurisdictions without NPDES authorization.

Today's final rule includes some new requirements for NPDES permitting authorities implementing the CWA section 402(p)(6) program. EPA has made a significant effort to build flexibility into the program while attempting to maintain an appropriate level of national consistency. Permitting authorities must ensure that NPDES permits issued to MS4s include the minimum control measures established under the program. Permitting authorities also have the ability to make numerous decisions including who is regulated under the program, i.e., case-by-case designations and waivers, and how responsibilities should be allocated between regulated entities.

Today's final rule extends the NPDES program to include discharges from the following: small MS4s within urbanized areas (with the exception of systems waived from the requirements by the NPDES permitting authority); other small MS4s meeting designation criteria to be established by the permitting authority; and any remaining MS4 that contributes substantially to the storm water pollutant loadings of a physically interconnected MS4 already subject to regulation under the NPDES program. Small MS4s include urban storm sewer systems owned by Tribes, States, political subdivisions of States, as well as the United States, and other systems located within an urbanized area that fall within the definition of an MS4. These include, for example, State departments of transportation (DOTs), public universities, and federal military bases.

Today's final rule requires all regulated small MS4s to develop and implement a storm water management program. Program components include, at a minimum, 6 minimum measures to address: public education and outreach; public involvement; illicit discharge detection and elimination; construction site runoff control; post-construction storm water management in new development and redevelopment; and pollution prevention and good housekeeping of municipal operations. These program components will be implemented through NPDES permits. A regulated small MS4 is required to submit to the NPDES permitting authority, either in its notice of intent (NOI) or individual permit application, the BMPs to be implemented and the measurable goals for each of the minimum control measures listed above.

The rule addresses all storm water discharges from construction site activities involving clearing, grading and excavating land equal to or greater than 1 acre and less than 5 acres, unless requirements are otherwise waived by the NPDES permitting authority. Discharges from such sites, as well as construction sites disturbing less than 1 acre of land that are designated by the permitting authority, are required to implement requirements set forth in the NPDES permit, which may reference the requirements of a qualifying local program issued to cover such discharges.

The rule also addresses certain other sources regulated under the existing NPDES program for storm water. For municipally-owned industrial sources required to be regulated under the existing NPDES storm water program but exempted from immediate compliance by the Intermodal Surface Transportation Act of 1991 (ISTEA), the rule revises the existing deadline for seeking coverage under an NPDES permit (August 7, 2001) to make it consistent with the application date for small regulated MS4s. (See section I.3. below.) The rule also provides relief from NPDES storm water permitting requirements for industrial sources with no exposure of industrial materials and activities to storm water.

3. Integration of Today's Rule With the Existing Storm Water Program

In developing an approach for today's final rule, numerous early interested stakeholders encouraged EPA to seek opportunities to integrate, where possible, the proposed Phase II requirements with existing Phase I requirements, thus facilitating a unified storm water discharge control program. EPA believes that this objective is met by using the NPDES framework. This framework is already applied to regulated storm water discharge sources and is extended to those sources designated under today's rule. This approach facilitates program consistency, public access to information, and program oversight.

EPA believes that today's final rule provides consistency in terms of program coverage and requirements for existing and newly designated sources. For example, the rule includes most of the municipal donut holes, those MS4s located in incorporated places, townships or towns with a population under 100,000 that are within Phase I counties. These MS4s are not addressed by the existing NPDES storm water program while MS4s in the surrounding county are currently addressed. In addition, the minimum control measures required in today's rule for regulated small MS4s are very similar to a number of the permit requirements for medium and large MS4s under the existing storm water program. Following today's rule, permit requirements for all regulated MS4s (both those under the existing program and those under today's rule) will require implementation of BMPs. Furthermore, with regard to the development of NPDES permits to protect water quality, EPA intends to apply the August 1, 1996, *Interim Permitting Approach for Water Quality-Based Effluent Limitations in Storm Water Permits* (hereinafter, "Interim Permitting Approach") (see Section II.L.1. for further description) to all MS4s covered by the NPDES program.

EPA is applying NPDES permit requirements to construction sites below 5 acres that are similar to the existing requirements for those above 5 acres and above. In addition, today's rule allows compliance with qualifying local, Tribal, or State erosion and sediment controls to meet the erosion and sediment control requirements of the general permits for storm water discharges associated with construction, both above and below 5 acres.

4. General Permits

EPA recommends using general permits for all newly regulated storm water sources under today's rule. The use of general permits, instead of individual permits, reduces the administrative burden on permitting authorities, while also limiting the paperwork burden on regulated parties seeking permit authorization. Permitting authorities may, of course, require individual permits in some cases to address specific concerns, including permit non-compliance.

EPA recommends that general permits for MS4s, in particular, be issued on a watershed basis, but recognizes that each permitting authority must decide how to develop its general permit(s). Permit conditions developed to address concerns and conditions of a specific watershed could reflect a watershed plan; such permit conditions must provide for attainment of applicable water quality standards (including designated uses), allocations of pollutant loads established by a TMDL, and timing requirements for implementation of a TMDL. If the permitting authority issues a State-wide general permit, the permitting authority may include separate conditions tailored to individual watersheds or urbanized areas. Of course, for a newly regulated MS4, modification of an existing individual MS4 permit to include the newly regulated MS4 as a "limited co-permittee" also remains an option.

5. Tool Box

During the FACA process, many Storm Water Phase II FACA Subcommittee representatives expressed an interest, which was endorsed by the full Committee, in having EPA develop a "tool box" to assist States, Tribes, municipalities, and other parties involved in the Phase II program. EPA made a commitment to work with Storm Water Phase II FACA Subcommittee representatives in developing such a tool box, with the expectation that a tool box would facilitate implementation of the storm water program in an effective and cost-efficient manner. EPA has developed a preliminary working tool box (available on EPA's web page at www.epa.gov/owm/sw/toolbox). EPA intends to have the tool box fully developed by the time of the first general permits. EPA also intends to update the tool box as resources and data become available. The tool box will include the following eight main components: fact sheets; guidances; a menu of BMPs for the six MS4 minimum measures; an information clearinghouse; training and outreach efforts; technical research; support for demonstration projects; and compliance monitoring/assistance tools. EPA intends to issue the menu of BMPs, both structural and non-structural, by October 2000. In addition, EPA will issue by October 2000 a "model" permit and will issue by October 2001 guidance materials on the development of measurable goals for municipal programs.

In an attempt to avoid duplication, the Agency has undertaken an effort to identify and coordinate sources of information that relate to the storm water discharge control program from both inside and outside the Agency. Such information includes research and demonstration projects, grants, storm water management-related programs, and compendiums of available documents, including guidances, related directly or indirectly to the comprehensive NPDES storm water program. Based on this effort, EPA is developing a tool box containing fact sheets and guidance documents pertaining to the overall program and rule requirements (e.g., guidance on municipal and construction programs, and permitting authority guidance on designation and waiver criteria); models of current programs aimed at assisting States, Tribes, municipalities, and others in establishing programs; a comprehensive list of reference documents organized according to subject area (e.g., illicit discharges, watersheds, water quality standards attainment, funding sources, and similar types of references); educational materials; technical research data; and demonstration project results. The information collected by EPA will not only provide the background for tool box materials, but will also be made available through an information clearinghouse on the world wide web.

With assistance from EPA, the American Public Works Association (APWA) developed a workbook and series of workshops on the proposed Phase II rule. Ten workshops were held from September 1998 through May 1999. Depending on available funding, these workshops may continue after publication of today's final rule. EPA also intends to provide training to enable regional offices to educate States, Tribes, and municipalities about the storm water program and the availability of the tool box materials.

The CWA currently provides funding mechanisms to support activities related to storm water. These mechanisms will be described in the tool box. Activities funded under grant and loan programs, which could be used to assist in storm water program development, include programs in the nonpoint source area, storm water demonstration projects, source water protection and wastewater construction projects. EPA has already provided funding for numerous research efforts in these areas, including a database of BMP effectiveness studies (described below), an assessment of technologies for storm water management, a study of the effectiveness of storm water BMPs for controlling the impacts of watershed imperviousness, protocols for wet weather monitoring, development of a dynamic model for wet weather flows, and numerous outreach projects.

EPA has entered into a cooperative agreement with the Urban Water Resources Research Council of the American Society of Civil Engineers (ASCE) to develop a scientifically-based management tool for the information needed to evaluate the effectiveness of urban storm water runoff BMPs nationwide. The long-term goal of the National Stormwater BMP Database project is to promote technical design improvements for BMPs and to better match their selection and design to the local storm water problems being addressed. The project team has collected and evaluated hundreds of existing published BMP performance studies and created a database covering about 75 test sites. The database includes detailed information on the design of each BMP and its watershed characteristics, as well as its performance. Eventually the database will include the nationwide collection of information on the characteristics of structural and non-structural BMPs, data collection efforts (*e.g.*, sampling and flow gaging equipment), climatological characteristics, watershed characteristics, hydrologic data, and constituent data. The database will continue to grow as new BMP data become available. The initial release of the database, which includes data entry and retrieval software, is available on CD-ROM and operates on Windows®-compatible personal computers. The ASCE project team envisions that periodic updates to the database will be distributed through the Internet. The team is currently developing a system for Internet retrieval of selected database records, and this system is expected to be available in early 2000.

EPA and ASCE invite BMP designers, owners and operators to participate in the continuing database development effort. To make this effort successful, a large database is essential. Interested persons are encouraged to submit their BMP performance evaluation data and associated BMP watershed characteristics for potential entry into the database. The software included in the CD-ROM allows data providers to enter their BMP data locally, retain and edit the data as needed, and submit them to the ASCE Database Clearinghouse when ready.

To obtain a copy of the database, please contact Jane Clary, Database Clearinghouse Manager, Wright Water Engineers, Inc., 2490 W. 26th Ave., Suite 100A, Denver, CO 80211; Phone 303–480–1700; E-mail clary@wrightwater.com.

In addition, EPA requests that researchers planning to conduct BMP performance evaluations compile and collect BMP reporting information according to the standard format developed by ASCE. The format is provided with the database software and is also available on the ASCE website at www.asce.org/peta/tech/nsbd01.html.

6. Deadlines Established in Today's Action

Exhibit 2 outlines the various deadlines established under today's final rule. EPA believes that the dates allow sufficient time for completion of both the NPDES permitting authority's and the permittee's program responsibilities.

EXHIBIT 2—STORM WATER PHASE II ACTIONS DEADLINES

Activity	Deadline date
NPDES-authorized States modify NPDES program if no statutory change is required.	1 year from date of publication of today's rule in the **Federal Register**.
NPDES-authorized States modify NPDES program if statutory change is required.	2 years from date of publication of today's rule in the **Federal Register**.
EPA issues a menu of BMPs for regulated small MS4s	October 27, 2000
ISTEA sources submit permit application	3 years and 90 days from date of publication of today's rule in the **Federal Register**.
Permitting authority issues general permit(s) (if this type of permit coverage is selected).	3 years from date of publication of today's rule in the **Federal Register**.
Regulated small MS4s submit permit application:	
a. If designated under § 122.32(a)(1) unless the permitting authority has established a phasing schedule under § 123.35(d)(3).	a. 3 years and 90 days from date of publication of today's rule in the **Federal Register**.
b. If designated under § 122.32(a)(2) or §§ 122.26(a)(9)(i) (C) or (D).	b. Within 180 days of notice.
Storm water discharges associated with small construction activity submit permit application:	
a. If designated under § 122.26(b)(15)(i)	a. 3 years and 90 days from date of publication of today's rule in the **Federal Register**
b. If designated under § 122.26(b)(15)(ii)	b. Within 180 days of notice.
Permitting authority designates small MS4s under § 123.35(b)(2)	3 years from date of publication of today's rule in the **Federal Register** or 5 years from date of publication of today's rule in the **Federal Register** if a watershed plan is in place
Regulated small MS4s' program fully developed and implemented	Up to 5 years from date of permit issuance.
Reevaluation of the municipal storm water rules by EPA	13 years from date of publication of today's rule in the **Federal Register**
Permitting authority determination on a petition	Within 180 days of receipt.
Non-municipal sources designated under § 122.26(a)(9)(i) (C) or (D) submit permit application.	Within 180 days of notice.
Submission of No Exposure Certification	Every 5 years.

B. Readable Regulations

Today, EPA is finalizing new regulations in a "readable regulation" format. This reader-friendly, plain language approach is a departure from traditional regulatory language and should enhance the rule's readability. These plain language regulations use questions and answers, "you" to identify the person who must comply, and terms like "must" rather than "shall" to identify a mandate. This new format, which minimizes layers of subparagraphs, should also allow the reader to easily locate specific provisions of the regulation.

Some sections of today's final rule are presented in the traditional language and format because these sections amend existing regulations. The readable regulation format was not used in these existing provisions in an attempt to avoid confusion or disruption

R0018110

of the readability of the existing regulations.

Most commenters supported EPA's use of plain language and agreed with EPA that the question and answer format makes the rule easier to understand. Three commenters thought that EPA should retain the traditional rule format. The June 1, 1998, Presidential memorandum directs all government agencies to write documents in plain language. Based on the majority of the comments, EPA has retained the plain language format used in the January 9, 1998, proposal in today's final rule.

The proposal to today's final rule included guidance as well as legal requirements. The word "must" indicates a requirement. Words like "should," "could," or "encourage" indicate a recommendation or guidance. In addition, the guidance was set off in parentheses to distinguish it from requirements.

EPA received numerous comments supporting the inclusion of guidance in the text of the Code of Federal Regulations (CFR), as well as comments opposing inclusion of guidance. Supporters stated that preambles and guidance documents are often not accessible when rules are implemented. Any language not included in the CFR is therefore not available when it may be most needed. Commenters that opposed including guidance in the CFR expressed the concern that any language in the rule might be interpreted as a requirement, in spite of any clarifying language. They suggested that guidance be presented in the preamble and additional guidance documents.

The majority of commenters on this issue thought that the guidance should be retained but the distinction between requirements and guidance should be better clarified. Suggestions included clarifying text, symbols, and a change from use of the word "should" to "EPA recommends" or "EPA suggests". EPA believes that it is important to include the guidance in the rule and agrees that the distinction between requirements and EPA recommendations must be very clear. In today's final rule, EPA has put the guidance in paragraphs entitled "Guidance" and replaced the word "should" with "EPA recommends." This is intended to clarify that the recommendations contained in the guidance paragraphs are not legally binding.

C. Program Framework: NPDES Approach

Today's rule regulates Phase II sources using the NPDES permit program. EPA interprets Clean Water Act section 402(p)(6) as authorizing the Agency to develop a storm water program for Phase II sources either as part of the existing NPDES permit program or as a stand alone non-NPDES program such as a self-implementing rule. Under either approach, EPA interprets section 402(p)(6) as directing EPA to publish regulations that "regulate" the remaining unregulated sources, specifically to establish requirements that are federally enforceable under the CWA. Although EPA believes that it has the discretion to not require sources regulated under CWA section 402(p)(6) to be covered by NPDES permits, the Agency has determined, for the reasons discussed below, that it is most appropriate to use NPDES permits in implementing the program to address the sources designated for regulation in today's rule.

As discussed in Section II.A, Overview, EPA sought to achieve certain goals in today's final rule. EPA believes that the NPDES program best achieves EPA's goals for today's final rule for the reasons discussed below.

Requiring Phase II sources to be covered by NPDES permits helps address the consistency problems currently caused by municipal "donut holes." Donut holes are gaps in program coverage where a small unregulated MS4 is located next to or within a regulated larger MS4 that is subject to an NPDES permit under the Phase I NPDES storm water program. The existence of such "donut holes" creates an equity problem because similar discharges may remain unregulated even though they cause or contribute to the same adverse water quality impacts. Using NPDES permits to regulate the unregulated discharges in these areas is intended to facilitate the development of a seamless regulatory program for the mitigation and control of contaminated storm water discharges in an urbanized area. For example, today's rule allows a newly regulated MS4 to join as a "limited" co-permittee with a regulated MS4 by referencing a common storm water management program. Such cooperation should be further encouraged by the fact that the minimum control measures required in today's rule for regulated small MS4s are very similar to a number of the permit requirements for medium and large MS4s under the Phase I storm water program. The minimum control measures applicable to discharges from smaller MS4s are described with slightly more generality than under the Phase I permit application regulations for larger MS4s, thus enabling maximum flexibility for operators of smaller MS4s to optimize efforts to protect water quality.

Today's rule also applies NPDES permit requirements to construction sites below 5 acres that are similar to the existing requirements for those 5 acres and above. In addition, the rule would allow compliance with qualifying local, Tribal, or State erosion and sediment controls to meet the erosion and sediment control requirements of the general permits for storm water discharges associated with construction, both above and below 5 acres.

Incorporating the CWA section 402(p)(6) program into the NPDES program capitalizes upon the existing governmental infrastructure for administration of the NPDES program. Moreover, much of the regulated community already understands the NPDES program and the way it works.

Another goal of the NPDES program approach is to provide flexibility in order to facilitate and promote watershed planning and sensitivity to local conditions. NPDES permits promote those goals in several ways. NPDES general permits may be used to cover a category of regulated sources on a watershed basis or within political boundaries. The NPDES permitting process provides a mechanism for storm water controls tailored on a case-by-case basis, where necessary. In addition, the NPDES permit requirements of a permittee may be satisfied by another cooperating entity. Finally, NPDES permits may incorporate the requirements of existing State, Tribal and local programs, thereby accommodating State and Tribes seeking to coordinate the storm water program with other programs, including those that focus on watershed-based nonpoint source regulation.

In promoting the watershed approach to program administration, EPA believes NPDES general permits can cover a category of dischargers within a defined geographic area. Areas can be defined very broadly to include political boundaries (e.g., county), watershed boundaries, or State or Tribal land.

NPDES permits generally require an application or a notice of intent(NOI) to trigger coverage. This information exchange assures communication between the permitting authority and the regulated community. This communication is critical in ensuring that the regulated community is aware of the requirements and the permitting authority is aware of the potential for adverse impacts to water quality from identifiable locations. The NPDES permitting process includes the public as a valuable stakeholder and ensures

R0018111

that the public is included and information is made publicly available.

Another concern for EPA and several stakeholders was that the program ensure citizen participation. The NPDES approach ensures opportunities for citizen participation throughout the permit issuance process, as well as in enforcement actions. NPDES permits are also federally enforceable under the CWA.

EPA believes that the use of NPDES permits makes a significant difference in the degree of compliance with regulations in the storm water program. The NPDES program provides for public participation in the development, enforcement and revision of storm water management programs. Citizen suit enforcement has assisted in focusing attention on adverse water quality impacts on a localized, public priority basis. Citizens frequently rely on the NPDES permitting process and the availability of NOIs to track program implementation and help them enforce regulatory requirements.

NPDES permits are also advantageous to the permittee. The NPDES permit informs the permittee about the scope of what it is expected do to be in compliance with the Clean Water Act. As explained more fully in EPA's April 1995 guidance, *Policy Statement on Scope of Discharge Authorization and Shield Associated with NPDES Permits*, compliance with an NPDES permit constitutes compliance with the Clean Water Act (see CWA section 402(k)). In addition, NPDES permittees are excluded from duplicative regulatory regimes under the Resource Conservation and Recovery Act and the Comprehensive Emergency Response, Compensation and Liability Act under RCRA's exclusions to the definition of "solid waste" and CERCLA's exemption for "federally permitted releases."

EPA considered suggestions that the Agency authorize today's rule to be implemented as a self-implementing rule. This would be a regulation promulgated at the Federal, State, or Tribal level to control some or all of the storm water dischargers regulated under today's rule. Under this approach, a rule would spell out the specific requirements for dischargers and impose the restrictions and conditions that would otherwise be contained in an NPDES permit. It would be effective until modified by EPA, a State, or a Tribe, unlike an NPDES permit which cannot exceed a duration of five years. Some stakeholders believed that this approach would reduce the burden on the regulated community (e.g., by not requiring permit applications), and considerably reduce the amount of additional paperwork, staff time and accounting required to administer the proposed permit requirements.

EPA is sensitive to the interest of some stakeholders in having a streamlined program that minimizes the burden associated with permit administration and maximizes opportunities for field time spent by regulatory authorities. Key provisions in today's rule address some of these concerns by promoting a streamlined approach to permit issuance by, for example, using general permits and allowing the incorporation of existing programs. By adopting the NPDES approach rather than a self-implementing rule, today's rule also allows for consistent regulation between larger MS4s and construction sites regulated under the existing storm water management rule and smaller sources regulated under today's rule.

EPA believes that it is most appropriate to use NPDES permits to implement a program to address the sources regulated by today's rule. In addition to the reasons discussed above, NPDES permits provide a better mechanism than would a self-implementing rule for tailoring storm water controls on a case-by-case basis, where necessary. One commenter reasoned this concern could be addressed by including provisions in the regulation that allow site-specific BMPs (*i.e.*, case-by-case permits), suggesting storm water discharges that might require site-specific BMPs can be identified during the designation process of the regulatory authority. EPA believes that, in addition to its complexity, the commenter's approach lacks the other advantages of the NPDES permitting process.

A self-implementing rule would not ensure the degree of public participation that the NPDES permit process provides for the development, enforcement and revision of the storm water management program. A self-implementing rule also might not have provided the regulated community the "permit shield" under CWA section 402(k) that is provided by an NPDES permit. Based on all these considerations, EPA declined to adopt a self-implementing rule approach and adopted the NPDES approach.

Some State representatives sought alternative approaches for State implementation of the storm water program for Phase II sources. These State representatives asserted that a non-NPDES alternative approach best facilitated watershed management and avoided duplication and overlapping regulations. These representatives believed the NPDES approach would undercut State programs that had developed storm water controls tailored to local watershed concerns. Finally, a number of commenters expressed the view that States implement a variety of programs not based on the CWA that are effective in controlling storm water, and that EPA should provide incentives for their implementation and improvement in performance.

Throughout the development of the rule, State representatives sought alternatives to the NPDES approach for State implementation of the storm water program for Phase II sources. Discussions focused on an approach whereby States could develop an alternative program that EPA would approve or disapprove based on identified criteria, including that the alternative non-NPDES program would result in "equivalent or better protection of water quality." The State representatives, however, were unable to propose or recommend criteria for gauging whether a program would provide equivalent protection. EPA also did not receive any suggestions for objective, workable criteria in response to the Agency's explicit request for specific criteria (by which EPA could objectively judge such programs) in the preamble to the proposed rule.

EPA evaluated several existing State initiatives to address storm water and found many cases where standards under State programs may be coordinated with the Federal storm water program. Where the NPDES permit is developed in coordination with State standards, there are opportunities to avoid duplication and overlapping requirements. Under today's rule, an NPDES permitting authority may include conditions in the NPDES permit that direct an MS4 to follow the requirements imposed under State standards, rather than the requirements of § 122.34(b). This is allowed as long as the State program at a minimum imposes the relevant requirements of § 122.34(b). Additional opportunities follow from other provisions in today's rule.

Seeking to further explore the feasibility of a non-NPDES approach, the Agency, after the proposal, had extensive discussions with representatives of a number of States. Discussions related specifically to possible alternatives for regulations of urban storm water discharges and MS4s specifically. The Agency also sought input on these issues from other stakeholders.

As a result of these discussions, many of the commenters provided input on issues such as: whether or not the Agency should require NPDES permits; whether location of MS4s in urbanized areas should be the basis for designation or whether designation should be based on other determinations relating to water quality; whether States should be allowed to satisfy the conditions of the rule through the use of existing State programs; and issues concerning timing and resources for program implementation.

In response, today's rule still follows the regulatory scheme of the proposed rule, but incorporates additional flexibility to address some of the concerns raised by commenters.

In order to facilitate implementation by States that utilize a watershed permitting approach or similar approach (*i.e.*, based on a State's unified watershed assessments), today's rule allows States to phase in coverage for MS4s in jurisdictions with a population less than 10,000. Under such an approach, States could focus their resources on a rolling basis to assist smaller MS4s in developing storm water programs.

In addition, in response to concerns that the rule should not require permit coverage for MS4s that do not significantly contribute to water quality impairments, today's rule provides options for two waivers for small MS4s. The rule allows permitting authorities to exempt from the requirement for a permit any MS4 serving a jurisdiction with a population less than 1,000, unless the State determines that the MS4 must implement storm water controls because it is significantly contributing to a water quality impairment. A second waiver option applies to MS4s serving a jurisdiction with a population less than 10,000. For those MS4s, the State must determine that discharges from the MS4 do not significantly contribute to a water quality impairment, or have the potential for such an impairment, in order to provide the exemption. The State must review this waiver on a periodic basis no less frequently than once every five years.

Throughout the development of today's rule, commenters questioned whether the Clean Water Act authorized the use of the NPDES permit program, pointing out that the text of CWA 402(p)(6) does not use the word "permit." Based on the absence of the word "permit" and the express mention of State storm water management programs, the commenters asserted that Congress did not intend for Phase II sources to be regulated using NPDES permits.

EPA disagrees with the commenters' interpretation of section 402(p)(6). Section 402(p)(6) does not preclude use of permits as part of the "comprehensive program" to regulate designated sources. The language provides EPA with broad discretion in the establishment of the "comprehensive program." Absence of the word "permit" (a term that the statute does not otherwise define) does not preclude use of a permit, which is a familiar and reasonably well understood regulatory implementation vehicle. First, section 402(p)(6) says that EPA must establish a comprehensive program that "shall, at a minimum, establish priorities, establish requirements for State stormwater management programs, and establish expeditious deadlines." The "at a minimum" language suggests that the Agency may, and perhaps should, develop a comprehensive program that does more than merely attend to these minimum criteria. Use of the term "at a minimum" preserves for the Agency broad discretion to establish a comprehensive program that includes use of NPDES permits.

Further, in the final sentence of the section, Congress included additional language to affirm the Agency's discretion. The final sentence clarifies that the Phase II program "may include performance standards, guidelines, guidance, and management practices and treatment requirements, as appropriate." Under existing CWA programs, performance standards, (effluent limitations) guidelines, management practices, and treatment requirements are typically implemented through NPDES or dredge and fill permits.

Although EPA believes that it had the discretion to not require permits, the Agency has determined that it is reasonable to interpret section 402(p)(6) to authorize permits. Moreover, for the reasons discussed above, the Agency believes that it is appropriate to use NPDES permits in implementing today's rule.

D. Federal Role

Today's final rule describes EPA's approach to expand the existing storm water program under CWA section 402(p)(6). As in all other Federal programs, the Federal government plays an integral role in complying with, developing, implementing, overseeing, and enforcing the program. This section describes EPA's role in the revised storm water program.

1. Develop Overall Framework of the Program

The storm water discharge control program under CWA section 402(p)(6) consists of the rule, tool box, and permits. EPA's primary role is to ensure timely development and implementation of all components. Today's rule is a refinement of the first step in developing the program. EPA is fully committed to continuing to work with involved stakeholders on developing the tool box and issuing permits. As noted in today's rule, EPA will assess the municipal storm water program based on (1) evaluations of data from the NPDES municipal storm water program, (2) research concerning water quality impacts on receiving waters from storm water, and (3) research on BMP effectiveness. (Section II.H, Municipal Role, provides a more detailed discussion of this provision.)

EPA is planning to standardize minimum requirements for construction and post-construction BMPs in a new rulemaking under Title III of the CWA. While larger construction sites are already subject to NPDES permits (and smaller sites will be subject to permits pursuant to today's rule), the permits generally do not contain specific requirements for BMP design or performance. The permits require the preparation of storm water pollution prevention plans, but actual BMP selection and design is at the discretion of permittees, in conformance with applicable State and local requirements. Where there are existing State and local requirements specific to BMPs, they vary widely, and many jurisdictions do not have such requirements.

In developing these regulations, EPA intends to evaluate the inclusion of design and maintenance criteria as minimum requirements for a variety of BMPs used for erosion and sediment control at construction sites, as well as for permanent BMPs used to manage post-construction storm water discharges. The Agency plans to consider the merits and performance of all appropriate management practices (both structural and non-structural) that can be used to reduce adverse water quality impacts. EPA does not intend to require the use of particular BMPs at specific sites, but plans to assist builders and developers in BMP selection by publishing data on the performance to be expected by various BMP types. EPA would like to build upon the successes of some of the effective State and local storm water programs currently in place around the country, and to establish nation-wide criteria to support builders and local jurisdictions in appropriate BMP selection.

2. Encourage Consideration of Smart Growth Approaches

In the proposal, EPA invited comment on possible approaches for providing

R0018113

incentives for local decision making that would limit the adverse impacts of growth and development on water quality. EPA asked for comments on this "smart growth" approach.

EPA received comments on all sides of this issue. A number of commenters supported the idea of "smart growth" incentives but did not present concrete ideas. Several commenters suggested "smart growth" criteria. States that have adopted "smart growth" laws were worried that EPA's focus on urbanized areas for municipal requirements could encourage development outside of designated growth areas. Today's final rule clearly allows States to expand coverage of their municipal storm water program outside of urbanized areas. In addition, the flexibility of the six municipal minimum measures should avoid encouragement of development into rural rather than urban areas. For example, as part of the post-construction minimum measure, EPA recommends that municipalities consider policies and ordinances that encourage infill development in higher density urban areas, and areas with existing infrastructure, in order to meet the measure's intent.

EPA also received several comments expressing concern that incorporating "smart growth" incentives threatened the autonomy of local governments. One commenter was worried that "incentives" could become more onerous than the minimum measures. EPA is very aware of municipal concerns about possible federal interference with local land use planning. EPA is also cognizant of the difficulty surrounding incentives for "smart growth" activities due to these concerns. However, the Agency believes it has addressed these concerns by proposing a flexible approach and will continue to support the concept of "smart growth" by encouraging policies that limit the adverse impacts of growth and development on water quality.

3. Provide Financial Assistance

Although Congress has not established a fund to fully finance implementation of the proposed extension of the existing NPDES storm water program under CWA section 402(p)(6), numerous federal financing programs (administered by EPA and other federal agencies) can provide some financial assistance. The primary funding mechanism is the Clean Water State Revolving Fund (SRF) program, which provides sources of low-cost financing for a range of water quality infrastructure projects, including storm water. In addition to the SRF, federal financial assistance programs include the Water Quality Cooperative Agreements under CWA section 104(b)(3), Water Pollution Control Program grants to States under CWA section 106, and the Transportation Equity Act for the 21st Century (TEA-21) among others. In addition, Section 319 funds may be used to fund any urban storm water activities that are not specifically required by a draft or final NPDES permit. EPA will develop a list of potential funding sources as part of the tool box implementation effort. EPA anticipates that some of these programs will provide funds to help develop and, in limited circumstances, implement the CWA section 402(p)(6) storm water discharge control program.

EPA received numerous comments that requested additional funding. Congress provided one substantial new source of potential funding for transportation related storm water projects—TEA-21. The Department of Transportation has included a number of water-related provisions in its TEA-21 planning. These include Transportation Enhancements, Environmental Restoration and Pollution Abatement, and Environmental Streamlining. More information on TEA-21 is available at the following internet sites: www.fhwa.dot.gov/tea21/outreach.htm and www.tea21.org.

4. Implement the Program in Jurisdictions Not Authorized To Administer the NPDES Program

Because today's final rule uses the NPDES framework, EPA will be the NPDES permitting authority in several States, Tribal jurisdictions, and Territories. As such, EPA will have the same responsibilities as any other NPDES permitting authority—issuing permits, designating additional sources, and taking appropriate enforcement actions—and will seek to tailor the storm water discharge control program to the specific needs in that State, Tribal jurisdiction, or Territory. EPA also plans to provide support and oversight, including outreach, training, and technical assistance to the regulated communities. Section II.G. of today's preamble provides a separate discussion related to the NPDES permitting authority's responsibilities for today's final rule.

5. Oversee State and Tribal Programs

Under the NPDES program, EPA plays an oversight role for NPDES-approved States and Tribes. In this role, EPA and the State or Tribe work together to implement, enforce, and improve the NPDES program. Part of this oversight role includes working with States and Tribes to modify their programs where programmatic or implementation concerns impede program effectivenes. This role will be vitally important whe States and Tribes make adjustments to develop, implement, and enforce today's extension of the existing NPDES storm water discharge control program. In addition, States maintain a continuing planning process (CPP) under CWA section 303(e), which EPA periodically reviews to assess the program's achievements.

In its oversight role, EPA takes action to address States and Tribes who have obtained NPDES authorization but are not fulfilling their obligations under the NPDES program. If an NPDES-authorized State or Tribe fails to implement an adequate NPDES storm water program, for example, EPA typically enters into extensive discussions to resolve outstanding issues. EPA has the authority to withdraw the entire NPDES program when resolution cannot be reached. Partial program withdrawal is not provided for under the CWA except for partial approvals.

EPA is also working with the States and Tribes to improve nonpoint source management programs and assessments to incorporate key program elements. Key nonpoint source program elements include setting short and long term goals and objectives; establishing public and private partnerships; using a balanced approach incorporating Statewide and watershed-wide abatement of existing impairments; preventing future impairments; developing processes to address both impaired and threatened waters; reviewing and upgrading all program components, including program revisions on a 5-year cycle; addressing federal land management and activities inconsistent with State programs; and managing State nonpoint source management programs effectively.

In particular, EPA works with the States and Tribes to strengthen their nonpoint source pollution programs to address all significant nonpoint sources, including agricultural sources, through the CWA section 319 program. EPA is working with other government agencies, as well as with community groups, to effect voluntary changes regarding watershed protection and reduced nonpoint source pollution.

In addition, EPA and NOAA have published programmatic and technical guidance to address coastal nonpoint source pollution. Under Section 6217 of the CZARA, States are developing and implementing coastal nonpoint pollution control programs approved by EPA and NOAA.

R0018114

6. Comply With Applicable Requirements as a Discharger

Today's final rule covers federally operated facilities in a variety of ways. These facilities are generally areas where people reside, such as a federal prison, hospital, or military base. It also includes federal parkways and road systems with separate storm sewer systems. Today's rule requires federal MS4s to comply with the same application deadlines that apply to regulated small MS4s generally. EPA believes that all federal MS4s serve populations of less than 100,000.

EPA received several comments that asked if individual buildings like post offices are considered to be small MS4s and thereby regulated in today's rule if they are in an urbanized area. Most of these buildings have at most a parking lot with runoff or a storm sewer that connects with a municipality's MS4. EPA does not intend that individual federal buildings be considered to be small MS4s. This is discussed in section II.H.2.b. of today's preamble.

Federal facilities can also be included under requirements addressing storm water discharges associated with small construction activities. In any case, discharges from these facilities will need to comply with all applicable NPDES requirements and any additional water quality-related requirements imposed by a State, Tribal, or local government. Failure to comply can result in enforcement actions. Federal facilities can act as models for municipal and private sector facilities and implement or test state-of-the-art management practices and control measures.

E. State Role

Today's final rule sets forth an NPDES approach for implementing the extension of the existing storm water discharge control program under CWA section 402(p)(6). State assumption of the NPDES program is voluntary, consistent with the principles of federalism. Because most States are approved to implement the NPDES program, they will tailor their storm water discharge control programs to address their water quality needs and objectives. While today's rule establishes the basic framework for the section 402(p)(6) program, States as well as Tribes (see discussion in section II.F) have an important role in fine-tuning the program to address the water quality issues within their jurisdictions. The basic framework allows for adjustments based on factors that vary geographically, including climate patterns and terrain.

Where States do not have NPDES authority, they are not required to implement the storm water discharge control program, but they may still participate in water quality protection through participation in the CWA section 401 certification process (for any permits) and through development of water quality standards and TMDLs.

1. Develop the Program

In expanding the existing NPDES program for storm water discharges, States must evaluate whether revisions to their NPDES programs are necessary. If so, modifications must be made in accordance with § 123.62. Under § 123.62, States must revise their NPDES programs within 1 year, or within 2 years if statutory changes are necessary.

Some States and departments of transportation (DOTs) commented that this timeframe is too short, anticipating that the State legislative process and the modification of regulations combined would take beyond 2 years. The deadline language in § 123.62 is not new language for the storm water discharge control program; it applies to all NPDES programs. EPA believes the vast majority of States will meet the deadline and will work with States in those cases where there may be difficulty meeting this deadline due to the timing of legislative sessions and the regulatory development process.

An authorized State NPDES program must meet the requirements of CWA section 402(b) and conform to the guidelines issued under CWA section 304(i)(2). Today's final rule under § 123.25 adds specific cross references to the storm water discharge control program components to ensure that States adequately address these requirements.

2. Comply With Applicable Requirements as a Discharger

Today's final rule covers State operated separate storm sewer systems in a variety of ways. These systems generally drain areas where people reside, such as a prison, hospital, or other populated facility. These systems are included under the definition of a regulated small MS4, which specifically identifies systems operated by State departments of transportation. Alternatively, storm water discharges from State activities may be regulated under the section addressing storm water discharges associated with small construction activities. In any case, discharges from these facilities must comply with all applicable NPDES requirements. Failure to comply can result in enforcement actions. State facilities can act as models for municipal and private sector facilities and implement or test state-of-the-art management practices and control measures.

3. Communicate With EPA

Under approved NPDES programs, States have an ongoing obligation to share information with EPA. This dialogue is particularly important in the CWA section 402(p)(6) storm water program where these governments continue to develop a great deal of the guidance and outreach related to water quality.

F. Tribal Role

The proposal to today's final rule provides background information on EPA's 1984 Indian Policy and the criteria for treatment of an Indian Tribe in the same manner as a State. Today's final rule extends the existing NPDES program for storm water discharges to two types of dischargers located in Indian country. First, the final rule designates storm water discharges from any regulated small MS4, including Tribal systems. Second, the final rule regulates discharges associated with construction activity disturbing between one and five acres of land, including sites located in Indian country. Operators in each of these categories of regulated activity must apply for coverage under an NPDES permit by 3 years and 90 days from the date of publication of today's final rule. Under existing regulations, however, EPA or an authorized NPDES Tribe may require a specified storm water discharger to apply for NPDES permit coverage before this deadline based on a determination that the discharge is contributing to a violation of a water quality standard (including designated uses) or is a significant contributor of pollutants.

Under today's rule, a Tribal governmental entity may regulate storm water discharges on its reservation in two ways—as either an NPDES-authorized Tribe or as a regulated MS4. If a Tribe is authorized to operate the NPDES program, the Tribe must implement today's final rule for the NPDES program for storm water for covered dischargers located within the EPA recognized boundaries. Otherwise, EPA is generally the permitting/program authority within Indian country. Discussions about the State Role in the preceding section also apply to NPDES authorized Tribes. For additional information on the role and responsibilities of the permitting authority in the NPDES storm water program, see § 123.35 (and Section II.G. of today's preamble) and § 123.25(a).

R0018115

Under today's final rule, if the Indian reservation is located entirely or partially within an "urbanized area," as defined in § 122.32(a)(1), the Tribe must obtain an NPDES permit if it operates a small MS4 within the urbanized area portion. Tribal MS4s located outside an urbanized area are not automatically covered, but may be designated by EPA pursuant to § 122.32(a)(2) of today's rule or may request designation as a regulated small MS4 from EPA. A Tribe that is a regulated MS4 for NPDES program purposes is required to implement the six minimum control measures to the extent allowable under Federal law.

The Tribal representative on the Storm Water Phase II FACA Subcommittee asked EPA to provide a list of the Tribes located in urbanized areas that would fall within the NPDES storm water program under today's final rule. In December 1996, EPA developed a list of federally recognized American Indian Areas located wholly or partially in Bureau of the Census-designated urbanized areas (see Appendix 1). Appendix 1 not only provides a listing of reservations and individual Tribes, but also the name of the particular urbanized area in which the reservation is located and an indication of whether the urbanized area contains a medium or large MS4 that is already covered by the existing Phase I regulations.

Some of the Tribes listed in Appendix 1 are only partially located in an urbanized area. If the Tribe's MS4 serves less than 1,000 people within an urbanized area, the permitting authority may waive the Tribe's MS4 storm water requirements if it meets the conditions of § 122.32(c). EPA does not have information on the Tribal populations within the urbanized areas, so it can not identify the Tribes that are eligible for a waiver. Therefore, a Tribe that believes it qualifies for a waiver should contact its permitting authority.

G. NPDES Permitting Authority's Role for the NPDES Storm Water Small MS4 Program

As noted previously, the NPDES permitting authority can be EPA or an authorized State or an authorized Tribe. The following discussion describes the role of the NPDES permitting authority under today's final rule.

1. Comply With Implementation Requirements

NPDES permitting authorities must perform certain duties to implement the NPDES storm water municipal program. Section 123.35(a) of today's final rule emphasizes that permitting authorities have existing obligations under the NPDES program. Section 123.35 focuses on specific issues related to the role of the NPDES authority to support administration and implementation of the municipal storm water program under CWA section 402(p)(6).

2. Designate Sources

Section 123.35(b) of today's final rule addresses the requirements for the NPDES permitting authority to designate sources of storm water discharges to be regulated under §§ 122.32 through 122.36. NPDES permitting authorities must develop a process, as well as criteria, to designate small MS4s. They must also have the authority to designate a small MS4 if and when circumstances that support a waiver under § 122.32(c) change. EPA may make designations if an NPDES-approved State or Tribe fails to do so.

NPDES permitting authorities must examine geographic jurisdictions that they believe should be included in the storm water discharge control program but are not located in an "urbanized area". Small MS4s in these areas are not designated automatically. Discharges from such areas should be brought into the program if found to have actual or potential exceedances of water quality standards, including impairment of designated uses, or other adverse impacts on water quality, as determined by local conditions or watershed and TMDL assessments. EPA's aim is to address discharges to impaired waters and to protect waters with the potential for problems. EPA encourages NPDES permitting authorities, local governments, and the interested public to work together in the context of a watershed plan to address water quality issues, including those associated with municipal storm water runoff.

EPA received comments stating that the process of developing criteria and applying it to all MS4s outside an urbanized area serving a population of 10,000 or greater and with a density of 1,000 people per square mile is too time-consuming and resource-intensive. These commenters believe that the permitting authority should decide which MS4s must be brought into the storm water discharge control program and that population and density should not be an overriding criteria. One suggested way of doing so was to only designate MS4s with demonstrated contributions to the impairment of water quality uses as shown by a TMDL. EPA disagrees with this suggestion. The TMDL process is time-consuming. MS4s outside of urbanized areas may cause water quality problems long before a TMDL is completed.

EPA believes that permitting authorities should consider the potential water quality impacts of storm water from all jurisdictions with a population of 10,000 or greater and a density of 1,000 people per square mile. EPA is using data summarized in the NURP study and in the CWA section 305(b) reports to support this approach for targeted designation outside of urbanized areas. EPA is not mandating which criteria are to be used, but has provided examples of criteria that may be useful in evaluating potential water quality impacts. EPA believes that the flexibility provided in this section of today's final rule allows the permitting authority to develop criteria and a designation process that is easy to use and protects water quality. Therefore, the provisions of § 123.35(b) remain as proposed.

a. Develop Designation Criteria

Under § 123.35(b), the NPDES permitting authority must establish designation criteria to evaluate whether a storm water discharge results in or has the potential to result in exceedances of water quality standards, including impairment of designated uses, or other significant water quality impacts, including adverse habitat and biological impacts.

EPA recommends that NPDES permitting authorities consider, in a balanced manner, certain locally-focused criteria for designating any MS4 located outside of an urbanized area on the basis of significant water quality impacts. EPA recommends consideration of criteria such as discharge to sensitive waters, high growth or growth potential, high population density, contiguity to an urbanized area, significant contribution of pollutants to waters of the United States, and ineffective control of water quality concerns by other programs. These suggested designation criteria are intended to help encourage the permitting authority to use an objective method for identifying and designating, on a local basis, sources that adversely impact water quality. More information about these criteria and the reasons why they are suggested by EPA is included in the January 9, 1998, proposal (63 FR 1561) for today's final rule.

The suggested criteria are meant to be taken in the aggregate, with a great deal of flexibility as to how each should be weighed in order to best account for watershed and other local conditions and to allow for a more tailored case-by-case analysis. The application of criteria is meant to be geographically specific. Furthermore, each criterion does not have to be met in order for a small MS4

R0018116

to qualify for designation, nor should an MS4 necessarily be designated on the basis of one or two criteria alone.

EPA believes that the application of the recommended designation criteria provides an objective indicator of real and potential water quality impacts from urban runoff on both the local and watershed levels. EPA encourages the application of the recommended criteria in a watershed context, thereby allowing for the evaluation of the water quality impacts of the portions of a watershed outside of an urbanized area. For example, situations exist where the urbanized area represents a small portion of a degraded watershed, and the adjacent nonurbanized areas of the watershed have significant cumulative effects on the quality of the receiving waters.

EPA received numerous suggestions of additional criteria that should be added and reasons why some of the criteria in the proposal to today's final rule were not appropriate. EPA developed its suggested designation criteria based on findings of the NURP study and other studies that indicate pollutants of concern, including total suspended solids, chemical oxygen demand, and temperature. These criteria were the subject of considerable discussion by the Storm Water Phase II FACA Subcommittee. EPA developed them in response to recommendations from the subcommittee during development of the proposed rule. The listed criteria are only suggestions. Permitting authorities are required to develop their own criteria. EPA has not found any reason to change its suggested list of criteria and the suggestions remain as proposed.

b. Apply Designation Criteria

After customizing the designation criteria for local conditions, the permitting authority must apply such criteria, at a minimum, to any MS4 located outside of an urbanized area serving a jurisdiction with a population of at least 10,000 and a population density of 1,000 people per square mile or greater (see § 123.35(b)(2)). If the NPDES permitting authority determines that an MS4 meets the criteria, the permitting authority must designate it as a regulated small MS4. This designation must occur within 3 years of publication of today's final rule. Alternatively, the NPDES authority can designate within 5 years from the date of final regulation if the designation criteria are applied on a watershed basis where a comprehensive watershed plan exists (a comprehensive watershed plan is one that includes the equivalents of TMDLs) (see § 123.35(b)(3)). The extended 5 year deadline is intended to provide incentives for watershed-based designations. If an NPDES-authorized State or Tribe does not develop and apply designation criteria within this timeframe, then EPA has the opportunity to do so in lieu of the authorized State or Tribe.

NPDES permitting authorities can designate any small MS4, including one below 10,000 in population and 1,000 in density. EPA established the 10,000/1,000 threshold based on the likelihood of adverse water quality impacts at these population and density levels. In addition, the 1,000 persons per square mile threshold is consistent with both the Bureau of the Census definition of an "urbanized area" (see Section II.H.2. below) and stakeholder discussions concerning the definition of a regulated small MS4.

One commenter requested that EPA develop interim deadlines for development of designation criteria. EPA believes that the designation deadline identified in today's final rule at § 123.35(b)(3) provides States and Tribes with a flexibility that allows them to develop and apply the criteria locally in a timely fashion, while at the same time establishing an expeditious deadline.

c. Designate Physically Interconnected Small MS4s

In addition to applying criteria on a local basis for potential designation, the NPDES permitting authority must designate any MS4 that contributes substantially to the pollutant loadings of a physically interconnected municipal separate storm sewer that is regulated by the NPDES program for storm water discharges (see § 123.35(b)(4)). To be "physically interconnected," the MS4 of one entity, including roads with drainage systems and municipal streets, is physically connected directly to the municipal separate storm sewer of another entity. This provision applies to all MS4s located outside of an urbanized area. EPA added this section in recognition of the concerns of local government stakeholders that a local government should not have to shoulder total responsibility for a storm water program when storm water discharges from another MS4 are also contributing pollutants or adversely affecting water quality. This provision also helps to provide some consistency among MS4 programs and to facilitate watershed planning in the implementation of the NPDES storm water program. EPA recommended physical interconnectedness in the existing NPDES storm water regulations as a factor for consideration in the designation of additional sources.

Today's final rule does not include interim deadlines for identifying physically interconnected MS4s. However, consistent with the deadlines identified in § 123.35(b)(3) of today's final rule, EPA encourages the permitting authority to make these determinations within 3 years from the date of publication of the final rule or within 5 years if the permitting authority is implementing a comprehensive watershed plan. Alternatively, the affected jurisdiction could use the petition process under 40 CFR 122.26(f) in seeking to have the permitting authority designate the contributing jurisdiction.

Several commenters expressed concerns about who could be designated under this provision (§ 123.35(b)(4)). One commenter requested that the word "substantially" be deleted from the rule because they believe any MS4 that contributes at all to a physically interconnected municipal separate storm sewer should be regulated. EPA believes that the word "substantially" provides necessary flexibility to the permitting authorities. The permitting authority can decide if an MS4 is contributing discharges to another municipal separate storm sewer in a manner that requires regulation. If the operator of a regulated municipal separate storm sewer believes that some of its pollutant loadings are coming from an unregulated MS4, it can petition the permitting authority to designate the unregulated MS4 for regulation.

d. Respond to Public Petitions for Designation

Today's final rule reiterates the existing opportunity for the public to petition the permitting authority for designation of a point source to be regulated to protect water quality. The petition opportunity also appears in existing NPDES regulations at 40 CFR 122.26(f). Any person may petition the permitting authority to require an NPDES permit for a discharge composed entirely of storm water that contributes to a violation of a water quality standard or is a significant contributor of pollutants to the waters of the United States (see § 123.32(b)). The NPDES permitting authority must make a final determination on any petition within 180 days after receiving the petition (see § 123.35(c)). EPA believes that a 180 day limit balances the public's need for a timely final determination with the NPDES permitting authority's need to prioritize its workload. If an NPDES-approved State or Tribe fails to act

R0018117

within the 180-day timeframe, EPA may make a determination on the petition. EPA believes that public involvement is an important component of the NPDES program for storm water and feels that this provision encourages public participation. Section II.K, Public Involvement/Public Role, further discusses this topic.

3. Provide Waivers

Today's rule provides two opportunities for the NPDES permitting authority to exempt certain small MS4s from the need for a permit based on water quality considerations. See §§ 122.32(d) and (e). The two waiver opportunities have different size thresholds and take different approaches to considering the water quality impacts of discharges from the MS4.

In the proposal, EPA requested comment on the option of waiving coverage for all MS4s with less than 1,000 people unless the permitting authority determined that the small MS4 should be regulated based on significant adverse water quality impacts. A number of commenters supported this option. They expressed concern that compliance with the rule requirements and certification of one of the waiver provisions were both costly for very small communities. They stated that the permitting authority should identify a water quality problem before requiring compliance. Today's rule essentially adopts this alternative approach for MS4s serving a population under 1,000.

The final rule has expanded the waiver provision that EPA proposed for small MS4s with a population less than 1,000. The proposed rule would have required a small MS4 operator to certify that storm water controls are not needed based on either wasteload allocations that are part of TMDLs that address the pollutants of concern, or a comprehensive watershed plan implemented for the waterbody that includes the equivalents of TMDLs and addresses the pollutant(s) of concern. Commenters noted that the proposed waivers would be unattainable if a TMDL or equivalent analysis was required for every pollutant that could possibly be present in any amount in discharges from an MS4 regardless of whether the pollutant is causing water quality impairment. Commenters asked that EPA identify what constitutes the "pollutant(s) of concern" for which a TMDL or its equivalent must be developed. For example, § 122.30(c) indicates that the MS4 program is intended to control "sediment, suspended solids, nutrients, heavy metals, pathogens, toxins, oxygen-demanding substances, and floatables." Commenters asked whether TMDLs or equivalent analyses have to address all of these.

EPA has revised the proposed waiver in response to these concerns. Under today's rule, NPDES permitting authorities may waive the requirements of today's rule for any small MS4 with a population less than 1,000 that does not contribute substantially to the pollutant loadings of a physically interconnected MS4, unless the small MS4 discharges pollutants that have been identified as a cause of impairment of the waters to which the small MS4 discharges. If the small MS4 does discharge pollutants that have been identified as impairing the water body into which the small MS4 discharges, the NPDES permitting authority may grant a waiver only if it determines that storm water controls are not needed based on an EPA approved or established TMDL that addresses the pollutant(s) of concern.

Unlike the proposed rule, § 122.32(d) does not allow the waiver for MS4s serving a population under 1,000 to be based on "the equivalent of a TMDL." Because § 122.32(d) requires a pollutant specific analysis only for a pollutant that has been identified as a cause of impairment, a TMDL is required for such pollutant before the waiver may be granted. Once a pollutant has been identified as the cause of impairment of a water body, the State should develop a TMDL for that pollutant for that water body. Thus, § 122.32(d) takes a different approach than that taken for the waiver in § 122.32(e) for MS4s serving a population under 10,000, which can be based upon an analysis that is "the equivalent of a TMDL." This is because § 122.32(d) requires an analysis to support the waiver for MS4s under 1,000 only if a waterbody to which the MS4 discharges has been identified as impaired. The § 122.32(e) waiver, on the other hand, would be available for larger MS4s but only after the State affirmatively establishes lack of impairment based upon a comprehensive analysis of smaller urban waters that might not otherwise be evaluated for the purposes of CWA section 303. Since § 122.32(e) requires the analysis of waters that have not been identified as impaired, an actual TMDL is not required and an analysis that is the equivalent of a TMDL can suffice to support the waiver.

Where a State is the NPDES permitting authority, the permitting authority is responsible for the development of the TMDLs as well as the assessment of the extent to which a small MS4's discharge contributes pollutants to a neighboring regulated system. In States where EPA is the permitting authority, EPA will use a State's TMDLs to determine whether storm water controls are required for the small MS4s.

The proposed rule would have required the operator of the small MS4 serving a population under 1,000 to certify that its discharge was covered under a TMDL that indicated that discharges from its particular system were not having an adverse impact on water quality (*i.e.*, it was either not assigned wasteload allocations under TMDLs or its discharge is within an assigned allocation). Many commenters expressed concerns that MS4 operators serving less than 1,000 persons may lack the technical capacity to certify that their discharges are not contributing to adverse water quality impacts. These commenters thought that the permitting authority should make such a certification. Today's rule provides flexibility as to how the waiver is administered. Permitting authorities are ultimately responsible for granting the waiver, but are free to determine whether or not to require small MS4 operators that are seeking waivers to submit information or a written certification.

Under § 122.32(e) a State may grant a waiver to an MS4 serving a population between 1,000 and 10,000 only if the State has made a comprehensive effort to ensure that the MS4 will not cause or contribute to water quality impairment. To grant a § 122.32(e) waiver, the NPDES permitting authority must evaluate all waters of the U.S. that receive a discharge from the MS4 and determine that storm water controls are not needed. The permitting authority's evaluation must be based on wasteload allocations that are part of an EPA approved or established TMDL or, if a TMDL has not been developed or approved, an equivalent analysis that determines sources and allocations for the pollutant(s) of concern. The pollutants of concern that the permitting authority must evaluate include biochemical oxygen demand (BOD), sediment or a parameter that addresses sediment (such as total suspended solids, turbidity or siltation), pathogens, oil and grease, and any other pollutant that has been identified as a cause of impairment of any water body that will receive a discharge from the MS4. Finally, the permitting authority must have determined that future discharges from the MS4 do not have the potential to result in exceedances of water quality standards, including impairment of designated uses, or other significant water quality impacts, including habitat and biological impacts.

Although EPA did not propose this specific approach, the Agency did request comment on whether to increase the proposed 1,000 population threshold for a waiver. The § 122.32(e) waiver was developed in response to comments, including States' concerns that they needed greater flexibility to focus their efforts on MS4s that were causing water quality impairment. Several commenters thought that the threshold should be increased from 1,000 to 5,000 or 10,000. Others suggested additional ways of qualifying for a waiver for MS4s that discharge to waters that are not covered by a TMDL or watershed plan. EPA carefully considered all the options for expanding the waiver provisions and has decided to expand the waiver only in the very narrow circumstances described above where a comprehensive analysis has been undertaken to demonstrate that the MS4 is not causing water quality impairment.

The NPDES permitting authority can, at any time, mandate compliance with program requirements from a previously waived small MS4 if circumstances change. For example, a waiver can be withdrawn in circumstances where the permitting authority later determines that a waived small MS4's storm water discharge to a small stream will cause adverse impacts to water quality or significantly interfere with attainment of water quality standards. A "change in circumstances" could involve receipt of new information. Changed circumstances can also allow a regulated small MS4 operator to request a waiver at any time.

Some commenters expressed concerns about allowing any small MS4 waivers. One commenter stated that storm water pollution prevention plans are necessary to control storm water pollution and should be required from all regulated small MS4s. For the reasons stated in the Background section above, EPA agrees that the discharges from most MS4s in urbanized areas should be addressed by a storm water management program outlined in today's rule. For MS4s serving very small areas, however, the TMDL development process provides an opportunity to determine whether an MS4 serving a population less than 1,000 is having a negative impact on any receiving water that is impaired by a pollutant that the MS4 discharges. MS4s serving populations up to 10,000 may receive a waiver only if a comprehensive analysis of its impact on receiving water has been performed.

Other commenters said that waivers should not be allowed for small MS4s that discharge into another regulated MS4. These commenters stated that the word "substantially" should be removed from § 122.32(d)(i) so that a waiver would not be allowed for any system "contributing to the storm water pollutant loadings of a physically interconnected regulated MS4." As previously mentioned under the designation discussion of section II.G.2.c, EPA believes that the word "substantially" provides needed flexibility to the permitting authorities. It is important to note that this is only one aspect that the permitting authority must consider when deciding on the appropriateness of a waiver.

4. Issue Permits

NPDES permitting authorities have a number of responsibilities regarding the permit process. Sections 123.35(d) through (g) ensure a certain level of consistency for permits, yet provide numerous opportunities for flexibility. NPDES permitting authorities must issue NPDES permits to cover municipal sources to be regulated under § 122.32, unless waived under § 122.32(c). EPA encourages permitting authorities to use general permits as the vehicle for permitting and regulating small MS4s. The Agency notes, however, that some operators may wish to take advantage of the option to join as a co-permittee with an MS4 regulated under the existing NPDES storm water program.

Today's final rule includes a provision, § 123.35(f), that requires NPDES permitting authorities to either include the requirements in § 122.34 for NPDES permits issued for regulated small MS4s or to develop permit limits based on a permit application submitted by a small MS4. See Section II.H.3.a, Minimum Control Measures, for more details on the actual § 122.34 requirements. See Section II.H.3.c for alternative and joint permitting options.

In an attempt to avoid duplication of effort, § 122.34(c) allows NPDES permitting authorities to include permit conditions that direct an MS4 to meet the requirements of a qualifying local, Tribal, or State municipal storm water management program. For a local, Tribal, or State program to "qualify," it must impose, at a minimum, the relevant requirements of § 122.34(b). A regulated small MS4 must still follow the procedural requirements for an NPDES permit (*i.e.*, submit an application, either an individual application or an NOI under a general permit) but will instead follow the substantive pollutant control requirements of the qualifying local, Tribal, or State program.

Under § 122.35(b), NPDES permitting authorities may also recognize existing responsibilities among governmental entities for the minimum control measures in an NPDES small MS4 storm water permit. For example, the permit might acknowledge the existence of a State administered program that addresses construction site runoff and require that the municipalities only develop substantive controls for the remaining minimum control measures. By acknowledging existing programs, this provision is meant to reduce the duplication of efforts and to increase the flexibility of the NPDES storm water program.

Section 123.35(e) of today's final rule requires permitting authorities to specify a time period of up to 5 years from the issuance date of an NPDES permit for regulated small MS4 operators to fully develop and implement their storm water programs. As discussed more fully below, permitting authorities should be providing extensive support to the local governments to assist them in developing and implementing their programs.

In the proposed rule, EPA stated that the permitting authority would develop the menu of BMPs and if they failed to do so, EPA would develop the menu. Commenters felt that EPA should develop a menu of BMPs, rather than just providing guidance. In the settlement agreement for seeking an extension to the deadline for issuing today's rule, EPA committed to developing a menu of BMPs by October 27, 2000. Permitting authorities can adopt EPA's menu or develop their own. The menu itself is not intended to replace more comprehensive BMP guidance materials. As part of the tool box efforts, EPA will provide separate guidance documents that discuss the results from EPA-sponsored nationwide studies on the design, operation and maintenance of BMPs. Additionally, EPA expects that the new rulemaking on construction BMPs may provide more specific design, operation and maintenance criteria.

5. Support and Oversee the Local Programs

NPDES permitting authorities are responsible for supporting and overseeing the local municipal programs. Section 123.35(h) of today's final rule highlights issues associated with these responsibilities.

To the extent possible, NPDES permitting authorities should provide financial assistance to MS4s, which often have limited resources, for the development and implementation of local programs. EPA recognizes that funding for programs at the State and Tribal levels may also be limited, but strongly encourages States and Tribes to provide whatever assistance is possible. In lieu of actual dollars, NPDES permitting authorities can provide cost-cutting assistance in a number of ways. For example, NPDES permitting authorities can develop outreach materials for MS4s to distribute or the NPDES permitting authority can actually distribute the materials. Another option is to implement an erosion and sediment control program across an entire State (or Tribal land), thus alleviating the need for the MS4 to implement its own program. The NPDES permitting authority must balance the need for site-specific controls, which are best handled by a local MS4, with its ability to offer financial assistance. EPA, States, Tribes, and MS4s should work as a team in making these kinds of decisions.

NPDES permitting authorities are responsible for overseeing the local programs. Permitting authorities should work with the regulated community and other stakeholders to assist in local program development and implementation. This might include sharing information, analyzing reports, and taking enforcement actions, as necessary. NPDES permitting authorities play a vital role in supporting local programs by providing technical and programmatic assistance, conducting research projects, and monitoring watersheds. The NPDES permitting authority can also assist the MS4 permittee in obtaining adequate legal authority at the local level in order to implement the local component of the CWA section 402(p)(6) program.

NPDES permitting authorities are encouraged to coordinate and utilize the data collected under several programs. States and Tribes address point and nonpoint source storm water discharges through a variety of programs. In developing programs to carry out CWA section 402(p)(6), EPA recommends that States and Tribes coordinate all of their water pollution evaluation and control programs, including the continuing planning process under CWA section 303(e), the existing NPDES program, the CZARA program, and nonpoint source pollution control programs.

In addition, NPDES permitting authorities are encouraged to provide a brief (*e.g.*, two-page) reporting format to facilitate compilation and analysis of data from reports submitted under § 122.34(g)(3). EPA intends to develop a model form for this purpose.

H. Municipal Role

1. Scope of Today's Rule

Today's final rule attempts to establish an equitable and comprehensive four-pronged approach for the designation of municipal sources. First, the approach defines for automatic coverage the municipal systems believed to be of highest threat to water quality. Second, the approach designates municipal systems that meet a set of objective criteria used to measure the potential for water quality impacts. Third, the approach designates on a case-by-case basis municipal systems that "contribute substantially to the pollutant loadings of a physically-interconnected [regulated] MS4." Finally, the approach designates on a case-by-case basis, upon petition, municipal systems that "contribute to a violation of a water quality standard or are a significant contributor of pollutants."

Today's final rule automatically designates for regulation small MS4s located in urbanized areas, and requires that NPDES permitting authorities examine for potential designation, at a minimum, a particular subset of small MS4s located outside of urbanized areas. Today's rule also includes provisions that allow for waivers from the otherwise applicable requirements for the smallest MS4s that are not causing impairment of a receiving water body. Qualifications for the waivers vary depending on whether the MS4 serves a population under 1,000 or a population under 10,000. See §§ 122.32(d) and (e). These waivers are discussed further in section II.G.3. Any small MS4 automatically designated by the final rule or designated by the permitting authority under today's final rule is defined as a "regulated" small MS4 unless it receives a waiver.

In today's final rule, all regulated small MS4s must establish a storm water discharge control program that meets the requirements of six minimum control measures. These minimum control measures are public education and outreach on storm water impacts, public involvement participation, illicit discharge detection and elimination, construction site storm water runoff control, post-construction storm water management in new development and redevelopment, and pollution prevention/good housekeeping for municipal operations.

Today's rule allows for a great deal of flexibility in how an operator of a regulated small MS4 is authorized to discharge under an NPDES permit, by providing various options for obtaining permit coverage and satisfying the required minimum control measures. For example, the NPDES permitting authority can incorporate by reference qualifying State, Tribal, or local programs in an NPDES general permit and can recognize existing responsibilities among different governmental entities for the implementation of minimum control measures. In addition, a regulated small MS4 can participate in the storm water management program of an adjoining regulated MS4 and can arrange to have another governmental entity implement a minimum control measure on their behalf.

2. Municipal Definitions

a. Municipal Separate Storm Sewer Systems (MS4s)

The CWA does not define the term "municipal separate storm sewer." EPA defined municipal separate storm sewer in the existing storm water permit application regulations to mean, in part, a conveyance or system of conveyances (including roads with drainage systems and municipal streets) that is "owned or operated by a State, city, town borough, county, parish, district, association, or other public body * * * designed or used for collecting or conveying storm water which is not a combined sewer and which is not part of a Publicly Owned Treatment Works as defined at 40 CFR 122.2" (see § 122.26(b)(8)(i)). Section 122.26 contains definitions of medium and large municipal separate storm sewer systems but no definition of a municipal separate storm sewer *system*, even though the term MS4 is commonly used. In today's rule, EPA is adding a definition of municipal separate storm sewer system and small municipal separate storm sewer system along with the abbreviations MS4 and small MS4.

The existing municipal permit application regulations define "medium" and "large" MS4s as those located in an incorporated place or county with a population of at least 100,000 (medium) or 250,000 (large) as determined by the latest Decennial Census (see §§ 122.26(b)(4) and 122.26(b)(7)). In today's final rule, these regulations have been revised to define all medium and large MS4s as those meeting the above population thresholds according to the 1990 Decennial Census.

Today's rule also corrects the titles and contents of Appendices F, G, H,& I to Part 122. EPA is adding those incorporated places and counties whose 1990 population caused them to be defined as a "medium" or "large" MS4. All of these MS4s have applied for

R0018120

permit coverage so the effect of this change to the appendices is simply to make them more accurate. They will not need to be revised again because today's rule "freezes" the definition of "medium" and "large" MS4s at those that qualify based on the 1990 census.

EPA received several comments supporting and opposing the proposal to "freeze" the definitions based on the 1990 census. Commenters who disagreed with EPA's position cited the unfairness of municipalities that reach the medium or large threshold at a later date having fewer permitting requirements compared to those that were already at the population thresholds when the existing storm water regulations took effect. EPA recognizes this disparity but does not believe it is unfair, as explained in the proposed rule. The decision was based on the fact that the deadlines from the existing regulations have lapsed, and because the permitting authority can always require more from operators of MS4s serving "newly over 100,000" populations.

b. Small Municipal Separate Storm Sewer Systems

The proposal to today's final rule added "the United States" as a potential owner or operator of a municipal separate storm sewer. This addition was intended to address an omission from existing regulations and to clarify that federal facilities are, in fact, covered by the NPDES program for municipal storm water discharges when the federal facility is like other regulated MS4s. EPA received a comment that this change would cause federal facilities located in Phase 1 areas to be considered Phase 1 dischargers due to the definition of medium and large MS4s. All MS4s located in Phase 1 cities or counties are defined as Phase 1 medium or large MS4s. EPA believes that all federal facilities serve a population of under 100,000 and should be regulated as small MS4s. Therefore, in § 122.26(a)(16) of today's final rule, EPA is adding federal facilities to the NPDES storm water discharge control program by changing the proposed definition of small municipal separate storm sewer system. Paragraph (i) of this section restates the definition of municipal separate storm sewer with the addition of "the United States" as a owner or operator of a small municipal separate storm sewer. Paragraph (ii) repeats the proposed language that states that a small MS4 is a municipal separate storm sewer that is not medium or large.

Most commenters agreed that federal facilities should be covered in the same way as other similar MS4s. However, EPA received several comments asking whether individual federal buildings such as post offices or urban offices of the U.S. Park Service must apply for coverage as regulated small MS4s. Most of these buildings have, at most, a parking lot with runoff or a storm sewer that connects with a municipality's MS4. In § 122.26(a)(16)(iii), EPA clarifies that the definition of small MS4 does not include individual buildings. These buildings may have a municipal separate storm sewer but they do not have a "system" of conveyances. The minimum measures for small MS4s were written to apply to storm sewer "systems" providing storm water drainage service to human populations and not to individual buildings. This is true of municipal separate storm sewers from State buildings as well as from federal buildings.

There will likely be situations where the permitting authority must decide if a federal or State complex should be regulated as a small MS4. A federal complex of two or three buildings could be treated as a single building and not be required to apply for coverage. In these situations, permitting authorities will have to use their best judgment as to the nature of the complex and its storm water conveyance system. Permitting authorities should also consider whether the federal or State complex cooperates with its municipality's efforts to implement their storm water management program.

Along with the questions about individual buildings, EPA received many questions about how various provisions of the rule should be interpreted for federal and State facilities. EPA acknowledges that federal and State facilities are different from municipalities. EPA believes, however, that the minimum measures are flexible enough that they can be implemented by these facilities. As an example, DOD commenters asked about how to interpret the term "public" for military installations when implementing the public education measure. EPA agrees with the suggested interpretation of "public" for DOD facilities as "the resident and employee population within the fence line of the facility."

EPA also received many comments from State departments of transportation (DOTs) that suggested the ways in which they are different from municipalities and should therefore be regulated differently. Storm water discharges from State DOTs in Phase 1 areas should already be regulated under Phase I. The preamble to Phase 1 clearly states that "all systems within a geographical area including highways and flood control districts will be covered." Many permitting authorities regulated State DOTs as co-permittees with the Phase 1 municipality in which the highway is located. State DOTs that are already regulated under Phase I are not required to comply with Phase II. State DOTs that are not already regulated have various options for meeting the requirements of today's rule. These options are discussed in Section II.H.3.c.iv below. Several DOTs commented that some of the minimum measures are outside the scope of their mission or that they do not have the legal authority required for implementation. EPA believes that the flexibility of the minimum measures allows them to be implemented by most MS4s, including DOTs. When a DOT does not have the necessary legal authority, EPA encourages the DOT to coordinate their storm water management efforts with the surrounding municipalities and other State agencies. Under today's rule, DOTs can use any of the options of § 122.35 to share their storm water management responsibilities. DOTs may also want to work with their permitting authority to develop a State-wide DOT storm water permit.

There are many storm water discharges from State DOTs and other State MS4s located in Phase 1 areas that were not regulated under Phase 1. Today's rule adds many more State facilities as well as all federal facilities located in urbanized areas. All of these State and federal facilities that fit the definition of a small MS4 must be covered by a storm water management program. The individual permitting authorities must decide what type of permit is most applicable.

The existing NPDES storm water program already regulates storm water from federally or State-operated industrial sources. Federal or State facilities that are currently regulated due to their industrial discharges may already be implementing some of today's rule requirements.

EPA received comments that questioned the apparent inconsistency between regulating a federal facility such as a hospital and not regulating a similar private facility. Normally, this type of private facility is regulated by the MS4. EPA believes that federal facilities are subject to local water quality regulations, including storm water requirements, by virtue of the waiver of sovereign immunity in CWA section 313. However, there are special problems faced by MS4s in their efforts to regulate federal facilities that have not been encountered in regulating similar private facilities. To ensure comprehensive coverage, today's rule merely clarifies the need for permit coverage for these federal facilities.

i. Combined Sewer Systems (CSS). The definition of small MS4s does not include combined sewer systems. A combined sewer system is a wastewater collection system that conveys sanitary wastewater and storm water through a single set of pipes to a publicly-owned treatment works (POTW) for treatment before discharging to a receiving waterbody. During wet weather events when the capacity of the combined sewer system is exceeded, the system is designed to discharge prior to the POTW treatment plant directly into a receiving waterbody. Such an overflow is a combined sewer overflow or CSO. Combined sewer systems are not subject to existing regulations for municipal storm water discharges, nor will they be subject to today's regulations. EPA addresses combined sewer systems and CSOs in the National Combined Sewer Overflow (CSO) Control Policy issued on April 19, 1994 (59 FR 18688). The CSO Control Policy contains provisions for developing appropriate, site-specific NPDES permit requirements for combined sewer systems. CSO discharges are subject to limitations based on the best available technology economically achievable for toxic pollutants and based on the best conventional pollutant control technology for conventional pollutants. MS4s are subject to a different technology standard for all pollutants, specifically to reduce pollutants to the maximum extent practicable.

Some municipalities are served by both separate storm sewer systems and combined sewer systems. If such a municipality is located within an urbanized area, only the separate storm sewer systems within that municipality is included in the NPDES storm water program and subject to today's final rule. If the municipality is not located in an urbanized area, then the NPDES permitting authority has discretion as to whether the discharges from the separate storm sewer system is subject to today's final rule. The NPDES permitting authority will use the same process to designate discharges from portions of an MS4 for permit coverage where the municipality is also served by a combined sewer system.

EPA recognizes that municipalities that have both combined and separate storm sewer systems may wish to find ways to develop a unified program to meet all wet weather water pollution control requirements more efficiently. In the proposal to today's final rule, EPA sought comment on ways to achieve such a unified program. Many municipalities that are served by CSSs and MS4s commented that it is inequitable to force them to comply with Phase II at this time because implementation of the CSO Control Policy through their NPDES permits already imposes a significant financial burden. They requested an extension of the implementation time frame. They did not provide ideas on how to unify the two programs. EPA encourages permitting authorities to work with these municipalities as they develop and begin implementation of their CSO and storm water management programs. If both sets of requirements are carefully coordinated early, a cost-effective wet weather program can be developed that will address both CSO and storm water requirements.

ii. Owners/Operators. Several commenters mentioned the difference between the existing storm water application requirement for municipal operators and the proposed municipal requirement for owners or operators to apply. They felt that this inconsistency is confusing. The preamble to the existing regulations makes numerous references to owner/operator so there was no intent to make a clear distinction between Phase I and Phase II. Section 122.21(b) states that when the owner and operator are different, the operator must obtain the permit. MS4s often have several operators. The owner may be responsible for one part of the system and a regional authority may be responsible for other aspects. EPA proposed the "owner or operator" language to convey this dual responsibility. However, when the owner is responsible for some part of a storm water management plan, it is also an operator.

EPA has revised the regulation language to clarify that "an operator" must apply for a permit. When responsibilities for the MS4 are shared, all operators must apply.

c. Regulated Small MS4s

In today's final rule, all small MS4s located in an urbanized area are automatically designated as "regulated" small MS4s provided that they were not previously designated into the existing storm water program. Unlike medium and large MS4s under the existing storm water regulations, not all small MS4s are designated under today's final rule. Therefore, today's rule distinguishes between "small" MS4s and "regulated small" MS4s.

EPA's definition of "regulated small MS4s" in the proposal to today's rule included mention of incorporated places and counties. Along with the definition, EPA included Appendices 6 and 7 to assist in the identification of areas that would probably require coverage as "automatically designated" (Appendix 6) or "potentially designated" (Appendix 7). The definition and the appendices raised many questions about exactly who was required to comply with the proposed requirements. Commenters raised issues about the definition of "incorporated place" and the status of towns, townships, and other places that are not considered incorporated by the Census Bureau. They also asked about special districts, regional authorities, MS4s already regulated, and other questions in order to clarify the rule's coverage.

EPA has revised § 122.32(a) to clarify that discharges are regulated under today's rule if they are from a small MS4 that is in an urbanized area and has not received a waiver or they are designated by the permitting authority. Today's rule does not regulate the county, city, or town. Today's rule regulates the MS4. Therefore, even though a county may be listed in Appendix 6, if that county does not own or operate the municipal storm sewer systems, the county does not have to submit an application or develop a storm water management program. If another entity does own or operate an MS4 within the county, for example, a regional utility district, that other entity needs to submit the application and develop the program.

Some commenters suggested that EPA should change the rule language to specifically allow regional authorities to be the permitted entity and to allow small MS4s to apply as co-permittees. EPA believes that the best way to clarify that regional authorities can be the primary permitted entity is the change to § 122.32(a) and the explanation above. Because EPA assumes that today's regulation will be implemented through general permits, MS4s will not be co-permittees under a general permit in the same manner as under individual permits. EPA has added § 122.33(a)(4) and made a minor change to § 122.35(a) to clarify that small MS4s can work together to share the responsibilities of a storm water management program. This is discussed further in Section II.H.3.c.iv below.

The proposed rule stated that when a county or Federal Indian reservation is only partially included in an urbanized area, only MS4s in the urbanized portion of the county or Federal Indian reservation would be regulated. In the rare cases when an incorporated place is only partially included in the urbanized area, the entire incorporated place would be regulated. EPA received comments asking about towns and

R0018122

townships, because they were not considered to be incorporated areas according to the Census Bureau's definition. Would the whole town/ township be covered or only the part of the town/township in the urbanized area? States use many different types of systems in their geographical divisions. Some towns are similar to incorporated cities and others are large areas that are more similar to counties. Some commenters thought that the urbanized area boundary was arbitrary, and if part of a town or county was covered, it all should be covered. Other commenters noted that some townships and counties encompass very large areas of which only a small portion is urbanized. Due to the great variety of situations, EPA has decided that for all geographical entities, only MS4s in the urbanized area are automatically designated. The population densities associated with the Census Bureau's designation of urbanized areas provide the basis for designation of these areas to protect water quality. This focused designation provides for consistency and allows for flexibility on the part of the MS4 and the permitting authority. In those situations where an incorporated place or a town is not all in an "urbanized area", there is a good possibility that it is served by more than one MS4. In those cases where the area is served by the same MS4, it makes sense to develop a storm water program for the whole area. Permitting authorities may also decide to designate all MS4s within a county or township, if they believe it is necessary to protect water quality.

Most operators of MS4s will not need to independently determine the status of coverage under today's rule. EPA has revised the proposed Appendices 6 and 7 to include towns and townships. Therefore, these appendices will alert most MS4s as to whether they are likely to be covered under today's rule. However, each permitting authority must make the decision as to who requires coverage. Most likely, an illustrative list of the regulated areas will be published with the general permit. If not, the operator can contact its permitting authority or the Bureau of the Census to find out if their separate storm sewer systems are within an urbanized area.

i. Urbanized Area Description. Under the Bureau of the Census definition of "urbanized area," adopted by EPA for the purposes of today's final rule, "an urbanized area (UA) comprises a place and the adjacent densely settled surrounding territory that together have a minimum population of 50,000 people." The proposal to today's rule provided the full definition and case studies to help explain the census category of "urbanized area." Appendix 2 is a simplified urbanized area illustration to help demonstrate the concept of urbanized areas in relation to today's final rule. The "urbanized area" is the shaded area that includes within its boundaries incorporated places, a portion of a Federal Indian reservation, portions of two counties, an entire town, and portions of another town. All small MS4s located in the shaded area are covered by the rule, unless and until waived by the permitting authority. Any small MS4s located outside of the shaded area are subject to potential designation by the permitting authority.

There are 405 urbanized areas in the United States that cover 2 percent of total U.S. land area and contain approximately 63 percent of the nation's population (see Appendix 3 for a listing of urbanized areas of the United States and Puerto Rico). These numbers include U.S. Territories, although Puerto Rico is the only territory to have Census-designated urbanized areas. Urbanized areas constitute the largest and most dense areas of settlement. The purpose of determining an "urbanized area" is to delineate the boundaries of development and map the actual built-up urban area. The Bureau of the Census geographers liken it to flying over an urban area and drawing a line around the boundary of the built-up area as seen from the air.

Using data from the latest decennial census, the Census Bureau applies the urbanized area definition nationwide (including U.S. Tribes and Territories) and determines which places and counties are included within each urbanized area. For each urbanized area, the Bureau provides full listings of who is included, as well as detailed maps and special CD-ROM files for use with computerized mapping systems (such as GIS). Each State's data center receives a copy of the list, and some maps, automatically. The States also have the CD-ROM files and a variety of publications available to them for reference from the Bureau of the Census. In addition, local or regional planning agencies may have urbanized area files already. New listings for urbanized areas based on the 2000 Census will be available by July/August 2001, but the more comprehensive computer files will not be available until late 2001/early 2002.

Additional designations based on subsequent census years will be governed by the Bureau of the Census' definition of an urbanized area in effect for that year. Based on historical trends, EPA expects that any area determined by the Bureau of the Census to be included within an urbanized area as of the 1990 Census will not later be excluded from the urbanized area as of the 2000 Census. However, it is important to note that even if this situation were to occur, for example, due to a possible change in the Bureau of the Census' urbanized area definition, a small MS4 that is automatically designated into the NPDES program for storm water under an urbanized area calculation for any given Census year will remain regulated regardless of the results of subsequent urbanized area calculations.

ii. Rationale for Using Urbanized Areas. EPA is using urbanized areas to automatically designate regulated small MS4s on a nationwide basis for several reasons: (1) studies and data show a high correlation between degree of development/ urbanization and adverse impacts on receiving waters due to storm water (U.S. EPA, 1983; Driver et al., 1985; Pitt, R.E. 1991. "Biological Effects of Urban Runoff Discharges." Presented at the Engineering Foundation Conference: *Urban Runoff and Receiving Systems; An Interdisciplinary Analysis of Impact, Monitoring and Management,* August 1991. Mt. Crested Butte, CO. American Society of Civil Engineers, New York. 1992.; Pitt, R.E. 1995. "Biological Effects of Urban Runoff Discharges," in *Storm water Runoff and Receiving Systems: Impact, Monitoring, and Assessment.* Lewis Publishers, New York.; Galli, J. 1990. *Thermal Impacts Associated with Urbanization and Storm water Management Best Management Practices.* Prepared for the Sediment and Storm water Administration of the Maryland Department of the Environment.; Klein, 1979), (2) the blanket coverage within the urbanized area encourages the watershed approach and addresses the problem of "donut-holes," where unregulated areas are surrounded by areas currently regulated (storm water discharges from donut hole areas present a problem due to their contributing uncontrolled adverse impacts on local waters, as well as by frustrating the attainment of water quality goals of neighboring regulated communities), (3) this approach targets present and future growth areas as a preventative measure to help ensure water quality protection, and (4) the determination of urbanized areas by the Bureau of the Census allows operators of small MS4s to quickly determine whether they are included in the NPDES storm water program as a regulated small MS4.

Urbanized areas have experienced significant growth over the past 50 years. According to EPA calculations based on Census data from 1980 to 1990, the national average rate of growth in the United States during that 10-year period was more than 4 percent. For the same period, the average growth within urbanized areas was 15.7 percent and the average for outside of urbanized areas was just more than 1 percent. The new development occurring in these growing areas can provide some of the best opportunities for implementing cost-effective storm water management controls.

EPA received many comments on the proposal to designate discharges based on location within urbanized areas. EPA considered numerous other approaches, several of which are discussed in the proposal to today's final rule. Several commenters wanted designation to be based on proven water quality problems rather than inclusion in an urbanized area. One commenter proposed an approach based on the CWA 303(d) listing of impaired waters and the wasteload allocation conducted under the TMDL process. (See section II.L. on the section 303(d) and TMDL process). The commenter's proposal would designate small MS4s on a case-by-case basis, covering only those discharges where receiving streams are shown to have water quality problems, particularly a failure to meet water quality standards, including designated uses. The commenter further described a non-NPDES approach where a State would require cost-effective measures based on a proportionate share under a waste load allocation, equitably allocated among all pollutant contributors. These waste load allocations would be developed with input from all stakeholders, and remedial measures would be implemented in a phased manner based on the probability of results and/or economic feasibility. The States would then periodically reassess the receiving streams to determine whether the remedial measures are working, and if not, require additional control measures using the same procedure used to establish the initial measures. What the commenter describes is almost a TMDL.

EPA considered a remedial approach based on water quality impairment and rejected it for failure to prevent almost certain degradation caused by urban storm water. EPA's main concern in opting not to take a case-by-case approach to designation was that this approach would not provide controls for storm water discharges in receiving streams until after a site-specific demonstration of adverse water quality impact. The commenter's suggestion would do nothing to prevent pollution in waters that may be meeting water quality standards, including supporting designated uses. The approach would also rely on identifying storm water management programs following comprehensive watershed plans and TMDL development. In most States, water quality assessments have traditionally been conducted for principal mainstream rivers and their major tributaries, not all surface waters. The establishment of TMDLs nationwide will take many years, and many States will conduct additional monitoring to determine water quality conditions prior to establishing TMDLs. In addition, a case-by-case approach would not address the problem of "donut holes" within urbanized areas and a lack of consistency among similarly situated municipal systems would remain commonplace. After careful consideration of all comments, EPA still believes that the approach in today's rule is the most appropriate to protect water quality. Protection includes prevention as well as remediation.

d. Municipal Designation by the Permitting Authority

Today's final rule also allows NPDES permitting authorities to designate MS4s that should be included in the storm water program as regulated small MS4s but are not located within urbanized areas. The final rule requires, at a minimum, that a set of designation criteria be applied to all small MS4s within a jurisdiction that serves a population of at least 10,000 and has a population density of at least 1,000. Appendix 7 to this preamble provides an illustrative list of places that the Agency anticipates meet this criteria. In addition, any small MS4 may be the subject of a petition to the NPDES permitting authority for designation. See Section II.G, NPDES Permitting Authority's Role for more details on the designation and petition processes. EPA believes that the approach of combining nationwide and local designation to determine municipal coverage balances the potential for significant adverse impacts on water quality with local watershed protection and planning efforts.

e. Waiving the Requirements for Small MS4s

Today's final rule includes some flexibility in the nationwide coverage of all small MS4s located in urbanized areas by providing the NPDES permitting authority with the discretion to waive the otherwise applicable requirements of the smallest MS4s that are not causing the impairment of a receiving water body. Qualifications for the waiver vary depending on whether the MS4 serves a population under 1,000 or a population between 1,000 and 10,000. Note that even if a small MS4 has requirements waived, it can subsequently be brought back into the program if circumstances change. See Section II.G, NPDES Permitting Authority's Role, for more details on this process.

3. Municipal Permit Requirements

a. Overview

i. Summary of Permitting Options. Today's rule outlines six minimum control measures that constitute the framework for a storm water discharge control program for regulated small MS4s that, when properly implemented, will reduce pollutants to the maximum extent practicable (MEP). These six minimum control measures are specified in § 122.34(b) and are discussed below in section "II.H.3.b, Program Requirements-Minimum Control Measures." All operators of regulated small MS4s are required to obtain coverage under an NPDES permit, unless the requirement is waived by the permitting authority in accordance with today's rule. Implementation of § 122.34(b) may be required either through an individual permit or, if the State or EPA makes one available to the facility, through a general permit. The process for issuing and obtaining these permits is discussed below in section "II.H.3.c, Application Requirements."

As an alternative to implementing a program that complies with the requirements of § 122.34, today's rule provides operators of regulated small MS4s with the option of applying for an individual permit under § 122.26(d). The permit application requirements in § 122.26 were originally drafted to apply to medium and large MS4s. Although EPA believes that the requirements of § 122.34 provide a regulatory option that is appropriate for most small MS4s, the operators of some small MS4s may prefer more individualized requirements. This alternative permitting option for regulated small MS4s that wish to develop their own program is discussed below in section "II.H.3.c.iii. Alternative Permit Option." The second alternative permitting option for regulated small MS4s is to become co-permittees with a medium or large MS4 regulated under § 122.26(d), as discussed below in section "II.H.3.c.v. Joint Permit Programs."

ii. Water Quality-Based Requirements. Any NPDES permit issued under today's rule must, at a minimum, require the operator to develop, implement, and

R0018124

enforce a storm water management program designed to reduce the discharge of pollutants from a regulated system to the MEP, to protect water quality, and satisfy the appropriate water quality requirements of the Clean Water Act (see MEP discussion in the following section). Absent evidence to the contrary, EPA presumes that a small MS4 program that implements the six minimum measures in today's rule does not require more stringent limitations to meet water quality standards. Proper implementation of the measures will significantly improve water quality. As discussed further below, however, small MS4 permittees should modify their programs if and when available information indicates that water quality considerations warrant greater attention or prescriptiveness in specific components of the municipal program. If the program is inadequate to protect water quality, including water quality standards, then the permit will need to be modified to include any more stringent limitations necessary to protect water quality.

Regardless of the basis for the development of the effluent limitations (whether designed to implement the six minimum measures or more stringent or prescriptive limitations to protect water quality), EPA considers narrative effluent limitations requiring implementation of BMPs to be the most appropriate form of effluent limitations for MS4s. CWA section 402(p)(3)(b)(iii) expresses a preference for narrative rather than numeric effluent limits, for example, by reference to "management practices, control techniques and system, design and engineering methods, and such other provisions as the Administrator or the State determines appropriate for the control of such pollutants." 33 U.S.C. 1342(p)(3)(B)(iii). EPA determines that pollutants from wet weather discharges are most appropriately controlled through management measures rather than end-of-pipe numeric effluent limitations. As explained in the Interim Permitting Policy for Water Quality-Based Effluent Limitations in Storm Water Permits, issued on August 1, 1996 [61 FR 43761 (November 26, 1996), EPA believes that the currently available methodology for derivation of numeric water quality-based effluent limitations is significantly complicated when applied to wet weather discharges from MS4s (compared to continuous or periodic batch discharges from most other types of discharge). Wet weather discharges from MS4s introduce a high degree of variability in the inputs to the models currently available for derivation of water quality based effluent limitations, including assumptions about instream and discharge flow rates, as well as effluent characterization. In addition, EPA anticipates that determining compliance with any such numeric limitations may be confounded by practical limitations in sample collection.

In the first two to three rounds of permit issuance, EPA envisions that a BMP-based storm water management program that implements the six minimum measures will be the extent of the NPDES permit requirements for the large majority of regulated small MS4s. Because the six measures represent a significant level of control if properly implemented, EPA anticipates that a permit for a regulated small MS4 operator implementing BMPs to satisfy the six minimum control measures will be sufficiently stringent to protect water quality, including water quality standards, so that additional, more stringent and/or more prescriptive water quality based effluent limitations will be unnecessary.

If a small MS4 operator implements the six minimum control measures in § 122.34(b) and the discharges are determined to cause or contribute to non-attainment of an applicable water quality standard, the operator needs to expand or better tailor its BMPs within the scope of the six minimum control measures. EPA envisions that this process will occur during the first two to three permit terms. After that period, EPA will revisit today's regulations for the municipal separate storm sewer program.

If the permitting authority (rather than the regulated small MS4 operator) needs to impose additional or more specific measures to protect water quality, then that action will most likely be the result of an assessment based on a TMDL or equivalent analysis that determines sources and allocations of pollutant(s) of concern. EPA believes that the small MS4's additional requirements, if any, should be guided by its equitable share based on a variety of considerations, such as cost effectiveness, proportionate contribution of pollutants, and ability to reasonably achieve wasteload reductions. Narrative effluent limitations in the form of BMPs may still be the best means of achieving those reductions.

See Section II.L, Water Quality Issues, for further discussion of this approach to permitting, consistent with EPA's interim permitting guidance. Pursuant to CWA section 510, States implementing their own NPDES programs may develop more stringent or more prescriptive requirements than those in today's rule.

EPA's interpretation of CWA section 402(p)(3)(B)(iii) was recently reviewed by the Ninth Circuit in *Defenders of Wildlife, et al* v. *Browner*, No. 98–71080 (September 15, 1999). The Court upheld the Agency's action in issuing five MS4 permits that included water quality-based effluent limitations. The Court did, however, disagree with EPA's interpretation of the relationship between CWA sections 301 and 402(p). The Court reasoned that MS4s are not compelled by section 301(b)(1)(C) to meet all State water quality standards, but rather that the Administrator or the State may rely on section 402(p)(3)(B)(iii) to require such controls. Accordingly, the *Defenders of Wildlife* decision is consistent with the Agency's 1996 "Interim Permitting Policy for Water Quality-Based Effluent Limitations in Storm Water Permits."

As noted, the 1996 Policy describes how permits would implement an iterative process using BMPs, assessment, and refocused BMPs, leading toward attainment of water quality standards. The ultimate goal of the iteration would be for water bodies to support their designated uses. EPA believes this iterative approach is consistent with and implements section 301(b)(1)(C), notwithstanding the Ninth Circuit's interpretation. As an alternative to basing these water quality-based requirements on section 301(b)(1)(C), however, EPA also believes the iterative approach toward attainment of water quality standards represents a reasonable interpretation of CWA section 402(p)(3)(B)(iii). For this reason, today's rule specifies that the "compliance target" for the design and implementation of municipal storm water control programs is "to reduce pollutants to the maximum extent practicable (MEP), to protect water quality, and to satisfy the appropriate water quality requirements of the CWA." The first component, reductions to the MEP, would be realized through implementation of the six minimum measures. The second component, to protect water quality, reflects the overall design objective for municipal programs based on CWA section 402(p)(6). The third component, to implement other applicable water quality requirements of the CWA, recognizes the Agency's specific determination under CWA section 402(p)(3)(B)(iii) of the need to achieve reasonable further progress toward attainment of water quality standards according to the iterative BMP process, as well as the determination that State or EPA officials who establish TMDLs could allocate waste loads to

MS4s, as they would to other point sources.

EPA does not presume that water quality will be protected if a small MS4 elects not to implement all of the six minimum measures and instead applies for alternative permit limits under § 122.26(d). Operators of such small MS4s that apply for alternative permit limits under § 122.26(d) must supply additional information through individual permit applications so that the permit writer can determine whether the proposed program reduces pollutants to the MEP and whether any other provisions are appropriate to protect water quality and satisfy the appropriate water quality requirements of the Clean Water Act.

iii. *Maximum Extent Practicable.* Maximum extent practicable (MEP) is the statutory standard that establishes the level of pollutant reductions that operators of regulated MS4s must achieve. The CWA requires that NPDES permits for discharges from MS4s "shall require controls to reduce the discharge of pollutants to the maximum extent practicable, including management practices, control techniques and system, design and engineering methods." CWA Section 402(p)(3)(B)(iii). This section also calls for "such other provisions as the [EPA] Administrator or the State determines appropriate for the control of such pollutants." EPA interprets this standard to apply to all MS4s, including both existing regulated (large and medium) MS4s, as well as the small MS4s regulated under today's rule.

For regulated small MS4s under today's rule, authorization to discharge may be under either a general permit or individual permit, but EPA anticipates and expects that general permits will be the most common permit mechanism. The general permit will explain the steps necessary to obtain permit authorization. Compliance with the conditions of the general permit and the series of steps associated with identification and implementation of the minimum control measures will satisfy the MEP standard. Implementation of the MEP standard under today's rule will typically require the permittee to develop and implement appropriate BMPs to satisfy each of the required six minimum control measures.

In issuing the general permit, the NPDES permitting authority will establish requirements for each of the minimum control measures. Permits typically will require small MS4 permittees to identify in their NOI the BMPs to be performed and to develop the measurable goals by which implementation of the BMPs can be assessed. Upon receipt of the NOI from a small MS4 operator, the NPDES permitting authority will have the opportunity to review the NOI to verify that the identified BMPs and measurable goals are consistent with the requirement to reduce pollutants under the MEP standard, to protect water quality, and to satisfy the appropriate water quality requirements of the Clean Water Act. If necessary, the NPDES permitting authority may ask the permittee to revise their mix of BMPs, for example, to better reflect the MEP pollution reduction requirement. Where the NPDES permit is not written to implement the minimum control measures specified under § 122.34(b), for example in the case of an individual permit under § 122.33(b)(2)(ii), the MEP standard will be applied based on the best professional judgment of the permit writer.

Commenters argued that MEP is, as yet, an undefined term and that EPA needs to further clarify the MEP standards by providing a regulatory definition that includes recognition of cost considerations and technical feasibility. Commenters argued that, without a definition, the regulatory community is not adequately on notice regarding the standard with which they need to comply. EPA disagrees that affected MS4 permittees will lack notice of the applicable standard. The framework for the small MS4 permits described in this notice provides EPA's interpretation of the standard and how it should be applied.

EPA has intentionally not provided a precise definition of MEP to allow maximum flexibility in MS4 permitting. MS4s need the flexibility to optimize reductions in storm water pollutants on a location-by-location basis. EPA envisions that this evaluative process will consider such factors as conditions of receiving waters, specific local concerns, and other aspects included in a comprehensive watershed plan. Other factors may include MS4 size, climate, implementation schedules, current ability to finance the program, beneficial uses of receiving water, hydrology, geology, and capacity to perform operation and maintenance.

The pollutant reductions that represent MEP may be different for each small MS4, given the unique local hydrologic and geologic concerns that may exist and the differing possible pollutant control strategies. Therefore, each permittee will determine appropriate BMPs to satisfy each of the six minimum control measures through an evaluative process. Permit writers may evaluate small MS4 operator's proposed storm water management controls to determine whether reduction of pollutants to the MEP can be achieved with the identified BMPs.

EPA envisions application of the MEP standard as an iterative process. MEP should continually adapt to current conditions and BMP effectiveness and should strive to attain water quality standards. Successive iterations of the mix of BMPs and measurable goals will be driven by the objective of assuring maintenance of water quality standards. If, after implementing the six minimum control measures there is still water quality impairment associated with discharges from the MS4, after successive permit terms the permittee will need to expand or better tailor its BMPs within the scope of the six minimum control measures for each subsequent permit. EPA envisions that this process may take two to three permit terms.

One commenter observed that MEP is not static and that if the six minimum control measures are not achieving the necessary water quality improvements, then an MS4 should be expected to revise and, if necessary, expand its program. This concept, it is argued, must be clearly part of the definition of MEP and thus incorporated into the binding and operative aspects of the rule. As is explained above, EPA believes that it is. The iterative process described above is intended to be sensitive to water quality concerns. EPA believes that today's rule contains provisions to implement an approach that is consistent with this comment.

b. Program Requirements'Minimum Control Measures

A regulated small MS4 operator must develop and implement a storm water management program designed to reduce the discharge of pollutants from their MS4 to protect water quality. The storm water management program must include the following six minimum measures.

i. *Public Education and Outreach on Storm Water Impacts.* Under today's final rule, operators of small MS4s must implement a public education program to distribute educational materials to the community or conduct equivalent outreach activities about the impacts of storm water discharges on water bodies and the steps to reduce storm water pollution. The public education program should inform individuals and households about the problem and the steps they can take to reduce or prevent storm water pollution.

EPA believes that as the public gains a greater understanding of the storm water program, the MS4 is likely to gain

R0018126

more support for the program (including funding initiatives). In addition, compliance with the program will probably be greater if the public understands the personal responsibilities expected of them. Well-informed citizens can act as formal or informal educators to further disseminate information and gather support for the program, thus easing the burden on the municipalities to perform all educational activities.

MS4s are encouraged to enter into partnerships with their States in fulfilling the public education requirement. It may be more cost-effective to utilize a State education program instead of numerous MS4s developing their own programs. MS4 operators are also encouraged to work with other organizations (e.g., environmental, nonprofit and industry organizations) that might be able to assist in fulfilling this requirement.

The public education program should be tailored, using a mix of locally appropriate strategies, to target specific audiences and communities (particularly minority and disadvantaged communities). Examples of strategies include distributing brochures or fact sheets, sponsoring speaking engagements before community groups, providing public service announcements, implementing educational programs targeted at school age children, and conducting community-based projects such as storm drain stenciling, and watershed and beach cleanups. Operators of MS4s may use storm water educational information provided by the State, Tribe, EPA, or environmental, public interest, trade organizations, or other MS4s. Examples of successful public education efforts concerning polluted runoff can be found in many State nonpoint source pollution control programs under CWA section 319.

The public education program should inform individuals and households about steps they can take to reduce storm water pollution, such as ensuring proper septic system maintenance, ensuring the use and disposal of landscape and garden chemicals including fertilizers and pesticides, protecting and restoring riparian vegetation, and properly disposing of used motor oil or household hazardous wastes. Additionally, the program could inform individuals and groups on how to become involved in local stream and beach restoration activities as well as activities coordinated by youth service and conservation corps and other citizen groups. Finally, materials or outreach programs should be directed toward targeted groups of commercial, industrial, and institutional entities likely to have significant storm water impacts. For example, MS4 operators should provide information to restaurants on the impact of grease clogging storm drains and to auto garages on the impacts of used oil discharges.

EPA received comments from representatives of State DOTs and U.S. Department of Defense (DOD) installations seeking exemption from the public education requirement. While today's rule does not exempt DOTs and military bases from the user education requirement, the Agency believes the flexibility inherent in the Rule addresses many of the concerns expressed by these commenters.

Certain DOT representatives commented that if their agencies were not exempt from the user education measure's requirements, they should at least be allowed to count DOT employee education as an adequate substitute. EPA supports the use of existing materials and programs, granted such materials and programs meet the rule's requirement that the MS4 user community (*i.e.*, the public) is also educated concerning the impacts of storm water discharges on water bodies and the steps to reduce storm water pollution.

Finally, certain DOD representatives requested that "public," as applied to their installations, be defined as the resident and employee populations within the fence line of the facility. EPA agrees that the education effort should be directed toward those individuals who frequent the federally owned land (*i.e.*, residents and individuals who come there to work and use the MS4 facilities).

EPA also received a number of comments from municipalities stating that education would be more thorough and cost effective if accomplished by EPA on the national level. EPA believes that a collaborative State and local approach, in conjunction with significant EPA technical support, will best meet the goal of targeting, and reaching, specific local audiences. EPA technical support will include a tool box which will contain fact sheets, guidance documents, an information clearinghouse, and training and outreach efforts.

Finally, EPA received comments expressing concern that the public education program simply encourages the distribution of printed material. EPA is sensitive to this concern. Upon evaluation, the Agency made changes to the proposal's language for today's rule. The language has been changed to reflect EPA's belief that a successful program is one that includes a variety of strategies locally designed to reach specific audiences.

ii. Public Involvement/Participation. Public involvement is an integral part of the small MS4 storm water program. Accordingly, today's final rule requires that the municipal storm water management program must comply with applicable State and local public notice requirements. Section 122.34(b)(2) recommends a public participation process with efforts to reach out and engage all economic and ethnic groups. EPA believes there are two important reasons why the public should be allowed and encouraged to provide valuable input and assistance to the MS4's program.

First, early and frequent public involvement can shorten implementation schedules and broaden public support for a program. Opportunities for members of the public to participate in program development and implementation could include serving as citizen representatives on a local storm water management panel, attending public hearings, working as citizen volunteers to educate other individuals about the program, assisting in program coordination with other pre-existing programs, or participating in volunteer monitoring efforts. Moreover, members of the public may be less likely to raise legal challenges to a MS4's storm water program if they have been involved in the decision making process and program development and, therefore, internalize personal responsibility for the program themselves.

Second, public participation is likely to ensure a more successful storm water program by providing valuable expertise and a conduit to other programs and governments. This is particularly important if the MS4's storm water program is to be implemented on a watershed basis. Interested stakeholders may offer to volunteer in the implementation of all aspects of the program, thus conserving limited municipal resources.

EPA recognizes that there are a number of challenges associated with public involvement. One challenge is in engaging people in the public meeting and program design process. Another challenge is addressing conflicting viewpoints. Nevertheless, EPA strongly believes that these challenges can be addressed by use of an aggressive and inclusive program. Section II.K. provides further discussion on public involvement.

A number of municipalities sought clarification from EPA concerning what the public participation program must actually include. In response, the actual requirements are minimal, but the Agency's *recommendations* are more comprehensive. The public participation program must only comply with applicable State and local public notice requirements. The remainder of the preamble, as well as the Explanatory Note accompanying the regulatory text, provide guidance to the MS4s concerning what elements a successful and inclusive program should include. EPA will provide technical support as part of the tool box (*i.e.*, providing model public involvement programs, conducting public workshops, *etc.*) to assist MS4 operators meet the intent of this measure.

Finally, the Agency encourages MS4s to seek public participation prior to submitting an NOI. For example, public participation at this stage will allow the MS4 to involve the public in developing the BMPs and measurable goals for their NOI.

iii. Illicit Discharge Detection and Elimination. Discharges from small MS4s often include wastes and wastewater from non-storm water "illicit" discharges. Illicit discharge is defined at 40 CFR 122.26(b)(2) as any discharge to a municipal separate storm sewer that is not composed entirely of storm water, except discharges pursuant to an NPDES permit and discharges resulting from fire fighting activities. As detailed below, other sources of non-storm water, that would otherwise be considered illicit discharges, do not need to be addressed unless the operator of the MS4 identifies one or more of them as a significant source of pollutants into the system. EPA's Nationwide Urban Runoff Program (NURP) indicated that many storm water outfalls still discharge during substantial dry periods. Pollutant levels in these dry weather flows were shown to be high enough to significantly degrade receiving water quality. Results from a 1987 study conducted in Sacramento, California, revealed that slightly less than one-half of the water discharged from a municipal separate storm sewer system was not directly attributable to precipitation runoff (U.S. Environmental Protection Agency, Office of Research and Development. 1993. *Investigation of Inappropriate Pollutant Entries Into Storm Drainage Systems—A User's Guide.* Washington, DC EPA 600/R–92/238.) A significant portion of these dry weather flows results from illicit and/or inappropriate discharges and connections to the municipal separate storm sewer system. Illicit discharges enter the system through either direct connections (*e.g.*, wastewater piping either mistakenly or deliberately connected to the storm drains) or indirect connections (*e.g.*, infiltration into the storm drain system or spills collected by drain inlets).

Under the existing NPDES program for storm water, permit applications for large and medium MS4s are to include a program description for effective prohibition against non-storm water discharges into their storm sewers (see 40 CFR 122.26 (d)(1)(v)(B) and (d)(1)(iv)(B)). Further, EPA believes that in implementing municipal storm water management plans under these permits, large and medium MS4 operators generally found their illicit discharge detection and elimination programs to be cost-effective. Properly implemented programs also significantly improved water quality.

In today's rule, any NPDES permit issued to an operator of a regulated small MS4 must, at a minimum, require the operator to develop, implement and enforce an illicit discharge detection and elimination program. Inclusion of this measure for regulated small MS4s is consistent with the "effective prohibition" requirement for large and medium MS4s. Under today's rule, the NPDES permit will require the operator of a regulated small MS4 to: (1) Develop (if not already completed) a storm sewer system map showing the location of all outfalls, and names and location of all waters of the United States that receive discharges from those outfalls; (2) to the extent allowable under State, Tribal, or local law, effectively prohibit through ordinance, or other regulatory mechanism, illicit discharges into the separate storm sewer system and implement appropriate enforcement procedures and actions as needed; (3) develop and implement a plan to detect and address illicit discharges, including illegal dumping, to the system; and (4) inform public employees, businesses, and the general public of hazards associated with illegal discharges and improper disposal of waste.

The illicit discharge and elimination program need only address the following categories of non-storm water discharges if the operator of the small MS4 identifies them as significant contributors of pollutants to its small MS4: water line flushing, landscape irrigation, diverted stream flows, rising ground waters, uncontaminated ground water infiltration (as defined at 40 CFR 35.2005(20)), uncontaminated pumped ground water, discharges from potable water sources, foundation drains, air conditioning condensation, irrigation water, springs, water from crawl space pumps, footing drains, lawn watering, individual residential car washing, flows from riparian habitats and wetlands, dechlorinated swimming pool discharges, and street wash water (discharges or flows from fire fighting activities are excluded from the definition of illicit discharge and only need to be addressed where they are identified as significant sources of pollutants to waters of the United States). If the operator of the MS4 identifies one or more of these categories of sources to be a significant contributor of pollutants to the system, it could require specific controls for that category of discharge or prohibit the discharges completely.

Several comments were received on the mapping requirements of the proposal. Most comments said that more flexibility should be given to the MS4s to determine their mapping needs, and that resources could be better spent in addressing problems once the illicit discharges are detected. EPA reviewed the mapping requirements in the proposed rule and agrees that some of the information is not necessary in order to begin an illicit discharge detection and elimination program. Today's rule requires a map or set of maps that show the locations of all outfalls and names and locations of receiving waters. Knowing the locations of outfalls and receiving waters are necessary to be able to conduct dry weather field screening for non-storm water flows and to respond to illicit discharge reports from the public. EPA recommends that the operator collect any existing information on outfall locations (*e.g.*, review city records, drainage maps, storm drain maps), and then conduct field surveys to verify the locations. It will probably be necessary to "walk" (*i.e.* wade small receiving waters or use a boat for larger receiving waters) the streambanks and shorelines, and it may take more than one trip to locate all outfalls. A coding system should be used to mark and identify each outfall. MS4 operators have the flexibility to determine the type (*e.g.* topographic, GIS, hand or computer drafted) and size of maps which best meet their needs. The map scale should be such that the outfalls can be accurately located. Once an illicit discharge is detected at an outfall, it may be necessary to map that portion of the storm sewer system leading to the outfall in order to locate the source of the discharge.

Several comments requested clarification of the requirement to develop and implement a plan to detect and eliminate illicit discharges. EPA recommends that plans include procedures for the following: locating priority areas; tracing the source of an illicit discharge; removing the source of the discharge; and program evaluation and assessment. EPA recommends that MS4 operators identify priority areas (*i.e.*, problems areas) for more detailed screening of their system based on higher likelihood of illicit connections (*e.g.*, areas with older sanitary sewer lines), or by conducting ambient sampling to locate impacted reaches. Once priority areas are identified, EPA recommends visually screening outfalls during dry weather and conducting field tests, where flow is occurring, of selected chemical parameters as indicators of the discharge source. EPA's manual for investigation of inappropriate pollutant entries into the storm drainage system (EPA, 1993) suggests the following parameter list: specific conductivity, fluoride and/or hardness concentration, ammonia and/or potassium concentration, surfactant and/or fluorescence concentration, chlorine concentration, pH and other chemicals indicative of industrial sources. The manual explains why each parameter is a good indicator and how the information can be used to determine the type of source flow. The Agency is not recommending that fluoride and chlorine, generally used to locate potable water discharges, be addressed under this program, therefore a short list of parameters may include conductivity, ammonia, surfactant and pH. Some MS4s have found it useful to measure for fecal coliform or E. coli in their testing program. Observations of physical characteristics of the discharge are also helpful such as flow rate, temperature, odor, color, turbidity, floatable matter, deposits and stains, and vegetation.

The implementation plan should also include procedures for tracing the source of an illicit discharge. Once an illicit discharge is detected and field tests provide source characteristics, the next step is to determine the actual location of the source. Techniques for tracing the discharge to its place of origin may include: following the flow up the storm drainage system via observations and/or chemical testing in manholes or in open channels; televising storm sewers; using infrared and thermal photography; conducting smoke or dye tests.

The implementation plan should also include procedures for removing the source of the illicit discharge. The first step may be to notify the property owner and specify a length of time for eliminating the discharge. Additional notifications and escalating legal actions should also be described in this part of the plan.

Finally, the implementation plan should include procedures for program evaluation and assessment. Procedures could include documentation of actions taken to locate and eliminate illicit discharges such as: number of outfalls screened, complaints received and corrected, feet of storm sewers televised, numbers of discharges and quantities of flow eliminated, number of dye or smoke tests conducted. Appropriate records of such actions should be kept and should be submitted as part of the annual reports for the first permit term, as specified by the permitting authority (reports only need to be submitted in years 2 and 4 in later permits). For more on reporting requirements, see § 122.34(g).

EPA received comments regarding an MS4's legal authority beyond its jurisdictional boundaries to inspect or take enforcement against illicit discharges. EPA recognizes that illicit flows may originate in one jurisdiction and cross into one or more jurisdictions before being discharged at an outfall. In such instances, EPA expects the MS4 that detects the illicit flow to trace it to the point where it leaves their jurisdiction and notify the adjoining MS4 of the flow, and any other physical or chemical information. The adjoining MS4 should then trace it to the source or to the location where it enters their jurisdiction. The process of notifying the adjoining MS4 should continue until the source is located and eliminated. In addition, because any non-storm water discharge to waters of the U.S. through an MS4 is subject to the prohibition against unpermitted discharges pursuant to CWA section 301 (a), remedies are available under the federal enforcement provisions of CWA sections 309 and 505.

EPA requested and received comments regarding the prohibition and enforcement provision for this minimum measure. Commenters specifically questioned the proposal that the operator only has to implement the appropriate prohibition and enforcement procedures "to the extent allowable under State or Tribal law." They raised concerns that by qualifying prohibition and enforcement procedures in this manner, the operator could altogether ignore this minimum measure where affirmative legal authority did not exist. Comments suggested that EPA require States to grant authority to those municipalities where it did not exist. Other comments, however, stated that municipalities cannot exercise legal authority not granted to them under State law, which varies considerably from one State to another. EPA has no intention of directing State legislatures on how to allocate authority and responsibility under State law. As noted above, there is at least one remedy (the federal CWA) to control non-storm water discharges through MS4s. If State law prevents political subdivisions from controlling discharges through storm sewers, EPA anticipates common sense will prevail to provide those MS4 operators with the ability to meet the requirements applicable for their discharges.

One comment reinforced the importance of public information and education to the success of this measure. EPA agrees and suggests that MS4 operators consider a variety of ways to inform and educate the public which could include storm drain stenciling; a program to promote, publicize, and facilitate public reporting of illicit connections or discharges; and distribution of visual and/or printed outreach materials. Recycling and other public outreach programs could be developed to address potential sources of illicit discharges, including used motor oil, antifreeze, pesticides, herbicides, and fertilizers.

EPA received comments that State DOT's lack authority to implement this measure. EPA believes that most DOTs can implement most parts of this measure. If a DOT does not have the necessary legal authority to implement any part of this measure, EPA encourages them to coordinate their storm water management efforts with the surrounding MS4s and other State agencies. Many DOTs that are regulated under Phase I of this program are co-permittees with the local regulated MS4. Under today's rule, DOTs can use any of the options of § 122.35 to share their storm water management responsibilities.

EPA received comments requesting clarification of various terms such as "outfall" and "illicit discharge." One comment asked EPA to reinforce the point that a "ditch" could be considered an outfall. The term "outfall" is defined at 40 CFR 122.26(b)(9) as "a point source at the point where a municipal separate storm sewer discharges to waters of the United States * * *". The term municipal separate storm sewer is defined at 40 CFR § 122.26(b)(8) as "a conveyance or system of conveyances (including roads with drainage systems, municipal streets, catch basins, curbs, gutters, ditches, man-made channels, or storm drains) * * *". Following the logic of these definitions, a "ditch" may be part of the municipal separate storm sewer, and at the point where the ditch discharges to waters of the United States, it would be an outfall. As with any determination about jurisdictional provisions of the CWA, however, final decisions require case specific evaluations of fact.

One commenter specifically requested clarification on the relationship between the term "illicit discharge" and non-storm water discharges from fire fighting. The comment suggested that it would be impractical to attempt to determine whether the flow from a specific fire (*i.e.*, during a fire) is a significant source of pollution. EPA intends that MS4s will address all allowable non-storm water flows categorically rather than individually. If an MS4 is concerned that flows from fire fighting are, as a category, contributing substantial amounts of pollutants to their system, they could develop a program to address those flows prospectively. The program may include an analysis of the flow from several sources, steps to minimize the pollutant contribution, and a plan to work with the sources of the discharge to minimize any adverse impact on water quality. During the development of such a program, the MS4 may determine that only certain types of flows within a particular category are a concern, for example, fire fighting flows at industrial sites where large quantities of chemicals are present. In this example, a review of existing procedures with the fire department and/or hazardous materials team may reveal weaknesses or strengths previously unknown to the MS4 operator.

EPA received comments requesting modifications to the rule to include on-site sewage disposal systems (i.e., septic systems) in the scope of the illicit discharge program. On-site sewage disposal systems that flow into storm drainage systems are within the definition of illicit discharge as defined by the regulations. Where they are found to be the source of an illicit discharge, they need to be eliminated similar to any other illicit discharge source. Today's rule was not modified to include discharges from on-site sewage disposal systems specifically because those sources are already within the scope of the existing definition of illicit discharge.

iv. Construction Site Storm Water Runoff Control. Over a short period of time, storm water runoff from construction site activity can contribute more pollutants, including sediment, to a receiving stream than had been deposited over several decades (see section I.B.3). Storm water runoff from construction sites can include pollutants other than sediment, such as phosphorus and nitrogen, pesticides, petroleum derivatives, construction chemicals, and solid wastes that may become mobilized when land surfaces are disturbed. Generally, properly implemented and enforced construction site ordinances effectively reduce these pollutants. In many areas, however, the effectiveness of ordinances in reducing pollutants is limited due to inadequate enforcement or incomplete compliance with such local ordinances by construction site operators (Paterson, R.G. 1994. "Construction Practices: The Good, the Bad, and the Ugly." *Watershed Protection Techniques* 1(2)).

Today's rule requires operators of regulated small MS4s to develop, implement, and enforce a pollutant control program to reduce pollutants in any storm water runoff from construction activities that result in land disturbance of 1 or more acres (see § 122.34(b)(4)). Construction activity on sites disturbing less than one acre must be included in the program if the construction activity is part of a larger common plan of development or sale that would disturb one acre or more.

The construction runoff control program of the regulated small MS4 must include an ordinance or other regulatory mechanism to require erosion and sediment controls to the extent practicable and allowable under State, Tribal or local law. The program also must include sanctions to ensure compliance (for example, non-monetary penalties, fines, bonding requirements, and/or permit denials for non-compliance). The program must also include, at a minimum: requirements for construction site operators to implement appropriate erosion and sediment control BMPS, such as silt fences, temporary detention ponds and diversions; procedures for site plan review by the small MS4 which incorporate consideration of potential water quality impacts; requirements to control other waste such as discarded building materials, concrete truck washout, chemicals, litter, and sanitary waste at the construction site that may adversely impact water quality; procedures for receipt and consideration of information submitted by the public to the MS4; and procedures for site inspection and enforcement of control measures by the small MS4.

Today's rule provides flexibility for regulated small MS4s by allowing them to exclude from their construction pollutant control program runoff from those construction sites for which the NPDES permitting authority has waived NPDES storm water small construction permit requirements. For example, if the NPDES permitting authority waives permit coverage for storm water discharges from construction sites less than 5 acres in areas where the rainfall erosivity factor is less than 5, then the regulated small MS4 does not have to include these sites in its storm water management program. Even if requirements for a discharge from a given construction site are waived by the NPDES permitting authority, however, the regulated small MS4 may still chose to control those discharges under the MS4's construction pollutant control program, particularly where such discharges may cause siltation problems in storm sewers. See Section II.I.1.b for more information on construction waivers by the permitting authority.

Some commenters suggested that the proposed construction minimum measure requirements went beyond the permit application requirements concerning construction for medium and large MS4s. In response, EPA has made changes to the proposed measure so that it more closely resembles the MS4 permit application requirements in existing regulations. For example, as described below, the Agency revised the proposed requirements for "pre-construction review of site management plans" to require "procedures for site plan review."

One commenter expressed concerns that addressing runoff from construction sites within urbanized areas (through the small MS4 program) differently from construction sites outside urbanized areas (which will not be covered by the small MS4 program) will encourage urban sprawl. Today's rule, together with the existing requirements, requires all construction greater than or equal to 1 acre, unless waived, to be covered by an NPDES permit whether it is located inside or outside of an urbanized area (see § 122.26(b)(15)). Today's rule does not require small MS4s to control runoff from construction sites more stringently or prescriptively than is required for construction site runoff outside urbanized areas. Therefore, today's rule imposes no substantively different onsite controls on runoff of storm water from construction sites in urbanized areas than from construction sites outside of urbanized areas.

One commenter recommended that the small MS4 construction site storm water runoff control program address all storm water runoff from construction sites, not just the runoff into the MS4. The commenter also believed that MS4s should provide clear, objective standards for all construction sites. EPA agrees. Because today's rule only regulates discharges from the MS4, the construction pollutant control measure only requires small MS4 operators to control runoff into its system. As a practical matter, however, EPA anticipates that MS4 operators will find that regulation of all construction site

R0018130

runoff, whether they runoff into the MS4 or not, will prove to be the most simple and efficient program. The Agency may provide more specific criteria for construction site BMPs in the forthcoming rule being developed under CWA section 402(m). See section II.D.1 of today's rule.

One commenter stated that there is no need for penalties at the local level by the small MS4 because the CWA already imposes sufficient penalties to ensure compliance. EPA disagrees and believes that enforcement and compliance at the local level is both necessary and preferable. Examples of sanctions, some not available under the CWA, include non-monetary penalties, monetary fines, bonding requirements, and denial of future or other local permits.

One commenter recommended that EPA should not include the requirement to control pollutants other than sediment from construction sites in this measure. EPA disagrees with this comment. The requirement is to control waste that "may cause adverse impacts on water quality." Such wastes may include discarded building materials, concrete truck washout, chemicals, pesticides, herbicides, litter, and sanitary waste. These wastes, when exposed to and mobilized by storm water, can contribute to water quality impairment.

The proposed rule required "procedures for pre-construction review of site management plans." EPA requested comment on expanding this provision to require both review and approval of construction site storm water plans. Many commenters expressed the concern that review and approval of site plans is not only costly and time intensive, but may unnecessarily delay construction projects and unduly burden staff who administer the local program. In addition, some commenters expressed confusion whether EPA proposed pre-construction review for all site management plans or only higher priority sites. To address these comments, and be consistent with the permit application requirements for larger MS4s, EPA changed "procedures for pre-construction review of site management plans" to "procedures for site plan review." Today's rule requires the small MS4 to develop procedures for site plan review so as to incorporate consideration of adverse potential water quality impacts. Procedures should include review of site erosion and sediment control plans, preferably before construction activity begins on a site. The objective is for the small MS4 operator and the construction site operator to address storm water runoff from construction activity early in the project design process so that potential consequences to the aquatic environment can be assessed and adverse water quality impacts can be minimized or eliminated.

One commenter requested that EPA delete the requirement for "procedures for receipt and consideration of information submitted by the public" because it went beyond existing storm water requirements. Another commenter stated that establishing a separate process to respond to public inquiries on a project is a burden to small communities, especially if the project has gone through an environmental review. One commenter requested clarification of this provision. EPA has retained this requirement in today's final rule to require some formality in the process for addressing public inquiries regarding storm water runoff from construction activities. EPA does not intend that small MS4s develop a separate, burdensome process to respond to every public inquiry. A small MS4 could, for example, simply log public complaints on existing storm water runoff problems from construction sites and pass that information on to local inspectors. The inspectors could then investigate complaints based on the severity of the violation and/or priority area.

One commenter believed that the proposed requirement of "regular inspections during construction" would require every construction project to be inspected more than once by the small MS4 during the term of a construction project. EPA has deleted the reference to "regular inspections." Instead, the small MS4 will be required to "develop procedures for site inspection and enforcement of control measures." Procedures could include steps to identify priority sites for inspection and enforcement based on the nature and extent of the construction activity, topography, and the characteristics of soils and receiving water quality.

In order to avoid duplication of small MS4 construction requirements with NPDES construction permit requirements, today's rule adds § 122.44(s) to recognize that the NPDES permitting authority can incorporate qualifying State, Tribal, or local erosion and sediment control requirements in NPDES permits for construction site discharges. For example, a construction site operator who complies with MS4 construction pollutant control programs that are referenced in the NPDES construction permit would satisfy the requirements of the NPDES permit. See section II.I.1.d for more information on incorporating qualifying programs by reference into NPDES construction permits. This provision has no impact on, or direct relation to, the small MS4 operator's responsibilities under the construction site storm water runoff control minimum measure. Conversely, under § 122.35(b), the permitting authority may recognize in the MS4's permit that another governmental entity, or the permitting authority itself, is responsible for implementing one or more of the minimum measures (including construction site storm water runoff control), and not include this measure in the small MS4's permit. In this case, the other governmental entity's program must satisfy all of the requirements of the omitted measure.

v. Post-Construction Storm Water Management in New Development and Redevelopment. The NURP study and more recent investigations indicate that prior planning and designing for the minimization of pollutants in storm water discharges is the most cost-effective approach to storm water quality management. Reducing pollutant concentrations in storm water after the discharge enters a storm sewer system is often more expensive and less efficient than preventing or reducing pollutants at the source. Increased human activity associated with development often results in increased pollutant loading from storm water discharges. If potential adverse water quality impacts are considered from the beginning stages of a project, new development and redevelopment provides more opportunities for water quality protection. For example, minimization of impervious areas, maintenance or restoration of natural infiltration, wetland protection, use of vegetated drainage ways, and use of riparian buffers have been shown to reduce pollutant loadings in storm water runoff from developed areas. EPA encourages operators of regulated small MS4s to identify specific problem areas within their jurisdictions and initiate innovative solutions and designs to focus attention on those areas through local planning.

In today's rule at § 122.34(b)(5), NPDES permits issued to an operator of a regulated small MS4 will require the operator to develop, implement, and enforce a program to address storm water runoff from new development and redevelopment projects that result in land disturbance of greater than or equal to one acre, including projects less than one acre that are part of a larger common plan of development or sale, that discharge into the MS4. Specifically, the NPDES permit will require the operator of a regulated small MS4 to: (1) Develop and implement

R0018131

strategies which include a combination of structural and/or non-structural best management practices (BMPs) appropriate for the community; (2) use an ordinance, or other regulatory mechanism to address post-construction runoff from new development and redevelopment projects to the extent allowable under State, Tribal or local law; (3) ensure adequate long-term operation and maintenance of BMPs; and (4) ensure that controls are in place that would minimize water quality impacts. EPA intends the term "redevelopment" to refer to alterations of a property that change the "footprint" of a site or building in such a way that results in the disturbance of equal to or greater than 1 acre of land. The term is not intended to include such activities as exterior remodeling, which would not be expected to cause adverse storm water quality impacts and offer no new opportunity for storm water controls.

EPA received comments requesting guidance and clarification of the rule requirements. The scope of the comments ranged from general requests for more details on how MS4 operators should accomplish the four requirements listed above, to specific requests for information regarding transfer of ownership for structural controls, as well as ongoing responsibility for operation and maintenance. By the term "combination" of BMPs, EPA intends a combination of structural and/or non-structural BMPs. For this requirement, the term "combination" is meant to emphasize that multiple BMPs should be considered and adopted for use in the community. A single BMP generally cannot significantly reduce pollutant loads because pollutants come from many sources within a community. The BMPs chosen should: (1) Be appropriate for the local community; (2) minimize water quality impacts; and (3) attempt to maintain pre-development runoff conditions. In choosing appropriate BMPs, EPA encourages small MS4 operators to participate in locally-based watershed planning efforts which attempt to involve a diverse group of stakeholders. Each new development and redevelopment project should have a BMP component. If an approach is chosen that primarily focuses on regional or non-structural BMPs, however, then the BMPs may be located away from the actual development site (*e.g.*, a regional water quality pond).

Non-structural BMPs are preventative actions that involve management and source controls such as: (1) Policies and ordinances that provide requirements and standards to direct growth to identified areas, protect sensitive areas such as wetlands and riparian areas, maintain and/or increase open space (including a dedicated funding source for open space acquisition), provide buffers along sensitive water bodies, minimize impervious surfaces, and minimize disturbance of soils and vegetation; (2) policies or ordinances that encourage infill development in higher density urban areas, and areas with existing storm sewer infrastructure; (3) education programs for developers and the public about project designs that minimize water quality impacts; and (4) other measures such as minimization of the percentage of impervious area after development, use of measures to minimize directly connected impervious areas, and source control measures often thought of as good housekeeping, preventive maintenance and spill prevention. Detailed examples of non-structural BMPs follow.

Preserving open space may help to protect water quality as well as provide other benefits such as recharging groundwater supplies, detaining storm water, supporting wildlife and providing recreational opportunities. Although securing funding for open space acquisition may be difficult, various funding mechanisms have been used. New Jersey uses a portion of their State sales tax (voter approved for a ten year period) as a stable source of funding to finance the preservation of historic sites, open space and farmland. Colorado uses part of the proceeds from the State lottery to acquire and manage open space. Some local municipalities use a percentage of the local sales tax revenue to pay for open space acquisition (*e.g.*, Jefferson County, CO has had an open space program in place since 1977 funded by a 0.50 percent sales tax). Open space can be acquired in the form of: fee simple purchase; easements; development rights; purchase and sellback or leaseback arrangements; purchase options; private land trusts; impact fees; and land dedication requirements. Generally, fee simple purchases provide the highest level of development control and certainty of preservation, whereas the other forms of acquisition may provide less control, though they would also generally be less costly.

Cluster development, while allowing housing densities comparable to conventional zoning practice, concentrates housing units in a portion of the total site area which provides for greater open space, recreation, stream protection and storm water control. This type of development, by reducing lot sizes, can protect sensitive areas and result in less impervious surface, as well as reduce the cost for roads and other infrastructure.

Minimizing directly connected impervious areas (DCIAs) is a drainage strategy that seeks to reduce paved areas and directs storm water runoff to landscaped areas or to structural controls such as grass swales or buffer strips. This strategy can slow the rate of runoff, reduce runoff volumes, attenuate peak flows, and encourage filtering and infiltration of storm water. It can be made an integral part of drainage planning for any development (Urban Drainage and Flood Control District, Denver, CO. 1992. *Urban Storm Drainage Criteria Manual, Volume 3—Best Management Practices).* The Urban Drainage and Flood Control District manual describes three levels for minimizing DCIAs. At Level 1 all impervious surfaces are made to drain over grass-covered areas before reaching a storm water conveyance system. Level 2 adds to Level 1 and replaces street curb and gutter systems with low-velocity grass-lined swales and pervious street shoulders. In addition to Levels 1 and 2, Level 3 over-sizes swales and configures driveway and street crossing culverts to use grass-lined swales as elongated detention basins.

Structural BMPs include: (1) Storage practices such as wet ponds and extended-detention outlet structures; (2) filtration practices such as grassed swales, sand filters and filter strips; and (3) infiltration practices such as infiltration basins and infiltration trenches.

EPA recommends that small MS4 operators ensure the appropriate implementation of the structural BMPs by considering some or all of the following: (1) Pre-construction review of BMP designs; (2) inspections during construction to verify BMPs are built as designed; (3) post-construction inspection and maintenance of BMPs; and (4) sanctions to ensure compliance with design, construction or operation and maintenance (O&M) requirements of the program.

EPA cautions that certain infiltration systems such as dry wells, bored wells or tile drainage fields may be subject to Underground Injection Control (UIC) program requirements (see 40 CFR Part 144.12.). To find out more about these requirements, contact your state UIC Program, or call EPA's Safe Drinking Water Hotline at 1–800–426–4791.

In order to meet the third post-construction requirement (ensuring adequate long-term O&M of BMPs), EPA recommends that small MS4 operators evaluate various O&M management agreement options. The most common options are agreements between the

MS4 operator and another party such as post-development landowners (*e.g.*, homeowners' associations, office park owners, other government departments or entities), or regional authorities (*e.g.*, flood control districts, councils of government). These agreements typically require the post-construction property owner to be responsible for the O&M and may include conditions which: allow the MS4 operator to be reimbursed for O&M performed by the MS4 operator that is the responsibility of the property owner but is not performed; allow the MS4 operator to enter the property for inspection purposes; and in some cases specify that the property owner submit periodic reports.

In providing the guidance above, EPA intends the requirements in today's rule to be consistent with the permit application requirements for large MS4s for post-construction controls for new development and redevelopment. MS4 operators have significant flexibility both to develop this measure as appropriate to address local concerns, and to apply new control technologies as they become available. Storm water pollution control technologies are constantly being improved. EPA recommends that MS4s be responsive to these changes, developments or improvements in control technologies. EPA will provide more detailed guidance addressing the responsibility for long-term O&M of storm water controls in guidance materials. The guidance will also provide information on appropriate planning considerations, structural controls and non-structural controls. EPA also intends to develop a broad menu of BMPs as guidance to ensure flexibility to accommodate local conditions.

EPA received comments suggesting that requirements for new development be treated separately from redevelopment in the rule. The comment stressed that new development on raw land presents fewer obstacles and more opportunities to incorporate elements for preventing water quality impacts, whereas redevelopment projects are constrained by space limitations and existing infrastructure. Another comment suggested allowing waivers from the redevelopment requirements if the redevelopment does not result in additional adverse water quality impacts, and where BMPs are not technologically or economically feasible. EPA recognizes that redevelopment projects may have more site constraints which narrow the range of appropriate BMPs. Today's rule provides small MS4 operators with the flexibility to develop requirements that may be different for redevelopment projects, and may also include allowances for alternate or off-site BMPs at certain redevelopment projects. Non-structural BMPs may be the most appropriate approach for smaller redevelopment projects.

EPA received comments requesting clarification on what is meant by "pre-development" conditions within the context of redevelopment. Pre-development refers to runoff conditions that exist onsite immediately before the planned development activities occur. Pre-development is not intended to be interpreted as that period before any human-induced land disturbance activity has occurred.

EPA received comments on the guidance language in the proposed rule and preamble which suggest that implementation of this measure should "attempt to maintain pre-development runoff conditions" and that "post-development conditions should not be different than pre-development conditions in a way that adversely affects water quality." Many comments expressed concern that maintaining pre-development runoff conditions is impossible and cost-prohibitive, and objected to any reference to "flow" or increase in volume of runoff. Other comments support the inclusion of this language in the final rule. Similar references in today's rule relating to pre-development runoff conditions are intended as *recommendations* to *attempt* to maintain pre-development runoff conditions. With these recommendations, EPA intends to prevent water quality impacts resulting from increased discharges of pollutants, which may result from increased volume of runoff. In many cases, consideration of the increased flow rate, velocity and energy of storm water discharges following development unavoidably must be taken into consideration in order to reduce the discharge of pollutants, to meet water quality standards and to prevent degradation of receiving streams. EPA recommends that municipalities consider these factors when developing their post-construction storm water management program.

Some comments said that the quoted phrases in the paragraph above are directives that imply federal land use control, which they argue is beyond the authority of the CWA. EPA recognizes that land use planning is within the authority of local governments.

EPA disagrees, however, with the implication that today's rule dictates any such land use decisions. The requirement for small MS4 operators to develop a program to address discharges resulting from new development and redevelopment is essentially a pollution prevention measure. The Rule provides the MS4 operator with flexibility to determine the appropriate BMPs to address local water quality concerns. EPA recognizes that these program goals may not be applied to every site, and expects that MS4s will develop an appropriate combination of BMPs to be applied on a site-by-site, regional or watershed basis.

vi. Pollution Prevention/Good Housekeeping for Municipal Operations. Under today's final rule, operators of MS4s must develop and implement an operation and maintenance program ("program") that includes a training component and has the ultimate goal of preventing or reducing storm water from municipal operations (in addition to those that constitute storm water discharges associated with industrial activity). This measure's emphasis on proper O&M of MS4s and employee training, as opposed to requiring the MS4 to undertake major new activities, is meant to ensure that municipal activities are performed in the most efficient way to minimize contamination of storm water discharges.

The program must include government employee training that addresses prevention measures pertaining to municipal operations such as: parks, golf courses and open space maintenance; fleet maintenance; new construction or land disturbance; building oversight; planning; and storm water system maintenance. The program can use existing storm water pollution prevention training materials provided by the State, Tribe, EPA, or environmental, public interest, or trade organizations.

EPA also encourages operators of MS4s to consider the following in developing a program: (1) Implement maintenance activities, maintenance schedules, and long-term inspection procedures for structural and non-structural storm water controls to reduce floatables and other pollutants discharged from the separate storm sewers; (2) implement controls for reducing or eliminating the discharge of pollutants from streets, roads, highways, municipal parking lots, maintenance and storage yards, waste transfer stations, fleet or maintenance shops with outdoor storage areas, and salt/sand storage locations and snow disposal areas operated by the MS4; (3) adopt procedures for the proper disposal of waste removed from the separate storm sewer systems and areas listed above in (2), including dredge

R0018133

spoil, accumulated sediments, floatables, and other debris; and (4) adopt procedures to ensure that new flood management projects are assessed for impacts on water quality and existing projects are assessed for incorporation of additional water quality protection devices or practices. Ultimately, the effective performance of the program measure depends on the proper maintenance of the BMPs, both structural and non-structural. Without proper maintenance, BMP performance declines significantly over time. Additionally, BMP neglect may produce health and safety threats, such as structural failure leading to flooding, undesirable animal and insect breeding, and odors. Maintenance of structural BMPs could include: replacing upper levels of gravel; dredging of detention ponds; and repairing of retention basin outlet structure integrity. Maintenance of non-structural BMPs could include updating educational materials periodically.

EPA emphasizes that programs should identify and incorporate existing storm water practices and training, as well as non-storm water practices or programs that have storm water pollution prevention benefits, as a means to avoid duplication of efforts and reduce overall costs. EPA recommends that MS4s incorporate these new obligations into their existing programs to the greatest extent feasible and urges States to evaluate MS4 programs with programmatic efficiency in mind. EPA designed this minimum control measure as a modified version of the permit application requirements for medium and large MS4s described at 40 CFR 122.26(d)(2)(iv), in order to provide more flexibility for these smaller MS4s. Today's requirements provide for a consistent approach to control pollutants from O&M among medium, large, and regulated small MS4s.

By properly implementing a program, operators of MS4s serve as a model for the rest of the regulated community. Furthermore, the establishment of a long-term program could result in cost savings by minimizing possible damage to the system from floatables and other debris and, consequently, reducing the need for repairs.

EPA received comments requesting clarification of what this measure requires. Certain municipalities expressed concern that the measure has the potential to impose significant costs associated with EPA's requirement that operators of MS4s consider implementing controls for reducing or eliminating the discharge of pollutants from streets, roads, highways, municipal parking lots, and salt/sand storage locations and snow disposal areas operated by the municipality. EPA disagrees that a requirement to *consider* such controls will impose considerable costs.

One commenter objected to the preamble language from the proposal suggesting that EPA does not expect the MS4 to undertake new activity. While it remains the Agency's expectation that major new activity will not be required, the MEP process should drive MS4s to incorporate the measure's obligations into their existing programs to achieve the pollutant reductions to the maximum extent practicable.

Certain commenters requested a definition for "municipal operations." EPA has revised the language to more clearly define municipal operations. Questions may remain concerning whether discharges from specific municipal activities constitute discharges associated with industrial activities (requiring NPDES permit authorization according to the requirements for industrial storm water that apply in that State) or from municipal operations (subject only to the controls developed in the MS4 control program). Even though there may be different substantive requirements that apply depending on the source of the discharge, EPA has modified the deadlines for permit coverage so that all the regulated municipally owned and operated sources become subject to permit requirements on the same date. The deadline is the same for permit coverage for this minimum measure as for permit coverage for municipally owned/operated industrial sources.

c. Application Requirements

An NPDES permit that authorizes the discharge from a regulated small MS4 may take the form of either an individual permit issued to one or more facilities as co-permittees or a general permit that applies to a group of MS4s. For reasons of administrative efficiency and to reduce the paperwork burden on permittees, EPA expects that most discharges from regulated small MS4s will be authorized under general permits. These NPDES general permits will provide specific instructions on how to obtain coverage, including application requirements. Typically, such application requirements will be satisfied by the submission of a Notice of Intent (NOI) to be covered by the general permit. In this section, EPA explains the small MS4 operator's application requirements for obtaining coverage under a NPDES permit for storm water.

i. Best Management Practices and Measurable Goals. Section 122.34(d) of today's rule requires the operator of a regulated small MS4 that wishes to implement a program under § 122.34 to identify and submit to the NPDES permitting authority a list of the best management practices ("BMPs") that will be implemented for each minimum control measure in their storm water management program. They also must submit measurable goals for the development and implementation of each BMP. The BMPs and the measurable goals must be included either in an NOI to be covered under a general permit or in an individual permit application.

The operator's submission must identify, as appropriate, the months and years in which the operator will undertake actions required to implement each of the minimum control measures, including interim milestones and the frequency of periodic actions. The Agency revised references to "starting and completing" actions from the proposed rule because many actions will be repetitive or ongoing. The submission also must identify the person or persons responsible for implementing or coordinating the small MS4 storm water program. See § 122.34(d). The submitted BMPs and measurable goals become enforceable according to the terms of the permit. The first permit can allow the permittee up to five years to fully implement the storm water management program.

Several commenters opposed making the measurable goals enforceable permit conditions. Some suggested that a permittee should be able to change its goals so that BMPs that are not functioning as intended can be replaced. EPA agrees that a permittee should be free to switch its BMPs and corresponding goals to others that accomplish the minimum measure or measures. The permittee is required to implement BMPs that address the minimum measures in § 122.34(b). If the permittee determines that its original combination of BMPs are not adequate to achieve the objectives of the municipal program, the MS4 should revise its program to implement BMPs that are adequate and submit to the permitting authority a revised list of BMPs and measurable goals. EPA suggests that permits describe the process for revising BMPs and measurable goals, such as whether the permittee should follow the same procedures as were required for the submission of the original NOI and whether the permitting authority's approval is necessary prior to the permittee implementing the revised

BMPs. The permittee should indicate on its periodic report whether any BMPs and measurable goals have been revised since the last periodic report.

Some commenters expressed concern that making the measurable goals enforceable would encourage the development of easily attained goals and, conversely, discourage the setting of ambitious goals. Others noted that it is often difficult to determine the pollutant reduction that can be achieved by BMPs until several years after implementation. Much of the opposition to the enforceability of measurable goals appears to have been based on a mistaken understanding that measurable goals must consist of pollutant reduction targets to be achieved by the corresponding BMPs.

Today's rule requires the operator to submit either measurable goals that serve as BMP design objectives or goals that quantify the progress of implementation of the actions or performance of the permittee's BMPs. At a minimum, the required measurable goals should describe specific actions taken by the permittee to implement each BMP and the frequency and the dates for such actions. Although the operator may choose to do so, it is not required to submit goals that measure whether a BMP or combination of BMPs is effective in achieving a specific result in terms of storm water discharge quality. For example, a measurable goal might involve a commitment to inspect a given number of drainage areas of the collection system for illicit connections by a certain date. The measurable goal need not commit to achieving a specific amount of pollutant reduction through the elimination of illicit connections. Other measurable goals could include the date by which public education materials would be developed, a certain percentage of the community participating in a clean-up campaign, the development of a mechanism to address construction site runoff, and a reduction in the percentage of imperviousness associated with new development projects.

To reduce the risk that permittees will develop inadequate BMPs, EPA intends to develop a menu of BMPs to assist the operators of regulated small MS4s with the development of municipal programs. States may also develop a menu of BMPs. Today's rule provides that the measurable goals that demonstrate compliance with the minimum control measures in §§ 122.34 (b)(3) through (b)(6) do not have to be met if the State or EPA has not issued a menu of BMPs at the time the MS4 submits its NOI. Commenters pointed out that the proposed rule would have made the measurable goals unenforceable if the menu of BMPs was not available, but the proposal was silent as to the enforceability of the implementation of BMPs. Today's rule clarifies that the operators are not free to do nothing prior to the issuance of a menu of BMPs; they still must make a good faith effort to implement the BMPs designed to comply with each measure. See § 122.34(d)(2). The operators would not, however, be liable for failure to meet its measurable goals if a menu of BMPs was not available at the time they submit their NOI.

The proposed rule provision in § 123.35 stated that the "[f]ailure to issue the menu of BMPs would not affect the legal status of the general permit." This concept is included in the final rule in § 122.34(d)(2)'s clarification that the permittee still must comply with other requirements of the general permit.

Unlike the proposed rule, today's rule does not require that each BMP in the menu developed by the State or EPA be regionally appropriate, cost-effective and field-tested. Various commenters criticized those criteria as unworkable, and one described them as "ripe for ambiguity and abuse." Other commenters feared that the operators of regulated small MS4s would never be required to achieve their goals until menus were developed that were cost-effective, field-tested and appropriate for every conceivable subregion.

While some municipal commenters supported the requirement that a menu of BMPs be made available that included BMPs that had been determined to be regionally appropriate, field-tested and cost-effective, others raised concerns that they would be restricted to a limited menu. Some commenters supported such a detailed menu because they thought they would only be able to select BMPs that were on the menu, while others thought that it was the permitting authority's responsibility to develop BMPs narrowly tailored to their situation. In response, EPA notes that the operators will not be restricted to implementing only, or all of, the BMPs included on the menu. Since the menu does not require permittees to implement the BMPs included on the menu, it is also not necessary to apply the public notice and other procedures that some commenters thought should be applied to the development of the menu of BMPs.

The purpose of the BMP menu is to provide guidance to assist the operators of regulated small MS4s with the development and refinement of their local program, not to limit their options. Permittees may implement BMPs other than those on the menu unless a State restricts its permittees to specific BMPs. To the extent possible, EPA will develop a menu of BMPs that describes the appropriateness of BMPs to specific regions, whether the BMPs have been field-tested, and their approximate costs. The menu, however, is not intended to relieve permittees of the need to implement BMPs that are appropriate for their specific circumstances.

If there are no known relevant BMPs for a specific circumstance, a permittee has the option of developing and implementing pilot BMPs that may be better suited to their circumstances. Where BMPs are experimental, the permittee should consider committing to measurable goals that address its schedule for implementing its selected BMPs rather than goals of achieving specific pollutant reductions. If the BMPs implemented by the permittee do not achieve the desired objective, the permittee may be required to commit to different or revised BMPs.

As stated in § 123.35(g), EPA is committed to issuing a menu of BMPs prior to the deadline for the issuance of permits. This menu would serve as guidance for all operators of regulated small MS4s nationwide. After developing the initial menu of BMPs, EPA intends to periodically modify, update, and supplement the menu of BMPs based on the assessments of the MS4 storm water program and research. States may rely on EPA's menu of BMPs or issue their own. If States develop their own menus, they would constitute additional guidance (or perhaps requirements in some States) for the operators to follow. Several commenters were confused by the proposed rule language that stated that States must provide or issue a menu of BMPs and, if they fail to do so, EPA "may" do so. Some read this language as not requiring either EPA or the State to develop the menu. EPA had intended that it would develop a menu and that States could either provide the EPA developed menu or one developed by the State.

EPA has dropped the proposed language that States "must" develop the menu of BMPs. Some commenters thought that it was inappropriate to require States to issue guidance. A menu of BMPs issued by either EPA or a permittee's State will satisfy the condition in § 122.34(d) that a regulatory authority provide a menu of BMPs. A State could require its permittees to follow its menu of BMPs provided that they are adequate to implement § 122.34(b).

Several commenters raised concerns that operators of small MS4s could be required to submit their BMPs and measurable goals before EPA or the State has issued a menu of BMPs. EPA has assumed primary responsibility for developing a menu of BMPs to minimize the possibility of this occurring. Should a general permit be issued before a menu of BMPs is available, the permit writer would have the option of delaying the date by which the identification of the BMPs and measurable goals must be submitted to the permitting authority until some time after a menu of BMPs is available.

Several municipal commenters raised concerns that they would begin to develop a program only to be later told by the permitting authority or challenged in a citizen suit that their BMPs were inadequate. They expressed a need for certainty regarding what their permit required. Several commenters suggested that EPA require permitting authorities to approve or disapprove the submitted BMPs and measurable goals. EPA disagrees that formal approval or disapproval by the permitting authority is needed.

EPA acknowledges that the lack of a formal approval process does place on the permittee some responsibility for designing and determining the adequacy of its BMPs. Once the permittee has submitted its BMPs to the permitting authority as part of its NOI, it must implement them in order to achieve the corresponding measurable goals. EPA does not believe that this results in the uncertainty to the extent expressed by some commenters or unduly expose the permittee to the risk of citizen suit. If the permit is very specific regarding what the permittee must do, then the uncertainty is eliminated. If the permit is less prescriptive, the permittee has greater latitude in determining for itself what constitutes an adequate program. A citizen suit could impose liability on the permittee only if the program that it develops and implements clearly does not satisfy the requirements of the general permit. EPA believes today's approach strikes a balance between the competing goals of providing certainty as to what constitutes an adequate program and providing flexibility to the permittees.

Commenters were divided on whether five years was a reasonable and expeditious schedule for a MS4 to implement its program. Some thought that it was an appropriate amount of time to allow for the development and implementation of adequate programs. One questioned whether the permittee had to be implementing all of its program within that time, and suggested that there may be cases where a permitting authority would need flexibility to allow more time. One commenter suggested that five years is too long and would amount to a relaxation of implementation in their area. EPA believes it will take considerable time to complete the tasks of initially developing a program, commencing to implement it, and achieving results. EPA notes, however, that full implementation of an appropriate program must occur as expeditiously as possible, and not later than five years.

EPA solicited comment on how an NOI form might best be formatted to allow for measurable goal information (*e.g.*, through the use of check boxes or narrative descriptions) while taking into account the Agency's intention to facilitate computer tracking. All commenters supported the development of a checklist NOI, but most noted that there would need to be room for additional information to cover unusual situations. One noted that, while a summary of measurable goals might be reduced to one sheet, attachments that more fully described the program and the planned BMPs would be necessary. EPA agrees that in most cases a "checklist" will not be able to capture the information on what BMPs a permittee intends to implement and its measurable goals for their implementation. EPA will continue to consider whether to develop a model NOI form and make it available for permitting authorities that choose to use it. What will be required on an MS4's NOI, however, is more extensive than what is usually required on an NOI, so a "form" NOI for MS4s may be impractical.

ii. Individual Permit Application for a § 122.34(b) program. In some cases, an operator of a regulated small MS4s may seek coverage under an individual NPDES permit, either because it chooses to do so or because the NPDES permitting authority has not made the general permit option available to that source. For small MS4s that are to implement a § 122.34(b) program in today's rule, EPA is promulgating simplified individual permit application requirements at § 122.33(b)(2)(i). Under the simplified individual permit application requirements, the operator submits an application to the NPDES permitting authority that includes the information required under § 122.21(f) and an estimate of square mileage served by the small MS4. They are also required to supply the BMP and measurable goal information required under § 122.34(d). Consistent with CWA section 308 and analogous State law, the permitting authority could request any additional information to gain a better understanding of the system and the areas draining into the system.

Commenters suggested that the requirements of § 122.21(f) are not necessarily applicable to a small MS4. One suggested that it was not appropriate to require the following information: a description of the activities conducted by the applicant which require it to obtain an NPDES permit; the name, mailing address, and location of the facility; and up to four Standard Industrial Classification ("SIC") codes which best reflect the principal products or services provided by the facility. In response, EPA notes that the requirements in § 122.21(f) are generic application requirements applicable to NPDES applicants. With the exception of the SIC code requirement, EPA believes that they are applicable to MS4s. In the SIC code portion of the standard application, the applicant may simply put "not applicable."

One commenter asked that EPA clarify whether § 122.21(f)(5)'s requirement to indicate "whether the facility is located on Indian lands," referred to tribal lands, Indian country, or Indian reservations. For some local governments this is a complex issue with no easy "yes" or "no" answer. See the discussion in the Section II.F in the proposal to today's rule regarding what tribal lands are subject to the federal trust responsibility for purposes of the NPDES program.

One commenter suggested that the application should not have to list the permits and approvals required under § 122.21(f)(6). EPA notes that the applicant must only list the environmental permits that the applicant has received that cover the small MS4. The applicant is not required to list permits for other operations conducted by the small MS4 operator (*e.g.*, for an operation of an airport or landfill). Again, in most cases the applicant could respond "not applicable" to this portion of the application.

One commenter suggested that the topographic map requirement of § 122.21(f)(7) was completely different from, and significantly more onerous than, the mapping requirement outlined in the proposed rule at § 122.34(b)(3)(i). EPA agrees and has modified the final rule to clarify that a map that satisfies the requirements of § 122.34(b)(3)(i) also satisfies the map requirements for MS4 applicants seeking individual permits under § 122.33(b)(2)(i).

EPA is adding a new paragraph to § 122.44(k) to clarify that requirements to implement BMPs developed pursuant to CWA 402(p) are appropriate permit

R0018136

conditions. While such conditions could be included under the existing provision in § 122.44(k)(3) for "practices reasonably necessary to achieve effluent limitations and standards or to carry out the purposes and intent of the CWA," EPA believes it is clearer to specifically list in § 122.44(k) BMPs that implement storm water programs in light of the frequency with which they are used as effluent limitations.

iii. Alternative Permit Options/Tenth Amendment. As an alternative to implementing a program that addresses each of the six minimum measures according to the requirements of § 122.34(b), today's rule provides the operators of regulated small MS4s with the option of applying for an individual permit under existing § 122.26(d). *See* § 122.33(b)(2)(ii). If a system operator does not want to be held accountable for implementation of each of the minimum measures, an individual permit option under § 122.33(b)(2)(ii) remains available. (As explained in the next section of this preamble, § 122.35(b) also provides an opportunity for relief from permit obligations for some of the minimum measures, but that relief exists within the framework of the minimum measures.)

EPA originally drafted the individual permit application requirements in § 122.26(d) to apply to medium and large MS4s. Today's rule abbreviates the individual permit application requirements for small MS4s. Although EPA believes that the storm water management program requirements of § 122.34, including the minimum measures, provide the most appropriate means to control pollutants from most small MS4s, the Agency does recognize that the operators of some small MS4s may prefer more individualized permit requirements. Among other possible reasons, an operator may seek to avoid having to "regulate" third parties discharging into the separate storm sewer system. Alternatively, an operator may determine that structural controls, such as constructed wetlands, are more appropriate or effective to address the discharges that would otherwise be addressed under the construction and/or development/redevelopment measures.

Some MS4s commenters alleged that an absolute requirement to implement the minimum measures violates the Tenth Amendment to the U.S. Constitution. While EPA disagrees that requiring MS4s to implement the minimum measures would violate the Constitution, today's rule does provide small MS4s with the option of developing more individualized measures to reduce the pollutants and pollution associated with urban storm water that will be regulated under today's rule.

Some commenters specifically objected that § 122.34's minimum measures for small MS4s violate the Tenth Amendment insofar as they require the operators of MS4s to regulate third parties. The minimum measures include requirements for small MS4 operators to prohibit certain non-storm water discharges, control storm water discharges from construction greater than one acre, and take other actions to control third party sources of storm water discharges into their MS4s. Commenters also argued that it was inappropriate for EPA to require local governments to enact ordinances that will consume local revenues and put local governments in the position of bearing the political responsibility for implementing the program. One commenter argued that EPA was prohibited from conditioning the issuance of an NPDES permit upon the small MS4 operators waiving their constitutional right to be free from such requirements to regulate third parties. The Agency replies to each comment in turn.

Because the rule does rely on local governments—who operate municipal separate storm sewer systems—to regulate discharges from third parties into storm sewers, EPA acknowledges that the rule implicates the Tenth Amendment and constitutional principles of federalism. EPA disagrees, however, that today's rule is inconsistent with federalism principles. [As political subdivisions of States, municipalities enjoy the same protections as States under the Tenth Amendment.]

The Supreme Court has interpreted the Tenth Amendment to preclude federal actions that compel States or their political subdivisions to enact or administer a federal regulatory program. *See New York* v. *United States,* 505 U.S. 144 (1992); *Printz* v. *United States,* 117 S.Ct. 2365 (1997). The *Printz* case, however, did acknowledge that the restriction does not apply when federal requirements of general applicability—requirements that regulate all parties engaging in a particular activity—do not excessively interfere with the functioning of State governments when those requirements are applied to States (or their political subdivisions). *See Printz,* 117 S.Ct. at 2383.

Today's rule imposes a federal requirement of general applicability, namely, the requirement to obtain and comply with an NPDES permit, on municipalities that operate a municipal separate storm sewer system. By virtue of this rule, the permit will require the municipality/storm sewer operator to develop a storm water control program. The rule specifies the components of the control program, which are primarily "management"-type controls, for example, municipal regulation of third party storm water discharges associated with construction, as well as development and redevelopment, when those discharges would enter the municipal system.

Unlike the circumstances reviewed in the *New York* and *Printz* cases, today's rule merely applies a generally applicable requirement (the CWA permit requirement) to municipal point sources. The CWA establishes a generally applicable requirement to obtain an NPDES permit to authorize point source discharge to waters of the United States. Because municipalities own and operate separate storm sewers, including storm sewers into which third parties may discharge pollutants, NPDES permits may require municipalities to control the discharge of pollutants into the storm sewers in the first instance. Because NPDES permits can impose end-of-pipe numeric effluent limits, narrative effluent limits in the form of "management" program requirements are also within the scope of Clean Water Act authority. As noted above, however, EPA believes that such narrative limitations are the most appropriate form of effluent limitation for these types of permits. For municipal separate storm sewer permits, CWA section 402(p)(3)(B)(iii) specifically authorizes "controls to reduce pollutants to the maximum extent practicable, including management practices, control techniques and system, design and engineering methods, and such other provisions as the Administrator or the State determines appropriate for the control of such pollutants."

The Agency did not design the minimum measures in § 122.34 to "commandeer" state regulatory mechanisms, but rather to reduce pollutant discharges from small MS4s. The permit requirement in CWA section 402 is a requirement of general applicability. The operator of a small MS4 that does not prohibit and/or control discharges into its system essentially accepts "title" for those discharges. At a minimum, by providing free and open access to the MS4s that convey discharges to the waters of the United States, the municipal storm sewer system enables water quality impairment by third parties. Section 122.34 requires the operator of a regulated small MS4 to control a third party only to the extent that the MS4 collection system receives pollutants from that third party and discharges it to the waters of the United States. The operators of regulated small MS4s cannot passively receive and discharge pollutants from third parties. The Agency concedes that administration of a municipal program will consume limited local revenues for implementation; but those consequences stem from the municipal operator's identity as a permitted sewer system operator. The Tenth Amendment does not create a blanket municipal immunity from generally applicable requirements. Development of a program based on the minimum measures and implementation of that program should not "excessively interfere" with the functioning of municipal government, especially given the "practicability" threshold under CWA section 402(p)(3)(B)(iii).

As noted above, today's rule also allows regulated small MS4s to opt out of the minimum measures approach. The individual permit option provides for greater flexibility in program implementation and also responds to the comment about requiring a municipal permit applicant's waiver of any arguable constitutional rights. The individual permit option responds to questions about the rule's alleged unconstitutionality by more specifically focusing on the pollutants discharged from municipal point sources. Today's rule gives operators of MS4s the option to seek an individual permit that varies from the minimum measures/ management approach that is otherwise specified in today's rule. Even if the minimum measures approach was constitutionally suspect, a requirement that standing alone would violate constitutional principles of federalism does not raise concerns if the entity subject to the requirement may opt for an alternative action that does not raise a federalism issue.

For municipal system operators who seek to avoid third party regulation according to all or some of the minimum measures, § 122.26(d) requires the operator to submit a narrative description of its storm water sewer system and any existing storm water control program, as well as the monitoring data to enable the permit writer to develop appropriate permit conditions. The permit writer can then develop permit conditions and limitations that vary from the six minimum measures prescribed in today's rule. The information will enable the permit writer to develop an NPDES permit that will result in pollutant reduction to the maximum extent practicable. *See NRDC* v. *EPA*, 966 F.2d at 1308, n17. If determined appropriate under CWA section 402(p)(3)(B)(iii), for example BMPs to meet water quality standards, the permit could also incorporate any more stringent or prescriptive effluent limits based on the individual permit application information.

For small MS4 operators seeking an individual permit, both Part 1 and Part 2 of the application requirements in § 122.26(d)(1) and (2) are required to be submitted within 3 years and 90 days of the date of publication of this **Federal Register** notice. Some of the information required in Part 1 will necessarily have to be developed by the permit applicant prior to the development of Part 2 of the application. The permit applicant should coordinate with its permitting authority regarding the timing of review of the information.

The operators of regulated small MS4s that apply under § 122.26(d) may apply to implement certain of the § 122.34(b) minimum control measures, and thereby focus the necessary evaluation for additional limitations on alternative controls to the § 122.34(b) measures that the small MS4 will not implement. The permit writer may determine "equivalency" for some or all of the minimum measures by developing a rough estimate of the pollutant reduction that would be achieved if the MS4 implemented the § 122.34 minimum measure and to incorporate that pollutant reduction estimate in the small MS4's individual permit as an effluent limitation. The Agency recognizes that, based on current information, any such estimates will probably have a wide range. Anticipation of this wide range is one of the reasons EPA believes MS4 operators need flexibility in determining the mix of BMPs (under the minimum measures) to achieve water quality objectives. Therefore, for example, if a system operator seeks to employ an alternative that involves structural controls, wide ranges will probably be associated with gross pollutant reduction estimates. Permit writers will undoubtedly develop other ways to ensure that permit limits ensure reduction of pollutants to the maximum extent practicable.

Small MS4 operators that pursue this individual permit option do not need to submit details about their future program requirements (*e.g.*, the MS4's future plans to obtain legal authority required by §§ 122.26(d)(1)(ii) and (d)(2)). A small MS4 operator might elect to supply such information if it intends for the permit writer to take those plans into account when developing the small MS4's permit conditions.

Several operators of small MS4s commented that they currently lacked the authority they would need to implement one or more of the minimum measures in § 122.34(b). Today's rule recognizes that the operators of some small MS4s might not have the authority under State law to implement one or more of the measures using, for example, an ordinance or other regulatory mechanism. To address these situations, each minimum measure in § 122.34(b) that would require the small MS4 operator to develop an ordinance or other regulatory mechanism states that the operator is only required to implement that requirement to "the extent allowable under State, Tribal or local law." See § 122.34(b)(3)(ii) (illicit discharge elimination), § 122.34(b)(4)(ii) (construction runoff control) and § 122.34(b)(5)(ii) (post-construction storm water management). This regulatory language does not mean that a operator of a small MS4 with ordinance making authority can simply fail to pass an ordinance necessary for a § 122.34(b) program. The reference to "the extent allowable under * * * local law" refers to the local laws of *other* political subdivisions to which the MS4 operator is subject. Rather, a small MS4 operator that seeks to implement a program under section § 122.34(b) may omit a requirement to develop an ordinance or other regulatory mechanism only to the extent its municipal charter, State constitution or other legal authority prevents the operator from exercising the necessary authority. Where the operator cannot obtain the authority to implement any activity that is only required to "the extent allowable under State, Tribal or local law," the operator may satisfy today's rule by administering the remaining § 122.34(b) requirements.

Finally, although today's rule provides operators of small MS4s with an option of applying for a permit under § 122.26(d), States authorized to administer the NPDES program are not required to provide this option. NPDES-authorized States could require all regulated small MS4s to be permitted under the minimum measures management approach in § 122.34 as a matter of State law. Such an approach would be deemed to be equally or more stringent than what is required by today's rule. *See* 40 CFR 123.2(i). The federalism concerns discussed above do not apply to requirements imposed by a State on its political subdivisions.

iv. Satisfaction of Minimum Measure Obligations by Another Entity. An operator of a regulated small MS4 may satisfy the requirement to implement one or more of the six minimum measures in § 122.34(b) by having a third party implement the measure or measures. Today's rule provides a variety of means for small MS4 operators to share responsibility for different aspects of their storm water management program. The means by which the operators of various MS4s share responsibility may affect who is ultimately responsible for performance of the minimum measure and who files the periodic reports on the implementation of the minimum measure. Section 122.35 addresses these issues. The rule describes two different variants on third party implementation with different consequences if the third party fails to implement the measure.

If the permit covering the discharge from a regulated small MS4 identifies the operator as the entity responsible for a particular minimum control measure, then the operator-permittee remains responsible for the implementation of that measure even if another entity has agreed to implement the control measure. Section 122.35(a). Another party may satisfy the operator-permittee's responsibility by implementing the minimum control measure in a manner at least as stringent or prescriptive as the corresponding NPDES permit requirement. If the third party fails to do so, the operator-permittee remains responsible for its performance. The operator of the MS4 should consider entering into an agreement with the third party that acknowledges the responsibility to implement the minimum measure. The operator-permittee's NOI and its annual § 122.34(f)(3) reports submitted to the NPDES permitting authority must identify the third party that is satisfying one or more of the permit obligations. This requirement ensures that the permitting authority is aware which entity is supposed to implement which minimum measures.

If, on the other hand, the regulated small MS4's permit recognizes that an NPDES permittee other than the operator-permittee is responsible for a particular minimum control measure, then the operator-permittee is relieved from the responsibility for implementing that measure. The operator-permittee is also relieved from the responsibility for implementing any measure that the operator's permit indicates will be performed by the NPDES permitting authority. Section 122.35(b). The MS4 operator-permittee would be responsible for implementing the remaining minimum measures.

Today's final rule differs from the proposed version of § 122.35(b), which stated that, even if the third party's responsibility is recognized in the permit, the MS4 operator-permittee remained responsible for performance if the third party failed to perform the measure consistent with § 122.34(b). Under today's rule, the operator-permittee is relieved from responsibility for performance of a measure if the third party is an NPDES permittee whose permit makes it responsible for performance of the measure (including, for example, a State agency other than the State agency that issues NPDES permits) or if the third party is the NPDES permitting authority itself. Because the permitting authority is acknowledging the third party's responsibility in the permit, commenters thought that the MS4 operator-permittee should not be responsible for ensuring that the other entity is implementing the control measure properly. EPA agrees that the operator-permittee should not be conditionally responsible when the requirements are enforceable against some other NPDES permittee. If the third party fails to perform the minimum measure, the requirements will be enforceable against the third party. In addition, the NPDES permitting authority could reopen the operator-permittee's permit under § 122.62 and modify the permit to make the operator responsible for implementing the measure. A new paragraph has been added to § 122.62 to clarify that the permit may be reopened in such circumstances.

Today's rule also provides that the operator-permittee is not conditionally responsible where it is the State NPDES permitting authority itself that fails to implement the measure. The permitting authority does not need to issue a permit to itself (i.e., to the same State agency that issues the permit) for the sole purpose of relieving the small MS4 from responsibility in the event the State agency does not satisfy its obligation to implement a measure. EPA does not believe that the small MS4 should be responsible in the situation where the NPDES permit issued to the small MS4 operator recognizes that the State agency that issues the permit is responsible for implementing a measure. If the State does fail to implement the measure, the State agency could be held accountable for its commitment in the permit to implement the measure. Where the State does not fulfill its responsibility to implement a measure, a citizen also could petition for withdrawal of the State's NPDES program or it could petition to have the MS4's permit reopened to require the MS4 operator to implement the measure.

EPA notes that not every State program that addresses erosion and sediment control from construction sites will be adequate to satisfy the requirement that each regulated small MS4 have a program to the extent required by § 122.34(b)(4). For example, although all NPDES States are required to issue NPDES permits for construction activity that disturbs greater than one acre, the State's NPDES permit program will not necessarily be extensive enough to satisfy a regulated small MS4's obligation under § 122.34(b)(4). NPDES States will not necessarily be implementing all of the required elements of that minimum measure, such as procedures for site plan review in each jurisdiction required to develop a program and procedures for receipt and consideration of information submitted by the public on individual construction sites. In order for a State erosion and sediment control program to satisfy a small MS4 operator's obligation to implement § 122.34(b)(4), the State program would have to include all of the elements of that minimum measure.

Where the operator-permittee is itself performing one or more of the minimum measures, the operator-permittee remains responsible for all of the reporting requirements under § 122.34(f)(3). The operator-permittee's reports should identify each entity that is performing the control measures within the geographic jurisdiction of the regulated small MS4. If the other entity also operates a regulated MS4 and files reports on the progress of implementation of the measures within the geographic jurisdiction of the MS4, then the operator-permittee need not include that same information in its own reports.

If the other entity operates a regulated MS4 and is performing all of the minimum measures for the permittee, the permittee is not required to file the reports required by § 122.34(f)(3). This relief from reporting is specified in § 122.35(a).

Section 122.35 addresses the concerns of some commenters who sought relief for governmental facilities that are classified as small MS4s under today's rule. These facilities frequently discharge storm water through another regulated MS4 and could be regulated by that MS4's program. For example, a State owned office complex that operates its storm sewer system in an urbanized area will be regulated as an MS4 under today's rule even though its system may be subject to the storm water controls of the municipality in

R0018139

which it is located. Today's rule specifically revised the definition of MS4 to recognize that different levels of government often operate MS4s and that each such separate entity (including the federal government) should be responsible for its discharges. If both MS4s agree, the downstream MS4 can develop a storm water management program that regulates the discharge from both MS4s. The upstream small MS4 operator still must submit an NOI that identifies the entity on which the upstream small MS4 operator is relying to satisfy its permit obligations. No reports are required from the upstream small MS4 operator, but the upstream operator must remain in compliance with the downstream MS4 operator's storm water management program. This option allows small MS4s to work together to develop one storm water management program that satisfies the permit obligations of both. If they cannot agree, the upstream small MS4 operator must develop its own program.

As mentioned previously, comments from federal facilities and State organizations that operate MS4s requested that their permit requirements differ from those of MS4s that are political subdivisions of States (cities, towns, counties, etc.). EPA acknowledges that there are differences; e.g., many federal and State facilities do not serve a resident population and thus might require a different approach to public education. EPA believes, however, that MS4s owned by State and federal governments can develop storm water management plans that address the minimum measures. Federal and State owned small MS4s may choose to work with adjacent municipally owned MS4s to develop a unified plan that addresses all of the required measures within the jurisdiction of all of the contiguous MS4s. The options in § 122.35 minimize the burden on small MS4s that are covered by another MS4's program.

One commenter recommended that if one MS4 discharges into a second MS4, the operator of the upstream MS4 should have to provide a copy of its NOI or permit application to the operator of the receiving MS4. EPA did not adopt this recommendation because the NOI and permit application will be publicly available; but EPA does recommend that NPDES permitting authorities consider it as a possible permit requirement. The commenter also suggested that monitoring data should be collected by the upstream MS4 and provided to the downstream MS4. EPA is not adopting such a uniform monitoring requirement because EPA believes it is more appropriate to let the MS4 operators work out the need for such data. If necessary, the downstream MS4s might want to make such data a condition to allowing the upstream MS4 to connect to its system.

v. Joint Permit Programs. Many commenters supported allowing the operators of small MS4s to apply as co-permittees so they each would not have to develop their own storm water management program. Today's rule specifically allows regulated small MS4s to join with either other small MS4s regulated under § 122.34(d) or with medium and large MS4s regulated under § 122.26(d).

As is discussed in the previous section, regulated small MS4s may indicate in their NOIs that another entity is performing one or more of its required minimum control measures. Today's rule under § 122.33(b)(1) also specifically allows the operators of regulated small MS4s to jointly submit an NOI. The joint NOI must clearly indicate which entity is required to implement which control measure in each geographic jurisdiction within the service area of the entire small MS4. The operator of each regulated small MS4 remains responsible for the implementation of each minimum measure for its MS4 (unless, as is discussed in the previous section above, the permit recognizes that another entity is responsible for completing the measure.) The joint NOI, therefore, is legally equivalent to each entity submitting its own NOI. EPA is, however, revising the rule language to specifically authorize the joint submission of NOIs in response to comments that suggested that such explicit authorization might encourage programs to be coordinated on a watershed basis.

Section 122.33(b)(2)(iii) authorizes regulated small MS4s to jointly apply for an individual permit to implement today's rule, where allowed by an NPDES permitting authority. The permit application should contain sufficient information to allow the permitting authority to allocate responsibility among the parties under one of the two permitting options in §§ 122.33(b)(2)(i) and (ii).

Section 122.33(b)(3) of today's rule also allows an operator of a regulated small MS4 to join as a co-permittee in an existing NPDES permit issued to an adjoining medium or large MS4 or source designated under the existing storm water program. This co-permittee option applies only with the agreement of all co-permittees. Under this co-permittee arrangement, the operator of the regulated small MS4 must comply with the terms and conditions of the applicable permit rather than the permit condition requirements of § 122.34 of today's rule. The regulated small MS4 that wishes to be a co-permittee must comply with the applicable requirements of § 122.26(d), but would not be required to fulfill all the permit application requirements applicable to medium and large MS4s. Specifically, the regulated small MS4 is not required to comply with the application requirements of § 122.26(d)(1)(iii) (Part 1 source identification), § 122.26 (d)(1)(iv) (Part 1 discharge characterization), and § 122.26(d)(2)(iii) (Part 2 discharge characterization data). Furthermore, the regulated small MS4 operator could satisfy the requirements in § 122.26(d)(1)(v) (Part 1 management programs) and § 122.26(d)(2)(iv) (Part 2 proposed management program) by referring to the adjoining MS4 operator's existing plan. An operator pursuing this option must describe in the permit modification request how the adjoining MS4's storm water program addresses or needs to be supplemented in order to adequately address discharges from the MS4. The request must also explain the role of the small MS4 operator in coordinating local storm water activities and describe the resources available to accomplish the storm water management plan.

EPA sought comments regarding the appropriateness of the application requirements in these subsections of § 122.26(d). One commenter stated that newly regulated smaller MS4s should not be required to meet the existing regulations' Part II application requirements under § 122.26(d) regarding the control of storm water discharges from industrial activity. EPA disagrees. The smaller MS4 operators designated for regulation in today's rule may satisfy this requirement by referencing the legal authority of the already regulated MS4 program to the extent the newly regulated MS4 will rely on such legal authority to satisfy its permit requirements. If the smaller MS4 operator plans to rely on its own legal authorities, it must identify it in the application. If the smaller MS4 operator does not elect to use its own legal authority, they may file an individual permit application for an alternate program under § 122.33(b)(2)(ii).

The explanatory language in § 122.33(b)(3) recommends that the smaller MS4s designated under today's rule identify how an existing plan "would need to be supplemented in order to adequately address your discharges." One commenter suggested that this must be regulatory language and not guidance. EPA disagrees that this needs to be mandatory language.

R0018140

Since many of the smaller MS4s designated today are "donut holes" within the geographic jurisdiction of an already regulated MS4, the larger MS4's program generally will be adequate to address the newly regulated MS4's discharges. The small MS4 applicant should consider the adequacy of the existing MS4's program to address the smaller MS4's water quality needs, but EPA is not imposing specific requirements. Where circumstances suggest that the existing program is inadequate with respect to the newly designated MS4 and the applicant does not address the issue, the NPDES permitting authority must require that the existing program be supplemented.

Commenters recommended that the application deadline for smaller MS4s designated today be extended so that existing regulated MS4s would not have to modify their permit in the middle of their permit term, provided that permit renewal would occur within a reasonable time (12 to 18 months) of the deadline. In response, EPA notes that today's rule allows operators of newly designated small MS4s up to three years and 90 days from the promulgation of today's rule to submit an application to be covered under the permit issued to an already regulated MS4. The permitting authority has a reasonable time after receipt of the application to modify the existing permit to include the newly designated source. If an existing MS4's permit is up for renewal in the near future, the operator of a newly designated small MS4 may take that into account when timing its application and the NPDES permitting authority may take that into account when processing the application.

Another commenter suggested that the rule should include a provision to allow permit application requirements for smaller MS4s designated today to be determined by the permitting authority to account for the particular needs/wants of an already regulated MS4 operator. EPA does not believe that the regulations should specifically require this approach. When negotiating whether to include a newly designated MS4 in its program, the already regulated MS4 operator may require the newly designated MS4's operator to provide any information that is necessary.

The co-permitting approach allows small MS4s to take advantage of existing programs to ease the burden of creating their own programs. The operators of regulated small MS4s, however, may find it simpler to apply for a program under today's rule, and to identify the medium or large MS4 operator that is implementing portions of its § 122.34(b) minimum measures.

d. Evaluation and Assessment

Under today's rule, operators of regulated small MS4s are required to evaluate the appropriateness of their identified BMPs and progress toward achieving their identified measurable goals. The purpose of this evaluation is to determine whether or not the MS4 is meeting the requirements of the minimum control measures. The NPDES permitting authority is responsible for determining whether and what types of monitoring needs to be conducted and may require monitoring in accordance with State/Tribe monitoring plans appropriate to the watershed. EPA does not encourage requirements for "end-of-pipe" monitoring for regulated small MS4s. Rather, EPA encourages permitting authorities to carefully examine existing ambient water quality and assess data needs. Permitting authorities should consider a combination of physical, chemical, and biological monitoring or the use of other environmental indicators such as exceedance frequencies of water quality standards, impacted dry weather flows, and increased flooding frequency. (Claytor, R. and W. Brown. 1996. *Environmental Indicators to Assess Storm Water Control Programs and Practices.* Center for Watershed Protection, Silver Spring, MD.) Section II.L., Water Quality Issues, discusses monitoring in greater detail.

As recommended by the Intergovernmental Task Force on Monitoring Water Quality (ITFM), the NPDES permitting authority is encouraged to consider the following watershed objectives in determining monitoring requirements: (1) To characterize water quality and ecosystem health in a watershed over time, (2) to determine causes of existing and future water quality and ecosystem health problems in a watershed and develop a watershed management program, (3) to assess progress of watershed management program or effectiveness of pollution prevention and control practices, and (4) to support documentation of compliance with permit conditions and/or water quality standards. With these objectives in mind, the Agency encourages participation in group monitoring programs that can take advantage of existing monitoring programs undertaken by a variety of governmental and nongovernmental entities. Many States may already have a monitoring program in effect on a watershed basis. The ITFM report is included in the docket for today's rule (Intergovernmental Task Force on Monitoring Water Quality. 1995. *The Strategy for Improving Water-Quality Monitoring in the United States: Final Report of the Intergovernmental Task Force on Monitoring Water Quality.* Copies can be obtained from: U.S. Geological Survey, Reston, VA.).

EPA expects that many types of entities will have a role in supporting group monitoring activities—including federal agencies, State agencies, the public, and various classes or categories of point source dischargers. Some regulated small MS4s might be required to contribute to such monitoring efforts. EPA expects, however, that their participation in monitoring activities will be relatively limited. For purposes of today's rule, EPA recommends that, in general, NPDES permits for small MS4s should not require the conduct of any additional monitoring beyond monitoring that the small MS4 may be already performing. In the second and subsequent permit terms, EPA expects that some limited ambient monitoring might be appropriately required for perhaps half of the regulated small MS4s. EPA expects that such monitoring will only be done in identified locations for relatively few pollutants of concern. EPA does not anticipate "end-of-pipe" monitoring requirements for regulated small MS4s.

EPA received a wide range of comments on this section of the rule. Some commenters believe that EPA should require monitoring; others want a strong statement that the newly regulated small MS4s should not be required to monitor. Many commenters raised questions about exactly what EPA expects MS4s to do to evaluate and assess their BMPs. EPA has intentionally written today's rule to provide flexibility to both MS4s and permitting authorities regarding appropriate evaluation and assessment. Permitting authorities can specify monitoring or other means of evaluation when writing permits. If additional requirements are not specified, MS4s can decide what they believe is the most appropriate way to evaluate their storm water management program. As mentioned above, EPA expects that the necessity for monitoring and its extent may change from permit cycle to permit cycle. This is another reason for making the evaluation and assessment rule requirements very flexible.

i. Recordkeeping. The NPDES permitting authority is required to include at least the minimum appropriate recordkeeping conditions in each permit. Additionally, the NPDES permitting authority can specify that permittees develop, maintain, and/or

R0018141

submit other records to determine compliance with permit conditions. The MS4 operator must keep these records for at least 3 years but is not required to submit records to the NPDES permitting authority unless specifically directed to do so. The MS4 operator must make the records, including the storm water management program, available to the public at reasonable times during regular business hours (see 40 CFR 122.7 for confidentiality provision). The MS4 operator is also able to assess a reasonable charge for copying and to establish advance notice requirements for members of the public.

EPA received a comment that questioned EPA's authority to require MS4s to make their records available to the public. EPA disagrees with the commenter and believes that the CWA does give EPA the authority to require that MS4 records be available. It is also more practical for the public to request records directly from the MS4 than to request them from EPA who would then make the request to the MS4. Based on comments, EPA revised the proposed rule so as not to limit the time for advance notice requirements to 2 business days.

ii. Reporting. Under today's rule, the operator of a regulated small MS4 is required to submit annual reports to the NPDES permitting authority for the first permit term. For subsequent permit terms, the MS4 operator must submit reports in years 2 and 4 unless the NPDES permitting authority requires more frequent reports. EPA received several comments supporting this timing for report submittal. Other commenters suggested that annual reports during the first permit cycle are too burdensome and not necessary. EPA believes that annual reports are needed during the first 5-year permit term to help permitting authorities track and assess the development of MS4 programs, which should be established by the end of the initial term. Information contained in these reports can also be used to respond to public inquiries.

The report must include (1) the status of compliance with permit conditions, an assessment of the appropriateness of identified BMPs and progress toward achieving measurable goals for each of the minimum control measures, (2) results of information collected and analyzed, including monitoring data, if any, during the reporting period, (3) a summary of what storm water activities the permittee plans to undertake during the next reporting cycle, and (4) a change in any identified measurable goal(s) that apply to the program elements.

The NPDES permitting authority is encouraged to provide a brief two-page reporting format to facilitate compiling and analyzing the data from submitted reports. EPA does not believe that submittal of a brief annual report of this nature is overly burdensome, and has not changed the required reporting time frame from the proposal. The permitting authority will use the reports in evaluating compliance with permit conditions and, where necessary, will modify the permit conditions to address changed conditions.

iii. Permit-As-A-Shield. Section 122.36 describes the scope of authorization (i.e. "permit-as-a-shield") under an NPDES permit as provided by section 402(k) of the CWA. Section 402(k) provides that compliance with an NPDES permit is deemed compliance, for purposes of enforcement under CWA sections 309 and 505, with CWA sections 301, 302, 306, 307, and 403, except for any standard imposed under section 307 for toxic pollutants injurious to human health.

EPA's Policy Statement on Scope of Discharge Authorization and Shield Associated with NPDES Permits, originally issued on July 1, 1994, and revised on April 11, 1995, provides additional information on this matter.

e. Other Applicable NPDES Requirements

Any NPDES permit issued to an operator of a regulated small MS4 must also include other applicable NPDES permit requirements and standard conditions, specifically the applicable requirements and conditions at 40 CFR 122.41 through 122.49. Reporting requirements for regulated small MS4s are governed by § 122.34 and not the existing requirements for medium and large MS4s at § 122.42(c). In addition, the NPDES permitting authority is encouraged to consult the Interim Permitting Approach, issued on August 1, 1996. The discussion on the Interim Permitting Approach in Section II.L.1, Water Quality Based Effluent Limits, provides more information. The provisions of §§ 122.41 through 122.49 establish permit conditions and limitations that are broadly applicable to the entire range of NPDES permits. These provisions should be interpreted in a manner that is consistent with provisions that address specific classes or categories of discharges. For example, § 122.44(d) is a general requirement that each NPDES permit shall include conditions to meet water quality standards. This requirement will be met by the specific approach outlined in today's rule for the implementation of BMPs. BMPs are the most appropriate form of effluent limitations to satisfy technology requirements and water quality-based requirements in MS4 permits (see the introduction to Section II.H.3, Municipal Permit Requirements, Section II.H.3.h, Reevaluation of Rule, and the discussion of the Interim Permitting Policy in Section II.L.1. below).

f. Enforceability

NPDES permits are federally enforceable. Violators may be subject to the enforcement actions and penalties described in CWA sections 309, 504, and 505 or under similar water pollution enforcement provisions of State, tribal or local law. Compliance with a permit issued pursuant to section 402 of the Clean Water Act is deemed compliance, for purposes of sections 309 and 505, with sections 301, 302, 306, 307, and 403 (except any standard imposed under section 307 for toxic pollutants injurious to human health).

g. Deadlines

Today's final rule includes "expeditious deadlines" as directed by CWA section 402(p)(6). In proposed § 122.26(e), the permit application for the "ISTEA" facilities was maintained as August 7, 2001 and the permit application deadline for storm water discharges associated with other construction activity was established as 3 years and 90 days from the final rule date. In proposed § 122.33(c)(1), operators of regulated small MS4s were required to seek permit coverage within 3 years and 90 days from the date of publication of the final rule. In proposed § 122.33(c)(2), operators of regulated small MS4s designated by the NPDES permitting authority on a local basis under § 122.32(a)(2) must seek coverage under an NPDES permit within 60 days of notice, unless the NPDES permitting authority specifies a later date.

In order to increase the clarity of today's final rule, EPA has changed the location of some of the above requirements. All application deadlines for both Phase I and Phase II are now listed or referenced in § 122.26(e). Section 122.26(e)(1) contains the deadlines for storm water associated with industrial activity. Paragraph (i) has been changed to correct a typographical error. Paragraph (ii) has been revised to reflect the changed application date for "ISTEA" facilities. (See discussion in section I.3, ISTEA Sources). The application deadline for storm water discharges associated with other construction activity is now in a new § 122.26(e)(8). The application deadline for regulated small MS4s remains in § 122.33(c) because this section is written in "readable regulation" format, but it is also described in a new § 122.26(e)(9).

Under today's rule, permitting authorities are allowed up to 3 years to issue a general permit and MS4s designated under § 122.32(a)(1) are allowed up to 3 years and 90 days to submit a permit application. Operators of regulated small MS4s that choose to be a co-permittee with an adjoining MS4 with an existing NPDES storm water permit must apply for a modification of that permit within the same time frame. Several commenters stated that 90 days was not adequate time to submit an NOI. This might be true if facilities did not start developing their storm water program until publication of their general permit. In fact, municipalities should start developing their storm water program upon publication of today's final rule, if they have not already done so. Municipalities that are uncertain if they fall within the urbanized area should ask their permitting authority. EPA believes that municipalities should not automatically take three years and 90 days to develop a program and submit their NOI. Three years is the maximum amount of time to issue a general permit. MS4s that are automatically designated under today's rule may have less than 3 years and 90 days if the permitting authority issues a permit that requires submission of NOIs before that time. EPA encourages States to modify their NPDES program to include storm water and issue their permits as soon as possible. It is important for permitting authorities to keep their municipalities informed of their progress in developing or modifying their NPDES storm water requirements.

EPA recognizes that MS4s brought into the program due to the 2000 Census calculations do not have as much time to develop a program as those already designated from the 1990 Census. However, the official Bureau of the Census urbanized area calculation for the 2000 Census is expected to be published in the **Federal Register** in the spring of 2002, which should give the potentially affected MS4s adequate time to prepare for compliance under the applicable permit. However, if the publication of this information is delayed, MS4s in newly designated urbanized areas will have 180 days from the time the new designations are published to submit an NOI, consistent with the time frame for other regulated 1S4s that are designated after promulgation of the rule.

The proposed application deadline for MS4s designated under § 122.32(a)(2) was within 60 days of notice. Many commenters stated that 60 days does not provide adequate time for the preparation of an NOI or permit application. EPA agrees that newly designated MS4s may not be aware that they might be designated since the permitting authority could take several years to develop designation criteria. EPA has decided that the application time frame for these facilities should be consistent with the 180 days allowed for facilities designated under §§ 122.26(a)(9)(i)(C) and (D). Section 122.33(c)(2) of today's final rule contains the modified time frame of 180 days to apply for coverage.

h. Reevaluation of Rule

The municipal caucus of the Storm Water Phase II FACA Subcommittee asked EPA to demonstrate its commitment to revisit the municipal requirements of today's rule and make changes where necessary after evaluating the storm water program and researching the effectiveness of municipal BMPs. In § 122.37 of today's final rule, EPA commits to revisiting the regulations for the municipal storm water discharge control program after completion of the first two permit terms. EPA intends to use this time to work closely with stakeholders on research efforts. Gathering and analyzing data related to the storm water program, including data regarding the effectiveness of BMPs, is critical to EPA's storm water program evaluation. EPA does not intend to change today's NPDES municipal storm water program until the end of this period, except under the following circumstances: a court decision requires changes; a technical change is necessary for implementation; or the CWA is modified, thereby requiring changes. After careful analysis, EPA might also consider changes from consensus-based stakeholder requests regarding requirements applicable to newly regulated MS4s. EPA will apply the August 1, 1996, Interim Permitting Approach to today's program during this interim period and encourages all permitting authorities to use this approach in municipal storm water permits for newly regulated MS4s and in determining MS4 permit requirements under a TMDL approach. After careful consideration of the data, EPA will make modifications as necessary.

EPA received comments that supported waiting two permit cycles before re-evaluating the rule and other comments that requested re-evaluation much sooner. EPA anticipates two full permit cycles are necessary to obtain enough data to significantly evaluate the rule. The re-evaluation time frame of 13 years from today remains as proposed.

I. Other Designated Storm Water Discharges

1. Discharges Associated with Small Construction Activity

Section 122.26(b)(15) of today's rule designates certain construction activities for regulation as "storm water discharges associated with small construction activity." Specifically, storm water discharges from construction activity equal to or greater than 1 acre and less than 5 acres are automatically designated except in those circumstances where the operator (i.e., person responsible for discharges that might occur) certifies to the permitting authority that one of two specific waiver circumstances (described in section b. below) applies. Sites below one acre may be designated under § 122.26(b)(15)(ii) where necessary to protect water quality.

Today's rule regulates these construction-related storm water sources under CWA section 402(p)(6) to protect water quality rather than under CWA section 402(p)(2). Designation under 402(p)(6) gives States and EPA the flexibility to waive the permit requirement for construction activity that is not likely to impair water quality, and to designate additional sources below one acre that are likely to cause water quality impairment. Thus, the one acre threshold of today's rule is not an absolute threshold like the five acre threshold that applies under the existing storm water rule.

Today's rule regulating certain storm water discharges from construction activity disturbing less than 5 acres is consistent with the 9th Circuit remand in *NRDC* v. *EPA*, 966 F.2d 1292 (9th Cir. 1992). In that case, the court remanded portions of the existing storm water regulations related to discharges from construction sites. The existing Phase I regulations define "storm water discharges associated with industrial activity" to include storm water discharges from construction sites disturbing 5 acres or more of total land area (see 40 CFR 122.26(b)(14)(x)). In its decision, the court concluded that the 5-acre threshold was improper because the Agency had failed to identify information "to support its perception that construction activities on less than 5 acres are non-industrial in nature" (966 F.2d at 1306). The court remanded the exemption to EPA for further proceedings (966 F.2d at 1310). EPA's objectives in today's action include an effort to (1) address the 9th Circuit

R0018143

remand to reconsider regulation of storm water discharges from construction activities that disturb less than 5 acres of land, (2) address water quality concerns associated with such activities, and (3) balance conflicting recommendations and concerns of stakeholders in the regulation of additional construction activity.

EPA responded to the Ninth Circuit's decision by designating discharges from construction activities that disturb between 1 and 5 acres as "discharges associated with small construction activity" under CWA section 402(p)(6), rather than as "discharges associated with industrial activity" under CWA section 402(p)(2)(B). Although a size criterion alone may be an indicator of whether runoff from construction sites between 1 and 5 acres is "associated with industrial activity," the Agency is instead relying on a size threshold in tandem with provisions that allow for designations and waivers based on potential for "predicted water quality impairments" to regulate construction sites between 1 and 5 acres under CWA section 402(p)(6). This approach was chosen by the Agency for the sake of simplicity and certainty and, most importantly, to protect water quality consistent with the mandate of CWA section 402(p)(6). Today's rule also includes extended application deadlines for this new category of dischargers under the authority of CWA section 402(p)(6) (see § 122.26(e)(8) of today's rule).

In today's rule, EPA is regulating storm water discharges from additional construction sites to better protect the Nation's waters, while remaining sensitive to a concern that the Agency should not regulate discharges from construction sites that might not or do not have adverse water quality impacts. EPA believes that today's rule will successfully accomplish this objective by establishing a 1-acre threshold nationwide that includes the flexibility to allow the permitting authority to both waive requirements for discharges from sites that are not expected to cause adverse water quality impacts and to designate discharges from sites below 1-acre based on adverse water quality impacts.

In addition to the diminishing water quality benefits of regulating all sites below one acre, the Agency relied on practical considerations in establishing a one acre threshold and not setting a lower threshold. Regardless of the threshold established by EPA, a NPDES permit can only be required if a construction site has a point source discharge. A point source discharge means that pollutants are added to waters of the United States through a discernible, confined, discrete conveyance. "Sheet flow" runoff from a small construction site would not result in a point source discharge unless and until it channelized. As the amount of disturbed land surface decreases, precipitation is less likely to channelize and create a "point source" discharge (assuming the absence of steep slopes or other factors that lead to increased channelization). Categorical designation of very small sites may create confusion about applicability of the NPDES permitting program to those sites. EPA's one acre threshold reflects, in part, the need to recognize that smaller sites are less likely to result in point source discharges. Of course, the NPDES permitting authority could designate smaller sites (below one acre, assuming point source discharges occur from the smaller designated sites) for regulation if a watershed or other local assessment indicated the need to do so. The Phase II rule includes this designation authority at 40 CFR 122.26(a)(9)(i)(D) and (b)(15)(ii).

The one acre threshold also provides an administrative tool for more easily identifying those sites that are identified for coverage by the rule (but may receive a waiver) and those that are not automatically covered (but may be designated for inclusion). Although all construction sites less than five acres could have a significant water quality impact cumulatively, EPA is automatically designating for permit coverage only those storm water discharges from construction sites that disturb land equal to or greater than one acre. Categorical regulation of discharges from construction below this one acre threshold would overwhelm the resources of permitting authorities and might not yield corresponding water quality benefits. Construction activities that disturb less than one acre make up, in total, a very small percentage of the total land disturbance from construction nationwide. The one acre threshold is reasonable for accomplishing the water quality goals of CWA section 402(p)(6) because it results in 97.5% of the total acreage disturbed by construction being designated for coverage by the NPDES storm water program, while excluding from automatic coverage the numerous smaller sites that represent 24.7% of the total number of construction sites.

Some commenters believed that EPA has not adequately identified water quality problems associated with storm water discharges from construction activity disturbing less than five acres. Other commenters believed that storm water discharges from small construction activity is a significant water quality problem nationwide. Section I.B.3, Construction Site Runoff provides a detailed discussion of adverse water quality impacts resulting from construction site storm water discharges. EPA is regulating storm water discharges from construction activity disturbing between 1 and 5 acres because the cumulative impact of many sources, and not just a single identified source, is typically the cause for water quality impairments, particularly for sediment-related water quality standards.

Several commenters requested that EPA regulate discharges from small construction activity as "discharges associated with industrial activity" under CWA 402(p)(4) and not, as proposed, as "storm water discharges associated with other activity" under CWA 402(p)(6). EPA is regulating discharges from small construction sites as "small construction activity" under the authority of CWA section 402(p)(6), rather than section 402(p)(4), to ensure that regulation of these sources is water quality-sensitive. CWA section 402(p)(6) affords the opportunity for designations and waivers of sources based on potential for "predicted water quality impairments." Regulation of storm water "associated with industrial activity" does not necessarily focus regulation to protect water quality.

a. Scope

The definition of "storm water discharges associated with small construction activity" includes discharges from construction activities, such as clearing, grading, and excavating activities, that result in the disturbance of equal to or greater than 1 acre and less than 5 acres (see § 122.26(b)(15)(i)). Such activities could include: road building; construction of residential houses, office buildings, or industrial buildings; or demolition activity. The definition of "storm water discharges associated with small construction activity" also includes any other construction activity, regardless of size, designated based on the potential for contribution to a violation of a water quality standard or for significant contribution of pollutants to waters of the United States (§ 122.26(b)(15)(ii)). This designation is made by the Director, or in States with approved NPDES programs, either the Director or the EPA Regional Administrator.

For the purposes of today's rule, the definition of "storm water discharges associated with small construction activity" includes discharges from activities disturbing less than 1 acre if that construction activity is part of a

R0018144

"larger common plan of development or sale" with a planned disturbance of equal to or greater than 1 acre of land. A "larger common plan of development or sale" means a contiguous area where multiple separate and distinct construction activities are planned to occur at different times on different schedules under one plan, *e.g.*, a housing development of five ¼ acre lots (§ 122.26(b)(15)(i)).

In addition to the regulatory text for smaller construction, the Agency is also revising the existing text of § 122.26(b)(14)(x) to clarify EPA's intention regarding construction projects involving a larger common plan of development or sale ultimately disturbing 5 or more acres. Operators of such sites are required to seek coverage under an NPDES permit regardless of the number of lots in the larger plan because designation for permit coverage is based on the total amount of land area to be disturbed under the common plan. This designation attempts to address the potential cumulative effects of numerous construction activities concentrated in a given area.

Several commenters asked that EPA allow the permitting authority to set the appropriate size threshold based on water quality studies. While EPA agrees that location-specific water quality studies provide an ideal information base from which to make regulatory decisions, today's rule establishes a default standard for regulation in the absence of location-specific studies. The rule does allow for deviation from the default standard through additional designations and waivers, however, when supported by location-specific water quality information. The rule codifies the ability of permitting authorities to provide waivers for sites greater than or equal to one acre (the default standard) and designate additional discharges from small sites below one acre when location-specific information suggests that the default 1 acre standard is either unnecessary (waivers) or too limited (designations) to protect water quality.

Some commenters wanted EPA to base the regulation of storm water discharges from construction sites not only on size, but also on the duration and intensity of activity occurring on the site. EPA believes that a national 1-acre threshold, in combination with waivers and additional designations, is the most effective and simplest way to address adverse water quality impacts from storm water from small construction sites. Moreover, as discussed below, the waiver for rainfall erosivity does account for projects of limited duration. EPA believes, however, that the intensity of activity occurring on-site would be a very difficult condition to quantify.

Many commenters requested that EPA maintain the 5 acre threshold from the existing regulations, which include opportunities for site-specific designation, as the regulatory scope for regulating storm water from construction sites, *i.e.*, that the Agency not automatically regulate storm water discharges from sites less than 5 acres. Several commenters wanted construction requirements to be applied to sites smaller than 1 acre, while some commenters suggested alternative thresholds of 2 or 3 acres. The rest of the commenters supported the 1 acre threshold. None of the commenters presented any data or rationales to support a specific size threshold.

EPA examined alternative size thresholds, including 0.5 acre, 1 acre, 2 acres and 5 acres. EPA had difficulty evaluating the alternative size thresholds because, while directly proportional to the size of the disturbed site, the water quality threat posed by discharges from construction sites of differing sizes varies nationwide, depending on the local climatological, geological, geographical, and hydrological influences. In order to ensure improvements in water quality nationwide, however, today's rule does not allow various permitting authorities to establish different size thresholds except based on the waiver and designation provisions of the rule. EPA believes that the water quality impact from small construction sites is as high as or higher than the impact from larger sites on a per acre basis. By selecting the 1 acre size threshold and coupling it with waivers and additional designations, EPA is seeking to standardize improvement of water quality on a national basis while providing permitting authorities with the opportunity to designate those unregulated activities causing water quality impairments regardless of site size, as well as to waive requirements when information demonstrates that regulation is unnecessary.

EPA recognizes that the size criterion alone may not be the most ideal predictor of the need for regulation, but effective protection of water quality depends as much on simplicity in implementation as it does on the scientific information underlying the regulatory criteria. The default size criterion of 1 acre will ensure protection against adverse water quality impacts from storm water from small construction sites while not overburdening the resources of permitting authorities and the construction industry to implement the program to protect water quality in the first place.

One commenter stated a need to clarify whether routine road maintenance is considered construction activity for the purpose of today's rule. The NPDES general permit for discharges from construction sites larger than 5 acres defined "commencement of construction" as the *initial* disturbance of soils associated with clearing, grading, or excavating activities or other construction activities (63 FR 7913). For construction sites disturbing less than 5 acres, EPA does not consider construction activity to include *routine* maintenance performed to maintain the *original* line and grade, hydraulic capacity, or original purpose of the facility.

Two commenters believed that the Multi-Sector General Permit for storm water discharges from industrial activities (MSGP) (60 FR 50804) already applies to storm water discharges from construction activities at oil and gas exploration and production sites and asked for a clarification on this issue. Commenters also requested a single general permit to authorize both industrial storm water discharges and construction site discharges which occur at the same industrial site.

Currently, when construction activity disturbing more than 5 acres occurs on an industrial site covered by the MSGP, authorization under a separate NPDES construction permit is needed because the MSGP does not include the "construction" industrial sector. While the MSGP does address sediment and erosion control, it is not as specific as the NPDES general permit for storm water discharges from construction activities disturbing more than 5 acres. Though permitting authorities could conceivably develop a single general permit to authorize storm water discharges associated with construction activity at these industrial facilities, the commenter's request is not addressed by today's rulemaking. When today's rule is implemented through general permits (to be issued later), the permitting authority will have discretion whether or not to incorporate the permit requirements for both the industrial storm water discharges and construction site storm water discharges into a single general permit. This type of request should be addressed to the permitting authority.

One commenter suggested that discharges from small construction sites should be regulated through a "self-implementing rule" approach. While today's rule is not a self-implementing rule, it does add § 122.28(b)(2)(v), which

R0018145

gives the permitting authority the discretion to authorize a construction general permit for sites less than 5 acres without submitting a notice of intent. Such non-registration general permits function similarly to self-implementing rules, but are, in fact, permits. Today's rule will be implemented through NPDES permits rather than self-implementing regulations to capitalize on the compliance, tracking, enforcement, and public participation associated with NPDES permits (see discussion in section II.C).

Other commenters believed that only the permitting authority should regulate construction site storm water discharges (under a NPDES permit) and that a small MS4 operator's regulation of storm water discharges associated with construction (under the small MS4 NPDES storm water program) is redundant. EPA disagrees that control measure implementation by the NPDES authority and the small MS4 operator is redundant. To the extent the two efforts overlap, today's rule provides for consolidation and coordination of substantive requirements via incorporation by reference permitting. Small MS4s operators may choose to impose more prescriptive requirements than an NPDES permitting authority based on localized water quality needs. In those cases, EPA intends that the substantive requirements from the small MS4 program should apply as the NPDES permit requirements for the construction site discharger. In cases where a small MS4 program does not prioritize and focus on storm water from construction sites (beyond the small MS4 minimum control measure in today's rule, which does not require the small MS4 operator to control construction site discharges in a manner as prescriptive as is expected for discharges regulated under NPDES permits), the Agency intends that the NPDES general permit will provide the substantive standards applicable to the construction site discharge. EPA does anticipate, however, that implementation of MS4 programs to address construction site runoff within their jurisdiction will enhance overall NPDES compliance by construction site dischargers. EPA also notes that under § 122.35(b), the permitting authority may recognize its own program to control storm water discharges from construction sites in lieu of requiring such a program in an MS4's NPDES permit, provided that the permitting authority's program satisfies the requirements of § 122.34(b)(4), including, for example, procedures for site plan reviews and consideration of information submitted by the public on individual construction sites in each jurisdiction required to be covered by the program.

b. Waivers

Under § 122.26(b)(15)(i) of today's rule, NPDES permitting authorities may waive today's requirement for construction site operators to obtain a permit in two circumstances. The first waiver is intended to apply where little or no rainfall is expected during the period of construction. The second waiver may be granted when a TMDL or equivalent analysis indicates that controls on construction site discharges are not needed to protect water quality.

The first waiver is based on "low predicted rainfall erosivity" which can be found using tables of rainfall-runoff erosivity (R) values published for each region in the U.S. R factors are published in the U.S. Department of Agriculture (USDA) Agricultural Handbook 703 (Renard, K.G., Foster, G.R., Weesies, G.A., McCool, D.K., and D.C. Yoder. 1997. *Predicting Soil Erosion by Water: A Guide to Conservation Planning with the Revised Universal Soil Loss Equation (RUSLE).* U.S. Department of Agriculture Handbook 703). The R factor varies based on the time during the year when construction activity occurs, where in the country it occurs, and how long the construction activity lasts. The permitting authority may determine, using Handbook 703, which times of year, if any, the waiver opportunity is available for construction activity. EPA will provide assistance either through computer programs or the World Wide Web on how to determine whether this waiver applies for a particular geographic area and time period. Application of this waiver for regulatory purposes will be determined by the authorized NPDES authority. This waiver is discussed further in the following section titled Rainfall-Erosivity Waiver.

The second waiver is based on a consideration of ambient water quality. This waiver is available after a State or EPA develops and implements TMDLs for the pollutant(s) of concern from storm water discharges associated with construction activity. This waiver is also available for sites discharging to non-impaired waters that do not require TMDLs, when an equivalent analysis has determined allocations for small construction sites for the pollutant(s) of concern or determined that such allocations are not needed to protect water quality based on consideration of existing in-stream concentrations, expected growth in pollutant contributions from all sources, and a margin of safety. The Agency envision an equivalent analysis that would demonstrate that water quality is *not* threatened by storm water discharges from small construction activity. This waiver is discussed further below in the sections titled TMDL Waiver and Water Quality Issues.

The proposed rule included a waiver based on "low predicted soil loss." This waiver provision would have been applicable on a case-by-case basis where the annual soil loss rate for the period of construction for a site, using the Revised Universal Soil Loss Equation (RUSLE), would be less than 2 tons/acre/year. The annual soil loss rate of less than 2 tons/acre/year would be calculated through the use of the RUSLE equation, assuming the constants of no ground cover and no runoff controls in place.

Several commenters found the low soil loss waiver too complex and impractical, and stated that expertise is not available at the local level to prepare and evaluate eligibility for the waiver. Another commenter questioned whether two tons/acre/year was an appropriate threshold for predicting adverse water quality impacts. Two other commenters said that RUSLE was never intended to predict off-site impacts and is not an indicator of potential harm to water quality. EPA agrees with the commenters on the difficulty associated with determining and implementing this waiver. Most construction site operators are not familiar with the RUSLE program, and the potential burden on the permitting authority, construction industry, USDA's Natural Resources Conservation Service and conservation districts probably would have been significant. The Agency has not included this waiver in the final rule.

Two commenters asked that EPA allow States the flexibility to develop their own waiver criteria but did not suggest how the Agency (or affected stakeholders) could evaluate the acceptability of alternative State waiver criteria. Therefore, the final rule does not provide for any such alternative waivers. If a State does seek to develop alternate waiver criteria, then EPA procedures afford the opportunity for subsequent actions, for example, under the Project XL Program in EPA's Office of Reinvention, which seeks cleaner, smarter, and cheaper solutions to environmental problems. Many commenters suggested that EPA extend these waivers to existing industrial storm water regulations for construction activity greater than 5 acres. These construction site discharges are regulated as industrial storm water discharges under CWA 402(p)(2) and are not eligible for such water quality-based waivers.

Two commenters were concerned that waivers would create a potential for significant degradation of small streams. EPA disagrees. If small streams are threatened, the permitting authority would choose not to provide any waivers. In addition, permitting authorities may protect small streams by designating discharges from small construction activity based on the potential for contribution to a violation of a water quality standard or for significant contribution of pollutants to waters of the U.S.

Two commenters asked that the waiver options be eliminated. They felt it would create a gross inequity within the construction community if some projects will not be subject to the requirements of today's rule. While the comments may be valid, EPA disagrees that waivers should be disallowed on this basis. Construction site discharges that qualify for a waiver from permitting requirements are not expected to present a threat to water quality, which is the basis for designation and regulation under today's rule.

A number of commenters suggested additional waivers in cases where new development will result in no additional adverse impacts to water quality as compared to the existing development it replaces. EPA believes these waivers are either unworkable or unnecessary. It would be very difficult for most construction operators to determine, as well as for other stakeholders to verify, on a site-by-site basis, that there is no potential for adverse impact to water quality compared to the replaced development.

Other commenters proposed waivers in cases where a local erosion and sediment control program covers the project or a separate waiver for small linear utility projects. Instead of waivers, today's rule addresses the first suggestion through the qualifying program provision described in the section titled Cross-Referencing State/Local Erosion and Sediment Control Programs below. Today's rule provides waivers for small linear projects in so far as they satisfy conditions for low rainfall erosivity. (See § 122.26(b)(15)(i)(A).)

Other commenters suggested waivers based on distance to water body, existence of vegetated buffer around water body, slope of disturbed land, or if discharging to very large bodies of water. As a result of public outreach, EPA believes that these proposed waivers would be generally unworkable for construction site dischargers and permitting authorities because of the difficulty in applying them to all small sites.

One commenter mentioned that waivers for the R factor (rainfall-erosivity) and soil loss are effluent standards that have not been developed in accordance with sections 301 and 304 of the CWA. EPA disagrees that these sections are relevant to the designation of sources in today's rule. The waiver provisions in this section of the rule are jurisdictional because they affect the scope of the universe of entities subject to the NPDES program. Therefore, the waiver provisions are not themselves substantive control standards implemented through NPDES permits, and thus, not subject to the statutory criteria in sections 301 and 304.

Another commenter stated that waivers would allow exemptions to the technology based requirements and would thus be inconsistent with the two-fold approach of the CWA (a technology based minimum and a water quality based overlay). EPA acknowledges that the CWA does not generally provide for waivers for the Act's technology-based requirements. The waiver provisions do not create exemptions from technology-based standards that apply to NPDES dischargers; they provide exemption from the underlying requirement for an NPDES permit in the first place. Protection of water quality is the reason these smaller sites are designated for regulation under NPDES. The Act's two fold approach imposes more stringent water quality based effluent limitations when technology-based limitations applicable to regulated dischargers are insufficient to meet water quality standards. Under today's rule, water quality protection is the basis for determining which of the unregulated sources should be regulated at all. Thus, today's rule is entirely consistent with the Act's two fold approach.

i. Rainfall-Erosivity Waiver. The rainfall-erosivity waiver under § 122.26(b)(15)(i)(A) is intended to exempt the requirements for a permit when and where negligible rainfall/runoff-erosivity is expected. In the development of the Universal Soil Loss Equation, analysis of data indicated that when factors other than rainfall are held constant, soil loss is directly proportional to a rainfall factor composed of total storm kinetic energy times the maximum 30 minute intensity. The average annual sum of the storm energy and intensity values for an area comprise the R factor—the rainfall erosivity index. A detailed explanation of the R factor can be found in *Predicting Soil Erosion by Water: A Guide to Conservation Planning With the Revised Universal Soil Loss Equation (RUSLE)* (USDA, 1997).

This waiver is time-sensitive and is dependent on when during the year a construction activity takes place, how long it lasts, and the expected rainfall and intensity during that time. R factors vary based on location. EPA anticipates that this waiver opportunity responds to concerns about the requirement for a permit when it is not expected to rain, especially in the arid areas of the U.S. Under today's rule, the permitting authority could waive the requirements for a permit for time periods when the rainfall-erosivity factor ("R" in RUSLE) is less than *five* during the period of construction. For the purposes of calculating this waiver, the period of construction activity starts at the time of initial disturbance and ends with the time of final stabilization. The operator must submit a written certification to the Director in order to apply for such a waiver. EPA believes that those areas receiving negligible rainfall during certain times of the year are unlikely to have storm events causing discharges that could adversely impact receiving streams. Consequently, BMPs would not be necessary on those smaller sites. This waiver is most applicable to projects of short duration and to the arid regions of the country where the occurrence of rainfall follows a cyclic pattern—between no rain and extremely heavy rain. EPA review of rainfall records for these areas indicates that, during periods of the year when the number of events and quantity of rain are low, storm water discharges from the smaller construction sites regulated under today's rule should be minimal.

Some commenters supported the use of the R factor as a waiver, while others felt that a waiver based on rainfall statistics ignores the fact that it may rain on any given day and it is the cumulative effect of wet weather discharges which cause water quality impairments. A commenter also asked what happens in "El Nino" years when significantly more rainfall than normal occurs. Another commenter also expressed concern that this waiver was not based on a measured water quality impact, but instead on an indicator of potential impact. In response to the previous comments, EPA notes that, under CWA 402(p)(6), sources are designated on their *potential* for adverse impact. Designation under the section is prospective, not retrospective or remedial only. For that reason, the waivers under today's rule also operate prospectively. EPA wanted to waive requirements for sites with little potential to impair water quality, and the R factor is the most straightforward way to do this. The permitting authority, if electing to use waivers, could always suspend the use of waivers in certain areas or during certain times. In addition, the permitting authority may choose to use a lower R factor threshold than the one set by EPA. Application of this waiver is at the discretion of the permitting authority, subject only to the limitation that R factors cannot exceed 5.

One commenter expressed the need for EPA to provide a justification for the threshold value used for the R factor. None of the commenters included any data to show that EPA's proposed R factor of 2 was either too high or too low. EPA is using the R factor as an indicator of the potential to impact water quality. In an effort to determine which R threshold should be used, EPA conducted additional analysis of the rainfall/runoff erosivity factor for 134 sites across the country. For an R factor threshold of 5, approximately 12% of sites would be waived if the project period lasted 6 months, 27% for 3 months, 47% for 1 month, and 60% of sites would be waived if the project lasted for only 15 days. None of the 134 sites would be waived if the project lasted an entire year. For an R factor threshold of 2, approximately 9% of sites would be waived if the project period lasted 6 months, 15% for 3 months, 31% for 1 month, and 43% for 15 days. For an R factor threshold of 10, approximately 22% of sites would be waived if the project period lasted 6 months, 37% for 3 months, 60% for 1 month, and 78% for 15 days. EPA believes that an R factor of 5 is an adequate threshold to waive requirements for sites because they would not reasonably be expected to impair water quality.

EPA will develop, as part of the tool box described in section II.A.5, guidance materials and computer or web-accessible programs to assist permitting authorities and construction site discharges in determining if any resulting storm water discharges from specific projects are eligible for this waiver.

ii. Water Quality Waiver. The water quality waiver under § 122.26(b)(15)(i)(B) is available where storm water controls are not needed based on a comprehensive, location-specific evaluation of water quality needs. The waiver is available based on either an EPA-approved "total maximum daily load" (TMDL) under section 303(d) of the CWA that addresses the pollutant(s) of concern or, for sites discharging to non-impaired waters that do not require TMDLs, an equivalent analysis that has either determined allocations for small construction sites for the pollutant(s) of concern or determined that such allocations are not needed to protect water quality based on consideration of existing in-stream concentrations, expected growth in pollutant contributions from all sources, and a margin of safety. The pollutants of concern that must be addressed include sediment or a parameter that addresses sediment (such as total suspended solids (TSS), turbidity or siltation) and any other pollutant that has been identified as a cause of impairment of any water body that will receive a discharge from the construction activity. The operator must certify to the NPDES permitting authority that the construction activity will take place, and storm water discharges will occur, within the applicable drainage area evaluated in the TMDLs or equivalent analyses.

Today's rule modifies the approach in the proposed rule. EPA proposed to allow a waiver of permit requirements for small construction if storm water controls were determined to be unnecessary based on "wasteload allocations that are part of 'total maximum daily loads' (TMDLs) that address the pollutants of concern," or "a comprehensive watershed plan, implemented for the water body, that includes the equivalents of TMDLs, and addresses the pollutants of concern."

Commenters asked for clarification of the terms "comprehensive watershed plans" and "equivalent of TMDLs." EPA intended that both terms would include a comprehensive analysis that determines that controls on small construction sites are not needed based on consideration of existing in-stream concentrations, expected growth in pollutant contributions from all sources, and a margin of safety. Today's rule makes this clarification.

One commenter pointed out that there are no water quality standards for suspended solids, the major pollutant expected in discharges from construction activity. The commenter asserted that no waiver would ever be available. Another commenter noted that there are no sediment criteria developed for streams, also making this waiver useless. EPA notes that a number of States and Tribes have water quality standards that address TSS, which are narrative in form, and that may serve as a basis for water quality-based effluent limits. As efforts to identify impairments and improve water quality progress, some States may yet develop water quality standards for suspended solids. Although several TMDLs for sediment and related parameters have been established, EPA does recognize that currently it is extremely difficult to develop TMDLs for sediment. EPA is partially addressing this concern by clarifying in today's rule that the waivers may be based on a TMDL or equivalent analyses for sediment or one of the various pollutant parameters that are a proxy for sediment. These include TSS, turbidity and siltation.

Other commenters noted that this waiver was unattainable if a TMDL or equivalent analysis must be available for every pollutant that could possibly be present in any amount in discharges from small construction sites regardless of whether the pollutant is causing water quality impairment. Commenters asked that EPA identify what constitutes the "pollutants of concern" for which a TMDL or its equivalent must be developed. EPA has revised the proposed rule in response to these concerns.

In order for discharges from construction sites under five acres to qualify for the water quality waiver of today's rule, the construction site operator must demonstrate that storm water controls are not necessary for sediment or a parameter that addresses sediment (such as TSS, turbidity or siltation) and any other pollutant that has been identified as a cause of impairment of any water body that will receive a discharge from the construction activity. Even if the water body is not currently impaired for sediment, today's rule requires an analysis of the potential impacts of sediment because the storm water discharges from the construction activity will be a new source of loading to the water body that could constitute a new impairment. Because the water body will not necessarily have been included on a "303(d) list" and a TMDL will not necessarily be required, the rule continues to allow an analysis that is the equivalent of a TMDL. The designation of storm water discharges from small construction activity for regulation in today's rule is intended to control pollutants other than sediment. This waiver provision requires a TMDL or equivalent analysis for a pollutant other than gross particulates (*i.e.*, sediment and other particulate-focused pollutant parameters) only if the receiving water is currently impaired for that pollutant.

One commenter expressed the concern that construction operators will not know if they are in a watershed covered by a TMDL. To the extent this is an operator's concern, he or she could contact their NPDES permitting authority before applying for permit coverage to determine if receiving water is subject to a TMDL. Alternatively, the permitting authority could identify the TMDL (or equivalent analysis) areas in the general permit or another operator-accessible information source.

Another commenter expressed the concern that a TMDL waiver is likely to be ineffective because the TMDL list is submitted only once every 2 years. By the time a water is listed, the activity may have been completed and stabilized. The commenter argued that, if a watershed is impaired due to sediment from construction, then storm water controls will still be needed, because small construction can only be waived when it is not identified as a source of impairment. In response, EPA notes that an analysis that is the equivalent of a TMDL (specifically, equivalent to the component of a TMDL that comprehensively analyses existing ambient conditions against the applicable water quality standards) may also provide a basis for waiver from the default 1 acre designation. Also, even if a water has been identified as impaired for sediment, it is possible that a site or category of sites may receive an allocation that is sufficiently high enough to allow discharges without storm water controls.

c. Permit Process and Administration

The operator of the construction site, as with any operator of a point source discharge, is responsible for obtaining coverage under a NPDES permit as required by § 122.21(b). The "operator" of the construction site, as explained in the current NPDES construction general permit, is typically the party or parties that either individually or collectively meet the following two criteria: (1) Operational control over the site specifications, including the ability to make modifications in the specifications; and (2) day-to-day operational control of those activities at the site necessary to ensure compliance with permit conditions (63 FR 7859). If more than one party meets these criteria, then each party involved would typically be a co-permittee with any other operators. The operator could be the owner, the developer, the general contractor, or individual contractor. When responsibility for operational control is shared, all operators must apply.

In today's rule, EPA is not requiring an NOI for NPDES general permits for storm water discharges from construction activities regulated by § 122.26(b)(15) if the NPDES permitting authority finds that the use of NOIs would be inappropriate (see § 122.28(b)(2)(v)). Under this approach, the NPDES permitting authority will have the discretion to decide whether or not to require NOIs for discharges from construction activity less than 5 acres. Compared to the existing storm water regulation, the permitting authority thus has increased flexibility in program implementation. EPA does recommend the use of NOIs, however because NOIs track permit coverage and provide a useful information source to prioritize inspections or enforcement. Requiring an NOI allows for greater accountability by, and tracking of, dischargers. This simple permit application and reporting mechanism also allows for better outreach to the regulated community, uses an existing and familiar mechanism, and is consistent with the existing requirements for storm water discharges from larger construction activities. Today's rule does not amend the requirement for NOIs in general permits for storm water discharges from construction activity disturbing 5 acres for more. See § 122.28(b)(2)(v).

EPA expects that the vast majority of discharges of storm water associated with small construction activity identified in § 122.26(b)(15) will be regulated through general permits. In the event that an NPDES permitting authority decides to issue an individual construction permit, however, individual application requirements for these construction site discharges are found at § 122.26(c)(1)(ii). For any discharges of storm water associated with small construction activity identified in § 122.26(b)(15) that are not authorized by a general permit, a permit application made pursuant to § 122.26(c) must be submitted to the Director by 3 years and 90 days after publication of the final rule.

Some commenters expressed concern that linear construction projects (*e.g.*, roads, highways, pipelines) that cross several jurisdictions will have to comply with multiple sets of requirements from various jurisdictions, including multiple local governments and States. EPA is limited in its options to address these concerns because the Agency cannot issue NPDES permits in States authorized to implement the NPDES program nor preempt other more stringent local and State requirements. EPA believes, however, that the option for incorporating by reference the State, Tribal or local requirements (see discussion in Section II.I.2.d., Cross-Referencing State/Local Erosion and Sediment Control Programs) should limit the administrative burden on the operator responsible for discharges from linear construction projects. If the operator were to implement the most comprehensive of the various requirements for the whole project, it could avoid confusion due to differing requirements for different sections of the project. In addition, linear utility projects, which usually have a shorter project period, are more likely to be eligible for the rainfall erosivity waiver.

One commenter stated there was no reason to delay the application period for regulated storm water discharges from small construction activities. The commenter requested that the newly regulated construction site discharges should be required to seek permit coverage within 90 days, as opposed to 3 years, of the effective date of the rule. The Agency does not accept this request. EPA anticipates that NPDES permitting authorities will need one to two years to develop adequate legal authority to implement a program to address this new category of discharges, as well as to develop and issue general permits. Moreover, to ensure effective implementation to protect water quality, regulatory authorities will need additional time to inform small construction site operators of requirements and provide guidance and training on these requirements.

Finally, EPA received a comment requesting that the three year file retention requirement be deleted for discharges from small construction sites. While EPA recognizes that the three year record retention schedule may be unnecessary for certain construction projects, the Agency has determined it is necessary to retain files after the completion of the project to ensure permit compliance, including applicable construction site stabilization enabling permit termination for such sites.

d. Cross-Referencing State, Tribal or Local Erosion and Sediment Control Programs

In developing the NPDES permit requirements for construction sites less than 5 acres, members of the Storm Water Phase II FACA Subcommittee asked EPA to try to minimize redundancy in the construction permit requirements. In response, today's rule at § 122.44(s) provides for incorporation of qualifying State, Tribal or local erosion and sediment control program requirements by reference into the NPDES permit authorizing storm water discharges from construction sites (described under §§ 122.26(b)(15) and (b)(14)(x)). The incorporation by reference approach applies not only to the newly regulated storm water discharges (from construction activity disturbing between 1 and 5 acres, including designated sites, but excluding waived sites) but also to discharges from construction activity disturbing 5 or more acres already covered by the existing storm water regulations. For this latter category of discharges from construction activity disturbing 5 or more acres, the incorporation by reference approach requires that the pollutant control requirements from the incorporated program also satisfy the statutory standard for limitations representing application of the best available technology economically achievable (BAT) and best conventional pollutant control technology (BCT).

For permits issued for discharges from small construction activity defined under § 122.26(b)(15), a qualifying State, Tribal, or local erosion and sediment control program is one that includes the program elements described under § 122.44(s)(1). These elements include requirements for construction site operators to implement appropriate erosion and sediment control BMPs, requirements to control waste, a requirement to develop a storm water pollution prevention plan, and requirements to submit a site plan for review. A storm water pollution prevention plan includes site descriptions, descriptions of appropriate control measures, copies of approved State, Tribal or local requirements, maintenance procedures, inspection procedures, and identification of non-storm water discharges. The construction site's permit would require it to follow the requirements of the qualifying local program rather than require it to follow two different sets of requirements. If a partially-qualifying program does not have all of the elements described under § 122.44(s)(1), then the NPDES permitting authority may still incorporate language in the small construction site discharge's permit that requires the construction site operator to follow the program, but the construction site discharge permit also must incorporate the missing required elements in order to satisfy CWA requirements.

The term "local" refers to the geographic area of applicability, not the form of government that develops and administers the program. Thus, a qualifying federal erosion and control program, such as certain programs developed and administered by the federal Bureau of Land Management, could be a qualifying local program.

As a result of this provision, local requirements will, in effect, provide the substantive construction site erosion and sediment control requirements for the NPDES permit authorization. Therefore, by following one set of erosion and sediment control requirements, construction site operators satisfy both local and NPDES permit requirements without duplicative effort. At the same time, noncompliance with the referenced local requirements will be considered noncompliance with the NPDES permit which is federally enforceable. The NPDES permitting authority will, of course, retain the discretion to decide whether to include the alternative requirements in the general permit. EPA believes that this approach will best balance the need for consideration of specific local requirements and local implementation with the need for federal and citizen oversight, and will extend supplemental NPDES requirements to control storm water discharges from construction sites.

EPA developed the "incorporation by reference" approach based on implementation efforts designed by the State of Michigan. Michigan relies on localities to develop substantive controls for storm water discharges associated with construction activities on a localized basis. Localities, however, are not required to do so. In areas where the local authority does not choose to participate, the State administers the sedimentation and erosion control requirements. The State agency, as the NPDES permitting authority, receives an NOI (termed "notice of coverage" by Michigan) under the general permit and tracks and exercises oversight, as appropriate, over the activity causing the storm water discharge. Michigan's goal under these procedures is to utilize the existing erosion and sediment control program infrastructure authorized under State law for storm water discharge regulation. (See U.S. Environmental Protection Agency, Office of Water. January 7, 1994. Memo: From Michael B. Cook, Director OWEC, to Water Management Division Directors, Regarding the "Approach Taken by Michigan to Regulate Storm Water Discharges from Construction Activities.")

Most commenters supported the general concept of incorporating by reference qualifying programs. Two commenters expressed concern that different local construction requirements will create an impossible regulatory scheme for builders who work in different localities. EPA believes that allowing States to incorporate qualifying programs by reference will minimize the differences for builders who work in different areas of the State. These differences already exist, however, not only for erosion and sediment controls, but also other aspects of construction. In any event, the criteria for qualification for localized programs should provide a certain degree of standardization for various localities' requirements. EPA expects that the new rule for construction and post-construction BMPs being developed under CWA section 304(m) will also encourage standardization of local requirements. (See discussion of this new rulemaking in section II.D.1, Federal Role of this preamble).

Two commenters requested that an "incorporation by reference" should include permission, in writing, from the qualifying local program administrator because of a perceived extra burden on the referenced program. Any program requirements incorporated by reference in NPDES permits should already apply to construction site dischargers in the applicable area and therefore should not add any additional burden to the referenced program. EPA has left to the discretion of the permitting authority the decision on whether to seek permission from the qualifying program before cross-referencing it in an NPDES permit.

One commenter stated that a qualifying local program should require a SWPPP. The proposed rule defined the qualifying local program as a program the meets the minimum program requirements established in the proposed construction minimum control measure for small MS4s. To ensure consistency in the controls for storm water discharges between the larger, already regulated construction sites and the discharges from smaller sites that will be regulated as a result of today's rule, EPA has made a change to define a qualifying local program as one that includes the elements described in § 122.44(s)(1). Section 122.44(s)(1) requires the development and implementation of a storm water pollution prevention plan as a criterion for qualification of local programs for incorporation by reference. As noted above, if a qualifying program does not include all the elements in § 122.44(s)(1) then the permitting authority will need to specify the missing elements in order to rely on the incorporation by reference approach.

One commenter asked what happens in regard to the use of qualifying programs when a construction site operator is also the qualifying local program operator. The provision for incorporation by reference applies in this situation also. The local program operator will be required to comply with requirements it has established for others.

e. Alternative Approaches

EPA received a number of comments on alternative permitting approaches. Several commenters supported regulating discharges only from those construction sites within urbanized areas. Other commenters opposed this approach. EPA chose to address storm water discharges from construction sites located both within and outside urbanized areas because of the potential for adverse water quality impact from storm water discharges from smaller sites in all areas. Regulating only those sites within urbanized areas would have excluded a large number of potential contributors to water quality impairment and would not address large areas of new development occurring on the outer fringes of urbanized areas. In fact, designating only small construction discharges within urbanized areas might create a perverse incentive for building only outside urbanized areas. Such an incentive would be inconsistent with the Agency's intention behind designating to protect water quality. The Agency intends that designation to protect water quality in today's rule should be both remedial and preventive.

A number of commenters encouraged EPA to cover municipal construction activities under the small MS4 general permit, instead of issuing a separate NPDES construction permit to these municipal construction projects. Similarly, a number of commenters supported EPA giving industrial facilities the option of having storm water from construction activities on the site covered by the industrial storm water permit. Several other commenters found that combining multiple permit types under one general permit introduced a degree of complexity which was confusing to permittees. Permitting authorities have the option of combining MS4 and construction permits or industrial and construction permits, however, specific requirements for each would still need to be included in the permit issued. EPA agrees that this would probably result in a more complex and confusing permit compared to the existing component permits.

Several commenters supported an alternative for regulated small MS4s where a local qualified program alone, without an NPDES permit, is sufficient to enforce compliance with construction site discharge requirements. On the other hand, one commenter stated that linking the local construction erosion and sediment control program to the existing NPDES program for storm water from larger construction has driven improvements in many local programs. Another commenter stated that the potential fines under the NPDES program will encourage compliance and will be much stronger than any fines a local program may have. EPA agrees that the NPDES program is the best approach to address water quality impacts from construction sites and provides benefits such as accountability and federal enforcement.

A number of commenters supported issuing one permit for each construction company, instead of a permit for each individual construction activity (also requested for storm water discharges from the larger, already regulated construction sites). Other commenters found that a 'licensing' program for construction site operators would have many problems, including identifying who to permit and tracking information on active sites. EPA is regulating only the storm water discharges associated with construction activity from small sites, not the construction activity itself. Separate NPDES permits (either individual or general permit coverage) for construction site discharges avoid potential problems in tracking sites and operator accountability. Section 122.28(b)(2)(v) gives permitting authorities the option to issue a general permit without requiring an NOI. If an NOI is not required for each activity, permitting authorities could pursue other options such as a company-wide NOI, license instead of an NOI, or another mechanism.

2. Other Sources

In the *Storm Water Discharges Potentially Addressed by Phase II of the National Pollutant Discharge Elimination System Storm Water Program*, Report to Congress, March 1995, ("Report") submitted by EPA pursuant to CWA section 402(p)(5), EPA examined the remaining unregulated point sources of storm water for the potential to adversely affect water quality. Due to very limited national data on which to estimate pollutant loadings on the basis of discharge categories, the discussion of the extent of unregulated storm water discharges is limited to an analysis of the number and geographic distribution of the unregulated storm water discharges. Therefore, EPA is not designating any additional unregulated point sources of storm water on a nationwide, categorical basis. Instead, the remainder of the sources will be regulated based on case-by-case post-promulgation designations by the NPDES permitting authority.

EPA did, however, evaluate a variety of categories of discharges for potential designation in the Report. EPA's efforts to identify sources and categories of unregulated storm water discharges for potential designation for regulation in today's rule started with an examination of approximately 7.7 million commercial, retail, industrial, and institutional facilities identified as "unregulated." In general, the distribution of these facilities follows the distribution of population, with a large percentage of facilities concentrated within urbanized areas (see page 4-35 of the Report). This examination resulted in identification of two general classes of facilities with the potential for discharging pollutants to waters of the United States through storm water point sources.

The first group (Group A) included sources that are very similar, or identical, to regulated "storm water discharges associated with industrial activity" but that were not included in the existing storm water regulations because EPA used SIC codes in defining the universe of regulated industrial activities. By relying on SIC codes, a classification system created to identify industries rather than environmental impacts from these industries discharges, some types of storm water discharges that might otherwise be considered "industrial" were not included in the existing NPDES storm water program. The second general class of facilities (Group B) was identified on the basis of potential for activities and pollutants that could contribute to storm water contamination.

EPA estimates that Group A has approximately 100,000 facilities. Discharges from facilities in this group, which may be of high priority due to their similarity to regulated storm water discharges from industrial facilities, include, for example, auxiliary facilities or secondary activities (*e.g.*, maintenance of construction equipment and vehicles, local trucking for an unregulated facility such as a grocery store) and facilities intentionally omitted from existing storm water regulations (*e.g.*, publicly owned treatment works with a design flow of less than 1 million gallons per day, landfills that have not received industrial waste).

Group B consists of nearly one million facilities. EPA organized Group B sources into 18 sectors for the purposes of the Report. The automobile service sector (*e.g.*, gas/service stations, general automobile repair, new and used car dealerships, car and truck rental) makes up more than one-third of the total number of facilities identified in all 18 sectors.

EPA conducted a geographical analysis of the industrial and commercial facilities in Groups A and

B. The geographical analysis shows that the majority are located in urbanized areas (see Section 4.2.2, Geographic Extent of Facilities, in the Report). In general, about 61 percent of Group A facilities and 56 percent of Group B facilities are located in urbanized areas. The analysis also showed that nearly twice as many industrial facilities are found in all urbanized areas as are found in large and medium municipalities alone. Notable exceptions to this generalization included lawn/garden establishments, small unregulated animal feedlots, wholesale livestock, farm and garden machinery repair, bulk petroleum wholesale, farm supplies, lumber and building materials, agricultural chemical dealers, and petroleum pipelines, which can frequently be located in smaller municipalities or rural areas.

In identifying potential categories of sources for designation in today's notice, EPA considered designation of discharges from Group A and Group B facilities. EPA applied three criteria to each potential category in both groups to determine the need for designation: (1) The likelihood for exposure of pollutant sources included in that category, (2) whether such sources were adequately addressed by other environmental programs, and (3) whether sufficient data were available at this time on which to make a determination of potential adverse water quality impacts for the category of sources. As discussed previously, EPA searched for applicable nationwide data on the water quality impacts of such categories of facilities.

By application of the first criterion, the likelihood for exposure, EPA considered the nature of potential pollutant sources in exposed portions of such sites. As precipitation contacts industrial materials or activities, the resultant runoff is likely to mobilize and become contaminated by pollutants. As the size of these exposed areas increases, EPA expects a proportional increase in the pollutant loadings leaving the site. If EPA concluded that a category of sources has a high potential for exposure of raw materials, intermediate products, final products, waste materials, byproducts, industrial machinery, or industrial activity to rainfall, the Agency rated that category of sources as having "high" potential for adverse water quality impact. EPA's application of the first criterion showed that a number of Group A and B sources have a high likelihood of exposure of pollutants.

Through application of the second criterion, EPA assessed the likelihood that pollutant sources are regulated in a comprehensive fashion under other environmental protection programs, such as programs under the Resource Conservation and Recovery Act (RCRA) or the Occupational Health and Safety Act (OSHA). If EPA concluded that the category of sources was sufficiently addressed under another program, the Agency rated that source category as having "low" potential for adverse water quality impact. Application of the second criterion showed that some categories were likely to be adequately addressed by other programs.

After application of the third criterion, availability of nationwide data on the various storm water discharge categories, EPA concluded that available data would not support any such nationwide designations. While such data could exist on a regional or local basis, EPA believes that permitting authorities should have flexibility to regulate only those categories of sources contributing to localized water quality impairments.

EPA received comments requesting designation of additional industrial, commercial and retail sources (*e.g.* industrial activity "look-alikes", roads, commercial facilities and institutions, and vehicle maintenance facilities) in the final rule, because the commenters believe that the data exist to support national designation of some of these sources. Other comments were received opposing designation of any additional sources. Today's rule does not designate any additional industrial or commercial category of sources either because EPA currently lacks information indicating a consistent potential for adverse water quality impact or because of EPA's belief that the likelihood of adverse impacts on water quality is low, with some possible exceptions on a more local basis. Since the time the Agency submitted the Report, EPA has continued to seek additional data and has requested available data from the FACA members. If sufficient regional or nationwide data become available in the future, the permitting authority could at that time designate a category of sources or individual sources on a case-by-case basis. Therefore, today's rule encourages control of storm water discharges from Groups A and B through self-initiated, voluntary BMPs, unless the discharge (or category of discharges) is designated for permitting by the permitting authority. See discussion in section I.D., EPA's Reports to Congress.

3. ISTEA Sources

Provisions within the Intermodal Surface Transportation and Efficiency Act (ISTEA) of 1991 temporarily exempted storm water discharges associated with industrial activity that are owned or operated by municipalities serving populations less than 100,000 people (except for airports, power plants, and uncontrolled sanitary landfills) from the need to apply for or obtain a storm water discharge permit (section 1068(c) of ISTEA). Congress extended the NPDES permitting moratorium for these facilities to allow small municipalities additional time to comply with NPDES requirements for certain sources of industrial storm water. The August 7, 1995 storm water final rule (60 FR 40230) further extended this moratorium until August 7, 2001. However, today's rule changes this deadline so that previously exempted industrial facilities owned or operated by municipalities serving populations less than 100,000 people, must now submit an application for a permit within 3 years and 90 days from date of publication of today's rule.

EPA received comments recommending that permit requirements for municipally owned or operated industrial storm water discharges, including those previously exempt under ISTEA, be included in a single NPDES permit for all MS4 storm water discharges. The existing NPDES regulations already provide permitting authorities the ability to issue a single "combination" permit for MS4 discharges. However, if the permitting authorities chose to issue this type of permit, they must make sure that in doing so, they are not creating a double standard for industrial facilities covered under the combination permit versus those covered under separate general or individual permits. In order to avoid this double standard, combination permits would have to contain requirements that are the same or very similar to the requirements found in separate MS4 and industrial permits, *i.e.*, the minimum measures and other necessary requirements of an MS4 permit, and the SWPPP, monitoring and reporting requirements, and other necessary requirements of an industrial permit. If such a combined MS4 general permit were issued, the regulations require that each discharger submit NOIs for their respective discharges, except for discharges from small construction activities. Flexibility exists in developing a combination NOI which could reduce the need to submit duplicative information, *e.g.* owner/operator name and address. The combination NOI would still need to require specific information for each separate municipally owned or operated industrial location, including

R0018152

construction projects disturbing 5 or more acres. The regulations at § 122.28(b)(2)(ii) list the necessary contents of an NOI, which require: the facility name, facility address, type of facility or discharge and receiving stream for each industrial discharge location. When viewed in its entirety, a combination permit, which by necessity would need to contain all elements of otherwise separate industrial and MS4 permit requirements, and require NOI information for each separate industrial activity, may have few advantages when compared to obtaining separate MS4 and industrial general permit coverage.

In order to allow the permitting authority to issue a single storm water permit for the MS4 and all municipally owned or operated industrial facilities, including those previously exempt under ISTEA, today's rule requires applications for ISTEA sources within 3 yrs and 90 days from date of publication of today's rule. The permitting authority has the ultimate decision to determine whether or not a single all-encompassing MS4 permit is appropriate.

4. Residual Designation Authority

The NPDES permitting authority's existing designation authority, as well as the petition provisions are being retained. Today's rule contains two provisions related to designation authority at §§ 122.26(a)(9)(i)(C) and (D). Subsection (C) adds designation authority where storm water controls are needed for the discharge based upon wasteload allocations that are part of TMDLs that address the pollutant(s) of concern. EPA intends that the NPDES permitting authority have discretion in the matter of designations based on TMDLs under subsection (C). Subsection (D) carries forward residual designation authority under former § 122.26(g), and has been modified to provide clarification on categorical designation. Under today's rule, EPA and authorized States continue to exercise the authority to designate remaining unregulated discharges composed entirely of storm water for regulation on a case-by-case basis (including § 123.35). Individual sources are subject to regulation if EPA or the State, as the case may be, determines that the storm water discharge from the source contributes to a violation of a water quality standard or is a significant contributor of pollutants to waters of the United States. This standard is based on the text of section CWA 402(p). In today's rule, EPA believes, as Congress did in drafting section CWA 402(p)(2)(E), that individual instances of storm water discharge might warrant special regulatory attention, but do not fall neatly into a discrete, predetermined category. Today's rule preserves the regulatory authority to subsequently address a source (or category of sources) of storm water discharges of concern on a localized or regional basis. For example, as States and EPA implement TMDLs, permitting authorities may need to designate some point source discharges of storm water on a categorical basis either locally or regionally in order to assure progress toward compliance with water quality standards in the watershed.

EPA received comments asking that § 122.26(a)(9)(i)(D) as proposed be modified to include specific language clarifying the permitting authority's ability to designate additional sources on a categorical basis as explained in the preamble to the proposed rule. One comment requested that the designation language include "categories of sources on a Statewide basis." EPA agrees that the intent of the language may not have been clear regarding categorical designation. Today's rule modifies subsection (D) to clarify that the designation authority can be applied within different geographic areas to any single discharge (i.e., a specific facility), or category of discharges that are contributing to a violation of a water quality standard or are significant contributors of pollutants to waters of the United States. The added term "within a geographic area" allows "State-wide" or "watershed-wide" designation within the meaning of the terms.

One commenter questioned the Agency's legal authority to provide for such residual designation authority. The stakeholder argued that the lapse of the October 1, 1994, permitting moratorium under CWA section 402(p)(1) eliminated the significance of the CWA section 402(p)(2) exceptions to the moratorium, including the exception for discharges of storm water determined to be contributing to a violation of a water quality standard or a significant contributor of pollutants under CWA section 402(p)(2)(E). The stakeholder further argued that EPA's authority to designate sources for regulation under CWA section 402(p)(6) is limited to storm water discharges other than those described under CWA section 402(p)(2). Because CWA section 402(p)(2)(E) describes individually designated discharges, the stakeholder concluded that regulations under CWA section 402(p)(6) cannot provide for post-promulgation designation of individual sources. EPA disagrees.

First, as explained previously, EPA anticipates that NPDES permitting authorities may yet determine that individual unregulated point sources of storm water discharges require regulation on a case-by-case basis. This conclusion is consistent with the Congress' recognition of the potential need for such designation under the first phase of storm water regulation as described in CWA section 402(p)(2)(E). Under CWA section 402(p)(2)(E), Congress recognized the need for both EPA and the State to retain authority to regulate unregulated point sources of storm water under the NPDES permit program. Second, to the extent that CWA section 402(p)(6) requires designation of a "category" of sources, the permitting authority may designate such (as yet unidentified) sources as a category that should be regulated to protect water quality. Though such sources may exist and discharge today, if neither EPA nor the State/Tribal NPDES permitting authority has designated the source for regulation under CWA section 402(p)(2)(E) to date, then CWA section 402(p)(6) provides the authority to designate such sources.

The Agency can designate a category of "not yet identified" sources to be regulated, based on local concerns, even if data do not exist to support nationwide regulation of such sources. EPA does not interpret the language in CWA section 402(p) to preclude States from exercising designation authority under these provisions because such designation (and subsequent regulation of designated sources) is within the "scope" of the NPDES program.

EPA also believes that sources regulated pursuant to a State designation are part of (and regulated under) a federally approved State NPDES program, and thus subject to enforcement under CWA sections 309 and 505. Under existing NPDES State program regulations, State programs that are "greater in scope of coverage" are not part of the federally-approved program. By contrast, any such State regulation of sources in this "reserved category" will be within the scope of the federal program because today's rule recognizes the need for such post promulgation designations of unregulated point sources of storm water. Such regulation will be "more stringent" than the federal program rather than "greater in scope of coverage" (40 CFR 123.1(h)).

EPA does not interpret the congressional direction in CWA section 402(p)(6) to preclude regulation of point sources of storm water that should be regulated to protect water quality. Under CWA section 510, Congress expressly recognized and preserved the authority of States to adopt and enforce more stringent regulation of point sources, as well as any requirement respecting the control or abatement of pollution. Section 510 applies, "except as expressly provided" in the CWA. CWA section 502(14) does expressly provide affirmative limitations on the regulation of certain pollutant sources through the point source control program, the NPDES permitting program. Section 502(14) excludes agricultural storm water and return flows from irrigated agriculture from the definition of point source, and section 402(l) limits applicability of the section 402 permit program for return flows from irrigated agriculture, as well as for storm water runoff from certain oil, gas, and mining operations. Unlike sections 502(14) and 402(l), EPA does not interpret CWA section 402(p)(6) as an express provision limiting the authority to designate point sources of storm water for regulation on a case-by-case basis after the promulgation of final regulations. Any source of storm water discharge is encouraged to assess its potential for storm water contamination and take preventive measures against contamination. Such proactive actions could result in the avoidance of future regulation.

One comment was received requesting clarification of the term "non-municipal" in § 122.26(a)(9)(ii). The commenter is concerned that the term "non-municipal," in this context, implies that municipally owned or operated facilities cannot be designated. The term "non-municipal" in this context refers to the universe of unregulated industrial and commercial facilities that could potentially be designated according to § 122.26(a)(9)(i) authority. There is no exemption for municipally owned or operated facilities under these designation provisions.

Finally, EPA received comments and evaluated the proposal under which operators of regulated small, medium, and large MS4s would be responsible for controlling discharges from industrial and other facilities into their systems in lieu of requiring NPDES permit coverage for such facilities. EPA did not adopt this framework due to concerns with administrative and technical burden on the MS4 operators, as well as concerns about such an intergovernmental mandate.

J. Conditional Exclusion for "No Exposure" of Industrial Activities and Materials to Storm Water

1. Background

In 1992, the Ninth Circuit court remanded to EPA for further rulemaking, a portion of the definition of "storm water discharge associated with industrial activity" that excluded the category of industrial activity identified as "light industry" when industrial materials and/or activities were not exposed to storm water. See *NRDC* v. *EPA*, 966 F.2d 1292, 1305 (9th Cir. 1992). Today's final rule responds to that remand. In the 1990 storm water regulations, EPA excluded the light industry category from the requirement for an NPDES permit if the industrial materials and/or activities were not "exposed" to storm water (see § 122.26(b)(14)). The Agency had reasoned that most of the activity at these types of facilities takes place indoors and that emissions from stacks, use of unhoused manufacturing equipment, outside material storage or disposal, and generation of large amounts of dust or particles would be atypical (55 FR 48008, November 16, 1990).

The Ninth Circuit determined that the exemption was arbitrary and capricious for two reasons. First, the court found that EPA had not established a record to support its assumption that light industry that was not exposed to storm water was not "associated with industrial activity," particularly when other types of industrial activity not exposed to storm water remained "associated with industrial activity." The court specifically found that "[t]o exempt these industries from the normal permitting process based on an unsubstantiated assumption about this group of facilities is arbitrary and capricious." Second, the court concluded that the exemption impermissibly "altered the statutory scheme" for permitting because the exemption relied on the unverified judgment of the light industrial facility operator to determine non-applicability of the permit application requirements. In other words, the court was critical that the operator would determine for itself that there was "no exposure" and then simply not apply for a permit without any further action. Without a basis for ensuring the effective operation of the permitting scheme—either that facilities would self-report actual exposure or that EPA would be required to inspect and monitor such facilities—the court vacated and remanded the rule to EPA for further rulemaking.

One of the major concerns expressed by the FACA Committee, was that EPA streamline and reinvent certain troublesome or problematic aspects of the existing permitting program for storm water discharges. One area identified was the mandatory applicability of the permitting program to all industrial facilities, even those "light industrial" activities that are of very low risk or of no risk to storm water contamination. Such dischargers may not have any industrial sources of storm water contamination on the plant site, yet they are still required to apply for an NPDES storm water permit and meet all permitting requirements. Examples of such facilities are a soap manufacturing plant (SIC Code 28) or hazardous waste treatment and disposal facility, where all industrial activities, even loading docks, are inside a building or under a roof.

Although they did not provide a written report, the FACA Committee members advised EPA that the existing storm water program should be revised to allow such facilities to seek an exclusion from the NPDES storm water permitting requirements. The Committee agreed that such an exclusion should also provide a strong incentive for other industrial facilities that conduct industrial activities outdoors to move the activities under cover or into buildings to prevent contamination of rainfall and storm water runoff. The committee believed that such a "no exposure" permit exclusion could be a valuable incentive for storm water pollution prevention.

In today's final rule, the Agency responds to both of the bases for the court's remand. The exclusion from permitting based on "no exposure" applies to all industrial categories listed in the existing storm water regulations except construction. The court's opinion rejected EPA's distinction between light industry and other industry, but it did not preclude an interpretation that treats all "non-exposed" industrial facilities in the same fashion. Presuming that an industrial facility adequately prevents exposure of industrial materials and activities to storm water, today's rule treats discharges from "non-exposed" industrial facilities in a manner similar to the way Congress intended for discharges from administrative buildings and parking lots. Specifically, permits will not be required for storm water discharges from these facilities on a categorical basis.

To assure that discharges from industrial facilities really are similar to discharges from administrative buildings and parking lots, and to respond to the second basis for the court's remand, the permitting exclusion is "conditional". The person responsible for a point source discharge from a "no exposure" industrial source must meet the conditions of the exclusion, and complete, sign and submit the certification to the permitting authority for tracking and

R0018154

accountability purposes. EPA believes today's rule, therefore, is fully consistent with the direction provided by the court.

EPA relied upon the "no exposure" concept discussed by the FACA Committee in developing the "no exposure" provisions of today's rule. EPA is deleting the sentence regarding "no exposure" for the facilities in § 122.26(b)(14)(xi) and adding a new § 122.26(g) titled "Conditional Exclusion for No Exposure of Industrial Activities to Storm Water." The "no exposure" provision will make storm water discharges from all classes of industrial facilities eligible for exclusion, except storm water discharges from regulated construction activities. Regulated construction activities cannot claim "no exposure" because the main pollutants of concern (*e.g.*, sediment) generally cannot entirely be sheltered from storm water.

Today's rule represents a significant expansion in the scope of the "no exposure" provision originally promulgated in the 1990 rule, which was only for storm water discharges from light industry. The intent of today's "no exposure" provision is to provide a simplified method for complying with the CWA to all industrial facilities that are entirely indoors. This includes facilities that are located within a large office building, or at which the only items permanently exposed to precipitation are roofs, parking lots, vegetated areas, and other non-industrial areas or activities.

EPA received several comments related to storm water runoff from parking lots, roof tops, lawns, and other non-industrial areas of an industrial facility. Storm water discharges from these areas, which may contain pollutants or which may result in additional storm water flows, are not directly regulated under the existing storm water permitting program because they are not "storm water discharges associated with industrial activity". Many comments on this issue supported maintaining the exclusion from the existing regulations for storm water permitting for discharges from administrative buildings, parking lots, and other non-industrial areas. Other comments opposed allowing the continued exclusion for discharges from non-industrial areas of the site because discharges from these areas are potentially a significant cause of receiving water impairment. These comments urged that such discharges should not be excluded from NPDES permit coverage. Today's rule does not require permit coverage for discharges from a facility's exposed areas that are separate from industrial activities such as runoff from office buildings and accompanying parking lots, lawns and other non-industrial areas. This approach is consistent with the existing storm water rules which were based on Congress's intent to exclude non-industrial areas such as "parking lots and administrative and employee buildings." 133 Cong. Rec. 985 (1987). EPA also lacks data indicating that discharges from these areas at an industrial facility cause significant receiving water impairments. Therefore, the non-industrial areas at a facility do not need to be assessed as part of the "no exposure" certification.

EPA received comments related to industrial facilities that achieve "no exposure" by constructing large amounts of impervious surfaces, such as roofs, where previously there were pervious or porous surfaces into which storm water could infiltrate. Some commenters made the point that large amounts of impervious area may cause a significant increase in storm water volume flowing off the industrial facility, and thus may cause adverse receiving water impacts simply due to the increased quantity of storm water flow. Some commenters said that storm water discharges from impervious areas at an industrial facility are generally more frequent, and often larger, than discharges from the pre-existing natural surfaces. They believe that these discharges will contain pollutants typical of commercial areas and roads and are an equal threat to direct human uses of the water and can cause equal damage to aquatic life and its habitat. Other commenters believe that if Congress or EPA addresses the issue of flow, it should be addressed on a broader scale than merely through the "no exposure" exclusion, and that EPA has no authority under any existing legal framework to regulate flow directly. Some commenters stated that developing federal parameters for the control of water quantity, *i.e.* flow, would result in federal intrusion into land use planning, an authority that they claim is solely within the purview of State governments and their political subdivisions.

EPA is not attempting to regulate flow via the "no exposure" provisions. EPA does agree, however, that increases in impervious surfaces can result in increased runoff volumes from the site which in turn may increase pollutant loading. In addition, the Agency notes that in some States water quality standards include water quality criteria for flow or turbidity. Therefore, in order to provide a minimal amount of information on possible impacts from increased pollutant loading and runoff volume, EPA's "no exposure" certification form (see Appendix 4) asks the discharger to indicate if they have paved or roofed over a formerly exposed, pervious area in order to qualify for the "no exposure" exclusion. If the answer is yes, the discharger must indicate, by choosing from three possible responses, approximately how much impervious area was created to achieve "no exposure". The choices are: (1) less than 1 acre, (2) 1 to 5 acres, and (3) more than 5 acres. This requirement provides additional information that will aid in determining if discharges from the facility are causing adverse receiving water impacts. EPA intends to prevent water quality impacts resulting from increased discharges of pollutants, which may result from increased volume of runoff. In many cases, consideration of the increased flow rate, velocity and energy of storm water discharges, following construction of large amounts of impervious surfaces, must be taken into consideration in order to reduce the discharge of pollutants, to meet water quality standards and to prevent degradation of receiving streams. EPA recommends that dischargers consider these factors when making modifications to their site in order to qualify for the "no exposure" exclusion.

2. Today's Rule

In order to claim relief under the "no exposure" provision, the discharger of an otherwise regulated facility must submit a no exposure certification that incorporates the questions of § 122.26(g)(4)(iii) to the NPDES permitting authority once every 5 years. This provision applies across all categories of industrial activity covered by the existing program, except discharges from construction activities.

In addition to submitting a "no exposure" certification every 5 years, the facility must allow the NPDES permitting authority or operator of an MS4 (where there is a storm water discharge to the MS4) to inspect the facility and to make such inspection reports publicly available upon request. Also, upon request, the facility must submit a copy of the "no exposure" certification to the operator of the MS4 into which the facility discharges (if applicable). All "no exposure" certifications must be signed in accordance with the signatory requirements of § 122.22. The "no exposure" certification is non-transferable. In the event that the facility operator changes, the new discharger must submit a new "no exposure" certification.

R0018155

Members of the FACA Committee urged that EPA not allow dischargers certifying "no exposure" to take actions to qualify for this provision that result in a net environmental detriment. In developing a regulatory implementation mechanism, however, EPA found that the phrase "no net environmental detriment," was too imprecise to use within this context. Therefore, today's rule addresses this issue by requiring information that should help the permitting authority to determine whether actions taken to qualify for the exclusion interfere with the attainment or maintenance of water quality standards, including designated uses. Permitting authorities will be able, where necessary, to make a determination by evaluating the activities that changed at the industrial site to achieve "no exposure", and assess whether these changes cause an adverse impact on, or have the reasonable potential to cause an instream excursion of, water quality standards, including designated uses. EPA anticipates that many efforts to achieve "no exposure" will employ simple good housekeeping and contaminant cleanup activities. Other efforts may involve moving materials and industrial activities indoors into existing buildings or structures.

In very limited cases, industrial operators may make major changes at a site to achieve "no exposure". These efforts may include constructing a new building or cover to eliminate exposure or constructing structures to prevent run-on and storm water contact with industrial materials or activities. Where major changes to achieve "no exposure" increase the impervious area of the site, the facility operator must provide this information on the "no exposure" certification form as discussed above. Using this and other available data and information, permitting authorities should be able to assess whether any major change has resulted in increased pollutant concentrations or loadings, toxicity of the storm water runoff, or a change in natural hydrological patterns that would interfere with the attainment and maintenance of water quality standards, including designated uses or appropriate narrative, chemical, biological, or habitat criteria where such State or Tribal water quality standards exist. In these instances, the facility operator and their NPDES permitting authority should take appropriate actions to ensure that attainment or maintenance of water quality standards can be achieved. The NPDES permitting authority should decide if the facility must obtain coverage under an individual or general permit to ensure that appropriate actions are taken to address adverse water quality impacts.

While the intent of today's "no exposure" provision is to reduce the regulatory burdens on industrial facilities and government agencies, the FACA Committee suggested that the NPDES permitting authority consider a compliance assessment program to ensure that facilities that have availed themselves of this "no exposure" option meet the applicable requirements. Inspections could be conducted at the discretion of the NPDES authority and be coordinated with other facility inspections. EPA expects, however, that the permitting authority will conduct inspections when it becomes aware of potential water quality impacts possibly caused by the facility's storm water discharges or when requested to do so by adversely affected members of the public. The intent of this provision is that the 5 year "no exposure" certification be fully available to, and enforceable by, appropriate federal and State authorities under the CWA. Private citizens can enforce against facilities for discharges of storm water that are inconsistent with a "no exposure" certification if storm water discharges from such facilities are not otherwise permitted and in compliance with applicable requirements.

EPA received comments from owners, operators and representatives of Phase I facilities classified as "light industry" as defined by the regulations at § 122.26(b)(14)(xi). The comments recommended maintaining the approach of the existing regulations which does not require the discharger to submit any supporting documentation to the permitting authority in order to claim the "no exposure" exclusion from permitting. As discussed previously, the "no exposure" concept was developed in response to the Ninth Circuit court's remand of part of the existing rules back to EPA. The court found that EPA cannot rely on the "unverified judgment" of the facility. The comments opposing documentation did not address the "unverified judgment" concern.

Today's rule is a "conditional" exclusion from permitting which requires all categories, including the "light industrial" facilities that have no exposure of materials to storm water, to submit a certification to the permitting authority. Upon receipt of a complete certification, the permitting authority can review the information, or call, or inspect the facility if there are doubts about the facility's "no exposure" claim. Also, if the facility discharges into an MS4, the operator of the MS4 can request a copy of the certification, and can inspect the facility. The public can request a copy of the certification and/or inspection reports. In adopting these conditional "no exposure" provisions, the Agency addressed the Ninth Circuit court's ruling regarding the discharger's unverified judgment.

EPA received one comment requesting clarification on whether the anti-backsliding provisions in the regulations at § 122.44(l) apply to industrial facilities that are currently covered under an NPDES storm water permit, and whether such facilities could qualify for the "no exposure" exclusion under today's rule. The anti-backsliding provisions will not prevent most industrial facilities that can certify "no exposure" under today's rule from qualifying for an exclusion from permitting. The anti-backsliding provisions contain 5 exceptions that allow permits to be renewed, reissued or modified with less stringent conditions. One exception at § 122.44(l)(2)(A) allows less stringent conditions if "material and substantial alterations or additions to the permitted facility occurred after permit issuance which justify the application of a less stringent effluent limitation." Section 122.44(l)(B)(1) also allows less stringent requirements if "information is available which was not available at the time of permit issuance and which would have justified the application of less stringent effluent limitations at the time of permit issuance." Facility's operators who certify "no exposure" and submit the required information once every 5 years will have provided the permitting authority "information that was not available at the time of permit issuance." Also, some facilities may, in order to achieve "no exposure", make "material and substantial alterations or additions to the permitted facility." Therefore, most facilities covered under existing NPDES general permits for storm water (e.g., EPA's Multi-Sector General Permit) will be eligible for the conditional "no exposure" exclusion from permitting without concern about the anti-backsliding provisions. Such dischargers will have met one or both of the anti-backsliding exceptions detailed above. Facilities that are covered under individual permits containing numeric limitations for storm water should consult with their permitting authority to determine whether the anti-backsliding provisions will prevent them from qualifying for the exclusion from permitting (for that discharge point) based on a certification of "no exposure".

EPA received several comments regarding the timing of when the "no exposure" certification should be submitted. The proposed rule said that the "no exposure" certification notice must be submitted "at the beginning of each permit term or prior to commencing discharges during a permit term." Some commenters interpreted this statement to mean that existing facilities can only submit the certification at the time a permit is being issued or renewed. EPA intended the phrase "at the beginning of each permit term" to mean "once every 5 years" and today's rule reflects this clarification. EPA envisions that the NPDES storm water program will be implemented primarily through general permits which are issued for a 5 year term. Likewise the "no exposure" certification term is 5 years. The NPDES permitting authority will maintain a simple registration list that should impose only a minor administrative burden on the permitting authority. The registration list will allow for tracking of industrial facilities claiming the exclusion. This change allows a facility to submit a "no exposure" certification at any time during the term of the permit, provided that a new certification is submitted every 5 years from the time it is first submitted (assuming that the facility maintains a "no exposure" status). Once a discharger has established that the facility meets the definition of "no exposure", and submits the necessary "no exposure" certification, the discharger must maintain their "no exposure" status. Failure to maintain "no exposure" at their facility could result in the unauthorized discharge of pollutants to waters of the United States and enforcement for violation of the CWA. Where a discharger believes that exposure could occur in the future due to some anticipated change at the facility, the discharger should submit an application and obtain coverage under an NPDES permit prior to such discharge to avoid penalties.

Where EPA is the permitting authority, dischargers may submit a "no exposure" certification at any time after the effective date of today's rule. Where EPA is not the permitting authority, dischargers may not be able to submit the certification until the non-federal permitting authority completes any necessary statutory or regulatory changes to adopt this "no exposure" provision. EPA recommends that the discharger contact the permitting authority for guidance on when the "no exposure" certification should be submitted.

EPA received comments on the proposed rule requirement that the discharger "must comply immediately with all the requirements of the storm water program including applying for and obtaining coverage under an NPDES permit," if changes occur at the facility which cause exposure of industrial activities or materials to storm water. The comments expressed the difficultly of immediate compliance. EPA expects that most facility changes can be anticipated, therefore dischargers should apply for and obtain NPDES permit coverage in advance of changes that result in exposure to industrial activities or materials. Permitting authorities may grant additional time, on a case-by-case basis, for preparation and implementation of a storm water pollution prevention plan.

Finally, today's rule at § 122.26(g)(4) includes the information which must be included on the "no exposure" certification. Authorized States, Tribes or U.S. Territories may develop their own form which includes this required information, at a minimum. EPA adopted the requirements (with modification) from the draft "No Exposure Certification Form" published as an appendix to the proposed rule. Modifications were made to the draft form to address comments received and to streamline the required information. EPA included these certification requirements in today's rule in order to preserve its integrity. Dischargers in areas where EPA is the permitting authority should use the "No Exposure Certification" form included in Appendix 4.

3. Definition of "No Exposure"

For purposes of this section, "no exposure" means that all industrial materials or activities are protected by a storm resistant shelter to prevent exposure to rain, snow, snowmelt, and/or runoff. Industrial materials or activities include, but are not limited to, material handling equipment or activities, industrial machinery, raw materials, intermediate products, by-products, final products, or waste products. Material handling activities include the storage, loading and unloading, transportation, or conveyance of any raw material, intermediate product, final product or waste product. However, storm resistant shelter is not required for: (1) Drums, barrels, tanks, and similar containers that are tightly sealed, provided those containers are not deteriorated and do not leak; (2) adequately maintained vehicles used in material handling; and (3) final products, other than products that would be mobilized in storm water discharge (e.g., rock salt). Each of these three exceptions to the no exposure definition are discussed in more detail below.

EPA intends the term "storm resistant shelter" to include completely roofed and walled buildings or structures, as well as structures with only a top cover but no side coverings, provided material under the structure is not otherwise subject to any run-on and subsequent runoff of storm water. While the Agency intends that this provision promote permanent "no exposure", EPA understands that certain vehicles could pass between buildings and, during passage, be exposed to rain and snow. Adequately maintained vehicles such as trucks, automobiles, forklifts, or other such general purpose vehicles at the industrial site that are not industrial machinery, and that are not leaking contaminants or are not otherwise a source of industrial pollutants, could be exposed to precipitation or runoff. Such activities alone does not prevent a discharger from being able to certify no exposure under this provision. Similarly, trucks or other vehicles awaiting maintenance at vehicle maintenance facilities, as defined at § 122.26(b)(14)(viii), that are not leaking contaminants or are not otherwise a source of industrial pollutants, are not considered exposed.

In addition, EPA recognizes that there are circumstances where permanent "no exposure" of industrial activities or materials is not possible. Under such conditions, materials and activities may be sheltered with temporary covers, such as tarps, between periods of permanent enclosure. The final rule does not specify every such situation. EPA intends that permitting authorities will address this issue on a case-by-case basis. Permitting authorities can determine the circumstances under which temporary structures will or will not meet the requirements of this section. Until permitting authorities specifically determine otherwise, EPA recommends application of the "no exposure" exclusion for temporary sheltering of industrial materials or activities only during facility renovation or construction, provided that the temporary shelter achieves the intent of this section. Moreover, "exposure" that results from a leak in protective covering would only be considered "exposure" if not corrected prior to the next storm water discharge event. EPA received one comment requesting that this allowance for temporary shelter be limited to facility renovation or construction directly related to the industrial activity requiring temporary shelter, and be scheduled to minimize the use of temporary shelter. Another comment suggested placing time limits

R0018157

on the use of temporary shelter. The commenter did not recommend a specific time period, rather the comment said that renovation in some instances may take years, and that EPA should not allow temporary shelter over prolonged periods. EPA agrees that the use of temporary shelter must be related to the renovation or construction at the site, and be scheduled or designed to minimize the use of temporary shelter. Further, EPA agrees that the use of temporary shelter should be limited in duration, but does not intend to define "temporary" or "prolonged period".

Many final products are intended for outdoor use and pose little risk of storm water contamination, such as new cars. Therefore, final products, except those that can be mobilized in storm water discharge, can be "exposed" and still allow the discharge to certify "no exposure". EPA intends the term "final products" to mean those products that are not used in producing another product. Any product that can be used to make another product is considered an "intermediate product." For example, a facility that makes horse trailers can store the finished trailers outdoors as a final product. The storage of those final products does not prevent eligibility to claim "no exposure". However, any facility that makes parts for the horse trailers (e.g., metal tubing, sheet metal, paint) is not eligible for the "no exposure" exclusion from permitting if those "intermediate products" are stored outdoors (i.e., "exposed").

EPA received comments related to materials in drums, barrels, tanks and similar containers. Some comments objected to the language in the preamble to the proposed rule that would have recommended that the "exposure" determination for drums and barrels be based on the "potential to leak." Those comments said that all drums and barrels have the potential to leak, thereby making certification impossible. They recommended allowing outdoor storage of drums and barrels except for those that "are leaking" at the time of certification. Other comments suggested allowing drums and barrels to be stored outside only if the drums and barrels: are empty; have secondary containment; or there is a spill contingency plan in place. Opposing comments suggested that allowing outdoor exposure of drums and barrels, based on existing integrity and condition, is inconsistent with the "however packaged" proposed rule language, and also would not satisfy the Ninth Circuit remand. The comments point out that the former rule was invalidated by the court in part because it relied on the "unverified judgment" of the light industrial facility operator to determine the non-applicability of the permit requirements, and that allowing the facility operator to determine the condition of their drums and barrels would result in the same flaw.

In response, EPA believes that drums and barrels that are stored outdoors pose little risk of storm water contamination unless they are open, deteriorated or leaking. The Agency has modified today's rule accordingly. EPA intends the term "open" to mean any container that is not tightly sealed and "sealed" to mean banded or otherwise secured and without operational taps or valves. Drums, barrels, tanks, and similar containers may only be *stored* outdoors under this conditional exclusion. The addition of material to or withdrawing of material from these containers while outside is deemed "exposure". Moving the containers while outside does not create "exposure" provided that the containers are not open, deteriorated or leaking. In order to complete the "no exposure" certification, a facility operator must inspect all drums, barrels, tanks or other containers stored outside to ensure that they are not open, deteriorated, or leaking. EPA recommends that the discharger designate someone at the facility to conduct frequent inspections to verify that the drums, barrels, tanks or other containers remain in a condition such that they are not open, deteriorated or leaking. Drums, barrels, tanks or other containers stored outside that have valves which are used to put material in or take material out of the container, and that have dripped or may drip, are considered to be "leaking" and must be under a storm resistant shelter in order to qualify for the no exposure exclusion. Likewise, leaking pipes containing contaminants exposed to storm water are deemed "exposed." If at any time drums, barrels, tanks or similar containers are opened, deteriorated or leaking, the discharger should take immediate actions to close or replace the container. Any resulting unpermitted discharge would violate the CWA. The Director, the operator of the MS4, or the municipality may inspect the facility to verify that all of the applicable areas meet the "no exposure" conditions as specified in the rule language. In requiring submission of the conditional "no exposure" certification and allowing the permitting authority and the operator of the MS4 to inspect the facility, today's rule does not rely on the unverified judgment of the facility to determine that the no exposure provision is being met.

EPA received several comments related to trash dumpsters that are located outside. The preamble to the proposed rule listed dumpsters in the same grouping as drums and barrels, which based exposure on the "potential to leak". Today's rule distinguishes between dumpsters and drums/barrels. In the Phase I Question and Answer document (volume 1, question 52) the Agency noted that a covered dumpster containing waste material that is kept outside is not considered "exposed" as long as "the container is completely covered and nothing can drain out holes in the bottom, or is lost in loading onto a garbage truck." EPA affirms this approach today. Industrial refuse and industrial trash that is left uncovered is deemed "exposed."

For purposes of this provision, particulate matter emissions from roof stacks/vents that are regulated and in compliance under other environmental protection programs, such as air quality control programs, and that do not cause storm water contamination, are considered "not exposed." EPA received comments on the phrase in the draft "no exposure" certification form that asked whether "particulate emissions from roof stacks/vents not otherwise regulated, and in quantities detectable in the storm water outflow," are exposed to precipitation. One comment expressed concern that the phrase "in quantities detectable in the storm water outflow" implies that the facility must conduct monitoring prior to completing the checklist, and must continue to monitor after receiving the no exposure exclusion, in order to be able to verify compliance with the no exposure provision. Another comment said that current measurement technology allows detection of pollutants at levels that may not cause environmental harm. EPA does not intend to require monitoring of runoff from facilities with roof stacks/vents prior to or after completing and submitting the no exposure certification. EPA has thus replaced the phrase "in quantities detectable" with "evident" to convey the message that emissions from some roof stacks/vents have the potential to contaminate storm water discharges in quantities that are considered significant or that cause or contribute to a water quality standards violation. In those instances where the permitting authority determines that particulate emissions from facility roof stacks/vents are a significant contributor of pollutants or contributing to water quality violations, the permitting authority may require the discharger to apply for and obtain coverage under a permit. Visible deposits of residuals (*e.g.*, particulate matter) near roof or side vents are considered "exposed". Likewise, visible "track out" (*i.e.*, pollutants carried on the tires of vehicles) or windblown raw materials are deemed "exposed."

EPA received a comment requesting an allowance under the "no exposure" provision for industrial facilities with several outfalls at a site where some, but not all of the outfalls drain non-exposed areas. The commenter provided an example of an industrial facility that has 5 outfalls draining different areas of the site, where two of those outfalls drain areas where industrial activities or materials are not exposed to storm water. The comment requested that the facility in this example be allowed to submit a "no exposure" certification in order to be relieved of permitting obligations for discharges from those two outfalls.

EPA agrees, but the comment would be implemented on an outfall-by-outfall basis in the permitting process, not through the "no exposure" exclusion. The "no exposure" provision was developed to allow exclusion from permitting of discharges from entire industrial facilities (except construction), based on a claim of "no exposure" for all areas of the facility where industrial materials or activities occur. Where exposure to industrial materials or activities exist at some but not all areas of the facility, the "no exposure" exclusion from permitting is not allowed because permit coverage is still required for storm water discharges from the exposed areas. Relief from permit requirements for outfalls draining non-exposed areas should be addressed through the permit process, in coordination with the permitting authority. Most NPDES general permits for storm water discharge provide enough flexibility to allow minimal or no requirements for non-exposed areas at industrial facilities. If the permitting authority determines that additional flexibility is needed for this scenario, the permits could be modified as necessary.

K. Public Involvement/Public Role

The Phase II FACA Subcommittee discussed the appropriate role of the public in successful implementation of a municipal storm water program. EPA believes that an educated and actively involved public is essential to a successful municipal storm water program. An educated public increases program compliance from residents and businesses as they realize their individual and collective responsibility for protecting water resources (*e.g.*, the residents and businesses could be subject to a local ordinance that prohibits dumping used oil down storm sewers). Finally, the program is also more likely to receive public support and participation when the public is actively involved from the program's inception and allowed to participate in the decision making process.

In a time of limited staff and financial resources, public volunteers offer diverse backgrounds and expertise that may be used to plan, develop, and implement a program that is tailored to local needs (*e.g.*, participate in public meetings and other opportunities for input, perform lawful volunteer monitoring, assist in program coordination with other preexisting and related programs, aid in the development and distribution of educational-materials, and provide public training activities). The public's participation is also useful in the areas of information dissemination/education and reporting of violators, where large numbers of community members can be more effective than a few regulators.

The public can also petition the NPDES permitting authority to require an NPDES permit for a discharge composed entirely of storm water that contributes to a violation of a water quality standard or is a significant contributor of pollutants to waters of the United States. In evaluating such a petition, the NPDES permitting authority is encouraged to consider the set of designation criteria developed for the evaluation of small MS4s located outside of an urbanized area in places with a population of at least 10,000 and a population density of 1,000 or more. Furthermore, any person can protect water bodies by taking civil action under section 505 of the CWA against any person who is alleged to be in violation of an effluent standard or permit condition. If civil action is taken, EPA encourages citizen plaintiffs to resolve any disagreements or concerns directly with the parties involved, either informally or through any available alternative dispute resolution process.

EPA recognizes that public involvement and participation pose challenges. It requires a substantial initial investment of staff and financial resources, which could be very limited. Even with this investment, the public might not be interested in participating. In addition, public participation could slow down the decision making process. However, the benefits are numerous.

EPA encourages members of the public to contact the NPDES permitting authority or local MS4s operator for information on the municipal storm water program and ways to participate. Such information may also be available from local environmental, nonprofit and industry groups.

Some commenters stressed the need to suggest to the public that they have a responsibility to fund the municipal storm water program. While EPA believes it is important that the program be adequately funded, today's rule does not address appropriate mechanisms or levels for such funding.

EPA received comments expressing concern that considerable public involvement requirements could result in increased litigation. EPA is not convinced there is a correlation between meaningful public education programs and any increased probability of litigation.

Finally, EPA received comments stating that the Agency should not en courage volunteer monitoring unless proper procedures are followed. EPA agrees. EPA encourages only lawful monitoring, *i.e.*, obtaining the necessary approval if there is any question about lawful access to sites. Moreover, as a matter of good practice and to enhance the validity and usefulness of the results, any party, public or private, conducting water quality monitoring is encouraged to use appropriate quality control procedures and approved sampling and analytic methods.

L. Water Quality Issues

1. Water Quality Based Effluent Limits

In addition to technology based requirements, all point source discharges of industrial storm water are subject to more stringent NPDES permitting requirements when necessary to meet water quality standards. CWA sections 402(p)(3)(A) and 301(b)(1)(C). For municipal separate storm sewers, EPA or the State may determine that other permit provisions (*e.g.* one of the minimum measures) are appropriate to protect water quality and, for discharges to impaired waters, to achieve reasonable further progress toward attainment of water quality standards pending implementation of a TMDL. CWA section 402(p)(3)(B)(iii). See *Defenders of Wildlife, et al. Browner*, No. 98–71080 (9th cir., August 11, 1999). Discharges of storm water also must comply with applicable antidegradation policies and implementation methods to maintain and protect water quality. 40 CFR 131.12. Section 122.34(a) emphasizes this point by specifically noting that a storm water management program designed to reduce the discharge of pollutants from the storm sewer system "to the maximum extent practicable" is also designed to protect water quality.

R0018159

Permits issued to non-municipal sources of storm water must include water quality-based effluent limits where necessary to meet water quality standards.

Commenters challenged EPA's interpretation of the CWA as requiring water quality-based effluent limits for MS4s when necessary to protect water quality. Commenters asserted that CWA 402(p)(3)(B), which addresses permit requirements for municipal discharges, limits the scope of municipal program requirements to an effective prohibition on non-storm water discharges to a separate storm sewer and to controls which reduce pollutants to the "maximum extent practicable, including management practices, control techniques and system design and engineering methods." They asserted that the final rule should clarify that neither numeric nor narrative water quality-based limits are appropriate or authorized for MS4s.

EPA disagrees that section 402(p)(3) divests permitting authorities of the tools necessary to issue permits to meet water quality standards. Section 402(p)(3)(B)(iii) specifically preserves the authority for EPA or the State to include other provisions determined appropriate to reduce pollutants in order to protect water quality. *Defenders of Wildlife*, slip op. at 11688. Small MS4s regulated under today's rule are designated under CWA 402(p)(6) "to protect water quality."

Commenters argued that water quality standards, particularly numeric criteria, were not designed to address storm water discharges. The episodic nature and magnitude of storm water events, they argue, make it impossible to apply the "end of pipe" compliance assessment approach, for example, in the development of water quality based effluent limits.

EPA's disagrees with the commenters arguments about the inability of water quality criteria to address high flow conditions. Today's final rule does, however, address the concern that numeric effluent limits will necessitate end of pipe treatment and the need to provide a workable alternative.

Today's rule was developed under the approach outlined in the Interim Permitting Policy for Water Quality-Based Effluent Limitations in Storm Water Permits, issued on August 1, 1996. 61 FR 43761 (November 26, 1996) (the "Interim Permitting Policy"). EPA intends to issue NPDES permits consistent with the Interim Permitting Policy, which provides as follows:

In response to recent questions regarding the type of water quality-based effluent limitations that are most appropriate for NPDES storm water permits, EPA is adopting an interim permitting approach for regulating wet weather storm water discharges. Due to the nature of storm water discharges, and the typical lack of information on which to base numeric water quality-based effluent limitations (expressed as concentration and mass), EPA will use an interim permitting approach for NPDES storm water permits.

"The interim permitting approach uses best management practices (BMPs) in first-round storm water permits, and expanded or better-tailored BMPs in subsequent permits, where necessary, to provide for the attainment of water quality standards. In cases where adequate information exists to develop more specific conditions or limitations to meet water quality standards, these conditions or limitations are to be incorporated into storm water permits, as necessary and appropriate. This interim permitting approach is not intended to affect those storm water permits that already include appropriately derived numeric water quality-based effluent limitations. Since the interim permitting approach only addresses water quality-based effluent limitations, it also does not affect technology-based effluent limitations, such as those based on effluent limitations guidelines or developed using best professional judgment, that are incorporated into storm water permits.

"Each storm water permit should include a coordinated and cost-effective monitoring program to gather necessary information to determine the extent to which the permit provides for attainment of applicable water quality standards and to determine the appropriate conditions or limitations of subsequent permits. Such a monitoring program may include ambient monitoring, receiving water assessment, discharge monitoring (as needed), or a combination of monitoring procedures designed to gather necessary information.

"This interim permitting approach applies only to EPA; however, EPA also encourages authorized States and Tribes to adopt similar policies for storm water permits. This interim permitting approach provides time, where necessary, to more fully assess the range of issues and possible options for the control of storm water discharges for the protection of water quality. This interim permitting approach may be modified as a result of the ongoing Urban Wet Weather Flows Federal Advisory Committee policy dialogue on this subject."

One commenter challenged the Interim Permitting Policy on a procedural basis, arguing that it was published without opportunity for public notice and comment. In response, EPA notes that the Policy was included verbatim and made available for public comment in the proposal to today's final rule. Prior to that proposal, the Agency defended the application of the Policy on a case-by-case basis in individual permit proceedings. Moreover, the essential elements of the Policy—that narrative effluent limitations are the most appropriate form of effluent limitations for storm water dischargers from municipal sources—was inherent in § 122.34(a) of the proposed rule, and was the subject of extensive public comment. In any event, the Policy does not constitute a binding obligation. It is policy, not regulation.

Consistent with the recognition of data needs underlying the Policy, EPA will evaluate the small MS4 storm water regulations after the second round of permit issuance. Section 122.34(e)(2) of today's rule expressly provides that for the interim ten-year period, "EPA strongly recommends that until the evaluation of the storm water program in § 122.37, no additional requirements beyond the minimum control measures be imposed on regulated small MS4s without the agreement of the operator of the affected small MS4, except where an approved TMDL or equivalent analysis provides adequate information to develop more specific measures to protect water quality." This approach addresses the concern for protecting water resources from the threat posed by storm water discharges with the important qualification that there must be adequate information on the watershed or a specific site as a basis for requiring tailored storm water controls beyond the minimum control measures. As indicated, the Interim Permitting Policy has several important limitations—it does not apply to technology-based controls or to sources that already have numeric end of pipe effluent limitations. EPA encourages authorized States and Tribes to adopt policies similar to the Interim Permitting Policy when developing storm water discharge programs. For a discussion of appropriate monitoring activities, see Section H.3.d., Evaluation and Assessment.

Where a water quality analysis indicates there is a need and basis for deriving water quality-based effluent limits in NPDES permits for storm water discharges regulated under today's rule, EPA believes that most of these cases would be satisfied by narrative effluent limitations that require the implementation of BMPs. NPDES permit limits will in most cases continue to be based on the specific approach outlined in today's rule for the implementation of BMPs as the most appropriate form of effluent limitation to satisfy technology and water quality-based requirements. See § 122.34(a). For storm water management plans with existing BMPs, this may require further tailoring of BMPs to address the pollutant(s) of concern, the nature of the discharge and the receiving water. If the permitting authority determines that, through implementation of appropriate BMPs required by the NPDES storm water permit, the discharge has the necessary controls to provide for attainment of water quality standards, additional controls are not needed in the permit. Conversely, if a discharger (MS4, industrial or construction) fails to adopt and implement adequate BMPs, the permittee and/or the permitting authority should consider a different mix of BMPs or more specific conditions to ensure water quality protection.

Some commenters observed that there was no evidence from the experience of storm water dischargers regulated under the existing NPDES storm water program, or from studies or reports that allegedly support EPA's position, that implementation of BMPs to satisfy the six minimum control measures would meet applicable water quality standards for a regulated small MS4. In response, EPA acknowledges that the six minimum measures are intended to implement the statutory requirement to control discharges to the maximum extent practicable, and they may not result in the attainment of water quality standards in all cases. The control measures do, however, focus on and address well-documented threats to water quality associated with storm water discharges. Based on the collective expertise of the FACA Subcommittee, EPA believes that implementation of the six minimum measures will, for most regulated small MS4s, be adequate to protect water quality, and for other regulated small MS4s will substantially reduce the adverse impacts of their discharges on water quality.

Some commenters asserted that analyses of existing water quality criteria suggest that numeric criteria for aquatic life may be overprotective if applied to storm water discharges. These comments maintained that an approach that prohibits exceedance of applicable water quality criteria is unworkable. Various commenters recommended wet weather specific criteria, variances to the criteria during wet weather events, and seasonal designated uses. Other commenters noted that water quality-based effluent limits in NPDES permits have traditionally been developed based on dry weather flow conditions (*e.g.*, assuming critical low-flow conditions in the receiving water to ensure protection of aquatic life and human health). Wet weather discharges, however, typically occur under high-flow conditions in the receiving water. Assumptions regarding mass balance equations and size of mixing zones may also not be pertinent during wet weather.

EPA acknowledges the need to devise a regulatory program that is both flexible enough to accommodate the episodic nature, variability and volume of wet weather discharges and prescriptive enough to ensure protection of the water resource. EPA believes that wet weather discharges can be adequately addressed in the existing regulations through refining designated uses and assigning criteria that are tailored to the level of water quality protection described by the refined designated use.

EPA believes that lack of precision in assigning designated uses and corresponding criteria by States and Tribes, in many cases may result in application of water quality criteria that may not appropriately match the intended condition of the water body. States and Tribes have frequently designated uses without regard to site-specific wet weather conditions. Because certain uses (swimming, for example) might not exist during high-intensity storm events or in the winter, States may factor such climatic conditions and seasonal uses into their use designations with appropriate analyses. This would acknowledge that a lower level of control, at lower compliance cost, would be appropriate to protect that use. Before modifying any designated use, however, States would need to evaluate the effect of less stringent water quality criteria on protecting other uses, including any threatened or endangered species, drinking water supplies and downstream uses. EPA will further evaluate these issues in the context of the Water Quality Standards Regulation; Advance Notice of Proposed Rule Making (ANPRM), 63 FR, 36742, July 7, 1998.

One of the major themes presented by EPA in the ANPRM is that refinement in use designations and tailoring of water quality criteria to match refined use designations is an important future direction of the water quality standards program. In assigning criteria to protect general use classifications, a State or Tribe must ensure that the criteria are sufficiently protective to safeguard the full range of waters of the State, *i.e.*, criteria would be based on the most sensitive use. This approach has been disputed, especially for aquatic life uses, where evidence suggests that the general use criteria will require controls more stringent than needed to protect the existing or potential aquatic life community for a specific water body. EPA recognizes that there is a growing need to more precisely tailor use descriptions and criteria to match site-specific conditions, ensuring that uses and criteria provide an appropriate level of protection, which, to the extent possible, are not overprotective. EPA is engaged in an ongoing evaluation of its regulations in this area through the ANPRM effort. At the same time, EPA continues to encourage States and Tribes to review the applicability of the designated uses and associated criteria using existing provisions in the water quality standards regulation.

2. Total Maximum Daily Loads and Analysis To Determine the Need for Water Quality-Based Limitations

The development and implementation of total maximum daily loads (TMDLs) provide a link between water quality standards and effluent limitations. CWA section 303(d) requires States to develop TMDLs to provide more stringent water quality-based controls when technology-based controls are inadequate to achieve applicable water quality standards. A TMDL is the sum of the individual wasteload allocations for point sources and load allocations for nonpoint sources, with consideration for natural background conditions. A TMDL quantifies the maximum allowable loading of a pollutant to a water body and allocates this maximum load to contributing point and nonpoint sources so that water quality criteria will not be exceeded and designated uses will be protected. A TMDL also includes a margin of safety to account for uncertainty about the relationship between pollutant loads and water quality.

Today's final rule refers to TMDLs in several provisions. For the purpose of today's rule, EPA relies on the component of the TMDL that evaluates existing conditions and allocates loads. For discharges to waters that are not impaired and for which a TMDL has not been developed, today's rule also refers to an "equivalent analysis." The discussion that follows uses the term "TMDL" for both.

Under revised § 122.26(a)(9)(i)(C), the permitting authority may designate

R0018161

storm water discharges that require NPDES permits based on TMDLs that address the pollutants of concern. For storm water discharges associated with small construction activity, § 122.26(b)(15)(i)(B) provides a waiver provision where it may be determined that storm water controls are not needed based on TMDLs that address sediment and any other pollutants of concern. The NPDES permitting authority may waive requirements under the program for certain small MS4s within urbanized areas serving less than 1,000 persons provided that, if the small MS4 discharges any pollutant that has been identified as a cause of impairment of a water body into which it discharges, the discharge is in compliance with a wasteload allocation in a TMDL for the pollutant of concern. The permitting authority may also waive requirements for MS4s in urbanized areas serving between 1,000 and 10,000 persons, if the permitting authority determines that storm water controls are not needed, as provided in § 123.35(d)(2). See § 122.32(c).

Under CWA section 303(d), States identify which of their water bodies need TMDLs and rank them in order of priority. Generally, once a TMDL has been completed for one or more pollutants in a water body, a wasteload allocation for each point source discharging the pollutant(s) is implemented as an enforceable condition in the NPDES permit. Regulated small MS4s are essentially like other point source discharges for purposes of the TMDL process.

A TMDL and the resulting wasteload allocations for pollutant(s) of concern in a water body may not be available because the water body is not on the State's 303(d) list, the TMDL has not yet been completed, or the TMDL did not include specific pollutants of concern. In these cases, the permitting authority must determine whether point sources discharge pollutant(s) in amounts that cause, have the reasonable potential to cause, or contribute to excursions above State water quality standards, including narrative water quality criteria. This so-called "reasonable potential" analysis is intended to determine whether and for what pollutants water quality based effluent limits are required. The analysis is, in effect, a substitute for a similar determination that would be made as part of a TMDL, where necessary. When "reasonable potential" exists, regulations at § 122.44(d) require a water quality-based effluent limit for the pollutant(s) of concern in NPDES permits. The water quality-based effluent limits may be narrative requirements to implement BMPs or, where necessary, may be numeric pollutant effluent limitations.

Commenters, generally from the regulated community, objected that, due to references to the need to develop a program "to protect water quality" and to additional NPDES permit requirements beyond the minimum control measures based on TMDLs or their equivalent, regulated small MS4s will be subject to uncertain permit limitations beyond the six minimum control measures. Commenters also asserted that through the imposition of a wasteload allocation under a TMDL in impaired water bodies, there is a likelihood that unattainable, yet enforceable narrative and numeric standards will be imposed on regulated small MS4s.

As is discussed in the preceding section, NPDES permits must include any more stringent limitations when necessary to meet water quality standards. However, even if a regulated small MS4 is subject to water quality based effluent limits, such limits may be in the form of narrative effluent limitations that require the implementation of BMPs. As discussed earlier, EPA has adopted the Interim Permitting Policy and incorporated it in the development of today's rule to recognize the appropriateness of BMP-based limits developed on a case-by-case basis.

EPA formed a Federal Advisory Committee to provide advice to EPA on identifying water quality-limited water bodies, establishing TMDLs for them as appropriate, and developing appropriate watershed protection programs for these impaired waters in accordance with CWA section 303(d). Operating under the auspices of the National Advisory Council for Environmental Policy and Technology (NACEPT), the committee produced its *Report of the Federal Advisory Committee on the Total Maximum Daily Load (TMDL) Program* (July 1998). EPA recently published a proposed rule to implement the Report's recommendations (64 FR 46012, August 23, 1999).

3. Anti-Backsliding

In general, the term "anti-backsliding" refers to statutory provisions at CWA sections 303(d)(4) and 402(o) and regulatory provisions at 40 CFR 122.44(l). These provisions prohibit the renewal, reissuance, or modification of an existing NPDES permit that contain effluent limits, permit terms, limitations and conditions, or standards that are less stringent than those established in the previous permit. There are also exceptions to this prohibition known as "antibacksliding exceptions."

The issue of backsliding from prior permit limits, standards, or conditions is not expected to initially apply to most storm water dischargers designated under today's proposal because they generally have not been previously authorized by an NPDES permit. However, the backsliding prohibition would apply if a storm water discharge was previously covered under another NPDES permit. Also, the backsliding prohibition could apply when an NPDES storm water permit is reissued, renewed, or modified. In most cases, however, EPA does not believe that these provisions would restrict revisions to storm water NPDES permits.

One commenter questioned whether, if BMPs implemented by a regulated small MS4 operator fail to produce results in removal of pollutants and the permittee attempts to substitute a more effective BMP, the small MS4 operator could be accused of violating the anti-backsliding provisions and also be exposed to citizen lawsuits. In response, EPA notes that in such circumstances the MS4's permit has not changed and, therefore, the prohibition against backsliding is not applicable. Further, any change in the mix of BMPs that was intended to be more effective at controlling pollutants would not be considered backsliding, even if it did not include all of the previously implemented BMPs.

4. Water Quality-Based Waivers and Designations

Several sections of today's final rule refer to water quality standards in identifying those storm water discharges that are and are not required to be permitted under today's rule. As noted in § 122.30 of today's rule, CWA section 402(p)(6) requires the designation of municipal storm water sources that need to be regulated to protect water quality and the establishment of a comprehensive storm water program to regulate these sources. Requirements applicable to certain municipal sources may be waived based on the absence of demonstrable water quality impacts. Section 122.32(c). The section 402(p)(6) mandate to protect water quality also provides the basis for regulating discharges associated with small construction. See also § 122.26(b)(15)(i). Further, today's rule carries forward the existing authority for the permitting authority to designate sources of storm water discharges based upon water quality considerations. Section 122.26(a)(9)(i)(C) and (D).

As is discussed above in sections II.H.2.e (for small MS4s) and II.I.1.b.ii

R0018162

(for small construction), the requirements of today's rule may be waived based on wasteload allocations that are part of "total maximum daily loads" (TMDLs) that address the pollutants of concern or, in the case of small construction and municipalities serving between 1,000 and 10,000 persons, the equivalents of TMDLs. One commenter stated that waivers would allow exemptions to the technology based requirements and would thus be inconsistent with the two-fold approach of the CWA (a technology based minimum and a water quality based overlay). EPA acknowledges that waivers are not allowed for other technology-based requirements under the CWA. A more flexible approach is allowed, however, for sources designated for regulation under 402(p)(6) to protect water quality. For such sources EPA may allow a waiver where it is demonstrated that an individual source does not present the threat to water quality that was the basis for EPA's designation.

III. Cost-Benefit Analysis

EPA has determined that the range of the rule's benefits exceeds the range of regulatory costs. The estimated rule costs range from $847.6 million to $981.3 million annually with corresponding estimated monetized annual benefits which range from $671.5 million to $1.628 billion, expected to exceed costs.

The rule's cost and benefit estimates are based on an annual comparison of costs and benefits for a representative year (1998) in which the rule is implemented. This differs from the approach used for the proposed rule which projected cost and benefits over three permit terms. EPA has chosen to use the current approach because it determined that the ratio of annual benefits and costs would not change significantly over time. Moreover, because there is not an initial outlay of capital costs with benefits accruing in the future (*i.e.*, benefits and costs are almost immediately at a steady state), it is not necessary to discount costs in order to account for a time differential.

EPA developed detailed estimates of the costs and benefits of complying with each of the incremental requirements imposed by the rule. The Agency used two approaches, a national water quality model and national water quality assessment, to estimate the potential benefits of the rule. Both approaches show that the benefits are likely to exceed costs.

These estimates, including descriptions of the methodology and assumptions used, are described in detail in the *Economic Analysis of the Final Phase II Rule*, which is included in the record of this rule making. Exhibit 3 summarizes costs and benefits associated with the basic elements of today's rule.

EXHIBIT 3.—COMPARISON OF ANNUAL COMPLIANCE COST AND BENEFIT ESTIMATES [1]

Monetized benefits	National water quality model (millions of 1998 dollars)	National water quality assessment (millions of 1998 dollars)
Municipal Minimum Measures		$131.0–$410.2
Controls for Construction Sites		$540.5–$686.0
Total Annual Benefits	$1,628.5	$671.5–$1,096.2

Costs	Millions of 1998 dollars [2]
Municipal Minimum Measures	$297.3
Controls/Waivers for Construction Sites	$545.0–$678.7
Federal/State Administrative Costs	$5.3
Total Annual Costs	$847.6–$981.31

[1] National level benefits are not inclusive of all categories of benefits that can be expected to result from the regulation.
[2] Total may not add due to rounding.

A. Costs

1. Municipal Costs

Initially, to determine municipal costs for the proposed rule, EPA used anticipated expenditure data included in permit applications from a sample of 21 Phase I MS4s. Certain commenters criticized the Agency for using anticipated expenditures because they could be significantly different from the actual expenditures. These commenters suggested that the Agency use the actual cost incurred by the Phase I MS4s. Other comments stated that because the Phase I MS4s, in general, are large municipalities, they may not be representative of the Phase II MS4s for estimating regulatory costs. Finally, one commenter noted that the sample of 21 municipalities used to project cost was relatively small.

To address the concerns of the commenters, EPA utilized a National Association of Flood and Stormwater Management Agencies (NAFSMA) survey of the Phase II community to obtain incremental cost estimates for Phase II municipalities. Using the list of potential Phase II designees published in the **Federal Register** (63 FR 1616), NAFSMA contacted more than 1,600 jurisdictions. The goal of the survey was to solicit information from those communities about the proposed Phase II NPDES storm water program. Several of the survey questions corresponded directly to the minimum measures required by the Phase II rule. One hundred twenty-one surveys were returned to NAFSMA and were used to develop municipal costs.

Using the NAFSMA information, EPA estimated average annual per household program costs for automatically designated municipalities. EPA also estimated an average annual per household administrative cost for municipalities to address application, record keeping, and reporting requirements of the Rule. The total average per household cost of the rule is expected to $9.16 per household.

To determine potential national level costs for municipalities, EPA multiplied the number of households (32.5 million) by the per household cost ($9.16). EPA estimates the annual cost of the Phase II municipal program at $298 million.

As an alternative method, and point of comparison, to the NAFSMA-based approach, EPA reviewed actual expenditures reported from 35 Phase I MS4s. The Agency targeted these 35 Phase I MS4s because they had participated in the NPDES program for

R0018163

nearly one permit term, were smaller in size and had detailed data reflecting their actual program implementation costs. Of the 35 MS4s, appropriate cost data was only available for 26 of those MS4s. EPA analyzed the expenditure data and identified the relevant expenditures, excluding costs presented in the annual reports unrelated to the requirements of the Rule. The cost range and annual per household program costs of $9.08 are similar to those found using the NAFSMA survey data.

2. Construction Costs

In order to estimate the rule's construction-related cost on a national level (the soil and erosion controls (SEC) requirements of the rule and the potential impacts of the post-construction municipal measure on construction), EPA estimated a per site cost for sites of one, three, and five acres and multiplied these costs by the total number of estimated Phase II construction starts across these size categories.

To estimate the percentage of starts subject to the soil and erosion control requirements between 1 and 5 acres, with respect to each category of building permits (residential, commercial, *etc.*), EPA initially used data from Prince George's County (PGC), Maryland, and applied these percentages to national totals. In the proposal, EPA recognized that the PGC data may not be representative of the entire country and requested data that could be used to develop better estimates of the number of construction sites between 1 and 5 acres. EPA did not receive any substantiated national data from commenters.

In view of the unavailability of national data from commenters, EPA made extensive efforts to collect construction site data around the country. The Agency contacted more than 75 municipalities. EPA determined that 14 of the contacted municipalities had useable construction site data. Using data from these 14 municipalities, EPA developed an estimate of the percentage of construction starts on one to five acres. EPA then multiplied this percentage by the number of building permits issued nationwide to determine the total number of construction starts occurring on one to five acres. Finally, to isolate the number of construction starts incrementally regulated by Phase II, EPA subtracted the number of activities regulated under equivalent programs (*e.g.*, areas covered by the Coastal Zone Act Reauthorization Amendments of 1990, and areas covered by equivalent State level soil and erosion control requirements). Ultimately, EPA estimated that 110,223 construction starts would be incrementally covered by the rule annually.

EPA then used standard cost estimates from *Building Construction Cost Data* and *Site Work Landscape Cost Data* (R.S. Means, 1997a and 1997b) to estimate construction BMP costs for 27 model sites in a variety of typical site conditions across the United States. The model sites included three different site sizes (one, three and five acres), three slope variations (3%, 7%, and 12%), and three soil erosivity conditions (low, medium, and high). EPA chose BMP combinations appropriate to the model site conditions. Based on the assumption that any combination of site factors is equally likely to occur in a given site, EPA developed average cost of sediment and erosion control for all model sites. EPA estimated that, on average, BMPs for a 1 acre site will cost $1,206, for a 3 acre site $4,598 and for a 5 acre site $8,709.

EPA then estimated administrative costs per construction site for the following elements required under the rule: Submittal of a notice of intent for permit coverage; notification to municipalities; development of a storm water pollution prevention plan; record retention; and submittal of a notice of termination. EPA estimated the average total administrative cost per site to be $937.

EPA also considered the cost implications of NPDES permit authorities waiving the applicability of requirements to storm water discharges from small construction sites based on two different criteria involving water quality impact and low rainfall. EPA received comments stating that a waiver would require a significant investment in training or acquisition of a consultant. Based on comments received, EPA eliminated one of the waiver conditions involving low soil loss threshold because it necessitated use of the Revised Universal Soil Loss Equation which could require extensive technical expertise.

Based on the opinions of construction industry experts, EPA estimates that 15 percent of the construction sites that would otherwise be covered by today's rule will be eligible to receive waivers. Therefore, the Agency has excluded 15 percent of the construction sites when deriving costs of sediment and erosion control. The average cost for sites to qualify for the waiver is expected to be $34 per site. The construction cost analysis for the proposed rule did not include any costs for the preparation and submission of waiver applications because EPA believed those costs would be negligible. However, in response to public comments, EPA has estimated these potential costs.

EPA has also estimated the potential costs for construction site operators to implement the post-construction minimum measure. These are costs that may be incurred by construction site operators if the MS4 chooses to meet the post-construction minimum measure by requiring on-site structural, site-by-site control of post-construction runoff. Municipalities may select from an array of structural and non-structural options in implementing this measure, so the potential costs to construction operators is uncertain. Nonetheless, EPA developed average annual BMP costs for sites of one, three, five and seven acres. EPA's analysis accounted for varying levels of imperviousness that characterize residential, commercial, and institutional land uses. Nationwide, these costs are expected to range from $44 million to $178 million annually.

Finally, to establish national incremental annual costs for Phase II construction starts, EPA multiplied the total costs of compliance for the chosen site size categories by the total number of Phase II construction starts and added post-construction costs. EPA estimates the annual compliance cost to range from $545 million to $678.7 million.

B. Quantitative Benefits

In the Economic Analysis for the proposed rule, a "top-down" approach was used to estimate economic benefits. Under this approach, the combined economic benefits for wet weather programs were estimated first, and then were divided among various water programs on the basis of expert opinion. As a result, the benefits estimates for an individual program were rather uncertain. Moreover, this approach was inconsistent with the approach used to estimate the cost of the proposed storm water rule, which was developed using municipal-based and cost-based data to develop "bottom-up" costs. Therefore, EPA decided to use a "bottom-up" approach for estimating benefits of the Phase II rule. To adequately reflect the quantifiable benefits of the rule, EPA used two different methods: (1) National Water Quality Model and (2) National Water Quality Assessment.

To monetize benefits in both approaches, the Agency applied Carson and Mitchell's (1993) estimates of household willingness-to-pay (WTP) for water quality improvement to estimates of waters impaired by storm water discharges. Carson and Mitchell's 1993 study reports the results of their 1983 national survey of WTP for incremental improvements in fresh water quality. Carson and Mitchell estimate the WTP for three minimum levels of fresh water quality: boatable, fishable, and sizable. EPA adjusted the WTP amounts to account for inflation, growth in real per capita income, and increased attitudes towards pollution control. The adjusted WTP amounts for improvements in fresh water quality are $210 for boatable, $158 for fishable, and $177 for sizable. A brief summary of the national water quality model and national water quality assessment approaches follow.

1. National Water Quality Model

One approach EPA used to estimate the benefits of the Phase II municipal and construction site controls was the National Water Pollution Control Assessment Model (NWPCAM). NWPCAM estimates benefits of the storm water program at the national level, including the impact on small streams. This model estimates water quality and the resultant use support for the 632,000 miles of rivers and streams in the USEPA Reach File Version 1 (RF1), which covers the continental United States. The model analyzes water quality changes by stream reach. The parameters modeled in the NWPCAM are biological oxygen demand (BOD), total suspended solids (TSS), dissolved oxygen (DO), and fecal coliforms (FC).

The model projects changes in water quality due to the Phase II municipal and construction site controls. To calculate the economic benefits of change in water quality, the number of households in the proximity of the stream reach are determined, by overlaying the model results on the 1990 Census of Populated Places and Minor Civil Divisions, and updating the population to 1998. Economic benefits are calculated using the Carson and Mitchell WTP values. The benefits are separately estimated for local and non-local waters on the basis of WTP values and proximity to water quality changes.

The value of the change in use support for local waters is greater than the value of the non-local waters because of the opportunity to use local waters by the local population. This model assumes that if improvement occurs in waters that are not close to population centers the economic value is lower. Therefore, benefits are estimated for local and non-local waters separately. This assumption is based on Carson and Mitchell's survey which asked respondents to apportion each of their stated WTP values between achieving the water quality goals in their own State and achieving those goals in the nation as a whole. On average, respondents allocated 67% of their values to achieving in-State water quality goals and the remainder to the nation as a whole. Carson and Mitchell argue that for valuing local water quality changes 67% is a reasonable upper bound for the local multiplier and 33% for the non-local water quality changes. For the purposes of this analysis, the locality is defined as urban sites and associated populations linked into the NWPCAM framework. Using this methodology, the total monetized benefits of Phase II control of urban and construction site runoff is estimated to be $1.628 billion per year. The local and non-local benefits due to Phase II controls are presented in Exhibit 4.

EXHIBIT 4.—LOCAL AND NON-LOCAL BENEFITS ESTIMATES DUE TO PHASE II CONTROLS NATIONAL WATER QUALITY MODEL ESTIMATE

Use support	Local benefits ($million/yr)	Non-local benefits[1] ($million/yr)	Total benefits ($million/yr)
Swimming, Fishing, and Boating	306.20	60.60	366.80
Fishing and Boating	395.10	51.90	447.00
Boating	700.10	114.60	814.70
Total	1401.40	227.10	1628.50

[1] To estimate non-local willingness to pay per household, the 33% of willingness is multiplied by the fraction of previously impaired national waters (in each use category) that attain the beneficial use as a result of the Phase II rule. To estimate the aggregate non-local benefits, non-local willingness to pay is multiplied with the total number of households in the US.

While the numbers of miles that are estimated to change their use support are small, the benefits estimates are quite significant. This is because urban runoff and, to a large extent, construction activity occurs where the people actually reside and the water quality changes mostly occur close to these population centers. NWPCAM indicates that changes in pollution loads have the most effect immediately downstream of pollution changes. As a result, the aggregate WTP is large because large numbers of households in these population centers are associated with the local waters that reflect improvement in designated use support.

2. National Water Quality Assessment

EPA also estimated benefits of the Phase II Storm Water program using the 1998 National Water Quality Inventory (305(b)) Report to Congress, rather than the NWPCAM as a basis for estimating impairment addressed by the rule. The Water Quality Assessment method separately estimates benefits associated with improvements to fresh water, marine water and construction site controls, and then aggregates these separate categories into an estimate of total annual benefits.

a. Municipal Measures

i. Fresh Waters Benefits

In order to develop estimates for the potential value of the municipal measures (except storm water runoff controls for construction sites), EPA applied Carson & Mitchell WTP values to estimated existing and projected future fresh water impairment. Carson & Mitchell did not evaluate marine waters, so only fresh water values were available from their research. Even though the Carson and Mitchell estimates apply to all fresh water, it is not clear how these values would be apportioned among rivers, lakes, and the Great Lakes. The 305(b) data indicate that lakes are the most impaired by urban runoff/storm sewers, followed closely by the Great Lakes, and then rivers. Therefore, EPA applied the WTP values to the categories separately and assumed that the higher resulting value for lakes represents the high end of the range (*i.e.*, assuming that lake impairment is more indicative of national fresh water impairment) and that the lower resulting value for impaired rivers represents the low end of a value range for all fresh waters (*i.e.*, assuming that river impairment is more indicative of national fresh water impairment). In addition, EPA estimated that the post-construction runoff

R0018165

requirements of the municipal program might result in benefits of at least $16.8 million annually from avoided future runoff. The post-construction estimate significantly underestimates potential program benefits because it does not account for avoided hydrologic changes and resulting water quality impairment associated with increases in imperviousness from development and redevelopment. Summing the benefits across the water quality use support levels yields an estimate of benefits ranging from approximately $121.9 million to $378.2 million per year.

ii. Marine Waters Benefits

In addition to the fresh water benefits captured by the Carson and Mitchell study, EPA anticipates benefits as a result of improvements to marine waters. Sufficient methods have not been developed to quantify national-level benefits for commercial or recreational fishing. EPA used beach closure data and visitation estimates from its Beach Watch Program to estimate potential reductions in marine swimming visits due to storm water runoff contamination events in 1997. The estimated 86,100 trips that did not occur because of beach closures in coastal Phase II communities is a lower bound because it represents only those beaches that report both closures and visitation data. EPA estimates potential swimming benefits from the rule to be at least $2.1 million annually.

EPA developed an analysis of potential benefits associated with avoided health impacts from exposure to contaminants in storm sewer effluent. Based on a study of incremental illnesses found among people who swam within one yard of storm drains in Santa Monica Bay, EPA estimated a range of incremental illnesses (Haile *et al.*, 1996). Depending on assumptions made about number of exposures to contaminants and contaminant concentrations, benefits ranged from $7.0 million to $29.9 million annually.

b. Construction Benefits

The major pollutant resulting from construction activities is sediment. However, in addition to sediment, construction activities also yield pollutants such as pesticides, petroleum products, and solvents. Because circumstances will vary considerably from site to site, data is not available with which to develop estimates of benefits for each site and aggregate to obtain a national-level estimate.

In the proposed rule, EPA estimated the combined benefits of all wet weather programs, and then used expert opinions to allocate them to different individual programs. To eliminate the possible overlap between the benefits of the soil and erosion control requirements, municipal measures, and other wet weather storm water programs, EPA chose to use an approach in today's final rule that directly estimates the benefits of soil and erosion requirements.

A survey of North Carolina residents (Paterson *et al.*, 1993) indicated that households are willing to pay for erosion and sediment controls similar to those in today's rule. Based on income and other indicators, the values derived from the study are expected to be similar to values held in the rest of the country. Using the mean value of the willingness to pay of $25 per household, EPA projects annual benefits of the soil and erosion requirements to range from $540.5–$686 million.

c. Summary of Benefits From the National Water Quality Assessment

Total benefits from municipal measures and construction site controls are expected to range from $671.5 million to $1.1 billion per year, including benefits of approximately $13.7 million per year associated with small stream improvements. A summary of the potential benefits is presented in Exhibit 5.

As shown in Exhibit 5, it was not possible to monetize all categories of benefits using the WTP estimates. In particular, benefits for improving marine water quality such as fishing and passive use benefits are not included in the values used to estimate the potential benefits of the municipal minimum measures (excluding construction sites controls), and they are not estimated separately, because information is not currently available.

EXHIBIT 5.—POTENTIAL ANNUAL BENEFITS OF THE PHASE II STORM WATER RULE NATIONAL WATER QUALITY ASSESSMENT ESTIMATE

Benefit category	Annual WTP
Municipal Minimum Measures [1]	
Fresh Water Use and Passive Use [2]	$121.9–$378.2
Marine Recreational Swimming	$2.1
Human Health (Marine Waters)	$7.0–$29.9
Other Marine Use and Passive Use	(+)
Erosion and Sediment Controls for Construction Sites	
Fresh Water and Marine Use and Passive Use [3]	$540.5–$686
Total Phase II Program	
Total Use & Passive Use (Fresh Water and Marine)	>$671.5–>$1,096.2

+= positive benefits expected but not monetized.

[1] Includes water quality benefit of municipal programs, based on 80% effectiveness of municipal programs.

[2] Based on research by Carson and Mitchell (1993). Fresh water value only. Does not include commercial fishery, navigation, or diversionary (*e.g.* municipal drinking water cost savings or risk reductions) benefits. May not fully capture human health risk reduction or ecological values.

[3] Based on research by Paterson *et al.* (1993). Although the survey's description of the benefits of reducing soil erosion from construction sites included reduced dredging, avoided flooding, and water storage capacity benefits, these benefit categories may not be fully incorporated in the WTP values. Small streams may account for over 2% of total benefits.

C. Qualitative Benefits

There are additional benefits to storm water control that cannot be quantified or monetized. Thus, the current estimate of monetized benefits may understate the true value of storm water controls because it omits many ways in which society is likely to benefit from reduced storm water pollution, such as improved aesthetic quality of waters, benefits to wildlife and to threatened and endangered species, cultural values, and biodiversity benefits.

A benefit that EPA did not monetize completely is the flood control benefits attributable to municipal storm water controls reducing downstream flooding, although flood control benefits associated with sediment and erosion control are already reflected to some extent in the construction benefits. Similarly, the Agency could not value the benefits from increased property value due to storm water controls reflected in the rule, even though a commenter suggested inclusion of these benefits in the estimates.

Moreover, while a number of commenters requested that EPA include ecological benefits, the Agency was not able to fully monetize these benefits. Urbanization usually increases the amount of sediment, nutrients, metals and other pollutants associated with land disturbance and development. Development usually not only results in a dramatic increase in the volume of water runoff, but also in a substantial decrease in that water's quality due to stream scour, runoff and dispersion of toxic pollutants, and oversiltation. These kinds of secondary benefits could not be fully reflected in the monetized benefits. EPA was able to only monetize the aquatic life support benefits for waters assumed to be impaired. Thus, only the aquatic life support benefits attributable to municipal controls, reflected through human satisfaction, are taken into account.

Reduced nutrient level is another benefit of the storm water control which is not fully captured by the economic analysis. High nutrient levels often lead to eutrophication of the aquatic system. The quality change in ecological sources as the result of storm water controls to reduce pollutants is not fully reflected in the present benefits.

D. National Economic Impact

Finally, the Agency determined that the rule will have minimal impacts on the economy or employment. This is because the final rule regulates small MS4s and construction sites under 5 acres, not the typical industrial plants or other non-construction activities that could directly impact production and thus those sectors of the economy.

Discussions with representatives within the construction industry indicate that construction costs will likely be passed on to buyers, thus not seriously affecting the housing industry directly. One commenter argued that the rule will have a negative employment effect because the builders will build fewer homes requiring less building materials as a result of the declining demand induced by the cost of the soil and erosion controls. EPA disagrees with this argument because the cost of the controls, as the percentage of the price of a median home, is negligible and will be passed on to final buyers.

Flexibility within the rule allows MS4s to tailor the storm water program requirements to their needs and financial position, minimizing impacts. For sedimentation and erosion controls on construction sites, the rule contemplates application of commonly used BMPs to reduce costs for the construction industry. Thus, the rule attempts to use existing practices to prevent pollution, which should minimize impacts on States, Tribes, municipalities and the construction industry.

Thus, EPA concludes that the effect of the rule, if any, on the national economy will be minimal. The benefits of today's rule more than offset any cost impacts on the national economy.

IV. Regulatory Requirements

A. Paperwork Reduction Act

The Office of Management and Budget (OMB) has approved some of the information collection requirements contained in this final rule (*i.e.* those found in 40 CFR 122.26(g) and 123.35(b)) under the provisions of the *Paperwork Reduction Act*, 44 U.S.C. 3501 *et seq.* and has assigned OMB control number 2040–0211.

The burden and costs described below are for the information collection, reporting, and record keeping requirements for the three year period beginning with the effective date of today's rule. Additional information collection requirements for regulated small MS4s and small construction sites will occur after this initial three year period and will be counted in a subsequent information collection requirement. The total burden of the information collection requirements for the first three years of this rule is estimated at 56,369 hours with a corresponding cost of $2,151,305 million annually. This burden and cost is for industrial facilities to complete and submit the no exposure certification, for NPDES-authorized States to process and review the no exposure certification, and for the NPDES-authorized States to develop designation criteria and assess additional MS4s outside of urbanized areas. Compliance with the applicable information collection requirements imposed under this rule are mandatory, pursuant to CWA section 402.

Exhibit 6 presents average annual burden and cost estimates for Phase II respondents for the first three years. Burden means the total time, effort, or financial resources expended by persons to generate, maintain, retain, disclose or provide information to or for a Federal agency. This includes the time needed to review instructions; develop, acquire, install, and utilize technology and systems for the purposes of collecting, validating, and verifying information, processing and maintaining information, and disclosing and providing information; adjust existing ways for complying with any previously applicable instructions and requirements; train personnel to be able to respond to a collection of information; search data sources; complete and review the collection of information; and transmit or otherwise disclose the information.

EXHIBIT 6.—AVERAGE ANNUAL BURDEN AND COST ESTIMATES FOR PHASE II RESPONDENTS

Information collection activity	A Respondents per year (projected) [1]	B Burden hours per respondent per year (predicted)	(A)×(B)=C Annual respondent burden hours (projected)	D Respondent labor cost ($/hr) (1998 $)	(C)×(D)=E Annual Cost ($) (projected)
Ind. No Expos. Facilities:[2]					
No Expos. Certification	36,377	1.0	36,377	44.35	1,613,320
Annual Subtotal			36,377		1,613,320
NPDES-Authorized States:[3]					
Designation of Addit. MS4s[4]	15	332.8	4,892	26.91	131,644

R0018167

EXHIBIT 6.—AVERAGE ANNUAL BURDEN AND COST ESTIMATES FOR PHASE II RESPONDENTS—Continued

Information collection activity	A Respondents per year (projected) [1]	B Burden hours per respondent per year (predicted)	(A)×(B)=C Annual respondent burden hours (projected)	D Respondent labor cost ($/hr) (1998 $)	(C)×(D)=E Annual Cost ($) (projected)
No Exp. Cert. Proc. & Rev	30,200	0.5	15,100	26.91	406,341
Annual Subtotal			19,992		537,985
Annual Totals			56,369		2,151,305

Notes:
[1] Source: U.S. EPA, Office of Wastewater Management. Economic Analysis for the Storm Water Phase II Rule.
[2] The total number of potential no exposure respondents was divided by 5 to estimate an annual total. It was assumed that the annual number of respondents for the no exposure certification would be spread over the five year period the exclusion applies.
[3] The number of respondents in each category represents only those respondents located within the 44 NPDES-authorized States and Territories. The burden and cost estimates provided in this section are for the NPDES-authorized States in their role as the permitting authority for municipal designations and industrial no exposure.
[4] The number of respondents for this activity, 15, represents the number of NPDES-authorized States and Territories that must develop designation criteria and assess small MS4s located outside of an urbanized area for possible Phase II coverage divided by the three year ICR period.

Given the requirements of today's regulation, EPA believes there will be no capital startup and no operation and maintenance costs associated with information collection requirements of the rule.

The government burden associated with today's rule will impact State, Tribal, and Territorial governments (NPDES-authorized governmental entities) that have storm water program authority, as well as the federal government (*i.e.*, EPA), where it is the NPDES permitting authority. As of March 1999, 43 States and the Virgin Islands had NPDES authority.

The annual burden imposed upon authorized governmental entities (delegated States and the Virgin Islands) and the federal government for the next three years is estimated to be 19,992 hours ($537,985) and 4,087 hours ($115,948) respectively, for a total of 24,079 hours ($653,933). This estimate is based on the average time that governments will expend to carry out the following activities: designate additional MS4s (332.8 hours) and process and review "no exposure" certificates from industrial dischargers (0.5 hour).

Under the existing rule, storm water discharges from light industrial activities identified under § 122.26(b)(14)(xi) were exempted from the permit application requirements if they were not exposed to storm water. Today's rule expands the applicability of the "no exposure" exclusion to include all industrial activity regulated under § 122.26(b)(14) (except category (x), construction). The "no exposure" provision is applied through the use of a written certification process, thus representing a slight reporting burden increase for "light" industries with "no exposure'.

In addition to the information collection, reporting, and record keeping burden for the next three years, today's rule contains information collection requirements that will not begin until three years or more from the effective date of today's rule. These information collection requirements were not included in the information collection request approved by OMB. EPA will submit these burden estimates for OMB approval when it submits ICR 2040–0211 to OMB for renewal in three years. The rule burdens for regulated small MS4s and small construction sites that will be included in the ICR renewal fall into three areas: application for an NPDES permit or submittal of waiver information, record keeping of storm water management activities, and submittal of reports to the permitting authority. There will also be an additional burden for the permitting authority to review this information.

An agency may not conduct or sponsor, and a person is not required to respond to a collection of information unless it displays a currently valid OMB control number. The OMB control numbers for EPA's regulations are listed in 40 CFR Part 9 and 48 CFR Chapter 15. EPA is amending the table in 40 CFR Part 9 of currently approved ICR control numbers issued by OMB for various regulations to list the first three years of information requirements contained in this final rule.

B. Executive Order 12866

Under Executive Order 12866, [58 FR 51,735 (October 4, 1993)] the Agency must determine whether the regulatory action is "significant" and therefore subject to OMB review and the requirements of the Executive Order. The Order defines "significant regulatory action" as one that is likely to result in a rule that may:

(1) have an annual effect on the economy of $100 million or more or adversely affect in a material way the economy, a sector of the economy, productivity, competition, jobs, the environment, public health or safety, or State, local, or tribal governments or communities;

(2) create a serious inconsistency or otherwise interfere with an action taken or planned by another agency;

(3) materially alter the budgetary impact of entitlements, grants, user fees, or loan programs or the rights and obligations of recipients thereof; or

(4) raise novel legal or policy issues arising out of legal mandates, the President's priorities, or the principles set forth in the Executive Order.

Pursuant to the terms of Executive Order 12866, it has been determined that this rule is a "significant regulatory action". As such, this action was submitted to OMB for review. Changes made in response to OMB suggestions or recommendations will be documented in the public record.

C. Unfunded Mandates Reform Act

Title II of the Unfunded Mandates Reform Act of 1995 (UMRA), Public Law 104–4, establishes requirements for Federal agencies to assess the effects of their regulatory actions on State, local, and tribal governments and the private sector. Under section 202 of the UMRA, EPA generally must prepare a written statement, including a cost-benefit analysis, for proposed and final rules with "Federal mandates" that may result in expenditures to State, local, and tribal governments, in the aggregate, or to the private sector, of $100 million or more in any one year. Before promulgating an EPA rule for which a written statement is needed, section 205 of the UMRA generally requires EPA to identify and consider a reasonable number of regulatory alternatives and adopt the least costly, most cost-effective or least burdensome alternative that achieves the objectives of the rule. The provisions of section 205 do not apply when they are inconsistent with applicable law. Moreover, section 205 allows EPA to adopt an alternative other than the least costly, most cost-effective or least burdensome alternative if the Administrator publishes with the final rule an explanation why that alternative was not adopted.

EPA has determined that today's rule contains a Federal mandate that may result in expenditures of $100 million or more in any one year for both State, local, and tribal governments, in the aggregate, and the private sector. Accordingly, EPA has prepared under section 202 of the UMRA a written statement which is summarized below.

1. Summary of UMRA Section 202 Written Statement

EPA promulgates today's storm water regulation pursuant to the specific mandate of Clean Water Act section 402(p)(6), as well as sections 301, 308, 402, and 501. (33 U.S.C. sections 1342(p)(6), 1311, 1318, 1342, 1361.) Section 402(p)(6) of the CWA requires that EPA designate sources to be regulated to protect water quality and establish a comprehensive program to regulate those sources.

In the *Economic Analysis of the Final Phase II Rule* (EA), EPA describes the qualitative and monetized benefits associated with today's rule and then compares the monetized benefits with the estimated costs for the rule. EPA developed detailed estimates of the costs and benefits of complying with each of the incremental requirements imposed by the rule. These estimates, including descriptions of the methodology and assumptions used, are described in detail in the EA. The Agency used two approaches, a national water quality model and national water quality assessment, to estimate the potential benefits of the rule. Both approaches show that the benefits are likely to exceed costs. Exhibit 3 in section III of this preamble summarizes the costs and benefits associated with the basic elements of today's rule.

There are additional benefits to storm water control that cannot be quantified or monetized. Thus, the current estimate of monetized benefits may understate the true value of storm water controls because it omits many ways by which society is likely to benefit from reduced storm water pollution, such as improved aesthetic quality of waters, benefits to wildlife and to threatened and endangered species, cultural values, and biodiversity benefits.

Several commenters asserted that today's rule is an unfunded mandate and that, without funding, the monitoring of the already existing pollution control programs would suffer. In section II.D.3 of the preamble, EPA lists some of the programs that EPA anticipates may provide funds to help develop and, in limited circumstances, implement storm water management programs.

In the EA, EPA reviewed the expected effect of today's rule on the national economy. The Agency determined that the rule will have minimal impacts on the economy or employment. This is because the final rule regulates small MS4s and construction sites under 5 acres, not the typical industrial plants or other non-construction activities that could directly impact production and thus those sectors of the economy.

Discussions with representatives within the construction industry indicate that construction costs will likely be passed on to buyers, thus not seriously affecting the housing industry directly. Flexibility within the rule allows MS4s to tailor the storm water program requirements to their needs and financial position, minimizing impacts. For sedimentation and erosion controls on construction sites, the rule contemplates application of commonly used BMPs to reduce costs for the construction industry. Thus, the rule attempts to use existing practices to prevent pollution, which should minimize impacts on States, Tribes, municipalities and the construction industry.

Thus, EPA concludes that the effect of the rule, if any, on the national economy would be minimal. The benefits of today's rule more than offset any cost impacts on the national economy.

Consistent with the intergovernmental consultation provisions of section 204 of the UMRA and Executive Order 12875, "Enhancing the Intergovernmental Partnership," EPA consulted with the governmental entities affected by this rule.

First, EPA provided States, Tribal and local governments with the opportunity to comment on draft alternative approaches for the proposed rule through publishing a notice requesting information and public comment in the Federal Register on September 9, 1992 (57 FR 41344). This notice presented a full range of regulatory alternatives. At that time, EPA received more than 130 comments, including approximately 43 percent from municipalities and 24 percent from State or Federal agencies. These comments were the genesis of many of the provisions in the today's rule, including reliance on the NPDES program framework (including general permits), providing State and local governments flexibility in selecting additional sources requiring regulation, and focusing on high priority polluters. These comments helped to focus on pollution prevention, watershed-based concerns and BMPs. They also led to certain exemptions for facilities that do not pollute national waters.

In early 1993, EPA, in conjunction with the Rensselaerville Institute, held public and expert meetings to assist in developing and analyzing options for identifying unregulated storm water sources and possible controls. These meetings provided participants an additional opportunity to provide input into the CWA section 402(p)(6) program development process. The final rule addresses several of the key concerns identified in these groups, including provisions that provide flexibility to the States to select sources to be controlled and types of permits to be issued, and flexibility to MS4s in selecting BMPs.

EPA also conducted outreach with representatives of small entities, including small government representatives, in conjunction with the convening of a Small Business Advocacy Review Panel under SBREFA which is discussed in section IV.E. of the preamble.

In addition, EPA established the Urban Wet Weather Flows Advisory Committee under the Federal Advisory Committee Act (FACA). The Urban Wet Weather Flows Advisory Committee, in turn established the Storm Water Phase II Subcommittee. Consistent with FACA, the membership of the Committee and the Storm Water Phase II Subcommittee was balanced among EPA's various outside stakeholder interests, including representatives from State governments, municipal governments (both elected officials and appointed officials) and Tribal governments, as well as industrial and commercial sectors, agriculture, environmental and public interest groups.

In general, municipal and Tribal government representatives supported the NPDES approach in today's rule for the following reasons: It will be uniformly applied on a nationwide basis; it provides flexibility to allow incorporation of State and local programs; it resolves the problem of donut holes that cause water quality impacts in urbanized areas; and it allows co-permitting of small regulated

MS4s with those regulated under the existing storm water program.

In contrast, State representatives sought alternative approaches for State implementation of the storm water program for Phase II sources. State representatives asserted that a non-NPDES alternative approach best facilitated watershed management and avoided duplication and overlapping regulations. These representatives pointed out that there are a variety of State programs—not based on the CWA—implementing effective storm water controls, and that EPA should provide incentives for their implementation and improvement in performance. EPA continues to believe that an NPDES approach is the best approach in order to adequately protect water quality. However, EPA has worked with States on an alternative approach that provides flexibility within the NPDES framework. The final rule allows States with a watershed permitting approach to phase in permit coverage for MS4s in jurisdictions with a population less than 10,000 and provides two waivers from coverage for small MS4s. This issue is discussed in section II.C of the preamble, Program Framework: NPDES Approach.

Some municipal governments objected that the rule's minimum measures for small MS4s violate the Tenth Amendment insofar as they require the operators of MS4s to regulate third parties according to the "minimum measures" for municipal storm water management programs. EPA disagrees that today's rule is inconsistent with Tenth Amendment principles. Permits issued under today's rule will not compel political subdivisions of States to regulate in their sovereign capacities, but rather to effectively control discharges out of their storm sewer systems in their owner/operator capacities. For MS4s that do not accept this "default" minimum measures-based approach (to control discharges out of the storm sewer system by exercising local powers to control discharges into the storm sewer system), today's rule allows for alternative permits through individual permit applications. EPA made revisions to the rule to allow regulated small MS4s to opt out of the minimum measures approach and instead apply for an individual permit. This issue is discussed in section II.H.3.c.iii of the preamble, Alternative Permit Option/ Tenth Amendment.

2. Selection of the Least Costly, Most Cost-Effective or Least Burdensome Alternative That Achieves the Objectives of the Statute

Today's rule evolved over time and incorporated aspects of alternatives that responded to concerns presented by the various stakeholders. A primary characteristic of today's rule is the flexibility it offers both the permitting authority and the regulated sources (small MS4s and small construction sites), by the use of general permits, implementation of BMPs suited to specific locations, and allowing MS4s to develop their own program goals.

In the administrative record supporting the proposed rule, EPA estimated ranges of costs associated with six different options, including a no action option, the proposed option, and four other options that considered various combinations of the following: Covering all the unregulated construction sites below 5 acres, all small MS4s, certain industrial and commercial activities, and all point sources. EPA developed detailed cost estimates for the incremental requirements imposed under the final regulation, and for each of the alternatives, and applied these estimates to the remaining unregulated point sources of storm water. The Agency compared the estimated annual range of costs imposed under today's rule and other major options considered. The range of values for each option included the costs for compliance, including paperwork requirements for the operators of small construction sites, industrial facilities, and MS4s and administrative costs for State and Federal NPDES permitting authorities.

Today's rule reflects the least costly option that achieves the objectives of the statute, thus meeting the requirements of section 205. EPA did not consider "no regulation" to be an "option" because it would not achieve the objectives of CWA section 402(p)(6). A portion of currently unregulated point sources of storm water need to reduce pollutants to protect water quality.

Today's rule is estimated to range in cost from $847.6 million to $981.3 million annually, although the cost estimate for the proposed rule was reported as a range of $138 to $869 million annually. That range reflected a unit cost range for the municipal minimum measures and a cost range per construction site for soil erosion control. EPA has since revised its cost analysis to allow it to report the current estimate, which is toward the high end of the original cost range. The four other regulatory options considered at proposal involved higher regulatory costs and, therefore, were not selected. These four options and their estimate costs are as follows:

(1) An option based on the August 7, 1995 direct final rule was estimated to cost between $2.2 billion and $78.9 billion per year.

(2) A "Plan B" option was estimated to cost between $0.6 billion and $3.2 billion per year.

(3) An option based on the September 30, 1996 draft proposed rule was estimated to cost between $0.2 billion and $3.7 billion per year.

(4) An option based on the February 13, 1997 draft proposed rule, was estimated to cost between $0.2 billion and $3.5 billion.

There are three reasons why the costs for these four options exceeded the estimated cost range for the proposed rule. The first two options regulated substantially more municipal governments. The first, third, and fourth options required industrial facilities to apply for permits. Finally, the first three options applied permit requirements to construction sites below 1 acre. Consequently, these options would be more costly than today's rule even with the revised analysis methods used to estimate costs.

3. Effects on Small Governments

Before EPA establishes any regulatory requirements that may significantly or uniquely affect small governments, including tribal governments, it must have developed under section 203 of the UMRA a small government agency plan. The plan must provide for notifying potentially affected small governments, enabling officials of affected small governments to have meaningful and timely input in the development of EPA regulatory proposals with significant Federal intergovernmental mandates, and informing, educating, and advising small governments on compliance with the regulatory requirements. EPA has determined that this rule contains no regulatory requirements that might significantly or uniquely affect small governments. Although today's rule expands the NPDES program (with modifications) to certain MS4s serving populations below 100,000 and although many MS4s are owned by small governments, EPA does not believe today's rule significantly or uniquely affects small governments. As explained in section IV.E. of the preamble, EPA today certifies that the rule will not have a significant impact on small governmental jurisdictions. In addition, the rule will not have a unique impact on small governments because the rule will affect small governments in to the same extent as (or to a lesser extent than) larger governments that are already covered by the existing storm water rules. Thus, today's rule is not subject to the requirements of section 203 of UMRA.

Notwithstanding this finding, in developing today's rule, EPA provided notice of the requirements to potentially affected small governments; enabled officials of affected small governments to provide meaningful and timely input in the development of regulatory proposals; and informed, educated and advised small governments on compliance with the requirements.

Concerning notice, EPA provided States, local, and Tribal governments with the opportunity to comment on alternative approaches for an early draft of the proposed rule by publishing a notice requesting information and public comment in the **Federal Register** on September 9, 1992 (57 FR 41344). This notice presented a full range of regulatory alternatives. At that time, EPA received more than 130 comments, including approximately 43 percent from municipalities and 24 percent from State or Federal agencies.

The Agency also provided, through the SBREFA panel process and the FACA process, the opportunity for elected officials of small governments (and their representatives) to meaningfully participate in the development of the rule. Through such participation and exchange, EPA not only notified potentially affected small governments of requirements of the developing rule, but also allowed officials of affected small governments to have meaningful and timely input into the development of regulatory proposals.

In addition to involving municipalities in the development of the rule, EPA also continues to inform, educate, and advise small governments on compliance with the requirements of today's rule. For example, EPA supported 10 workshops, presented by the American Public Works Association from September 1998 through May 1999, designed to educate local governments on the implementation of the rule. The workshop curriculum included information on a variety of key issues such as anticipated regulatory requirements, agency reporting, best management practices, construction site controls, post construction management for new and redeveloped sites, public education and public involvement strategies, detection and control of illicit discharges, and good housekeeping practices. Moreover, EPA has prepared a series of fact sheets, available on the EPA website at www.epa.gov/owm/sw/toolbox, that explains the rule in detail.

Finally, to assist small governments in implementing the Phase II program, EPA is committed to the following: (1) developing a tool box of implementation strategies; (2) providing written technical assistance, including guidance on developing BMPs and measurable goals; and (3) compiling a comprehensive evaluation of the NPDES municipal storm water Phase II program over the next 13 years.

D. Executive Order 13132

Executive Order 13132, entitled "Federalism" (64 FR 43255, August 10, 1999), requires EPA to develop an accountable process to ensure "meaningful and timely input by State and local officials in the development of regulatory policies that have federalism implications." "Policies that have federalism implications" is defined in the Executive Order to include regulations that have "substantial direct effects on the States, on the relationship between the national government and the States, or on the distribution of power and responsibilities among the various levels of government." Under Executive Order 13132, EPA may not issue a regulation that has federalism implications, that imposes substantial direct compliance costs, and that is not required by statute, unless the Federal government provides the funds necessary to pay the direct compliance costs incurred by State and local governments, or EPA consults with State and local officials early in the process of developing the proposed regulation. EPA also may not issue a regulation that has federalism implications and that preempts State law unless the Agency consults with State and local officials early in the process of developing the proposed regulation.

If EPA complies by consulting, Executive Order 13132 requires EPA to provide to the Office of Management and Budget (OMB), in a separately identified section of the preamble to the rule, a federalism summary impact statement (FSIS). The FSIS must include a description of the extent of EPA's prior consultation with State and local officials, a summary of the nature of their concerns and the agency's position supporting the need to issue the regulation, and a statement of the extent to which the concerns of State and local officials have been met. For final rules subject to Executive Order 13132, EPA also must submit to OMB a statement from the agency's Federalism Official certifying that EPA has fulfilled the Executive Order's requirements.

EPA has concluded that this final rule may have federalism implications. As discussed above in section IV.C., the rule contains a Federal mandate that may result in the expenditure by State, local and tribal governments, in the aggregate, of $100 million or more in any one year. Accordingly, the rule may have substantial direct effects on the States, on the relationship between the national government and the States, or on the distribution of power and responsibilities among the various levels of government, as specified in Executive Order 13132. Moreover, the rule will impose substantial direct compliance costs on State or local governments. Accordingly, EPA provides the following FSIS under section 6(b) of Executive Order 13132.

1. Description of the Extent of the Agency's Prior Consultation with State and Local Governments

Although this rule was proposed long before the November 2, 1999 effective date of Executive Order 13132, EPA consulted extensively with affected State and local governments pursuant to the intergovernmental consultation provisions of Executive Order 12875, "Enhancing the Intergovernmental Partnership" (now revoked by Executive Order 13132) and section 204 of UMRA.

First, EPA provided State and local governments the opportunity to comment on draft alternative approaches for the proposed rule through publishing a notice requesting information and public comment in the **Federal Register** on September 9, 1992 (57 FR 41344). This notice presented a full range of regulatory alternatives. At that time, EPA received more than 130 comments, including approximately 43 percent from municipalities and 24 percent from State or Federal agencies. These comments were the genesis of many of the provisions in the today's rule, including reliance on the NPDES program framework (including general permits), providing State and local governments flexibility in selecting additional sources requiring regulation, and focusing on high priority polluters. These comments helped to focus on pollution prevention, watershed-based concerns and BMPs. They also led to certain exemptions for facilities that do not pollute national waters.

In early 1993, EPA, in conjunction with the Rensselaerville Institute, held public and expert meetings to assist in developing and analyzing options for identifying unregulated storm water sources and possible controls. These meetings provided participants an additional opportunity to provide input into the CWA section 402(p)(6) program

R0018171

development process. The final rule addresses several of the key concerns identified in these groups, including provisions that provide flexibility to the States to select sources to be controlled and types of permits to be issued, and flexibility to MS4s in selecting BMPs.

EPA also conducted outreach with representatives of small entities, including small governments, in conjunction with the convening of a Small Business Advocacy Review Panel under SBREFA which is discussed in section III.F. of the preamble.

In addition, EPA established the Urban Wet Weather Flows Advisory Committee (FACA), which in turn established the Storm Water Phase II Subcommittee. Consistent with the Federal Advisory Committee Act, the membership of the Committee and the Storm Water Phase II Subcommittee was balanced among EPA's various outside stakeholder interests, including representatives from State governments, municipal governments (both elected officials and appointed officials) and Tribal governments, as well as industrial and commercial sectors, agriculture, environmental and public interest groups.

2. Summary of Nature of State and Local Government Concerns, and Statement of the Extent to Which Those Concerns Have Been Met

In general, municipal government representatives supported the NPDES approach in today's rule for the following reasons: it will be uniformly applied on a nationwide basis; it provides flexibility to allow incorporation of State and local programs; it resolves the problem of donut holes that cause water quality impacts in urbanized areas; and it allows co-permitting of small regulated MS4s with those regulated under the existing storm water program.

In contrast, State representatives sought alternative approaches for State implementation of the storm water program for Phase II sources. State representatives asserted that a non-NPDES alternative approach best facilitated watershed management and avoided duplication and overlapping regulations. These representatives pointed out that there are a variety of State programs—not based on the CWA—implementing effective storm water controls, and that EPA should provide incentives for their implementation and improvement in performance. EPA continues to believe that an NPDES approach is the best approach in order to adequately protect water quality. However, EPA has worked with States on an alternative approach that provides flexibility within the NPDES framework. The final rule allows States with a watershed permitting approach to phase in permit coverage for MS4s in jurisdictions with a population less than 10,000 and provides two waivers from coverage for small MS4s. This issue is discussed in section II.C of the preamble, Program Framework: NPDES Approach.

Some municipal governments objected that the rule's minimum measures for small MS4s violate the Tenth Amendment insofar as they require the operators of MS4s to regulate third parties according to the "minimum measures" for municipal storm water management programs. EPA disagrees that today's rule is inconsistent with Tenth Amendment principles. Permits issued under today's rule will not compel political subdivisions of States to regulate in their sovereign capacities, but rather to effectively control discharges out of their storm sewer systems in their owner/operator capacities. For MS4s that do not accept this "default" minimum measures-based approach (to control discharges out of the storm sewer system by exercising local powers to control discharges into the storm sewer system), today's rule allows for alternative permits through individual permit applications. EPA made revisions to the rule to allow regulated small MS4s to opt out of the minimum measures approach and instead apply for an individual permit. This issue is discussed in section II.H.3.c.iii of the preamble, Alternative Permit Option/ Tenth Amendment.

3. Summary of the Agency's Position Supporting the Need To Issue the Regulation

As discussed more fully in section I.B. above, today's rule is needed because uncontrolled storm water discharges from areas of urban development and construction activity have been shown to have negative impacts on receiving waters by changing the physical, biological, and chemical composition of the water, resulting in an unhealthy environment for aquatic organisms, wildlife, and people. As discussed in section II.C., the NPDES approach in today's rule is needed to ensure uniform application on a nationwide basis, to provide flexibility to allow incorporation of State and local programs, to resolve the problem of donut holes that cause water quality impacts in urbanized areas, and to allow co-permitting of small regulated MS4s with those regulated under the existing storm water program.

The draft final rule was transmitted to OMB on July 6, 1999. Because transmittal occurred before the November 2, 1999 effective date of Executive Order 13132, certification under section 8 of the Executive Order is not required.

E. Regulatory Flexibility Act (RFA), as amended by the Small Business Regulatory Enforcement Fairness Act of 1996 (SBREFA), 5 U.S.C. 601 et seq.

The RFA generally requires an Agency to prepare a regulatory flexibility analysis of any rule subject to notice and comment rulemaking requirements under the Administrative Procedure Act or any other statute unless the agency certifies that the rule will not have a significant economic impact on a substantial number of small entities. Small entities include small businesses, small organizations, and small governmental jurisdictions.

For purposes of assessing the impact of today's rule on small entities, small entity is defined as: (1) a building contractor (SIC 15) with up to $17.0 million in annual revenue; (2) a small governmental jurisdiction that is a government of a city, county, town, school district, or special district with a population of less than 50,000; and (3) a small organization that is any not-for-profit enterprise which is independently owned and operated and is not dominant in its field.

After considering the economic impacts of today's final rule on small entities, I certify that this action will not have a significant economic impact on a substantial number of small entities.

Although this final rule will not have a significant economic impact on a substantial number of small entities, EPA nonetheless has tried to reduce the impact of this rule on small entities.

For purposes of evaluating the economic impact of this rule on small governmental jurisdictions, EPA compared annual compliance costs with annual government revenues obtained from the 1992 Census of Governments, using state-specific estimates of annual revenue per capita for municipalities in three population size categories (fewer than 10,000, 10,000–25,000, and 25,000–50,000).

In order to estimate the annual compliance cost for small governmental jurisdictions, EPA used the mean variable municipal cost of $8.93 per household as calculated in a 1998 study of 121 municipalities conducted by the national Association of Flood and Stormwater Management Agencies (NAFSMA). In addition, EPA used the estimated fixed administrative costs of $1,545 per municipality for reporting, recordkeeping, and application requirements for today's rule.

In evaluating the economic impact of this rule on small governmental jurisdictions, EPA determined that compliance costs represent more than 1 percent of estimated revenues for only 10 percent of small governments and more than 3 percent of the revenue for 0.7 percent of these entities. In both absolute and relative terms, EPA does not consider this a significant economic impact on a substantial number of small entities.

EPA normally uses the "sales test" for determining the economic impact on small businesses. Under a sales test, annual compliance costs are compared with the small business's total annual sales. However, the direct application of the sales test is not suitable in this case, because of the uncertainty associated with estimating the number of units an "average" developer/contractor develops or builds in a typical year. For this rule, EPA has approximated the sales test by estimating compliance costs for three sizes of construction sites and comparing them with a representative sale price for three building categories. Although EPA's analysis is not exactly a "sales test," it is similar to the sales test, producing comparable results.

For small building contractors, EPA estimated administrative compliance costs of $870 per site for applying for coverage, reporting, record keeping, monitoring and preparing a storm water pollution prevention plan. EPA estimated compliance costs for installing soil and erosion controls as ranging from $1,206 to $8,709 per site. EPA compliance cost estimates are based on 27 theoretical model construction sites designed to mimic the mostly likely used best management practices around the country.

In evaluating the economic impact on small building contractors, EPA divided the revised compliance costs per construction start by the appropriate homes-to-site ratio for each of the three sizes of construction sites. The average compliance cost per home ranges from approximately $450 to $650. EPA concluded that compliance costs are roughly 0.22 to 0.43 percent of both the mean, $181,300, and median, $151,000, sale price of a home.

The absence of data to specifically assess annual compliance costs for building contractors as a percentage of annual sales (i.e., a very direct estimate of the impact on potentially affected small businesses) led EPA to perform additional market analysis to examine the ability of potentially affected firms to pass along regulatory costs to buyers for single-family homes constructed subject to today's rule. If the small building contractors covered by the rule are able to pass on the costs of compliance, either completely or partially, to their purchasers, then the rule's impact on these small business entities is significantly reduced. The market analysis shows that demand for homes is not overly sensitive to small changes in price, therefore builders should be able to pass on at least a significant fraction of the compliance costs to buyers.

EPA also assessed the effect of the building contractors' costs on average monthly mortgage rates and on the demand for new homes. Based on that screening analysis, EPA concludes that the costs to building contractors, and the potential changes in housing prices and monthly mortgage payments for single-family home buyers, are not expected to have a significant impact on the market for single-family houses. In both absolute and relative terms, EPA does not consider this a significant economic impact on a substantial number of small entities.

EPA also certified this rule at proposal. Even though the Agency was not required to, we convened a Small Business Advocacy Review Panel ("Panel") in June 1997. A number of small entity representatives had already been actively involved with EPA through the FACA process, and were, therefore, broadly knowledgeable about the development of the proposed and final rules. Prior to convening the Panel, EPA consulted with the Small Business Administration to identify a group of small entity representatives to advise the Panel. The Agency distributed a briefing package describing its preliminary analysis under the RFA to the small entity representatives (as well as to representatives from OMB and SBA) and conducted two telephone conference calls and an all-day meeting at EPA Headquarters in May of 1997 with small entity representatives. With this preliminary work complete, in June 1997, EPA formally convened the SBREFA Panel, comprising representatives from OMB, SBA, EPA's Office of Water and EPA's Small Business Advocacy Chair. The Panel received written comments from small entity representatives based on their involvement in the earlier meetings, and invited additional comments.

Consistent with requirements of the RFA, the Panel evaluated the assembled materials and small-entity comments on issues related to: (1) a description and the number of small entities that would be regulated; (2) a description of the projected record keeping, reporting and other compliance requirements applicable to small entities; (3) identification of other Federal rules that may duplicate, overlap, or conflict with the proposal to the final rule; and (4) regulatory alternatives that would minimize any significant economic impact of the rule on small entities while accomplishing the stated objectives of the CWA section 402(p)(6).

On August 7, 1997, the Panel provided a Final Report (hereinafter, "Report") to the EPA Administrator. A copy of the Report is included in the docket for the rule. The Panel acknowledged and commended EPA's efforts to work with stakeholders, including small entities, through the FACA process. The SBREFA Panel stated that, because of EPA's extensive outreach and responsiveness in addressing stakeholder concerns, commenters during the SBREFA process raised fewer concerns than might otherwise have been expected. Based on the advice and recommendations of the Panel, today's rule includes a number of provisions designed to minimize any significant impact on small entities. (See Appendix 5).

F. National Technology Transfer And Advancement Act

Section 12(d) of the National Technology Transfer and Advancement Act of 1995 ("NTTAA"), Public Law 104–113, section 12(d) (15 U.S.C. 272 note) directs EPA to use voluntary consensus standards in its regulatory activities unless to do so would be inconsistent with applicable law or otherwise impractical. Voluntary consensus standards are technical standards (*e.g.*, materials specifications, test methods, sampling procedures, and business practices) that are developed or adopted by voluntary consensus standard bodies. The NTTAA directs EPA to provide Congress, through OMB, explanations when the Agency decides not to use available and applicable voluntary consensus standards.

This action does not mandate the use of any particular technical standards, although in designing appropriate BMPs regulated small MS4s and small construction sites are encouraged to use any voluntary consensus standards that may be applicable and appropriate. Because no specific technical standards are included in the rule, section 12(d) of the NTTAA is not applicable.

G. Executive Order 13045

Executive Order 13045: "Protection of Children from Environmental Health Risks and Safety Risks" (62 FR 19885, April 23, 1997) applies to any rule that: (1) Is determined to be "economically significant" as defined under E.O. 12866, and (2) concerns an environmental health or safety risk that EPA has reason to believe may have a disproportionate effect on children. If the regulatory action meets both criteria, the Agency must evaluate the environmental health or safety effects of the planned rule on children, and explain why the planned regulation is preferable to other potentially effective and reasonably feasible alternatives considered by the Agency.

This final rule is not subject to E.O. 13045 because it does not concern an environmental health or safety risk that may have a disproportionate effect on children. The rule expands the scope of the existing NPDES permitting program to require small municipalities and small construction sites to regulate their storm water discharges. The rule does not itself, however, establish standards or criteria that would be included in permits for those sources. Such standards or criteria will be developed through other actions, for example, in the establishment of water quality standards or subsequently in the issuance of permits themselves. As such, today's action does not concern an environmental health or safety risk that may have a disproportionate effect on children. To the extent it does address a risk that may have a disproportionate effect on children, expanding the scope of the permitting program will have a corresponding disproportionate benefit to children to protect them from such risk.

H. Executive Order 13084

Under Executive Order 13084, EPA may not issue a regulation that is not required by statute, that significantly or uniquely affects the communities of Indian tribal governments, and that imposes substantial direct compliance costs on those communities, unless the Federal government provides the funds necessary to pay the direct compliance costs incurred by the Tribal governments, or EPA consults with those governments. If EPA complies by consulting, Executive Order 13084 requires EPA to provide to the Office of Management and Budget, in a separately identified section of the preamble to the rule, a description of the extent of EPA's prior consultation with representatives of affected Tribal governments, a summary of the nature of their concerns, and a statement supporting the need to issue the regulation. In addition, Executive Order 13084 requires EPA to develop an effective process permitting elected officials and other representatives of Indian Tribal governments "to provide meaningful and timely input in the development of regulatory policies on matters that significantly or uniquely affect their communities."

Today's rule does not significantly or uniquely affect the communities of Indian Tribal governments. Even though the Agency is not required to address Tribes under the Regulatory Flexibility Act, EPA used the same revenue test that was used for municipalities to assess the impact of the rule on communities of Tribal governments and determine that they will not be significantly affected. In addition, the rule will not have a unique impact on the communities of Tribal governments because small municipal governments are also covered by this rule and larger municipal governments are already covered by the existing storm water rules. Accordingly, the requirements of section 3(b) of Executive Order 13084 do not apply to this rule.

I. Congressional Review Act

The Congressional Review Act, 5 U.S.C. section 801 *et seq.*, as added by the Small Business Regulatory Enforcement Fairness Act of 1996, generally provides that before a rule may take effect, the agency promulgating the rule must submit a rule report, which includes a copy of the rule, to each House of the Congress and the Comptroller General of the United States. EPA will submit a report containing this rule and other required information to the U.S. Senate, the U.S. House of Representatives, and the Comptroller General of the United States prior to publication of the rule in the Federal Register. A major rule cannot take effect until 60 days after it is published in the **Federal Register**. This rule is a "major rule" as defined by 5 U.S.C. 804(2). This rule will be effective on February 7, 2000.

List of Subjects

40 CFR Part 9

Environmental protection, Reporting and recordkeeping requirements.

40 CFR Part 122

Administrative practice and procedure, Confidential business information, Environmental protection, Hazardous substances, Incorporation by reference, Reporting and recordkeeping requirements, Sewage disposal, Waste treatment and disposal, Water pollution control.

40 CFR Part 123

Administrative practice and procedure, Confidential business information, Hazardous materials, Indians—lands, Intergovernmental relations, Penalties, Reporting and recordkeeping requirements, Sewage disposal, Waste treatment and disposal, Water pollution control, Penalties.

40 CFR Part 124

Administrative practice and procedure, Air pollution control, Hazardous waste, Indians—lands, Reporting and recordkeeping requirements, Water pollution control, Water supply.

Dated: October 29, 1999.

Carol M. Browner,

Administrator.

Appendices to the Preamble

APPENDIX 1 TO PREAMBLE—FEDERALLY-RECOGNIZED AMERICAN INDIAN AREAS LOCATED FULLY OR PARTIALLY IN BUREAU OF THE CENSUS URBANIZED AREAS

[Based on 1990 Census data]

State	American Indian Area	Urbanized Area
AZ	Pascua Yacqui Reservation (pt.): Pascua Yacqui Tribe of Arizona	Tucson, AZ (Phase I).
AZ	Salt River Reservation (pt.): Salt River Pima-Maricopa Indian Community of the Salt River Reservation, California.	Phoenix, AZ (Phase I).
AZ	San Xavier Reservation (pt.): Tohono O'odham Nation of Arizona (formerly known as the Papago Tribe of the Sells, Gila Bend & San Xavier Reservation).	Tucson, AZ (Phase I).
CA	Augustine Reservation: Augustine Band of Cahuilla Mission of Indians of the Augustine Reservation, CA.	Indio-Coachella, CA (Phase I).
CA	Cabazon Reservation: Cabazon Band of Cahuilla Mission Indians of the Cabazon Reservation, CA.	Indio-Coachella, CA (Phase I).

APPENDIX 1 TO PREAMBLE—FEDERALLY-RECOGNIZED AMERICAN INDIAN AREAS LOCATED FULLY OR PARTIALLY IN BUREAU OF THE CENSUS URBANIZED AREAS—Continued

[Based on 1990 Census data]

State	American Indian Area	Urbanized Area
CA	Fort Yuma (Quechan) (pt.): Quechan Tribe of the Fort Yuma Indian Reservation, California & Arizona.	Yuma, AZ–CA.
CA	Redding Rancheria: Redding Rancheria of California	Redding, CA.
FL	Hollywood Reservation: Seminole Tribe	Fort Lauderdale, FL (Phase I).
FL	Seminole Trust Lands: Seminole Tribe of Florida, Dania, Big Cypress & Brighton Reservations.	Fort Lauderdale, FL (Phase I).
ID	Fort Hall Reservation and Trust Lands: Shosone-Bannock Tribes of the Fort Hall Reservation of Idaho.	Pocatello, ID.
ME	Penobscot Reservation and Trust Lands (pt.): Penobscot Tribe of Maine	Bangor, ME.
MN	Shakopee Community: Shakopee Mdewakanton Sioux Community of Minnesota (Prior Lake).	Minneapolis-St. Paul, MN (Phase I).
NM	Sandia Pueblo (pt.): Pueblo of Sandia, New Mexico	Albuquerque, NM (Phase I).
NV	Las Vegas Colony: Las Vegas Tribe of Paiute Indians of the Las Vegas Indian Colony, Nevada.	Las Vegas, NV (Phase I).
NV	Reno-Sparks Colony: Reno-Sparks Indian Colony, Nevada	Reno, NV (Phase I).
OK	Osage Reservation (pt.): Osage Nation of Oklahoma	Tulsa, OK (Phase I).
OK	Absentee Shawnee-Citizens Band of Potawatomi TJSA (pt.): Absentee-Shawnee Tribe of Indians of Oklahoma; Citizen Potawatomi Nation, Oklahoma.	Oklahoma City, OK (Phase I).
OK	Cherokee TJSA 9 (pt.): Cherokee Nation of Oklahoma; United Keetoowah Band of Cherokee Indians of Oklahoma.	Ft. Smith, AR–OK; Tulsa, OK (Phase I).
OK	Cheyenne-Arapaho TJSA (pt.): Cheyenne-Arapaho Tribes of Oklahoma	Oklahoma City, OK (Phase I).
OK	Choctaw TJSA (pt.): Choctaw Nation of Oklahoma	Ft. Smith, AR–OK (Phase I).
OK	Creek TJSA (pt.): Alabama-Quassarte Tribal Town of the Creek Nation of Oklahoma; Kialegee Tribal Town of the Creek Indian Nation of Oklahoma; Muscogee (Creek) Nation of Oklahoma; Thlopthlocco Tribal Town of the Creek Nation of Oklahoma.	Tulsa, OK (Phase I).
OK	Kiowa-Comanche-Apache-Ft. Sill Apache: Apache Tribe of Oklahoma; Comanche Indian Tribe, Oklahoma; Fort Sill Apache Tribe of Oklahoma; Kiowa Indian Tribe of Oklahoma.	Lawton, OK.
TX	Ysleta del Sur Reservation: Ysleta Del Sur Pueblo of Texas	El Paso, TX–NM (Phase I).
WA	Muckleshoot Reservation and Trust Lands (pt.): Muckleshoot Indian Tribe of the Muckleshoot Reservation.	Seattle, WA (Phase I).
WA	Puyallup Reservation and Trust Lands (pt.): Puyallup Tribe of the Puyallup Reservation, WA.	Tacoma, WA (Phase I).
WA	Yakima Reservation (pt.): Confederated Tribes and Bands of the Yakama Indian Nation of the Yakama Reservation, WA.	Yakima, WA.
WI	Oneida (West) (pt.): Oneida Tribe of Wisconsin	Green Bay, WI.

Please Note

"(pt.)" indicates that the American Indian Area (AIA) listed is only partially located within the referenced urbanized area.

The first line under "American Indian Area" is the name of the federally-recognized reservation/colony/rancheria or trust land as it appears in the Bureau of the Census data. After this first line, the names of the tribes included in the AIA are listed as they appear in the Bureau of Indian Affairs' list of Federally Recognized Indian Tribes. (**Federal Register**: Nov. 13, 1998, Vol. 66, No. 220, pgs. 58211–58216)

"TJSAs" are Tribal Jurisdiction Statistical Areas in Oklahoma that are defined in conjunction with the federally-recognized tribes in Oklahoma who have definite land areas under their jurisdiction, but do not have reservation status.

"(Phase I)" indicates that the referenced urbanized area includes a medium or large MS4 currently regulated under the existing NPDES storm water program (i.e., Phase I). Any Tribally operated MS4 within these such urban areas would not automatically have been covered under Phase I, however.

Appendix 4 to the Preamble—No Exposure Certification Form

NPDES FORM 3510-11

EPA

United States Environmental Protection Agency
Washington, DC 20460

Form Approved
OMB No. 2040-0211

NO EXPOSURE CERTIFICATION for Exclusion from NPDES Storm Water Permitting

Submission of this No Exposure Certification constitutes notice that the entity identified in Section A does not require permit authorization for its storm water discharges associated with industrial activity in the State identified in Section B under EPA's Storm Water Multi-Sector General Permit due to the existence of a condition of no exposure.

A condition of no exposure exists at an industrial facility when all industrial materials and activities are protected by a storm resistant shelter to prevent exposure to rain, snow, snowmelt, and/or runoff. Industrial materials or activities include, but are not limited to, material handling equipment or activities, industrial machinery, raw materials, intermediate products, by-products, final products, or waste products. Material handling activities include the storage, loading and unloading, transportation, or conveyance of any raw material, intermediate product, final product or waste product. A storm resistant shelter is not required for the following industrial materials and activities:

- drums, barrels, tanks, and similar containers that are tightly sealed, provided those containers are not deteriorated and do not leak. "Sealed" means banded or otherwise secured and without operational taps or valves;
- adequately maintained vehicles used in material handling; and
- final products, other than products that would be mobilized in storm water discharges (e.g., rock salt).

A No Exposure Certification must be provided for each facility qualifying for the no exposure exclusion. In addition, the exclusion from NPDES permitting is available on a facility-wide basis only, not for individual outfalls. If any industrial activities or materials are or will be exposed to precipitation, the facility is not eligible for the no exposure exclusion.

By signing and submitting this No Exposure Certification form, the entity in Section A is certifying that a condition of no exposure exists at its facility or site, and is obligated to comply with the terms and conditions of 40 CFR 122.26(g).

ALL INFORMATION MUST BE PROVIDED ON THIS FORM.

Detailed instructions for completing this form and obtaining the no exposure exclusion are provided on pages 3 and 4.

A. Facility Operator Information

1. Name: ______ 2. Phone: ______

3. Mailing Address: a. Street: ______

b. City: ______ c. State: ___ d. Zip Code: _____-____

B. Facility/Site Location Information

1. Facility Name: ______

2. a. Street Address: ______

b. City: ______ c. County: ______

d. State: ___ e. Zip Code: _____-____

3. Is the facility located on Indian Lands? Yes ☐ No ☐

4. Is this a Federal facility? Yes ☐ No ☐

5. a. Latitude: ___° ___' ___" b. Longitude: ___° ___' ___"

6. a. Was the facility or site previously covered under an NPDES storm water permit? Yes ☐ No ☐

b. If yes, enter NPDES permit number: ______

7. SIC/Activity Codes: Primary: ____ Secondary (if applicable): ____

8. Total size of site associated with industrial activity: ______ acres

9. a. Have you paved or roofed over a formerly exposed, pervious area in order to qualify for the no exposure exclusion? Yes ☐ No ☐

b. If yes, please indicate approximately how much area was paved or roofed over. Completing this question does not disqualify you for the no exposure exclusion. However, your permitting authority may use this information in considering whether storm water discharges from your site are likely to have an adverse impact on water quality, in which case you could be required to obtain permit coverage.

Less than one acre ☐ One to five acres ☐ More than five acres ☐

R0018180

NPDES FORM 3510-11 | EPA | **NO EXPOSURE CERTIFICATION for Exclusion from NPDES Storm Water Permitting** | Form Approved OMB No. 2040-0211

C. Exposure Checklist

Are any of the following materials or activities exposed to precipitation, now or in the foreseeable future? (Please check either "Yes" or "No" in the appropriate box.) ***If you answer "Yes" to any of these questions (1) through (11), you are not eligible for the no exposure exclusion.***

	Yes	No
1. Using, storing or cleaning industrial machinery or equipment, and areas where residuals from using, storing or cleaning industrial machinery or equipment remain and are exposed to storm water	☐	☐
2. Materials or residuals on the ground or in storm water inlets from spills/leaks	☐	☐
3. Materials or products from past industrial activity	☐	☐
4. Material handling equipment (except adequately maintained vehicles)	☐	☐
5. Materials or products during loading/unloading or transporting activities	☐	☐
6. Materials or products stored outdoors (except final products intended for outside use [e.g., new cars] where exposure to storm water does not result in the discharge of pollutants)	☐	☐
7. Materials contained in open, deteriorated or leaking storage drums, barrels, tanks, and similar containers	☐	☐
8. Materials or products handled/stored on roads or railways owned or maintained by the discharger	☐	☐
9. Waste material (except waste in covered, non-leaking containers [e.g., dumpsters])	☐	☐
10. Application or disposal of process wastewater (unless otherwise permitted)	☐	☐
11. Particulate matter or visible deposits of residuals from roof stacks and/or vents not otherwise regulated (i.e., under an air quality control permit) and evident in the storm water outflow	☐	☐

D. Certification Statement

I certify under penalty of law that I have read and understand the eligibility requirements for claiming a condition of "no exposure" and obtaining an exclusion from NPDES storm water permitting.

I certify under penalty of law that there are no discharges of storm water contaminated by exposure to industrial activities or materials from the industrial facility or site identified in this document (except as allowed under 40 CFR 122.26(g)(2)).

I understand that I am obligated to submit a no exposure certification form once every five years to the NPDES permitting authority and, if requested, to the operator of the local municipal separate storm sewer system (MS4) into which the facility discharges (where applicable). I understand that I must allow the NPDES permitting authority, or MS4 operator where the discharge is into the local MS4, to perform inspections to confirm the condition of no exposure and to make such inspection reports publicly available upon request. I understand that I must obtain coverage under an NPDES permit prior to any point source discharge of storm water from the facility.

Additionally, I certify under penalty of law that this document and all attachments were prepared under my direction or supervision in accordance with a system designed to assure that qualified personnel properly gathered and evaluated the information submitted. Based on my inquiry of the person or persons who manage the system, or those persons directly responsible for gathering the information, the information submitted is to the best of my knowledge and belief true, accurate and complete. I am aware that there are significant penalties for submitting false information, including the possibility of fine and imprisonment for knowing violations.

Print Name: ______________________

Print Title: ______________________

Date: __________

R0018181

NPDES FORM 3510-11 | EPA | Instructions for the NO EXPOSURE CERTIFICATION for Exclusion from NPDES Storm Water Permitting | Form Approved OMB No. 2040-0211

Who May File a No Exposure Certification

Federal law at 40 CFR Part 122.26 prohibits point source discharges of storm water associated with industrial activity to waters of the U.S. without a National Pollutant Discharge Elimination System (NPDES) permit. However, NPDES permit coverage is not required for discharges of storm water associated with industrial activities identified at 40 CFR 122.26(b)(14)(i)-(ix) and (xi) if the discharger can certify that a condition of "no exposure" exists at the industrial facility or site.

Storm water discharges from construction activities identified in 40 CFR 122.26(b)(14)(x) and (b)(15) are not eligible for the no exposure exclusion.

Obtaining and Maintaining the No Exposure Exclusion

This form is used to certify that a condition of no exposure exists at the industrial facility or site described herein. This certification is only applicable in jurisdictions where EPA is the NPDES permitting authority and must be re-submitted at least once every five years.

The industrial facility operator must maintain a condition of no exposure at its facility or site in order for the no exposure exclusion to remain applicable. If conditions change resulting in the exposure of materials and activities to storm water, the facility operator must obtain coverage under an NPDES storm water permit immediately.

Where to File the No Exposure Certification Form

Mail the completed no exposure certification form to:

Storm Water No Exposure Certification (4203)
USEPA
401 M Street, SW
Washington, D.C. 20460

Completing the Form

You <u>must</u> type or print, using uppercase letters, in appropriate areas only. Enter only one character per space (i.e., between the marks). Abbreviate if necessary to stay within the number of characters allowed for each item. Use one space for breaks between words. One form must be completed for each facility or site for which you are seeking to certify a condition of no exposure. Additional guidance on completing this form can be accessed through EPA's web site at www.epa.gov/owm/sw. Please make sure you have addressed all applicable questions and have made a photocopy for your records before sending the completed form to the above address.

Section A. Facility Operator Information

1. Provide the legal name of the person, firm, public organization, or any other entity that operates the facility or site described in this certification. The name of the operator may or may not be the same as the name of the facility. The operator is the legal entity that controls the facility's operation, rather than the plant or site manager.
2. Provide the telephone number of the facility operator.
3. Provide the mailing address of the operator (P.O. Box numbers may be used). Include the city, state, and zip code. All correspondence will be sent to this address.

Section B. Facility/Site Location Information

1. Enter the official or legal name of the facility or site.
2. Enter the complete street address (if no street address exists, provide a geographic description [e.g., Intersection of Routes 9 and 55]), city, county, state, and zip code. Do not use a P.O. Box number.
3. Indicate whether the facility is located on Indian Lands.
4. Indicate whether the industrial facility is operated by a department or agency of the Federal Government (see also Section 313 of the Clean Water Act).
5. Enter the latitude and longitude of the approximate center of the facility or site in degrees/minutes/seconds. Latitude and longitude can be obtained from United States Geological Survey (USGS) quadrangle or topographic maps, by calling 1-(888) ASK-USGS, or by accessing EPA's web site at <u>http://www.epa.gov/owm/sw/industry/index.htm</u> and selecting Latitude and Longitude Finders under the Resources/Permit section.

   Latitude and longitude for a facility in decimal form must be converted to degrees (°), minutes ('), and seconds (") for proper entry on the certification form. To convert decimal latitude or longitude to degrees/minutes/seconds, follow the steps in the following example.

   <u>Example</u>: Convert decimal latitude 45.1234567 to degrees (°), minutes ('), and seconds (").

   a) The numbers to the left of the decimal point are the degrees: 45°.
   b) To obtain minutes, multiply the first four numbers to the right of the decimal point by 0.006: 1234 x 0.006 = 7.404.
   c) The numbers to the left of the decimal point in the result obtained in (b) are the minutes: 7'.
   d) To obtain seconds, multiply the remaining three numbers to the right of the decimal from the result obtained in (b) by 0.06: 404 x 0.06 = 24.24. Since the numbers to the right of the decimal point are not used, the result is 24".
   e) The conversion for 45.1234567 = 45° 7' 24".
6. Indicate whether the facility was previously covered under an NPDES storm water permit. If so, include the permit number.
7. Enter the 4-digit SIC code which identifies the facility's primary activity, and second 4-digit SIC code identifying the facility's secondary activity, if applicable. SIC codes can be obtained from the <u>Standard Industrial Classification Manual, 1987</u>.
8. Enter the total size of the site associated with industrial activity in acres. Acreage may be determined by dividing square footage by 43,560, as demonstrated in the following example.

   <u>Example</u>: Convert 54,450 ft^2 to acres

   Divide 54,450 ft^2 by 43,560 square feet per acre:
   54,450 ft^2 ÷ 43,560 ft^2/acre = 1.25 acres.
9. Check "Yes" or "No" as appropriate to indicate whether you have paved or roofed over a formerly exposed, pervious area (i.e., lawn, meadow, dirt or gravel road/parking lot) in order to qualify for no exposure. If yes, also indicate approximately how much area was paved or roofed over and is now impervious area.

R0018182

NPDES FORM 3510-11 EPA

Instructions for the NO EXPOSURE CERTIFICATION for Exclusion from NPDES Storm Water Permitting

Form Approved OMB No. 2040-0211

Section C. Exposure Checklist

Check "Yes" or "No" as appropriate to describe the exposure conditions at your facility. If you answer "Yes" to **ANY** of the questions (1) through (11) in this section, a potential for exposure exists at your site and you cannot certify to a condition of no exposure. You must obtain (or already have) coverage under an NPDES storm water permit. After obtaining permit coverage, you can institute modifications to eliminate the potential for a discharge of storm water exposed to industrial activity, and then certify to a condition of no exposure.

Section D. Certification Statement

Federal statutes provide for severe penalties for submitting false information on this application form. Federal regulations require this application to be signed as follows:

For a corporation: by a responsible corporate officer, which means:

(i) president, secretary, treasurer, or vice-president of the corporation in charge of a principal business function, or any other person who performs similar policy or decision making functions for the corporation, or

(ii) the manager of one or more manufacturing, production, or operating facilities, provided the manager is authorized to make management decisions which govern the operation of the regulated facility including having the explicit or implicit duty of making major capital investment recommendations, and initiating and directing other comprehensive measures to assure long term environmental compliance with environmental laws and regulations; the manager can ensure that the necessary systems are established or actions taken to gather complete and accurate information for permit application requirements; and where authority to sign documents has been assigned or delegated to the manager in accordance with corporate procedures;

For a partnership or sole proprietorship: by a general partner or the proprietor; or

For a municipal, State, Federal, or other public facility: by either a principal executive or ranking elected official.

Paperwork Reduction Act Notice

Public reporting burden for this certification is estimated to average 1.0 hour per certification, including time for reviewing instructions, searching existing data sources, gathering and maintaining the data needed, and completing and reviewing the collection of information. Burden means the total time, effort, or financial resources expended by persons to generate, maintain, retain, or disclose to provide information to or for a Federal agency. This includes the time needed to review instructions; develop, acquire, install, and utilize technology and systems for the purposes of collecting, validating, and verifying information, processing and maintaining information, and disclosing and providing information; adjust the existing ways to comply with any previously applicable instructions and requirements; train personnel to be able to respond to a collection of information; search data sources; complete and review the collection of information; and transmit or otherwise disclose the information. An agency may not conduct or sponsor, and a person is not required to respond to, a collection of information unless it displays a currently valid OMB control number. Send comments regarding the burden estimate, any other aspect of the collection of information, or suggestions for improving this form, including any suggestions which may increase or reduce this burden to: Director, OPPE Regulatory Information Division (2137), USEPA, 401 M Street, SW, Washington, D.C. 20460. Include the OMB control number of this form on any correspondence. Do not send the completed No Exposure Certification form to this address.

EPA Form 3510-11 (10-99) Page 4 of 4

BILLING CODE 6560-50-C

Appendix 5 to Preamble—Regulatory Flexibility for Small Entities

A. Regulatory Flexibility for Small Municipal Storm Sewer Systems (MS4s)

Different Compliance, Reporting, or Timetables That Are Responsive to Resources of Small Entities

NPDES permitting authorities can issue general permits instead of requiring individual permits. This flexibility avoids the high application costs and administrative burden associated with individual permits.

NPDES permitting authorities can specify a time period of up to five years for small MS4s to fully develop and implement their program

Analytic monitoring is not required.

After the first permit term and subsequent permit terms, submittal of a summary report is only required in years two and four (Phase I municipalities are currently required to submit a detailed report each year).

A brief reporting format is encouraged to facilitate compiling and analyzing data from submitted reports. EPA intends to develop a model form for this purpose.

NPDES Permitting Authorities can phase in permit coverage for small MS4s serving jurisdictions with a population under 10,000 on a schedule consistent with a State watershed permitting approach.

Clarifying, Consolidating, or Simplifying Compliance and Reporting Requirements

The rule avoids duplication in permit requirements by allowing NPDES permitting authorities to include permit conditions that direct an MS4 to follow the requirements of a qualifying local program rather than the requirements of a minimum measure. Compliance with these programs is considered compliance with the NPDES general permit.

The rule allows NPDES permitting authorities to recognize existing responsibilities among different municipal entities to satisfy obligations for the minimum control measures.

A further alternative allows a small MS4 to satisfy its NPDES permit obligations if another governmental entity is already implementing a minimum control measure in the jurisdiction of the small MS4. The following conditions must be met:

1. The other entity is implementing the control measure,

2. The particular control measure (or component thereof) is at least as stringent as the corresponding NPDES permit requirement, and

3. The other entity agrees to implement the control measure on your behalf.

The rule allows a covered small MS4 to "piggy-back" on to the storm water management program of an adjoining Phase I MS4. A small MS4 is waived from the application requirements of § 122.26(d)(1)(iii), (iv) and (d)(2)(iii) [discharge characterization] and may satisfy the requirements of § 122.26(d)(1)(v) and (d)(2)(iv) [identifying a management plan] by referencing the adjoining Phase I MS4's storm water management plan.

The rule accommodates the use of the watershed approach through NPDES general permits that could be issued on a watershed basis. The small MS4 can develop measures that are tailored to meet their watershed requirements. The small MS4's storm water management program can tie into watershed-wide plans.

Performance Rather Than Design Standards for Small Entities

Small governmental jurisdictions whose MS4s are covered by this rule are allowed to choose the best management practices (BMPs) to be implemented and the measurable goals for each of the minimum control measures:

1. Public education and outreach on storm water impacts

2. Public Involvement/Participation

3. Illicit discharge detection and elimination

R0018183

4. Construction site storm water runoff control
5. Post-construction storm water management in new development and redevelopment
6. Pollution prevention/good housekeeping for municipal operations

EPA will provide guidance and recommend, but not mandate, certain BMPs for some of the minimum control measures listed above. States can provide guidance to supplement or supplant EPA guidance.

Small MS4s can identify the measurable goals for each of the minimum control measures listed above. In their reports to the NPDES permitting authority, the small MS4s must evaluate their progress towards achievement of their identified measurable goals.

Waivers for Small Entities From Coverage

The rule allows permitting authorities to waive from coverage MS4s operated by small governmental jurisdictions located within an urbanized area and serving a population less than 1,000 people where the permitting authority has determined the MS4 is not contributing substantially to the pollutant loadings of an interconnected MS4 and, if the MS4 discharges pollutants that have been identified as a cause of impairment in the receiving water of the MS4 then the permitting authority has determined that storm water controls are not needed based on a TMDL that addresses the pollutants of concern.

The rule allows the permitting authority to waive from coverage MS4s serving a population under 10,000 where the permitting authority has evaluated all waters that receive a discharge from the MS4 and the permitting authority has determined that storm water controls are not needed based on a TMDL that addresses the pollutants of concern and future discharges do not have the potential to result in exceedances of water quality standards.

B. Regulatory Flexibility for Small Construction Activities

Different Compliance, Reporting, or Timetables That Are Responsive to Resources of Small Entities

The rule gives NPDES permitting authorities discretion not to require the submittal of a notice of intent (NOI) for coverage under a NPDES general permit, thereby reducing administrative and financial burden. All construction sites disturbing greater than 5 acres must submit an NOI.

Clarifying, Consolidating, or Simplifying Compliance and Reporting Requirements

The rule avoids duplication by allowing the NPDES permitting authority to incorporate by reference State, Tribal, or local programs under a NPDES general permit. Compliance with these programs is considered compliance with the NPDES general permit.

Performance Rather Than Design Standards for Small Entities

The operator of a covered construction activity selects and implement the BMPs most appropriate for the construction site based on the operator's storm water pollution prevention plan.

Waivers for Small Entities From Coverage

Waivers could be granted based on the use of a rainfall erosivity factor or a comprehensive analysis of water quality impacts.

(A) *Low rainfall waiver:* When the rainfall erosivity factor ("R" from Revised Universal Soil Loss Equation) is less than 5 during the period of construction activity, a permit is not required.

(B) *Determination based on Water Quality Analysis:* The NPDES permitting authority can waive from coverage construction activities disturbing from 1 acre up to 5 acres of land where storm water controls are not needed based on:

1. A TMDL approved or established by EPA that addresses the pollutants of concern, or
2. For non-impaired waters, an equivalent analysis that determines that such allocations are not needed to protect water quality based on consideration of existing in-stream concentrations, expected growth in pollutant contributions from all sources, and a margin of safety.

C. Regulatory Flexibility for Industrial/Commercial Facilities

Waivers for Small Entities From Coverage

The rule provides a "no-exposure" waiver provision for Phase I industrial/commercial facilities. Qualifying facilities seeking this provision simply need to complete a self-certification form indicating that no industrial materials or activities are exposed to rain, snow, snow melt and/or runoff.

Appendix 6 of Preamble—Governmental Entities Located Fully or Partially Within an Urbanized Area

(This is a reference list only, *not* a list of all operators of small MS4s subject to §§ 122.32–122.36. For example, a listed governmental entity is only regulated if it operates a small MS4 within an "urbanized area" boundary as determined by the Bureau of the Census. Furthermore, entities such as military bases, large hospitals, prison complexes, universities, sewer districts, and highway departments that operate a small MS4 within an urbanized area are also subject to the permitting regulations but are not individually listed here. See § 122.26(b)(16) for the definition of a small MS4 and § 122.32(a) for the definition of a regulated small MS4.)

Appendix 7 of Preamble—Governmental Entities (Located Outside of an Urbanized Area) That Must Be Examined By the NPDES Permitting Authority for Potential Designation Under § 123.35(b)(2)

(All listed entities have a population of at least 10,000 and a population density of at least 1,000. A listed entity would only be potentially designated if it operates a small MS4. See § 122.26(b)(16) for the definition of a small MS4.)

(This list does not include all operators of small MS4s that may be designated by the NPDES permitting authority. Operators of small MS4s in areas with populations below 10,000 and densities below 1,000 may also be designated but examination of them is not required. Also, entities such as military bases, large hospitals, prison complexes, universities, sewer districts, and highway departments that operate a small MS4 in an area listed here, or in an area otherwise designated by the NPDES permitting authority, may be designated and become subject to permitting regulations.) (Source: 1990 Census of Population and Housing, U.S. Bureau of the Census. This list is subject to change with the Decennial Census)

For the reasons set forth in the preamble, chapter I of title 40 of the Code of Federal Regulations is amended as follows:

PART 9—OMB APPROVALS UNDER THE PAPERWORK REDUCTION ACT

1. The authority citation for part 9 continues to read as follows:

Authority: 7 U.S.C. 135 *et seq.*, 136–136y; 15 U.S.C. 2001, 2003, 2005, 2006, 2601–2671; 21 U.S.C. 331j, 346a, 348; 31 U.S.C. 9701; 33 U.S.C. 1251 *et seq.*, 1311, 1313d, 1314, 1318, 1321, 1326, 1330, 1342, 1344, 1345 (d) and (e), 1361; E.O. 11735, 38 FR 21243, 3 CFR, 1971–1975 Comp. p. 973; 42 U.S.C. 241, 242b, 243, 246, 300f, 300g, 300g–1, 300g–2, 300g–3, 300g–4, 300g–5, 300g–6, 300j–1, 300j–2, 300j–3, 300j–4, 300j–9, 1857 *et seq.*, 6901–6992k, 7401–7671q, 7542, 9601–9657, 11023, 11048.

2. In § 9.1 the table is amended by adding entries in numerical order under the indicated heading to read as follows:

§ 9.1 OMB approvals under the Paperwork Reduction Act.

* * * * *

R0018209

40 CFR citation	OMB control No.
* * * * * * *	
EPA Administered Permit Programs: The National Pollutant Discharge Elimination System	
* * * * * * *	
122.26(g)	2040–0211
* * * * * * *	
State Permit Requirements	
* * * * * * *	
123.35(b)	2040–0211
* * * * * * *	

PART 122—EPA ADMINISTERED PERMIT PROGRAMS: THE NATIONAL POLLUTANT DISCHARGE ELIMINATION SYSTEM

1. The authority citation for part 122 continues to read as follows:

Authority: The Clean Water Act, 33 U.S.C. 1251 *et seq.*

2. Revise § 122.21(c)(1) to read as follows:

§ 122.21 Application for a permit (applicable to State programs, see § 123.25).

* * * * *

(c) *Time to apply.* (1) Any person proposing a new discharge, shall submit an application at least 180 days before the date on which the discharge is to commence, unless permission for a later date has been granted by the Director. Facilities proposing a new discharge of storm water associated with industrial activity shall submit an application 180 days before that facility commences industrial activity which may result in a discharge of storm water associated with that industrial activity. Facilities described under § 122.26(b)(14)(x) or (b)(15)(i) shall submit applications at least 90 days before the date on which construction is to commence. Different submittal dates may be required under the terms of applicable general permits. Persons proposing a new discharge are encouraged to submit their applications well in advance of the 90 or 180 day requirements to avoid delay. See also paragraph (k) of this section and § 122.26(c)(1)(i)(G) and (c)(1)(ii).

* * * * *

3. Amend § 122.26 as follows:

a. Revise paragraphs (a)(9), (b)(4)(i), (b)(7)(i), (b)(14) introductory text, (b)(14)(x), (b)(14)(xi);

b. Redesignate paragraph (b)(15) as paragraph (b)(20) and add new paragraphs (b)(15) through (b)(19);

c. Revise the heading for paragraph (c), the first sentence of paragraph (c)(1) introductory text, the first sentence of paragraph (c)(1)(ii) introductory text, paragraphs (e) heading and introductory text, (e)(1), (e)(5) introductory text, and (e)(5)(i);

d. Add paragraphs (e)(8) and (e)(9); and

e. Revise paragraphs (f)(4), (f)(5), and (g).

The additions and revisions read as follows:

§ 122.26 Storm water discharges (applicable to State NPDES programs, see § 123.25).

(a) * * *

(9)(i) On and after October 1, 1994, for discharges composed entirely of storm water, that are not required by paragraph (a)(1) of this section to obtain a permit, operators shall be required to obtain a NPDES permit only if:

(A) The discharge is from a small MS4 required to be regulated pursuant to § 122.32;

(B) The discharge is a storm water discharge associated with small construction activity pursuant to paragraph (b)(15) of this section;

(C) The Director, or in States with approved NPDES programs either the Director or the EPA Regional Administrator, determines that storm water controls are needed for the discharge based on wasteload allocations that are part of "total maximum daily loads" (TMDLs) that address the pollutant(s) of concern; or

(D) The Director, or in States with approved NPDES programs either the Director or the EPA Regional Administrator, determines that the discharge, or category of discharges within a geographic area, contributes to a violation of a water quality standard or is a significant contributor of pollutants to waters of the United States.

(ii) Operators of small MS4s designated pursuant to paragraphs (a)(9)(i)(A), (a)(9)(i)(C), and (a)(9)(i)(D) of this section shall seek coverage under an NPDES permit in accordance with §§ 122.33 through 122.35. Operators of non-municipal sources designated pursuant to paragraphs (a)(9)(i)(B), (a)(9)(i)(C), and (a)(9)(i)(D) of this section shall seek coverage under an NPDES permit in accordance with paragraph (c)(1) of this section.

(iii) Operators of storm water discharges designated pursuant to paragraphs (a)(9)(i)(C) and (a)(9)(i)(D) of this section shall apply to the Director for a permit within 180 days of receipt of notice, unless permission for a later date is granted by the Director (see § 124.52(c) of this chapter).

(b) * * *

(4) * * *

(i) Located in an incorporated place with a population of 250,000 or more as determined by the 1990 Decennial Census by the Bureau of the Census (Appendix F of this part); or

* * * * *

(7) * * *

(i) Located in an incorporated place with a population of 100,000 or more but less than 250,000, as determined by the 1990 Decennial Census by the Bureau of the Census (Appendix G of this part); or

* * * * *

(14) *Storm water discharge associate with industrial activity* means the discharge from any conveyance that is used for collecting and conveying storm

water and that is directly related to manufacturing, processing or raw materials storage areas at an industrial plant. The term does not include discharges from facilities or activities excluded from the NPDES program under this part 122. For the categories of industries identified in this section, the term includes, but is not limited to, storm water discharges from industrial plant yards; immediate access roads and rail lines used or traveled by carriers of raw materials, manufactured products, waste material, or by-products used or created by the facility; material handling sites; refuse sites; sites used for the application or disposal of process waste waters (as defined at part 401 of this chapter); sites used for the storage and maintenance of material handling equipment; sites used for residual treatment, storage, or disposal; shipping and receiving areas; manufacturing buildings; storage areas (including tank farms) for raw materials, and intermediate and final products; and areas where industrial activity has taken place in the past and significant materials remain and are exposed to storm water. For the purposes of this paragraph, material handling activities include storage, loading and unloading, transportation, or conveyance of any raw material, intermediate product, final product, by-product or waste product. The term excludes areas located on plant lands separate from the plant's industrial activities, such as office buildings and accompanying parking lots as long as the drainage from the excluded areas is not mixed with storm water drained from the above described areas. Industrial facilities (including industrial facilities that are federally, State, or municipally owned or operated that meet the description of the facilities listed in paragraphs (b)(14)(i) through (xi) of this section) include those facilities designated under the provisions of paragraph (a)(1)(v) of this section. The following categories of facilities are considered to be engaging in "industrial activity" for purposes of paragraph (b)(14):

* * * * *

(x) Construction activity including clearing, grading and excavation, except operations that result in the disturbance of less than five acres of total land area. Construction activity also includes the disturbance of less than five acres of total land area that is a part of a larger common plan of development or sale if the larger common plan will ultimately disturb five acres or more;

(xi) Facilities under Standard Industrial Classifications 20, 21, 22, 23, 2434, 25, 265, 267, 27, 283, 285, 30, 31 (except 311), 323, 34 (except 3441), 35, 36, 37 (except 373), 38, 39, and 4221–25;

(15) *Storm water discharge associated with small construction activity* means the discharge of storm water from:

(i) Construction activities including clearing, grading, and excavating that result in land disturbance of equal to or greater than one acre and less than five acres. Small construction activity also includes the disturbance of less than one acre of total land area that is part of a larger common plan of development or sale if the larger common plan will ultimately disturb equal to or greater than one and less than five acres. Small construction activity does not include routine maintenance that is performed to maintain the original line and grade, hydraulic capacity, or original purpose of the facility. The Director may waive the otherwise applicable requirements in a general permit for a storm water discharge from construction activities that disturb less than five acres where:

(A) The value of the rainfall erosivity factor ("R" in the Revised Universal Soil Loss Equation) is less than five during the period of construction activity. The rainfall erosivity factor is determined in accordance with Chapter 2 of *Agriculture Handbook Number 703, Predicting Soil Erosion by Water: A Guide to Conservation Planning With the Revised Universal Soil Loss Equation (RUSLE)*, pages 21–64, dated January 1997. The Director of the Federal Register approves this incorporation by reference in accordance with 5 U.S.C 552(a) and 1 CFR part 51. Copies may be obtained from EPA's Water Resource Center, Mail Code RC4100, 401 M St. S.W., Washington, DC 20460. A copy is also available for inspection at the U.S. EPA Water Docket , 401 M Street S.W., Washington, DC. 20460, or the Office of the Federal Register, 800 N. Capitol Street N.W. Suite 700, Washington, DC. An operator must certify to the Director that the construction activity will take place during a period when the value of the rainfall erosivity factor is less than five; or

(B) Storm water controls are not needed based on a "total maximum daily load" (TMDL) approved or established by EPA that addresses the pollutant(s) of concern or, for non-impaired waters that do not require TMDLs, an equivalent analysis that determines allocations for small construction sites for the pollutant(s) of concern or that determines that such allocations are not needed to protect water quality based on consideration of existing in-stream concentrations, expected growth in pollutant contributions from all sources, and a margin of safety. For the purpose of this paragraph, the pollutant(s) of concern include sediment or a parameter that addresses sediment (such as total suspended solids, turbidity or siltation) and any other pollutant that has been identified as a cause of impairment of any water body that will receive a discharge from the construction activity. The operator must certify to the Director that the construction activity will take place, and storm water discharges will occur, within the drainage area addressed by the TMDL or equivalent analysis.

(ii) Any other construction activity designated by the Director, or in States with approved NPDES programs either the Director or the EPA Regional Administrator, based on the potential for contribution to a violation of a water quality standard or for significant contribution of pollutants to waters of the United States.

EXHIBIT 1 TO § 122.26(B)(15).—SUMMARY OF COVERAGE OF "STORM WATER DISCHARGES ASSOCIATED WITH SMALL CONSTRUCTION ACTIVITY" UNDER THE NPDES STORM WATER PROGRAM

Automatic Designation: Required Nationwide Coverage.	• Construction activities that result in a land disturbance of equal to or greater than one acre and less than five acres. • Construction activities disturbing less than one acre if part of a larger common plan of development or sale with a planned disturbance of equal to or greater than one acre and less than five acres. (see § 122.26(b)(15)(i).)
Potential Designation: Optional Evaluation and Designation by the NPDES Permitting Authority or EPA Regional Administrator..	• Construction activities that result in a land disturbance of less than one acre based on the potential for contribution to a violation of a water quality standard or for significant contribution of pollutants. (see § 122.26(b)(15)(ii).)

R0018211

EXHIBIT 1 TO § 122.26(B)(15).—SUMMARY OF COVERAGE OF "STORM WATER DISCHARGES ASSOCIATED WITH SMALL CONSTRUCTION ACTIVITY" UNDER THE NPDES STORM WATER PROGRAM—Continued

Potential Waiver: Waiver from Requirements as Determined by the NPDES Permitting Authority..	Any automatically designated construction activity where the operator certifies: (1) A rainfa erosivity factor of less than five, or (2) That the activity will occur within an area where controls are not needed based on a TMDL or, for non-impaired waters that do not require a TMDL, an equivalent analysis for the pollutant(s) of concern. (see § 122.26(b)(15)(i).)

(16) *Small municipal separate storm sewer system* means all separate storm sewers that are:

(i) Owned or operated by the United States, a State, city, town, borough, county, parish, district, association, or other public body (created by or pursuant to State law) having jurisdiction over disposal of sewage, industrial wastes, storm water, or other wastes, including special districts under State law such as a sewer district, flood control district or drainage district, or similar entity, or an Indian tribe or an authorized Indian tribal organization, or a designated and approved management agency under section 208 of the CWA that discharges to waters of the United States.

(ii) Not defined as "large" or "medium" municipal separate storm sewer systems pursuant to paragraphs (b)(4) and (b)(7) of this section, or designated under paragraph (a)(1)(v) of this section.

(iii) This term includes systems similar to separate storm sewer systems in municipalities, such as systems at military bases, large hospital or prison complexes, and highways and other thoroughfares. The term does not include separate storm sewers in very discrete areas, such as individual buildings.

(17) *Small MS4* means a small municipal separate storm sewer system.

(18) *Municipal separate storm sewer system* means all separate storm sewers that are defined as "large" or "medium" or "small" municipal separate storm sewer systems pursuant to paragraphs (b)(4), (b)(7), and (b)(16) of this section, or designated under paragraph (a)(1)(v) of this section.

(19) *MS4* means a municipal separate storm sewer system.

* * * * *

(c) *Application requirements for storm water discharges associated with industrial activity and storm water discharges associated with small construction activity*—(1) *Individual application.* Dischargers of storm water associated with industrial activity and with small construction activity are required to apply for an individual permit or seek coverage under a promulgated storm water general permit. * * *

* * * * *

(ii) An operator of an existing or new storm water discharge that is associated with industrial activity solely under paragraph (b)(14)(x) of this section or is associated with small construction activity solely under paragraph (b)(15) of this section, is exempt from the requirements of § 122.21(g) and paragraph (c)(1)(i) of this section. * * *

* * * * *

(e) *Application deadlines.* Any operator of a point source required to obtain a permit under this section that does not have an effective NPDES permit authorizing discharges from its storm water outfalls shall submit an application in accordance with the following deadlines:

(1) *Storm water discharges associated with industrial activity.* (i) Except as provided in paragraph (e)(1)(ii) of this section, for any storm water discharge associated with industrial activity identified in paragraphs (b)(14)(i) through (xi) of this section, that is not part of a group application as described in paragraph (c)(2) of this section or that is not authorized by a storm water general permit, a permit application made pursuant to paragraph (c) of this section must be submitted to the Director by October 1, 1992;

(ii) For any storm water discharge associated with industrial activity from a facility that is owned or operated by a municipality with a population of less than 100,000 that is not authorized by a general or individual permit, other than an airport, powerplant, or uncontrolled sanitary landfill, the permit application must be submitted to the Director by March 10, 2003.

* * * * *

(5) A permit application shall be submitted to the Director within 180 days of notice, unless permission for a later date is granted by the Director (see § 124.52(c) of this chapter), for:

(i) A storm water discharge that the Director, or in States with approved NPDES programs, either the Director or the EPA Regional Administrator, determines that the discharge contributes to a violation of a water quality standard or is a significant contributor of pollutants to waters of the United States (see paragraphs (a)(1)(v) and (b)(15)(ii) of this section);

* * * * *

(8) For any storm water discharge associated with small construction activity identified in paragraph (b)(15)(i) of this section, see § 122.21(c)(1). Discharges from these sources require permit authorization by March 10, 2003, unless designated for coverage before then.

(9) For any discharge from a regulated small MS4, the permit application made under § 122.33 must be submitted to the Director by:

(i) March 10, 2003 if designated under § 122.32(a)(1) unless your MS4 serves a jurisdiction with a population under 10,000 and the NPDES permitting authority has established a phasing schedule under § 123.35(d)(3) (see § 122.33(c)(1)); or

(ii) Within 180 days of notice, unless the NPDES permitting authority grants a later date, if designated under § 122.32(a)(2) (see § 122.33(c)(2)).

(f) * * *

(4) Any person may petition the Director for the designation of a large, medium, or small municipal separate storm sewer system as defined by paragraph (b)(4)(iv), (b)(7)(iv), or (b)(16) of this section.

(5) The Director shall make a final determination on any petition received under this section within 90 days after receiving the petition with the exception of petitions to designate a small MS4 in which case the Director shall make a final determination on the petition within 180 days after its receipt.

(g) *Conditional exclusion for "no exposure" of industrial activities and materials to storm water.* Discharges composed entirely of storm water are not storm water discharges associated with industrial activity if there is "no exposure" of industrial materials and activities to rain, snow, snowmelt and/or runoff, and the discharger satisfies the conditions in paragraphs (g)(1) through (g)(4) of this section. "No exposure" means that all industrial materials and activities are protected by a storm resistant shelter to prevent exposure to rain, snow, snowmelt, and/or runoff. Industrial materials or activities include, but are not limited to, material handling equipment or activities, industrial machinery, raw materials, intermediate products, by-products, final products, or waste products. Material handling activities include the storage, loading and unloading, transportation, or conveyance of any raw material, intermediate product, final product or waste product.

(1) *Qualification*. To qualify for this exclusion, the operator of the discharge must:

(i) Provide a storm resistant shelter to protect industrial materials and activities from exposure to rain, snow, snow melt, and runoff;

(ii) Complete and sign (according to § 122.22) a certification that there are no discharges of storm water contaminated by exposure to industrial materials and activities from the entire facility, except as provided in paragraph (g)(2) of this section;

(iii) Submit the signed certification to the NPDES permitting authority once every five years;

(iv) Allow the Director to inspect the facility to determine compliance with the "no exposure" conditions;

(v) Allow the Director to make any "no exposure" inspection reports available to the public upon request; and

(vi) For facilities that discharge through an MS4, upon request, submit a copy of the certification of "no exposure" to the MS4 operator, as well as allow inspection and public reporting by the MS4 operator.

(2) *Industrial materials and activities not requiring storm resistant shelter*. To qualify for this exclusion, storm resistant shelter is not required for:

(i) Drums, barrels, tanks, and similar containers that are tightly sealed, provided those containers are not deteriorated and do not leak ("Sealed" means banded or otherwise secured and without operational taps or valves);

(ii) Adequately maintained vehicles used in material handling; and

(iii) Final products, other than products that would be mobilized in storm water discharge (e.g., rock salt).

(3) *Limitations*. (i) Storm water discharges from construction activities identified in paragraphs (b)(14)(x) and (b)(15) are not eligible for this conditional exclusion.

(ii) This conditional exclusion from the requirement for an NPDES permit is available on a facility-wide basis only, not for individual outfalls. If a facility has some discharges of storm water that would otherwise be "no exposure" discharges, individual permit requirements should be adjusted accordingly.

(iii) If circumstances change and industrial materials or activities become exposed to rain, snow, snow melt, and/or runoff, the conditions for this exclusion no longer apply. In such cases, the discharge becomes subject to enforcement for un-permitted discharge. Any conditionally exempt discharger who anticipates changes in circumstances should apply for and obtain permit authorization prior to the change of circumstances.

(iv) Notwithstanding the provisions of this paragraph, the NPDES permitting authority retains the authority to require permit authorization (and deny this exclusion) upon making a determination that the discharge causes, has a reasonable potential to cause, or contributes to an instream excursion above an applicable water quality standard, including designated uses.

(4) *Certification*. The no exposure certification must require the submission of the following information, at a minimum, to aid the NPDES permitting authority in determining if the facility qualifies for the no exposure exclusion:

(i) The legal name, address and phone number of the discharger (see § 122.21(b));

(ii) The facility name and address, the county name and the latitude and longitude where the facility is located;

(iii) The certification must indicate that none of the following materials or activities are, or will be in the foreseeable future, exposed to precipitation:

(A) Using, storing or cleaning industrial machinery or equipment, and areas where residuals from using, storing or cleaning industrial machinery or equipment remain and are exposed to storm water;

(B) Materials or residuals on the ground or in storm water inlets from spills/leaks;

(C) Materials or products from past industrial activity;

(D) Material handling equipment (except adequately maintained vehicles);

(E) Materials or products during loading/unloading or transporting activities;

(F) Materials or products stored outdoors (except final products intended for outside use, e.g., new cars, where exposure to storm water does not result in the discharge of pollutants);

(G) Materials contained in open, deteriorated or leaking storage drums, barrels, tanks, and similar containers;

(H) Materials or products handled/stored on roads or railways owned or maintained by the discharger;

(I) Waste material (except waste in covered, non-leaking containers, e.g., dumpsters);

(J) Application or disposal of process wastewater (unless otherwise permitted); and

(K) Particulate matter or visible deposits of residuals from roof stacks/vents not otherwise regulated, i.e., under an air quality control permit, and evident in the storm water outflow;

(iv) All "no exposure" certifications must include the following certification statement, and be signed in accordance with the signatory requirements of § 122.22: "I certify under penalty of law that I have read and understand the eligibility requirements for claiming a condition of "no exposure" and obtaining an exclusion from NPDES storm water permitting; and that there are no discharges of storm water contaminated by exposure to industrial activities or materials from the industrial facility identified in this document (except as allowed under paragraph (g)(2)) of this section. I understand that I am obligated to submit a no exposure certification form once every five years to the NPDES permitting authority and, if requested, to the operator of the local MS4 into which this facility discharges (where applicable). I understand that I must allow the NPDES permitting authority, or MS4 operator where the discharge is into the local MS4, to perform inspections to confirm the condition of no exposure and to make such inspection reports publicly available upon request. I understand that I must obtain coverage under an NPDES permit prior to any point source discharge of storm water from the facility. I certify under penalty of law that this document and all attachments were prepared under my direction or supervision in accordance with a system designed to assure that qualified personnel properly gathered and evaluated the information submitted. Based upon my inquiry of the person or persons who manage the system, or those persons directly involved in gathering the information, the information submitted is to the best of my knowledge and belief true, accurate and complete. I am aware there are significant penalties for submitting false information, including the possibility of fine and imprisonment for knowing violations."

4. Revise § 122.28(b)(2)(v) to read as follows:

§ 122.28 General permits (applicable to State NPDES programs, see § 123.25).

* * * * *

(b) * * *

(2) * * *

(v) Discharges other than discharges from publicly owned treatment works, combined sewer overflows, municipal separate storm sewer systems, primary industrial facilities, and storm water discharges associated with industrial activity, may, at the discretion of the Director, be authorized to discharge under a general permit without submitting a notice of intent where the Director finds that a notice of intent requirement would be inappropriate. In making such a finding, the Director shall consider: the type of discharge; the expected nature of the discharge; the potential for toxic and conventional pollutants in the discharges; the expected volume of the discharges; other means of identifying discharges covered by the permit; and the estimated number of discharges to be covered by the permit. The Director shall provide in the public notice of the general permit the reasons for not requiring a notice of intent.

* * * * *

5. Add §§ 122.30 through 122.37 to subpart B to read as follows:

§ 122.30 What are the objectives of the storm water regulations for small MS4s?

(a) Sections 122.30 through 122.37 are written in a "readable regulation" format that includes both rule requirements and EPA guidance that is not legally binding. EPA has clearly distinguished its recommended guidance from the rule requirements by putting the guidance in a separate paragraph headed by the word "guidance".

(b) Under the statutory mandate in section 402(p)(6) of the Clean Water Act, the purpose of this portion of the storm water program is to designate additional sources that need to be regulated to protect water quality and to establish a comprehensive storm water program to regulate these sources. (Because the storm water program is part of the National Pollutant Discharge Elimination System (NPDES) Program, you should also refer to § 122.1 which addresses the broader purpose of the NPDES program.)

(c) Storm water runoff continues to harm the nation's waters. Runoff from lands modified by human activities can harm surface water resources in several ways including by changing natural hydrologic patterns and by elevating pollutant concentrations and loadings. Storm water runoff may contain or mobilize high levels of contaminants, such as sediment, suspended solids, nutrients, heavy metals, pathogens, toxins, oxygen-demanding substances, and floatables.

(d) EPA strongly encourages partnerships and the watershed approach as the management framework for efficiently, effectively, and consistently protecting and restoring aquatic ecosystems and protecting public health.

§ 122.31 As a Tribe, what is my role under the NPDES storm water program?

As a Tribe you may:

(a) Be authorized to operate the NPDES program including the storm water program, after EPA determines that you are eligible for treatment in the same manner as a State under §§ 123.31 through 123.34 of this chapter. (If you do not have an authorized NPDES program, EPA implements the program for discharges on your reservation as well as other Indian country, generally.);

(b) Be classified as an owner of a regulated small MS4, as defined in § 122.32. (Designation of your Tribe as an owner of a small MS4 for purposes of this part is an approach that is consistent with EPA's 1984 Indian Policy of operating on a government-to-government basis with EPA looking to Tribes as the lead governmental authorities to address environmental issues on their reservations as appropriate. If you operate a separate storm sewer system that meets the definition of a regulated small MS4, you are subject to the requirements under §§ 122.33 through 122.35. If you are not designated as a regulated small MS4, you may ask EPA to designate you as such for the purposes of this part.); or

(c) Be a discharger of storm water associated with industrial activity or small construction activity under §§ 122.26(b)(14) or (b)(15), in which case you must meet the applicable requirements. Within Indian country, the NPDES permitting authority is generally EPA, unless you are authorized to administer the NPDES program.

§ 122.32 As an operator of a small MS4, am I regulated under the NPDES storm water program?

(a) Unless you qualify for a waiver under paragraph (c) of this section, you are regulated if you operate a small MS4, including but not limited to systems operated by federal, State, Tribal, and local governments, including State departments of transportation; and:

(1) Your small MS4 is located in an urbanized area as determined by the latest Decennial Census by the Bureau of the Census. (If your small MS4 is not located entirely within an urbanized area, only the portion that is within the urbanized area is regulated); or

(2) You are designated by the NPDES permitting authority, including where the designation is pursuant to §§ 123.35(b)(3) and (b)(4) of this chapter, or is based upon a petition under § 122.26(f).

(b) You may be the subject of a petition to the NPDES permitting authority to require an NPDES permit for your discharge of storm water. If the NPDES permitting authority determines that you need a permit, you are required to comply with §§ 122.33 through 122.35.

(c) The NPDES permitting authority may waive the requirements otherwise applicable to you if you meet the criteria of paragraph (d) or (e) of this section. If you receive a waiver under this section, you may subsequently be required to seek coverage under an NPDES permit in accordance with § 122.33(a) if circumstances change. (See also § 123.35(b) of this chapter.)

(d) The NPDES permitting authority may waive permit coverage if your MS4 serves a population of less than 1,000 within the urbanized area and you meet the following criteria:

(1) Your system is not contributing substantially to the pollutant loadings of a physically interconnected MS4 that is regulated by the NPDES storm water program (see § 123.35(b)(4) of this chapter); and

(2) If you discharge any pollutant(s) that have been identified as a cause of impairment of any water body to which you discharge, storm water controls are not needed based on wasteload allocations that are part of an EPA approved or established "total maximum daily load" (TMDL) that addresses the pollutant(s) of concern.

(e) The NPDES permitting authority may waive permit coverage if your MS4 serves a population under 10,000 and you meet the following criteria:

(1) The permitting authority has evaluated all waters of the U.S., including small streams, tributaries, lakes, and ponds, that receive a discharge from your MS4;

(2) For all such waters, the permitting authority has determined that storm water controls are not needed based on wasteload allocations that are part of an EPA approved or established TMDL that addresses the pollutant(s) of concern or, if a TMDL has not been developed or approved, an equivalent analysis that determines sources and allocations for the pollutant(s) of concern;

(3) For the purpose of this paragraph (e), the pollutant(s) of concern include biochemical oxygen demand (BOD), sediment or a parameter that addresses sediment (such as total suspended solids, turbidity or siltation), pathogens, oil and grease, and any pollutant that has been identified as a cause of impairment of any water body that will receive a discharge from your MS4; and

R0018214

(4) The permitting authority has determined that future discharges from your MS4 do not have the potential to result in exceedances of water quality standards, including impairment of designated uses, or other significant water quality impacts, including habitat and biological impacts.

§ 122.33 If I am an operator of a regulated small MS4, how do I apply for an NPDES permit and when do I have to apply?

(a) If you operate a regulated small MS4 under § 122.32, you must seek coverage under a NPDES permit issued by your NPDES permitting authority. If you are located in an NPDES authorized State, Tribe, or Territory, then that State, Tribe, or Territory is your NPDES permitting authority. Otherwise, your NPDES permitting authority is the EPA Regional Office.

(b) You must seek authorization to discharge under a general or individual NPDES permit, as follows:

(1) If your NPDES permitting authority has issued a general permit applicable to your discharge and you are seeking coverage under the general permit, you must submit a Notice of Intent (NOI) that includes the information on your best management practices and measurable goals required by § 122.34(d). You may file your own NOI, or you and other municipalities or governmental entities may jointly submit an NOI. If you want to share responsibilities for meeting the minimum measures with other municipalities or governmental entities, you must submit an NOI that describes which minimum measures you will implement and identify the entities that will implement the other minimum measures within the area served by your MS4. The general permit will explain any other steps necessary to obtain permit authorization.

(2)(i) If you are seeking authorization to discharge under an individual permit and wish to implement a program under § 122.34, you must submit an application to your NPDES permitting authority that includes the information required under §§ 122.21(f) and 122.34(d), an estimate of square mileage served by your small MS4, and any additional information that your NPDES permitting authority requests. A storm sewer map that satisfies the requirement of § 122.34(b)(3)(i) will satisfy the map requirement in § 122.21(f)(7).

(ii) If you are seeking authorization to discharge under an individual permit and wish to implement a program that is different from the program under § 122.34, you will need to comply with the permit application requirements of § 122.26(d). You must submit both Parts of the application requirements in §§ 122.26(d)(1) and (2) by March 10, 2003. You do not need to submit the information required by §§ 122.26(d)(1)(ii) and (d)(2) regarding your legal authority, unless you intend for the permit writer to take such information into account when developing your other permit conditions.

(iii) If allowed by your NPDES permitting authority, you and another regulated entity may jointly apply under either paragraph (b)(2)(i) or (b)(2)(ii) of this section to be co-permittees under an individual permit.

(3) If your small MS4 is in the same urbanized area as a medium or large MS4 with an NPDES storm water permit and that other MS4 is willing to have you participate in its storm water program, you and the other MS4 may jointly seek a modification of the other MS4 permit to include you as a limited co-permittee. As a limited co-permittee, you will be responsible for compliance with the permit's conditions applicable to your jurisdiction. If you choose this option you will need to comply with the permit application requirements of § 122.26, rather than the requirements of § 122.34. You do not need to comply with the specific application requirements of § 122.26(d)(1)(iii) and (iv) and (d)(2)(iii) (discharge characterization). You may satisfy the requirements in § 122.26 (d)(1)(v) and (d)(2)(iv) (identification of a management program) by referring to the other MS4's storm water management program.

(4) Guidance: In referencing an MS4's storm water management program, you should briefly describe how the existing plan will address discharges from your small MS4 or would need to be supplemented in order to adequately address your discharges. You should also explain your role in coordinating storm water pollutant control activities in your MS4, and detail the resources available to you to accomplish the plan.

(c) If you operate a regulated small MS4:

(1) Designated under § 122.32(a)(1), you must apply for coverage under an NPDES permit, or apply for a modification of an existing NPDES permit under paragraph (b)(3) of this section by March 10, 2003, unless your MS4 serves a jurisdiction with a population under 10,000 and the NPDES permitting authority has established a phasing schedule under § 123.35(d)(3) of this chapter.

(2) Designated under § 122.32(a)(2), you must apply for coverage under an NPDES permit, or apply for a modification of an existing NPDES permit under paragraph (b)(3) of this section, within 180 days of notice, unless the NPDES permitting authority grants a later date.

§ 122.34 As an operator of a regulated small MS4, what will my NPDES MS4 storm water permit require?

(a) Your NPDES MS4 permit will require at a minimum that you develop, implement, and enforce a storm water management program designed to reduce the discharge of pollutants from your MS4 to the maximum extent practicable (MEP), to protect water quality, and to satisfy the appropriate water quality requirements of the Clean Water Act. Your storm water management program must include the minimum control measures described in paragraph (b) of this section unless you apply for a permit under § 122.26(d). For purposes of this section, narrative effluent limitations requiring implementation of best management practices (BMPs) are generally the most appropriate form of effluent limitations when designed to satisfy technology requirements (including reductions of pollutants to the maximum extent practicable) and to protect water quality. Implementation of best management practices consistent with the provisions of the storm water management program required pursuant to this section and the provisions of the permit required pursuant to § 122.33 constitutes compliance with the standard of reducing pollutants to the "maximum extent practicable." Your NPDES permitting authority will specify a time period of up to 5 years from the date of permit issuance for you to develop and implement your program.

(b) *Minimum control measures*—(1) *Public education and outreach on storm water impacts.* (i) You must implement a public education program to distribute educational materials to the community or conduct equivalent outreach activities about the impacts of storm water discharges on water bodies and the steps that the public can take to reduce pollutants in storm water runoff.

(ii) Guidance: You may use storm water educational materials provided by your State, Tribe, EPA, environmental, public interest or trade organizations, or other MS4s. The public education program should inform individuals and households about the steps they can take to reduce storm water pollution, such as ensuring proper septic system maintenance, ensuring the proper use and disposal of landscape and garden chemicals including fertilizers and pesticides, protecting and restoring riparian vegetation, and properly disposing of used motor oil or household hazardous wastes. EPA recommends that the program inform individuals and groups how to become involved in local stream and beach restoration activities as well as activities that are coordinated by youth service and conservation corps or other citizen groups. EPA recommends that the public education program be tailored, using a mix of locally appropriate strategies, to target specific audiences and communities. Examples of strategies include distributing brochures or fact sheets, sponsoring speaking engagements before community groups, providing public service announcements, implementing educational programs targeted at school age children, and conducting community-based projects such as storm drain stenciling, and watershed and beach cleanups. In addition, EPA recommends that some of the materials or outreach programs be directed toward targeted groups of commercial, industrial, and institutional entities likely to have significant storm water impacts. For example, providing information to restaurants on the impact of grease clogging storm drains and to garages on the impact of oil discharges. You are encouraged to tailor your outreach program to address the viewpoints and concerns of all communities, particularly minority and disadvantaged communities, as well as any special concerns relating to children.

(2) *Public involvement/participation.* (i) You must, at a minimum, comply with State, Tribal and local public notice requirements when implementing a public involvement/participation program.

(ii) Guidance: EPA recommends that the public be included in developing, implementing, and reviewing your storm water management program and that the public participation process should make efforts to reach out and engage all economic and ethnic groups. Opportunities for members of the public to participate in program development and implementation include serving as citizen representatives on a local storm water management panel, attending public hearings, working as citizen volunteers to educate other individuals about the program, assisting in program coordination with other pre-existing programs, or participating in volunteer monitoring efforts. (Citizens should obtain approval where necessary for lawful access to monitoring sites.)

(3) *Illicit discharge detection and elimination.* (i) You must develop, implement and enforce a program to detect and eliminate illicit discharges (as defined at § 122.26(b)(2)) into your small MS4.

(ii) You must:

(A) Develop, if not already completed, a storm sewer system map, showing the location of all outfalls and the names and location of all waters of the United States that receive discharges from those outfalls;

(B) To the extent allowable under State, Tribal or local law, effectively prohibit, through ordinance, or other regulatory mechanism, non-storm water discharges into your storm sewer system and implement appropriate enforcement procedures and actions;

(C) Develop and implement a plan to detect and address non-storm water discharges, including illegal dumping, to your system; and

(D) Inform public employees, businesses, and the general public of hazards associated with illegal discharges and improper disposal of waste.

(iii) You need address the following categories of non-storm water discharges or flows (i.e., illicit discharges) only if you identify them as significant contributors of pollutants to your small MS4: water line flushing, landscape irrigation, diverted stream flows, rising ground waters, uncontaminated ground water infiltration (as defined at 40 CFR 35.2005(20)), uncontaminated pumped ground water, discharges from potable water sources, foundation drains, air conditioning condensation, irrigation water, springs, water from crawl space pumps, footing drains, lawn watering, individual residential car washing, flows from riparian habitats and wetlands, dechlorinated swimming pool discharges, and street wash water (discharges or flows from fire fighting activities are excluded from the effective prohibition against non-storm water and need only be addressed where they are identified as significant sources of pollutants to waters of the United States).

(iv) Guidance: EPA recommends that the plan to detect and address illicit discharges include the following four components: procedures for locating priority areas likely to have illicit discharges; procedures for tracing the source of an illicit discharge; procedures for removing the source of the discharge; and procedures for program evaluation and assessment. EPA recommends visually screening outfalls during dry weather and conducting field tests of selected pollutants as part of the procedures for locating priority areas. Illicit discharge education actions may include storm drain stenciling, a program to promote, publicize, and facilitate public reporting of illicit connections or discharges, and distribution of outreach materials.

(4) *Construction site storm water runoff control.* (i) You must develop, implement, and enforce a program to reduce pollutants in any storm water runoff to your small MS4 from construction activities that result in a land disturbance of greater than or equal to one acre. Reduction of storm water discharges from construction activity disturbing less than one acre must be included in your program if that construction activity is part of a larger common plan of development or sale that would disturb one acre or more. If the NPDES permitting authority waives requirements for storm water discharges associated with small construction activity in accordance with § 122.26(b)(15)(i), you are not required to develop, implement, and/or enforce a program to reduce pollutant discharges from such sites.

(ii) Your program must include the development and implementation of, at a minimum:

(A) An ordinance or other regulatory mechanism to require erosion and sediment controls, as well as sanctions to ensure compliance, to the extent allowable under State, Tribal, or local law;

(B) Requirements for construction site operators to implement appropriate erosion and sediment control best management practices;

(C) Requirements for construction site operators to control waste such as discarded building materials, concrete truck washout, chemicals, litter, and sanitary waste at the construction site that may cause adverse impacts to water quality;

(D) Procedures for site plan review which incorporate consideration of potential water quality impacts;

(E) Procedures for receipt and consideration of information submitted by the public, and

(F) Procedures for site inspection and enforcement of control measures.

(iii) Guidance: Examples of sanctions to ensure compliance include non-monetary penalties, fines, bonding requirements and/or permit denials for non-compliance. EPA recommends that procedures for site plan review include the review of individual pre-construction site plans to ensure consistency with local sediment and erosion control requirements. Procedures for site inspections and enforcement of control measures could include steps to identify priority sites for inspection and enforcement based on the nature of the construction activity, topography, and the characteristics of soils and receiving water quality. You are encouraged to provide appropriate educational and training measures for construction site operators. You may wish to require a storm water pollution prevention plan for construction sites within your jurisdiction that discharge into your system. See § 122.44(s) (NPDES permitting authorities' option to incorporate qualifying State, Tribal and local erosion and sediment control programs into NPDES permits for storm water discharges from construction sites). Also see § 122.35(b) (The NPDES permitting authority may recognize that another government entity, including the permitting authority, may be responsible for implementing one or more of the minimum measures on your behalf.)

(5) *Post-construction storm water management in new development and redevelopment.*

(i) You must develop, implement, and enforce a program to address storm water runoff from new development and redevelopment projects that disturb greater than or equal to one acre, including projects less than one acre that are part of a larger common plan of development or sale, that discharge into your small MS4. Your program must ensure that controls are in place that would prevent or minimize water quality impacts.

(ii) You must:

(A) Develop and implement strategies which include a combination of structural and/or non-structural best management practices (BMPs) appropriate for your community;

(B) Use an ordinance or other regulatory mechanism to address post-construction runoff from new development and redevelopment projects to the extent allowable under State, Tribal or local law; and

(C) Ensure adequate long-term operation and maintenance of BMPs.

(iii) Guidance: If water quality impacts are considered from the beginning stages of a project, new development and potentially redevelopment provide more opportunities for water quality protection. EPA recommends that the BMPs chosen: be appropriate for the local community; minimize water quality impacts; and attempt to maintain pre-development runoff conditions. In choosing appropriate BMPs, EPA encourages you to participate in locally-based watershed lanning efforts which attempt to involve a diverse group of stakeholders including interested citizens. When developing a program that is consistent with this measure's intent, EPA recommends that you adopt a planning process that identifies the municipality's program goals (*e.g.*, minimize water quality impacts resulting from post-construction runoff from new development and redevelopment), implementation strategies (e.g., adopt a combination of structural and/or non-structural BMPs), operation and maintenance policies and procedures, and enforcement procedures. In developing your program, you should consider assessing existing ordinances, policies, programs and studies that address storm water runoff quality. In addition to assessing these existing documents and programs, you should provide opportunities to the public to participate in the development of the program. Non-structural BMPs are preventative actions that involve management and source controls such as: policies and ordinances that provide requirements and standards to direct growth to identified areas, protect sensitive areas such as wetlands and riparian areas, maintain and/or increase open space (including a dedicated funding source for open space acquisition), provide buffers along sensitive water bodies, minimize impervious surfaces, and minimize disturbance of soils and vegetation; policies or ordinances that encourage infill development in higher density urban areas, and areas with existing infrastructure; education programs for developers and the public about project designs that minimize water quality impacts; and measures such as minimization of percent impervious area after development and minimization of directly connected impervious areas. Structural BMPs include: storage practices such as wet ponds and extended-detention outlet structures; filtration practices such as grassed swales, sand filters and filter strips; and infiltration practices such as infiltration basins and infiltration trenches. EPA recommends that you ensure the appropriate implementation of the structural BMPs by considering some or all of the following: pre-construction review of BMP designs; inspections during construction to verify BMPs are built as designed; post-construction inspection and maintenance of BMPs; and penalty provisions for the noncompliance with design, construction or operation and maintenance. Storm water technologies are constantly being improved, and EPA recommends that your requirements be responsive to these changes, developments or improvements in control technologies.

(6) *Pollution prevention/good housekeeping for municipal operations.*

(i) You must develop and implement an operation and maintenance program that includes a training component and has the ultimate goal of preventing or reducing pollutant runoff from municipal operations. Using training materials that are available from EPA, your State, Tribe, or other organizations, your program must include employee training to prevent and reduce storm water pollution from activities such as park and open space maintenance, fleet and building maintenance, new construction and land disturbances, and storm water system maintenance.

(ii) Guidance: EPA recommends that, at a minimum, you consider the following in developing your program: maintenance activities, maintenance schedules, and long-term inspection procedures for structural and non-structural storm water controls to reduce floatables and other pollutants discharged from your separate storm sewers; controls for reducing or eliminating the discharge of pollutants from streets, roads, highways, municipal parking lots, maintenance and storage yards, fleet or maintenance shops with outdoor storage areas, salt/sand storage locations and snow disposal areas operated by you, and waste transfer stations; procedures for properly disposing of waste removed from the separate storm sewers and areas listed above (such as dredge spoil, accumulated sediments, floatables, and other debris); and ways to ensure that new flood management projects assess the impacts on water quality and examine existing projects for incorporating additional water quality protection devices or practices. Operation and maintenance should be an integral component of all storm water management programs. This measure is intended to improve the efficiency of these programs and require new programs where necessary. Properly developed and implemented operation and maintenance programs reduce the risk of water quality problems.

(c) If an existing qualifying local program requires you to implement one or more of the minimum control measures of paragraph (b) of this section, the NPDES permitting authority may include conditions in your NPDES permit that direct you to follow that qualifying program's requirements rather than the requirements of paragraph (b) of this section. A qualifying local program is a local, State or Tribal municipal storm water management program that imposes, at a minimum, the relevant requirements of paragraph (b) of this section.

(d)(1) In your permit application (either a notice of intent for coverage under a general permit or an individual permit application), you must identify and submit to your NPDES permitting authority the following information:

(i) The best management practices (BMPs) that you or another entity will implement for each of the storm water minimum control measures at paragraphs (b)(1) through (b)(6) of this section;

(ii) The measurable goals for each of the BMPs including, as appropriate, the months and years in which you will undertake required actions, including interim milestones and the frequency of the action; and

(iii) The person or persons responsible for implementing or coordinating your storm water management program.

(2) If you obtain coverage under a general permit, you are not required to meet any measurable goal(s) identified in your notice of intent in order to demonstrate compliance with the minimum control measures in paragraphs (b)(3) through (b)(6) of this section unless, prior to submitting your NOI, EPA or your State or Tribe has provided or issued a menu of BMPs that addresses each such minimum measure. Even if no regulatory authority issues the menu of BMPs, however, you still must comply with other requirements of the general permit, including good faith implementation of BMPs designed to comply with the minimum measures.

(3) Guidance: Either EPA or your State or Tribal permitting authority will provide a menu of BMPs. You may choose BMPs from the menu or select others that satisfy the minimum control measures.

(e)(1) You must comply with any more stringent effluent limitations in your permit, including permit requirements that modify, or are in addition to, the minimum control measures based on an approved total maximum daily load (TMDL) or equivalent analysis. The permitting authority may include such more stringent limitations based on a TMDL or equivalent analysis that determines such limitations are needed to protect water quality.

(2) Guidance: EPA strongly recommends that until the evaluation of the storm water program in § 122.37, no additional requirements beyond the minimum control measures be imposed on regulated small MS4s without the agreement of the operator of the affected small MS4, except where an approved TMDL or equivalent analysis provides adequate information to develop more specific measures to protect water quality.

(f) You must comply with other applicable NPDES permit requirements, standards and conditions established in the individual or general permit, developed consistent with the provisions of §§ 122.41 through 122.49, as appropriate.

(g) *Evaluation and assessment*—(1) *Evaluation.* You must evaluate program compliance, the appropriateness of your identified best management practices, and progress towards achieving your identified measurable goals.

Note to Paragraph (g)(1): The NPDES permitting authority may determine monitoring requirements for you in accordance with State/Tribal monitoring plans appropriate to your watershed. Participation in a group monitoring program is encouraged.

(2) *Recordkeeping.* You must keep records required by the NPDES permit for at least 3 years. You must submit your records to the NPDES permitting authority only when specifically asked to do so. You must make your records, including a description of your storm water management program, available to the public at reasonable times during regular business hours (see § 122.7 for confidentiality provision). (You may assess a reasonable charge for copying. You may require a member of the public to provide advance notice.)

(3) *Reporting.* Unless you are relying on another entity to satisfy your NPDES permit obligations under § 122.35(a), you must submit annual reports to the NPDES permitting authority for your first permit term. For subsequent permit terms, you must submit reports in year two and four unless the NPDES permitting authority requires more frequent reports. Your report must include:

(i) The status of compliance with permit conditions, an assessment of the appropriateness of your identified best management practices and progress towards achieving your identified measurable goals for each of the minimum control measures;

(ii) Results of information collected and analyzed, including monitoring data, if any, during the reporting period;

(iii) A summary of the storm water activities you plan to undertake during the next reporting cycle;

(iv) A change in any identified best management practices or measurable goals for any of the minimum control measures; and

(v) Notice that you are relying on another governmental entity to satisfy some of your permit obligations (if applicable).

§ 122.35 As an operator of a regulated small MS4, may I share the responsibility to implement the minimum control measures with other entities?

(a) You may rely on another entity to satisfy your NPDES permit obligations to implement a minimum control measure if:

(1) The other entity, in fact, implements the control measure;

(2) The particular control measure, or component thereof, is at least as stringent as the corresponding NPDES permit requirement; and

(3) The other entity agrees to implement the control measure on your behalf. In the reports you must submit under § 122.34(g)(3), you must also specify that you rely on another entity to satisfy some of your permit obligations. If you are relying on another governmental entity regulated under section 122 to satisfy all of your permit obligations, including your obligation to file periodic reports required by § 122.34(g)(3), you must note that fact in your NOI, but you are not required to file the periodic reports. You remain responsible for compliance with your permit obligations if the other entity fails to implement the control measure (or component thereof). Therefore, EPA encourages you to enter into a legally binding agreement with that entity if you want to minimize any uncertainty about compliance with your permit.

(b) In some cases, the NPDES permitting authority may recognize, either in your individual NPDES permit or in an NPDES general permit, that another governmental entity is responsible under an NPDES permit for implementing one or more of the minimum control measures for your small MS4 or that the permitting authority itself is responsible. Where the permitting authority does so, you are not required to include such minimum control measure(s) in your storm water management program. (For example, if a State or Tribe is subject to an NPDES permit that requires it to administer a program to control construction site runoff at the State or Tribal level and that program satisfies all of the requirements of § 122.34(b)(4), you could avoid responsibility for the construction measure, but would be responsible for the remaining minimum control measures.) Your permit may be reopened and modified to include the requirement to implement a minimum control measure if the entity fails to implement it.

§ 122.36 As an operator of a regulated small MS4, what happens if I don't comply with the application or permit requirements in §§ 122.33 through 122.35?

NPDES permits are federally enforceable. Violators may be subject to the enforcement actions and penalties described in Clean Water Act sections 309 (b), (c), and (g) and 505, or under applicable State, Tribal, or local law. Compliance with a permit issued pursuant to section 402 of the Clean Water Act is deemed compliance, for purposes of sections 309 and 505, with sections 301, 302, 306, 307, and 403, except any standard imposed under section 307 for toxic pollutants injurious to human health. If you are covered as a co-permittee under an individual permit or under a general permit by means of a joint Notice of Intent you remain subject to the enforcement actions and penalties for the failure to comply with the terms of the permit in your jurisdiction except as set forth in § 122.35(b).

§ 122.37 Will the small MS4 storm water program regulations at §§ 122.32 through 122.36 and § 123.35 of this chapter change in the future?

EPA will evaluate the small MS4 regulations at §§ 122.32 through 122.36 and § 123.35 of this chapter after December 10, 2012 and make any necessary revisions. (EPA intends to conduct an enhanced research effort and compile a comprehensive evaluation of the NPDES MS4 storm water program. EPA will re-evaluate the regulations based on data from the NPDES MS4 storm water program, from research on receiving water impacts from storm water, and the effectiveness of best management practices (BMPs), as well as other relevant information sources.)

6. In § 122.44, redesignate paragraphs (k)(2) and (k)(3) as paragraphs (k)(3) and (k)(4), remove the comma at the end of newly redesignated paragraph (k)(3) and add a semicolon in its place, and add new paragraphs (k)(2) and (s) to read as follows:

§ 122.44 Establishing limitations, standards, and other permit conditions (applicable to State NPDES programs, see § 123.25).

* * * * *

(k) * * *

(2) Authorized under section 402(p) of CWA for the control of storm water discharges;

* * * * *

(s) *Qualifying State, Tribal, or local programs.* (1) For storm water discharges associated with small construction activity identified in § 122.26(b)(15), the Director may include permit conditions that incorporate qualifying State, Tribal, or local erosion and sediment control program requirements by reference. Where a qualifying State, Tribal, or local program does not include one or more of the elements in this paragraph (s)(1), then the Director must include those elements as conditions in the permit. A qualifying State, Tribal, or local erosion and sediment control program is one that includes:

(i) Requirements for construction site operators to implement appropriate erosion and sediment control best management practices;

(ii) Requirements for construction site operators to control waste such as discarded building materials, concrete truck washout, chemicals, litter, and sanitary waste at the construction site that may cause adverse impacts to water quality;

(iii) Requirements for construction site operators to develop and implement a storm water pollution prevention plan. (A storm water pollution prevention plan includes site descriptions, descriptions of appropriate control measures, copies of approved State, Tribal or local requirements, maintenance procedures, inspection procedures, and identification of non-storm water discharges); and

(iv) Requirements to submit a site plan for review that incorporates consideration of potential water quality impacts.

(2) For storm water discharges from construction activity identified in § 122.26(b)(14)(x), the Director may include permit conditions that incorporate qualifying State, Tribal, or local erosion and sediment control program requirements by reference. A qualifying State, Tribal or local erosion and sediment control program is one that includes the elements listed in paragraph (s)(1) of this section and any additional requirements necessary to achieve the applicable technology-based standards of "best available technology" and "best conventional technology" based on the best professional judgment of the permit writer.

7. Add § 122.62(a)(14) to read as follows:

§ 122.62 Modification or revocation and reissuance of permits (applicable to State programs, see § 123.25).

* * * * *

(a) * * *

(14) For a small MS4, to include an effluent limitation requiring implementation of a minimum control measure or measures as specified in § 122.34(b) when:

(i) The permit does not include such measure(s) based upon the determination that another entity was responsible for implementation of the requirement(s); and

(ii) The other entity fails to implement measure(s) that satisfy the requirement(s).

* * * * *

8. Revise Appendices F, G, H, and I to Part 122 to read as follows:

APPENDIX F TO PART 122.—INCORPORATED PLACES WITH POPULATIONS GREATER THAN 250,000 ACCORDING TO THE 1990 DECENNIAL CENSUS BY THE BUREAU OF THE CENSUS

State	Incorporated Place
Alabama	Birmingham.
Arizona	Phoenix.
	Tucson.
California	Long Beach.
	Los Angeles.
	Oakland.
	Sacramento.
	San Diego.
	San Francisco.
	San Jose.
Colorado	Denver.
District of Columbia	
Florida	Jacksonville.
	Miami.
	Tampa.
Georgia.	Atlanta.
Illinois	Chicago.
Indiana	Indianapolis.
Kansas	Wichita.
Kentucky	Louisville.
Louisiana	New Orleans.
Maryland	Baltimore.
Massachusetts	Boston.
Michigan	Detroit.
Minnesota	Minneapolis.
	St. Paul.
Missouri	Kansas City.
	St. Louis.
Nebraska	Omaha.
New Jersey	Newark.
New Mexico	Albuquerque.
New York	Buffalo.
	Bronx Borough.
	Brooklyn Borough.
	Manhattan Borough.
	Queens Borough.
	Staten Island Borough.
North Carolina	Charlotte.
Ohio	Cincinnati.
	Cleveland.
	Columbus.
	Toledo.
Oklahoma	Oklahoma City.
	Tulsa.
Oregon	Portland.
Pennsylvania	Philadelphia.
	Pittsburgh.
Tennessee	Memphis.
	Nashville/Davidson.
Texas	Austin.
	Dallas.
	El Paso.
	Fort Worth.
	Houston.

APPENDIX F TO PART 122.—INCORPORATED PLACES WITH POPULATIONS GREATER THAN 250,000 ACCORDING TO THE 1990 DECENNIAL CENSUS BY THE BUREAU OF THE CENSUS—Continued

State	Incorporated Place
	San Antonio.
Virginia	Norfolk.
	Virginia Beach.
Washington	Seattle.
Wisconsin	Milwaukee.

APPENDIX G TO PART 122.—INCORPORATED PLACES WITH POPULATIONS GREATER THAN 100,000 BUT LESS THAN 250,000 ACCORDING TO THE 1990 DECENNIAL CENSUS BY THE BUREAU OF THE CENSUS

State	Incorporated place
Alabama	Huntsville.
	Mobile.
	Montgomery.
Alaska	Anchorage.
Arizona	Mesa.
	Tempe.
Arkansas	Little Rock.
California	Anaheim.
	Bakersfield.
	Berkeley.
	Chula Vista.
	Concord.
	El Monte.
	Escondido.
	Fremont.
	Fresno.
	Fullerton.
	Garden Grove.
	Glendale.
	Hayward.
	Huntington Beach.
	Inglewood.
	Irvine.
	Modesto.
	Moreno Valley.
	Oceanside.
	Ontario.
	Orange.
Colorado	Aurora.

APPENDIX G TO PART 122.—INCORPORATED PLACES WITH POPULATIONS GREATER THAN 100,000 BUT LESS THAN 250,000 ACCORDING TO THE 1990 DECENNIAL CENSUS BY THE BUREAU OF THE CENSUS—Continued

State	Incorporated place
	Colorado Springs.
	Lakewood.
	Pueblo.
Connecticut	Bridgeport.
	Hartford.
	New Haven.
	Stamford.
	Waterbury.
Florida	Fort Lauderdale.
	Hialeah.
	Hollywood.
	Orlando.
	St. Petersburg.
	Tallahassee.
Georgia	Columbus.
	Macon.
	Savannah.
Idaho	Boise City.
Illinois	Peoria.
	Rockford.
Indiana	Evansville.
	Fort Wayne.
	Gary.
	South Bend.
Iowa	Cedar Rapids.
	Davenport.
	Des Moines.
Kansas	Kansas City.
	Topeka.
Kentucky	Lexington-Fayette.
Louisiana	Baton Rouge.
	Shreveport.
Massachusetts	Springfield.
	Worcester.
Michigan	Ann Arbor.
	Flint.
	Grand Rapids.
	Lansing.
	Livonia.
	Sterling Heights.
	Warren.
Mississippi	Jackson.
Missouri	Independence.
	Springfield.
Nebraska	Lincoln.
Nevada	Las Vegas.
	Reno.

APPENDIX G TO PART 122.—INCORPORATED PLACES WITH POPULATIONS GREATER THAN 100,000 BUT LESS THAN 250,000 ACCORDING TO THE 1990 DECENNIAL CENSUS BY THE BUREAU OF THE CENSUS—Continued

State	Incorporated place
New Jersey	Elizabeth.
	Jersey City.
	Paterson.
New York	Albany.
	Rochester.
	Syracuse.
	Yonkers.
North Carolina	Durham.
	Greensboro.
	Raleigh.
	Winston-Salem.
Ohio	Akron.
	Dayton.
	Youngstown.
Oregon	Eugene.

	Pasadena.
	Plano.
	Waco.
Utah	Salt Lake City.
Virginia	Alexandria.
	Chesapeake.
	Hampton.
	Newport News.
	Portsmouth.
	Richmond.
	Roanoke.
Washington	Spokane.
	Tacoma.
Wisconsin	Madison.

APPENDIX H TO PART 122.—COUNTIES WITH UNINCORPORATED URBANIZED AREAS WITH A POPULATION OF 250,000 OR MORE ACCORDING TO THE 1990 DECENNIAL CENSUS BY THE BUREAU OF THE CENSUS

State	County	Unincorporated urbanized population
California	Los Angeles	886,780
	Sacramento	594,889
	San Diego	250,414
Delaware	New Castle	296,996
Florida	Dade	1,014,504
Georgia	DeKalb	448,686
Hawaii	Honolulu [1]	114,506
Maryland	Anne Arundel	344,654
	Baltimore	627,593
	Montgomery	599,028

R0018220

APPENDIX H TO PART 122.—COUNTIES WITH UNINCORPORATED URBANIZED AREAS WITH A POPULATION OF 250,000 OR MORE ACCORDING TO THE 1990 DECENNIAL CENSUS BY THE BUREAU OF THE CENSUS—Continued

State	County	Unincorporated urbanized population
	Prince George's	494,369
Texas	Harris	729,206
Utah	Salt Lake	270,989
Virginia	Fairfax	760,730
Washington	King	520,468

[1] County was previously listed in this appendix; however, population dropped to below 250,000 in the 1990 Census.

APPENDIX I TO PART 122.—COUNTIES WITH UNINCORPORATED URBANIZED AREAS GREATER THAN 100,000 BUT LESS THAN 250,000 ACCORDING TO THE 1990 DECENNIAL CENSUS BY THE BUREAU OF THE CENSUS

State	County	Unincorporated urbanized population
Alabama	Jefferson	78,608
Arizona	Pima	162,202
California	Alameda	115,082
	Contra Costa	131,082
	Kern	128,503
	Orange	223,081
	Riverside	166,509
	San Bernardino	162,202
Colorado	Arapahoe	103,248
Florida	Broward	142,329
	Escambia	167,463
	Hillsborough	398,593
	Lee	102,337
	Manatee	123,828
	Orange	378,611
	Palm Beach	360,553
	Pasco	148,907
	Pinellas	255,772
	Polk	121,528
	Sarasota	172,600
	Seminole	127,873
Georgia	Clayton	133,237
	Cobb	322,595
	Fulton	127,776
	Gwinnett	237,305
	Richmond	126,476
Kentucky	Jefferson	239,430
Louisiana	East Baton Rouge	102,539
	Parish	331,307
	Jefferson Parish	
Maryland	Howard	157,972
North Carolina	Cumberland	146,827
Nevada	Clark	327,618
Oregon	Multnomah [1]	52,923
	Washington	116,687
South Carolina	Greenville	147,464
	Richland	130,589
Virginia	Arlington	170,936
	Chesterfield	174,488
	Henrico	201,367
	Prince William	157,131
Washington	Pierce	258,530
	Snohomish	157,218

[1] County was previously listed in this appendix; however, population dropped to below 100,000 in the 1990 Census.

PART 123—STATE PROGRAM REQUIREMENTS

1. The authority citation for part 123 continues to read as follows:

Authority: The Clean Water Act, 33 U.S.C. 1251 *et seq.*

2. Amend § 123.25 by removing the word "and" at the end of paragraph (a)(37), by removing the period at the end of paragraph (a)(38) and adding a semicolon in its place, and by adding paragraphs (a)(39) through (a)(45) to read as follows:

§ 123.25 Requirements for permitting.

(a) * * *

R0018221

(39) § 122.30 (What are the objectives of the storm water regulations for small MS4s?);

(40) § 122.31 (For Indian Tribes only) (As a Tribe, what is my role under the NPDES storm water program?);

(41) § 122.32 (As an operator of a small MS4, am I regulated under the NPDES storm water program?);

(42) § 122.33 (If I am an operator of a regulated small MS4, how do I apply for an NPDES permit? When do I have to apply?);

(43) § 122.34 (As an operator of a regulated small MS4, what will my NPDES MS4 storm water permit require?);

(44) § 122.35 (As an operator of a regulated small MS4, may I share the responsibility to implement the minimum control measures with other entities?); and

(45) § 122.36 (As an operator of a regulated small MS4, what happens if I don't comply with the application or permit requirements in §§ 122.33 through 122.35?).

* * * * *

3. Add § 123.35 to subpart B to read as follows:

§ 123.35 As the NPDES Permitting Authority for regulated small MS4s, what is my role?

(a) You must comply with the requirements for all NPDES permitting authorities under Parts 122, 123, 124, and 125 of this chapter. (This section is meant only to supplement those requirements and discuss specific issues related to the small MS4 storm water program.)

(b) You must develop a process, as well as criteria, to designate small MS4s other than those described in § 122.32(a)(1) of this chapter, as regulated small MS4s to be covered under the NPDES storm water discharge control program. This process must include the authority to designate a small MS4 waived under paragraph (d) of this section if circumstances change. EPA may make designations under this section if a State or Tribe fails to comply with the requirements listed in this paragraph. In making designations of small MS4s, you must:

(1)(i) Develop criteria to evaluate whether a storm water discharge results in or has the potential to result in exceedances of water quality standards, including impairment of designated uses, or other significant water quality impacts, including habitat and biological impacts.

(ii) Guidance: For determining other significant water quality impacts, EPA recommends a balanced consideration of the following designation criteria on a watershed or other local basis: discharge to sensitive waters, high growth or growth potential, high population density, contiguity to an urbanized area, significant contributor of pollutants to waters of the United States, and ineffective protection of water quality by other programs;

(2) Apply such criteria, at a minimum, to any small MS4 located outside of an urbanized area serving a jurisdiction with a population density of at least 1,000 people per square mile and a population of at least 10,000;

(3) Designate any small MS4 that meets your criteria by December 9, 2002. You may wait until December 8, 2004 to apply the designation criteria on a watershed basis if you have developed a comprehensive watershed plan. You may apply these criteria to make additional designations at any time, as appropriate; and

(4) Designate any small MS4 that contributes substantially to the pollutant loadings of a physically interconnected municipal separate storm sewer that is regulated by the NPDES storm water program.

(c) You must make a final determination within 180 days from receipt of a petition under § 122.26(f) of this chapter (or analogous State or Tribal law). If you do not do so within that time period, EPA may make a determination on the petition.

(d) You must issue permits consistent with §§ 122.32 through 122.35 of this chapter to all regulated small MS4s. You may waive or phase in the requirements otherwise applicable to regulated small MS4s, as defined in § 122.32(a)(1) of this chapter, under the following circumstances:

(1) You may waive permit coverage for each small MS4s in jurisdictions with a population under 1,000 within the urbanized area where all of the following criteria have been met:

(i) Its discharges are not contributing substantially to the pollutant loadings of a physically interconnected regulated MS4 (see paragraph (b)(4) of this section); and

(ii) If the small MS4 discharges any pollutant(s) that have been identified as a cause of impairment of any water body to which it discharges, storm water controls are not needed based on wasteload allocations that are part of an EPA approved or established "total maximum daily load" (TMDL) that address the pollutant(s) of concern.

(2) You may waive permit coverage for each small MS4 in jurisdictions with a population under 10,000 where all of the following criteria have been met:

(i) You have evaluated all waters of the U.S., including small streams, tributaries, lakes, and ponds, that receive a discharge from the MS4 eligible for such a waiver.

(ii) For all such waters, you have determined that storm water controls are not needed based on wasteload allocations that are part of an EPA approved or established TMDL that addresses the pollutant(s) of concern or, if a TMDL has not been developed or approved, an equivalent analysis that determines sources and allocations for the pollutant(s) of concern.

(iii) For the purpose of paragraph (d)(2)(ii) of this section, the pollutant(s) of concern include biochemical oxygen demand (BOD), sediment or a parameter that addresses sediment (such as total suspended solids, turbidity or siltation), pathogens, oil and grease, and any pollutant that has been identified as a cause of impairment of any water body that will receive a discharge from the MS4.

(iv) You have determined that current and future discharges from the MS4 do not have the potential to result in exceedances of water quality standards, including impairment of designated uses, or other significant water quality impacts, including habitat and biological impacts.

(v) Guidance: To help determine other significant water quality impacts, EPA recommends a balanced consideration of the following criteria on a watershed or other local basis: discharge to sensitive waters, high growth or growth potential, high population or commercial density, significant contributor of pollutants to waters of the United States, and ineffective protection of water quality by other programs.

(3) You may phase in permit coverage for small MS4s serving jurisdictions with a population under 10,000 on a schedule consistent with a State watershed permitting approach. Under this approach, you must develop and implement a schedule to phase in permit coverage for approximately 20 percent annually of all small MS4s that qualify for such phased-in coverage. Under this option, all regulated small MS4s are required to have coverage under an NPDES permit by no later than March 8, 2007. Your schedule for phasing in permit coverage for small MS4s must be approved by the Regional Administrator no later than December 10, 2001.

(4) If you choose to phase in permit coverage for small MS4s in jurisdictions with a population under 10,000, in accordance with paragraph (d)(3) of this section, you may also provide waivers in accordance with paragraphs (d)(1) and (d)(2) of this section pursuant to your approved schedule.

(5) If you do not have an approved schedule for phasing in permit coverage, you must make a determination whether to issue an NPDES permit or allow a waiver in accordance with paragraph (d)(1) or (d)(2) of this section, for each eligible MS4 by December 9, 2002.

(6) You must periodically review any waivers granted in accordance with paragraph (d)(2) of this section to determine whether any of the information required for granting the waiver has changed. At a minimum, you must conduct such a review once every five years. In addition, you must consider any petition to review any waiver when the petitioner provides evidence that the information required for granting the waiver has substantially changed.

(e) You must specify a time period of up to 5 years from the date of permit issuance for operators of regulated small MS4s to fully develop and implement their storm water program.

(f) You must include the requirements in §§ 122.33 through 122.35 of this chapter in any permit issued for regulated small MS4s or develop permit limits based on a permit application submitted by a regulated small MS4. (You may include conditions in a regulated small MS4 NPDES permit that direct the MS4 to follow an existing qualifying local program's requirements, as a way of complying with some or all of the requirements in § 122.34(b) of this chapter. See § 122.34(c) of this chapter. Qualifying local, State or Tribal program requirements must impose, at a minimum, the relevant requirements of § 122.34(b) of this chapter.)

(g) If you issue a general permit to authorize storm water discharges from small MS4s, you must make available a menu of BMPs to assist regulated small MS4s in the design and implementation of municipal storm water management programs to implement the minimum measures specified in § 122.34(b) of this chapter. EPA plans to develop a menu of BMPs that will apply in each State or Tribe that has not developed its own menu. Regardless of whether a menu of BMPs has been developed by EPA, EPA encourages State and Tribal permitting authorities to develop a menu of BMPs that is appropriate for local conditions. EPA also intends to provide guidance on developing BMPs and measurable goals and modify, update, and supplement such guidance based on the assessments of the NPDES MS4 storm water program and research to be conducted over the next thirteen years.

(h)(1) You must incorporate any additional measures necessary to ensure effective implementation of your State or Tribal storm water program for regulated small MS4s.

(2) Guidance: EPA recommends consideration of the following:

(i) You are encouraged to use a general permit for regulated small MS4s;

(ii) To the extent that your State or Tribe administers a dedicated funding source, you should play an active role in providing financial assistance to operators of regulated small MS4s;

(iii) You should support local programs by providing technical and programmatic assistance, conducting research projects, performing watershed monitoring, and providing adequate legal authority at the local level;

(iv) You are encouraged to coordinate and utilize the data collected under several programs including water quality management programs, TMDL programs, and water quality monitoring programs;

(v) Where appropriate, you may recognize existing responsibilities among governmental entities for the control measures in an NPDES small MS4 permit (see § 122.35(b) of this chapter); and

(vi) You are encouraged to provide a brief (e.g., two page) reporting format to facilitate compiling and analyzing data from submitted reports under § 122.34(g)(3) of this chapter. EPA intends to develop a model form for this purpose.

PART 124—PROCEDURES FOR DECISIONMAKING

1. The authority citation for part 124 continues to read as follows:

Authority: Resource Conservation and Recovery Act, 42 U.S.C. 6901 *et seq.*; Safe Drinking Water Act, 42 U.S.C. 300(f) *et seq.*; Clean Water Act, 33 U.S.C. 1251 *et seq.*; Clean Air Act, 42 U.S.C. 7401 *et seq.*

2. Revise § 124.52(c) to read as follows:

§ 124.52 Permits required on a case-by-case basis.

* * * * *

(c) Prior to a case-by-case determination that an individual permit is required for a storm water discharge under this section (see § 122.26(a)(1)(v), (c)(1)(v), and (a)(9)(iii) of this chapter), the Regional Administrator may require the discharger to submit a permit application or other information regarding the discharge under section 308 of the CWA. In requiring such information, the Regional Administrator shall notify the discharger in writing and shall send an application form with the notice. The discharger must apply for a permit within 180 days of notice, unless permission for a later date is granted by the Regional Administrator. The question whether the initial designation was proper will remain open for consideration during the public comment period under § 124.11 or § 124.118 and in any subsequent hearing.

ENVIRONMENTAL PROTECTION AGENCY

[FRL-6472-8]

Report to Congress on the Phase II Storm Water Regulations

AGENCY: Environmental Protection Agency (EPA).

ACTION: Notice of availability of Report to Congress.

SUMMARY: EPA submitted a Report to Congress prior to promulgation of the new Phase II storm water regulations. The Report was required in the Agency's appropriation legislation for fiscal year 2000. The appropriation legislation also requires that USEPA invite public comment on the Report. By this notice, USEPA invites public comment.

DATES: Written comments on this notice and the Report to Congress must be submitted on or before January 7, 2000.

ADDRESSES: The Report to Congress on the Phase II Storm Water Regulations is available through the Internet on the EPA Office of Wastewater Management web site at http://www.epa.gov/owm/sw/phase2. Hard copies may be obtained by contacting the U.S. EPA Water Resource Center, 401 M Street, S.W., Washington, D.C. 20460; telephone: (202) 260-7786 (24-hour voice mail), fax: (202) 260-0386, e-mail: center.resource@epa.gov. Comments should be mailed to George Utting, USEPA, Office of Wastewater Management, Mail Code 4203, 401 M Street, S.W., Washington, D.C. 20460. Comments also may be faxed to (202) 260-1460 or submitted via the Internet to sw2@epamail.epa.gov.

FOR FURTHER INFORMATION CONTACT: George Utting, Office of Wastewater Management, Mail Code 4203, 401 M Street, S.W., Washington, D.C. 20460; telephone (202) 260-9530; email: sw2@epamail.epa.gov.

SUPPLEMENTARY INFORMATION: On October 29, 1999, the Administrator of EPA signed a regulation that implements Section 402(p)(6) of the Clean Water Act. This rulemaking is referred to as the final Phase II storm water rule and is also published in today's **Federal Register**.

The Phase II storm water rule expands the existing National Pollutant Discharge Elimination System (NPDES) permitting program to address storm water runoff from construction sites between one and five acres and municipal separate storm sewer systems in urbanized areas serving populations of less than 100,000. The Phase II rule builds on the existing Phase I program, which controls storm water runoff from municipalities with populations greater than 100,000 and 11 industrial categories, including construction disturbing over five acres.

Statutory Authority

The Report to Congress on the Phase II Storm Water Regulations was required by section 431(a) of the Departments of Veterans Affairs and Housing and Urban Development and Independent Agencies Appropriations Act of 2000, Public Law 106-74 (1999) (Appropriations Act). Section 431(a) of the Appropriations Act directed EPA to submit a report that addresses the following issues with respect to the Phase II Storm Water Rule: (1) An analysis of the impact of the rule on local governments, (2) an explanation of the rationale for lowering the threshold for regulation of construction sites from 5 acres to 1 acre, (3) an explanation of why the coverage of the regulation is based on a census-determined population instead of a water quality threshold and documentation that storm water runoff is generally a problem in communities with populations of 50,000 to 100,000, and (4) information that supports the position of the Administrator that the Phase II storm water program should be administered as part of the NPDES permit program.

On October 28, 1999, EPA delivered to the Committee on Environment and Public Works in the Senate and the Committee on Transportation and Infrastructure in the House of Representatives a report that satisfied the mandate of section 431(a). Section 431(c) of the Appropriations Act directs EPA to publish the report in the **Federal Register** for public comment. By today's notice, EPA invites public comment by January 7, 2000. EPA will carefully review and evaluate comments received and determine whether the comments warrant further action.

Dated: November 4, 1999.

J. Charles Fox,

Assistant Administrator, Office of Water.

FINAL REPORT

Benchmarking Decision Criteria for Urban Wet Weather Abatement

Combined Sewer Overflow

Sanitary Sewer Overflow

Stormwater

Abatement

Decision Criteria Benchmarking

Project 97-CTS-6
1999

Water Environment Research Foundation

Urban wet weather pollution manifests itself in three different ways: combined sewer overflow (CSO), sanitary sewer overflows (SSO), and stormwater runoff (SW). Urban wet weather pollution is a reflection of the watershed or sewershed from which it is generated and the climatic patterns the area experiences. The result is a wide-scale challenge that requires very site-specific solutions.

This report presents data from CSO and SSO and SW communities. The major data categories include public participation, issues driving technical considerations, financial considerations, watershed approach and water quality issues. The data is presented in such a way as to facilitate benchmarking. This report also presents guidance issues including public participation, watershed framework approach, receiving water impacts, monitoring / modeling of impacts, and cost effectiveness analysis.

Twenty-six CSO, sixteen SSO, and fourteen SW communities participated in this project. The findings suggest that; (1) since the publication of the Federal CSO policy in 1994, many CSO communities have begun the process of CSO abatement, (2) while SSOs are common, the lack of federal guidance has dulled the initiative for SSO abatement and (3) communities using the watershed approach have moved forward with SW abatement.

Environmental Stewardship Through Innovative Science and Technology

The Water Environment Research Foundation (WERF) was established to advance science and technology for the benefit or the water quality profession and its customers. Funded through voluntary contributions, WERF manages research under three major thrust areas: Collection and Treatment Systems, Human Health Effect and Products, and Watershed and Ecosystem Management. WERF seeks cost-effective, publicly acceptable, environmentally sound solutions to water pollution control problems. A 15-member Board of Directors composed of water quality professionals; volunteers from utilities, academia, consulting firms, and industry; a Utility Council and Corporate Council composed of subscribing entities; and a Research Council of knowledgeable leaders in environmental sciences and engineering are actively involved in applied and basic research program management.

While WERF manages the research and coordinates with the parties involved, the actual work is carried out by individual organizations, primarily utilities, universities, and industrial and commercial firms. To ensure objectivity, an independent advisory group (the Project Subcommittee) of distinguished scientists and engineers helps select researchers, oversees the studies, and provides periodic technical peer review and advice. Benefits accrue in the form of services, technological advances, and information for direct application by the profession for its customers.

The Water Environment Research Foundation is successfully building a cooperative research and development program serving the water quality profession. The Foundation's goal is to apply sound and objective scientific information to better serve the public.

Executive Director:	Glenn Reinhardt
Deputy Director:	Charles I. Noss, Sc.D.
Project Manager:	Patricia Haddon

BENEFITS

- Presents the most current federal combined sewer overflow, sanitary sewer overflow, and stormwater policies.
- Provides communities essential criteria to use as guidance for wet weather pollution abatement. These criteria include public participation, technical considerations, financial considerations, watershed approach, and water quality.
- Benchmarks policy interpretations and progress of various municipalities in achieving water quality goals.
- Provides communities with data that may be useful for wet weather pollution stakeholders engaging in self-evaluation activities.
- Provides cost-benefit analysis procedures.
- Presents a history of wet weather pollution management control strategies.

R0018235

EXECUTIVE SUMMARY

Criteria by which municipalities make decisions for abatement of wet-weather pollution are as variable as the very subject itself. This variability is due to the site specific nature of the tributary area as it relates to the receiving-water in question; interpretation of regulations which can differ among U.S. Environmental Protection Agency (U.S. EPA) regions as well as states; and sense of urgency which may be permit related or related to a particular episode. Wet weather pollution manifests itself as combined sewer overflow (CSO), sanitary sewer overflow (SSO), and stormwater (SW). Although these wet weather discharges can affect receiving waters in a similar way, each is distinctly different in the manner in which it is regulated, how the regulations are enforced, and the sense of urgency to abate the related pollution.

This report identifies the experiences of municipalities as well as regulatory agencies in dealing with wet weather issues. The data are presented in such a way as to facilitate benchmarking of decision criteria. Benchmarking, as used in this report, identifies the status of various municipalities and their progress toward achieving water quality objectives; such benchmarking can provide to any municipality the benefit of real experience.

CSOs generally were recognized as a significant source of pollution in the late 1960s and specifically identified at the federal level through the landmark 1972 Amendments to the Federal Water Pollution Control Act. Much of the CSO work was started through federal R & D programs initiated in the early 1970s. These programs were also instrumental in identifying SSOs as a pollution source. Subsequent sewer system evaluations revealed SSOs as a real, but illegal, component of sewer systems.

The activity directed toward CSOs has been greater than SSOs and SW owing to the earlier awareness and recognition of this type of pollution and, perhaps more important, the urgency associated with the health risks stemming from the sewage component. The intensity of regulatory and municipal activities sharply increased in September 1989 when U.S. EPA published the draft National CSO Control Strategy. Until then, in the absence of clear guidelines, most municipalities were unwilling to forge ahead.

SSOs were specifically identified as part of the facility planning required under the 1972 amendments. However, remediation of many SSOs has been slow due to the lack of a definite federal policy or state guidelines. In many cases, the demand by regulatory agencies that SSOs simply be eliminated has met with resistance and active debate. One of the major issues has been whether or not SSOs that react directly to rainfall could or should in fact be treated as CSOs.

It wasn't until some years later after CSO and SSO problems were addressed by the regulating community that SW became a focus. The significance of SW pollution was understood as an outgrowth of many CSO characterization studies. In a similar manner to CSO, SW activities increased sharply with the release of federal regulations on Nov. 16, 1990. Nevertheless, SW abatement activities on a national scale have been spotty owing largely to variability in enforcement. In those EPA regions and states where CSOs have been a major problem, SW has taken a back seat. In those EPA regions and states where there is a prevalence of separately sewered areas, SW activities have been greater.

In consideration of the above-stated differences, this report categorizes the CSO, SSO and SW experiences separately. As expected, the CSO activity and number of municipalities reported are by far greater than either the SSO or SW activities reported: 26 CSO communities versus 16 SSO communities and 14 SW communities.

SSO activities may be far more numerous than has been recorded, since such discharges are viewed as illegal and are not always openly acknowledged. Also, virtually all moderately aged separated sanitary sewers will overflow a during severe, infrequent storm event, and this phenomenon probably will continue. Stormwater activities are more openly documented; limitations in activity are more a reflection of other factors such as regulatory pressure and specific water quality needs.

ES.1 CSO

The communities included in this CSO benchmarking survey represent a range of geographic locations, population, demographics, CSO system sizes, abatement strategies and schedules. Annual rainfall for these communities ranged from 20 in. to more than 40 in.; however, the majority had annual rainfall greater than 30 in. Most discharge CSO into rivers.

The data collected show that public concern for water quality expressed through state initiatives started the abatement process for many communities. Such initiatives took the form of requirements for CSO facility planning which included alternative and cost-benefit analyses. The most prevalent parameters were and continue to be bacteria and floatables. Solids, biological oxygen demand (BOD) and nutrients are of some concern, with dissolved oxygen and metals being the parameters least of concern.

Upon the release of the Draft National CSO Control Policy in 1994, many CSO facility plans were revisited to determine compliance with either "presumption" or "demonstration" provisions and to develop the required long term control plan (LTCP). The same number of communities followed the presumption approach as followed the demonstration approach; however, the majority of smaller communities followed the presumption approach.

The most prevalent form of implementation has been best management practices (BMP) due to the "housekeeping" nature of such steps and the low cost-to-benefit relationship. Reductions of annual CSO volume from BMPs were reported as high as 90%.

Abatement beyond BMPs was implemented by only a limited number of communities prior to the national policy. In some cases, communities with high enough state priorities were able to take advantage of federally available grant funds. For the most part, however, abatement has taken place after 1994 and has not included federal grants. State revolving funds have become available in place of the previous U.S. EPA Construction Grants Program.

As a consequence of little or no federal or state funding currently available for design and construction, financial considerations have become that much more important, resulting in a greater emphasis on cost-benefit evaluations and reviewing the affordability guidelines within the policy.

The watershed perspective has been introduced only in the last few years. States have embraced this approach largely upon the release of U.S. EPA's total maximum daily load (TMDL) guidelines, which relate to a watershed approach. The TMDL guidelines provide a basis for proceeding in the absence of a basin-wide wet weather plan which is the responsibility of states to develop. However, almost no communities used a watershed approach to determine CSO abatement needs. A limited number of communities have recently started either a watershed or TMDL approach to verify total wet weather readings and identify needs to achieve water quality goals.

Most communities acted to abate their CSOs due to regulatory requirements which can take the form of permit renewals, administrative orders or consent orders. Generally communities acted upon requirements more or less in that order. Most responding communities have completed their LTCP. However, only 20% of the responding communities have completed abatement, and only one, Rochester, N.Y., completed abatement through the construction grant monies made available in the 1970s. Most responding communities received funding from one or more of a variety of sources, including construction grants, state revolving funds and increased taxes.

Two parameters that are serving as the focus for abatement and permits are floatables and bacteria. Concerns are often expressed for other parameters, such as solids, BOD, nutrients, and heavy metals, but limits can and have been challenged, and in some cases watershed efforts are being undertaken. Floatables limits have taken the form of substantial removal or capture up to a specific size storm, for example a one-year frequency. Generally bacteria are specified as a maximum or average concentration for a specific event or monthly basis.

In setting permit parameters, little consistency exists from case to case, which is understandable in light of their site-specific nature and related health risks. States prefer to await site-specific information so that the most practical permit limits can be established. The most notable parameters that vary are:

- design storm frequency;
- bacteria type, concentration and violation frequency; and
- methodology for assessing annual impacts.

ES.2 SSO

The Urban Institute (1984) estimated that as an annual average there are 825 sewer backups and 140 sewer breaks every year for every 1,000 miles of sewer. The Urban Institute survey attributed backups to a variety of factors: the location of pipe in trouble-prone areas, the pipe material, the size of pipes, the material, construction methods, local soils, and maintenance practices.

In 1994, the Civil Engineering Research Foundation found that three-quarters of the sanitary sewer systems function at 50% of capacity or less. Root penetration, corrosion, soil movement and inadequate construction are the cause of most structural failures.

As a result of reduced sewer capacity and failures, SSOs during wet and dry weather are a reality. The Association of State and Interstate Water Pollution Control Administrators (ASIWPCA) found that 3% of municipal systems have at least an occasional dry weather SSO.

In a Water Pollution Control Federation study (1989), 1,003 wastewater treatment plants identified facility performance problems. Infiltration and inflow (I/I) was the most frequent performance problem cited.

Different National Pollution Discharge Elimination System (NPDES) authorities have historically provided different emphasis on oversight of sanitary sewer collection systems. In addition, some of the NPDES regulatory provisions addressing sanitary sewer collection systems are unclear, and different NPDES authorities have provided different interpretations regarding SSOs. For example, the ASIWPCA (1996) study found that many states do not issue permits for smaller sanitary sewer systems that discharge into a larger system; however, some states issue permits to all sanitary sewer systems. The ASIWPCA study also found that some states authorize wet weather control facilities that provide some level of treatment or flow control, while other states do not authorize such facilities.

The communities included in this SSO benchmarking survey represent a range of geographic locations, demographics, abatement strategies and schedules. The majority of responding communities serve a population of less than 500,000 and manage total drainage areas of more than 55,000 acres. Annual rainfall for these communities ranged from 20 in. to more than 40 in. Most discharge SSO into rivers or streams.

Most communities have not defined their annual discharge quantity, unlike the case of CSO. Wayne County, Mich., was one of the few exceptions. Flow monitoring in 13 Wayne County communities was used to evaluate the relative contribution of each to the wet weather pollution.

Public participation has been minimal compared to CSO and SW. Public concerns have ranged from aesthetics and water quality to flooding. The major water quality parameters of concern have been bacteria, BOD and dissolved oxygen.

The major abatement solution has been I/I reductions at the source based upon cost-benefit analysis. In a few select cases, such as Johnson County, Kan., and Houston, Texas, satellite treatment of SSOs has been approved. Satellite treatment technology included screening, settling tanks or ponds, and disinfection. Such an approach provided a cost-effective means of complying with water quality requirements.

ES.3 Stormwater

In most cities, very little has been done beyond basic SW drainage. In a few communities (as this report documents), early concerns by the public on declining water quality resulted in attempts to manage SW quality. After drainage problems were brought under control, usually through master planning and the construction of large-scale facilities, construction-erosion control was usually implemented in those communities. With these important considerations addressed, some of the communities were able to address SW quality. Some stressed controls with new development, while a very few examined retrofit opportunities.

With the SW NPDES permit program in place, SW quality management has been brought to the attention of most medium and large cities in the country (communities > 100,000). In October 1999, the permit program will be expanded to smaller municipalities (< 100,000).

Because of the large number of communities involved in the first and second phases of the NPDES SW permit program, the federal and state approach has been to define basic requirements for the permits, with little specified in the way of controls. Obviously, the submission of all the municipal industrial SW permits has produced a financial, logistic, and management problem for the state agencies and EPA regions.

The requirements included in the issued permits rarely specified any control or management needs beyond conducting an outfall monitoring program of about three storms a year at about five land use sites. The permits are generally issued for five years, with the expectation that specific control requirements would be added during later permitting periods as local problems become better defined. However, after almost ten years of the SW NPDES program, medium sized cities have also submitted permit applications; most have received their initial permits, and some small communities will be included in the program within a year. Therefore, the SW permit program has increased the burden on regulatory agencies. This has resulted in little opportunity for increased site-specific control objectives to be included in the permits.

Most of the specific accomplishments of improved SW quality have occurred in communities with flooding/drainage problems, scarce water resources, and the financial ability (usually through local funding). Specific requirements by local communities, and some state agencies, are the driving force behind these major accomplishments.

Decision criteria are usually expressed as meeting the federal SW regulations, with only a few exceptions where local residents expressed early and loud concerns over declining water quality.

In general, monitoring of urban SW runoff has indicated that the biological beneficial uses of urban receiving waters are most likely affected in terms of habitat destruction and contaminated sediment, while documented effects associated from acute exposures to toxicants in the water column are rare. Receiving-water investigations of runoff events have not indicated significant short-term receiving water problems, but long-term problems are common.

It is therefore difficult to relate such pollution to conventional numerical standards. Nevertheless there is interest in developing special wet weather standards.

In order to investigate the current state of thinking in SW design, in 1997 University of Alabama at Birmingham distributed a survey to which 85 communities responded. About 75% of the respondents indicated that local or county authorities specified drainage system levels of service (design storms). The most common design storm was a 10-year storm (10% probability of occurrence in any one year) for all land uses (42%). Several responses also indicated that most systems were checked for flooding with respect to the 100-year storm. About 86% of all survey respondents routinely used computerized tools for storm drainage design. The respondents also identified water quality concerns that were associated with SW runoff. More than 60% of the participants indicated sediment as a pollutant of concern. Nutrients (35%) and metals (34%) were the other most frequent answers. Other common answers were oils and grease, bacteria, toxicants, floatables, and salts.

The communities included in this SW benchmarking survey represent a range of geographic locations, demographics, abatement strategies and schedules. All the responding communities manage total drainage areas of more than 1,000 acres and had more than 50 outfalls. Annual rainfall for these communities ranged from 20 in. to more than 40 in. Most discharge SW into rivers or streams.

Most communities indicated a public participation program. General water quality, along with basement flooding, were the most commonly listed public concerns.

Almost all the communities had completed a SW facility plan or are currently developing one. Almost all respondents indicated that regulatory requirements were the main driving force in their SW quality management efforts. A wide range of technologies was considered by these communities, including construction site erosion controls, public works practices, infiltration, and sedimentation.

Most SW communities did not have significant past investments in a SW abatement infrastructure. However, there is some indication that more money will be spent in the future. The funding sources were varied, with fees from utility districts being most common, followed by federal grant money, state grant money, and increased taxes.

About one-half of the responding communities used mathematical models of their SW systems and almost all indicated that a watershed approach has been taken or is in progress.

CHAPTER 1.0

INTRODUCTION

1.1 Introduction

Urban wet weather pollution manifests itself in three different ways: combined sewer overflow (CSO), sanitary sewer overflows (SSO), and stormwater runoff (SW). CSOs are the result of the "designed" relief of a sewer system that intentionally carries SW and sanitary sewage. SSOs, on the other hand, are the result of the unplanned relief of a sewer system intended only for sanitary sewage but also carrying rainfall-induced infiltration, illegal SW connections, and invasions of SW. Stormwater runoff discharges include flows that have been collected in a separate storm sewer system or a surface drainage system.

Urban wet weather pollution is a reflection of the watershed or sewershed from which it is generated and the climatic patterns the area experiences. The impacts of wet weather discharges are determined by a variety of complex relationships. These relationships include the type and magnitude of pollutant loads being transported, the ecological and hydraulic nature of the receiving water, as well as the designated beneficial uses, and the desires and expectations of stakeholders. The result is a wide-scale challenge that requires very site-specific solutions.

Solutions to wet weather pollution require investigation of a wide variety of management options and the relationship between the costs of management and water quality benefits. Benchmarks for effectiveness are also useful to determine if the control program is working. The most successful control programs are often part of an overall watershed management strategy.

Benchmarking as used in this report identifies the status of various municipalities (to include sewerage agencies) and their progress in achieving water quality objectives.

1.2 Objectives

The objective of this project is to document federal regulations and benchmark policy interpretations of U.S. Environmental Protection Agency (U.S. EPA) and select state regulatory agencies, and to document the progress of various municipalities in achieving water quality goals. Information is presented in case histories and summarized in matrices. Such benchmarking information can provide municipalities with real experiences to better develop solutions to their own CSO, SSO, and SW challenges. This report identifies where municipalities are, what has been achieved, and where they are going; but it must be recognized that each municipality reflects site-specific conditions and any comparisons are highly dependent on such conditions.

CHAPTER 2.0

BACKGROUND

2.1 Chronicle of Water Pollution Regulations

The first comprehensive federal involvement in controlling water pollution was the Water Pollution Control Act of 1948 (PL 80-845). It required the Surgeon General to develop programs to eliminate or reduce the pollution of interstate waters and was the first statute to provide federal financial assistance to state and local governments for water pollution control programs. This law was specific in limiting federal enforcement activities to involvement in pollution of interstate waters.

Federal interest in controlling water pollution increased through the 1960s. The Federal Water Pollution Control Act of 1956 (PL 84-660), the 1961 amendments to that act (PL 87-88), the Water Quality Act of 1965 (PL 89-234), and the Clean Water Restoration Act of 1966 (PL 89-753) all resulted in increased federal funding of water pollution control efforts and in the enforcement of environmental laws. The Water Quality Act of 1965 created the Federal Water Pollution Control Administration, the predecessor of U.S. EPA. Water quality standards also were a prominent feature of that law and were used to define actual occurrences of water pollution in interstate waters.

Throughout the 1960s public interest in environmental affairs heightened as the seriousness of pollution became painfully evident when the Cuyahoga River caught fire. The Cuyahoga River fire, along with the pesticide dangers documented in Rachel Carson's Silent Spring, President Lyndon Johnson's declaration that the Potomac River near Washington, D.C., was a "national disgrace," and a major oil spill off the coast of Santa Barbara, Calif., influenced people to take action to protect the environment.

In the 1970s, increased environmental awareness resulted in mounting public frustration over the slow pace of cleanup efforts. Congress overrode a presidential veto to enact the Federal Water Pollution Control Act Amendments of 1972 (PL 92-500). While the title implied that it amended the previous legislation, it actually represented a fundamental change in the structure and organization of U.S. water pollution control programs. The 1972 Amendments brought a shift of program responsibility from the states to the federal government.

The major provisions of PL 92-500 state that all discharges are illegal unless they are in compliance with requirements set forth by the act and that all point source discharges must obtain a permit. This permitting requirement encouraged the formation of the National Pollutant Discharge Elimination System (NPDES). The purpose of these authorities is to administer permits establishing pollution limits, and specifying monitoring and reporting requirements for point source pollution. The objective of the act was to restore and maintain the physical, chemical, and biological integrity of the nation's waters, the so-called "swimmable-fishable designation." The act was notable in terms of both its national comprehensiveness and its specificity; virtually all forms of pollution were recognized. The act also provided citizens the right to bring a civil action against any person in violation of an effluent standard.

In the early '70s, attempts were made to identify and prioritize pollution sources and their relative importance through a national "needs surveys" required of all municipalities by the federal government. These surveys served as the basis for planning the Federal Construction Grants Program. This resulted in a special report to Congress on CSOs (EPA -430/9-78-006), as well as in a 1978 needs survey entitled *Cost Methodology for Control of Combined Sewer Overflow and Stormwater Discharge* (EPA -430/9-79-003). The latter estimated the capital costs to meet the "swimmable" goal to be $61.7 billion (in year 2000 dollars).

In the 1970s, funding assistance was increased to municipalities; but with the increased funding came more program requirements and involvement of federal and state regulators. The U.S. EPA , through numerous research and demonstration grants to municipalities, made significant advances in the areas of receiving water/water impact analysis, impact analysis, sewer-system characterization, control and treatment technology, and cost effectiveness analysis. As a result of these studies, technology-based effluent limits were established.

The Clean Water Act of 1977 (PL 95-217) included revisions in the areas of construction grants funding and the definition of conventional, unconventional, and toxic pollutants. It also allowed states to assume responsibility for federal programs, thereby encouraging the formation of the State Pollutant Discharge Elimination System (SPDES) Authority.

The "208" planning studies were an incentive to local governments to develop their own plans, with minimal federal input. These plans were to characterize all point and nonpoint pollutant discharges in designated areas and to develop treatment schemes that would allow the goals to be met. Unfortunately, most of these plans were conducted in short time periods with limited technical success. Control measures were recommended with few local demonstrations of their potential success. Recognizing these technical shortcomings, Congress authorized the Nationwide Urban Runoff Program (NURP) to demonstrate the applicability of various urban runoff control measures in about 30 cities. These studies were completed in 1983 (EPA , 1983).

In 1981, Congress revised the municipal construction grants program as part of the Construction Grant Amendments of 1981 (PL 97-117). This law marked the beginning of the end of the grants program, with limitations on grant-eligible categories and a reduction in the level of grant assistance for eligible projects. The Construction Grant Amendments of 1981 empowered state governors to use 20% of the states' federal allotment of construction grant funds for the correction of CSOs, if deemed a major priority. Also, a separate material fund of $200 million annually was established for marine bays and estuaries. The Water Quality Act of 1987 (PL 100-4) established the revolving loan program as the successor to the grants program. This law also continued the efforts to address controlling toxins in wet weather pollution and designated water use, and began efforts to address nonpoint sources of pollution.

After the 1987 Water Quality Act amendments, the U.S. EPA issued new regulations that required states to provide scientific justification if surface water was not designated to protect aquatic life and recreational uses. In the event that the designation turned out to be inappropriate, the U.S. EPA provided the means for making adjustments by way of the Use Attainability Analysis (UAA). UAA is a structured scientific assessment of the chemical, physical, and biological conditions in a water body. The comprehensive evaluation focuses on water quality, available habitat, and flow regimes. The UAA offers the best potential to direct scarce resources where they will provide the greatest environmental benefits. However, this process is time-consuming, expensive, and potentially controversial because of the lack of clear legal and scientific decision criteria.

U.S. EPA regulations to control SW runoff were first published in the Dec. 7, 1988 issue of the Federal Register. These regulations initiated a permit process for urban runoff, but the reporting information required and the schedules vary depending on the land use and the size of the community. Large- and medium-sized communities are currently developing SW permits under the Phase I SW policy, and small communities will be targeted in the future under the Phase II SW policy. The general application requirements stress descriptive information concerning the drainage area, with minimal runoff monitoring requirements.

Throughout the 1980s many citizens exercised their right to bring a civil action against persons in violation of effluent standards. In 1987, the number of civil actions increased, partly due to the publicity produced by the *Gwaltney of Smithfield, Ltd. v. Chesapeake Bay Foundation Inc.*, U.S. Supreme Court decision. The court ruled that citizens may bring civil action in federal court if they make a good faith allegation of continuous or intermittent violation. The plaintiffs need not prove their allegations of ongoing noncompliance before the civil action, since the statute does not require that a defendant "be in violation" at the commencement of the suit, but only that the defendant be "alleged to be in violation." The public realized that these suits are an effective deterrent against polluters and provide additional enforcement power to that of the regulatory agencies.

In 1989, U.S. EPA published the draft National CSO Control Strategy that established the foundation for states to develop their own strategies and for communities to begin to appreciate the ramifications of CSO abatement. Following extensive review by several "stakeholder" groups, U.S. EPA published the Final CSO Control Policy in April 1994. Very few states were willing to embark upon their own requirements until the federal government issued its own policy. Some communities did proceed with CSO abatement planning and certain best management practices (BMP) in the early 1980s but at the risk of not complying with forthcoming requirements. Generally, communities were concerned that if they forged ahead, they would be required to change their approach if it did not meet the forthcoming requirements. The national strategy served to initiate dialogue and to some extent accommodate such concerns.

The CSO policy was developed as the result of input from individuals, communities, public interest groups, regulatory agencies, and professional organizations such as the Water Environment Federation, CSO Partnership, and Association of Municipal Sewerage Agencies. Consequently, it evolved into a document that accommodates the latest technological approaches to defining the pollution and associated impacts, and at the same time addresses the needs of communities both large and small. Most important, it recognizes the site-specific nature of CSOs.

In 1992, the U.S. EPA initiated a consultative process to help develop framework documents for controlling CSOs. A work group was established with membership from public interest groups such as the National League of Cities, Environmental Defense Fund, and Lower James River Association. The objective of the group was to develop a set of criteria to be used in determining long-term CSO control programs and implementing NPDES permits.

In 1994, the general lack of clarity and consistency in the nationwide approach to SSOs led a number of municipalities to approach the U.S. EPA Office of Water and ask that an advisory committee be formed to make recommendations on how to apply the NPDES program to SSOs (SSO Federal Advisory Subcommittee, 1996). As a result, the SSO Federal Advisory Subcommittee was formed and began meeting in late 1994. The subcommittee was instrumental in developing draft federal policy and this is acknowledged in the March 7, 1996 memorandum accompanying a new addition to the Enforcement Management System (EMS) Guide. The EMS Guide establishes guiding principles and priorities for the various U.S. EPA regions and NPDES states in responding to separate sanitary sewer discharge violations (U.S. EPA , 1996a).

In 1996, more than 1,100 viewers participated in the live satellite seminar, "The Clean Water Act: New Directions." Experts noted that more collaboration among regulators, the regulated community, and the public could produce cleaner water more cost effectively while addressing the needs of individual communities. As a result of the 1996 seminar, the U.S. EPA is leading an "Adopt Your Watershed" campaign. Through this effort, U.S. EPA challenges citizens to join together to protect and restore our water resources.

2.2 Combined Sewer Overflow

CSOs originate from sewer systems that collect both SW runoff and sanitary sewage in the same pipe. During dry weather, these sewer systems convey sanitary sewage directly to a wastewater treatment plant (WWTP). However, during wet weather events the volume of SW runoff and sanitary sewage can exceed the capacity of the sewer system or WWTP. Under these conditions the combined sewer systems are designed to overflow and discharge excess SW runoff and sanitary sewage into streams, rivers, lakes, or estuary receiving waters.

Overflows from combined sewers during storm events result in the discharges to receiving waters of untreated sanitary sewage, which also may contain pre-treated industrial wastewater and untreated SW. Combined sewer overflows contain pollutants that are present in the domestic and industrial wastewater, as well as pollutants in the urban SW runoff that enters the combined sewer system. CSOs are among the major sources responsible for beach closings, shellfishing restrictions, and other water body impairments

In many cases, these discharges have an adverse effect on receiving water quality and attainment of designated uses. In recent years, there has been an enhanced regulatory focus on CSOs and their control, and communities with combined sewer systems are being called upon to develop and implement programs for control of CSOs.

Combined sewer systems serve roughly 950 communities throughout the U.S. with about 40 million people. Most communities with CSOs are located in the Northeast and Great Lakes regions, particularly in New England, Pennsylvania, Indiana, Ohio, Illinois, Michigan, New York and West Virginia. Although large cities like New York, Philadelphia, and Atlanta have combined sewer systems, most communities with combined sewer systems have fewer than 10,000 people.

2.2.1 U.S. Combined Sewer Overflow Policy

The National CSO Control Policy was signed by Carol Browner, the Administrator of the U.S. EPA , on April 8, 1994. This signing culminated a lengthy process of policy development and negotiation among CSO communities, U.S. EPA , the states, and environmental groups. Based upon the NPDES program, the CSO policy establishes a consistent national approach for controlling CSOs.

Consistency within the CSO policy is established by requirements for all CSO communities to implement Nine Minimum Controls (NMCs). The NMCs are technology-based controls that can be used to abate CSO impacts without extensive engineering studies or substantial construction costs. The NMCs place emphasis on maintenance and proper operation of the combined sewer system to ensure maximum use of the collection system and treatment capacity of the WWTP. The NMCs are documented in Appendix A. Consistency is also established by requiring CSO communities to develop comprehensive long term control plans (LTCP) tailored to site-specific conditions. The development of LTCPs is a comprehensive effort that leads to the identification and implementation of technically feasible, effective and affordable controls. Key principles of the LTCP are documented in Appendix A.

The significance of the CSO policy is its recognition of the site-specific nature of combined sewer systems and the variability of receiving water conditions and impacts. Non- and low-structurally intensive pollution controls (i.e., BMPs) are normally the first item that has to be addressed in accordance with best professional judgment. Communities unable to mitigate serious water quality impacts with the implementation of BMPs alone are normally required to provide additional control measures based on water quality requirements.

The features of the CSO policy that can be considered perhaps the most helpful in assisting communities to address their CSO challenges are:

- identification of the presumption and demonstration approaches, and
- guidance on affordability.

The presumption and demonstration approaches provide CSO communities with targets for controls that achieve compliance with the Clean Water Act, particularly the protection of designated uses. Under the demonstration approach, water quality modeling or other tools are used to demonstrate that predicted CSO discharges resulting from the LTCP would be sufficient to attain water quality standards. The presumption approach is based on the premise that a LTCP that meets certain minimum defined performance criteria in terms of expected frequency of overflow, or percent capture of the CSO pollutant load would be presumed to provide an adequate level of control to meet the water quality-based requirements of the Clean Water Act. Key principles of the presumption and demonstration approaches are documented in Appendix A.

The purpose of guidance on affordability is to provide criteria for assessing financial capability and to relate that capability to an appropriate compliance schedule. Its goal is to provide general boundaries to aid all parties in negotiating reasonable and effective schedules for implementing CSO controls. Key principles of the guidance on affordability are documented in Appendix A.

The CSO policy also provides flexibility to CSO communities so that control programs can be developed to fit local needs. The policy contains specific considerations for small municipalities. For example, populations under 75,000 may only need to comply with the nine minimum controls, public participation, and sensitive areas portions of the policy.

2.2.1.1 U.S. EPA Regional Combined Sewer Overflow Policy Interpretation

Some variability exists among U.S. EPA regions with respect to CSO policy interpretation; however, much of the variability may be from the interpretation of the federal CSO policy by delegated states. For example, 91% of the CSO discharges throughout the U.S. are in EPA Regions 1, 2, 3 and 4; all of these CSO states have delegated program authority. However, the EPA regions are required to oversee these states, so it is likely that these regions generally acknowledge and try to accommodate the states' interpretation of the federal CSO policy. For example, within Region 1 there is significant variability in state interpretation. Maine and Massachusetts, for example, do not recognize the presumptive approach. Some of the more obvious differences among the EPA regions are with respect to the use of modeling and certain control technologies and in the implementation of the NMCs versus a LTCP. These differences are often dependent upon the individuals involved and their comfort level with approaches and technologies. To reduce this variability, U.S. EPA produced a memorandum for the purpose of discussing the federal CSO policy and identifying areas where heightened efforts are needed. This memorandum can be found in Appendix B.

2.2.2 States Combined Sewer Overflow Policy

The federal CSO policy has shifted the burden of implementation from the federal government to the states. Of the 33 CSO states and Washington D.C., 30 states submitted CSO permitting strategies consistent with the 1989 federal draft CSO policy and received U.S. EPA approval, while one state received conditional approval. U.S. EPA serves an oversight role for these delegated states, and EPA regional offices bear the burden of permitting for non-delegated states.

The delegated states and U.S. EPA regional offices, as appropriate, are designated authority to implement the CSO policy. In the case of the delegated states, CSOs are permitted through a SPDES that follows the federal CSO policy and additional state requirements. It is the responsibility of SPDES authorities to ensure permits meet the requirements of the Clean Water Act, and that CSO permittees develop long-term CSO control plans, where appropriate. Additionally, they are responsible for coordinating review of the long-term CSO control plan and permit development in association with the states authority to determine if specific revisions to water quality standards are needed. Water quality standards are state or federal requirements which serve as the legal basis for the water quality- based NPDES permit requirements under the Clean Water Act. Water quality standards consist of state-designated uses for water bodies and the criteria to protect these uses.

A summary of several of the state and EPA region CSO requirements is provided below. This summary is not intended to address all CSO programs, but rather to provide the reader with an idea of the federal policy implementation variability throughout the United States.

New York is a delegated NPDES state; therefore, SPDES permits are issued in accordance with the state's CSO control strategy and the federal CSO policy. The state's CSO control strategy encompasses two major elements, BMPs and additional control measures. New York has 13 BMPs that are equivalent to the NMC measures specified in the federal CSO policy. Additional control measures are water quality-based permit requirements that are necessary for SPDES permittees unable to mitigate serious water quality problems through the BMPs alone. These measures are equivalent to the LTCPs specified in the federal policy.

Indiana has three submittal requirements for its CSO discharge permit requirements that include (1) technology-based controls that meet the requirement of the federal NMC measures, (2) a stream reach characterization that exceeds the NMC measures, and (3) a cost-benefit analysis of alternative CSO abatement controls. The use determination in Indiana is "fishable and swimmable."

Illinois has a CSO policy more stringent than the federal presumption or demonstration approaches. Complete treatment is required for flows produced by the 1-year, 1-hour storm with a peak of 1.2 inches per hour (in./hr). Flows in excess of the specified storm must receive primary treatment sized at 10 times the dry-weather capacity. Illinois was very progressive; CSO regulations have existed there since 1962, and many of the CSO communities used Construction Grant monies to fund their CSO abatement in the 1970s.

Ohio also is implementing the federal CSO policy through the NPDES permit program. Ohio has 92 CSO communities, of which 70 have populations of less than 10,000. Most Ohio CSO communities are required to implement the NMC measures; however, several small communities are spending their money on sewer separation projects instead of implementing the NMCs. Approximately 50% of Ohio's CSO communities have implemented LTCPs, are in the process of implementing them, or have requirements to do so in their permits. Many communities are being asked to characterize and monitor before developing a LTCP (Hun, 1998).

Some delegated states have very few CSO communities. For example, California has two CSO communities (Sacramento and San Francisco) and Virginia has four CSO communities. California's CSO policy was developed solely for San Francisco and included control of CSOs to specified frequencies, capture of floatables, measuring water quality, and implementation of the NMC measures. Virginia's CSO communities were only required to implement the NMC measures.

In contrast to these other states, Iowa, Kansas, Missouri, and Nebraska are not delegated states and are therefore represented by EPA Region 4. Most cities in Region 4 have separated sewer systems; therefore none of the states accepted the responsibilities of program authority. Because CSOs are not an extensive problem, Region 4 has focused most of its efforts on WWTPs. The only CSO requirement is to provide technology-based controls. No LTCPs are required.

2.2.3 Canada Combined Sewer Overflow Policy

The Ministry of Environment and Energy CSO regulations is entitled *Determination of Treatment Requirements for Municipal and Private Combined and Partially Separated Sewer Systems*. These regulations are similar to those set forth in U.S. CSO policy. The Ministry of Environment and Energy regulations require a pollution prevention and control plan which is similar to the LTCP, implementation of minimum SSO controls that are similar to the NMCs, and a minimal level of treatment.

2.3 Sanitary Sewer Overflows

Sanitary sewer overflows are the result of the unplanned relief of a sewer system intended only for sanitary sewage. An SSO typically occurs when the flow exceeds the carrying capacity of the system, and although SSOs can, and do, occur during dry weather, they are most commonly associated with wet weather events. SSOs are caused by a variety of system faults, exacerbated by excess wet weather flows. These causes include (EPA, 1996b):

- rainfall or snowmelt entering the subsurface and subsequently entering the sewer system through defective or deteriorated pipes, joints, manholes, or connections. This is known as infiltration;
- stormwater entering the sewer system through illegal or unintentional connections. This is known as inflow. Together infiltration and inflow are referred to as rainfall-induced infiltration and inflow (I/I);
- pumps and sewers too small to handle the increased flows created by urbanization; and
- faulty equipment, power failures, blocked or broken sewers, and other acute system failures.

Although a large number of SSOs occur in the collection system, they may also occur at the WWTP. Wastewater treatment plants are often not capable of handling the excess flows that occur during large storms. As a result, the WWTP must allow some of the flow to bypass treatment and discharge directly into the receiving waters.

Regardless of the cause or location of the SSO, the end result is that untreated sewage is introduced in an uncontrolled manner into the environment, leading to concerns for public health and safety. The health, social, and economic costs of SSOs are significant. The health and environmental risks attributed to SSOs are a function of several factors including location and season, discharge frequency, discharge volume, the amount and type of pollutants present in the discharge, and the uses, conditions, and characteristics of the receiving waters (SSO Federal Advisory Subcommittee, 1996). The most serious health risks associated with SSOs involve discharges to water bodies and other areas with a potential for human contact. In addition, SSOs, along with other sources of pollution, impair or damage water bodies for one or more uses such as drinking water, swimming, fish and wildlife habitat, and non-contact recreation. Areas heavily affected by chronic and uncorrected SSOs can experience social and economic losses due to widespread health issues, beach closures, reduced property values, a reduced sense of community, reduced tourism, and loss of recreational opportunities, among others.

There are more than 18,500 sanitary sewer systems in the U.S.. All are capable, under the right circumstances, of producing SSOs (EPA , 1996a). In a 1994 survey conducted by the Association of Metropolitan Sewerage Agencies, 79 members reported SSO problems (AMSA, 1994). Another study estimated that SSOs closed beaches for 300 days in the U.S. during 1994 (National Resources Defense Council, 1995). The U.S. EPA noted that over 1,000 systems in the U.S. experience SSOs (EPA , 1997). While difficult to quantify precisely, it is clear that the sanitary sewer overflows are a widespread issue.

2.3.1 Federal Sanitary Sewer Overflow Policy

The Clean Water Act is the central piece of legislation governing the quality of the nation's waters, including SSOs (EPA , 1999). SSOs are point source discharges of pollutants and must be permitted. This is true for overflows that are released directly into a surface water or indirectly through subsurface flows or through streets and then into a storm drainage system. Operators of systems with SSOs not authorized by an NPDES permit must either eliminate the SSOs or seek a permit.

At this time standards for controlling SSOs are uncertain (EPA , 1999). The Clean Water Act requires secondary treatment for all publicly owned treatment works (POTWs) (i.e., WWTP). For all other point-source discharges, the Clean Water Act requires "best available technology economically achievable" for toxic and non-conventional pollutants and "best conventional pollutant control technology" for conventional pollutants. The system that conveys wastewater to a WWTP is included in the regulatory definition of a POTW, and thus it could be inferred that SSOs from these systems must meet the secondary treatment standard. However, the U.S. EPA has decided that for combined sewer systems, "bypasses" can occur at a WWTP after primary treatment; thus CSOs are not subject to the secondary treatment standard. Where SSOs fall in this quandary has not been decided.

A logical SSO control policy might be based on current CSO control policy. However, there are significant differences between CSOs and SSOs that preclude the direct application of the CSO Control Policy. The key differences are (U.S. EPA , Region 6, 1995):

- sanitary sewers have no diversion and discharge structures designed into the system to release the excess flows to receiving water bodies at controlled discharge locations; and
- the overflows in sanitary systems occur through manholes and defective lines, releasing the flows indiscriminately throughout the system.

Since there are no centralized discharge points in a sanitary system, the application of the technology-based and water quality-based standards of the Clean Water Act is difficult. However, if system improvements can be implemented to contain and divert SSOs to centralized locations, the differences between SSOs and CSOs lessen and a CSO-type approach becomes feasible. (The National CSO Control Policy is described in Section 2.2.1)

In 1994, the general lack of clarity and consistency in the nationwide approach to SSOs led a number of municipalities to approach the U.S. EPA Office of Water and ask that an advisory committee be formed to make recommendations on how to apply the NPDES program to SSOs. As a result, the SSO Federal Advisory Subcommittee was formed and began meeting in late 1994. The subcommittee was instrumental in developing draft federal SSO policy. This policy was documented as a new chapter in the EMS Guide on March 7, 1996. This chapter, "Setting Priorities for Addressing Discharges from Separate Sanitary Sewers," established guiding principles and priorities for the various EPA regions and NPDES delegated states in responding to separate sanitary sewer discharge violations (EPA, 1996a). This chapter is presented in Appendix C.

2.4 Stormwater

Stormwater is water from precipitation that flows across the ground and pavement when it rains or when snow and ice melt. The water seeps into the ground or drains into a storm drain system and discharges without treatment into streams, lakes, and estuary ecosystems.

Stormwater runoff contains pollutants that are collected as rainwater or snowmelt flow across the ground surface. Such pollutants include oil and grease, chemicals, nutrients, heavy metals, bacteria, viruses, and oxygen-demanding compounds.

Stormwater pollution has many sources. Three general source types are residential, industrial, and construction. The most common residential sources are from building materials (especially metal flashing), fertilizer and other landscape chemicals, pet waste, and pollutants associated with the use of automobiles. At industrial sites, chemical spills that contain toxic substances and uncovered or unprotected outdoor storage or waste areas can contribute pollutants to SW runoff. During construction, chemicals and materials can wash into ditches leading to waterbodies during rainy weather. Inappropriate discharge of sanitary and industrial wastewaters into storm drains can also contribute to the pollutant load of SW flows during dry periods. Environmental degradation associated with SW runoff may be magnified due to hydraulic changes in a developed area. When undeveloped land is urbanized, much of the land surface is paved with impervious materials (buildings, asphalt, and concrete). This increases the runoff volumes and rates during rains and decreases the receiving water flow during dry weather.

Regardless of the source of SW, the end result is that polluted water is introduced into the environment and leads to concerns for public health and safety. The U.S. EPA has identified urban runoff as one of several potential sources of more than 1,000 toxic organics that have been detected in drinking water supplies (45 FR 77870). Studies have also detected increased salt concentrations in shallow groundwater in areas where large quantities of salts are used on roads for ice control (Terry, 1974).

2.4.1 Federal Stormwater Policy

In 1973, U.S. EPA promulgated its first SW regulations in the form of an exemption. Any conveyances carrying SW runoff uncontaminated by industrial or commercial activity were exempt from the NPDES regulations. However, the Natural Resources Defense Council brought suit in the U.S. District Court for the District of Columbia, challenging the agency's authority to create such exemptions. The court ultimately held that U.S. EPA could not exempt discharges identified as point sources from regulations under the NPDES permit program.

Subsequently, U.S. EPA issued a rule in 1976 establishing a permit program for all SW discharges except for rural runoff uncontaminated by industrial or commercial activity. What followed was a series of suits brought by major trade associations and their member companies, a process that culminated in the NPDES Settlement Agreement in 1982.

During U.S. EPA 's evaluation of appropriate changes, Congress passed the Water Quality Act of 1987 (WQA) which amended the Clean Water Act of 1977 and included specific provisions related to SW.

The directives of the 1987 WQA were threefold. First, Congress specifically directed U.S. EPA to address SW discharges under the NPDES program and established statutory deadlines for the initial phases of the program. Second, Congress affirmed that SW discharges from industrial sites must be issued NPDES permits, and that the full panoply of traditional NPDES permit requirements, including technology-based and water quality-based standards, must be applied. Third, Congress established slightly different permitting requirements and standards for municipal SW discharges than for industrial SW discharges, including the new "maximum extent practicable" standard.

Through the WQA and amendments to the Clean Water Act, a two-phased approach addressing SW discharges was developed. A brief summary of the municipal SW portion of this policy can be found in Appendix D. Phase I, currently being implemented, requires permits for separate SW systems serving large- and medium-sized communities (those with over 100,000 inhabitants), and for SW discharges associated with industrial and construction activity involving at least five acres.

Phase II, which is currently under development (finalized Oct. 29, 1999), would expand this existing national program to smaller municipalities and construction sites that disturb 1 to 5 acres. In this expansion, U.S. EPA is proposing to allow certain sources to be excluded from the national program based on the lack of impact on water quality, as well as to pull in other sources not regulated on a national basis based on localized adverse impact on water quality. Finally, U.S. EPA is proposing to conditionally exclude from the NPDES SW program industrial facilities that have "no exposure" of industrial activities to SW, thereby reducing application of the program to many industrial activities currently covered by the program that have no industrial SW discharges.

2.4.2 States Stormwater Policy

Federal policy for SW management has also shifted the burden of implementation from the federal government to the states. Through the WQA and amendments to the Clean Water Act, a two-phased approach addressing SW discharges has developed. All states must follow guidelines that are no less stringent than the NPDES permit guidelines.

A summary of several state and regional SW management programs is provided below. This summary is not intended to address all SW programs, but rather to provide the reader with an idea of the federal policy implementation variability throughout the United States. A more detailed documentation of state SW policy can be found in Appendix E.

In response to U.S. EPA's SW policy, many states have imposed additional requirements. California is an U.S. EPA NPDES-delegated state with permitting authority that has instituted many more stringent requirements. For example, a regulated SW area is considered individually from the property's primary activity (the vehicle service area at a school would be considered a transportation area, requiring permitting). Point source guidelines are also more stringent (sheet flow from parking lots is considered a point source requiring a permit).

In contrast to California, Maine does not have NPDES permitting authority. However, the Maine Department of Environmental Protection Bureau of Land and Water Quality wrote the Natural Resources Protection Act that is used to protect the quality of the receiving waters by imposing additional regulations to those prescribed by the U.S. EPA . Proposed construction projects require permits directing adherence to SW quality and quantity standards.

Similar to the U.S. EPA guidelines, some states have imposed numerical standards. Hawaii, an NPDES- delegated state with permitting authority, requires that permitted discharges must comply with the state's basic water quality criteria. These criteria include prohibited substances. Discharges must conform to specific concentration allowances and cannot contain pollutants in 24-hour average concentrations greater than the values obtained by multiplying the minimum dilution by the acceptable standard. In addition, BMP plans must be implemented for construction SW runoff controls.

Arkansas has also established numerical guidance in addition to the U.S. EPA's guidelines. For example, coal pile runoff should not exceed 50 milligrams per liter (mg/L) maximum suspended solids and the hydrogen ion concentration (pH) must be within 6-9 standard units (SU). Iowa also has this limit. The Arkansas Department of Pollution Control and Ecology has specifications for detention ponds and erosion controls. Required detention pond volumes and sizing are determined using a "simplified volume formula" or the "modified rational hydrograph method."

Colorado, an NPDES delegated state, also issues permits requiring adherence to numerical limits. In addition to the numerical control limits, control measures also govern reclamation, acid runoff from mines, drainage control, subsidence, and grading activities.

Some states take a watershed approach to SW management instead of the point source approach. In response to contamination of its groundwater supply by continued urban development, Austin, Texas, passed a watershed protection ordinance in 1981. The 1986 amendment to the ordinance specifies standards for development within critical watersheds. These include buffer zones, building restrictions on slopes greater than 15%, and required setbacks from springs, creeks, and sinkholes.

Wisconsin also uses the watershed approach towards SW management and control. In 1983, the state initiated its priority watershed protection program, which involves retrofitting nonpoint source controls in watersheds where point source controls alone cannot meet water quality objectives.

The SW utility was pioneered by the city of Bellevue, Wash. Many cities now have SW utilities modeled after Bellevue's, which uses natural drainage systems such as swales, lakes, ponds, wetlands, and detention ponds to transport and dispose of SW. The primary mission of the Bellevue storm drainage utility is to "manage the storm and surface water system, to maintain a hydrologic balance, to prevent property damage, and to protect water quality for the health, safety, and enjoyment of citizens and for the preservation and enhancement of wildlife habitat" (Bissonette, 1985).

2.5 History of Wet Weather Pollution Management Control Strategies

Throughout history, many strategies have been implemented to control wet weather pollution for reasons such as flood control, water quality improvement, aesthetic improvement, waste removal, and others. To provide guidance for developing communities, a reference manual for wet weather flow systems in newly urbanizing areas is being developed as part of a cooperative agreement among the Urban Watershed Management Branch of the U.S. EPA , the University of Alabama at Birmingham (Pitt, et al. 1997), and ASCE (Heaney, et al. 1997). The reference manual includes a historical summary of wet weather pollution management control strategies (Pitt, et al. 1997), which is presented in Appendix F.

CHAPTER 3.0

APPROACH

3.1 Essential Wet Weather Pollution Abatement Criteria

To provide a sound program for abating wet weather pollution, a community should adopt a multi-faceted approach which includes encouraging public participation; monitoring and modeling impacts, including the impacts on receiving water; examining the usefulness of a watershed approach; and looking at the cost-effectiveness of any proposed program. These considerations, along with the experiences documented in the benchmark matrices and case histories, can be used as a starting point to develop site-specific wet weather pollution abatement programs.

3.2 Questionnaire Development

The project team used role-playing activities to identify wet weather abatement criteria. Participants included EPA regions, state regulatory agencies, municipalities, and the public. Each role player was responsible for identifying respective abatement criteria. The role-playing provided information used to facilitate the questionnaire development and interview process.

The questionnaire was categorized into six sections, namely public participation, conveyance system information, watershed approach, water quality, issues driving technical considerations, and financial considerations. A copy of the questionnaire is included in Appendix G.

The questionnaire was sent to CSO, SSO and SW communities throughout the United States and Canada. These communities were originally identified through data provided by U.S. EPA and private consultants. The communities represent a range of geographical locations, population, economic bases, and abatement strategies and schedules. In general, communities were initially reached via a personal telephone call. If the contact expressed interest in participating, then a questionnaire was sent to the attention of that person.

The number of questionnaires returned was less than anticipated. Of the approximately 150 questionnaires sent to communities throughout the United States and Canada, only 50 were returned. (Appendix H contains the list of questionnaire contact persons.) Despite this low return rate, the communities that participated do represent a wide range of geographic locations, demographics, and abatement strategies and schedules. More importantly, they provided meaningful data for the purpose of allowing other communities to benchmark their own wet weather pollution abatement progress. Though the data presented in this report is not representative of communities who have not begun wet weather abatement, those communities may find Chapter 4, Essential Wet Weather Pollution Abatement Criteria, and the benchmark data (Chapters 5-7) very useful in planning and starting their abatement programs.

3.3 Benchmark Matrices and Case Histories

Benchmarking is the process of documenting existing experiences for the purpose of culling out best practices, innovative ideas, and highly effective operating procedures that could assist in developing effective solutions.

The benchmark matrices and case histories for CSO, SSO and SW communities provide data that may be useful to stakeholders seeking to improve their wet weather pollution abatement process. Information is provided in two forms: benchmark matrices and case histories.

Data from the questionnaires were tabulated to facilitate interpretation. CSO, SSO and SW benchmark matrices can be found in Chapters 5, 6 and 7, respectively. The matrices are categorized into five sections, namely, general community statistics, public participation, systems characterization, issues driving technical considerations, and financial considerations.

Case histories for CSO, SSO and SW were developed for a select number of surveyed communities that exemplify common approaches to wet weather pollution abatement. These communities provided meaningful data for the purpose of allowing other communities to benchmark their own wet weather pollution abatement progress.

A discussion of decision criteria used to determine benefits of CSO, SSO, SW abatement follows the benchmark matrices and case histories in each chapter.

CHAPTER 4.0

ESSENTIAL WET WEATHER POLLUTION ABATEMENT CRITERIA

4.1 Criteria Development

The following guidance issues provide a fundamental approach to abating wet weather pollution. These guidance issues, along with experiences documented in the benchmark matrices and case histories, can be used as a starting point to develop a site-specific, wet weather pollution abatement program. These issues include public participation, watershed approach, receiving water impacts, monitoring and modeling of impacts and cost effectiveness analysis. The issues are structured in the form of a methodology, and are organized in a sequential manner. For example, public participation, while not always the highest priority for a municipality, should at least be considered early in the abatement process to gain the greatest returns from the program. The watershed approach, receiving water impacts and monitoring and modeling of impact issues pertain to understanding and gathering meaningful information about wet weather pollution sources and their impacts in terms of the entire watershed. Once the pollution sources and impacts are identified, a cost effectiveness analysis may be used to select alternatives and prioritize capital projects. Figure 4-1 illustrates the general methodology.

4.2 Public Participation

Public participation is the process of seeking the views and concerns of stakeholders and including them in the decision-making process. It includes open information sharing, teaming with stakeholders, gaining public input, and solving problems jointly. Stakeholders are any citizens or groups who have an interest or stake in the outcome of a decision made by the municipality. In that sense, every taxpayer in the municipality is a stakeholder. Stakeholders include federal agencies, state and local governments, environmental groups, labor organizations, citizen's groups, and community members.

The following are guides to and benefits of public participation:

- Public involvement in the process should occur early and often. Public participation takes more time and effort up front, but will result in a better decision that is less controversial and requires less outreach, education, and defense.

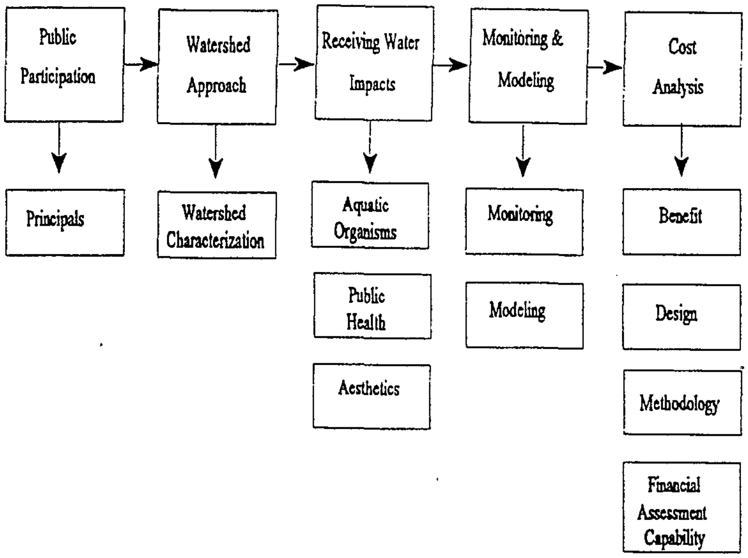

Figure 4-1. Wet Weather Issue Methodology Outline

- Public trust is earned through openness, outreach, consistency, and results. Public involvement is crucial to sound decision making. Public participation allows the municipality to enlist a much broader range of expertise than it has available in-house.
- Public dialogue increases understanding among all interests affected by decisions. Effective participation means two-way communication and the willingness of the public to take advantage of the various opportunities to participate. Public dialogue can aid both the regulated community and the public in understanding their individual expectations, resulting in more workable and widely acceptable solutions.
- Public input should be solicited from all sectors of society. Equal opportunity for comment and equal consideration of comments from the private and public sectors should be provided.
- The municipality should carefully consider all public comments, regardless of their origin, and provide a response through a comment and response document, not just an acknowledgment.

For the public to successfully participate in the decision-making process they should be informed of how and when they can get involved. The municipality should notify both the regulated community and the general public and ask for input regarding the wet weather pollution circumstances. There are many methods for obtaining public input. Each community and pollution scenario is different; therefore the most effective method, or combination of methods, should be selected on a case-by-case basis.

The following are a few methods of obtaining public input:

- *Advisory Committees.* An advisory committee is generally composed of volunteers from a wide range of occupations who are appointed by the municipality to represent the entire community. The committee generally serves as a sounding board for the public and an advisory board for the municipality. Advisory committees should be used to review technical documents and public comments and may also make recommendations to the municipality.
- *Notice and Advance Notice of Proposed and Final Milestone Decisions.* The advance notice of proposed and final decisions enables the municipality to solicit comments from the community prior to action. Information about the proposed and final decisions can be disseminated via quarterly newsletters, community newspaper articles, public service announcements, world wide web pages and local radio/television advertisements. These announcements should explain the status of the wet weather pollution abatement process and solicit input from the community. In addition, the municipality should distribute information and solicit comments through the appropriate advisory committee. In this way, the public has additional opportunities to comment on decisions, thereby developing solutions with greater community concensus.

- *Public Information Meetings.* The municipality should consider holding public information meetings on proposed decisions when it anticipates a need to inform the public on environmental impacts or explain a new wet weather pollution abatement scenario and respond to questions. Public meetings should be publicized using the forums listed above.
- *Public Hearings.* To receive comments on proposed decisions, the municipality should conduct public hearings, particularly when significant interest is generated by a proposal. These hearings should be used to officially record public comments. Public hearings should be scheduled at locations and times that allow for the greatest number of affected people to attend. Public hearings should also be publicized using the forums listed above.

4.3 Watershed Approach

4.3.1 Definition of Watershed Approach

Today's challenges require more comprehensive solutions to further restore and maintain the physical, chemical, and biological quality of our nation's waters. One such solution is the watershed approach, a coordinating framework for environmental management that focuses public and private sector efforts to address the highest priority problems within hydrologically defined geographic areas, taking into consideration both ground and surface water flow. The watershed approach has three key components:

- *Geographic Focus.* Watersheds are defined by natural boundaries. They are the areas that drain to surface water bodies. A watershed generally includes lakes, rivers, estuaries, wetlands, streams, and the surrounding landscape. Groundwater recharge areas are also considered.

- *Continuous Improvement Based on Sound Science.* Sound scientific data, tools, and techniques are critical to guide the process. Actions taken include characterizing priority watershed problems and solutions, developing action plans, and evaluating their effectiveness within the watershed.

- *Partnerships/Stakeholder Involvement.* Watersheds transcend political, social, and economic boundaries. Therefore, all affected interests should be involved in designing and implementing goals for the watershed. Watershed teams may include representatives from all levels of government, public interest groups, industry, academic institutions, private landowners, concerned citizens, and others.

4.3.2 The Urban Watershed

Within the watershed lies the urban watershed, a subset of the complete watershed bound by topography and city limits. It holds most of the population and contributes significantly to water quality problems.

At a minimum, the urban watershed includes, but is not limited to, SW runoff, sanitary- and combined-sewer discharges, and NPDES-permitted industrial and commercial discharges. Urban watersheds therefore include (1) all sources (point and nonpoint) originating within the urban center or urban fringe, and (2) water entering the urban watershed (surface and groundwaters entering from upstream sources, source waters supplying the urban population, and rain events). These contributions must be included to adapt to the situations exemplified by TMDL trading that allows upstream reductions to substitute for NPDES discharges. The urban watershed evaluation should also recognize the probability of the expanding urban geographic area as the national population is moving from the urban core to the surrounding areas.

4.3.3 Watershed Characteristics

The first step in abating wet weather pollution is to identify the sources and prioritize them before developing criteria for wet weather pollution abatement.

The most recent National Water Quality Inventory reports that runoff from urban areas is the leading source of impairments to estuaries and the third largest source of water quality impairments to surveyed lakes. Therefore, in characterizing a watershed, emphasis is placed on the subwatershed known as the urban watershed, even when the entire watershed may also include agricultural and suburban point and nonpoint pollution sources. The urban watershed can be characterized in three general categories: urban, environmental and infrastructure characteristics.

4.3.3.1 Urban Characteristics

The urban characteristics of a watershed may be illustrated by its physical properties, percent porosity and economic/social basis.

R0018259

The physical nature of the urban watershed such as size, topographic relief, and local hydrologic conditions will determine the runoff and erosion from the watershed. Characteristics such as land use and the creeks and storm drainage system in the watershed may be used to delineate sub-watersheds, so that different attributes of the watershed may be clearly differentiated and addressed.

Nonporous urban landscapes like roads, bridges, parking lots, and buildings do not permit precipitation to percolate into the ground. Water remains at the surface, accumulates, and runs off in large amounts. When leaving the system and emptying into a stream, it erodes streambanks, damages streamside vegetation, and widens stream channels, resulting in lower water depths during non-storm periods, higher than normal water levels during wet weather events, increased sediment loads, and higher water temperatures. Native fish and other aquatic life cannot survive in urban streams severely affected by urban runoff.

Urbanization also increases the variety and amount of pollutants transported to receiving waters: sediment from development and new construction; oil, grease, and toxic chemicals from vehicles; nutrients and pesticides from turf management and gardening; viruses and bacteria from sewer systems; and heavy metals from industrial activity. Sediments and solids constitute the largest volume of pollutant loads to receiving waters in urban areas. Toxins from wet weather pollution can generally be considered a primary concern in industrialized areas that are served by combined sewers.

4.3.3.2 Environmental Characteristics

The primary concern for wet weather pollution abatement is the receiving water that must support the fishable and swimmable goals set forth in the Federal Clean Water Act Amendments of 1972. The approach to plan development should address the identification of specific environmental features that are adversely affected by wet weather pollution.

The receiving water body is usually the primary focus of attention in defining the environmental characteristics. These characteristics include:

- size relative to loadings,
- type (river, sea, estuary, ocean, reservoir, etc.),
- seasonal changes (flow, temperature, and ice cover),
- physical factors (slope, velocity, mixing zones, pools and riffles, etc.), and
- beneficial uses (historical, present, and future).

Characterizing aquatic life helps identify what types of pollutants are of concern, as well as whether adverse impacts are expected to be seasonal, transient, or long term. Differentiation can initially be made between bottom organisms (subject to sediment accumulation) and water column organisms. If fish are of concern, the most sensitive type of fish should be identified to develop an approach to protect them. Important factors are:

- seasonal aspects (migration and spawning),
- transient variances in dissolved oxygen and in ammonia and other toxins,
- type and diversity of other organisms required, and
- relative importance of the physiology of the water body.

Bottom organisms are often more important to consider than fish and other aquatic life in the water column because wet weather pollution contains such a significant amount of settleable solids. These settleable solids account for a significant portion of the heavy metals and other toxins found in wet weather pollution. In addition, the deposition of inert particles can cover bottom organisms and adversely affect the environment. Wherever these solids settle, the impact can be long term, affecting both the water column and aquatic life.

There may be other constraints to realizing water quality improvements if only wet weather pollution is abated. One constraint is the effect of the bottom deposits from wet weather pollution that have accumulated previously. These bottom deposits might be classified as toxic, which complicates their removal and safe disposal; unless removed, they will continue to exert a significant oxygen demand, remain a source of toxicity in the food chain, and/or retard improvements to the fishery (spawning, bottom organisms, etc.).

Stream physiology may also be a constraint. Factors of importance include current velocity, water temperatures, bottom structure and shading for spawning, barriers to migration and movement, and diversity of aquatic organisms. Navigation uses may adversely constrain other uses perceived as beneficial. Recreational uses can be constrained by barge traffic, access limitations, stream physiology, and other pollutant loads.

4.3.3.3 *Infrastructure Characteristics*

Combined, separated and SW sewers are a significant component of a community's infrastructure. Development of a plan to abate wet weather pollution should thus include consideration of the collection system, WWTPs, and other related infrastructure components.

Some collection systems are 50 to 100 years old. Other systems were designed for a smaller population or a less impervious land than currently exists. Such issues can affect the conveyance capacity of these systems.

An assessment of the structural condition is important for two reasons. First, it may provide a rational basis for separating the sewer system, an abatement strategy used for CSO. Second, it may provide a basis for estimating the financial resources required to maintain the present level of service. Collapsed or clogged sewers will require investment to improve or maintain service.

In some urban areas, in addition to concern for the receiving water body, a significant public health and safety concern from basement and street flooding may also exist. Increasing conveyance capacity to mitigate basement and/or street flooding could have a major impact on developing a plan for wet weather pollution abatement. In some areas, the importance of protecting basements relative to street flooding could point the program toward sewer separation or use of inlet controls to avoid overloading.

Wet weather pollution abatement facilities may affect existing WWTPs and residual solids handling. Use of existing WWTPs as part of a wet weather pollution abatement plan will affect the amount of land available for future upgrading or expansion. Consideration should also be given to converting decommissioned WWTPs to wet weather pollution treatment plants rather than abandoning them.

Wet weather pollution abatement facilities will require careful consideration in siting; however, disruption during construction and interference with other utilities can be expected. Investigation of other urban improvements, such as road repairs or flood control, may lead to ways of mitigating disruption and interference by undertaking multipurpose projects. Coordination of construction activities with road or street surface improvements could be a major cost saving. In some areas it may be prudent to keep utility corridors free from obstructions or to coordinate general locations and depths of crossings.

4.4 Receiving Water Impacts

The specific receiving water impacts from wet weather pollution vary depending on the urban, environmental, and infrastructure characteristics. Depending on the particular combination of these factors, wet weather pollution impacts can be visible and intense. The size and type of the receiving water body determine its ability to dilute and assimilate intermittent wet weather pollution without toxicity. Therefore, receiving water impacts should be evaluated based on each site's particular characteristics. In each case, wet weather pollution impacts can be evaluated with respect to three basic considerations:

- water quality changes and effects on aquatic organisms,
- public health risks, and
- aesthetic deterioration.

4.4.1 Water Quality Changes and Effects on Aquatic Organisms

The wet weather pollution impacts on receiving waters depend on the rate and volume of the discharge, the degree of mixing and dilution, and the receiving water's assimilative capacity. Obviously, the larger the water body and smaller the discharge, the better likelihood of minimal impacts. For example, in some large rivers and estuaries, wet weather pollution has minimal impacts because of rapid dilution and mixing. In contrast, small streams that receive wet weather pollution with little dilution can be severely affected even for small storms. Therefore, solutions to wet weather pollution require site-specific monitoring and evaluation.

Most water quality impacts are measured by a determination of the increases (or decreases) in receiving water concentrations of toxicants as they relate to a violation of water quality criteria or standards. Such criteria are generally used to assess the potential for effects on aquatic organisms and impaired use. Although wet weather pollution is intermittent, the resultant problems may not be temporary and can persist to varying degrees. Figure 4-2 provides preliminary guidance for the time frames to be considered for different water quality problems. These different time frames can require different strategies for monitoring and calculating wet weather pollution impacts.

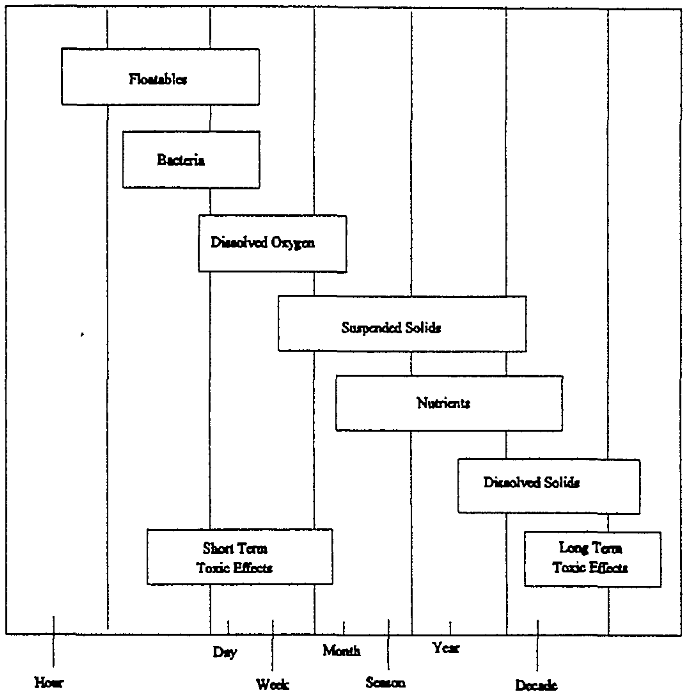

Figure 4-2. Time Scale for Wet Weather Pollution Water Quality Concerns (Moffa, 1997)

Dissolved oxygen levels, nutrient enrichment, sediment impairment, and toxicity are the major problems resulting from wet weather pollution.

Temporary depression of dissolved oxygen levels is a possible water quality problem attributable to wet weather pollution. Even though SW dilution minimizes the immediate impact, which generally lasts only hours, dissolved oxygen reductions may impair aquatic growth or reproduction and, in severe situations, cause biologic mortality. The severity, frequency, and duration of dissolved oxygen reductions caused by wet weather are dependent on the specific receiving water in question.

Nutrient enrichment from phosphorus and nitrogen is another potential problem resulting from wet weather pollution. Nutrient additions cause increased algae or aquatic weed growth. In turn, this may cause dissolved oxygen problems, reduce biological diversity, degrade aesthetics, or impair use for water supply. In fast-moving streams, nutrient contributions are typically flushed out before any impact can be realized, but in slower-moving water bodies the nutrients accumulate and assimilate into the biota. Sources of nutrients cannot easily be distinguished. However, performing relative comparisons of seasonal nutrient loadings at critical locations in the watershed can aid in the assessment of nutrient enrichment and eutrophication.

Another common problem from wet weather pollution is accumulated bottom-sediment contamination. Wet weather pollution typically has high levels of suspended materials that settle to the bottom in receiving waters. The accumulation and persistence of solids in sediments are typically long-term, not transient problems. The results can be high sediment oxygen demand due to biological oxidation and accumulation of toxic substances in the sediments. These conditions are usually present in slower-moving rivers, estuaries, or lakes, but not in fast-moving streams where sediments are routinely scoured from the bottom. Sediment criteria and standards for evaluating the severity of a problem are lacking. The U.S. EPA provides general guidelines for disposal of dredged sediments (EPA, 1997; EPA, 1977), but beyond these, the significance of sediment contamination should be evaluated on a site-specific basis.

Receiving water toxicity is the fourth general impact from wet weather pollution. In general, toxicity problems fall into two categories: (1) acute toxicity at higher concentrations, causing short-term mortality, or (2) chronic, long-term exposure to toxins, causing reduced growth and reproduction. Acute effects can often be observed as immediate fish kills or severely reduced biological diversity. Chronic effects are more subtle and harder to identify but at times can be observed by lower productivity and biomass (numbers of organisms), by bioaccumulation of chemicals, or by reduced biological diversity. Fortunately, chronic effects generally do not result from wet weather pollution because discharges are intermittent and infrequent in nature.

Toxic discharges from wet weather events can be a concern in industrialized areas served by combined sewers. Pretreatment programs are a good source of information to screen for potential toxicity from rainfall events. The more common toxicity concerns are for ammonia and dissolved trace metals, but concentrations generally are diluted enough to be of little concern. Preliminary screening for toxic effects can be performed using average dry weather discharge concentrations in combination with wet weather peak hourly flow rates for calculating a range of dilution. If such considerations are relevant to a site, then existing state and U.S. EPA water quality criteria are available for making preliminary assessments (EPA, 1986).

4.4.2 Public Health Risks

The major source of concern related to wet weather pollution, a concern in nearly all types of receiving waters, is the public health risk associated with diseases caused by pathogenic bacteria and viruses that may be carried in excrement. When people are exposed to contaminated receiving waters through wading, bathing, shellfish ingestion, and fishing, they risk becoming ill. Levels of bacteria observed in wet weather pollution varies. CSOs and SSOs have higher pathogenic bacteria counts than SW discharges; nonetheless, each type of discharge generally contains bacteria counts that are several orders of magnitude greater than applicable receiving water quality standards. For this reason, wet weather pollution can cause potential problems even in receiving waters with very high dilution. The potential risk is typically greatest at the beginning of a wet weather event, due to the "first flush" effect that delivers much of the waste that had accumulated during the preceding dry weather period. However, the risk can diminish quickly thereafter due to bacterial die-off, settling, and dilution. Significant public health risks from exposure to pathogens rarely persist more than two or three days after a storm overflow event. Wet weather pollution laden with bacteria is a special concern during warm weather when water contact recreation peaks and human exposure is greatest.

Protecting public health from exposure to microbial pathogens is complicated by the extreme difficulty in measuring concentrations of pathogenic organisms. For this reason, water quality standards are based on the presence of more easily measured indicator organisms. The most commonly used indicator of fecal materials has been fecal coliform bacteria, based upon work of the U.S. Department of Interior's National Technical Advisory Committee in 1968. Many state water quality standards are based upon this work, and consist of a standard of 200 fecal counts/100 milliliters (ml) for total body contact recreation, and 1,000 fecal counts/100 ml for partial body contact recreation. U.S. EPA revised these suggested numbers in 1986 to be based upon concentration of *Escherichia coli* and *enterococci*.

Generally, receiving water concentrations above 200-1,000 organisms/100 mL are considered to represent a greater disease risk. Concentrations of indicator bacteria in wet weather pollution usually number in the millions, and hence, dilution is rarely sufficient to eliminate all potential risk. Therefore, increased public health risks from wet weather pollution is a potentially serious issue. At times, the concern may be only transient and local (near discharge location), but in many systems the concern may extend for miles and days beyond the discharge. In all cases, wet weather pollution risks to public health should be given the highest priority.

4.4.3 Aesthetic Deterioration

Aside from physical/chemical contamination and public health risks, wet weather pollution can also impair the aesthetics of receiving waters. Wet weather pollution can contain an assortment of debris from runoff and wastes from sanitary sewage that are obvious and unsightly. Increased suspended solids, sanitary debris, plastics, floatables, and oils and grease are generally associated with wet weather pollution. Such debris is common to all receiving waters, but may persist for different periods depending on the current strength and dilution. Although aesthetic impairment may not reduce aquatic health or cause obvious human health risk, it does have socioeconomic significance. Debris and suspended solids from wet weather pollution can reduce recreational use and appreciation of receiving waters, thereby limiting recreational expenditures and near-shore development. Increased suspended solids can cause reduced water clarity, which also affects recreational use. Because aesthetics are typically an integral component of a water's designed use, aesthetic impairment can be considered a violation of water quality standards. Quantitative measures of aesthetic reduction are rare, but visual observations and resident interviews often adequately define the scope of the problem.

4.5 Monitoring/Modeling of Impacts

In every wet weather pollution abatement study, there is a recurring debate on the best means to define impacts and benefits of alternative control strategies. Should it be monitoring or modeling? Practically speaking, it is not an either/or decision, but rather how much of each. The two activities need to be balanced and designed for an integrated assessment. Monitoring is needed to identify existing problems, define baseline conditions, and support the development of reliable and verified mathematical models. Nothing provides stronger evidence of existing receiving water impacts than actual measurements and observations. However, monitoring alone has limitations; therefore, modeling should generally be used to complement monitoring and to forecast and analyze conditions other than those monitored.

4.5.1 Monitoring Impacts

Receiving water monitoring to document wet weather effects requires an integrated approach combining biological, chemical, and physical parameters, especially considering the biological community, the physical habitat, aesthetics, human health, contaminated sediments, and ambient water quality. Relying on water quality alone may be misleading. Monitoring programs should include initial wet weather pollution reconnaissance surveys involving a few stations downstream of a discharge and at least one station upstream. The reconnaissance monitoring should be conducted during seasons expected to encompass the most significant impacts and extend from a day before a storm to as much as four days afterwards. Parameters should include BOD, dissolved oxygen, temperature, bacteria, and other parameters suspected of having impacts, plus visual observations for debris and floatables. Occasionally, routine fixed-frequency monitoring data can be used to assess trends, the presence of impacts, and the periods or seasons when the receiving water is most susceptible to wet weather pollution. However, most often the timing of the fixed-frequency sampling does not coincide well with storm impacts. Therefore, surveys should be designed with this specific need in mind.

The reconnaissance surveys should be used as a basis to design more intensive surveys in terms of sampling location, duration, and frequency. Subsequent to the reconnaissance survey(s), at least two or three additional intensive surveys are recommended to better define impacts for different conditions and support model development. Often, impacts are only evident for large storms and not apparent for the smaller events. Hence, multiple surveys are recommended for defining the recurrence of problems and representing a fuller range of conditions.

In general, station locations and frequency for intensive surveys must be in sufficient numbers to clearly define spatial and temporal trends. Sufficient usually means sampling every 3 - 6 hours at stations located with time of travel between locations of approximately 6 - 12 hours. In rivers, the sampling logistics are the simplest because all impacts flow downstream. Station locations and timing are easy to define. For estuaries, choosing station locations is still relatively easy, but consideration of tidal movement and timing becomes important. Sampling at fixed times in each tidal cycle (usually a slack) are most desired to help standardize analysis and presentation of the data. For lakes, timing is less difficult, but station locations are more difficult to select due to multidimensional and sometimes erratic transport. In lakes, drogue or current studies can be used to define current transport. The circulation patterns in a lake may vary depending on wind stratification and other variable factors. Therefore, a network of lake stations should be set up to encompass the probable horizontal and vertical transport directions. Preliminary data can be used to refine the sampling network. Also, reconnaissance data may show minimal localized effects, in which case coarse whole-lake sampling may be more appropriate than a localized network. In all cases for rivers, estuaries, and lakes, the reconnaissance sampling is indispensable for defining adequate station locations and sampling frequency.

The sampling parameters should focus on the anticipated wet weather pollution related problems. However, all wet weather pollution impact surveys should routinely include measurement of bacteria, dissolved oxygen, BOD, and ammonia. Temperature and visual observations of cloud cover, sunlight, water transparency, floatables, debris, and other conditions are inexpensive and should also be routine. Daily composites are usually suitable for other parameters such as nutrients and chlorophyll. Toxic substances, such as trace metals, typically need only be measured immediately before the storm to define pre-storm conditions, immediately after the storm to define maximum impacts, and at the end of the survey to determine persistence. Diurnal dissolved oxygen variations due to photosynthetic activity can be very important and, if present, generally dictate the need for continuous monitoring and/or station measurements at 3-to-5-hour intervals. Photosynthetic activity can often confuse or mask the interpretation of wet weather pollution impacts on dissolved oxygen, especially since a reduction in both sunlight and photosynthesis usually accompanies storms. Therefore, if high productivity is present, careful evaluation of diurnal and light conditions is essential.

Some special note should be made concerning the scheduling of storm event monitoring. Obviously, it is impossible to "plan" for storms to occur conveniently for sampling, and it is also generally impractical to use automatic samplers for the receiving water. Therefore, a well-developed mobilization plan is essential to capture immediate post-storm impact, since impacts related to solids, bacteria, and toxins are best captured immediately after the storm, during the first flush of pollutants from the sewers. Weather forecasting services and routine fixed-frequency monitoring programs can also be valuable sources of pre-storm data and for identifying cumulative impacts.

4.5.2 Modeling Impacts

With data in hand, the planner/engineer can proceed to more fully analyze a wider range of conditions after developing and calibrating a mathematical model. Models are well suited for providing information not available from data alone. In particular, models can be used to simulate water quality for conditions not monitored. This could include larger, more intense storms, or more critical environmental conditions such as lower stream flow. It is generally infeasible to simply extrapolate to non-monitored conditions from data due to the large number of variable factors without the use of modeling. Modeling incorporates the mechanistic factors of a relationship, thus enabling more reliable projections under various conditions. The advantage of modeling is that virtually all such conditions can be assessed quickly. Furthermore, models can be used to examine impacts and benefits from proposed control strategies.

4.6 Cost-Effectiveness Analysis

In simple terms, a cost-effective solution is one in which the most value is received for money expended. When benefits are plotted against costs, the break, or the "knee" of the curve, is that point where additional benefits result in more rapidly rising unit costs, or the period beyond which there are diminishing returns, as illustrated by Figure 4-3. This approach becomes particularly important in light of the dwindling nature of federal and state monies and the greater reliance on local monies. Local authorities will require more information on the return on a major investment to improve water quality when making a decision regarding abatement alternatives.

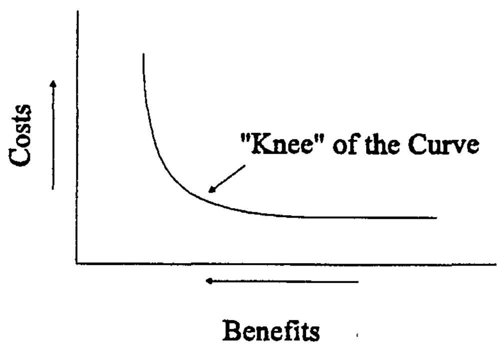

Figure 4-3. Cost-benefit Knee of the Curve

4.6.1 Benefits

There are four general methods for estimating benefits of water quality management projects (EPA-625/4-79-013):

1. The first method assumes that benefits will automatically be realized from the proposed activity and are large enough to justify the allocation of required resources. It completely avoids the benefit measurement problem. An example of this method is the federal requirement for secondary treatment at POTWs (i.e.,WWTPs).
2. In the second method, certain water quality standards are associated with the protection of water uses. Once standards to protect desired beneficial uses have been established, the comparison of projected water quality with the standards provides an estimate of benefit.
3. In the third method, estimates of increased water use potential are developed by translating improvements in water quality into numerical increases in usable length of beaches, swimming days, fishing days, or waterfront property values, to name a few possibilities. This method is, in effect, a refinement of the water quality standards approach, allowing benefits to be estimated directly.

R0018265

4. The best known method is the classical cost-benefit analysis. In this method, each anticipated water usage has a dollar value assigned as a measure of unit worth or willingness to pay. The actual project usages are multiplied by the corresponding unit values, and the sum is compared directly to total project costs.

The first approach is unacceptable for wet weather pollution control planning because the benefits are not obvious; they are highly contingent on both SW volumes and the receiving water. The second approach poses a near-impossible situation for regulatory agencies to address, particularly during storms when the overflow and receiving waters are both changing rapidly. Using the second and third approach together (i.e., relating mandated water quality requirements to lost resources and real benefits of recovery) appears to offer the most effective means of obtaining approvals and funding from all levels. The fourth approach involves a great deal of subjectivity and could result in lengthy dialogue over the unit worth of various usages on both the local and regulatory levels.

4.6.2 Design Conditions

Once data are gathered and modeling is performed to characterize wet weather pollution and identify water quality impacts, a basic decision becomes necessary: What combination of storm event and receiving water conditions should be selected for abatement? To answer this question, the joint probability of a specific storm occurring at a specified receiving water stage must be understood. For example, a 1-year storm occurring during a high river stage condition may easily exceed a once in 10-year occurrence. Thus, it becomes necessary to review rainfall records in combination with receiving water flow records before selecting design conditions.

4.6.3 Methodology

This section outlines a general methodology for determining cost-effective solutions. The general approach for analysis of wet weather pollution abatement is illustrated in Figure 4-4.

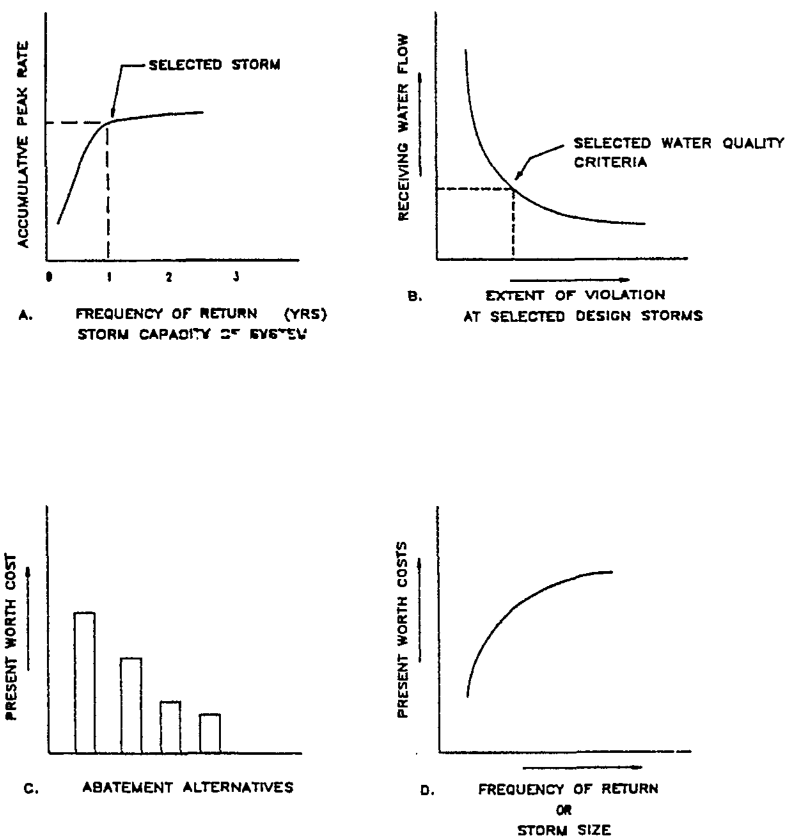

Figure 4-4. General Approach for Cost-Effective Analysis

Subfigure A illustrates the relationship between total volume discharged from a system and accumulative peak rate versus the storm size in terms of frequency of return. Generally, frequency of return is based on a constant duration such as two hours and varying rainfall intensity. The Storm Water Management Model (SWMM) can be used to develop total volume discharged, which represents total discharges irrespective of their location. This model is valid for developing a uniform set of design conditions throughout a system. In large systems with a wide range of receiving water types (e.g., small streams and large bays), it may be desirable to develop this relationship for each specific water body. Such a curve can also be developed for an accumulative peak rate, which is the summation of peak rates of all discharges at a given frequency storm, irrespective of the timing of the peak. This parameter is an indication of the peak carrying capacity of the system and complements the plot of total volume. These data can then be plotted to yield a curve as illustrated by Subfigure A, which can be used to designate the "selected storm" storm condition. At some storm frequencies, the system can no longer accept more SW flow, resulting in street ponding and either subsequent discharge to the system or evaporation or infiltration into the ground.

Subfigure B illustrates the relationship between receiving water flow and the extent of violation at the selected design storm (e.g., 1-year frequency of return). This relationship must be plotted for each of the water quality parameters of concern. This particular curve is more illustrative of the relationship for bacteria where the degree or extent of violation increases as the dilution from water flow decreases. At some point in the decision-making process, a receiving water flow must be selected which is reasonable when combined with the probability of the particular storm frequency chosen. A reasonable receiving water flow might represent the dry months of July, August, and September, when the highest intensity storms are expected. Once the evaluation for each of the water quality parameters is performed, the required removals can be determined.

Subfigure C, given the removals required, can then be developed on the basis of specific abatement technology. Various abatement alternatives that would accomplish the same reductions can be evaluated with respect to present-worth costs. Costs have been selected merely as a comparative term. In many cases, the Y-axis may represent a combination of regulatory, institutional, and local requirements, in addition to costs.

Subfigure D, given the selected abatement alternative, is a plot of the variation of different-sized facilities for that alternative, as required to treat different sized storms against the relative costs. In this way, a final evaluation of the most cost-effective sized facility can be determined.

4.6.4 Financial Capability Assessments

A community's financial capability is particularly necessary in the case of wet weather pollution abatement because there are no clear standards in most states, and the selection of a "design" storm has become a subjective decision based upon cost-benefit relationships. Additionally, other pollutants from a watershed may preclude the attainment of the fishable-swimmable goals of the Federal Clean Water Act Amendments of 1972.

A community's financial capability may be assessed by identifying the following seven factors:

1. median household income,
2. total annual wastewater and wet weather pollution abatement control costs per household as a percent of median household income,
3. overall net debt as a percent of full market property value,
4. property tax revenues as a percent of full market property value,
5. property tax collection rate,
6. bond rating, and
7. unemployment.

In 1996, the U.S. EPA released a draft guidance document on economic capability for communities with CSOs. The document, "Draft CSO Guidance on Financial Capability Assessment and Schedule Development," established boundaries for compliance schedules for CSO communities implementing U.S. EPA's national CSO policy. Although this information was written with respect to CSO, it is applicable to all wet weather pollution.

The following is a summary of the guidance developed by the CSO Partnership (The CSO Bulletin, April 1996).

The guidance proposes a two-step approach for calculating economic capability. The first step focuses on the financial impact of current and proposed wastewater and CSO controls on individual households. The second step examines the debt, socioeconomic, and financial condition of a CSO community. The results of both steps are then combined into a "Financial Capability Matrix" which is used to assess the financial burden attributable to CSO controls and to establish what U.S. EPA views as appropriate compliance schedules.

The first step calculates a residential indicator (RI), a measure of the CSO community's average cost per household for existing and proposed wastewater treatment and CSO controls, expressed as a percentage of local median household income (MHI). The guidance proposes establishing three ranges for RIs with RIs of less than 1 percent MHI characterized as imposing a "low" financial impact, RIs from 1 or 2% of MHI imposing a mid-range impact and RIs above 2% of MHI imposing a high impact.

The second step considers a community's financial capability indicators. U.S. EPA specifies six proposed indicators in the guidance for evaluating community debt, socioeconomic, and financial conditions that affect a community's financial capability to implement CSO controls. The results of the six indicators are used to classify the community's financial capability as "weak," "mid-range," or "strong."

The results these two steps are then combined in a financial capability matrix that provides the basis for the permittee and NPDES permitting authority to negotiate an appropriate compliance schedule. The financial capability matrix divides communities into three categories based upon their calculated burden under the guidance (low, medium, or high), with equal weight given to the community's RI and financial capability indicators.

Finally, the guidance proposes the following general boundaries for compliance schedules based upon a community's calculated burden:

Low burden:	0 - 5 year compliance schedule
Mid-range burden:	5 - 10 year compliance schedule
High burden:	10 - 15 year compliance schedule

According to the U.S. EPA guidance, communities in the "High burden" category may be able to negotiate compliance schedules as long as 20 years.

The lack of supporting information to explain and justify U.S. EPA's selection of the residential indicator categories and the financial capability indicator categories will make it difficult to evaluate whether the proposed categories are appropriate for CSO communities nationwide. For example, U.S. EPA does not provide any discussion of the number of CSO communities that can be expected to fall into the three categories proposed in the Financial Capability Matrix (low, mid-range, or high burden). Also, it is unclear how U.S. EPA arrived at its proposed ranges for the compliance schedules for communities falling within the three categories of financial burden.

An example of how a financial analysis can be performed is illustrated in the case history of Syracuse, N.Y. (Section 5.2.5).

CHAPTER 5.0

CSO Benchmark Data and Case Histories

5.1 Benchmark Data for CSO Communities

The following section includes benchmark matrices for general CSO community statistics (Table 5-1), CSO public participation (Table 5-2), CSO systems characterization (Table 5-3), issues driving CSO technical considerations (Table 5-4), and CSO financial considerations (Table 5-5).

5.2 Case Histories for CSO Communities

Case histories for CSO communities include Atlanta, Ga., Augusta, Me., Decatur, Ill., San Francisco, Calif., and Syracuse, N.Y. Each community represents an important and distinct element of the CSO abatement process. For example, the Atlanta case history highlights CSO policy interpretation, Augusta highlights the cost-benefit analysis, Decatur highlights one of many technical approaches, San Francisco highlights the evolving funding basis for CSO abatement, and Syracuse highlights a staged construction approach that meets the presumption and demonstration approaches of the federal CSO policy.

CSO Community Characteristics

♦ Population	700,000
♦ CSO Area	> 10,000 Ac
♦ Annual Rainfall	50"
♦ # of Discharge Points	7

Distinctive CSO Community Attributes

- Existing natural drainageways used as original sewers
- Intensive legal negotiations
- CSO policy interpretation

5.2.1 Atlanta, Ga.

Atlanta is a typical case where small, intermittent streams and rivers evolved into combined sewers. Before the city developed, these streams flowed from what is now the center of the city either west to the Chattahoochee River and on to the Gulf of Mexico, or east to the South River and on to the Atlantic Ocean. As the city grew, sanitary flows and SW were discharged into these waterways. Odor and health concerns led to the enclosure of the streams in pipes that became the present-day combined sewer system. As the city continued to expand, construction of combined sewer systems ceased and separated systems were initiated. The city's combined sewer system is located in the older, central business district and serves as headwaters to several small streams.

Improvements are currently being made to the WWTPs to meet effluent phosphorous limits (not to exceed 0.64 mg/l). In addition, the Georgia Environmental Protection Division is calibrating a new model that will be used to derive TMDLs. The results of this model may affect future permitting. The model considers the urban streams that are a direct result of overflows as point sources to the Chattahoochee.

Georgia first issued NPDES permits for CSO discharges in 1992. Atlanta's NPDES permits for all CSO treatment facilities are identical. The permits require that CSOs not violate water quality standards.

Atlanta's first CSO treatment facilities were built in the mid-1980s to address water quality problems in the South River Basin. The controls included two first-flush storage and treatment facilities and two small sewer separation projects. Additionally, five on-line screening and disinfection facilities were designed in 1989 to control CSOs in the Chattahoochee River Basin.

Questionnaire Date: July 1998.

Before the facilities were constructed public dissension grew and the state legislature passed a bill mandating that "discharges from CSOs shall not cause a violation of water quality standards." As a result only three of the five CSO treatment facilities were constructed as originally designed and delays in construction caused the city to incur significant fines.

Citizen concerns continued and in 1996, a lawsuit was filed against the city claiming that CSOs violated water quality standards for metals and fecal coliform. In 1997, a federal district judge ruled in favor of the plaintiffs, saying that the concrete culverts into which CSOs discharge are waters of the state and therefore must meet water quality standards. The district court ruling and subsequent consent order are currently in negotiation. Various improvements to the CSO facilities include storage and treatment, relocation of outfalls, and separation. These improvements are estimated to cost between $400 to $600 million.

Motivated by the public dissension, in 1996 the Metro Atlanta Watershed Initiative was started to deal with citizen concerns and regulatory ambiguity; integrate and prioritize CSO controls to best use available money; and coordinate city agencies and stakeholders. As presented in Table 5-6, the watershed initiative faced many challenges.

The initiative started a comprehensive watershed study that was designed to determine the current conditions and uses of the urban streams, assess the type and magnitude of various impacts on these streams, and evaluate and recommend options for improving the water quality in the streams. However, the watershed study was dealt a major set back when a judge ruled that waters of the state begin at CSO discharges. Therefore, water quality standards need to be met in the small, intermittent streams that are solely produced by CSO discharges. As a result the watershed study was replaced by a mathematical model of the combined sewer system that simulates the impacts of the point-source CSOs.

Questionnaire Date: July 1998.

Current funding for the watershed initiative is $2.6 million. The City of Atlanta presently is the sole funding source, even though the watershed plan includes other communities and jurisdictions. The estimated cost for bringing the urban streams to good/fair standards for biotic indices, a goal created through the initiative, is approximately $1.4 billion.

5.2.2 Augusta, Me.

The combined sewer area of Augusta, Me., comprises approximately 620 acres with 40 diversion structures and 29 active CSOs that discharge either directly to or into tributaries of the Kennebec River, which serves as an excellent fishery as well as a heavily used recreation area. Eleven alternatives were evaluated as part of the CSO facility plan. Evaluated storm frequencies were based upon the system capacity curves shown in Figure 5-1. Due to the large size of the Kennebec River, the primary water quality concern was bacteria.

Figure 5-2 illustrates maximum *E. Coli* concentrations in the Kennebec River at a minimal flow of 1,000 cubic feet per second (cfs) for different recurrence interval storms. As shown, the 1-year recurrence interval represents the knee of the curve. Consequently, a series of abatement alternatives were evaluated for the 1-year storm. Present-worth costs for several prime alternatives are illustrated in Figure 5-3. The least costly alternative included the construction of two satellite vortex facilities; however the second least costly alternative, which included a single vortex facility at the WWTP, was selected due to nonmonetary factors such as facility siting, the desire to avoid satellite facilities, and flexibility for future expansion or upgrades.

The selected alternative involves retrofitting the existing WWTP to include a CSO-related bypass to treat 44% of Augusta's current annual CSO volume. Other improvements involve constructing consolidation conduits, two CSO pumping stations, and a vortex treatment facility at the site of the WWTP. This solution has been approved by U.S. EPA and the State of Maine Department of Environmental Protection.

The retrofits to the existing WWTP include new headworks that contain mechanical screens and an aerated grit chamber; new distribution structures; and new high-rate disinfection technology. Currently, when peak flow at the WWTP approaches 9 million gallons per day (MGD), excess flow is bypassed to the chlorine contact tank after physical degritting. The retrofit improvements will allow the full 29 MGD of connected interceptor capacity to receive preliminary treatment. Daily maximum flows of 12 MGD will receive secondary treatment, and 17 MGD will receive primary treatment followed by high-rate disinfection.

Later phases of the CSO abatement program will include a consolidation conduit to intercept CSO discharges throughout the system and convey the flow to the WWTP; three new vortex separators at the WWTP; and additional high-rate disinfection volume at the WWTP. After all phases are completed, the total influent peak flow capacity to the WWTP will be increased from 29 MGD to 107 MGD. Up to 78 MGD will be treated in the vortex separators. The phases of the CSO abatement program are scheduled to be completed by 2009.

CSO Community Characteristics

◆ Population	95,000
◆ CSO Area	7,000 Ac
◆ Annual Rainfall	40"
◆ # of Discharge Points	4

Distinctive CSO Community Attributes

- CSO abatement program cmpleted in 1992
- Operation of full-scale CSO treatment facilities including one EPA swirl concentrator and six Fluidsep units

Decatur, Ill. is located in the center of Illinois along the Sangamon River. A dam on the river forms Lake Decatur, which serves as a recreational resource and public water supply. The area has a population of approximately 95,000 and has a heavily industrial economic base. The combined sewer area is surrounded on three sides by newer sanitary sewers and on the fourth side by Lake Decatur.

Prior to 1992, the CSO outfalls discharged directly downstream of the Lake Decatur dam. During the summer, brief rains caused the combined sewers to overflow; however, the rains did not produce enough runoff to cause the lake to spill over the dam. Therefore, the sewer overflows resulted in stagnant pools and subsequent fish kills.

The city and sanitary district began facilities planning in 1976. At that time the WWTP was frequently overloaded, standards violations were common, and there was no CSO treatment. Between 1976 and 1980 planning concentrated on the main WWTP. Beginning in 1980 CSO control and treatment became a topic of interest when the Illinois Environmental Protection Agency (EPA) documented that the CSOs were polluting the river and control was required.

In 1982 the Sanitary District of Decatur signed a federal consent decree which ordered the upgrading of the main WWTP, implementation of an industrial pretreatment program, and compliance with Illinois rules and regulations pertaining to CSOs. The consent decree set time limits for completing work in each area. The CSO control measures were to be completed by 1986, later extended to 1992. The extension helped the cash flow of both the Illinois EPA Grants Section and local government. The schedule also allowed for a step-by-step approach to the CSO improvements

The consent decree helped both parties. The sanitary district gained assurance of grant funding for the necessary work, avoided enforcement actions until the completion date, and obtained authority to issue bonds for local funding. The Illinois EPA benefited by having a federal court order to ensure compliance by a specific date and gained the cooperation of the Sanitary District.

The overall CSO control plan included four satellite treatment facilities: the McKinley Ave., Oakland Ave., Seventh Ward, and Lincoln Park CSO Treatment Facilities. The McKinley Ave. Facility was completed in 1986 and includes a 500,000-gallon first flush storage tank and a 40 MGD U.S. EPA vortex unit. The storage tank collects the first 500,000 gallons of CSO, which is later pumped to the WWTP. CSO beyond the first 500,000 gallons is diverted to the vortex unit. The Lincoln Park CSO facility was completed in 1992 and was the final and largest treatment facility. The Lincoln Park and McKinley Ave. facilities are similar in concept; however, Lincoln Park utilizes a 1.33 million-gallon storage tank and four Fluidsep vortex units capable of treating 416 MGD (see Figure 5-4). The total CSO control plan improvements cost $34.4 million, $20.5 million coming from state and federal grants and the balance coming from the local community.

5.2.4 San Francisco, Calif.

CSO Community Characteristics

♦ Population	727,000
♦ CSO Area	25,000 Ac
♦ Annual Rainfall	21"
♦ # of Discharge Points	36

Distinctive CSO Community Attributes

- CSO abatement program cmpleted in 1997
- Diverse funding source
- Conversion of WWTP into wet weather pollution treatment facility

San Francisco is a city of 727,000 people located on a peninsula surrounded by the San Francisco Bay and the Pacific Ocean. Almost 100% of the city's 25,000 acres are served by a combined sewer system. Each of the 36 CSOs discharge into the San Francisco Bay or the Pacific Ocean. The city is highly urbanized, with a large central business district. Very little space is available for the construction of treatment facilities or large storage and conveyance systems needed to handle CSO.

R0018277

March, 1997 marked the completion of the major components of the city's wastewater facility improvement program. This construction program cost more than $1.4 billion dollars over a 20-year period. The earliest projects were funded by federal (68%), state (12%) and sewer service (20%) monies. Subsequent projects used state revolving funds and sewer service charges. One project used U.S. EPA marine CSO funds.

At the time of the 1972 Federal Clean Water Act Amendments, the City of San Francisco was planning improvements to its wastewater facilities. The State of California directed the city to undertake measures to reduce impacts from WWTPs and CSOs in the early 1960s. The city's first study of water quality impacts from CSOs was completed in 1967.

Motivated by federal and state policy and the need to improve its wastewater facilities, the city committed to upgrade secondary WWTPs and eliminate SW discharges along the shoreline within reasonable costs, times, and with minimal public disruption. To meet this challenge, the city developed a "Wastewater Master Plan" (1971) and an "Environmental Impact Statement and Report" (1974). The original plan was based on cost-benefit considerations; the resulting requirements closely matched those of the federal presumption approach.

San Francisco used a combination of in-line storage, off-line storage, and wet weather treatment. Wet weather treatment included primary treatment at the city's two WWTPs and conversion of a third WWTP to a wet weather facility. In addition the CSO storage boxes were designed to capture large settleable and floatable solids (see Figure 5-5).

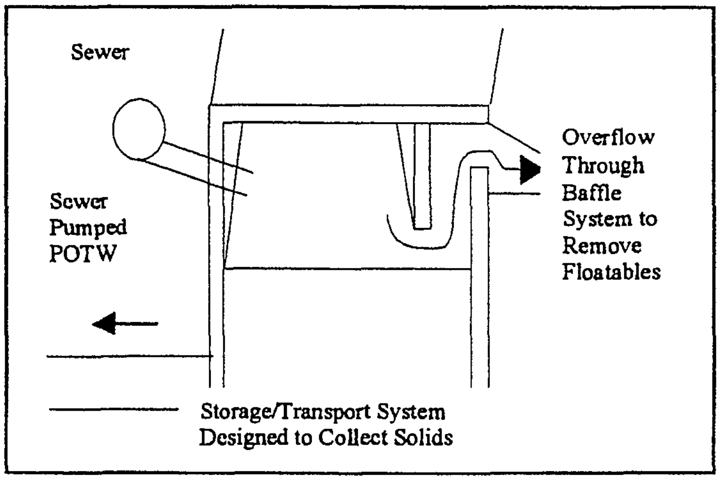

Figure 5-5. Typical Storage Boxes for San Francisco

San Francisco appears to be meeting the CSO frequency requirements (see Table 5-7). The number of days with elevated coliform levels dropped between 78% and 98%. An evaluation of a large CSO storage basin found a 33% reduction in total suspended solids and BOD through the storage and decanting of captured flows.

Table 5-7. San Francisco CSO Frequency Requirements

Waterbody	Frequency
Estuarine Shellfish Area	1/year
North Shore Area	4/year

5.2.5 Syracuse, N.Y.

CSO Community Characteristics

- Population 475,000
- CSO Area 67,000 Ac
- Annual Rainfall 37"
- # of Discharge Points 66

Distinctive CSO Community Attributes

- Cost-benefit Analysis
- Staged construction that meets the presumption and demonstration approaches

The Syracuse is located in Onondaga County, N.Y. and has a population of 475,000. Approximately 40% of the city of Syracuse's 16,600 acres are served by a combined sewer system. Each of the 66 combined sewer overflows discharge into one of three receiving streams that are tributary to Onondaga Lake. Onondaga Lake has become a matter of national interest as one of the most polluted lakes in the country. This urban lake and its drainage area lie wholly within Onondaga County and serve as a good opportunity to assess CSO impacts within the context of an entire watershed.

After a period of more than 25 years of evaluating the CSO problem involving demonstrating various abatement technologies, characterizing the sewer system and receiving waters, implementing a BMP program and performing extensive cost-benefit analyses, a comprehensive CSO abatement program for the city of Syracuse, estimated at over $140 million, is underway. The final phase of this process began in 1988, when the county entered into a consent order, and was completed in 1996 upon its signing.

Between 1982 and 1984, the county instituted a successful BMP program. The results showed more than an 85% reduction in annual pollutants to the receiving waters. The major elements of the BMP program were: sewer cleaning, overflow-structure modifications, and sewer replacement to assure maximum system storage and conveyance to the Syracuse Metropolitan WWTP. Table 5-8 illustrates the improvements as a result of this $10 million BMP program.

Table 5-8. Pre & Post-BMP CSO Discharge Statistics, Syracuse, N.Y.

CSO Discharge Characterization	Pre-BMP	Post-BMP
Number of Events/Year	165	56
Annual CSO Volume (million gallons)	11,000	1,654
1-year Storm Volume (million gallons)	72	59
90 Percentile Storm Volume (million gallons)	54	40

Water quality concerns were investigated during the middle 1970s and verified in the early 1990s. These investigations utilized sewer modeling and flow monitoring combined with water quality sampling and analyses to estimate CSO loadings to receiving waters. Floatables and bacteria were the parameters of most concern. A bacteria model was also used to estimate the number of violations, defined as exceeding 200 fecal coliform per 100 ml, within the Onondaga Lake.

A limited watershed effort became necessary to put the CSO component of solids and nutrients in proper perspective. Agriculture comprises the major land actively outside of the city of Syracuse and the urban areas. Using a watershed model, solids and nutrient loadings were calculated for an average rainfall year (1991). Table 5-9 illustrates the loadings relative to the WWTP. The net result was that phosphorus, nitrogen, and solids were found to be of less significance than was thought before the watershed estimates were made.

Table 5-9. Pollutant Loading Summary to Onondaga Lake, Syracuse, N.Y.

Pollutant Source	Total Phosphorous (lbs)	Total Phosphorous % of Total	Total Nitrogen (lbs)	Total Nitrogen % of Total	Total Suspended Solids (lbs)	Total Suspended Solids % of Total
WWTP	134,320	31	5,752,620	80	1,167	7
CSO	16,800	4	25,432	2	3,739	22
Nonpoint	275,349	65	1,313,434	18	12,107	71
Total	426,469		7,201,486		17,013	

Several abatement alternatives were evaluated based on costs and benefits. The county chose regional treatment with vortex units and high-rate disinfection because it was the least costly alternative that met water quality standards. In addition, the plan includes netting devices for capturing floatables and restoration of an existing 5 MG storage facility.

High cost/benefit projects and projects designed to demonstrate effectiveness were scheduled in the initial phase. The scheduling of the projects became decisive in that the proposed regional facilities would ultimately meet both the presumption and demonstration clauses of the federal CSO policy. The next step in the process was to phase the construction of the facilities over a 15-year, build-out period to provide both a reasonable compliance schedule and an affordable cash flow. Figure 5-6 illustrates the compliance schedule.

5.3 CSO Case Histories and Benchmark Data Discussion

5.3.1 General CSO Discussion

CSOs generally were recognized as a significant source of pollution in the late 1960s and specifically identified at the federal level through the landmark 1972 Amendments to the Federal Water Pollution Control Act. Much of the CSO work was started through federal R & D programs initiated in the early 1970s.

The activity directed toward CSOs has been greater than SSOs and SW owing to the earlier awareness and recognition of this type of pollution and, perhaps more importantly, the urgency associated with the health risks stemming from the sewage component. The intensity of regulatory and municipal activities sharply increased in 1989 when U.S. EPA published the draft National CSO Control Strategy. Until then, in the absence of clear guidelines, most municipalities were unwilling to forge ahead. Upon the release of the National CSO Control Policy in

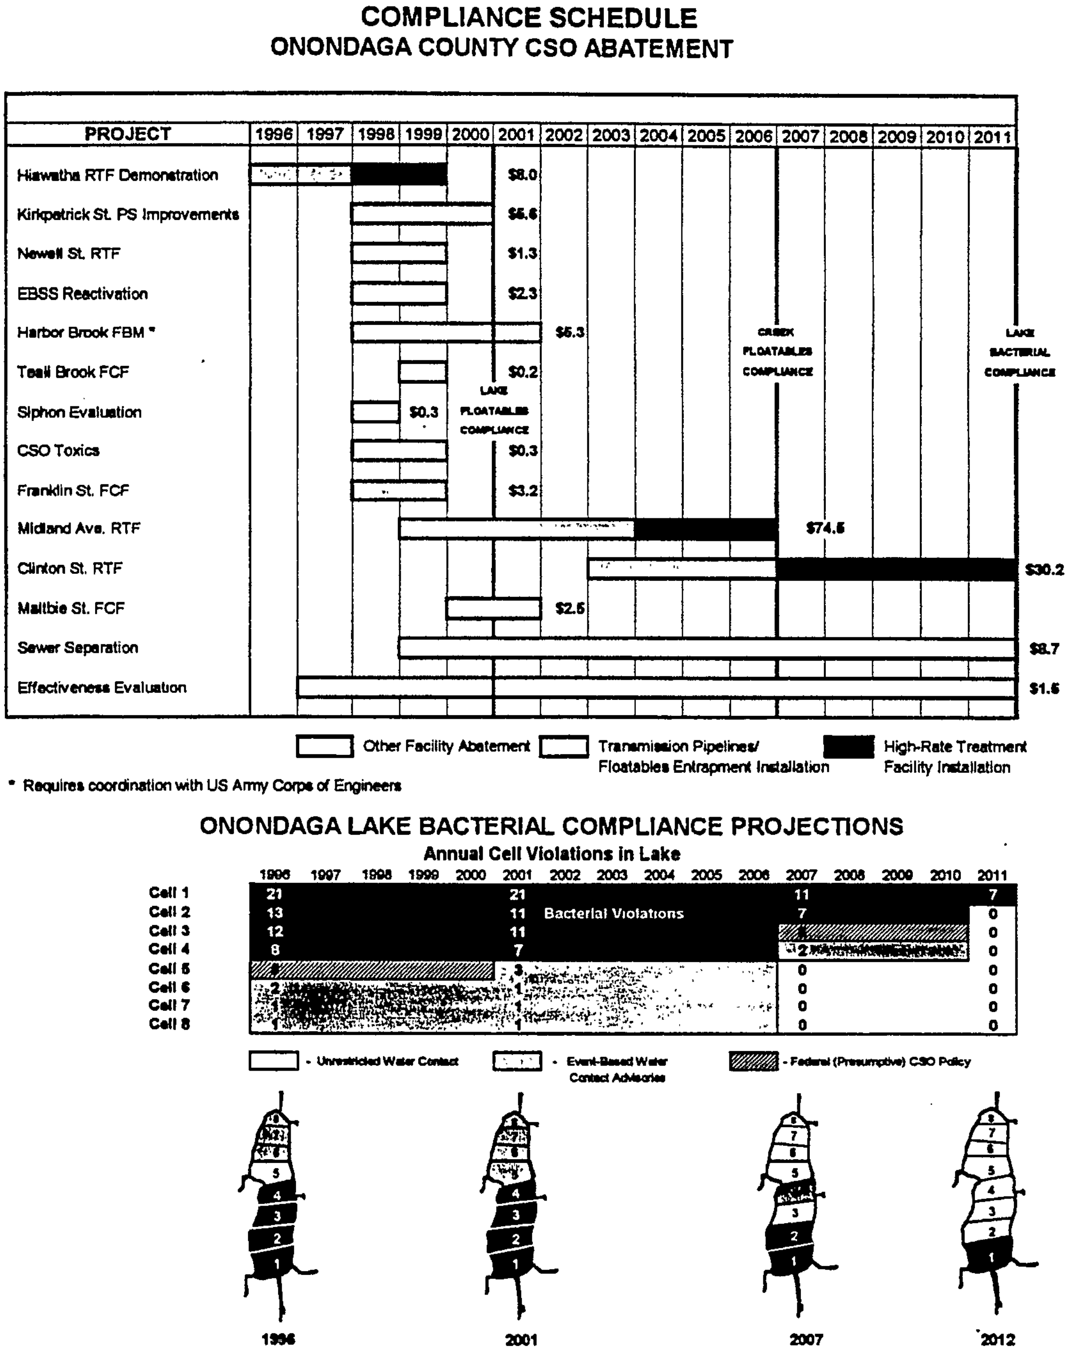

Figure 5-6. CSO Abatement Compliance Schedule, Onondaga County, N.Y.

1994, many CSO facility plans were revisited to determine compliance with either the presumption or demonstration provisions and to develop the required LTCP.

The most prevalent form of implementation has been BMPs due to the "housekeeping" nature of such steps and the low cost to benefit relationship. Reductions of annual CSO volume from BMP steps were reported as high as 90%.

Abatement beyond BMPs was implemented by only a limited number of communities prior to the national policy. In some cases, communities with high enough state priorities were able to take advantage of federally available grant funds. However, for the most part, abatement has taken place after 1989 and has not included federal grants. State revolving funds have become available in place of the previous U.S. EPA construction grants program.

As a consequence of little or no federal or state funding currently available for design and construction, financial considerations have become that much more important, resulting in a greater emphasis on cost/benefit evaluations and reviewing the affordability guidelines within the policy.

Most communities acted to abate their CSOs due to regulatory requirements which can take the form of permit renewals, administrative orders, or consent orders. Generally communities acted upon requirements more or less in that order.

There is a noticeable lack of consistency from case to case in setting permit parameters, which is understandable in consideration of their site-specific nature and related health risks. States should await site-specific information before setting permit limits.

5.3.2 CSO Questionnaire Findings

5.3.2.1 CSO Community Statistics

The communities included in these benchmark matrices represent a range of geographic locations, demographics, abatement strategies and schedules. The differences found between these communities stress the site-specific nature of CSO control and abatement.

Combined sewer systems serve roughly 950 communities with about 40 million people. Most communities with CSOs are located in the Northeast and Great Lakes regions, particularly in New England, Ohio, Illinois, Michigan, and New York. Although large cities like New York, Philadelphia, and Atlanta, have combined sewer systems, most communities with CSO problems have fewer than 10,000 people (EPA, 1998). Most sewer systems have evolved with the community, and therefore no two systems are identical. For example, some communities such as San Francisco are served entirely by combined sewer, while others, such as Atlanta, have a relatively old combined sewer system surrounded by a newer separated system. The wastewater/CSO characteristic for each community is different and is largely related to the economic base of the community. Some communities such as Detroit have an industrial economic base, while others like Auburn are residential and commercial in nature. The locations of CSO communities across the county are illustrated in Figure 5-7.

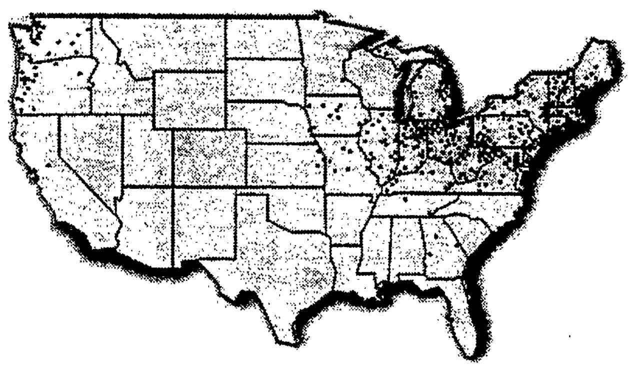

Figure 5-7. CSO Communities in the US. (EPA, 1998)

5.3.2.2 CSO Public Participation

Based on questionnaire responses, active public participation programs tend to be integrated with a watershed approach. For example, communities such as Atlanta and Detroit (Rouge River) have active public participation and watershed programs. Other communities that have public participation programs are: Astoria, Augusta, Chicago, Cincinnati, Cleveland, Hartford, Louisville, San Francisco and Winnipeg.

Public participation approaches for CSO abatement programs throughout the country appear to follow similar trends. The information provided by each municipality suggests that the public participation philosophy was established at or before the initiation of the formal CSO abatement program. At the beginning of the abatement process, a municipality either decided to actively include the public in the decision-making process or to include the public only as mandated by law. It is likely that the municipalities that identified themselves as "reactive" were including the public as required by law but increased public involvement as public demand grew. The most popular forms of public participation are newsletters, public hearings/meetings, and newspaper articles. The majority of the public was concerned about the effectiveness of the abatement strategy to meet water quality and associated aesthetics and recreational expectations. Construction impacts during implementation of abatement infrastructure were also a notable public concern.

From the viewpoint of the municipal agency, public participation programs can provide assistance but can also create obstacles. The clear advantage of engaging the public is recognizing and addressing public concerns early in the process, thus making the public a stakeholder. This process is best for the community in the long term; however, as in Atlanta, it may create ancillary work in the short term. Atlanta also noted that open public participation is difficult when litigation is brought by public stakeholders.

5.3.2.3 CSO Systems Characterization

Nearly all communities used a mathematical model to describe their sewer system. The U.S. EPA Storm Water Management Model tended to be the most preferred model. Communities have found that replicating the sewer system with a model can answer questions that would be impractical to answer through field measurements and observation.

Currently, however, most communities are focusing on abating only municipal and industrial point sources and not embodying the entire watershed and other pollution sources. Such action is driven by federal CSO policy and lack of policy for other types of pollution (e.g., agricultural runoff). The municipal and industrial point sources of pollution tend to be more easily controlled and managed at the source, whether it is at the end of a pipe in the case of a CSO, or a pretreatment program at an industrial site.

Many CSO communities are looking to the future and realizing the need to address nonpoint sources such as urban and agricultural runoff. As a result, these communities have used a watershed approach to prioritize pollutant sources and plan for the future but have not begun to use the watershed approach to abate pollution.

Some communities have initiated a watershed approach, including Atlanta, Chicago, Cleveland, Detroit and Syracuse. The watershed approach in Detroit has come to national attention. Wayne County is spearheading the watershed approach via the Rouge River National Wet weather Demonstration Project (Rouge Project) with funding from U.S. EPA and local communities. The Rouge Project oversees the 17 combined sewer overflow abatement projects (11 retention treatment basins and 6 sewer separation projects). These control technologies are currently being evaluated to help quantify their effect on the quality of the river and thereby suggest the most appropriate CSO method. The following are some findings from the Rouge Project (Rouge River National Wet Weather Demonstration Project, March 1998):

- *E. coli* concentrations discharged from the CSO treatment basins are small compared to the instream *E. coli* concentrations. Instream *E. coli* concentrations during wet weather are frequently above body contact standards due to non-CSO pollution sources.
- Dissolved oxygen sags are attributed to CSO treatment basin effluent and other non-CSO pollution sources
- Dissolved oxygen impairment during dry weather is attributed to a combination of high sediment oxygen demand and low re-aeration due to naturally flat river slope.
- CSO treatment basin effluent contributes 15% of instream BOD at points of discharge.

Because CSO control will not eliminate all pollution to the river, the Rouge Project is assessing and implementing nonpoint source controls as well and pollution prevention programs for watershed residents and businesses. Findings from this study will be shared with other urban watersheds.

Syracuse exemplifies a community that assessed pollution sources from throughout the watershed before developing abatement alternatives for CSOs. This evaluation included the use of a watershed model, sewer system model, and geographic information system to calculate solids and nutrient loadings. The major finding suggested that phosphorous loading from CSOs was less significant than loadings from the WWTP and agricultural runoff. Identifying that significant phosphorous loadings came from sources other than CSOs allowed the municipality to proceed with physical treatment and disinfection rather than storage for CSOs, representing a huge savings to the city.

5.3.2.4 *Issues Driving CSO Technical Considerations*

Most CSO communities have completed or are in the process of completing a long term control plan. However, some variability exists in the initiation of the plan. As documented in the 1994 federal CSO policy, the LCTP is to be submitted within two years of an enforcement action, which can take the form of a state permit (generally the most preferred) or a specific administrative or consent order. Many large communities, such as Boston and New York City, were targeted as high priorities by regulatory agencies. As such, enforcement actions were served even before the federal CSO policy was finalized. On the other hand, medium-sized communities, such as Gardiner, Me., were a lower priority to regulatory agencies and therefore were not served an enforcement action as early. In this same manner, small CSO communities may not have to complete a LCTP in the near future because of their low priority status. The CSO policy states, at the discretion of the NPDES authority, that communities with populations less then 75,000 may need to comply with only the nine minimum controls. Yet, still other communities, such as Rochester, N.Y., moved ahead with a LCTP before the CSO policy was developed. The motivation for such a progressive stance was the availability of federal and state grant money.

Most communities acted to abate their CSOs due to regulatory requirements. These regulations may be enforced by either the state government (delegated state) or by the U.S. EPA. Communities who have not completed a LTCP are generally required to complete the plan. Communities who have an approved LTCP are required to follow either the presumption or demonstration approach. If a community follows the demonstration approach, the critical permit requirements generally relate to an effluent standard. If a community follows the presumption approach, the critical permit requirements tend to specify some level of capture/treatment. Regardless of the approach bacteria and floatables tend to be the pollutants of most concern.

Some communities were motivated to abate their CSOs because of litigation. In the case Decatur, the litigation and resulting consent decree helped both parties. The Sanitary District gained assurance of grant funding for the necessary work, avoided enforcement actions until the completion date, and obtained authority to issue bonds for local funding. The Illinois EPA benefited by having a federal court order to ensure compliance by a specific date and gained the cooperation of the Sanitary District.

Almost the same number of communities followed the presumption approach as followed the demonstration approach; however, the majority of smaller communities followed the Presumption approach. The major advantage of the presumption approach is that it allows smaller communities that cannot afford extensive water quality monitoring and impact studies to proceed with abatement planning. Some larger communities proceed with presumption approach because it provides an opportunity to avoid any stalemate until a consensus is reached over water quality impacts. And yet some communities, with diverse combined sewer systems, used both approaches where appropriate.

The major receiving water criteria were floatables and bacteria. Solids and BOD follow, with nutrients and dissolved oxygen being the parameters of least concern. These criteria originate from public interest; however, they are enforced through the CSO policy and ultimately the Clean Water Act. It is clear that the public desires aesthetically pleasing waters (i.e., no floatables) that are safe for recreation (i.e., no harmful bacteria). These criteria are addressed in the CSO policy as part of the presumption and demonstration approaches. The presumption approach requires a community to meet any one of three predefined conditions, thereby presuming that water quality requirements are being met. The demonstration approach requires that water quality standards and designated uses be met on a case-by-case basis consistent with a LTCP, unless uses cannot be met as a result of other pollution sources (e.g., natural background conditions). Regardless of the approach, the obligation is to meet the requirements of the Clean Water Act, the protection of designated uses.

Generally the technology chosen by a community should and did reflect the site-specific nature/characteristics of CSOs within that community. The majority of the communities are planning to implement many different abatement technologies to most effectively meet water quality criteria. BMPs as prescribed by the nine minimal controls are currently the most popular form of CSO control. Implementation of BMPs has made a positive impact on water quality. For example, in Syracuse, BMP improvements such as sewer cleaning and raising weirs were implemented in the early 1980s to optimize flows to the WWTP. Comparisons of pre-BMP to post-BMP rainfall versus CSO overflow volume relationships showed a reduction in annual overflow pollutants of 85% to 90%. Many communities are in the process of planning for the implementation of structurally intensive solutions. In-system and offline storage, screening, disinfection, and vortex solid separators are the most popular control approaches among the communities responding.

R0018284

5.3.2.5 CSO Financial Considerations

In the last 25 years, the federal government has spent more than $60 billion through grants and low-interest loans for the construction of WWTPs and sewer lines. States and municipalities have spent additional billions in matching funds for these improvements. A large percentage of the federally available funds was spent throughout the '70s and early '80s making improvements to WWTPs.

Some CSO communities took advantage of the federally available funds to abate CSOs while making improvements to WWTPs. In some respects this approach was uncertain because the federal CSO policy was in its infancy and no clear CSO related standards were available as guidance. A good example of this type of community is Rochester, N.Y., which moved to abate CSOs by separating the sewer system during WWTP improvements. The federal government funded almost the entire CSO abatement project. A small portion of Rochester's CSO abatement was completed without federal funds. The remaining CSO abatement included in-line and off-line storage, a more cost-effective approach reflecting the local funding source.

San Francisco started its CSO abatement program while federal funds were available and before the federal CSO policy was promulgated. However, San Francisco, being much larger than Rochester, could not implement a CSO abatement program as quickly. San Francisco started its program in 1978 and completed the major parts by 1997. As a result, San Francisco accepted funding from the entire range of available sources. The earliest projects were funded from approximately 68% federal, 12% state and 20% local sources. Subsequent projects used state revolving funds and local funds. One project used a special U.S. EPA marine CSO fund.

Many smaller communities such as Astoria and Augusta did not start their CSO abatement programs until the '90s. Their size and low priority, as discussed in the Issues Driving CSO Technical Considerations section, can explain this timing. Nonetheless, communities that began their CSO abatement programs in the '90s with the dawn of the federal CSO policy were too late to take advantage of federal grant money. These communities tended to rely on state revolving loans and local funding. As a result the local authorities required more information on the returns of these major investments to improve water quality before being willing to proceed. Also, these local authorities were more apt to challenge the legality of water quality standards. Owing to the greater sensitivity to costs, communities became more interested in satellite treatment as opposed to centralized treatment.

Selected abatement controls tend to reflect the source of funding. This may be illustrated by comparing the cost of sewer separation to satellite treatment such as vortex facilities. Sewer separation costs, including the cost for new SW treatment, for 6,813 acres in the City of Syracuse were estimated to be $612 million. Satellite treatment costs, including vortex units, netting devices and disinfection for the same area were estimated to be $144 million (Moffa & Associates, 1996). Obviously the cash flow for these approaches is very different. Sewer separation projects tend to be large up-front capital expenditures with smaller future operation and maintenance (O&M) costs, while satellite treatment tends to have smaller up-front capital expenditures with larger future O&M costs. Separate sewers also produce SW issues that need to be addressed.

CHAPTER 6.0

SSO BENCHMARK DATA AND CASE HISTORIES

6.1 Benchmark Data for SSO Communities

The following section includes a benchmark matrix for general SSO community statistics (Table 6-1), SSO public participation (Table 6-2), SSO systems characterization (Table 6-3), issues driving SSO technical considerations (Table 6-4), and SSO financial considerations (Table 6-5).

6.2 Case Histories for SSO Communities

6.2.1 Bloomington, Ind.

SSO Community Characteristics

♦ Population	110,000
♦ Sewer Area	77,000 Ac
♦ Annual Rainfall	60"
♦ # of SSO Discharge Points	15

Distinctive SSO Community Attributes

- Formation of utulity specifically for wet weather flows
- Retrofitting decommissioned WWTP as for off-line storage of wet weather flows

Bloomington's 250 miles of sanitary sewer are separate from the storm sewer system. However, during wet weather, the "separate" sewer system overflows at a number of points in the collection system, backs up into basements, and violates the NPDES permit for WWTPs. Bloomington's wet weather problem has been ongoing since the formation of the utility in the early 1970s. A sanitary sewer evaluation survey performed in conjunction with U.S. EPA's construction grants program identified a number of pipe replacement projects. The most recent project increased the capacity of two large pump stations in the collection system where SSOs frequently occurred. Unfortunately, these pipe replacement projects have done little to reduce the impact of wet weather discharges. These impacts have, for the most part, merely been transferred downstream.

In 1996, Bloomington experienced significantly higher than normal rainfall and the resulting wet weather impacts for that year were excessive. Also, the South WWTP consistently exceeded its design flow, and preliminary planning efforts began to either expand or replace the existing plant. At this point, Bloomington recognized the need to better manage wet weather flows and establish a wet weather management program. The focus of the $26 million dollar program was to reduce infiltration/inflow (I/I). Sewer system rehabilitation and replacement, off-line storage, and WWTP expansion are some of the strategies being investigated to reduce wet weather impacts.

A wet weather focus group consisting of a cross section of interested citizens was formed in 1997 and assisted in the selection of an engineering consultant to manage the wet weather program. The focus group meets on a regular basis and advises the wet weather management team in pursuing wet weather reduction strategies.

Currently, Bloomington is evaluating a number of cost-effective strategies. The South WWTP will add capacity through a combination of physical and process improvements. The lagoons at the decommissioned WWTP near the center of the collection system will be converted for off-line storage of peak flows during wet weather. Rehabilitation and replacement of the sewer pipe and manholes will be more aggressive, particularly in three problem areas of the city where SSOs and basement flooding have been concentrated. A number of direct SW connections to the sanitary sewer system have already been identified and eliminated. Bloomington has also formed a local SW utility in an effort to comprehensively manage wet weather impacts. Formerly operated and maintained at a minimum level under the city's public works department, the new utility dedicates funds especially for the operation and maintenance of the SW system in addition to capital repair of the long neglected infrastructure.

6.2.2 Houston, Texas

SSO Community Characteristics

♦ Population	1,800,00
♦ Sewer Area	385,000 Ac
♦ Annual Rainfall	46"
♦ # of SSO Discharge Points	20

Distinctive SSO Community Attributes

- Selection of SSO controls based on flow and water quality monitoring
- Use of wet weather treatment facilities for SSO
- Stakeholder involvement created wide support

Located 40 miles inland of the Gulf of Mexico, Houston is the fourth largest metropolitan area in the United States. Houston experienced a period of rapid growth early in the 20th century after a shipping channel connected the city to Galveston Bay and the gulf, making it a deepwater port. Other than the channel, most of the surface waters in and around Houston are classified as bayous. However, as Houston's bayous approach Galveston Bay they become wider and more closely approximate shallow tidal wetlands. During periods of wet weather, the bayous fill rapidly and carry SW away from the city to Galveston Bay.

The city's wastewater system is one of the country's largest. Currently, the average daily wastewater treatment demand is 250 MGD. With a service area of 600 square miles, it incorporates 46 WWTPs, 377 lift stations, 5,700 miles of separate sanitary sewers, and 100,000 manholes. The city provides water and wastewater service to approximately 378,000 customers and a total population of nearly 1.8 million. Much of Houston's growth in the last 25 years occurred as the city annexed previously unincorporated county areas. This rapid growth exceeded WWTP capacity. By the late 1980s, moratoriums on new construction existed in 90% of the metropolitan area.

Houston received administrative orders from the Texas Natural Resources Conservation Commission (TNRCC) and EPA Region 6 in 1987 requiring the city to control SSOs and upgrade the collection system by December, 1997. The administrative orders resulted in an investment of $1.2 billion by the city of Houston in SSO control.

Houston invested $65 million between 1988 and 1991 to evaluate its collection system and conduct extensive flow monitoring. The physical analysis identified infiltration due to leaking joints, cracks, and breaks in the city's sewers and laterals on private property as the primary sources of the increased wet weather flows. In 1992, the Greater Houston Wastewater Program (GHWP) was formed as an integrated organization of city employees and consultant staff, developed specifically for complying with the mandates of state and federal regulatory agencies. In the absence of a national SSO policy, the GHWP, TNRCC, and EPA Region 6 had to consider two principal issues regarding control of wet weather SSOs. These were: (1) the level of design storm protection that the collection system would provide for customers; and (2) the level of treatment required for overflows in excess of the design storm flow, based on impact to receiving water quality.

In 1994, Houston completed a water quality study of local receiving waters (bayous) for the purpose of quantifying the surface water quality benefits associated with SSO control alternatives. Monitoring confirmed that the quality of wet weather discharges from the constructed overflows was roughly equivalent to wet weather bayou water quality, so the city concluded that selection of a design storm for development of the capital improvements program was an issue of customer service, not water quality.

The capital improvements program, completed in December 1997, consisted of approximately 400 projects made up of relief sewers, sewer rehabilitation, new or upgraded pump stations, WWTP expansions, and wet weather facilities at a cost of nearly $1.2 billion. All engineering was performed by more than 70 local design firms, and most construction contracts were awarded to local firms, using local labor, equipment, and materials. The capital improvements program provided a significant boost to the local economy.

The GHWP was one of the most ambitious collection system improvement efforts ever undertaken in the country. Now complete, this comprehensive response to regulatory mandates and customer needs encompassed more than 400 projects. Both EPA Region 6 and TNRCC officials have given the city high marks for its progress and meeting the December 1997 deadline.

In November, 1997 TNRCC lifted the final set of administrative orders against Houston. This marked the first time in 24 years that the city was not under any administrative orders. The GHWP not only improved the reliability of the collection system, but also fostered local economic growth. New development boomed following completion of the SSO abatement program. In 1997 Houston issued building permits for $2 billion of new construction. This would not have been possible without the city's capital investment in its wastewater infrastructure.

6.2.3 Johnson County, Kan.

SSO Community Characteristics

◆ Population	400,000
◆ Sewer Area	120,000 Ac
◆ Annual Rainfall	37"
◆ # of SSO Discharge Points	20

Distinctive SSO Community Attributes

- Successful private property I/I reduction program
- Use of wet weather treatment facilities for SSO

Johnson County is located in eastern Kansas, on the southwest edge of the Kansas City, Mo., metropolitan area. The county includes 22 separate city governments. Johnson County Wastewater (JCW) operates three WWTPs throughout the county, treating a combined average dry weather flow of slightly more than 38 MGD. JCW also operates six wet weather treatment facilities that provide primary treatment to excess wet weather flows. These facilities were developed in the 1960s. JCW cleans and maintains more than 1,500 miles of sewer line and 32,000 manholes.

In the early 1980s, the sanitary sewer system was experiencing both excessive groundwater infiltration and SW inflow. In the districts, the considerable amount of I/I caused the wet weather facilities to activate frequently. Moderate amounts of rainfall often resulted in surcharging manholes, bypassing of raw wastewater to receiving streams, and backups of sewage into basements. The bypasses and backups of raw wastewater were a potential health hazard and resulted in considerable financial loss each year. During heavy rainfall events, JCW would receive hundreds of telephone calls from residents concerning basement flooding and sewage backups. In 1983, the Board of County Commissioners of Johnson County recognized the need for an aggressive public and private property I/I reduction program.

JCW's effort to control SSOs has two primary components: (1) an aggressive I/I reduction program; and (2) the operation of satellite wet weather treatment facilities. Numerous complaints by residents of sewers backing up into homes motivated JCW in 1985 to begin the extensive I/I reduction program. The program included a comprehensive sanitary sewer evaluation study to inspect all structures, including more than 55,000 private connections to residential and commercial properties.

The initial efforts of the I/I reduction program included inspection of numerous commercial and residential properties and public sector projects (manhole inspections, sewer line smoke testing, and television inspections) to ascertain the structural condition of the collection system. The goal was to determine the total number of I/I sources in the districts. Public notices were placed in local newsletters and area newspapers, explaining that inspectors would visit each property to obtain information from residents and owners concerning past problems with the collection system. While on site, the inspectors also located rainwater downspouts, area drains, and sump pump connections. As the information was collected, it was entered into a database, which allowed JCW to identify direct and suspect connections that were contributing inflow to the collection system. The inspection program covered more than 55,000 homes and businesses, eventually identifying approximately 15,600 sources on private property. The five most common private-property sources of I/I were foundation drains, basement entry drains, sump pumps, cleanouts and downspouts, and driveway and other area drains. Additionally, the program inspected more than 17,000 manholes and found that nearly all had some defect that allowed for inflow.

Following source identification and hydraulic modeling, the I/I reduction program focused on the elimination of as many of the known sources as possible in a prompt, orderly, and cost-effective manner. It was determined that a phased implementation would result in the lowest possible construction and administrative costs. The phased approach was based on a combination of watershed location, unit inflow rate, and the local history of sewer backups. The phasing tended to concentrate survey and construction activities in the same geographic area, thereby producing measurable improvements early in the program.

The I/I reduction program work was completed in 1994. The public and private property I/I reduction programs together resulted in a net reduction of nearly 280 MGD during the 10-year, 1-hour storm. The removal of 15,632 private property sources is estimated to have eliminated more than 110 MGD of the 280 MGD. Out of the 55,000 buildings in the districts, only nine remain to either be inspected (refused entry) or to have a source disconnected, and these are being addressed through the appropriate legal channels.

The total cost for the overall I/I reduction program was approximately $60 million. The private property work cost nearly $10.3 million, the public sector work (I/I reduction and relief sewers) almost $30 million and the remainder consisted of engineering and administrative expenses. JCW received almost $12 million in grant funds and nearly $18 million in state revolving fund low interest loans. However, the private property I/I reduction program expenditures were not grant or loan eligible and were funded with obligation bonds.

JCW's SSO control plan also includes the use of six satellite wet weather treatment facilities to provide primary treatment and disinfection to excess flows during wet weather. Although these facilities are somewhat controversial in that they are discharging partially treated sewage, JCW believes that they are a viable component of its effort to reduce direct human exposure to raw sewage. JCW has performed water quality monitoring during wet weather events and determined that the facilities have a minimal impact on the small urban creeks into which they discharge. JCW has also looked at the cost of eliminating the wet weather facilities while maintaining the same level of storm protection, and found costs prohibitive.

JCW believes that the I/I reduction program has significantly reduced I/I. The I/I work has met or exceeded the expected reductions in wet weather flows throughout the system. The focus on private property I/I was a proactive approach to reducing peak flows. EPA Region 7 and Kansas state officials agree that the allocation of local public funds to address private property I/I sources is an effective approach to solving I/I problems.

Through what is believed to be the largest private property I/I reduction program in the country, JCW has eliminated all capacity-related uncontrolled SSOs during events up to the 10-year, 1-hour (2.5 inches) storm.

Mr. Chris Burns
Johnson County Wastewater
Johnson County, Kansas
(913) 681-3200 x2108

6.2.4 **Oklahoma City, Okla.**

SSO Community Characteristics	
♦ Population	470,000
♦ Sewer Area	400,000 Ac
♦ Annual Rainfall	40"
♦ # of SSO Discharge Points	20

Distinctive SSO Community Attributes

- ♦ Successful sewer rehabilitation and replacement program
- ♦ "Business" approach has markedly improved funding base and customer service

Oklahoma City is located in central Oklahoma, approximately 200 miles north of Dallas, Texas, spanning more than 620 square miles. Oklahoma City's central business district contains large numbers of commercial and single family residential properties, while the outskirts are primarily agricultural. Oklahoma City Water and Wastewater Department (OCW) provides water and wastewater services to more than 470,000 people spread across 320 square miles — nearly 96% of the city's total population. OCW maintains more than 2,400 miles of sewer line, including 63 lift stations and 4 WWTPs with a combined capacity of 101 MGD. The average dry weather flow to these plants is 75 MGD.

In the mid-1980s, SSOs in Oklahoma City sewers were a daily occurrence. The OCW, now part of the Oklahoma City Utility Trust, had a substantial backlog of complaints of sewer stoppages and overflows. Basement flooding occurred regularly in parts of the city. In 1986, OCW adopted an "enterprise system" under which all revenues derived from the water and wastewater utilities were put back into the system, instead of the city's general fund. With the inception of the enterprise system, OCW became committed to implementing efficient business practices and delivering quality water and sewer services. This effort, which continues today, included a dedication to sewer rehabilitation and repair which has virtually eliminated capacity constraints within the system and vastly improved customer service.

OCW does not have a specific SSO control plan. The progress it has made in controlling SSOs was not driven by water quality concerns. Rather, OCW established a goal of eliminating sewer back-ups in homes and has dedicated much of the work of the capital improvements program (CIP) to this end. At an annual cost of $6 million, or slightly less than $13 per capita, OCW replaces approximately 1%, or 120,000 linear feet of sewer line each year. The focus on sewer line replacement has been a continuous and sustained element of the CIP since 1986. The CIP has also included a number of improvements in the city's WWTP capabilities.

OCW tracks sewer system complaints and uses this information to gauge the success of the CIP investment in line replacement. Each complaint is entered into a database that helps identify persistent problem areas. By systematically replacing the weakest portions of the sewer system, OCW has dramatically improved wastewater service in Oklahoma City.

Fully 95% of OCW's maintenance activities are preventative, rather than reactive. Increased levels of routine maintenance have proved valuable in eliminating line blockages and in identifying the need for repairs before problems are elevated to emergencies.

The OCW management believes that there are three primary components to a well functioning utility: adequate financing, control over planning, and dedicated personnel. In Oklahoma City, the enterprise system has given OCW control over financing and planning for the water and wastewater utilities. The city's conversion to the enterprise system has resulted in excellent water and wastewater improvements. The revenues generated by the utility are controlled by the utility and put back into projects to improve utility services.

R0018294

The CIP focus on line replacement and I/I control has allowed Oklahoma City to decrease total flows to the WWTPs, while the population has grown, and virtually eliminate capacity related overflows within the system. Sewer rehabilitation programs have had numerous benefits, including: reduced frequency of emergency maintenance; lower incidence of damage to public and private property; extended infrastructure life; and decreased overflows and stoppages. All these contribute to the ultimate goal of improved customer service. Both the Oklahoma Department of Environmental Quality and EPA Region 6 officials believe that OCW has found an effective, proactive means of controlling SSOs and would like to see their efforts emulated by other jurisdictions.

Patrick Yonikas
(405) 297-3811

6.2.5 Wayne County (Downriver Communities), Mich.

SSO Community Characteristics	
♦ Population	320,000
♦ Sewer Area	100,000 Ac
♦ Annual Rainfall	34"
♦ # of SSO Discharge Points	20

Distinctive SSO Community Attributes

- Michigan state rigorous SSO abatement criteria
- Construction of a regional storage-transport system as SSO control

The Downriver Collection System (DCS) in Wayne County, Mich., serves more than 320,000 people in 13 communities. These communities are located southwest of Detroit and are known as the Downriver Communities.

Administered by the Michigan Department of Environmental Quality (MDEQ), Michigan has one of the most rigorous state-mandated abatement criteria for controlling SSOs. In deriving the criteria for controlling SSOs, MDEQ started by assuming wet sanitary sewers closely approximate storm sewers. Therefore, the design criteria is based loosely on standard storm sewer requirements. Storm sewers are normally designed to transport the 10-year, 1-hour storm in residential areas, and the 25-year, 1-hour storm in commercial areas. To be conservative, MDEQ initially considered using the 25-year, 1-hour storm event as a uniform standard for all areas. However, a storm of such short duration did not provide enough information about the volume required to contain a longer, equally intense storm. Hence, MDEQ adopted the 25-year, 24-hour design storm. With such rigorous design criteria, MDEQ expects very few overflow events. Most will be attributable to extreme conditions such as large back-to-back events; storms having intensities greater than the design storm; or theoretical system capacities reduced by high groundwater, snowmelt, or late winter rains on frozen ground. Therefore, each overflow event is reviewed on a case-by-case basis, with MDEQ giving careful consideration to extenuating circumstances before levying fines.

When MDEQ initiated legal action against the DCS in 1987, the collection system was experiencing 25 to 35 SSO events annually with an estimated total volume of 366 MG per year. Basement flooding due to sewer backups was also widespread within the DCS service area.

During the fall of 1990, as part of the Downriver Improvements Program, system-wide flow, rainfall, and groundwater information was collected. The flow monitoring revealed a number of system deficiencies and evidence that many of the tributary communities routinely exceeded their contractual peak flow, which in turn caused the hydraulic capacity of the system to be exceeded. Excess flows were determined to be attributable to high I/I in many communities, excessive pumping from the city of River Rouge, and a non-operational regulator in the city of Ecorse. It was also determined that the WWTP did not have sufficient capacity to handle the resultant flow if all communities were to simultaneously discharge at their contractual peaks.

Flow monitors in the thirteen communities were used to evaluate the relative contribution of each to the wet weather flow problem. The measured flows were also used in negotiations between the communities when determining an equitable distribution of the Downriver Improvement Program costs. In order to direct local rehabilitation efforts, most of the communities also undertook a concurrent flow-monitoring program to identify areas subject to the greatest wet weather inflows. In general, the older communities had higher levels of I/I, often two to three times those of newer areas. These high rates were mainly attributable to SW connections, footing drains, the relatively large older sewers, deteriorating pipes, and leaks in manholes.

The Downriver Communities entered into a consent agreement with MDEQ in 1994 after numerous violations of both the Federal Clean Water Act, the Mich. Water Resource Commission Act, and the terms and conditions of the county's NPDES permit. The objectives of the improvements program, mandated by the consent decree were:

- reducing discharges of untreated sanitary sewage,
- reducing basement flooding related to the DCS capacity or WWTP constraints, and
- reducing wet weather inflows into the collection system.

In order to meet these objectives, the collection system and the WWTP must have the capacity to transport and treat all flows (blend of primary and secondary treatment) up to the 25-year, 24-hour storm (roughly equivalent to 3 inches). The collection system must also have the capacity to transport all flows up to the 100-year, 24-hour storm (roughly equivalent to 4-5 inches) to the WWTP. The WWTP must provide secondary treatment for flow up to 125 MGD and a blend of primary and secondary for an additional 25 MGD. Flow that exceeds 150 MGD up to 225 MGD must receive preliminary treatment (screening, grit removal, and disinfection). Flows greater than those generated by the 100-year, 24-hour storm can be routed to "inactive" emergency bypass structures spread throughout the system.

The consent agreement put the DCS on a compliance schedule to reduce the occurrence and volume of SSOs. A number of alternatives, representing both "local" and "regional" approaches, were considered for meeting the requirements of the consent decree. These included: WWTP relief capacity for peak flows; off-line storage basins; on-line storage basins; and a regional storage-transport system including relief sewers and a large diameter tunnel. The regional storage-transport system was selected because it was the most cost effective on an annualized basis. This alternative was also particularly attractive because all flows would receive some treatment; all emergency discharges would, for the most part, go to the Detroit River (rather than smaller tributary streams); a minimum amount of site acquisition was required; and because of the lower O&M requirements associated with the operation of a regional facility compared to a series of satellite storage basins. In addition to the regional storage-transport system, the mandated SSO abatement plan includes the expansion of the WWTP, implementation of localized sewer rehabilitation programs, and construction of an off-line basin facility and an emergency discharge outfall.

Implementation of various aspects of the mandated improvements began in 1994. The rehabilitation of county interceptors and community sewers was completed in the fall of 1995, with significant state revolving fund loan assistance. Subsequently, system flows have been monitored to track the effectiveness of improvements and to provide data for sizing the regional storage-transport system. Work on the WWTP upgrades began in 1994, including the construction of dechlorination facilities, the installation of a new solids handling facility, and construction of a new maintenance facility. The WWTP is currently being expanded to provide reliable primary/secondary treatment for flows up to 150 MGD and preliminary treatment for emergency flows up to 225 MGD. The WWTP improvements also include expansion of the disinfection and outfall facilities, which will bring the capacity of these facilities in line with the increased capacity of the rest of the plant. The final component of the mandated improvements is the construction of community relief sewers and a large diameter tunnel. Construction of the upper portion of the tunnel and a county relief sewer began late in 1996. Local relief sewer projects commenced in 1997. Construction of the main portion of the tunnel began in 1998 and should be completed in 2001.

In general, water quality is a primary concern for local governments, and Wayne County officials do not believe that the SSOs within the DCS service area represented a $270 million water quality problem. Wayne County's Director of Public Works, James Murray, stated that: "SSO water quality objectives need to be integrated with CSO and SW quality objectives. Substantial costs are being incurred by the DCS to eliminate SSO discharges, while at the same time current SW and CSO programs provide for discharges into the same watercourse with effluent quality far less stringent."

Wayne County officials advocate a watershed-based approach, which would integrate the control of all sources of wet weather pollutants and yield a more cost effective solution with maximum water quality benefits. They also indicated that:

- it is not practical to assume that SSO events will never occur;
- it would be more appropriate to clearly define emergency conditions, identifying specific circumstances when a system bypass would be acceptable; and
- emergency conditions should not necessarily be based on a design storm, but rather on the frequency of occurrence of overflow events.

6.3 SSO Case Histories and Benchmark Data Discussion

6.3.1 General SSO Discussion

Although surveys and studies have collected information on sanitary sewer collection systems and SSOs, information on the status of the collection systems and extent of SSO problems remain limited. However, these surveys and studies have identified SSOs as a common characteristic of most sanitary sewer collection systems.

Because many municipalities have not quantified their SSOs, very few have moved to correct or abate this pollution source. The lack of a national SSO policy, and the rarely enforced NPDES requirements also make SSO abatement a low priority for most municipalities.

SSOs during dry weather conditions are less common today then they were in the past due to efforts to increase WWTP and collection system capacities. However, SSOs during wet weather conditions continue to be a common occurrence around the nation. Although many communities have not moved forward in abating wet weather SSO related concerns, some generalizations can be made about the condition of sanitary sewer collection systems and SSOs, and permitting inconsistencies around the nation.

There are many potential strategies that municipalities may adopt to abate SSOs. Most involve some combination of upgrading the WWTP, removing sources of I/I, and increasing the storage capacity of the collection systems. Some strategies involve technology used for CSO control, such as off-line storage and satellite treatment facilities. However, currently this approach is atypical. Reasons for abating SSOs come from customer complaints regarding sewer backups as much as from water quality concerns.

6.3.1.1 Sanitary Sewer Failures and Resulting Overflows

The Urban Institute (1984) estimated that as an annual average there are 825 sewer backups and 140 sewer breaks every year for every 1,000 miles of sewer. A system of 1,000 miles of sewer serves about 250,000 people. The Urban Institute also proposed that sewer backup rates were highest in the northeast and economically distressed cities and were generally higher in communities with the oldest sewer systems. High sewer break rates in the south and west are particularly associated with large, growing cities. The Urban Institute survey attributed backups to a variety of factors: the location of pipe in trouble-prone areas, the pipe material, the size of pipes, the material, construction methods, local soils, and maintenance practices.

In 1994, the Civil Engineering Research Foundation found that three quarters of the sanitary sewer systems function at 50% of capacity or less. Root penetration, corrosion, soil movement, and inadequate construction are the cause of most structural failures.

As a result of reduced sewer capacity and failures, SSOs during wet and dry weather are a reality. The Association of State and Interstate Water pollution Control Administrators (ASIWPCA) found that 31% of municipal systems have at least an occasional dry weather SSO. The estimated annual number of dry weather SSOs was 1,962 for the 25 states providing information. The ASIWPA study also found that 29% of the municipal sanitary sewer systems experience wet weather SSOs and 25% of the WWTPs experience some problems during wet weather.

In a Water Pollution Control Federation study (1989), 1,003 WWTPs identified facility performance problems. I/I was the most frequently cited problem.

6.3.1.2 NPDES Inconsistencies

Different NPDES authorities have historically provided different emphasis on oversight of sanitary sewer collection systems. In addition, some of the NPDES regulatory provisions addressing sanitary sewer collection systems are unclear, and different NPDES authorities have provided different interpretations regarding SSOs. For example, the ASIWPCA study (1996) found that only two states issue permits to municipalities that discharge from their sanitary sewer system to another municipal sewer collection system, five states issue permits for some of these types of system, and 26 states do not issue permits for these systems. The ASIWPCA study also found that 13 states authorize wet weather control facilities that provide some level of treatment or flow control. EPA Region 6 and states in at least four other EPA regions (2, 3, 5 and 9) have issued permits for controlled discharges from wet weather facilities. Other states and EPA regions have not currently decided whether or not to allow wet weather facilities.

6.3.2 SSO Questionnaire Findings

6.3.2.1 SSO Community Statistics

The SSO benchmark questionnaires returned cover a wide range of conditions and receiving waters. Most SSOs discharge into rivers, but lakes, the ocean, estuaries, and streams are also represented, and most communities discharge into several different types of receiving waters. The surveyed SSO communities also represent a wide range of populations and service areas. Annual rainfall for these communities varies significantly. Many communities had not determined the quantity of annual SSO discharge, in part because many SSOs occur as basement and street flooding which is difficult to quantify.

In contrast to CSO and SW, most communities have not defined their SSO annual discharge quantity; Wayne County, Mich. was one of the few exceptions. Flow monitoring in 13 Wayne County communities was used to evaluate the relative contribution of each to the wet weather pollution.

6.3.2.2 SSO Public Participation

Public participation for SSO tends to be different as compared to CSO and SW. SSO public participation efforts tend to originate from sewer backup-related occurrences rather than environmental issues or water quality. Therefore SSO public participation tends to be more of a pragmatic approach rather than environmental education approach. For example, Houston, Texas needed to move ahead simultaneously with initial planning, design, and construction activities in order to meet a consent agreement deadline. The local engineers and construction community, along with the municipality staff, organized together during the initial phase of planning and program development. This relationship helped the stakeholders to become fully committed to the process well ahead of actual design and construction contracts.

General water quality, along with basement flooding and other sewer backup related occurrences, were the most commonly listed public concerns. The major water quality parameters of concern were bacteria, BOD, and dissolved oxygen.

6.3.2.3 SSO Systems Characteristics

The majority of the communities responding had used a mathematical model to estimate flow in their sanitary sewer collection systems. Houston invested $65 million between 1988 and 1991 to evaluate its collection system and conduct extensive flow monitoring. The physical analysis identified infiltration due to leaking joints, cracks, and breaks in city sewers and private property laterals as the primary source of increased wet weather flows. The collection system modeling helped Houston better define the size of the satellite treatment facilities.

Although many communities say they use a watershed approach, some interpret this approach as encompassing all the sewers and laterals in the sewershed when planning for rehabilitation or abatement. Houston and the Downriver Communities, however, pursued a more ideal watershed approach. The city completed a water quality study of local receiving waters for the purposes of evaluating surface water quality benefits associated with SSO control. Monitoring and modeling confirmed that the water quality of wet weather pollution from constructed overflows was roughly equivalent to wet weather receiving water quality. As a result, the goals of the SSO control program were more concerned about customer service (i.e., sewer backups) than receiving water quality. The Downriver Communities in Wayne County also pursued a watershed approach, but the results were not as successful as Houston. The Downriver Communities identified other pollution sources in the watershed such as CSOs and SW. However, the regulatory agency viewed each pollution source separately and held the Downriver Communities to rigid SSO effluent standards regardless of water quality impacts of other pollution sources.

Current pollutant abatement included municipal and industrial point sources, plus urban runoff, from practically all cities. Control efforts for the same targeted pollutant sources were generally expected to remain in the future.

6.3.2.4 *Issues Driving SSO Technical Considerations*

Two cities, Flagstaff and Oklahoma City, indicated that an SSO facility plan has not been initiated. The remaining communities were equally split between developing a plan and completion of a facility plan. Of the many potential strategies municipalities may adopt to abate SSOs, most involve some combination of upgrading the WWTP, removing sources of I/I, and increasing the storage capacity of the collection systems. Some abatement strategies involve technology used for CSO control, such as off-line storage and satellite treatment facilities. However, currently this approach is atypical. Bacteria, BOD, and dissolved oxygen were the most prevalent water quality criteria for local receiving waters. Floatables, sediments, and nutrients were also notable water quality concerns.

Planned sewer improvements and regulatory requirements were listed as the most common reason for SSO abatement. A few communities, such as Downriver Communities, Hillsboro, Houston, and New Orleans, responded to litigation.

SSO abatement is almost exclusively accomplished by I/I reduction. However, upgrading the WWTP and increasing the storage capacity of the collection systems are also common. In a few select cases, such as Johnson County and Houston, satellite treatment of SSOs have been approved. Satellite treatment technology included screening, settling tanks or ponds, and disinfection. Such an approach provided a cost-effective means of complying with water quality requirements.

6.3.2.5 *SSO Financial Considerations*

Most communities spent less than $10 million for past SSO costs, indicating that the communities have not started major infrastructure-type abatement. Most communities have acquired or plan to acquire funding for SSO abatement through increased sewer rates. Another common funding source was revolving loans.

CHAPTER 7.0

SW Benchmark Data and Case Histories

7.1 Benchmark Data for SW Communities

The following section includes a benchmark matrix for general SW community statistics (Table 7-1), SW public participation (Table 7-2), SW systems characterization (Table 7-3), issues driving SW technical considerations (Table 7-4), and SW financial considerations (Table 7-5).

7.2 Case Histories for SW Communities

Stormwater case histories are useful in documenting the successes and disappointments of SW management in areas having up to several decades of experience. Most U.S. cities are just beginning to consider local SW controls as a result of federal regulations. However, the literature (especially technical conference publications) shows that many cities throughout the country have been involved to a certain extent in some SW control. The following case histories present five municipalities that have been involved in local SW management longer than many in the nation: Bellevue, Wash., Denver, Colo., Austin, Texas, Milwaukee, Wis., and Orlando, Fla. These mature SW management programs have all progressed through many phases of operation and are renowned for developing or making major advances in certain specific aspects of SW management, such as utility district financing, integrating drainage and water quality issues, addressing groundwater problems, and dealing with watershed-scale problems.

7.2.1 Austin, Texas

Austin has been long known as an innovator for SW controls, especially the sand filter. It was also one of the earliest cities to enact comprehensive SW management regulations specifically to protect both surface and groundwater receiving water quality.

Austin was incorporated in 1839 and is a rapidly growing city, with a population of about 460,000 (1990 census). It is the capital of Texas, home to the University of Texas, and an important high-technology center. The city covers an area of 116 square miles and the land elevation ranges from about 400 to over 1,000 ft. The area receives about 32 inches of rain a year, but can have prolonged dry periods with large amounts of evapotranspiration, resulting in arid characteristics. The separate storm drainage system discharges into several heavily urbanized streams which drain to the Colorado River. The river is dammed in Austin into a chain of three large lakes (Lake Travis, Lake Austin, and Town Lake) that comprise the local water supply. The Edwards Aquifer recharge zone underlies parts of Austin, making groundwater protection an additional important component of local SW management efforts.

Austin's peak discharge control regulations were implemented in the mid-1970s in response to the city's rapid growth and associated increased flooding and erosion. SW quality regulations were first implemented in the early 1980s to protect the city's water supply. A drainage fee was established in 1982 and the Drainage Utility was established in 1991.

Questionnaire Date: July 1998.

Austin has enacted three major watershed ordinances to protect both surface water and groundwater resources:

- the Comprehensive Watersheds Ordinance (1986),
- the Urban Watersheds Ordinance (1991), and
- the Barton Springs Ordinance (1992).

The objectives of the local SW management program are to:

- protect citizens from flooding,
- preserve the natural and traditional character of the city's waterways,
- protect the water quality of the Edwards Aquifer and the city's drinking water supply, and
- protect the city's recreational and aesthetic resources (such as Town Lake and Barton Springs).

Some of the ordinance requirements are very specific, such as those for source controls as part of the Barton Springs ordinance. Because of some of these requirements, especially for areas outside the city limits, successful court challenges by developers have weakened some of the laws.

Current funding for the city's erosion and sediment control program is about $750,000 (evenly derived from general city appropriations, permit fees, and from the SW utility fee). The SW management program is funded at about $8 million (mostly from the SW utility fee).

Cost Estimates ENR: 5921 July 1998
Questionnaire Date: July 1998.

The city has long conducted local monitoring activities. The city worked with the U.S. Geological Survey on a cooperative effort starting in 1975 to evaluate SW from eight large mixed land use watersheds. Starting in 1981, the city also participated in NURP, monitoring runoff from two residential areas and one undeveloped area. The city expanded its efforts in 1984 to include a total of 11 single land use areas representing new development. Five additional single land use sites (older, existing areas) were monitored as part of the NPDES SW permit. Selected event mean concentration data from these monitoring activities are shown in Table 7-6.

Table 7-6. Land Use versus Event Mean Concentrations, Austin, Texas

mg/L	Suspended Solids	COD	Total P	TKN	NO2 NO3	Lead	Copper	Zinc
Open/Vacant/Parkland	80	26	0.10	0.52	0.15	0.004	0.01	0.008

Major roads/highways	143	103	0.44	1.78	0.83	0.53	0.05	0.37

In 1989, the city started a study to identify and quantify the critical pollutants and sources adversely affecting the Town Lake water supply, listed below, along with their removal goals, in order of decreasing importance:

- nutrients (25 - 30%),
- toxic metals (50%),
- suspended solids (50%),
- trash and debris (50 - 90%), and
- oil and grease (25%)

Concentration reduction efficiencies for various SW control devices have been extensively evaluated in Austin to support the city's SW management planning activities. Table 7-7 summarizes some of the expected concentration reductions for the flows being treated. Because some devices bypass significant amounts of untreated SW due to clogging (especially in sand filters due to inadequate maintenance) or because they are undersized (such as for oil/water separators), the actual annual pollutant removals may be substantially less. In addition, Table 7-7 only reflects concentration reductions and not the greater pollutant mass reductions associated with devices having significant infiltration benefits (such as for grassed waterways).

Table 7-7. Concentration Reduction Efficiencies for SW Controls, Austin, Texas

% Reduction	Wet Pond	Sand Filter (no pretreat)	Dry Pond (earth/grass lined)	Oil/Water Separator	Grassed Waterway

7.2.2 Bellevue, Wash.

SW Community Characteristics

♦ Population	100,000
♦ Sewer Area	19,000 Ac
♦ Annual Rainfall	35" - 40"
♦ # of SSO Discharge Points	>100

Distinctive SW Community Attributes

- One of the first communities to establish SW utility
- Rate structure based on runoff volume generated

Bellevue has a long history of SW management. It was one of the first communities in the U.S. to establish a SW utility district and to develop a method for local financing of both flood control and water quality enhancements. Bellevue is a rapidly growing community near Seattle, with a population of about 87,000 (1990 census) and covering more than 30 square miles. The area receives 35 to 40 inches of rainfall a year with a separate drainage system. The SW is discharged to many small heavily urbanized streams which lead to Lake Washington.

Washington state law was changed in 1965 to allow the establishment of utilities as a funding mechanism for SW control. The city established its storm and surface water (SSW) utility in 1974, after several years of discussion and planning based on citizen concerns about declining water quality in Bellevue streams. The SSW utility's founding mission was "to maintain the hydrological balance, to prevent property damage, and to protect water quality; for the health, safety, and enjoyment of citizens and the preservation and enhancement of wildlife habitat." During the initial five years, the utility focused mostly on runoff volume and velocity, and erosion control. After these fundamental problems began to be addressed, the utility was able to shift its focus to also include water quality objectives.

A critical part of the development of the SSW utility was the establishment of a rate structure based on volumetric runoff coefficient (Rv) generated:

- undeveloped (Rv <0.25),
- light (0.25 <Rv<0.4),
- moderate (0.4<Rv<0.5),
- heavy (0.5<Rv<0.75), and
- very heavy (0.75<Rv<1.0).

Onsite runoff controls result in rate reductions. A major public education program was conducted to emphasize the benefits of the utility and the costs. In 1991, the average single-family household paid about $90 per year to the SSW utility. The 1986 budget was about $4.3 million, and the 1980 to 1986 capital improvement budget was

$13 million. In 1997, the SW program was funded at about $450,000 per year from permit fees, and the erosion and sediment control program is funded at about $500,000 per year from the SW utility fee and permit fees. Both programs have a combined staff of two administrators, three full-time development reviewers (plus four part-time reviewers), four inspectors (plus two part-time inspectors), and three others, including support staff.

Some opposition continued to the utility fee within the city, but it has subsided greatly as the citizens understand the benefits of the utility. The main benefit is in preventing problems instead of responding to existing problems, which tends to diminish the utility's perceived value. Adding a stronger component to more adequately address water quality issues is a future challenge being currently addressed by Bellevue.

Preferred SW practices include wet detention ponds, grass roadside drainage swales, catchbasins, oil-water separators, and filters. Ground infiltration practices are not allowed due to slowly percolating soils and problems with these practices in the past. During 1992 and 1993, 13 biofiltration facilities, 8 extended dry detention ponds, and 1 filtration facility were installed.

The SSW major programs include:

- capital improvement (by 1991, 11 ponds with real-time control had been established for flood control);
- operations and maintenance (operating flood control facilities to minimize fishery impacts, consulting with private property owners to solve private drainage problems, cleaning inlets and storm drainage, repairing structural facilities, emergency response, etc.);
- water quality (routine monitoring of all receiving waters, stream enhancement and lake restoration projects, inspection of private SW systems, etc.);
- development regulations (using the city's land use authority to regulate construction, enforce clearing, grading, and development of sensitive areas, inspect construction sites, etc.);
- public education (award-winning "stream teams" and "business partners for clean water" programs, etc.); and
- administration (policy development, financial management, rate administration, drainage planning, etc.).

Bellevue participated in NURP, resulting in much data on local characterization and control effectiveness. With this local data, the city applied for a general NPDES permit for SW in 1985, more than ten years before the SW NPDES permit program was established for the country.

The SSW utility operates a spill response team on 24-hour call to respond to accidents or citizen calls for inappropriate or illegal discharges to the drainage system or streams. It also operated one of the first oil recycling programs in the nation.

The Bellevue SSW utility efforts have succeeded because:

- the utility is a unified agency (although city reorganization in 1993 resulted in the erosion and sediment control program being assigned to a different city unit);
- the utility has the backing of strong regulations;
- the utility has strong citizen support;
- all enforcement and maintenance activities are staffed within the utility; and
- the utility coordinates extensively with other agencies and governments in the region.

The SSW utility programs do have some current conflicts with other city programs, such as biofiltration conflicting with the city's land use code landscaping requirements, and the preferred use of swales conflicting with the city's transportation code.

7.2.3 Denver, Colo.

SW Community Characteristics

♦ Population	>1,000,000
♦ Sewer Area	>100,000 Ac
♦ Annual Rainfall	15"
♦ # of SSO Discharge Points	2,000

Distinctive SW Community Attributes

- Successful SW utilities
- Flood control receives more emphasis than water quality

Denver is known for its efforts in flood control in an arid, high elevation area that receives large amounts of runoff from upstream areas. The city's efforts to develop and evaluate site-specific SW quality control practices and its experiences with utility district are also noteworthy.

Denver was incorporated in 1858 and had a population of about 470,000 in 1990. The city covers an area of about 155 square miles and is at an elevation of more than 5,000 ft. The area receives only about 15 inches of rain a year and experiences cold and long winters. The separate stormwater system has more than 1,000 outfalls in the metropolitan area that discharge into small streams that, in turn, eventually discharge into the Platte River. Rain occurs on about 60 days a year, but only about 30 storms per year are of sufficient size to produce runoff.

The Urban Drainage and Flood Control District (UDFCD) serves an area of about 400 square miles, having a total population of more than 2 million. Flood control has received the most emphasis from the district, and receiving water quality problems are not generally thought to be associated with wet weather flows because of other influencing factors. However, a watershed approach has been taken locally where urban runoff, municipal point sources, and industrial point sources are being addressed. Federal and state regulatory requirements are the major driving forces behind local wet weather flow water quality control efforts.

Denver was a participant in NURP in the early 1980s, monitoring several catchments and control practices over several years.

About $4 million has been spent in the past on wet weather pollution control efforts, and about $10 million is projected to be spent in the future, coming from increased taxes, user fees from the utility district, and by reallocation of funds from other municipal activities. The UDFCD is coordinating NPDES SW permit activities for the cities of Denver, Aurora, and Lakewood. As more communities in the Denver area are required to participate in the

NPDES permit program, the UDFCD will be available to assist these other areas also. A joint task force was created in 1990 to define the goals, objectives, and responsibilities necessary to meet the needs of the permit process. The initial goals were to:

- coordinate application efforts of the three cities,
- jointly negotiate application requirements with the state of Colorado,
- jointly conduct activities whenever possible,
- share knowledge and experience,
- facilitate use of resources of other organizations,
- evaluate candidate SW control practices,
- develop dry weather screening work plan, and
- develop a joint SW monitoring program.

In addition to helping to coordinate these activities, the UDFCD, in conjunction with local colleges, also conducts erosion control training courses for local contractors.

The NPDES SW permits were issued by the state to the three cities in May 1996. All permit requirements must be implemented within three years. Some of the permit requirements, such as street and inlet cleaning and trash removal from channels, has been an on-going activity, but other activities will need to be implemented, including:

- annual reporting and cost estimates,
- industrial facilities program,
- municipal facility runoff controls,
- wet weather monitoring program,
- dry weather sampling protocols, and
- other major programs (including public education, new development planning procedures, and construction site sediment control).

Local construction site erosion control efforts typically include mulching, diversions, filter fencing, and sedimentation practices. Stormwater control is accomplished through many activities, including public works practices (street and inlet cleaning, litter control, oil/water separators, inappropriate discharge elimination, grass swales, and grit chambers), infiltration (porous pavement and grass filters), sedimentation (wet detention ponds and wetlands), and other activities (including dry detention ponds, filtration, and public education). The performance of many of these devices has been determined through local monitoring. The district identified severe problems with typically constructed sand filters, such as clogging caused excessive bypassing of untreated water. Design guidelines need to be modified to account for expected high suspended solids loadings and to enable more efficient maintenance. Monitoring a wet pond followed by a series of wetland cells showed moderate to high levels of control of many pollutants over a wide range of runoff conditions.

Stream restoration along the Platte River has also been successful. Denver is well known for Confluence Park, a $7.5 million project that incorporates flood control, boating access, recreation, 5 acres of wetlands, wildlife and aquatic habitat, plus a cooling water diversion structure for a power plant. Denver also had constructed more than 12 miles of recreational trails along the South Platte River within the city, which connects with six other trails having an additional 50 miles.

7.2.4 Milwaukee, Wis.

SW Community Characteristics

◆ Population	630,000
◆ Sewer Area	61,500 Ac
◆ Annual Rainfall	30"
◆ # of SSO Discharge Points	Unknown

Distinctive SW Community Attributes

- Extensive SW quality information
- Watershed approach and nonpoint source pollution control

Milwaukee has a great deal of SW quality information and a state regulatory program that has put these data to good use in a watershed context.

Milwaukee was incorporated in 1846 and has been known as a heavily industrialized city, although it is more diversified now. It had a population of abut 630,000 in 1990 and a land area of about 96 mi^2. Its elevation is about 600 ft. The central part of Milwaukee has a combined sewer system, but the vast majority of the city and most of the surrounding communities have separate storm drainage. The storm drains flow to Lake Michigan, with most stormwater flowing from the Milwaukee, Kinnickinnic, and Menomonee Rivers (which form the inner harbor) from urbanized tributaries (such as Lincoln Creek). The annual rainfall in Milwaukee is about 30 inches, and snow cover is common for several months each winter. Winter temperatures can be severe and snowmelt is an important contributor to urban runoff pollution, in addition to rainfall induced runoff.

Stormwater quality management in the Milwaukee area was initiated as part of the Wisconsin Priority Watershed Program. This program (one of the oldest in the nation funding nonpoint pollution abatement) was developed in 1978 to help combat both urban and rural nonpoint sources of pollution. An important element of the program is retrofitting control practices in both rural and urban areas. Initially the program was heavily involved in rural areas, with technical assistance from the National Resources Conservation Service (NRCS). A unique aspect of the program is that it is implemented on a watershed and not on a political jurisdiction basis. Of the state's 330 watersheds, 130 (mostly located in the southern part of Wisconsin) will likely require comprehensive management activities to control nonpoint pollutants. A 25-year plan was developed in 1982 that requires the startup of about eight or nine new watershed abatement efforts per year. The watershed plans are prepared by the state with cooperation and reviews by local government agencies. They contain detailed analyses of the water resources objectives (existing and desired beneficial uses including the problems and threats to these uses), the critical sources of problem pollutants, and the control practices that can be applied within each watershed. The plans also include implementation schedules and budgets to meet the pollution reduction objectives.

Each plan requires one year to prepare, including the necessary fieldwork. Various field inventory activities are needed to prepare the plans, including aquatic biology and habitat surveys to identify existing and potential fishery uses, streambank surveys to identify the nature and magnitude of streambank erosion problems and to help design needed controls, field and barnyard surveys to supply information needed to estimate and rank their pollution potentials and to design farm control practices, and urban surveys needed to evaluate urban runoff pollution potential and its control.

Urban planning was initiated in 1983 in the Milwaukee and Madison areas, with other urban areas of the state following. The urban practices eligible for cost sharing identified in these plans have included streambank protection, detention basins, and infiltration devices for existing urbanized areas. Construction site erosion controls are also usually required as a condition for a grant agreement in an urban area, but they are not eligible for state cost sharing. About $3 to $5 million per year will be used by the nonpoint source program over a 20-year period in controlling urban runoff.

The Wisconsin nonpoint source plan addresses watersheds, not just political areas. The Milwaukee River basin contains 500 streams, 100 lakes, and 60,000 acres of wetlands in its 900-square-mile watershed. The city of Milwaukee is at the terminus of the river, where it discharges into Lake Mich. The water quality in the watershed varies dramatically, from excellent in many headwater trout streams to poor in the heavily urbanized southern portions of the basin. The Milwaukee Basin Priority Watershed Program started in 1985 as a voluntary program to address both urban and rural sources of nonpoint pollution. More than 500 rural landowners and 26 local governments have participated in the program, with total local and state investments of about $40 million.

An outcome of the Milwaukee River South Watershed plan included goals for reducing urban SW discharges. These goals were 50% reduction for suspended solids and heavy metals, and 50% to 70% reduction for phosphorus. The city cleanup program has four elements:

- local controls on construction erosion,
- improved SW management,
- better urban housekeeping, and
- streambank erosion controls.

The city identified construction site erosion as the leading cause of sediment into the Milwaukee River South watershed. Of the annual 26,000 tons of sediment, about 62% comes from construction sites, while only 16% comes from cropland, with the remainder from urban SW and streambank erosion.

A Wisconsin Pollutant Discharge Elimination System permit (under EPA NPDES authority) was issued to Milwaukee in October 1994. It covers SW discharges from more than 200 major outfalls to area streams and Lake Mich. The permit addresses discharges from Milwaukee and another 26 local communities. These communities each pay the Wisconsin Department of Natural Resources $5,000 per year as a permit fee, totaling more than $1 million for the 5-year permit period.

An important part of the Milwaukee wet weather flow program is monitoring urban streams to identify and quantify actual receiving water problems. Milwaukee participated in the early International Joint Commission studies with Canada to characterize discharges into the Great Lakes. Milwaukee was also a participant of NURP in the early 1980s. During NURP, eight single land use catchments were extensively monitored for three years in cooperation with the U.S. Geological Survey. The benefits of street cleaning as a pollutant discharge reduction practice were included in this effort. Snowmelt characterization monitoring and effects of de-icing compounds have also been extensively studied in Milwaukee. Recently, detailed studies on toxicant sources, effects, and controls have also been conducted in Milwaukee, including a study conducted in heavily urbanized Lincoln Creek (a 19mi.^{2} watershed, 9 miles long). A seven-tiered indicator program, incorporating many physical, chemical, and biological tests, was simultaneously conducted which identified long-term toxicity problems likely associated with re-suspended contaminated sediments having high levels of organic compounds. It was found that discharges of these fine sediments could be significantly reduced through the use of well-designed and maintained wet detention basins. The instream toxicity monitoring methods developed and used during the Lincoln Creek study can be used by other municipalities to answer the following basic questions:

- Are toxic conditions present?
- What is causing the toxicity?
- How much is too much urbanization? and
- Can SW controls reduce these problems?

The benefits of SW controls have also been evaluated in Milwaukee, especially grass swales, wet detention ponds, and underground devices for critical source areas. The Southeastern Wisconsin Regional Planning Commission also prepared a comprehensive report documenting costs associated with construction site erosion and SW control.

In addition, the Wisconsin Nonpoint Source Program includes an important public education component. Milwaukee conducted a survey to identify the most likely successful public education program. The more than 3,000 responses indicated that TV news stories, newspaper articles, targeted newsletters, and pamphlets would be most effective. Site visits, workshops, and videos were unlikely to be successful. The survey also found that more than 90% of Milwaukee respondents were willing or are already doing activities to protect water quality (recycling used oil, separating household hazardous wastes, limiting landscaping chemicals, controlling dog wastes, etc.). Virtually all of the respondents rated the local waters as poor to fair and less than 10% used the local waters for any recreational activities. However, more than half were willing to pay more than $50 per household per year for programs to protect and restore local waters.

7.2.5 Orlando, Fla.

SW Community Characteristics	
◆ Population	165,000
◆ Sewer Area	100,000 Ac
◆ Annual Rainfall	50"
◆ # of SSO Discharge Points	1,000

Distinctive SW Community Attributes

- Recipient of EPA's SW award in 1990

Orlando is known for its long history of SW management, including receiving the U.S. EPA's SW award in 1990. The city has extensive local data, especially concerning the performance of SW controls in its unique area, which has heavy rains, flat topography, high groundwater, and highly percolating sandy soils.

Orlando is located in central Florida and had a 1990 population of about 165,000. The area receives about 50 inches of rainfall each year, mostly occurring in the summer. Most of the area is underlain with sandy soils. Therefore, urban development produces dramatic increases in runoff volumes and rates as the highly percolating soils are covered with impervious surfaces. The infiltrating water recharges the Floridan Aquifer, the major drinking water supply for most of central Florida. The area is relatively flat, at about 100 feet elevation. The city of Orlando contains 82 named lakes and several hundred drainage wells that receive SW runoff from the separate storm drainage system.

Florida began to investigate SW pollutant sources in the 1970s as part of the Section 208 requirements of the Clean Water Act. The Florida Department of Environmental Regulation and 12 regional agencies received many large Section 208 grants to assess the extent of the state's nonpoint pollution problem and to develop technical and administrative methods for treatment and control. The state had authority to draft regulations pertaining to SW control as part of its existing environmental laws. The first official state regulation addressing SW was adopted in 1979 based on the results of the Section 208 studies that found urban SW was responsible for:

- 80 to 95% of the heavy metal loadings to Florida surface waters,
- almost all of the sediment deposited in state waters,
- 450 times the suspended solids and 9 times the BOD loads compared to typical municipal wastewater treatment facilities, and
- nutrient loads about the same as those being discharged from typical municipal wastewater treatment facilities.

The state regulations were revised several times for clarification and to ensure long-term operation through adequate maintenance and better design.

The Florida Department of Environmental Regulation requires SW controls for new development. The requirements specify that the first 0.5 inch of runoff, or the runoff from 1 inch of rain, whichever is greatest, be treated. This regulation is thought to result in about 80% to 85% of the annual pollutant loads being treated. Orlando published one of the earliest SW management guides (Orlando Urban Storm Water Management Manual) in 1984 to assist developers in meeting these requirements. Stormwater wet detention ponds, excavated into the groundwater, were the first controls commonly used. Research has investigated the performance of these and other devices, including their potential impacts on groundwaters. Outfall screening devices and street cleaning (especially in March when the leaves from oak trees fall) were also thought to be an effective control for lakes. Sand filters, grass swales, wetlands, and alum injection have also been used and tested in the Orlando area.

The Orlando urban stormwater management program was established in the early 1980s to address increasing SW runoff quality and quantity problems resulting from new development. Orlando sponsored a lake assessment study in 1983 to evaluate the city's lakes in response to residents complaints of deteriorating water quality. The assessment study resulted in a priority listing of lakes needing remediation assistance. Large regional facilities (such as the Lake Greenwood Urban Wetland project) have been retrofitted in existing urban areas, and alum injection facilities have also been added to several existing urban lakes.

The preferred SW control practices in Orlando are off-line retention, filtration, and both dry and wet detention ponds. Source controls, as described in the local manual, are encouraged. The performance standards are to reduce the annual average suspended solids loadings by 80%.

The city received its NPDES SW permit and funds local oversight through the Orlando SW utility. The current utility fee is $36 per residential household equivalent per year. The total annual budget is $1.25 million, of which about 90% is from the utility fee. The utility has four administrators, four engineers, 18 inspectors, two scientists, and five clerical support staff. Educational programs are a voluntary component of the program, with the utility presenting more than 40 programs each year to educate the general public about SW management. Local volunteers also participate in the Florida Lake Watch program. The city has a limited program to monitor the water quality in the city's lakes to measure success of the SW management program. As noted previously, numerous research projects have also been conducted in Orlando to evaluate the performance of SW management practices.

7.3 SW Case Histories and Benchmark Data Discussion

7.3.1 General SW Discussion

Community accomplishments in addressing SW concerns are highly varied throughout the U.S. In most cities, very little has been done beyond basic SW drainage. In a few communities (such as those selected for discussion in the case studies), early concerns by the public about declining water quality resulted in attempts to manage SW quality. After drainage problems were brought under control, usually through master planning and the construction of large-scale facilities, construction erosion control was usually implemented. With these important considerations addressed, some of the communities were able to address SW quality. Some stressed controls for new developments, while a very few examined retrofit opportunities (Wisconsin's Priority Watershed Program, for example).

Historically in almost all communities in the U.S., SW management only addressed drainage issues, because scarce local resources were needed for more pressing issues. Such communities are only able and willing to participate in SW management at the most basic and minimal level. Without specific guidance and requirements contained in local and state ordinances, very little SW quality management was conducted in most communities. In fact, some communities backed off from prior rigorous attempts at SW quality management to more minimal efforts that barely meet existing regulations.

With the Clean Water Act SW NPDES permit program in place, SW quality management is no longer a luxury program only being conducted in rapidly growing sunbelt communities that have the resources and motivation. Because of the large number of communities involved in the first and second phases of the NPDES SW permit program, the federal and state approach has been to define relatively basic requirements for the permits, with generally few specified control goals. Obviously, submitting all the municipal permits (along with the new industrial SW permits required at the same time) has produced a financial, logistic, and management problem for state agencies and EPA regions. It is apparent that the main goal was to get the permits issued in a timely manner, while accomplishing such basic and necessary goals as drainage area characterization information; screening for inappropriate discharges at storm drain outfalls; starting erosion control programs; establishing local authority over the drainage system; and developing a financial basis for management of the program. Even with the relatively simplified permit process and requirements, however, large municipalities (in phase one of the program) often spent more than $1 million each to gather the necessary information and to prepare and submit the permit applications.

The requirements included in the issued permits rarely specified any control goals or management needs beyond conducting an outfall monitoring program of about three storms a year at about five land use sites. The permits are generally issued for 5 years, with the expectation that specific control requirements would be added during subsequent periods as local problems become better defined. Nearing the tenth year of the SW NPDES program, medium cities (between 100,000 and 500,000 population) have also submitted permit applications and most have received their initial permits, and small communities (greater than 10,000 in population) are to be included in the program within a year. Therefore, the SW permit program burden on the regulatory agencies has increased, with little opportunity for increased site-specific control objectives to be included in the permits. The role of TMDL allocations was to be a tool to determine allowable discharges of SW and point source permits to a watershed's receiving waters. However, there is still much concern, and therefore delay, in allocations.

Most of the specific accomplishments of SW quality have occurred in communities with flooding/drainage problems, scarce water resources, and the financial ability (usually through local funding mechanisms). Specific requirements by local communities, and some state agencies, are the driving force behind these major accomplishments. Federal legislation now requires SW quality management at most levels of government. However, the direct application of approaches from the few communities currently having successful SW quality management programs may not be workable. All these communities have found that advances have been slow and greater public awareness and understanding (especially when local funding is involved) is needed. Specific guidance and requirements, along with strenuous enforcement, are also necessary components of successful programs; voluntary efforts by themselves are rarely adequate.

7.3.1.1 *Stormwater Quality Problems as the Driving Force*

The main purpose of treating SW is to reduce its adverse impacts on receiving water beneficial uses. Therefore, any urban SW runoff study must assess the detrimental effects that runoff is actually having on receiving water. Urban receiving waters may have many beneficial use goals, including:

- stormwater conveyance (flood prevention);
- biological uses (warm water fishery, aquatic life use, biological integrity, etc.);
- non-contact recreation (linear parks, aesthetics, boating, etc.);
- contact recreation (swimming and wading); and
- water supply.

With full development in an urban watershed and no SW controls, it is unlikely that any of these uses can be attained. With less development and the application of SW controls, some uses may be possible. But unreasonable expectations should not be placed on urban waters, as the cost to obtain these uses may be prohibitive. With full-scale development and lack of adequate SW controls, severely degraded streams will be common. However, SW conveyance and aesthetics should be the basic beneficial-use goals for all urban waters. Aquatic life use should also be a goal, but with the realization that the natural stream ecosystem will be severely modified with urbanization.

Certain basic SW controls, installed at the time of development, plus protecting stream habitat, may enable partial realization of some of these basic goals in urbanized watersheds, but careful planning and optimal utilization of SW controls are necessary to obtain these basic goals in most watersheds. Water contact recreation, consumptive fisheries, habitat for sensitive aquatic organisms, and water supplies are not appropriate goals for most urbanized watersheds. However, these higher uses may be possible in urban areas where the receiving waters are large and drain mostly undeveloped areas.

The latest National Water Quality Inventory released by the U.S. EPA showed only slight improvement in attaining beneficial uses in the nation's waters. Urban runoff was cited as the leading source of problems in estuaries, primarily from nutrients and bacteria. Problems in rivers and lakes were mostly caused by agricultural runoff, with urban runoff the third-ranked source for lakes and fourth ranked for rivers. Bacteria, siltation, and nutrients were the most significant problems in rivers and lakes.

In general, urban SW runoff monitoring has indicated that the biological beneficial uses of urban receiving waters are most likely affected by habitat destruction and long-term pollutant exposures (especially for macroinvertebrates via contaminated sediment), while documented effects from acute exposures to toxicants in the water column are rare. Receiving water pollutant concentrations resulting from runoff events and typical laboratory bioassay test results have indicated few significant short-term receiving water problems. Therefore relating actual receiving water problems to conventional numeric standards is difficult. Interest in developing special wet weather standards, especially considering contaminated sediments, intermittent exposures to high flows, and habitat destruction exists. Using local reference stations for comparison is usually necessary to identify local problems and the needed extent of SW discharge reductions.

7.3.1.2 Changes in Stormwater Management and Attitudes with Time

In 1967, researchers at the University of Wisconsin distributed a survey to engineers in the state, the main objective of which was to determine the level of service considered adequate. This questionnaire explored design procedures and policies. In 1997 a survey by the University of Alabama at Birmingham was mailed to over 350 recipients in engineering firms and municipal water authorities across the nation. This recent survey was designed to examine changes in design methods, objectives, and understanding of SW quality problems over this 30-year period. The university received about 85 responses (mostly from Minnesota, Ohio, New York, Florida and California), about half of whom were consulting engineers in private practice and the other half engineers with municipalities. Tables 7-7 and 7-8 present the findings from the 1997 survey and compare them to the 1967 survey.

7.3.2 SW Questionnaire Findings

7.3.2.1 SW Community Statistics

The returned SW benchmark questionnaires cover communities with a wide range of conditions and receiving waters. Most discharge SW into rivers, streams, or lakes, but the ocean, groundwater, and estuaries are also represented by one city each. Almost all communities discharge into several different types of receiving waters.

Three communities (Boston, Denver, and Detroit) have populations greater than 1 million, while the other 12 cities have populations less than 500,000. All manage total drainage areas of more than 1,000 acres (most greater than 10,000 acres) and had more than 50 outfalls (except for Orem, Utah, which reported less than 10 discharge points). Annual rainfall was less than 20 inches for three cities (Burbank, Denver, and Orem), between 20 and 30 inches in one city (Fridley), between 30 to 40 inches in six cities (Austin, Bellevue, Detroit, Hillsboro, River Falls, and Struthers), and more than 40 inches in four cities (Birmingham, Boston, Frederick, and Orlando).

Table 7-8. 1997 Stormwater Management Design Survey Responses

Practice	Response (Percentage of Respondents if Reported)				
Design Storm Used	5 year (10%)	10 year (42%)	25 year (7%)	100 year (9%)	
Method of Design	Rational (41%)	NRCS (SCS) (14%)	Combination (31%)	Regional (13%)	
Tools Used	Computerized tools (86%)	SWMM (25%)	HEC-1 (17%)		
Conditions of Failure	Manhole covers popping off	Water rising above curbs	Water in Basements		
Water Quality Concern	Sediment (60%)	Nutrients (35%)	Metals (34%)	Oil & Grease, Bacteria, Toxicants, Floatables, and Salts.	Staying within regulated discharge limits

Table 7-9. Stormwater Management Design Survey Comparison 1967 versus 1997 Results

	1967 Survey Responses	1997 Survey Responses
Design Storm	5 to 10 year (70%)	Approximately the same range, most using the 10 year.
Method of Design	Rational (Most cities misapplied the runoff coefficient or rainfall intensity)	Rational (Understood the use of Time of Concentration)
Indicator of Failure	Water ponding at inlets Water ponding in back yards.	Water ponding at inlets, but not a prevalent concern. Not a high priority for today's design engineers.
Water Quality Concerns	Sediments, Nutrients, Metals, Oil & Grease, Bacteria, Toxicants, Floatables, Salts, and Staying within regulated discharge limits.	

Few cities reported annual SW discharge quantity; however, the quantity may be estimated using a few assumptions. As an example, for the smallest reported service areas of 1,000 acres and 10 inches of annual rainfall with a reasonable arid area volumetric runoff coefficient of 0.2, the annual runoff volume would be about 50 million gallons. In a small city of only 10,000 acres (15 square miles), with an annual rainfall of 30 inches and a Rv of 0.3, the annual SW runoff discharges would be increased to more than 2,500 million gallons.

7.3.2.2 SW Public Participation

Only five communities (Birmingham, Frederick, Fridley, Orem, and Struthers) reported no public participation. However, at least Birmingham and Frederick do have public participation programs, but the responders possibly thought that their programs did not include any of the program elements listed. It is hard to imagine that public hearings would not be used for all major public works projects associated with SW projects.

Signs and general public education were most commonly indicated methods for informing the public, while the more successful TV addresses and newsletters were parts of only two community efforts. The least successful *tools, neighborhood meetings and videos available for loan from the local libraries,* were not listed by any of the respondents. Bellevue sponsored community educational projects, and receiving water monitoring by citizen volunteers was reported by Austin and Orlando. As part of its NPDES permit requirements, Birmingham is starting a new monitoring effort using local volunteers to investigate inappropriate discharges into storm drainage.

Basement flooding, along with general water quality, were the most commonly listed public concerns (11 and 9 cities, respectively). Aquatic life, street flooding, general recreation, water contact recreation, and public health were all noted by 3 cities each.

7.3.2.3 *SW Systems Characteristics*

Seven responding cities did not have a mathematical model of their SW systems, while three did. However, all (except Birmingham and Orem) indicated that a watershed approach has been taken.

Almost all cities included municipal and industrial point sources plus urban runoff among their current pollutant abatement efforts. Four communities indicated that agricultural runoff was also being controlled in their watersheds. Control efforts for the same targeted pollutant sources were generally expected to remain in the future. However, little documented performance information for urban runoff abatement efforts is available from the cities. Most cities listed estimated abatement levels only, with no monitoring programs either in the receiving waters or at outfalls to quantify any discharge reductions.

7.3.2.4 *Issues Driving SW Technical Considerations*

Only three cities (Birmingham, Boston, and Frederick) indicated that a SW facility plan was not started yet, three (Austin, Bellevue, and Detroit) indicated that the facility plans were completed, while six others indicated that plans were in progress.

All respondents indicated that regulatory requirements were the main driving force in their SW quality management efforts, with the exception of Boston. Litigation and lawsuits were also primary motivation sources for SW abatement in three cities. Five of the cities had no permitted facilities, while three cities listed up to 10 permitted facilities, and one city (Frederick) listed more than 100 permitted facilities.

Water quality criteria for local receiving waters included the following parameters (in order of most frequent mention): bacteria, dissolved oxygen, nutrients/floatables (tie), BOD/toxicants/sediment (tie), and finally temperature and heavy metals (only one city each).

Cost/benefit analyses were used by six cities, but regulatory requirements directed the selection of the abatement technology in 11 of the cities. Almost all technologies (construction site erosion controls, public works practices, and sedimentation) were being used by almost all communities. Infiltration practices were the least popular option.

7.3.2.5 *SW Financial Considerations*

Only Detroit listed significant past expenditures for past SW abatement efforts (at more than $500 million), while five others (Austin, Boston, Denver, Orem, and Struthers) all listed less than $10 million. Detroit also listed a similar level for future expenditures, while the others remained the same, except for Denver and Orem which expected an increase of $10 million to $50 million. Birmingham is starting a stream corridor protection program at a cost of about $30 million, as part of the settlement of a local lawsuit concerning wet weather flow pollution abatement.

The funding sources were varied, with fees from utility districts being most common (five cities), followed by "other" (four cities), then increased sewer rates, state grant money, federal grant money, and increased taxes (tied with three cities each), and finally revolving loans (two cities).

CHAPTER 8.0

COST-BENEFIT ANALYSIS

8.1 Syracuse, N.Y., Case Study

The Syracuse, N.Y., case study serves as a good example of a cost-benefit approach to abating wet weather pollution in that the decision-making process involved all the critical components of the community, from the technical engineers to the municipal government budget and financial management departments.

Syracuse began its CSO abatement program in the early 1970s with the country's first full-scale demonstration of an U.S. EPA vortex and disinfection facility. A very successful BMP program followed in the middle 1980s. The CSO abatement program was expedited in 1989 as a result of a legal consent order. During the early stages of the consent order process, several planning meetings were held under Section 208 of the 1972 Clean Water Act Amendments. These meetings culminated in a work plan for the CSO abatement program, which required the consensus of stakeholders on the storm frequency that would serve as a reasonable target for abatement.

All parties, including local health and state regulatory agencies, agreed that a 1-year storm frequency would be used to size the wet weather pollution abatement facilities. Figure 8-1 illustrates an inflection (knee of the curve) in the system conveyance capacity at the 1-year storm recurrence interval. It was agreed that such a storm would likely be a convective storm occurring in the summer months when base flow in receiving water streams would be low. It was also agreed that such a combination of wet weather pollution and low stream flow represented reasonably stringent conditions.

Once the 1-year storm recurrence interval was agreed upon, five abatement strategies were evaluated using a cost-benefit analysis on the basis of bacteria, solids, and BOD improvements in the receiving water. Figures 8-2 and 8-3 show these relationships. Figure 8-3 illustrates the point of inflection for the cost curve occurring at the "Regional" abatement alternative. The regional abatement alternative included satellite treatment facilities designed to control bacteria, solids and floatables, in-system storage, and some sewer separation. This alternative was adopted as the accepted CSO abatement plan. The location of these satellite treatment facilities, known as regional treatment facilities, is illustrated in Figure 8-4.

Further application of the cost-benefit analysis was used to justify the need for all satellite treatment facilities to control bacteria, solids, and floatables. Detailed system and receiving water bacterial modeling demonstrated that the facilities needed to control bacteria and solids loadings to the receiving waters were not as great as originally estimated. All parties agreed to reduce some of the regional treatment facilities to floatables control facilities. This reduced the CSO abatement costs from $267 million to $144 million.

The construction planning for the regional treatment facilities and floatables control facilities ultimately culminated in a 15-year build out period that would progressively achieve full compliance during that time. This compliance was in terms of both the presumption and demonstration clauses of the federal CSO policy as illustrated by Figures 8-5 and 8-6.

Figure 8-6. Wet Weather Combined Sewer Flows, Syracuse, N.Y.

An integral part of the decision making process during construction planning was resolving the issue of affordability. The affordability analysis was used to evaluate the financial impacts of the CSO abatement program. Once the technical solution was agreed on and planning level cost estimates were developed, the municipal budget and financial management department began to evaluate the cost impacts of various construction schedules; 15 distinct projects were evaluated in time frames varying from 15 to 25 years. An example is shown in Figure 8-7. Corresponding plots of unit charge and debit service as a percent of median household income were developed as illustrated by Figures 8-8 and 8-9, respectively. These dollars represent the combined costs of the CSO abatement program and the WWTP improvements program.

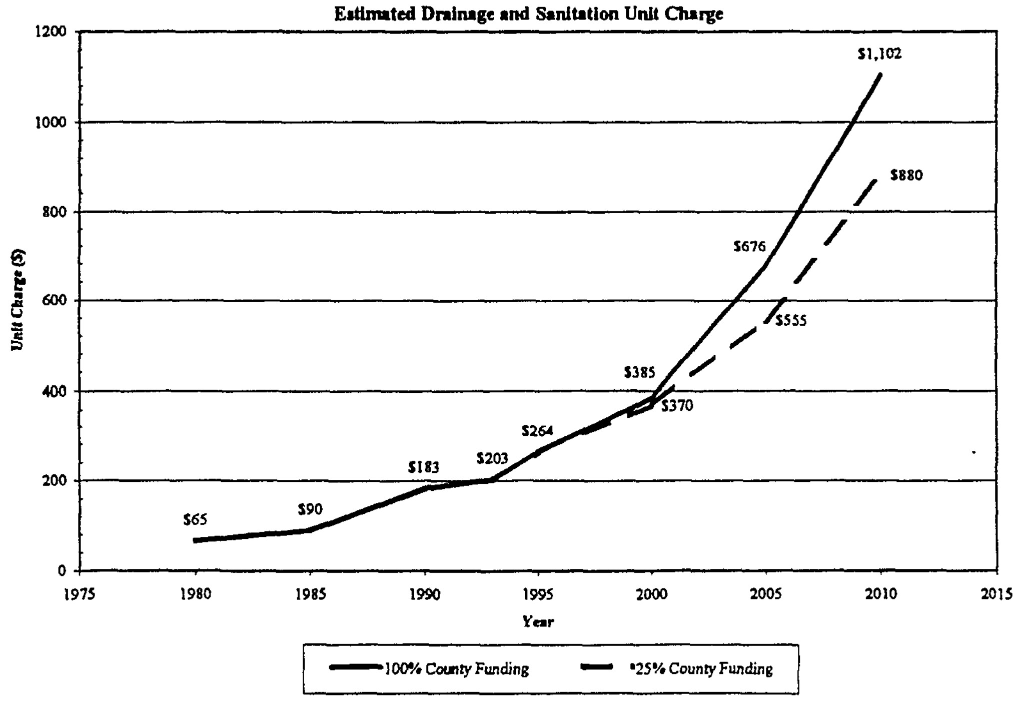

Figure 8-8. Estimated Drainage and Sanitation Unit Charges, Syracuse, N.Y.

R0018325

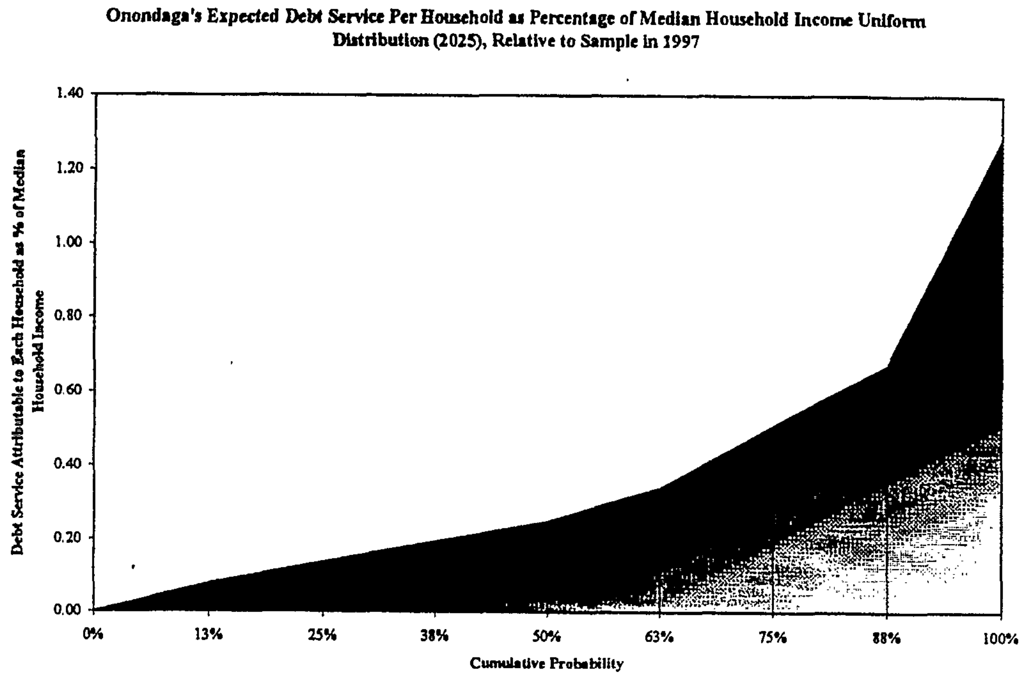

Figure 8-9. Expected Debt per Household as Percentage of Median Income, Onondaga County, N.Y.

Despite the fairly flat growth of population and service expected in the Syracuse area, the debt service fell within the allowable 2% guide stated in the federal CSO control policy. Consequently, the state and U.S. EPA required that a 15-year schedule be implemented. Milestone dates for specific completion projects of construction were incorporated into the Consent Order which was signed in October 1997.

APPENDIX A

NATIONAL CSO CONTROL POLICY

The National CSO Control Policy contains four key principles intended to ensure that CSO controls are cost effective and meet the requirements of the Clean Water Act (CWA) of 1972 and its amendments:

- provide clear levels of control that would be presumed to meet appropriate health and environmental objectives;
- provide sufficient flexibility to CSO communities, especially those that are financially disadvantaged, to consider the site-specific nature of CSOs and to determine the most cost-effective means of reducing pollutants and meeting CWA objectives and requirements;
- allow a phased approach for implementation of CSO controls considering a community's financial capability; and
- review and revise, as appropriate, water quality standards and their implementation procedures when developing LTCPs to reflect the site-specific wet weather impacts of CSOs.

Nine Minimum Controls

1. Proper operation and regular maintenance programs for the sewer system and the CSOs. This control should consist of a program that clearly establishes operation, maintenance, and inspection procedures to ensure that a combined sewer system (CSS) and treatment facility will function in a way to maximize treatment of combined sewage and still comply with NPDES permit limitations.

2. Maximum use of the collection system for storage. This control consists of making relatively simple modifications to the CSS to enable the system to store wet weather flows until downstream sewers and treatment facilities can handle them.

3. Review and modification of pretreatment requirements to ensure that CSO impacts are minimized. The objective of this control is to minimize the impacts of discharges into CSSs from nondomestic sources during wet weather events and to minimize CSO occurrences by modifying inspection, reporting, and oversight procedures within an approved pretreatment program.

4. Maximizing flow to the POTW for treatment. This control entails simple modifications to the CSS and treatment plant to enable as much wet weather flow as possible to reach the treatment plant.

5. Eliminating CSOs during dry weather. This control includes any measures taken to ensure that the CSS does not overflow during dry weather conditions.

6. Controlling solid and floatable materials in CSOs. This control is intended to reduce, if not eliminate visible floatables and solids using relatively simple measures including baffles, screens, racks, booms, and skimmer vessels.

7. Pollution prevention programs to reduce contaminants in CSOs. This control is intended to keep contaminants from entering the CSS and prevent subsequent discharge to receiving waters through street cleaning, public education, solid waste collection, and recycling.

8. Public notification to ensure that the public receives adequate notification of CSO occurrences and CSO impacts. This control is intended to let the public know where outfalls are located, when CSOs occur, what possible health and environmental effects are, and what recreational or commercial activities may be curtailed as a result of CSOs.

9. Monitoring to effectively characterize CSO impacts and the efficacy of CSO controls. This control involves visual inspections and other simple methods to determine the occurrence and apparent impacts of CSOs.

Long Term Control Plan

The LTCP is a comprehensive plan that recognizes the site-specific nature of CSOs and their impacts on receiving waters. The long term planning approach consists of four major elements: system characterization; development and evaluation of alternatives; selection and implementation of controls; and compliance monitoring. A primary objective of the LTCP is to develop and evaluate a reasonable range of CSO control alternatives sufficient to meet water quality standards, including attainment and protection of designated uses on CSO-affected receiving waters. The CSO policy is flexible in allowing a CSO community to select controls that are cost effective and tailored to meet local conditions.

Two general approaches to attaining water quality standards are recognized in the CSO policy. These are the "demonstration" approach and the "presumption" approach. Both approaches provide CSO communities with targets for controls that achieve compliance with the CWA, particularly the protection of designated uses. Under the "demonstration" approach, water quality modeling or other tools are used to demonstrate that predicted CSO discharges resulting from the LTCP would be sufficient to attain water quality standards. The "presumption" approach is based on the premise that a LTCP that meets certain minimum defined performance criteria in terms of expected frequency of overflow or percent capture of the CSO pollutant load would be presumed to provide an adequate level of control to meet the water quality-based requirements of the CWA.

CSO communities are encouraged to meet and coordinate frequently with state water quality standards authorities and NPDES permitting authorities and to engage the general public in the planning process through public participation activities. In particular, developing goals, evaluating alternatives, and considering the local financial impacts of the LTCP should be a collaborative effort among all the participating interests. The developing performance measures or other measures of success to quantify environmental improvements and benefits related to CSO control is also a major element of the LTCP. Because of the site-specific nature of CSSs and CSO impacts, a strong linkage between performance measures and locally defined objectives is essential.

Presumption Approach

This approach allows a community to achieve an adequate level of control to meet the water quality- based requirements of the CWA if one of the following conditions are met.

1. No more than an average of four (4) overflow events per year. The permitting authority may allow up to two additional overflow events per year. An overflow event is one or more overflows from a CSS as a result of a precipitation event that does not receive the minimum treatment specified as:

    - primary clarification (removal of floatation and settleable solids equivalent to primary clarification) and
    - disinfection of effluent to meet water quality standards, including removal of harmful disinfection chemical residuals if feasible.

    Or, if the above is not met:

2. The elimination or capture for treatment of no less than 85 percent by volume of the combined sewage collected on a system-wide annual average basis; or

3. The elimination or removal of no less than the mass of the pollutants identified as causing water quality impairment through the sewer system characterization, monitoring, and modeling effort, for the volumes that would be eliminated or captured for treatment under paragraph 2 above.

Demonstration Approach

The community that undertakes this approach should demonstrate each of the following:

1. The long-term plan is adequate to meet water quality standards (WQS) and protect designated uses, unless uses cannot be met as a result of other pollution sources, e.g., natural background conditions.

2. The CSO discharges remaining after plan implementation will not preclude the attainment of WQS designated uses of the receiving waters or contribute to their impairment. Where these conditions are not met in part because of natural background conditions or other pollutant sources, then wasteload allocations should be used to apportion loads. The total maximum daily load should serve as the basis for such allocations.

3. The long-term plan will provide the maximum pollution reduction benefits reasonably attainable.

4. The plan is designed to allow cost-effective expansion if additional controls are necessary.

Financial Capability Assessments

For CSO abatement, a community's financial capability is particularly important, since there are no clear wet weather standards for most states; the selection of a "design" storm has become a subjective decision based upon cost-benefit relationships. Additionally, other pollutants from the watershed in question may preclude the attainment of the "fishable-swimmable" goals of the CWA.

The policy identifies seven factors to be included in consideration of a community's financial capability, namely:

1. median household income;

2. total annual wastewater and CSO control costs per household as a percent of median household income;

3. overall net debt as a percent of full market property value;

4. property tax revenues as a percent of full market property value;

5. property tax collection rate;

6. bond rating; and

7. unemployment.

The following is an excerpt of the U.S. EPA document, "Draft CSO Guidance on Financial Capability Assessment and Schedule Development," developed by the CSO Partnership (*The CSO Bulletin*, April 1996).

"The CSO Policy provides that implementation schedules for CSO controls may be phased, based in part on a community's financial capability. The Guidance seeks to provide criteria for assessing financial capability and to relate that capability to appropriate compliance schedules. The goal of the guidance is to 'provide general boundaries to aid all parties in negotiating reasonable and effective schedules' for implementing CSO controls.

"The Guidance proposes a two-step approach for calculating economic capability. The first step focuses on the financial impact of current and proposed wastewater and CSO controls on individual households. The second step examines the debt, socioeconomic, and financial condition of a CSO community. The results of both steps are then combined into a 'Financial Capability Matrix' which is used to assess the financial burden attributable to CSO controls and to establish what EPA views as appropriate compliance schedules.

"Step One. This step calculates a Residential Indicator (RI), which is a measure of the CSO community's average cost per household for existing and proposed wastewater treatment and CSO controls, expressed as a percentage of local median household income (MHI). The Guidance proposes to establish three ranges for RIs with RIs of less than one percent MHI characterized as imposing a 'low' financial impact, RIs from one or two percent of MHI imposing a mid-range impact and RIs above two percent of MHI imposing a high impact.

"Step Two. The second step is to consider a community's financial Capability Indicators. EPA specifies six proposed indicators in the Guidance for evaluating community debt, socioeconomic, and financial conditions which affect a community's financial capability to implement CSO controls. The results of the six indicators are used to classify the community's financial capability as 'weak,' 'mid-range,' or 'strong.'

"The results of step one (Residential Indicator) and step two (Financial Capability Indicators) are then combined in a financial Capability Matrix which provides the basis for the permittee and NPDES permitting authority to negotiate an appropriate compliance schedule. The Financial Capability Matrix divides communities into three categories based upon their calculated burden under the Guidance (low, medium, o high), with equal weight given to the Community's RI and Financial Capability Indicators.

"Finally, the Guidance proposes the following general boundaries for compliance schedules based upon a community's calculated burden:

Low burden:	0-5 year compliance schedule
Mid-Range burden:	5-10 year compliance schedule
High burden:	10-15 year compliance schedule

"According to the Guidance, communities in the 'High burden' category may be able to negotiate compliance schedules as long as 20 years.

"The lack of supporting information to explain and justify EPA's selection of the Residential Indicator categories and the Financial Capability Indicator categories will make it difficult to evaluate whether the proposed categories are appropriate for CSO communities nationwide. For example, EPA does not provide any discussion of the number of CSO communities that can be expected to fall into the three categories proposed in the Financial Capability Matrix (low, mid-range, or high burden). Also, it is unclear how EPA arrived at its proposed ranges for the compliance schedules for communities falling with the three categories of financial burden."

MEMORANDUM: IMPLEMENTATION OF THE CSO CONTROL POLICY (REPRINT FROM U.S. EPA — OFFICE OF WATER)

UNITED STATES ENVIRONMENTAL PROTECTION AGENCY
WASHINGTON, D.C. 20460

MAY 19 1998

MEMORANDUM

SUBJECT: Implementation of the CSO Control Policy

FROM: Robert Perciasepe
Assistant Administrator
Office of Water

Bob Perciasepe

Steven A. Herman
Assistant Administrator
Office of Enforcement and Compliance Assurance

TO: Water Management Division Directors, Regions 1-10
Regional Counsels, Regions 1-10
State Directors

The purpose of this memorandum is to discuss implementation of the Combined Sewer Overflow Control Policy (CSO Policy) and identify areas where heightened efforts are necessary.

The Environmental Protection Agency (EPA) published the CSO Policy on April 19, 1994 (59 FR 18688), following a negotiated policy dialogue among representatives from States, environmental groups, municipal organizations, and EPA. The CSO Policy provides for a phased process to bring communities with combined sewer systems into compliance with the technology-based and water quality-based requirements of the Clean Water Act. To date, EPA has released six guidance documents and continues to work with stakeholders to foster implementation of the Policy.

The CSO Policy is now four years old and continues to be recognized as an example of innovation and good government. In principle, EPA and its stakeholders continue to affirm the Policy's key themes, such as permitting flexibility, stakeholder coordination and public participation, financial capability as a factor affecting implementation schedules, and examination of water quality standards as appropriate. In practice, however, many challenges remain, and implementation of the Policy has not met some initial expectations.

Nine Minimum Controls. The CSO Policy's first key milestone was implementation of the nine minimum controls by January 1, 1997. The nine minimum controls are measures that can reduce CSOs and their effects on receiving water quality without requiring significant engineering studies, construction activity, or financial investment. In a November 18, 1996, memorandum to the Regional and State Directors, we communicated the importance of meeting this deadline.

Under the CSO Policy, implementation of the nine minimum controls should become an enforceable obligation through inclusion in an appropriate enforceable mechanism. The Policy describes how the nine minimum controls and other CSO requirements are to be included in National Pollutant Discharge Elimination System (NPDES) permits (renewed permits or reopened and reissued permits) or administrative orders. The November 18, 1996, memorandum reminded NPDES authorities that the approach identified in the CSO Policy — not to seek civil penalties for past CSO violations — would not apply unless the permittee has no discharges during dry weather and meets the objectives and schedules of the CSO Policy, including the January 1, 1997, deadline for implementing the nine minimum controls. By now, every CSO community should be implementing the nine minimum controls, and most NPDES permits should contain measurable, enforceable, and specific conditions requiring implementation of the nine minimum controls, including submittal of appropriate documentation.

Although the January 1, 1997, implementation deadline has passed, our best information from EPA Regions and States indicates that only about 52 percent of CSO communities are currently implementing the nine minimum controls. Approximately another 25 percent have not yet implemented the nine minimum controls but are under an enforceable requirement to do so in the future.

There are several reasons for this. Many communities' permits have not yet been reissued to include the nine minimum controls, and permittees are reluctant to implement the nine minimum controls in the absence of an enforceable requirement. Some States have focused their efforts on requiring long-term control plans or have resisted using enforcement mechanisms as implementation tools. We believe, however, that the nine minimum controls are an essential element of any community's CSO program and that full implementation of the nine minimum controls is crucial to the success of the CSO Policy. The goal of 100 percent implementation remains a high Agency priority. We will continue to track implementation of the nine minimum controls and coordinate with EPA and State enforcement authorities as necessary to foster compliance.

We also stress the need for communities to provide appropriate documentation that they have implemented the nine minimum controls and for NPDES authorities to review this information thoughtfully. To date, although 52 percent of CSO communities have implemented the nine minimum controls, approximately 42 percent have submitted documentation. The Agency does not believe documentation is simply a "paperwork" exercise. Rather, documentation describes the community's comprehensive effort to use the nine minimum controls to reduce the frequency, volume, and impacts of CSOs. Without strong documentation, a CSO community and its permitting authority cannot meaningfully assess the effectiveness of the nine minimum controls and the extent to which additional controls, if any, may be needed.

Long-Term Control Plans. The CSO Policy calls for initial ("Phase I") NPDES permits to require development of a long-term CSO control plan as soon as practicable, but generally within two years after issuance of the permit, Section 308 information request, or enforcement action requiring a plan. The long-term control plan should include measures that provide for compliance with the technology-based and water quality-based requirements of the Clean Water Act, including attainment of water quality standards under either the "presumption approach" or the "demonstration approach." The subsequent ("Phase II") permit should require immediate implementation of the control measures in the long-term control plan. The long-term control plan should include a fixed-date implementation schedule. Requirements for expeditious implementation of the long-term control plan should be placed in an appropriate enforceable mechanism.

Regions and States indicate that approximately 33 percent of CSO communities are moving ahead to implement long-term CSO controls. Approximately another 28 percent are subject to an enforceable requirement to develop a long-term CSO control plan. We do not have adequate information to determine how much of the current CSO planning and control activity is being undertaken consistent with the CSO Policy.

Long-term planning consistent with the CSO Policy is key to the success of local CSO control efforts. We urge Regional and State authorities to work actively with permittees to ensure that long-term control plans address important elements of the CSO Policy such as characterization, monitoring, and modeling of the combined sewer system and receiving water; public participation; evaluation of the cost and performance of alternatives; and coordination with State water quality standards authorities and NPDES authorities. EPA Headquarters will continue to track progress in the development of long-term control plans consistent with the CSO Policy.

Water Quality Standards (WQS). Long-term CSO control plans must ensure that both the technology-based and water quality-based requirements of the CWA are met. With respect to water quality-based requirements, the CSO Policy provides that "[d]evelopment of the long-term plan should be coordinated with the review and appropriate revision of WQS and implementation procedures on CSO-impacted receiving waters to ensure that the long-term controls will be sufficient to meet water quality standards" (59 FR 18694). The CSO Policy places a high priority on eliminating or redirecting CSOs that discharge to sensitive areas such as beach areas and shellfish beds. Remaining overflows must neither cause nor contribute to a violation of WQS.

In locations where uses have been designated without consideration for the wet weather conditions of urban streams, it is appropriate to evaluate the attainability of WQS. The CSO Policy recognizes the States' flexibility to review their WQS and encourages them to define recreational and aquatic life uses more explicitly where appropriate. Such refinements could define, for example, seasonal conditions or a particular size storm event when primary contact recreation would not occur. In making such adjustments to uses, however, States must ensure that downstream uses are protected and that the use is fully protected during other seasons or after the storm event has passed. Furthermore, a use attainability analysis would be required in such cases, since use attainability analyses are required prior to the removal of a designated use or the modification of a use to one requiring less stringent criteria. Such a structured scientific analysis is an appropriate mechanism for determining the attainability of a use. In any case, if a State has a reasonable basis to determine that the current designated use could be attained after implementation of the technology-based controls of the CWA, then the use could not be removed.

We strongly encourage Regions and States to work with permittees to ensure that long-term plans are developed consistent with WQS. We also encourage greater coordination among EPA, States, and permittees in refining designated uses as appropriate in CSO-impacted receiving waters. In many cases the permittee's development of a long-term control plan, and the State's review and revision of WQS, will occur concurrently and interdependently. Site-specific data collected as part of the development of the long-term control plan and data from watershed analyses should assist States in evaluating the adequacy of the long-term control plan to contribute to the attainment of WQS. Such data will also provide important information necessary for determining whether a use is attainable and, where the designated use is not attainable, the appropriateness of a variance or other revision to the applicable WQS. Variances may be appropriate, in limited circumstances on CSO-impacted waters, where the State is uncertain as to whether the WQS can be attained and time is needed for the State to conduct additional analyses on the attainability of the WQS.

Measuring Program Performance. The CSO Policy continues to have a high level of support within EPA and among stakeholder groups. With visibility, of course, comes scrutiny. Understandably, the Policy continues to provoke questions about how well a flexible approach can address a costly and complex environmental issue. In addition, implementation of the CSO Policy is occurring amid public demands that investments in pollution control yield tangible environmental benefits.

Under the Government Performance and Results Act (GPRA), EPA developed a pilot performance plan to track the implementation status of the CSO Policy. Program indicators developed under the performance plan include progress in implementation of the nine minimum controls, development of long-term plans, and reduction in the frequency, volume, and adverse water quality impacts of CSOs. The data base developed to implement the performance plan will continue to provide useful insights into the status of CSO Policy implementation and will be a useful program management tool.

Accountability for the CSO Program is also embodied in the Agency's Strategic Plan under GPRA for the water program. Objectives to be attained by 2005 currently include a 30 percent reduction from 1992 levels in annual point source loadings from CSOs, publicly owned treatment works, and industrial sources. EPA's FY 1998 goal is for 80 percent of CSO communities' permits to be issued consistent with the CSO Policy; for FY 1999, the goal is 100 percent consistency.

We also encourage you to support efforts by CSO communities to develop other, locally defined, indicators of progress in controlling CSOs. Locally defined measures of success can provide meaningful incentives to select and implement CSO controls that not only meet CWA requirements but are cost-effective, tailored to local water quality objectives, and likely to yield results that the public, and specifically rate-payers, will support.

In closing, we urge you to help make the CSO Policy a success. We remind you that implementation of the CSO Policy continues to be a high priority for the Water Program and is among the top program priorities for the Office of Regulatory Enforcement in FY 1998. It is essential that all CSO communities be moving aggressively toward two important goals: full implementation of the nine minimum controls and coordination with NPDES and WQS authorities in the development and implementation of long-term control plans. We welcome continued dialogue among EPA Headquarters, Regional, and State permitting and enforcement authorities on removing any identified impediments to achieving these goals.

If you have questions concerning this memorandum, please contact either Ross Brennan of the Office of Wastewater Management at (202) 260-6928, or John Lyon of the Office of Regulatory Enforcement at (202) 564-4051.

ENFORCEMENT MANAGEMENT SYSTEM — CHAPTER X (REPRINT FROM U.S. EPA — OFFICE OF WATER)

Setting Priorities for Addressing Discharges from Separate Sanitary Sewers

Discharges of raw or diluted sewage from separate sanitary sewers before treatment can cause significant public health and environmental problems. The exposure of the public to these discharges and the potential health and environmental impacts are the primary reasons EPA is developing this additional guidance on these discharges. This document provides a method of setting priorities for regulatory response, and serves as a supplement to the Enforcement Management System guidance (EMS, revised February 27, 1986). As such, this document addresses only those discharges which are in violation of the Clean Water Act. As a general rule, the discharges covered by this guidance constitute a subset of all discharges from separate sanitary sewer systems.

Legal Status

In the context of this document, a "discharge from a separate sanitary sewer system" (or "discharge") is defined as any wastewater (including that combined with rainfall induced infiltration/inflow) which is discharged from a separate sanitary sewer that reaches waters of the United States prior to treatment at a wastewater treatment plant. Some permits have specific requirements for these discharges, others have specific prohibitions under most circumstances, and still other permits are silent on the status of these discharges.

The legal status of any of these discharges is specifically related to the permit language and the circumstances under which the discharge occurs. Many permits authorize these discharges when there are no feasible alternatives, such as when there are circumstances beyond the control of the municipality (similar to the concepts in the bypass regulation at 40 CFR Part 122.41 (m)). Other permits allow these discharges when specific requirements are met, such as effluent limitations and monitoring/reporting.

Most permits require that any non-compliance including overflows be reported at the end of each month with the discharge monitoring report (DMR) submittal. As a minimum, permits generally require that overflow summaries include the date, time, duration, location, estimated volume, cause, as well as any observed environmental impacts, and what actions were taken or are being taken to address the overflow. Most permits also require that any non-compliance including overflows which may endanger health or the environment be reported within 24 hours, and in writing within five days. Examples of overflows which may endanger health or the environment include major line breaks, overflow events which result in fish kills or other significant harm, and overflow events which occur in environmentally sensitive areas.

For a person to be in violation of the Clean Water Act: 1) a person must own, operate, or have substantial control over the conveyance from which the discharge of pollutants occurs, 2) the discharge must be prohibited by a permit, be a violation of the permit language, or not be authorized by a permit, and 3) the discharge must reach waters of the United States. In addition, discharges that do not reach waters of the United States may nevertheless be in violation of Clean Water Act permit requirements, such as those requiring proper operation and maintenance (O&M), or may be in violation of state law.

Statement of Principles

The following six principles should be considered as EPA Regions and States set priorities for addressing violating discharges from separate sanitary sewers:

1. All discharges (wet weather or dry weather) which cause or contribute significantly to water quality or public health problems (such as a discharge to a public drinking water supply) should be addressed as soon as physically and financially possible. Other discharges may, if appropriate, be addressed in the context of watershed/basin plans (in conjunction with state or federal NPDES authorities).

2. Discharges which occur in high public use or public access areas and thus expose the public to discharges of raw sewage (i.e., discharges which occur in residential or business areas, near or within parks or recreation areas, etc.) should be addressed as soon as physically and financially possible.

3. Dry weather discharges should be addressed as soon as physically and financially possible.

4. Discharges due to inadequate operation and routine maintenance should be addressed as soon as possible. (Physical and financial considerations should be taken into account only in cases where overflow remedies are capital intensive.)

5. Discharges which could be addressed through a comprehensive preventive maintenance program or with minor capital investment should be addressed as soon as physically and financially possible.

6. With respect to principles 1 through 5 above, schedules of compliance which require significant capital investments should take into account the financial capabilities of the specific municipality, as well as any procedures required by state and local law for publicly owned facilities in planning, design, bid, award, and construction. (See later sections on Schedules).

Stormwater Regulations

Phase I: The Municipal Stormwater Program

Under the WQA of 1987, U.S. EPA must issue NPDES permits to large- and medium-sized municipal separate storm sewer systems (MS4s). Under the statute, the permits:

- may be issued on a system or jurisdiction-wide basis;
- shall include a requirement to effectively prohibit non-stormwater discharges into the storm sewers;
- must apply a new standard to " require controls to reduce the discharge of pollutants to the maximum extent practicable, including management practices, control techniques and design and engineering methods" . 33 U.S.C. § 1342(p)(3)(B).

Large and medium MS4s are defined by EPA as those:

- located in an incorporated place with population of (i) 100,000 or more but less than 250,000 (medium MS4s) or (ii) 250,000 or more (large MS4s);
- located in counties with a population of 100,000 or more but less than 250,000 (medium MS4s) or located in counties with a population of 250,000 or more (large MS4s), excepting, in both instances, systems located in the incorporated places, townships or towns within such counties; or
- designated by EPA as part of a large or medium MS4 due to the interrelationship between the discharges of the designated MS4 and a large or medium MS4.

EPA has listed the jurisdictions that are covered under the definitions of medium and large MS4s in the permit application rule, and in Appendixes F, G, H and I to 40 C.F.R. Part 122. 55 Fed. Reg. 48073-74. The listing was based on the 1980 census. As data from the 1990 census becomes available, EPA will revise the list.

To date, EPA has only issued a rule with permit application requirements for MS4s. 55 Fed. Reg. 47990 (November 16, 1990). Permit applications for MS4s have two parts. Part 1 was due November 18, 1991 for large MS4s and May 18, 1992 for medium MS4s. 40 C.F.R. § 122.26(e)(3) and (4). Part 2 was due November 16, 1992 for large MS4s and May 17, 1993 for medium MS4s. Id. EPA was supposed to have issued final permits to large MS4s by October 1, 1993 and to medium MS4s by May 17, 1994. 40 C.F.R. § 122.26(e)(7).

The regulations define " municipal separate stormwater" as a conveyance or system of conveyances (including roads with drainage systems, municipal streets, catch basins, curbs, gutters, ditches, manmade channels or storm drains) owned or operated by a state or local government entity and is designed or used for collecting or conveying stormwater that is not a combined sewer or part of a POTW. 40 C.F.R. § 122.26(b)(8). Operators of combined sewer systems (systems designed as both sanitary and storm sewers) or POTWs are excluded from the permit application requirement because these systems should already be permitted under existing NPDES programs.

Operators of medium and large MS4s may submit a jurisdiction or systemwide permit application. 40 C.F.R. § 122.26(d). Where more than one public entity owns or operates a municipal separate storm sewer system within a geographic area (including adjacent or interconnected MS4s), such operators may be co-applicants to the same application.

Part 1 of the MS4 permit application must include the following elements:

- General Information. Information about the permit applicant or co-applicant.
- Legal Authority. A description of the legal authority to control discharges to the MS4. If existing legal authority is inadequate to control pollutants in stormwater discharges, a plan to augment existing legal authority must be submitted.
- Source Identification. Detailed identification of all discharges to the MS4, including a topographic map, location of municipal outfalls, projected growth, location of structural controls, and location of waste disposal facilities.
- Discharge Characterization. Information characterizing the nature of system discharges including existing quantitative data, the results of field screening analysis to detect illicit discharges, identification of receiving waters, a plan to characterize discharges from the system, and a plan to obtain representative data.
- Management Programs. A description of the existing management programs to control the discharge of pollutants from the system, including a description of existing structural and non-structural controls.
- Fiscal Resources. A description of the financial resources currently available to complete Part 2 of the application.

Part 2 of the permit application provides information to supplement Part 1 and gives municipalities an opportunity to propose a program of structural and non-structural measures to control the discharge of pollutants" to the maximum extent practicable." 55 Fed. Reg. 48045. Part 2 requires:

- Satisfaction of the Criteria. A demonstration that the legal authority of the permit applicant to control discharges of pollutants to the system satisfies the criteria set out in 40 C.F.R. § 122.26(d)(2)(i).
- Supplementation of the Source Identification Information Submitted Under Part 1. This includes identification of all " major outfalls" (a defined term) and an industrial activity description of each facility which may discharge stormwater associated with industrial activity to the system.
- Characterization Data. Discharge characterization data from between 5 and 10 outfalls or field screening points designated by EPA or the state as representative of commercial, residential and industrial land use activities based on Part 1 information. The data shall also include estimates of the annual pollutant load of the cumulative discharges to waters of the United States, a proposed schedule to provide seasonal pollutant load and event mean concentration data for any constituent detected in any required sampling, and a proposed monitoring program for representative data collection for the term of the permit.
- Proposed Management Program. A proposed stormwater management program to reduce the discharge of pollutants to the maximum extent practicable.
- Assessment of Controls. Estimated reductions in loadings of pollutants from system discharges resulting from the municipal stormwater management program.
- Fiscal Analysis. An analysis of capital, operation and maintenance expenditures, by fiscal year for each year of the permit term, to complete the characterization data requirements and stormwater management program requirements.

The centerpiece of the Part 2 application is the proposed stormwater management plan. This plan's purpose is to reduce the discharge of pollutants to the "maximum extent practicable using management practices, control techniques, and system design and engineering methods" 40 C.F.R. § 122.26(d)(2)(iv). Under the regulations, proposed programs will be considered by the permit writer when developing permit conditions. Id. The management plan allows the permittee to propose, in the first instance, the components of a program it believes are appropriate for preventing or controlling the discharge of pollutants. 55 Fed. Reg. 48052.

Stormwater management programs are to be based on:

- a description of structural and source control measures to reduce pollutants from runoff from commercial and residential areas;
- a description of a program, including a schedule, to detect and remove or permit illicit discharges and improper disposal in the system;
- a program to monitor and control pollutants in stormwater from municipal landfills, hazardous waste treatment, disposal and recovery facilities, industrial facilities subject to section 313 of SARA Title III, and other municipal facilities identified as contributing a substantial pollutant loading to the system; and
- a program to implement and maintain structural and non-structural best management practices to reduce pollutants from construction sites.

The stormwater management program must address illicit discharges to the system. The regulations define illicit discharges as any discharge to an MS4 that is not composed entirely of stormwater, except discharges pursuant to an NPDES permit and discharges resulting from fire fighting activities. 40 C.F.R. § 122.26(b)(2). However, as noted in the requirements for a stormwater management plan, not all such flows must be prohibited. Certain types of flows such as landscape irrigation, groundwater infiltration, air conditioning condensate, lawn watering, and street wash waters only need to be prohibited when such flows are identified as significant sources of pollutants. 55 Fed. Reg. 48037.

Phase II: Stormwater Regulations

The 1987 Water Quality Act required EPA to establish a two-phased approach for the control of stormwater discharges. Phase I consists primarily of permitting stormwater discharge associated with industrial activity or stormwater discharges from large or medium municipal separate storm sewers. Phase II covers all stormwater discharges not addressed under Phase I and could include all other municipalities, as well as light industrial and commercial activities.

CWA Section 402(p)(5) requires EPA to conduct two studies on Phase II stormwater discharges. The first study will identify those classes of discharges that may be addressed in Phase II and evaluate the nature and extent of pollutants in such discharges. The second study will evaluate procedures and methods to control Phase II stormwater discharges to the extent necessary to mitigate impacts on water quality. EPA has requested public comment on ways to implement the second phase of the stormwater permitting program for sources and activities not regulated under Phase I. 57 Fed. Reg. 41344 (September 4, 1993). EPA specifically requested comment on a variety of options that range from comprehensive permitting of all municipal, light, industrial, and commercial activities that generate stormwater runoff to little or no NPDES permitting of Phase II sources. EPA's final approach to the Phase II stormwater permit program will be developed in the near future.

Summary of Current Statewide SW Management Programs

The following is a summary of some of the current statewide stormwater management programs gathered from late 1997 to mid 1998:

Alabama

Alabama has NPDES-delegated authority from the U.S. EPA Alabama Department of Environmental Management (ADEM) issues general permits through its Industrial Branch as well as its Mining and Nonpoint Source Section. ADEM requires municipal stormwater permits for Birmingham, Huntsville, Montgomery, and Mobile. Construction site sedimentation and erosion control regulations are implemented by the Mining and Nonpoint Source Section of ADEM. Along the Gulf of Mexico construction site discharges and other industrial operations are regulated by the Coastal Zone Management Program (Thompson). Local communities can also provide additional requirements. As an example, Mobile has experienced flooding problems for many years. An engineering study identified 92 separate stormwater drainage projects having an estimated cost of about $100 million (Steeves and Chapman 1988). This study recommended that a stormwater management utility be established within the city's Department of Public Works. In 1987, after many public meetings, Mobile adopted a water management plan and approved the concept of a user's fee to pay for these needed stormwater drainage improvements. Besides flood control objectives, this utility would also monitor water quality and plan for future water quality improvement projects. The annual operations and maintenance budget for this utility was estimated to be about $3.5 million. The estimated fees to pay for this service would be about $3 per household per month.

Alaska

Alaska does not have NPDES permitting authority. However, permits issued by the USEPA become state permits once the Alaska Department of Environmental Conservation demonstrates its ability to issue and enforce these permits. Aside from the basic EPA stormwater permit requirements, the state of Alaska also requires a "qualified personnel provided by the discharger" to inspect certain areas. These areas include disturbed areas of construction sites that have not been stabilized, storage areas exposed to precipitation, structural control measures, and locations of entrance and exit to the site. These designated areas must be inspected within 24 hours of any rain event greater than 0.5 inches.

Arizona

Stormwater permits in Arizona are issued by the USEPA, as the state does not have permitting authority. Therefore the stormwater permit requirements are nearly identical to those in the general nationwide program, with a few additional requirements. Arizona requires a secondary containment system able to hold the entire contents of *the largest single tank plus adequate freeboard to accommodate* a 25-year, 24-hour rain event for industries storing chemicals defined as priority under SARA. Best management practices have been outlined with regard to runoff control. These BMPs are currently required for agricultural operations using nitrogen fertilizers. Other sources of runoff, such as urban stormwater runoff, resource extraction, grazing, and silviculture, will soon be subject to BMP compliance as well. Several cities in Arizona have additional regulations to prevent pollution from stormwater discharge. Examples are the cities of Phoenix, Tempe, and Mesa, which all require retention basins to control construction site runoff.

Arkansas

Arkansas has delegated stormwater permitting authority, meaning it issues and regulates its own permits based on the guidelines set forth by the EPA. In addition to these guidelines, the state has established some numeric effluent limitations. For example, coal pile runoff should not exceed concentrations of 50 mg/L maximum suspended solids and pH must be within 6-9. The state has determined parameters which must be measured by permittees as well. Primary metal industries and wood treatment facilities must sample for BOD5, and land disposal facilities must test for ammonia and nitrate plus nitrite nitrogen.

The Arkansas Department of Pollution Control and Ecology publishes guidance for detention ponds and erosion control. If a study of a proposed development indicates flooding problems, a development permit would be denied without stormwater control. Examples of acceptable controls are onsite storage, offsite storage, or an improved drainage system. The method used for stormwater detention is the modified rational hydrograph method. This guidance includes tables and graphs for determining time of concentration and rain intensity. The required volume of detention is evaluated according to the following methods:

Volume of detention for projects of less than 50 acres shall be evaluated by the "simplified volume formula." Volume of detention for projects 50 acres or greater but less than 200 acres may be evaluated either by the "simplified volume formula" or the "modified rational hydrograph method." For projects larger than 200 acres, the owner's engineer shall submit a proposed method of evaluation for sizing the retention basin or detention basin to the Department Public Works. The method will be evaluated for professional acceptance, applicability, and reliability by the city engineer. No detailed review for projects larger than 200 acres will be made before the method of evaluating the retention or detention basin is approved. Other analytical methods of evaluating volume of detention require approval by the city engineer.

California

California is an NPDES-delegated state with general permitting authority; however, the state has instituted a fairly large number of requirements stricter than those outlined by the EPA. In contrast to the EPA permit, California has established that the primary activity at a facility does not necessarily determine the category of industrial activity at a location. Each area of the facility is treated differently. For example, at a school, although its primary activity is education, the vehicle service area is nevertheless treated as a transportation area. Whether the activity is primary or auxiliary is of no concern under the regulations; each use is considered individually under the permit. Strict guidelines are also in effect as to sources considered to be point sources. Sheet flow from a parking lot is considered to be a point source requiring a permit. This is not the case in most states. Monitoring programs are also stricter than those in effect nationally; guidelines for establishing these programs and the objectives they must accomplish are clearly outlined in the regulations. Sampling must include pH, total suspended solids, specific conductance, and total organic carbon, as well as toxic chemicals specific to an individual site. The state has determined that it is not feasible at this time to establish numeric limits for those parameters not listed under a specific industry. Construction site permits require erosion and sediment controls, post-construction stormwater controls, and inspection of the site before and after storm events to evaluate the effectiveness of the measures taken.

Colorado

Colorado issues its own stormwater permits as an NPDES-delegated state. The state has established some numeric effluent limitations. Concentrations of pollutants are limited for the following industries: phosphate manufacturing, fertilizer manufacturing, petroleum refining, cement manufacturing, and coal pile runoff. Construction sites having stormwater permits must be inspected every 14 days and after any precipitation or snowmelt event that causes surface runoff. Coal mining permits establish specific numeric limits for effluents at active and post-mining outfalls. In addition to these limits, control measures also govern drainage control, subsidence, acid runoff control, grading, and other reclamation activities. Any drainage from coal mines must flow into a treatment pond, which is then treated as a point source discharge. In order to obtain a municipal stormwater permit, an area must first establish a record of all stormwater outfalls requiring a lot of monitoring. Secondly, a stormwater management program must be established. Ben Urbonas of the City of Denver, at a 1987 Maryland training program, reported that simple peak runoff rate controls were not adequately protecting Denver's streams. Urbanization increased flooding flow rates by about two times in the Denver area, but the critical pollutant carrying flows associated with common storms were increased by several hundred times. Denver then began concentrating on the use of on-site detention, along with sand filters coupled to extended detention facilities, to better control stormwater quality.

Connecticut

NPDES permitting authority has been delegated to the state of Connecticut by EPA. Permit guidelines have been made more stringent for some specific permits. Industrial sites must have additional means by which to store potentially hazardous materials and measures must be made so that chemicals are stored under a roof to minimize stormwater contamination. Salt storage piles must follow the same general guidelines. Monitoring must be done for a range of pollutants three times a year. Acute biomonitoring tests must be conducted yearly for a large number of permittees. Also, industrial stormwater permits disallow visible floatables including scum, except for those naturally occurring. Construction permits, too, have a relatively large number of additional requirements. Sediment basins must accommodate drainage areas greater than 5 acres of disturbed soil; full descriptions of measures to be taken to eliminate or reduce stormwater runoff when construction is finished must be included; permittees need to install stormwater management programs that will remove 80% of total suspended solids from stormwater; and velocity dissipation devices are also required.

Delaware

Delaware is an NPDES-delegated permitting state, following for the most part the general guidelines set forth by EPA. The state has established additional regulations to address stormwater runoff from construction activities. No more than 20 acres of a single development may be disturbed at a time, and any site that is not worked for more than 14 days must be stabilized. In new developments, stormwater management measures are required. Permanent measures must remove 80% of the total suspended solids for the site and be capable of storing runoff from storms up to 100 years. Acceptable BMPs are detention ponds, retention ponds, or sand filter systems. The method encouraged by the state is the development of wetlands to manage the stormwater.

District of Columbia

The District of Columbia does not have NPDES permitting authority and therefore permits for this region are issued by EPA. It follows that this region's regulations are nearly identical to those enforced nationally. However, there have been some additional restrictions put on industrial dischargers. A numeric limit of 50 mg/L total suspended solids has been set for effluent consisting entirely of coal pile runoff. It is unlawful to meet this limit by merely diluting the runoff with other flows, such as stormwater. Values for pH from coal runoff must fall between 6 and 8.5. In the Chesapeake Bay drainage, industrial dischargers must provide control measures to achieve a 40% reduction in nitrogen and phosphorous loads entering the waters of the bay.

Florida

Florida has had stormwater regulations since 1979 (Livingston 1988). The initial stormwater rule was revised in 1982 and requires a stormwater permit for all new stormwater discharges and for modifications to existing discharges that were changed to increase flow or pollutant loadings. This state permit program had to be implemented within the framework of the Clean Water Act. Required best management practices must be designed according to site-specific conditions and are to be monitored to ensure correct performance. If the monitoring indicates poor performance, the controls must be corrected.

Controls that may be required for specific projects include grass drainage swales, percolation ponds, wet detention ponds with filtration, and wetland treatment. Florida has encouraged innovative control designs that promote multiple uses and can be located on city-owned property. Examples of recent innovative controls include the construction of a spreader swale that causes stormwater to overflow onto a city park for percolation. Existing lakes are also being modified to enhance their stormwater control capabilities.

Florida is a state with NPDES permitting authority. Additional regulations have been placed on several industries. For example, SWP3 site descriptions for construction sites must include rational method estimates of runoff coefficients for before, during, and after the construction project. Post- construction controls are to be designed to remove at least 80% of the average annual pollutant loads from a given site that has discharge flows into outstanding Florida waters. These controls may include stormwater detention structures, retention structures, the use of vegetated swales, or other such similar measures. Velocity dissipation devices must be employed to supply non-erosive outfall discharges. The main goal of these stipulations is to "equalize pre and post development stormwater peak discharge rates and volumes." The state has stormwater management programs at the state, watershed and local level. In 70 communities in the state, stormwater utilities have been set up and financed by local user fees. Charges are applied based on parcel size and proportion of impervious area to natural area.

Georgia

The Georgia Erosion and Sediment Control Act of 1975 requires that a permit be obtained for many land disturbing activities. These permits examine specific development and erosion control plans but were not required to specifically address stormwater quality controls.

Local governments can adopt ordinances to enforce this law, but the Environmental Protection Division of the Georgia Department of Natural Resources will have permitting and enforcement responsibilities if no local regulations are passed. However, local review of erosion control plans by the regional Soil and Water Conservation District must be provided. The Natural Resources Conservation Service (NRCS) is commonly asked to provide technical assistance in these reviews..Georgia erosion control plans are prepared with little specific guidance from the Erosion and Sediment Control Act and therefore rely on close working relationships with the local NRCS offices.

Georgia is a permitting state under the NPDES program. The major difference in Georgia's stormwater regulation is the addition of the Georgia Erosion and Sedimentation Act of 1975. This act requires a permit for any land disturbing activity larger than 1.1 acres.

Hawaii

Hawaii has NPDES-delegated permitting authority. All permittees in this state must comply with the state's basic water quality criteria, which lists prohibited substances. Examples of these are oil, materials that will form objectionable sludge, substances that will affect the taste or odor of water, pathogenic organisms, and others. Discharges are further restricted as to the specific concentrations allowed. They can not contain pollutants in 24-hour average concentrations greater than the values obtained by multiplying the minimum dilution by the applicable standards, and non-carcinogenic pollutants in 30-day average concentrations. For construction sites, BMP plans must be implemented to control construction runoff; these controls must be checked weekly during dry periods and within 24 hours after any rainfall of 0.5 inches or greater. Pre-construction groundcover may not be disturbed more than 20 days before construction begins. Temporary soil erosion measures must be used where construction will continue for 30 days or more. Measures must be taken to ensure that runoff does not cause erosion. Examples of these measures are: runoff must be discharged through a lined channel or pipe; and "all surface water" flowing toward a construction area should be diverted. Muddy waters that have been pumped from a construction site must be held in a settling basin and treated before being released. In addition to the state regulations, many local city and county governments have additional regulations for controlling stormwater pollution.

Monitoring requirements are outlined for industrial dischargers. Stormwater pollution control plans (SWPCPs) must be developed and implemented by industrial dischargers. These SWPCPs parallel EPA's baseline SWPCPs. Hawaii requires a secondary containment system for industries handling chemicals defined as priority under SARA.

Idaho

Idaho does not have NPDES permitting authority; its permits are issued by EPA Region 10. The state has an additional voluntary program for controlling agricultural nonpoint source pollution. Idaho has additional regulations for runoff from silvicultural and mining sites. The following tables on pages E-5 and E-6 "summarizes the current regulations for storm water pollution control" in Idaho.

Illinois

Illinois has NPDES delegated permitting authority from U.S. EPA. The Illinois EPA has general permitting requirements similar to the EPA's baseline general permit for the following: industrial dischargers, stormwater pollution prevention plans (SPW3), and construction sites disturbing 5 acres or more of land. Individual municipalities have provisions in their building codes to regulate construction site erosion. The state of Illinois does not regulate detention ponds used for flow attenuation purposes. Those facilities are regulated by some Illinois counties. The Illinois EPA publishes the Illinois Urban Manual which includes soil conservation service conservation practice standards "Impoundment Structure – Full Flow" and "Impoundment Structure – Routed." This agency also distributes U.S. EPA publication, Storm Water Management for Construction Activities: Developing Pollution Prevention Plans and Best Management Practices.

Land Use Activity	Agency of Local Function	Permit, Approved Process, or Authority	Type of Construction
Plan Review			
Storm Water Pollution Prevention Plan Review (optional at local level)	U.S. Environmental Protection Agency (EPA)	National Pollutant Discharge Elimination System (NPDES) discharge permits	industrial, commercial and residential over 5 acres
Drainage Plan review	Local public works or building department	Consult local authority	commercial, residential
Storm Water Discharges			
To a right-of-way	Local or county highway district	Consult local authority	industrial, commercial, residential
To a natural waterway	EPA and/or local/watershed-based authority	NPDES discharge permit	industrial, commercial, residential
To a privately owned canal or drain	Local canal or drainage district or EPA	Permission from local canal company or drainage district, NPDES discharge permit	industrial, commercial, residential
To a Bureau of Reclamation (BOR) canal	BOR, EPA	Permission from BOR, NPDES discharge permit	industrial, commercial, residential
From selected industrial facilities	EPA	NPDES stormwater discharge permit	Industrial
Storm Water Disposal			
To subsurface through an injection well	Idaho Department of Water Resources (IDWR) regional office	Underground Injection Control (UIC) Program	Industrial, commercial, residential

Indiana

Indiana has NPDES-delegated general permitting authority from EPA. Indiana issues general stormwater permits for industrial dischargers and construction sites disturbing 5 acres or more of land. IDEM (Indiana Department of Environmental Management) also regulates stormwater runoff from certain industries using NPDES wastewater permits. Examples of these industries would include the steel and coal mining industries. There are no state level requirements for stormwater (only) detention ponds. A facility is free to build one if and how it chooses. Sometimes to control flooding at the local level, there are requirements for stormwater detention. If a pond is going to receive wastewater in addition to stormwater (i.e., process wastewater) then it would be considered a water pollution treatment/control facility, and there are criteria that must be met.

Iowa

Iowa has NPDES-delegated permitting authority. State regulations dictate that facilities in sensitive watersheds that contribute to the water quality problems of the area must follow more stringent guidelines. Coal pile runoff is subject to numeric limits of less than 50 mg/L total suspended solids, and pH must be between 6 and 9. The state has also passed sedimentation and erosion regulations for agricultural and construction sites. These laws are enforced on a complaint-driven basis and can lead to an order to undertake corrective action.

Site Preparation/Construction			
All new development/ redevelopment	Local public works or building department	Local or county ordinance(s)	commercial, residential
Construction over 5 acres	EPA	NPDES stormwater permit	industrial, commercial, residential
Development project potentially affecting an existing highway	Idaho Transportation Department, local or county highway district	Idaho Code, Title 18, Chapter 39, Section 7-8	industrial, commercial, residential
Development project potentially affecting an existing drainage facility	Local public works or building department, canal company, drainage district	Local or county ordinance(s)	industrial, commercial, residential
Dewatering			
Discharges to right-of-way	Local or county highway district	Consult local authority	industrial, commercial, residential
Discharge to a privately-owned canal or drain	Local canal company, Drainage district	Permission from canal company or drainage district, NPDES discharge permit	industrial, commercial, residential
Other Permits			
Stream Channel Alteration	IDWR	Stream Channel Alteration Permit	industrial, commercial, residential
Filling of wetlands, other natural waterways of the U.S.	U.S. Army Corps of Engineers 343-0671	404 (dredge and fill) permit	industrial, commercial, residential

Kansas

NPDES permitting authority has been delegated to the state of Kansas by EPA. The Kansas Department of Health and Environment (KDHE) administers the NPDES program which follows the EPA's baseline general permit with additional requirements for conforming to water quality standards established by the state. Construction site permitees are required to prepare stormwater pollution prevention plans (SPW3s). However, industrial stormwater dischargers are not required to develop SPW3s. A sediment basin is required for construction sites were 10 or more acres of land are disturbed at one time. The basin will provide at least 3,600 cubic feet of storage per acre drained, unless the flows are diverted around both the disturbed area and the sediment basin. KDHE has a nonpoint source pollution program and the Department of Agriculture has statewide authority to develop pesticide management areas. One of these has been instituted for the area over the Delaware River.

Kentucky

Kentucky is another state with NPDES delegating authority. In Kentucky, this program falls under the Kentucky Pollution Discharge Elimination System (KPDES) permit program administered by the Kentucky Division of Water. This program applies to construction sites that will disturb 5 acres or more of land and other industrial facilities. Required BMPs for industrial dischargers are similar to EPA's baseline general permit. Construction site permits suggest BMPs that are baseline and are mostly voluntary. However, mandatory requirements at local municipality levels are required to be included and implemented.

Louisiana

Louisiana is an NPDES-delegated state with the authority to issue its own discharge permits. In addition to the guidelines set forth by EPA, Louisiana has implemented some supplementary standards. Numeric limits have been set for industrial dischargers, limiting the amount of total organic carbon that may be discharged to 50 mg/L and oil and grease discharges are limited to 15 mg/L. Oil and gas exploration activities have standards for COD (daily max 100 mg/L), total organic carbon (50mg/L), and oil and grease (15 mg/L). These activities are also limited in the amount of chlorides they may discharge into brackish waters. Facilities covered by industrial permits must have a stormwater pollution prevention plan that outlines how numeric limits will be achieved. This plan must also identify potential pollution sources and describe the practices that will reduce pollution and fulfill permit requirements. Louisiana has also developed state stormwater regulations that require a Louisiana Water Pollution Discharge System permit if the potential for water contamination exists, or large volumes of stormwater will be discharged, or in areas where industrial materials are stored. Coastal areas are also of great concern and are therefore subject to additional regulations. Projects within coastal areas must be designed to avoid discharge of nutrients into coastal waters, and to prevent the alteration of oxygen concentration. Development may not damage streams, wetlands, or other features of the environment, and must attempt to avoid the destructive discharges of sediment, pathogens, or toxic substance and to prevent reductions in the productivity of the waters. Attention must also be paid to dissolved oxygen content and heavy metals.

Maine

Maine does not have NPDES permitting authority; therefore its permits are issued by EPA Region 1. The program requirements are similar to EPA's baseline; however, the Maine Department of Environmental Protection (DEP) Bureau of Land and Water Quality wrote the Natural Resources Protection Act that imposes additional regulations intended to protect the quality of the receiving water. Under this act, nearly all types of water bodies, as well as dunes, fragile mountain areas, wildlife habitats, and wetlands are protected through regulations covering activities of concern. Permits are required when the soil will be altered, or discharges (including fill) may be introduced into these areas. Maine's Stormwater Management Law requires construction permits for proposed projects in the direct watershed of a water body most at risk with 20,000 square feet or more impervious area, or in any watershed with 1 acre or more of impervious area or 5 acres or more of disturbed area. This law contains rule standards regarding construction site stormwater quantity and quality. The peak flow of stormwater must not exceed the peak flow prior to construction and does not increase the peak flow of the receiving waters. To protect the quality of the receiving waters three standards are contained in the rule: total suspended solids (TSS), phosphorous, and basic stabilization. The table on the following page is a summary of these standards.

Maryland

Maryland enacted its first statewide erosion control legislation in 1970 (McElroy and Halka 1985). This initial legislation required an erosion control plan before a building permit was granted. It also required that all Maryland cities and counties adopt grading and sediment control ordinances acceptable to the Maryland Water Resources Administration. After ten years experience with this legislation, it was deemed ineffective because of the lack of consistency in local ordinances, inadequate local administrative commitment, inadequate field inspections, and inadequate enforcement processes. It was concluded that most of the communities did not have the necessary financial resources to adequately fund the program. Therefore, several changes were made to the legislation. As of 1978, all project engineers or foremen in charge of onsite clearing were required to attend a state training program. In 1984, all inspection and enforcement operations were assumed by the state and the inspection staff was increased to 34 people.

The objective of the Maryland stormwater program was to maintain as nearly as possible natural runoff characteristics. Infiltration and detention facilities are important control practices used to meet this objective. The state found that a more comprehensive approach was needed to control stormwater runoff than was provided with a peak flow criterion alone. It therefore gave consideration to volume reduction, low flow augmentation, water quality control, and ecological protection.

Maryland prepared a model stormwater ordinance in 1985 for consideration by local governments. Because of its involvement in ongoing efforts to improve water quality in the Chesapeake Bay, Maryland is also retrofitting stormwater controls in existing developed areas. The state's nonpoint pollution control program also includes agricultural sources, shoreline protection, retention of existing forestland, providing conservation easements, controlling dredging and fill projects, controlling mining area runoff, and repairing failing septic tanks.

NPDES permits are issued through the state. Releases of oil and other hazardous substances must be prevented or minimized in stormwater discharges. The state has also established a sediment and erosion control

Project Location/Type	Standards
Watershed of a lake not most at risk. Project with <3 acres of impervious area or £ 5 acres of disturbed area	Basic Stabilization Standard
Watershed of a lake most at risk (severely blooming lake)	Basic Stabilization Standard and Phosphorous Standard
Watershed of a lake most at risk (not severely blooming lake). Project with ≥ 3 acres of disturbed area	Basic Stabilization Standard and Phosphorous Standard
Watershed of a lake most at risk (not severely blooming lake). Project with <3 acres of impervious area and <5 acres of disturbed area	Basic Stabilization Standard and 80% TSS Standard or Basic Stabilization Standard and Phosphorous Standard
Direct watershed of a lake other than a lake most at risk and project with > 3 acres of impervious area	Basic Stabilization Standard and Sliding Scale TSS Standard or Basic Stabilization Standard and Phosphorous Standard (may be waived by DEP)
Direct watershed of a lake other than a lake most at risk and project with ≥5 acres of disturbed area and <3 acres impervious area	Basic Stabilization Standard and Phosphorous Standard
Direct watershed of a coastal wetland most at risk	Sliding Scale TSS Standard
Watershed of a river, stream, or brook most at risk and the project drains to the water body at or above a public water supply intake	Basic Stabilization Standard and Sliding Scale TSS Standard
Watershed or a river, stream, or brook identified as a sensitive or threatened area and drains to the water body at or within two miles above a public water supply intake	Basic Stabilization Standard

Source: *A Developer's Guide to the Maine Stormwater Management Law (Organized Areas)*

program for implementation at construction sites, which includes requirements for runoff controls. Stormwater management is a requirement at construction sites both during and after construction activity. Developers must implement runoff controls for 2- and 10-year storm events that will restrict the flow from exceeding the pre-development level. A list of recommended BMPs is provided by the state, with the most preferred being infiltration devices, followed by vegetative swales, retention ponds, and detention ponds.

Massachusetts

Permits in Massachusetts are issued by EPA as the state does not have permitting authority. It does however impose some state-specific regulations on the permits. New or increased stormwater discharges to coastal or outstanding resource waters are ineligible for permits. In order to minimize erosion, outfall pipes must be set back from receiving waters whenever the discharges are increased, or the system altered in any way. BMPs are also outlined for use in stormwater management in the state, and the best practical method of treatment must be employed in maintaining the goals of the program.

Michigan

The Michigan Environmental Protection Act of 1970 imposed a duty on all governmental agencies and individuals to prevent and minimize water pollution while carrying on normal activities (Dean 1981). A number of

Michigan court cases thereafter determined that local governments had the responsibility to consider the environmental effects of new subdivision developments, including stormwater effects. Previously, the Michigan Subdivision Control Act of 1967 required local drain commissioners to review subdivision plat proposals only to assure adequate drainage.

A number of county drainage laws in Michigan now also affect stormwater quality. As an example, Oakland County prefers the use of infiltration of stormwater in wetlands, lowlands, and depressions to the use of dry detention basins in providing drainage control. Infiltration can have a positive effect on preventing surface water quality degradation caused by stormwater discharges, while dry detention ponds have little stormwater quality benefit. In addition, almost all of the 35 Oakland County local governments encourage the use of swales and other on-site controls. Wet detention ponds are also used when necessary. However, many local governments are concerned by the lack of maintenance of detention facilities and therefore discourage their use.

Michigan issues its own permits under the delegated authority of EPA. Of particular note is Michigan's requirement for certification of stormwater operators. Each industrial facility with a general permit must have treatment and control measures, and these must be carried out by a certified individual. A list of requirements are also provided for applicants for the permit; some of these are: erosion controls must be properly implemented, inspection of controls must be performed on a pre-determined basis, containment for spills of material must be provided, waste material produced in the treatment of stormwater must be properly disposed of, and there are several guidelines as to certified operators.

Minnesota

Minnesota has NPDES-delegated authority. Construction site controls more stringent than the national standard have been applied in this state. They are as follows: temporary protection must be provided for areas of exposed soil with a continuous positive slope within 100 feet from a water of the state or other devices connected to a water of the state; and exposed soils on positive slope areas must be protected with either temporary or permanent cover within certain time frames:

Type of slope	Area has not been or will not be worked by contractor for
Steeper than 3:1	7 days
10:1 to 3:1	14 days
Flatter than 10:1	21 days

In addition, the bottoms of temporary drainage ditches must be stabilized within 100 feet of the receiving water within 24 hours of the ditch being connected to the water. In order for a pipe to be connected to a drainage ditch, it must first be equipped with a velocity dissipation device. Sedimentation BMPs must be installed on the down-gradient perimeters of the site before any up-gradient activities may begin. These BMPs must remain in place until the site has been permanently stabilized. Vehicle transport of sediment must also be minimized.

Temporary sedimentation basins must be provided to collect runoff from disturbed sites of 10 or more continuous acres. Basins shall provide 1,800 ft3 per acre drained storage below the outlet pipe. The basin outlets must be designed to prevent short circuiting and discharge of floating debris.

The Minnesota Pollution Control Agency (MPCA) publishes a best management practice manual entitled *Protecting Water Quality in Urban Areas*. The MPCA issues NPDES/SDS general stormwater permits for industrial and construction activity. These permits list the requirements at the federal and state level. The industrial activity permit covers "facilities discharging storm water associated with industrial activity as defined in 40 CFR 122.26(b)(14)." This permit requires a storm water pollution prevention plan, including drainage maps, significant materials inventory, and exposure evaluation; BMPs categorized as source reduction, diversion, and treatment; implementation schedule; inspections and maintenance; reporting; etc. The construction activity permit covers erosion control and inspection and maintenance requirements for construction activities that disturb 5 or more acres of total land area.

Mississippi

Permits are issued by the state of Mississippi under authority delegated to it through EPA NPDES program. Mississippi issues nine different types of general stormwater permits including one for construction sites and one that is a baseline permit. Special criteria for chlorides, sulfates, and total dissolved solids apply to all discharges into the Mississippi River. Stormwater permits state that discharges must be free of debris, oil scum or other floating material except in trace amounts, eroded soils that will form objectionable deposits, suspended solids, turbidity, and color at levels higher than the receiving water, and chemical concentrations higher than the state limits allow.

Stormwater controls, including erosion control measures, are required for all construction sites. These must divert flow away from disturbed soils, keep exposed soil time and area to a minimum, implement BMPs and remove sediment from stormwater before it leaves the site. Sediment basins are required for sites with drainage areas over 5 acres. The recommended capacity of the basin (SCS manual) should be 67 yd^3 per acre drainage area, with maximum surface area and an outlet as far from the inlet as possible. Stormwater controls must be described with respect to vegetative controls, structural controls, post-construction controls, and measures to minimize vehicle transport of sediment.

Missouri

Missouri has a unique method for funding nonpoint runoff controls. In 1983, the Missouri legislature passed a constitutional amendment to raise the state sales tax by 0.1 percent to increase state funding for parks and historical sites, and for soil conservation (Howland 1985). State voters, in turn, passed the amendment in the 1984 general election. This tax increase was only to be in effect for 5 years (from 1985 to 1990), and the soil conservation portion (about $15 million per year) was mostly to be used for cost-sharing of agricultural runoff controls. However, this funding method could also be used to fund urban stormwater controls.

Missouri has NPDES-delegated permitting authority. Construction site permits similar to EPA's general construction permit are required for sites disturbing 5 or more acres of land, over the life of the project. Construction sites over 10 acres are required to construct sedimentation basins. The basin shall be sized to contain 0.5 inch of sediment from the drainage area and be able to contain a 2-year, 24-hour storm. Industrial-specific stormwater pollution prevention plans are required for general industrial permits. Permits for some activities in this state place numeric effluent limits on stormwater discharges with respect to oil and grease, total suspended solids, pH, and other pollutants.

Montana

Montana has NPDES-delegated permitting authority. The Montana Department of Environmental Quality (DEQ) issues three general permits: a permit authorizing discharges from construction sites, a permit authorizing discharges associated with industrial activity, and a permit for oil and gas and mining activities.

Nebraska

Nebraska has NPDES-delegated permitting authority. Nebraska Department of Environmental Quality (NDEQ) issues two general permits: a permit authorizing discharges from construction sites of 5 acres or more and a permit authorizing discharges associated with industrial activity. Permittees of either general permit are required to develop and implement a stormwater pollution prevention plan (SWPPP) that will minimize erosion on disturbed areas, minimize the discharge of sediment and other pollutants in stormwater runoff, and maintain compliance with the requirements of the permit. A detention pond is required on construction sites where slopes are equal to or steeper than 3:1. Clay soils are present in many areas of Nebraska, and when erosion occurs suspended clay particles are not efficiently removed simply by use of a detention facility. Therefore, use of a detention pond does not circumvent the need to implement erosion and sediment controls. NDEQ does not have authority related to flow management issues, only water quality issues. Many local municipalities require new developments to construct permanent detention basins for the purpose of stormwater flow management. These requirements are intended to help prevent and reduce downstream flooding that would otherwise result from the increase in runoff that typically occurs with development. SWPPs for industrial permittees do not require use of detention basins.

Nevada

Nevada has NPDES-delegated permitting authority. The state general permit is identical to EPA's baseline NPDES stormwater program. Construction sites disturbing 5 or more acres, industrial facilities, and mining sites are covered by this permit. Specific BMPs are not required. Detention facilities are regulated by local governments. In the Lake Tahoe area there are stricter regulations administered by the Tahoe Regional Planning Agency.

New Hampshire

New Hampshire does not have NPDES permitting authority. Its permits are issued by EPA Region 1. The program requirements are identical to EPA's. In addition, the state has a shoreline protection program that issues site-specific permits for construction sites in or on the border of surface waters with contiguous area of 50,000 ft^2 if within a protected shoreline, or 100,000 ft^2 or more in all other areas.

New Jersey

New Jersey has NPDES-delegated permitting authority. The Department of Environmental Protection (DEP) issues two general permits: a permit authorizing discharges from construction sites of 5 acres or more and a permit *authorizing discharges associated with industrial activity.* Industrial dischargers must implement a SWPPP. Construction sites disturbing 5,000 ft2 of land are regulated by state erosion and sediment control laws.

New Mexico

New Mexico is a non-delegated state for the NPDES program. The NPDES program is under the direction of EPA Region 6 in Dallas, Texas. Questions about this program can be directed to the Stormwater Hotline at 1-800 245-6510.

New York

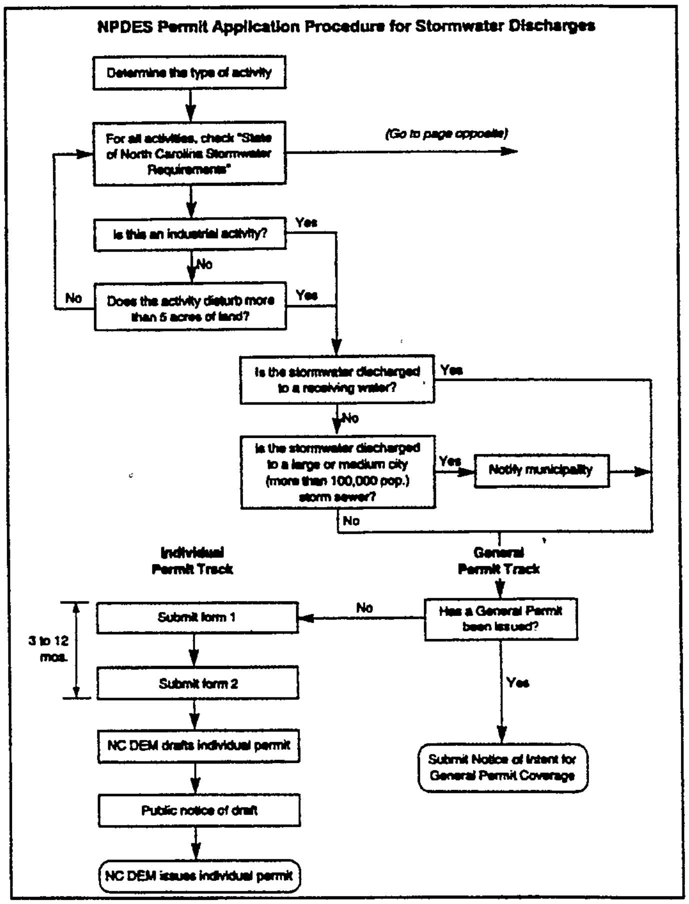
New York has NPDES-delegated permitting authority. The state includes some additional requirements in its construction permits. Structural practices must be built to divert stormwater from exposed soils and limit runoff from these areas. State guidelines also mandate that there may not be any visible and substantial changes with respect to color, taste, odor or turbidity downstream from construction sites. Vegetative and structural practices must be used to ensure that stormwater discharges do not vary significantly from pre-development conditions.

North Carolina

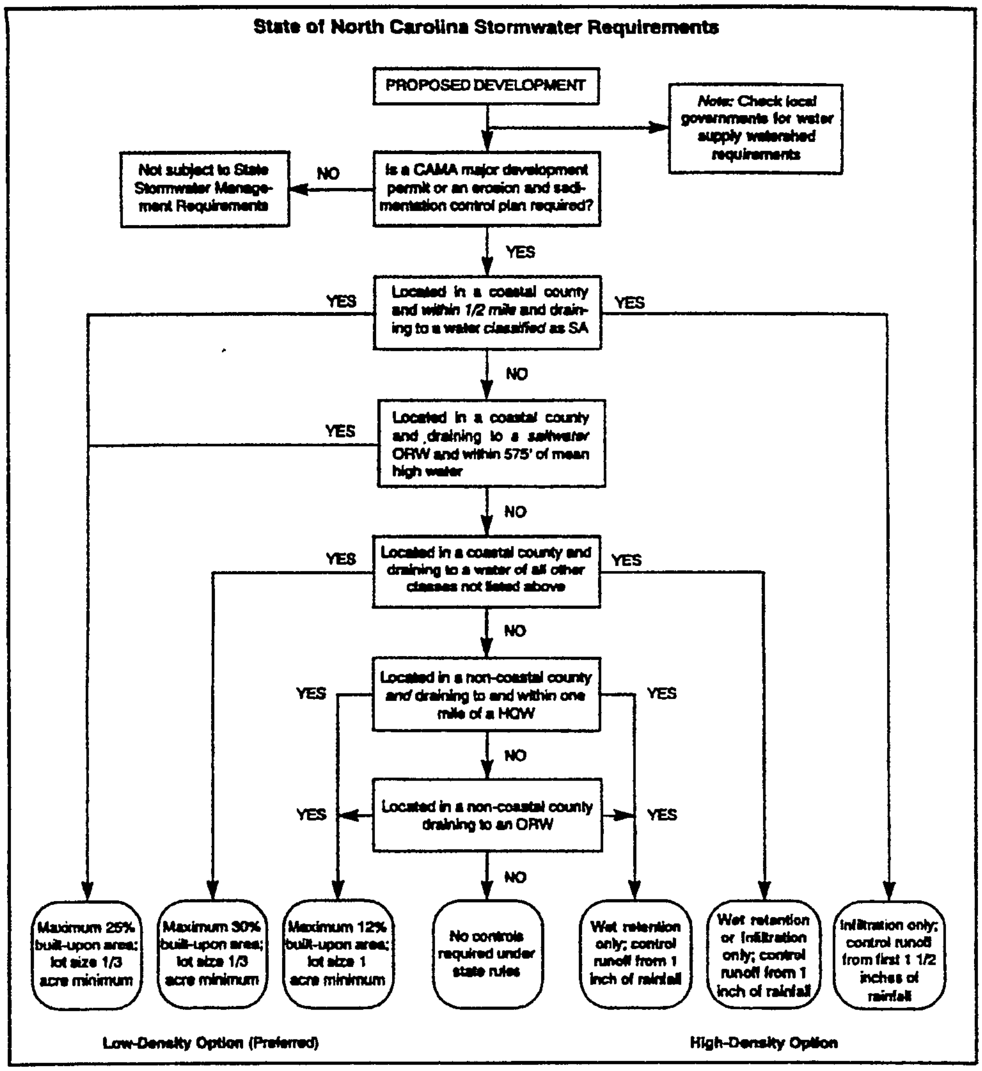
North Carolina has NPDES-delegated permitting authority. North Carolina presently issues 23 types of general permits including a permit for construction sites disturbing 5 or more acres of land and permits for various types of industrial activities. All types of permits require the implementation of a SWPPP. The state also imposes a set of regulations specific to stormwater for coastal waters, outstanding waters of the state, high quality waters, and water supply waters. To help the public determine what regulations are applicable for a project or industrial activity the following flow charts are published by the state in its Stormwater Management Guidance Manual.

North Dakota

North Dakota has NPDES-delegated permitting authority. The North Dakota Department of Health (NDDH) issues three general permits: a permit for construction sites disturbing 5 or more acres of land, a permit for industrial activity, and a permit for mining activities.



R0018353



Ohio

Ohio issues its own NPDES permits under authority delegated by EPA. The state imposes additional runoff guidelines. Revegetation of construction sites must be achieved on a specified time scale, regulations apply to the protection of waters flowing near a site, and statewide regulations require the use of sediment ponds if sediment fences are determined to be insufficient. Ponds capable of holding 67 cubic yards of runoff per acre are required.

Oklahoma

NPDES permits in Oklahoma are issued by the state. Oklahoma Pollution Discharge Elimination System (OPDES) administers the NPDES program. OPDES's permit is identical to EPA's construction permit. Several cities in Oklahoma require builders and developers to design detention facilities so that the rate of runoff from a new building or development does not exceed the historic rate before development or construction runoff.

Industries in the state are subject to additional regulations. Oklahoma plans to adopt EPA's multi-sector permit for industrial sites. Whole effluent toxicity testing is required for dischargers twice annually. The Oklahoma Conservation Commission coordinates the runoff programs in the state, which are voluntary and provide assistance in making management decisions.

Oregon

Oregon has delegated NPDES permitting authority. Discharge limits are set for some industrial stormwater dischargers for certain parameters. These parameters typically include settleable solids, debris, conductivity, and *enterococci*.

Pennsylvania

The state of Pennsylvania has NPDES-delegated permitting authority. The general permit for industrial dischargers resembles EPA's baseline with the following numeric limits: 7 mg/L for dissolved iron, pH from 6 to 9, and a limit of 50 mg/L total suspended solids for coal pile runoff. The state's general construction permit covers sites between 5 and 25 acres unless the runoff from the site will be discharged into a protected water of the state. Any disturbed area, regardless of size, must implement erosion controls. For disturbed areas less than 5 acres, sedimentation traps with the capacity of 2,000 ft^3 may be used. A sedimentation basin is required at construction sites disturbing more than 5 acres. The basin must have a capacity of 7,000 ft^3 per acre, have a 24" freeboard, and have outlets designed to pass a minimum flow of 2 ft^3 per second per acre. A permit is required for timber harvesting operations that would disturb more than 25 acres of land. Water quality based limits may be established for any discharger to ensure adequate water quality in receiving waters.

Rhode Island

Rhode Island has NPDES permitting authority. The state has developed some additional regulations above baseline EPA guidelines. Rhode Island has standards for stormwater practices that include BMPs that must be incorporated into developments. Local governmental agencies may regulate stormwater discharges, but their regulations must be at least as strict as the state regulations. To limit suspended solids releases, the state's Coastal Zone Management Program requires new developments within 200 feet from a shoreline to remove 80% of the suspended solids discharged from a site after development.

South Dakota

South Dakota has NPDES-delegated permitting authority from EPA. The South Dakota Department of Environment and Natural Resources (DENR) has general permitting requirements similar to EPA's baseline general permit for industrial dischargers and construction sites disturbing 5 or more acres of land.

Tennessee

Tennessee has NPDES-delegated permitting authority. In addition to the basic requirements, the state has developed some additional provisions. At construction sites, vegetative and structural management techniques must be applied. Examples of these are: clearing and grubbing is minimized, soil exposure must be minimized through sequencing, large projects must be built in stages; strict checking and maintenance of controls is required; a responsible individual must be established and temporary and permanent soil stabilization measures must be used.

Texas

Austin has had a watershed protection ordinance since 1981 after it was found that continued urban development was having adverse affects on the local groundwater supply. This ordinance was amended in 1986 and contains specific standards for development within critical watersheds (Austin 1986). The Austin program is currently funded by a combination of user's fees and city general revenues. Common controls in all proposed land uses include buffer zones adjacent to all streams where no development is allowed, severe building restrictions on slopes greater than 15 percent, and required setbacks from springs, seeps, and sinkholes. Many innovative erosion and stormwater controls have been used in Austin, including sand filters, portable filter fence supports, and suspension of all city-required building inspections for any site in violation of its erosion and stormwater control plan. Porous pavement is not considered an effective stormwater quality control when protecting groundwater and is therefore not given any credit when calculating allowable impervious covers. Austin also has an ongoing monitoring program to evaluate the performance and required maintenance of stormwater controls.

Texas is in the process of becoming an NPDES-delegated state. Until that time, its permits will be issued by EPA. Texas has established probably the most extensive list of numeric standards for stormwater discharges There are discharge limits for arsenic, barium, cadmium, chromium, copper, lead, manganese, mercury, nickel, selenium, silver and zinc.

Utah

Utah has NPDES-delegated permitting authority. In addition to the basic permit requirements, the state imposes supplementary regulations in some cases. Coal mining facilities are subject to restrictions on the total maximum flow and concentrations of total suspended solids in their discharges. To remediate these concerns, mines must use sedimentation controls, such as detention ponds, and mine site dewatering. Dewatering discharges are subject to limits in the concentration of iron, total dissolved solids, pH, suspended solids, and grease. The Salt Lake City Stormwater Utility has been established and institutes a user fee for use of stormwater systems. Several other cities in Utah have adopted similar plans.

Vermont

The state of Vermont has permitting authority under the NPDES program. A statewide permitting program has also been established that requires treatment and volume control measures to manage runoff from new developments once construction is completed. These management plans, including project designs, hydrologic calculations, and planned controls, must all be submitted to the DEP. Permits are issued on a site-specific basis. These are often issued with the stipulation that the post- development discharge rate does not exceed the rate before development. Sites have guidelines to follow during construction, as well. Ten environmental criteria have been established, addressing wetlands, headwaters, floodways, streams, shorelines, traffic concerns, water and air pollution, waste disposal, esthetics, and impacts on wildlife habitats.

Virginia

Virginia has NPDES-delegated permitting authority. As with most states, Virginia has instituted some additional guidelines. With respect to development, post-construction pollutant concentrations must not increase compared to pre-development concentrations. The Chesapeake Bay area uses phosphorous as an indicator pollutant. Sites that undergo redevelopment must implement measures to achieve a 10 percent reduction in average pollutant loads. Construction activities sponsored by the state also have a set of stormwater regulations they must follow.

Washington

The city of Bellevue has had a storm drainage utility since 1974. Its primary mission is to "manage the storm and surface water system, to maintain a hydrologic balance, to prevent property damage, and to protect water quality for the health, safety, and enjoyment of citizens and for the preservation and enhancement of wildlife habitat" (Bissonnette 1985). Bellevue stresses the use of natural drainage systems to transport and dispose of stormwater. Swales, lakes, ponds, wetlands, and detention ponds form important parts of this system. In 1985, the utility's operating budget was more than $5 million and the 1980 to 1985 capital improvement budget was about $13 million. The necessary revenues are obtained through user service fees, assessed according to the amount of runoff and pollutants generated for each area served.

A number of cities throughout the U.S. currently have storm drainage utilities, mostly modeled after Bellevue's. These utility districts all charge a fee to provide urban runoff control services. Bellevue's runoff and receiving waters were extensively studied during the Nationwide Urban Runoff Program. It was found that the beneficial uses of the streams were being seriously impaired by excessive flows, erosion, and sedimentation (Pitt and Bissonnette 1984). These problems are currently being reduced by runoff and erosion controls. Metallic and organic toxicants will also need to be controlled in future years in Bellevue.

West Virginia

West Virginia has been granted NPDES permitting authority by EPA. West Virginia issues two general permits, one for industrial dischargers and one for construction sites disturbing 3 or more acres of land. Construction sites having a drainage area of 5 acres or less should have a sediment trap with a storage volume equal to 3,600 ft^3 per acre. Sites over 5 acres should have a sediment basin which will provide a storage volume equal to 3,600 ft^3 per acre. The state has established additional numeric effluent limitations for coal piles with respect to pH and total suspended solids.

Wisconsin

Wisconsin has had a priority watershed protection program for more than 15 years. This program involves extensive state-funded cost sharing to retrofit nonpoint water pollution controls in watersheds that cannot meet water quality objectives with point source controls alone. Initially, this program almost exclusively involved agricultural water pollutant sources, with little urban runoff controls. In 1983, the state legislature passed legislation requiring the preparation of a model ordinance to control construction site erosion and stormwater runoff (Pitt 1986). The state will spend about $100 million over the next twenty years in retrofitting urban runoff controls in the priority watersheds. In order to protect this investment, all state funded and conducted construction, along with urban areas participating in the priority watershed program, are required to follow these ordinances.

The Wisconsin model ordinance for the control of construction site erosion has been adopted by many communities, including Milwaukee. This ordinance includes basic controls to reduce such erosion sources as vehicle tracking and dewatering of excavations, along with required diverting of up-slope waters, mulching of disturbed areas, and the use of downstream sedimentation controls. Extensive plan reviews and site inspections are also included in the ordinance. The ordinance is supplemented with a manual to ensure uniform design and appropriate applications of construction control practices.

Wisconsin has NPDES-delegated permitting authority. The DNR limits its stormwater program to municipalities in urban areas with documented water quality problems. These municipalities are required to collect data and assess their specific stormwater problems as well as develop a plan to address these concerns. Permits mandate that municipalities make and meet a timeline for development of a stormwater program, implement a successful program that reduces and prevents stormwater pollution, screen all storm sewer outfalls for sewer connections and other improper waste disposal; estimate pollutant loadings to the waters of the state; calculate the concentrations and constituents of pollutants in stormwater; monitor stormwater with respect to pollutant loads; assess the effectiveness of their stormwater program; and report on their progress.

Wyoming

Wyoming has NPDES-delegated permitting authority. The state has imposed additional controls on construction site activities. Sites that discharge into perennial water bodies must not increase the turbidity by more than 10-15 turbidity units above the background. Discharges into water bodies that are ephemeral are exempt from this standard but may not deposit sediment that degrades the habitat. All stormwater control devices must remove 80% of total suspended solids. Sites must establish structured runoff control plans with a designated responsible individual. Sites with a high potential for soil erosion should identify and implement BMPs to control erosion.

Historical Review of Wet Weather Pollution Management

Throughout history, many strategies have been implemented to control wet weather pollution for reasons such as flood control, water quality improvement, aesthetic improvement, waste removal, and others. To provide guidance for developing communities, a reference manual for wet weather flow systems in newly urbanizing areas is being developed as part of a cooperative agreement among the Urban Watershed Management Branch of EPA, the University of Alabama at Birmingham (Pitt, et al. 1997) and ASCE (Heaney, et al. 1997). The following historical review is a summary from this effort (Pitt, et al. 1997) and was mostly prepared by Steven J. Burian, a Ph.D. student at the University of Alabama.

F.1 Wet Weather Pollution Management: Ancient Times

Management of wet weather pollution is an age-old problem. Several ancient civilizations can be credited with implementing successful surface water drainage systems. Evidence exists that the dwellers of the city of Mohenjo-Daro (now part of West Pakistan) used sanitary sewer systems and had drains to remove stormwater from the streets (Webster 1962).

Mesopotamian engineers planned and built effective drainage and sanitary works, including vaulted sewers and drains for household waste, gutters and drains for surface runoff, and other appurtenances made of baked brick and asphalt (Maner 1966).

Of all the societies of western Asia and Europe, from antiquity until the 19th century, only the Romans set out to build a carefully planned road system with properly drained surfaces (Hill 1984). Virtually all that the early Romans knew about engineering came to them out of the civilizations of the eastern Mediterranean (Kirby, et al. 1990). Specific drainage structures used by the Romans included occasional curbs and gutters to direct surface runoff to open drainage channels alongside roadways (Hill 1984). To improve drainage, the roads would be graded in such a fashion to direct the surface runoff from the streets toward the drainage channels.

Draining excess water was not the only function of the system. It was soon discovered that disposal of wastes in these trenches removed the waste from the immediate area. However, the trenches relied on heavy rainfalls to adequately flush them of waste and debris, since overflow discharges from aqueducts were not sufficient to effectively convey the wastes. The wastes would therefore accumulate and cause unsanitary, not to mention repugnant, conditions. The solution to this was to cover the trenches; these covered trenches eventually evolved into planned sewers.

The Romans planned and constructed the "cloacae," or sewers, to drain their uplands to the nearby network of low-lying streams (Gest 1963). These sewers were originally open streams that drained most of the land prior to urbanization. The philosophy was to use the existing natural drainage channels to remove wet weather flows and pollution. It was decided that the proper way to use the channels was to build the city over them and provide drains from the surface to the underground streams. As time progressed, the Romans became more elaborate with their construction of sewers (Gest 1963).

F.2 Wet Weather Pollution Management: Middle Ages to the 1800s

The first sewers built in Europe following the fall of the Roman Empire were simply open ditches. Examples of this type of sewerage system in Europe are evident in Paris and London as well as in a few other European cities during the 1300s and 1400s (Kirby and Laurson 1932; Reid 1991). The open ditches used for drainage of stormwater were usually constructed in existing drainage pathways (Kirby and Laurson 1932) or down the centers of streets (Reid 1991). Besides being conveyances for stormwater, the open drainage channels became receptacles for trash, kitchen wastes, and sanitary wastes, the accumulation of which caused hazardous and nuisance conditions. To remedy this situation, Europeans simply covered the drainage channels, or sewers, which were emitting terrible odors and producing unsightly conditions. Interestingly, this solution is similar to that used 1,500 years earlier by the Romans during the construction of the "cloacae."

From the time of the Roman Empire to the 1800s, wet weather pollution management strategies experienced very little noteworthy advances, and in fact regressed considerably in terms of sanitation. However, towards the start of the Middle Ages, as disease epidemics occurred in major metropolitan areas of Europe, some believed proper sanitation was partly dependent on adequate sewerage.

Paris and London provide examples of European cities that developed piecemeal drainage systems in response to crisis situations and funding availability. A consequence of developing wet weather and sanitary systems in this way was an incoherent and varied overall system. In addition to the poor design and construction practices at the end of the Middle Ages, maintenance and operation of the systems were virtually neglected in most situations. Sewer systems of urban areas in Europe during the 1600s and 1700s were grossly under-planned, poorly constructed, and inadequately maintained.

F.3 Wet Weather Pollution Management: 1800s

The enlightened, post-renaissance society began to realize that adequate sewerage was necessary to promote proper sanitation. The early part of the 1800s marked the beginning of a series of decisions and technical advances that resulted in improvements related to wet weather pollution management.

F.3.1 Improvements in Design and Construction Practices

Innovations in construction materials improved sewerage systems in the early 1800s. As an example, in Paris until the 1820s, sewers had been constructed of cut stone or brick with rectangular or roughly rounded bases, which led to solids deposition problems (Reid 1991). Engineers substituted millstone and cement mortar for the hewn stone, which allowed for the construction of curved and smooth sewer floors. This lessened the flushing effort required for sewer cleansing. The quality of brick and clay pipe also improved during this time and became the materials of choice. The next major improvement in sewer materials was the use of concrete, which did not occur until the end of the 1800s (Metcalf and Eddy 1928).

In addition to improvements in construction, several advances were made in the design of sewer pipes. Sewers could now be constructed in curved shapes instead of simply rectangular shapes. These curved shapes included egg-shaped, oval, and v-notched patterns for combined sewer systems and provided improved hydraulic transport efficiencies over the rectangular sewer shape. Studies in England indicated that the lower part of a v-notch channel could carry sanitary waste well, while the upper portion could provide sufficient capacity to transport stormwater from the streets (Gayman 1997).

Another problem with sewers was the grade at which they were constructed. Often, caution was not exercised either during design or construction, and the sewers did not have a sufficient slope to transport wastewater during dry weather periods. Sewers began to be constructed on slopes sufficient to prevent ponding in the system.

F.3.2 Beginnings of Comprehensive Sewerage Design

The improvement in construction practices and pipe designs did not eliminate the problems with sewer systems in Europe. System design strategy became the focus of the next wave of innovations in sewerage practice. Hamburg, in 1843, is considered to have implemented the first comprehensively planned sewerage system (Metcalf and Eddy 1928). The circumstances were advantageous for this, as a large part of the city had been destroyed by fire in 1842.

London followed suit with a detailed study by many engineers of note, resulting in the decision to devise a comprehensive sewerage plan. In 1852, Joseph William Bazalgette was commissioned to plan and design the system (Kirby and Laurson 1932). Actual work on the main drainage of London began in 1859 and was practically completed in 1865.

Meanwhile, the sewers of Paris were still being constructed without any coordinated plan until 1823. At that time, construction practices began to improve, which allowed engineers such as Duleau to plan an adequate system of drainage for portions of the city. The interceptor sewer concept dates to this period in Paris and London (Kirby and Laurson 1932).

The 1800s saw rapid urbanization in the United States. In response to this urbanization in the United States, comprehensive design of wet weather pollution management systems began to be practiced. Chicago had the first comprehensive design implemented by a major American city. E.S. Chesbrough designed the system in a report completed in 1858 (Metcalf and Eddy 1928). He and other contemporary engineers soon consulted on similar comprehensive plans for additional U.S. cities (J.W. Adams for Brooklyn, New York for example).

The planning of early American sewerage was influenced by two general factors, the topography of the city and the place of disposal (Metcalf and Eddy 1928). The grade of the ground surface affected decisions concerning the mode of sewer transport, the size of the sewers, and the arrangement of small- and large-sized sewers, with gravity being the desired vehicle for transportation. In most situations, the use of natural drainage patterns in conveying stormwater was preferred, especially when streets were planned according to the lay of the land. The second factor mainly concerned the direction and distance that the sewage would be conveyed. Specific considerations included the dilution capability of the receiving stream and determination of the proper disposal location.

The comprehensive designs implemented in the U.S. made use of empirical data obtained from European practice for capacity and probable quantities of rainwater to be carried by the sewers (Webster 1921). It is noteworthy that among the branches of engineering, American sewerage is observed to have developed many of its features through experience, rather than experimenting (Metcalf and Eddy 1928).

F.3.3 Combined Versus Separate Systems of Sewerage

Although sanitary waste was a constant input to the stormwater systems of Europe, designs did not recognize the addition of sanitary wastewater in combined systems until 1843 in Hamburg. This does not imply that illegal connections of sanitary wastewater were not present, as this was often the case. The first types of wastewater legally allowed into the sewer system were dishwater and other liquid kitchen wastes. When the flushing toilet (water closet) came into general use in the early 1800s existing cesspools became overwhelmed. Eventually, this led to the permitted discharge of sanitary wastes into the sewers previously restricted to surface runoff, creating combined sewage. London did not allow legal sanitary connections to its sewer system until 1847 (Kirby and Laurson 1932), and Paris followed suit in 1880 (Reid 1991).

The combined sewage scheme became widely implemented in spite of the opponents who thought it sensible to keep the sanitary wastes and stormwater separate. Edwin Chadwick and John Phillips, both from England, were two of the earliest proponents of the separate system of sewage. Phillips proposed the separate system for London in 1849, but eventually Bazalgette's combined system with interceptors was implemented (Metcalf and Eddy 1928). Although supporters for separate systems existed, combined systems were mostly constructed because they were usually cheaper to design and build.

Bourne (1866) made one of the first American arguments for separate sewerage. He advocated the separate system for reasons of sanitation. Benezette Williams designed one of the earliest comprehensive separate systems in the U.S. in 1880 for Pullman, Ill., which was eventually implemented (Odell 1881). Another adamant supporter of separate sewer systems in the U.S. was Col. George E. Waring, Jr. (Waring 1879). Waring designed several early separate systems, including one for Memphis, Tenn. in 1880. Other cities that implemented separate sewer systems, constructed only sanitary sewer lines for the most part, with no pipes for stormwater (gutters and ditches carried this water) (Tarr and McMichael 1977). Some systems performed adequately, but others failed miserably with repeated blockages and backups in the sanitary sewer lines. Waring's designs called for the size of the house connection to the lateral sewer to be small (typically 4 inches) (Metcalf and Eddy 1928). This small size (in comparison to other designs of 6 inches or more) is what many believed to be the basic cause of failures in Waring's systems.

To learn more about separate and combined sewer systems, an American named Rudolph Hering visited Europe in 1881 at the behest of the U.S. National Board of Health. His findings from the trip became a report to the National Board of Health on the benefits and drawbacks of each type of system (Hering 1881). Hering's recommendations included using combined systems in large or rapidly growing cities, while using separate systems for areas where rainwater did not need to be removed underground. Despite Hering's report and the support of his conclusions by many, the debate continued between the advocates of the two types of sewerage.

F.3.4 Identification of Water-Borne Diseases

Several individuals throughout history have conjectured that sanitary and other types of wastes and unsanitary living conditions could be linked to diseases (Tarr and McMichael 1977). During the early 1800s, evidence pointed to the link between sewage discharges, polluted receiving waters, and disease outbreaks. A key factor was the new knowledge that had come from the researches of noted scientists such as L. Pasteur, R. Koch, R. Warington, T. Schlösing & A. Muntz into the nature and activities of bacteria.

A publication by Dr. Jack Snow in 1849 discussed the communication of cholera by contaminated water; he later had a hand in identifying the source of the Broad Street cholera epidemic in London during 1854. But it was Pasteur, in 1857, who established the formative theory that infectious disease is caused by germs or bacteria (Kirby, et al. 1990). By the 1880s the theory was firmly established by Koch and others. This research led to the attempt to filter drinking water during the late 1800s to remove water-borne disease-causing organisms.

F.3.5 Treatment of Separate Sanitary and Combined Wastewater

Regardless of the type of sewerage (combined or separate), the primary method of disposal was still discharging to local receiving waters in the late 1800s; control and treatment of sewer discharges was very limited. Typically, combined sewage, sanitary wastewater, and stormwater were simply discharged into a stream or river of adequate capacity to dilute the waste. The sewerage systems would be designed such that the maximum amount the receiving water system could dilute would be discharged. In the late 1800s, sewage was treated primarily by three methods: irrigation of farmlands, intermittent filtration, or chemical precipitation (Whipple, et al. 1906; Tarr and McMichael 1977). These systems of treatment were more conducive to the smaller and easier controlled sanitary sewage flows from a separate system. Centralized municipal wastewater treatment facilities were just beginning to be constructed in the late 1800s.

Whipple, et al. (1906) discussed the combined sewage treatment operations being used in the U.S. at the beginning of the 1900s. The usual method for combined sewer systems entailed sending as much of the storm flow/sanitary sewage mixture to a dry weather wastewater treatment plant by way of an intercepting sewer. In most cases, the interceptor sewer conveyed a certain amount of the waste stream to the plant, with the remainder being overflowed directly to the receiving water system, thus creating a combined sewer overflow (CSO). Treatment plants and collection systems were typically designed to treat twice the flow rate, or more, of the typical dry weather flow (Whipple, et al. 1906). During wet weather, sewer system flows were observed to increase by a factor of 100 over dry weather flows on occasion. Occurrences such as this could not be economically considered in conveyance or treatment system design, and thus, excess sewage flows greater than the design capacity of the conveyance system would result in frequent overflows.

Although research had displayed the connection between sewage-polluted waters and disease, sewage treatment was not widely practiced. It was debated whether it was more economical to treat the sewage prior to discharge or treat the water source before distributing as potable water. It was argued that the sewage could be assimilated or treated in the receiving water and would be much less polluted by the time it was withdrawn for drinking water supplies. This argument had validity, except it neglected the fact that sewage discharges were detrimental to the receiving water in addition to the drinking water supply.

F.3.6 Urban Hydrology

In the mid-1800s, estimating surface runoff was based on empirical results. For example, much of the European engineering community used Roe's table to size sewer pipes draining a specified size catchment (Metcalf and Eddy 1928). The table was supposedly empirically derived from Roe's observations of London sewers in the Holborn and Finsbury divisions over a span of 20 years.

In the second half of the 1800s the hydrologic and hydraulic design methods used to size sewers were enhanced. Most notably, Mulvaney (1851) and Kuichling (1889) developed the rational method in this time period. The rational method, in general, was based on the assumption that a realistic flow of the chosen frequency can be obtained if the rain intensity of duration similar to the travel time of water in the sewer system was applied to the drainage catchment. The flow was subsequently used to design the size of the sewer pipes. Prior to the rational method, runoff determinations took the form of empirical formulae. These equations were all derived based on site-specific data; consequently, they yielded poor results when applied to other drainage basins (Buerger 1915).

Intensive efforts in rainfall data collection and analysis occurred in the U.S. during the second half of the 19th century (Berwick, et al. 1980). The primary motivation was to study the relationship between the intensity of the rain and its duration for the needs of storm drain design. Talbot, in 1899, performed some of the initial work, using U.S. Weather Bureau records at 499 stations to plot storm intensities versus duration on a cross-section paper. Two envelope curves were drawn, one depicting the very rare rainfalls, and the other the ordinary rainfalls. These curves became the forerunner of the present day intensity-duration-frequency curves for drainage design. Since the time Talbot constructed his curves, many cities, public agencies, and engineering firms have developed similar equations for specific locations (Berwick, et al. 1980), while some still use Talbot's results directly.

F.4 Wet Weather Pollution Management: 1900s

F.4.1 Urban Hydrology Continued

The engineering community did not immediately accept the rational method. Well into the 1900s, the older empirical formulae mentioned above were still being used (Buerger 1915). Only after a slow transition in the early part of the 1900s did the rational method become the dominant technique for drainage design in the U.S. and worldwide.

The early 1900s also witnessed attempts to describe the rainfall/runoff process more accurately (Rafter 1903; Gregory 1907; Justin 1914; Buerger 1915; Grunsky 1922). By the 1920s the use of rain gauge records enabled more typical "design storms" to be used, in which rainfall intensity rose to a peak and then died away. The unit hydrograph (UH) concept is an example of these enhanced procedures based on design storms. Sherman (1932) developed the concept of the UH for gauged watersheds, and subsequently others modified it and applied it in different manners (Pettis 1938; Brater 1939). Until the introduction of unit hydrographs, few design techniques had considered using the storm hydrograph and runoff hydrograph; only the peak rate of runoff was used. Horner and Flynt (1936) first applied hydrograph techniques to storm sewer design (Horner and Flynt 1936; Eagleson 1962).

Following the UH applications, a renewed interest in the rainfall/runoff process was observed in the 1940s. Previous methods for determining runoff from rainfall had been mostly based on coefficients to account for losses of rainfall. In the late 1930s and early 1940s, rainfall abstractions became a concentrated topic of research. Horner and Jens (1942) developed a methodology to mathematically describe the process of infiltration, among other abstractions, and applied hydrograph techniques to a small basin.

F.4.2 Environmental Awareness and Receiving Water Impacts

During the 1960s, wet weather pollution was recognized by many as causing receiving water quality problems. To mitigate the problems, methods of control and treatment for urban runoff and CSOs were devised. Although it was known that controlling wet weather flows and pollution would not eliminate the problem, such methods were considered helpful in reducing the problems and in certain situations to be more cost effective than improving the capacity for dry weather wastewater treatment.

With the interest in reducing receiving water impacts through control and treatment of wet weather pollution, numerous research projects were initiated in the 1960s and 1970s. The main focus of these projects was to evaluate the effectiveness of control and treatment alternatives for combined sewer overflows. The control and treatment alternatives included physical/chemical methods such as detention, swirl technology, filtration, screening, and disinfection; biological methods such as rotating biological contactors, contact stabilization, trickling filters, treatment lagoons, and activated sludge; and storage/treatment methods.

The next step in the 1970s was the attempt to evaluate problems on a larger scale. This was manifested in Section 208 (from the Federal Water Pollution Control Act of 1972) planning studies and the watershed-wide planning philosophy that gained attention in the late 1970s and early 1980s. The planning studies focused on mitigating the impacts of urban runoff on receiving waters on a watershed scale versus a single outfall or a single stream reach.

In the early 1980s, problems remained with attempting to predict relationships between wet weather discharges and receiving water impacts. To remedy this problem, data was sought that would characterize the pollutants of concern and the impacts they would have on receiving waters. One of the major research efforts was the Nationwide Urban Runoff Program (NURP), conducted in the United States by EPA and USGS (EPA 1983). The overall goal of NURP was to collect data and develop information for use by local decisionmakers, states, EPA, and other interested parties.

F.4.3 Technical Tools and Design Methods

In the late 1960s and early 1970s computer development and its applications to the field of wet weather pollution management had a significant impact on the direction of development of wet weather pollution management. Computer applications were used in modeling environmental systems and processes, such as STORM (HEC 1973) and SWMM (Metcalf & Eddy Engineers, et al. 1971), and analysis and design of wet weather conveyance systems became more dependent on new computer applications.

In addition to computers, the mathematical and statistical methods being applied to wet weather pollution management were also improving. The use of statistics was seen in the analysis of long-term simulation results, the analysis of collected rainfall, runoff, water quality data, the evaluation of the optimum urban runoff control system configuration, among other uses (Howard 1976; DiToro and Small 1979; Hydroscience, Inc. 1979). The 1980s involved improving much of the technology and ideas initially introduced in the 1960s, 1970s and early 1980s. Personal computer advancements during the late 1980s and early 1990s were such that most wet weather pollution management technology currently revolves around the use of personal computers. Computational aids such as GIS, databases, and model pre- and post-processors have seen many advances during the 1990s, the use of which has improved the planning, design, and operation stages of wet weather pollution management significantly in terms of time, effort, and money.

F.5 Wet Weather Pollution Management: Lessons Learned from the Past

An advantage of developing user-friendly design methods and tools is the reduction in the time lag between development and implementation. Practitioners generally embrace technology that is simple to understand while still providing the means to perform the job in the most cost-effective manner possible. The methods and tools that have gained acceptance through history have been simple to implement and easy to understand, although not necessarily the most accurate or appropriate.

Considering the other points previously discussed, a sustainable system development will have the benefit of significantly reducing the environmental impacts associated with a project over time, while promoting economic stability as well. The literature is replete with examples of entire systems (Paris in the Middle Ages) or parts of systems that were designed without considering the long-term sustainability of the project. The systems performed poorly and resulted in additional time, effort, and money being used to rehabilitate and maintain the design.

Another consideration noticed during the review of the literature is that past design engineers and planners were forced to consider the socioeconomic, political, and legal ramifications associated with their plans and designs. These topics can be the primary inhibitors to the implementation of innovative technology and in the future must be addressed for progress to be made (Berwick, et al. 1980).

WERF QUESTIONNAIRE

QUESTIONNAIRE
WATER ENVIRONMENT RESEARCH FOUNDATION
ASSESSMENT OF DECISION CRITERIA USED TO DETERMINE BENEFITS OF CSO/SSO/SW INVESTMENTS

The Water Environment Research Foundation has contracted with Moffa & Associates to assess decision criteria used to determine benefits of CSO, SSO and stormwater investments. The objectives of this project are to document or benchmark policy interpretations of EPA regions and state regulatory agencies and the progress of various municipalities in achieving water quality goals. This information will be structured in the form of matrices wherever possible so that a municipality could better appreciate their relative position in developing solutions to their CSO, SSO and stormwater problems.

Your assistance in providing this information is needed to produce these guidance documents.

General Information

Date Completed:

1. Contact Person | Title | Organization Name

Street Address | City | State | Zip Code | Phone No.

2. What type(s) of wet-weather pollution are you responding about? (Circle all that apply)

(a) CSO (b) Stormwater (c) SSO

3. What type(s) of receiving water are impacted by the wet-weather pollution? (Circle all that apply)

(a) River (b) Stream (c) Lake (d) Ocean (e) Estuary
(f) Other

4. (a) Total Population:______________________ (c) Ownership of Sewer System:______________________

(b) Area of Sewer System:______________________ (d) Area of Watershed:______________________

5. (a) Annual Rainfall: (b) Number of Raindays:

Public Participation

1. What are the concerns of the public?

2. Is there a public participation program? (Circle) Yes No

If Yes, describe how the public participation program engages / educates the pubic.

Conveyance System Information

1. Has the conveyance system been mathematically modeled? (Circle)

CSO:	Yes	No
SSO:	Yes	No
Stormwater:	Yes	No

2. Number of discharge sources:

CSO: | Stormwater: | SSO:

3. Frequency of discharges per year:

CSO: | Stormwater: | SSO:

4. Volume of discharge per year, if available:

CSO: | Stormwater: | SSO:

QUESTIONNAIRE
WATER ENVIRONMENT RESEARCH FOUNDATION

Watershed Approach

1. Has a watershed approach been considered for planning wet-weather pollution abatement? (Circle) Yes No

2. Has a watershed approach been used to plan wet-weather pollution abatement? (Circle) Yes No

   If Yes, what are the other sources of pollution? (Circle all that apply)

   (a) Municipal Point Source (b) Industrial Point Source (c) Agricultural Runoff (d) Urban Runoff
   (e) Other:

   If Yes, has the watershed been mathematically modeled? (Circle) Yes No

3. Has a watershed approach been used to manage wet-weather pollution abatement? (Circle) Yes No

4. What pollution sources are currently being addressed? (Circle all that apply)

   (a) Municipal Point Source (b) Industrial Point Source (c) Agricultural Runoff (d) Urban Runoff
   (e) Other:

5. What pollution sources are going to be addressed in the future? (Circle all that apply)

   (a) Municipal Point Source (b) Industrial Point Source (c) Agricultural Runoff (d) Urban Runoff
   (e) Other:

Water Quality

1. When did your organization recognize the wet-weather pollution?

2. Why did your organization take action to abate the wet-weather pollution? (Circle all that apply)

   (a) Planned Sewer System Improvements (b) Regulatory Requirements
   (c) Significant Pollution Event (d) Litigation/Lawsuit

3. Describe the significant pollution event:

4. Are any wet-weather facilities permitted? (Circle)

CSO:	Yes	No
SSO:	Yes	No
Stormwater:	Yes	No

   If yes, how many CSO: __________; how many SSO: __________; how many Stormwater: __________

5. Describe the critical permit requirement(s).

Technical Considerations

1. Is a Facility Plan completed? (Circle) Yes No

2. Is a Facility Plan being developed? (Circle) Yes No

QUESTIONNAIRE
WATER ENVIRONMENT RESEARCH FOUNDATION

3. What is the basis for technical considerations? (Circle all that apply)

(a) Regulatory Requirements (Federal, State)

(1) CSO
a. Demonstrative Approach
b. Presumptive Approach

(2) Stormwater
a. Regulations

(3) SSO

(b) Receiving Water Criteria

(1) Bacteria (2) Floatables (3) BOD (4) Dissolved Oxygen (5) Nutrients (6) Solids (7) Other

(c) Public Concern

4. How were the technical controls selected? (Circle all that apply)

(a) Cost - Benefit Analysis (b) Regulatory Requirements (Federal, State) (c) Other

If Regulatory Requirements or Other, describe.

5. What control technologies have been or will be implemented to abate wet-weather pollution? (Circle all that apply)

CSO
(a) BMPs
(b) Vortex
(c) Out-of-System Storage
(d) Screening
(e) In-System Storage
(f) Disinfection
(g) Flow Balance Method
(h) Netting
(i) Other:

SSO
(a) I / I Reduction
(b) Other

Stormwater
(a) Source Control
(b) Other

6. Describe the effectiveness of the control technologies, if available.

7. Describe the impact of the control technologies on receiving water quality, if available.

Financial Considerations

1. What are the total capital costs for wet-weather pollution abatement? (do not include life-cycle replacement) (Include year dollar figure represents)

Past: $________________ In 19_____ dollars

Projected $________________ In 19_____ dollars

2. What are the impacts on annual sewer rates?

Percent Increase:

3. What are the sources of funding? (Circle all that apply)

(a) Revolving Loan
(b) Federal Grant Money
(c) State Grant Money
(d) Increased Taxes
(e) Increased Sewer Rates
(f) Other:

Aesthetics: Of or pertaining to the sense of attractiveness.

Assimilation: In water bodies, the process that removes pollutants and/or their impacts.

Best management practices (BMP): Non- and low-structurally intensive wet weather flow and pollution control methods that can have multi-benefits, including drainage network enhancement and flood control; groundwater recharge; aesthetic enhancement; pavement cleansing and reduction of dust, dirt, litter, and debris; subpotable water reuse; etc.

Biochemical oxygen demand (BOD): An operational measure of potential for depletion of dissolved oxygen by the biological and chemical degradation of organic material by bacteria.

Biological treatment processes: Means of treatment in which bacterial or biochemical action is intensified to stabilize, oxidize, and nitrify the unstable organic matter present. Trickling filters, activated sludge processes, and lagoons are examples.

Catchbasin: A chamber or well, usually at the street curbline, for the admission of surface water to a sewer or subdrain, having at its base a sediment sump to retain grit and detritus below the point of overflow; whereas, a stormwater inlet does not have a sump and does not trap sediment.

Catchment: The area producing the runoff passing a particular channel or stream location.

Collection system control: A method of abating wet weather flow or pollution in the collection or drainage system.
Combined sewer: A sewer receiving intercepted surface (dry and wet weather) runoff, municipal (sanitary and industrial) sewage, and subsurface waters from infiltration.

Combined sewer overflow (CSO) Flow from an outfall (discharge conduit) of a combined sewer collection system in excess of the interceptor capacity that is discharged into a receiving water and/ or an auxiliary CSO control (storage) treatment system.

Computer model: A model in which the mathematical operations are carried out on a computer.

Cost-benefit relationship: The relationship between unit costs to unit benefits usually represented as a curve.

Cost-effective solution: A solution to a problem that has been identified as being financially optional (e.g., the solution associated with the knee-of-the-curve of a cost-benefit relationship).

Critical design conditions: Environmental and flow conditions chosen to represent the conditions under which compliance with water quality standards, criteria, or objectives is desired.

Detention: The slowing, dampening, or attenuating of flows either entering the sewer system or within the sewer system by temporarily holding the water on a surface area, in a storage basin, or within the sewer itself.

Detention time: The time period that flow is detained in a storage/sedimentation basin or tank.

Disinfection: The killing or inactivation of human disease-causing microorganisms or pathogens.

Dispersion: Pollutant or concentration mixing due to turbulent physical processes.

Dissolved oxygen deficit: Difference between saturated dissolved oxygen and ambient concentrations.

Domestic sewage: Sewage derived principally from dwellings, business buildings, institutions, and the like. It may or may not contain groundwater.

Dry weather flow (DWF): Usually referred to as the flow in a combined sewer system without stormwater.

Dual treatment: Those processes or facilities designed for operating on both dry and wet weather flows.

Ecological habitat: The environmental niche in which an organism lives.

End-of-pipe impacts: Impacts that occur in the immediate vicinity of an outfall.

Engineering News Record (ENR): A recognized magazine providing accepted construction-cost indices.

Eutrophication: The process of aging whereby the increase of mineral and organic nutrients favors aquatic plants over animal life and results in increasing daily variations in dissolved oxygen concentrations, reduced biologic diversity, and reduced water clarity.

First flush: The condition, often occurring in wet weather flow discharges, in which a disproportionately high pollution load is carried in the first portion of the discharge or overflow.

Floatables: Large floating material sometimes characteristic of sanitary wastewater and storm runoff.

Frequency of return: The rate at which a particular type storm can be expected to occur (e.g., 1 year), such storms being classified by storm intensity and duration.

Infiltration: The process whereby water enters a sewer system from underground through such means as defective pipes, pipe joints, connections, or manhole walls. Infiltration does not include, and is distinguished from, inflow.

Inflow: The process whereby water enters a sewer system through such means as cellar and foundation drains, roof leaders, surface drainage, and cross connections from storm drains and catch basins. Inflow does not include, and is distinguished from, infiltration.

In-line storage: A type of storage that has no pumping requirements and can consist of either storage within the sewer (in-sewer/in-pipe) or channel, or storage in the in-line basins.

Interceptor: A sewer designed to receive dry weather flow from a number of transverse combined sewer trunks and additional quantities of intercepted surface runoff during low-flowing sanitary sewage periods and to convey such waters to a point for treatment.

Knee-of-the-curve: The point along a cost-benefit curve at which there is a noticeable change in the quantity of cost for an increment of benefit.

Lateral: A sewer that has no other common sewer discharging into it.

Longitudinal dispersion: One-dimensional dispersion (mixing) occurring along the length of the stream or estuary.

Mathematical modeling: Application of mathematical formulae to represent the processes and effects of natural and manmade systems for the purpose of forecasting responses to different conditions and inputs.

Model: Any representation of a system by something other than the system itself.

Model calibration: Refinement of mathematical model parameters and coefficients through comparison to data by making scientifically consistent and rational adjustments.

Model parameter: A quantity that cannot vary in a particular model run.

Model variable: A quantity that can vary in a particular model run.

Nonpoint: Diffuse; not attributable to a particular location.

Nonpoint source pollution: Any unconfined and nondiscrete conveyance from which pollutants are discharged.

Off-line storage: A type of storage that requires detention facilities (basins or tunnels) and facilities for pumping storm flow either into or out of the detention facilities.

Pathogen: A disease-causing microorganism.

Pathogenic bacteria and viruses: Bacteria and viruses capable of causing disease in humans.

Physical treatment processes: Means of treatment in which the application of physical forces predominate. Screening, sedimentation, flotation, and filtration are examples. Physical treatment operations may or may not include chemical additions.

Physical with/without chemical treatment processes: Means of treatment in which the removal of pollutants is brought about primarily by physical processes, with or without chemical addition to enhance removal efficiency.

Receiving waters: Natural or manmade water systems into which materials are discharged.

Recurrent frequency. The historical frequency at which a condition or situation occurs.

Regulator: A structure that controls the amount of sewage entering an interceptor by storing in the upstream trunk line or by diverting some portion of the flow to an outfall.

Sanitary sewer: A sewer that carries liquid and water-carried wastes from residences, commercial buildings, industrial plants, and institutions, together with relatively low quantities of ground-, storm-, and surface waters that are not admitted intentionally.

Sanitary sewer overflow (SSO): A sanitary sewer overflow is flow from an outfall (discharge conduit) of a sanitary sewer collection system in excess of the interceptor capacity that is discharged into a receiving water. Sanitary sewer overflows are the result of the unplanned relief of a sewer system intended only for sanitary sewage. An SSO typically occurs when the flow exceeds the carrying capacity of the system and although SSOs can, and do, occur during dry weather, they are most commonly associated with wet weather events.

Sanitary wastewaters: Wastewater of human origin.

Satellite facilities: Storage/treatment facilities at remote locations upstream of the dry weather flow sewage treatment plant and usually at the regulator/overflow site.

Sediment oxygen demand: Biochemical consumption of dissolved oxygen in overlying waters by decaying sediments across the water-sediment surface.

Sensitivity analysis: The variation of model parameters to determine the sensitivity of the model to each parameter.

Sewer: A pipe or conduit generally closed, and normally not flowing full, for carrying sewage or other waste liquids.

Sewer flushing: Flushing applied to combined sewer systems during dry weather flow periods to remove settled material periodically or as it accumulates, and to hydraulically convey it to the treatment facilities, thus preventing resuspension and overflow of a portion of the solids during storm-flow periods and lessening the need for CSO treatment.

Sewerage: System of piping, with appurtenances, for collecting and conveying wastewaters from source to treatment and/or discharge.

Simulation: The application of a model.

Source control: A method of abating wet weather flow or pollution at the upstream, upland source where the pollutants originate and/or accumulate.

Storage The slowing, dampening, or attenuating of storm-generated or combined sewer flows either entering the sewer/drainage system or within the sewer/drainage system by temporarily holding the flow on a surface area, in a storage basin, within the sewer itself, or within a receiving water.

Storm duration: The period over which rainfall occurs.

Storm flow: Overland flow, sewer flow, or receiving-stream flow caused totally or partially by surface storm runoff, storm-related subsurface infiltration, or snowmelt.

Storm frequency: See *frequency of return.*

Storm intensity: The rate of rainfall usually expressed as inches per hour.

Storm sewer: A sewer that carries intercepted surface runoff, street wash and other wash waters, or drainage, but excludes domestic sewage and industrial wastes except for unauthorized cross-connections.

Storm sewer discharge: Flow from a storm sewer that is discharged into a receiving water or to a sewer system.

Stormwater: Water resulting from precipitation that percolates into the soil; runs off freely from the surface; or is captured by storm sewer/drainage, combined sewer, and, to a limited degree, sanitary sewer facilities.

Subcatchment: A portion of a catchment producing the runoff that passes a channel or stream location upstream of the location defining the catchment.

Supernatant: The relatively clear liquid layer above the sediment layer in the vertical column.

Surcharging: The transition between open channel flow and pressure flow in sewers.

Surface runoff: Precipitation and water (e.g., street wash) that falls onto the surfaces of roofs, streets, ground, and so on, and is not absorbed or retained by that surface, thereby collecting and running off.

Swirl regulator/concentrator: A cylindrically-shaped CSO control device that provides the dual function of a regulator and a solids-liquid concentrator. As a concentrator, it achieves good removal of the heavier settleable solids fraction in CSO. (See also *regulator.)*

Toxicity: The degree to which a pollutant causes physiological harm to the health of an organism.

Trace metals: Metals present in small concentrations. From a regulatory standpoint, this usually refers to metal concentrations that can cause toxicity at trace concentrations.

Trunk: A sewer, also known as a main sewer, that receives the discharge of one or more submain sewers.

Urban runoff: Surface runoff from an urban drainage area that reaches a stream or other body of water or a sewer/channel.

Water quality criteria: A threshold value or concentration for a pollutant or pollutant effect as chosen by regulatory agencies to distinguish between acceptable and nonacceptable environmental conditions; usually chosen based on laboratory observations of organism response.

Water quality standard: A threshold value or concentration enforced by law as a requirement to maintain acceptable environmental water quality conditions; usually chosen based on laboratory observations of organism response.

Wet weather flow: Usually referred to as the flow in a combined sewer system with stormwater, but may also constitute the flow in a separate storm or sanitary drainage system with stormwater.

Wet weather pollution: The discharge from a conveyance system resulting from wet weather flows. This discharge may occur to a receiving water as well as streets and basements (street and basement flooding).

WERF Publications Order Form

Stock #	Publication Title/Project Number	WERF Subscriber	WEF Member	Other
D0013	Guidance Manual for Polymer Selection in Wastewater Treatment Plants (91-ISP-5)	$10	$55	$75
D0015	Document Long-Term Experience of Biosolids Land Application Programs (91-ISP-4)	$10	$55	$75

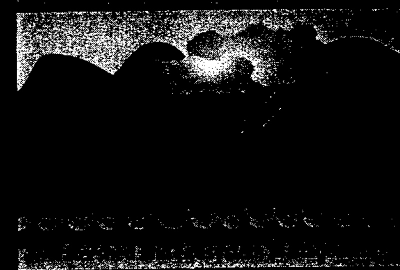
FINAL REPORT



Benchmarking Decision Criteria for Urban Wet Weather Abatement

Combined Sewer Overflow

Sanitary Sewer Overflow

Stormwater

Abatement

Decision Criteria Benchmarking

Project 97-CTS-6
1999

Water Environment Research Foundation

Urban wet weather pollution manifests itself in three different ways: combined sewer overflows (CSO), sanitary sewer overflows (SSO), and stormwater runoff (SW). Urban wet weather pollution is a reflection of the watershed or sewershed from which it is generated and the climatic patterns the area experiences. The result is a wide-scale challenge that requires very site-specific solutions.

This report presents data from CSO and SSO and SW communities. The major data categories include public participation, issues driving technical considerations, financial considerations, watershed approach and water quality issues. The data is presented in such a way as to facilitate benchmarking. This report also presents guidance issues including public participation, watershed framework approach, receiving water impacts, monitoring, modeling of impacts, and cost effectiveness analysis.

Twenty-six CSO, sixteen SSO, and fourteen SW communities participated in this project. The findings suggest that: (1) since the publication of the Federal CSO policy in 1994, many CSO communities have begun the process of CSO abatement, (2) while SSOs are common, the lack of federal guidance has stalled the initiative for SSO abatement and (3) communities using the watershed approach have moved forward with SW abatement.

Water Environment Research Foundation

Environmental Stewardship Through Innovative Science and Technology

The Water Environment Research Foundation (WERF) was established to advance science and technology for the benefit of the water quality profession and its customers. Funded through voluntary contributions, WERF manages research under three major thrust areas: Collection and Treatment Systems, Human Health Effect and Products, and Watershed and Ecosystem Management. WERF seeks cost-effective, publicly acceptable, environmentally sound solutions to water pollution control problems. A 15-member Board of Directors composed of water quality professionals; volunteers from utilities, academia, consulting firms, and industry; a Utility Council and Corporate Council composed of subscribing entities; and a Research Council of knowledgeable leaders in environmental sciences and engineering are actively involved in applied and basic research program management.

While WERF manages the research and coordinates with the parties involved, the actual work is carried out by individual organizations, primarily utilities, universities, and industrial and commercial firms. To ensure objectivity, an independent advisory group (the Project Subcommittee) of distinguished scientists and engineers helps select researchers, oversees the studies, and provides periodic technical peer review and advice. Benefits accrue in the form of services, technological advances, and information for direct application by the profession for its customers.

The Water Environment Research Foundation is successfully building a cooperative research and development program serving the water quality profession. The Foundation's goal is to apply sound and objective scientific information to better serve the public.

SSO Case Histories:

The following SSO case histories were used with authorization of EPA Office of Water.

Houston, Texas
Johnson County, Kansas
Oklahoma City, Okla.
Wayne County (Downriver Communities), Mich.

These SSO case histories will be published in an EPA report entitled, *Developing Case Studies on Sanitary Sewer Overflow Abatement Programs*, by Limno-Tech Inc. as a sub-contractor to Parsons Engineering Science.

Water Environment Research Foundation Staff

Executive Director: Glenn Reinhardt
Deputy Director: Charles I. Noss, Sc.D.
Project Manager: Patricia Haddon

R0018399

BENEFITS

- Presents the most current federal combined sewer overflow, sanitary sewer overflow, and stormwater policies.
- Provides communities essential criteria to use as guidance for wet weather pollution abatement. These criteria include public participation, technical considerations, financial considerations, watershed approach, and water quality.
- Benchmarks policy interpretations and progress of various municipalities in achieving water quality goals.
- Provides communities with data that may be useful for wet weather pollution stakeholders engaging in self-evaluation activities.
- Provides cost-benefit analysis procedures.
- Presents a history of wet weather pollution management control strategies.

8-9 Expected Debt per Household as Percentage of Median Income, Onondaga County, NY 8-6

R0018405

Executive Summary

Criteria by which municipalities make decisions for abatement of wet-weather pollution are as variable as the very subject itself. This variability is due to the site specific nature of the tributary area as it relates to the receiving-water in question; interpretation of regulations which can differ among U.S. Environmental Protection Agency (U.S. EPA) regions as well as states; and sense of urgency which may be permit related or related to a particular episode. Wet weather pollution manifests itself as combined sewer overflow (CSO), sanitary sewer overflow (SSO), and stormwater (SW). Although these wet weather discharges can affect receiving waters in a similar way, each is distinctly different in the manner in which it is regulated, how the regulations are enforced, and the sense of urgency to abate the related pollution.

This report identifies the experiences of municipalities as well as regulatory agencies in dealing with wet weather issues. The data are presented in such a way as to facilitate benchmarking of decision criteria. Benchmarking, as used in this report, identifies the status of various municipalities and their progress toward achieving water quality objectives; such benchmarking can provide to any municipality the benefit of real experience.

CSOs generally were recognized as a significant source of pollution in the late 1960s and specifically identified at the federal level through the landmark 1972 Amendments to the Federal Water Pollution Control Act. Much of the CSO work was started through federal R & D programs initiated in the early 1970s. These programs were also instrumental in identifying SSOs as a pollution source. Subsequent sewer system evaluations revealed SSOs as a real, but illegal, component of sewer systems.

The activity directed toward CSOs has been greater than SSOs and SW owing to the earlier awareness and recognition of this type of pollution and, perhaps more important, the urgency associated with the health risks stemming from the sewage component. The intensity of regulatory and municipal activities sharply increased in September 1989 when U.S. EPA published the draft National CSO Control Strategy. Until then, in the absence of clear guidelines, most municipalities were unwilling to forge ahead.

SSOs were specifically identified as part of the facility planning required under the 1972 amendments. However, remediation of many SSOs has been slow due to the lack of a definite federal policy or state guidelines. In many cases, the demand by regulatory agencies that SSOs simply be eliminated has met with resistance and active debate. One of the major issues has been whether or not SSOs that react directly to rainfall could or should in fact be treated as CSOs.

It wasn't until some years later after CSO and SSO problems were addressed by the regulating community that SW became a focus. The significance of SW pollution was understood as an outgrowth of many CSO characterization studies. In a similar manner to CSO, SW activities increased sharply with the release of federal regulations on Nov. 16, 1990. Nevertheless, SW abatement activities on a national scale have been spotty owing largely to variability in enforcement. In those EPA regions and states where CSOs have been a major problem, SW has taken a back seat. In those EPA regions and states where there is a prevalence of separately sewered areas, SW activities have been greater.

In consideration of the above-stated differences, this report categorizes the CSO, SSO and SW experiences separately. As expected, the CSO activity and number of municipalities reported are by far greater than either the SSO or SW activities reported: 26 CSO communities versus 16 SSO communities and 14 SW communities.

SSO activities may be far more numerous than has been recorded, since such discharges are viewed as illegal and are not always openly acknowledged. Also, virtually all moderately aged separated sanitary sewers will overflow a during severe, infrequent storm event, and this phenomenon probably will continue. Stormwater activities are more openly documented; limitations in activity are more a reflection of other factors such as regulatory pressure and specific water quality needs.

ES.1 CSO

The communities included in this CSO benchmarking survey represent a range of geographic locations, population, demographics, CSO system sizes, abatement strategies and schedules. Annual rainfall for these communities ranged from 20 in. to more than 40 in.; however, the majority had annual rainfall greater than 30 in. Most discharge CSO into rivers.

The data collected show that public concern for water quality expressed through state initiatives started the abatement process for many communities. Such initiatives took the form of requirements for CSO facility planning which included alternative and cost-benefit analyses. The most prevalent parameters were and continue to be bacteria and floatables. Solids, biological oxygen demand (BOD) and nutrients are of some concern, with dissolved oxygen and metals being the parameters least of concern.

Upon the release of the Draft National CSO Control Policy in 1994, many CSO facility plans were revisited to determine compliance with either "presumption" or "demonstration" provisions and to develop the required long term control plan (LTCP). The same number of communities followed the presumption approach as followed the demonstration approach; however, the majority of smaller communities followed the presumption approach.

The most prevalent form of implementation has been best management practices (BMP) due to the "housekeeping" nature of such steps and the low cost-to-benefit relationship. Reductions of annual CSO volume from BMPs were reported as high as 90%.

Abatement beyond BMPs was implemented by only a limited number of communities prior to the national policy. In some cases, communities with high enough state priorities were able to take advantage of federally available grant funds. For the most part, however, abatement has taken place after 1994 and has not included federal grants. State revolving funds have become available in place of the previous U.S. EPA Construction Grants Program.

As a consequence of little or no federal or state funding currently available for design and construction, financial considerations have become that much more important, resulting in a greater emphasis on cost-benefit evaluations and reviewing the affordability guidelines within the policy.

The watershed perspective has been introduced only in the last few years. States have embraced this approach largely upon the release of U.S. EPA's total maximum daily load (TMDL) guidelines, which relate to a watershed approach. The TMDL guidelines provide a basis for proceeding in the absence of a basin-wide wet weather plan which is the responsibility of states to develop. However, almost no communities used a watershed approach to determine CSO abatement needs. A limited number of communities have recently started either a watershed or TMDL approach to verify total wet weather readings and identify needs to achieve water quality goals.

Most communities acted to abate their CSOs due to regulatory requirements which can take the form of permit renewals, administrative orders or consent orders. Generally communities acted upon requirements more or less in that order. Most responding communities have completed their LTCP. However, only 20% of the responding communities have completed abatement, and only one, Rochester, N.Y., completed abatement through the construction grant monies made available in the 1970s. Most responding communities received funding from one or more of a variety of sources, including construction grants, state revolving funds and increased taxes.

Two parameters that are serving as the focus for abatement and permits are floatables and bacteria. Concerns are often expressed for other parameters, such as solids, BOD, nutrients, and heavy metals, but limits can and have been challenged, and in some cases watershed efforts are being undertaken. Floatables limits have taken the form of substantial removal or capture up to a specific size storm, for example a one-year frequency. Generally bacteria are specified as a maximum or average concentration for a specific event or monthly basis.

In setting permit parameters, little consistency exists from case to case, which is understandable in light of their site-specific nature and related health risks. States prefer to await site-specific information so that the most practical permit limits can be established. The most notable parameters that vary are:

- design storm frequency;
- bacteria type, concentration and violation frequency; and
- methodology for assessing annual impacts.

ES.2 SSO

The Urban Institute (1984) estimated that as an annual average there are 825 sewer backups and 140 sewer breaks every year for every 1,000 miles of sewer. The Urban Institute survey attributed backups to a variety of factors: the location of pipe in trouble-prone areas, the pipe material, the size of pipes, the material, construction methods, local soils, and maintenance practices.

In 1994, the Civil Engineering Research Foundation found that three-quarters of the sanitary sewer systems function at 50% of capacity or less. Root penetration, corrosion, soil movement and inadequate construction are the cause of most structural failures.

As a result of reduced sewer capacity and failures, SSOs during wet and dry weather are a reality. The Association of State and Interstate Water Pollution Control Administrators (ASIWPCA) found that 3% of municipal systems have at least an occasional dry weather SSO.

In a Water Pollution Control Federation study (1989), 1,003 wastewater treatment plants identified facility performance problems. Infiltration and inflow (I/I) was the most frequent performance problem cited.

Different National Pollution Discharge Elimination System (NPDES) authorities have historically provided different emphasis on oversight of sanitary sewer collection systems. In addition, some of the NPDES regulatory provisions addressing sanitary sewer collection systems are unclear, and different NPDES authorities have provided different interpretations regarding SSOs. For example, the ASIWPCA (1996) study found that many states do not issue permits for smaller sanitary sewer systems that discharge into a larger system; however, some states issue permits to all sanitary sewer systems. The ASIWPCA study also found that some states authorize wet weather control facilities that provide some level of treatment or flow control, while other states do not authorize such facilities.

The communities included in this SSO benchmarking survey represent a range of geographic locations, demographics, abatement strategies and schedules. The majority of responding communities serve a population of less than 500,000 and manage total drainage areas of more than 55,000 acres. Annual rainfall for these communities ranged from 20 in. to more than 40 in. Most discharge SSO into rivers or streams.

Most communities have not defined their annual discharge quantity, unlike the case of CSO. Wayne County, Mich., was one of the few exceptions. Flow monitoring in 13 Wayne County communities was used to evaluate the relative contribution of each to the wet weather pollution.

Public participation has been minimal compared to CSO and SW. Public concerns have ranged from aesthetics and water quality to flooding. The major water quality parameters of concern have been bacteria, BOD and dissolved oxygen.

The major abatement solution has been I/I reductions at the source based upon cost-benefit analysis. In a few select cases, such as Johnson County, Kan., and Houston, Texas, satellite treatment of SSOs has been approved. Satellite treatment technology included screening, settling tanks or ponds, and disinfection. Such an approach provided a cost-effective means of complying with water quality requirements.

ES.3 Stormwater

In most cities, very little has been done beyond basic SW drainage. In a few communities (as this report documents), early concerns by the public on declining water quality resulted in attempts to manage SW quality. After drainage problems were brought under control, usually through master planning and the construction of large-scale facilities, construction-erosion control was usually implemented in those communities. With these important considerations addressed, some of the communities were able to address SW quality. Some stressed controls with new development, while a very few examined retrofit opportunities.

With the SW NPDES permit program in place, SW quality management has been brought to the attention of most medium and large cities in the country (communities > 100,000). In October 1999, the permit program will be expanded to smaller municipalities (< 100,000).

Because of the large number of communities involved in the first and second phases of the NPDES SW permit program, the federal and state approach has been to define basic requirements for the permits, with little specified in the way of controls. Obviously, the submission of all the municipal industrial SW permits has produced a financial, logistic, and management problem for the state agencies and EPA regions.

The requirements included in the issued permits rarely specified any control or management needs beyond conducting an outfall monitoring program of about three storms a year at about five land use sites. The permits are generally issued for five years, with the expectation that specific control requirements would be added during later permitting periods as local problems become better defined. However, after almost ten years of the SW NPDES program, medium sized cities have also submitted permit applications; most have received their initial permits, and some small communities will be included in the program within a year. Therefore, the SW permit program has increased the burden on regulatory agencies. This has resulted in little opportunity for increased site-specific control objectives to be included in the permits.

Most of the specific accomplishments of improved SW quality have occurred in communities with flooding/drainage problems, scarce water resources, and the financial ability (usually through local funding). Specific requirements by local communities, and some state agencies, are the driving force behind these major accomplishments.

Decision criteria are usually expressed as meeting the federal SW regulations, with only a few exceptions where local residents expressed early and loud concerns over declining water quality.

In general, monitoring of urban SW runoff has indicated that the biological beneficial uses of urban receiving waters are most likely affected in terms of habitat destruction and contaminated sediment, while documented effects associated from acute exposures to toxicants in the water column are rare. Receiving-water investigations of runoff events have not indicated significant short-term receiving water problems, but long-term problems are common.

It is therefore difficult to relate such pollution to conventional numerical standards. Nevertheless there is interest in developing special wet weather standards.

In order to investigate the current state of thinking in SW design, in 1997 University of Alabama at Birmingham distributed a survey to which 85 communities responded. About 75% of the respondents indicated that local or county authorities specified drainage system levels of service (design storms). The most common design storm was a 10-year storm (10% probability of occurrence in any one year) for all land uses (42%). Several responses also indicated that most systems were checked for flooding with respect to the 100-year storm. About 86% of all survey respondents routinely used computerized tools for storm drainage design. The respondents also identified water quality concerns that were associated with SW runoff. More than 60% of the participants indicated sediment as a pollutant of concern. Nutrients (35%) and metals (34%) were the other most frequent answers. Other common answers were oils and grease, bacteria, toxicants, floatables, and salts.

The communities included in this SW benchmarking survey represent a range of geographic locations, demographics, abatement strategies and schedules. All the responding communities manage total drainage areas of more than 1,000 acres and had more than 50 outfalls. Annual rainfall for these communities ranged from 20 in. to more than 40 in. Most discharge SW into rivers or streams.

Most communities indicated a public participation program. General water quality, along with basement flooding, were the most commonly listed public concerns.

Almost all the communities had completed a SW facility plan or are currently developing one. Almost all respondents indicated that regulatory requirements were the main driving force in their SW quality management efforts. A wide range of technologies was considered by these communities, including construction site erosion controls, public works practices, infiltration, and sedimentation.

Most SW communities did not have significant past investments in a SW abatement infrastructure. However, there is some indication that more money will be spent in the future. The funding sources were varied, with fees from utility districts being most common, followed by federal grant money, state grant money, and increased taxes.

About one-half of the responding communities used mathematical models of their SW systems and almost all indicated that a watershed approach has been taken or is in progress.

CHAPTER 1.0

INTRODUCTION

1.1 Introduction

Urban wet weather pollution manifests itself in three different ways: combined sewer overflow (CSO), sanitary sewer overflows (SSO), and stormwater runoff (SW). CSOs are the result of the "designed" relief of a sewer system that intentionally carries SW and sanitary sewage. SSOs, on the other hand, are the result of the unplanned relief of a sewer system intended only for sanitary sewage but also carrying rainfall-induced infiltration, illegal SW connections, and invasions of SW. Stormwater runoff discharges include flows that have been collected in a separate storm sewer system or a surface drainage system.

Urban wet weather pollution is a reflection of the watershed or sewershed from which it is generated and the climatic patterns the area experiences. The impacts of wet weather discharges are determined by a variety of complex relationships. These relationships include the type and magnitude of pollutant loads being transported, the ecological and hydraulic nature of the receiving water, as well as the designated beneficial uses, and the desires and expectations of stakeholders. The result is a wide-scale challenge that requires very site-specific solutions.

Solutions to wet weather pollution require investigation of a wide variety of management options and the relationship between the costs of management and water quality benefits. Benchmarks for effectiveness are also useful to determine if the control program is working. The most successful control programs are often part of an overall watershed management strategy.

Benchmarking as used in this report identifies the status of various municipalities (to include sewerage agencies) and their progress in achieving water quality objectives.

1.2 Objectives

The objective of this project is to document federal regulations and benchmark policy interpretations of U.S. Environmental Protection Agency (U.S. EPA) and select state regulatory agencies, and to document the progress of various municipalities in achieving water quality goals. Information is presented in case histories and summarized in matrices. Such benchmarking information can provide municipalities with real experiences to better develop solutions to their own CSO, SSO, and SW challenges. This report identifies where municipalities are, what has been achieved, and where they are going; but it must be recognized that each municipality reflects site-specific conditions and any comparisons are highly dependent on such conditions.

CHAPTER 2.0

BACKGROUND

2.1 Chronicle of Water Pollution Regulations

The first comprehensive federal involvement in controlling water pollution was the Water Pollution Control Act of 1948 (PL 80-845). It required the Surgeon General to develop programs to eliminate or reduce the pollution of interstate waters and was the first statute to provide federal financial assistance to state and local governments for water pollution control programs. This law was specific in limiting federal enforcement activities to involvement in pollution of interstate waters.

Federal interest in controlling water pollution increased through the 1960s. The Federal Water Pollution Control Act of 1956 (PL 84-660), the 1961 amendments to that act (PL 87-88), the Water Quality Act of 1965 (PL 89-234), and the Clean Water Restoration Act of 1966 (PL 89-753) all resulted in increased federal funding of water pollution control efforts and in the enforcement of environmental laws. The Water Quality Act of 1965 created the Federal Water Pollution Control Administration, the predecessor of U.S. EPA. Water quality standards also were a prominent feature of that law and were used to define actual occurrences of water pollution in interstate waters.

Throughout the 1960s public interest in environmental affairs heightened as the seriousness of pollution became painfully evident when the Cuyahoga River caught fire. The Cuyahoga River fire, along with the pesticide dangers documented in Rachel Carson's Silent Spring, President Lyndon Johnson's declaration that the Potomac River near Washington, D.C., was a "national disgrace," and a major oil spill off the coast of Santa Barbara, Calif., influenced people to take action to protect the environment.

In the 1970s, increased environmental awareness resulted in mounting public frustration over the slow pace of cleanup efforts. Congress overrode a presidential veto to enact the Federal Water Pollution Control Act Amendments of 1972 (PL 92-500). While the title implied that it amended the previous legislation, it actually represented a fundamental change in the structure and organization of U.S. water pollution control programs. The 1972 Amendments brought a shift of program responsibility from the states to the federal government.

The major provisions of PL 92-500 state that all discharges are illegal unless they are in compliance with requirements set forth by the act and that all point source discharges must obtain a permit. This permitting requirement encouraged the formation of the National Pollutant Discharge Elimination System (NPDES). The purpose of these authorities is to administer permits establishing pollution limits, and specifying monitoring and reporting requirements for point source pollution. The objective of the act was to restore and maintain the physical, chemical, and biological integrity of the nation's waters, the so-called "swimmable-fishable designation." The act was notable in terms of both its national comprehensiveness and its specificity; virtually all forms of pollution were recognized. The act also provided citizens the right to bring a civil action against any person in violation of an effluent standard.

In the early '70s, attempts were made to identify and prioritize pollution sources and their relative importance through a national "needs surveys" required of all municipalities by the federal government. These surveys served as the basis for planning the Federal Construction Grants Program. This resulted in a special report to Congress on CSOs (EPA -430/9-78-006), as well as in a 1978 needs survey entitled *Cost Methodology for Control of Combined Sewer Overflow and Stormwater Discharge* (EPA -430/9-79-003). The latter estimated the capital costs to meet the "swimmable" goal to be $61.7 billion (in year 2000 dollars).

In the 1970s, funding assistance was increased to municipalities; but with the increased funding came more program requirements and involvement of federal and state regulators. The U.S. EPA , through numerous research and demonstration grants to municipalities, made significant advances in the areas of receiving water/water impact analysis, impact analysis, sewer-system characterization, control and treatment technology, and cost effectiveness analysis. As a result of these studies, technology-based effluent limits were established.

The Clean Water Act of 1977 (PL 95-217) included revisions in the areas of construction grants funding and the definition of conventional, unconventional, and toxic pollutants. It also allowed states to assume responsibility for federal programs, thereby encouraging the formation of the State Pollutant Discharge Elimination System (SPDES) Authority.

The "208" planning studies were an incentive to local governments to develop their own plans, with minimal federal input. These plans were to characterize all point and nonpoint pollutant discharges in designated areas and to develop treatment schemes that would allow the goals to be met. Unfortunately, most of these plans were conducted in short time periods with limited technical success. Control measures were recommended with few local demonstrations of their potential success. Recognizing these technical shortcomings, Congress authorized the Nationwide Urban Runoff Program (NURP) to demonstrate the applicability of various urban runoff control measures in about 30 cities. These studies were completed in 1983 (EPA , 1983).

In 1981, Congress revised the municipal construction grants program as part of the Construction Grant Amendments of 1981 (PL 97-117). This law marked the beginning of the end of the grants program, with limitations on grant-eligible categories and a reduction in the level of grant assistance for eligible projects. The Construction Grant Amendments of 1981 empowered state governors to use 20% of the states' federal allotment of construction grant funds for the correction of CSOs, if deemed a major priority. Also, a separate material fund of $200 million annually was established for marine bays and estuaries. The Water Quality Act of 1987 (PL 100-4) established the revolving loan program as the successor to the grants program. This law also continued the efforts to address controlling toxins in wet weather pollution and designated water use, and began efforts to address nonpoint sources of pollution.

After the 1987 Water Quality Act amendments, the U.S. EPA issued new regulations that required states to provide scientific justification if surface water was not designated to protect aquatic life and recreational uses. In the event that the designation turned out to be inappropriate, the U.S. EPA provided the means for making adjustments by way of the Use Attainability Analysis (UAA). UAA is a structured scientific assessment of the chemical, physical, and biological conditions in a water body. The comprehensive evaluation focuses on water quality, available habitat, and flow regimes. The UAA offers the best potential to direct scarce resources where they will provide the greatest environmental benefits. However, this process is time-consuming, expensive, and potentially controversial because of the lack of clear legal and scientific decision criteria.

U.S. EPA regulations to control SW runoff were first published in the Dec. 7, 1988 issue of the Federal Register. These regulations initiated a permit process for urban runoff, but the reporting information required and the schedules vary depending on the land use and the size of the community. Large- and medium-sized communities are currently developing SW permits under the Phase I SW policy, and small communities will be targeted in the future under the Phase II SW policy. The general application requirements stress descriptive information concerning the drainage area, with minimal runoff monitoring requirements.

Throughout the 1980s many citizens exercised their right to bring a civil action against persons in violation of effluent standards. In 1987, the number of civil actions increased, partly due to the publicity produced by the *Gwaltney of Smithfield, Ltd. v. Chesapeake Bay Foundation Inc.*, U.S. Supreme Court decision. The court ruled that citizens may bring civil action in federal court if they make a good faith allegation of continuous or intermittent violation. The plaintiffs need not prove their allegations of ongoing noncompliance before the civil action, since the statute does not require that a defendant "be in violation" at the commencement of the suit, but only that the defendant be "alleged to be in violation." The public realized that these suits are an effective deterrent against polluters and provide additional enforcement power to that of the regulatory agencies.

In 1989, U.S. EPA published the draft National CSO Control Strategy that established the foundation for states to develop their own strategies and for communities to begin to appreciate the ramifications of CSO abatement. Following extensive review by several "stakeholder" groups, U.S. EPA published the Final CSO Control Policy in April 1994. Very few states were willing to embark upon their own requirements until the federal government issued its own policy. Some communities did proceed with CSO abatement planning and certain best management practices (BMP) in the early 1980s but at the risk of not complying with forthcoming requirements. Generally, communities were concerned that if they forged ahead, they would be required to change their approach if it did not meet the forthcoming requirements. The national strategy served to initiate dialogue and to some extent accommodate such concerns.

The CSO policy was developed as the result of input from individuals, communities, public interest groups, regulatory agencies, and professional organizations such as the Water Environment Federation, CSO Partnership, and Association of Municipal Sewerage Agencies. Consequently, it evolved into a document that accommodates the latest technological approaches to defining the pollution and associated impacts, and at the same time addresses the needs of communities both large and small. Most important, it recognizes the site-specific nature of CSOs.

In 1992, the U.S. EPA initiated a consultative process to help develop framework documents for controlling CSOs. A work group was established with membership from public interest groups such as the National League of Cities, Environmental Defense Fund, and Lower James River Association. The objective of the group was to develop a set of criteria to be used in determining long-term CSO control programs and implementing NPDES permits.

In 1994, the general lack of clarity and consistency in the nationwide approach to SSOs led a number of municipalities to approach the U.S. EPA Office of Water and ask that an advisory committee be formed to make recommendations on how to apply the NPDES program to SSOs (SSO Federal Advisory Subcommittee, 1996). As a result, the SSO Federal Advisory Subcommittee was formed and began meeting in late 1994. The subcommittee was instrumental in developing draft federal policy and this is acknowledged in the March 7, 1996 memorandum accompanying a new addition to the Enforcement Management System (EMS) Guide. The EMS Guide establishes guiding principles and priorities for the various U.S. EPA regions and NPDES states in responding to separate sanitary sewer discharge violations (U.S. EPA , 1996a).

In 1996, more than 1,100 viewers participated in the live satellite seminar, "The Clean Water Act: New Directions." Experts noted that more collaboration among regulators, the regulated community, and the public could produce cleaner water more cost effectively while addressing the needs of individual communities. As a result of the 1996 seminar, the U.S. EPA is leading an "Adopt Your Watershed" campaign. Through this effort, U.S. EPA challenges citizens to join together to protect and restore our water resources.

2.2 Combined Sewer Overflow

CSOs originate from sewer systems that collect both SW runoff and sanitary sewage in the same pipe. During dry weather, these sewer systems convey sanitary sewage directly to a wastewater treatment plant (WWTP). However, during wet weather events the volume of SW runoff and sanitary sewage can exceed the capacity of the sewer system or WWTP. Under these conditions the combined sewer systems are designed to overflow and discharge excess SW runoff and sanitary sewage into streams, rivers, lakes, or estuary receiving waters.

Overflows from combined sewers during storm events result in the discharges to receiving waters of untreated sanitary sewage, which also may contain pre-treated industrial wastewater and untreated SW. Combined sewer overflows contain pollutants that are present in the domestic and industrial wastewater, as well as pollutants in the urban SW runoff that enters the combined sewer system. CSOs are among the major sources responsible for beach closings, shellfishing restrictions, and other water body impairments

In many cases, these discharges have an adverse effect on receiving water quality and attainment of designated uses. In recent years, there has been an enhanced regulatory focus on CSOs and their control, and communities with combined sewer systems are being called upon to develop and implement programs for control of CSOs.

Combined sewer systems serve roughly 950 communities throughout the U.S. with about 40 million people. Most communities with CSOs are located in the Northeast and Great Lakes regions, particularly in New England, Pennsylvania, Indiana, Ohio, Illinois, Michigan, New York and West Virginia. Although large cities like New York, Philadelphia, and Atlanta have combined sewer systems, most communities with combined sewer systems have fewer than 10,000 people.

2.2.1 U.S. Combined Sewer Overflow Policy

The National CSO Control Policy was signed by Carol Browner, the Administrator of the U.S. EPA , on April 8, 1994. This signing culminated a lengthy process of policy development and negotiation among CSO communities, U.S. EPA , the states, and environmental groups. Based upon the NPDES program, the CSO policy establishes a consistent national approach for controlling CSOs.

Consistency within the CSO policy is established by requirements for all CSO communities to implement Nine Minimum Controls (NMCs). The NMCs are technology-based controls that can be used to abate CSO impacts without extensive engineering studies or substantial construction costs. The NMCs place emphasis on maintenance and proper operation of the combined sewer system to ensure maximum use of the collection system and treatment capacity of the WWTP. The NMCs are documented in Appendix A. Consistency is also established by requiring CSO communities to develop comprehensive long term control plans (LTCP) tailored to site-specific conditions. The development of LTCPs is a comprehensive effort that leads to the identification and implementation of technically feasible, effective and affordable controls. Key principles of the LTCP are documented in Appendix A.

The significance of the CSO policy is its recognition of the site-specific nature of combined sewer systems and the variability of receiving water conditions and impacts. Non- and low-structurally intensive pollution controls (i.e., BMPs) are normally the first item that has to be addressed in accordance with best professional judgment. Communities unable to mitigate serious water quality impacts with the implementation of BMPs alone are normally required to provide additional control measures based on water quality requirements.

The features of the CSO policy that can be considered perhaps the most helpful in assisting communities to address their CSO challenges are:

- identification of the presumption and demonstration approaches, and
- guidance on affordability.

The presumption and demonstration approaches provide CSO communities with targets for controls that achieve compliance with the Clean Water Act, particularly the protection of designated uses. Under the demonstration approach, water quality modeling or other tools are used to demonstrate that predicted CSO discharges resulting from the LTCP would be sufficient to attain water quality standards. The presumption approach is based on the premise that a LTCP that meets certain minimum defined performance criteria in terms of expected frequency of overflow, or percent capture of the CSO pollutant load would be presumed to provide an adequate level of control to meet the water quality-based requirements of the Clean Water Act. Key principles of the presumption and demonstration approaches are documented in Appendix A.

The purpose of guidance on affordability is to provide criteria for assessing financial capability and to relate that capability to an appropriate compliance schedule. Its goal is to provide general boundaries to aid all parties in negotiating reasonable and effective schedules for implementing CSO controls. Key principles of the guidance on affordability are documented in Appendix A.

The CSO policy also provides flexibility to CSO communities so that control programs can be developed to fit local needs. The policy contains specific considerations for small municipalities. For example, populations under 75,000 may only need to comply with the nine minimum controls, public participation, and sensitive areas portions of the policy.

2.2.1.1 U.S. EPA Regional Combined Sewer Overflow Policy Interpretation

Some variability exists among U.S. EPA regions with respect to CSO policy interpretation; however, much of the variability may be from the interpretation of the federal CSO policy by delegated states. For example, 91% of the CSO discharges throughout the U.S. are in EPA Regions 1, 2, 3 and 4; all of these CSO states have delegated program authority. However, the EPA regions are required to oversee these states, so it is likely that these regions generally acknowledge and try to accommodate the states' interpretation of the federal CSO policy. For example, within Region 1 there is significant variability in state interpretation. Maine and Massachusetts, for example, do not recognize the presumptive approach. Some of the more obvious differences among the EPA regions are with respect to the use of modeling and certain control technologies and in the implementation of the NMCs versus a LTCP. These differences are often dependent upon the individuals involved and their comfort level with approaches and technologies. To reduce this variability, U.S. EPA produced a memorandum for the purpose of discussing the federal CSO policy and identifying areas where heightened efforts are needed. This memorandum can be found in Appendix B.

2.2.2 States Combined Sewer Overflow Policy

The federal CSO policy has shifted the burden of implementation from the federal government to the states. Of the 33 CSO states and Washington D.C., 30 states submitted CSO permitting strategies consistent with the 1989 federal draft CSO policy and received U.S. EPA approval, while one state received conditional approval. U.S. EPA serves an oversight role for these delegated states, and EPA regional offices bear the burden of permitting for non-delegated states.

The delegated states and U.S. EPA regional offices, as appropriate, are designated authority to implement the CSO policy. In the case of the delegated states, CSOs are permitted through a SPDES that follows the federal CSO policy and additional state requirements. It is the responsibility of SPDES authorities to ensure permits meet the requirements of the Clean Water Act, and that CSO permittees develop long-term CSO control plans, where appropriate. Additionally, they are responsible for coordinating review of the long-term CSO control plan and permit development in association with the states authority to determine if specific revisions to water quality standards are needed. Water quality standards are state or federal requirements which serve as the legal basis for the water quality- based NPDES permit requirements under the Clean Water Act. Water quality standards consist of state-designated uses for water bodies and the criteria to protect these uses.

A summary of several of the state and EPA region CSO requirements is provided below. This summary is not intended to address all CSO programs, but rather to provide the reader with an idea of the federal policy implementation variability throughout the United States.

New York is a delegated NPDES state; therefore, SPDES permits are issued in accordance with the state's CSO control strategy and the federal CSO policy. The state's CSO control strategy encompasses two major elements, BMPs and additional control measures. New York has 13 BMPs that are equivalent to the NMC measures specified in the federal CSO policy. Additional control measures are water quality-based permit requirements that are necessary for SPDES permittees unable to mitigate serious water quality problems through the BMPs alone. These measures are equivalent to the LTCPs specified in the federal policy.

Indiana has three submittal requirements for its CSO discharge permit requirements that include (1) technology-based controls that meet the requirement of the federal NMC measures, (2) a stream reach characterization that exceeds the NMC measures, and (3) a cost-benefit analysis of alternative CSO abatement controls. The use determination in Indiana is "fishable and swimmable."

Illinois has a CSO policy more stringent than the federal presumption or demonstration approaches. Complete treatment is required for flows produced by the 1-year, 1-hour storm with a peak of 1.2 inches per hour (in./hr). Flows in excess of the specified storm must receive primary treatment sized at 10 times the dry-weather capacity. Illinois was very progressive; CSO regulations have existed there since 1962, and many of the CSO communities used Construction Grant monies to fund their CSO abatement in the 1970s.

Ohio also is implementing the federal CSO policy through the NPDES permit program. Ohio has 92 CSO communities, of which 70 have populations of less than 10,000. Most Ohio CSO communities are required to implement the NMC measures; however, several small communities are spending their money on sewer separation projects instead of implementing the NMCs. Approximately 50% of Ohio's CSO communities have implemented LTCPs, are in the process of implementing them, or have requirements to do so in their permits. Many communities are being asked to characterize and monitor before developing a LTCP (Hun, 1998).

Some delegated states have very few CSO communities. For example, California has two CSO communities (Sacramento and San Francisco) and Virginia has four CSO communities. California's CSO policy was developed solely for San Francisco and included control of CSOs to specified frequencies, capture of floatables, measuring water quality, and implementation of the NMC measures. Virginia's CSO communities were only required to implement the NMC measures.

In contrast to these other states, Iowa, Kansas, Missouri, and Nebraska are not delegated states and are therefore represented by EPA Region 4. Most cities in Region 4 have separated sewer systems; therefore none of the states accepted the responsibilities of program authority. Because CSOs are not an extensive problem, Region 4 has focused most of its efforts on WWTPs. The only CSO requirement is to provide technology-based controls. No LTCPs are required.

2.2.3 Canada Combined Sewer Overflow Policy

The Ministry of Environment and Energy CSO regulations is entitled *Determination of Treatment Requirements for Municipal and Private Combined and Partially Separated Sewer Systems.* These regulations are similar to those set forth in U.S. CSO policy. The Ministry of Environment and Energy regulations require a pollution prevention and control plan which is similar to the LTCP, implementation of minimum SSO controls that are similar to the NMCs, and a minimal level of treatment.

2.3 Sanitary Sewer Overflows

Sanitary sewer overflows are the result of the unplanned relief of a sewer system intended only for sanitary sewage. An SSO typically occurs when the flow exceeds the carrying capacity of the system, and although SSOs can, and do, occur during dry weather, they are most commonly associated with wet weather events. SSOs are caused by a variety of system faults, exacerbated by excess wet weather flows. These causes include (EPA, 1996b):

- rainfall or snowmelt entering the subsurface and subsequently entering the sewer system through defective or deteriorated pipes, joints, manholes, or connections. This is known as infiltration;
- stormwater entering the sewer system through illegal or unintentional connections. This is known as inflow. Together infiltration and inflow are referred to as rainfall-induced infiltration and inflow (I/I);
- pumps and sewers too small to handle the increased flows created by urbanization; and
- faulty equipment, power failures, blocked or broken sewers, and other acute system failures.

Although a large number of SSOs occur in the collection system, they may also occur at the WWTP. Wastewater treatment plants are often not capable of handling the excess flows that occur during large storms. As a result, the WWTP must allow some of the flow to bypass treatment and discharge directly into the receiving waters.

Regardless of the cause or location of the SSO, the end result is that untreated sewage is introduced in an uncontrolled manner into the environment, leading to concerns for public health and safety. The health, social, and economic costs of SSOs are significant. The health and environmental risks attributed to SSOs are a function of several factors including location and season, discharge frequency, discharge volume, the amount and type of pollutants present in the discharge, and the uses, conditions, and characteristics of the receiving waters (SSO Federal Advisory Subcommittee, 1996). The most serious health risks associated with SSOs involve discharges to water bodies and other areas with a potential for human contact. In addition, SSOs, along with other sources of pollution, impair or damage water bodies for one or more uses such as drinking water, swimming, fish and wildlife habitat, and non-contact recreation. Areas heavily affected by chronic and uncorrected SSOs can experience social and economic losses due to widespread health issues, beach closures, reduced property values, a reduced sense of community, reduced tourism, and loss of recreational opportunities, among others.

There are more than 18,500 sanitary sewer systems in the U.S.. All are capable, under the right circumstances, of producing SSOs (EPA , 1996a). In a 1994 survey conducted by the Association of Metropolitan Sewerage Agencies, 79 members reported SSO problems (AMSA, 1994). Another study estimated that SSOs closed beaches for 300 days in the U.S. during 1994 (National Resources Defense Council, 1995). The U.S. EPA noted that over 1,000 systems in the U.S. experience SSOs (EPA , 1997). While difficult to quantify precisely, it is clear that the sanitary sewer overflows are a widespread issue.

2.3.1 Federal Sanitary Sewer Overflow Policy

The Clean Water Act is the central piece of legislation governing the quality of the nation's waters, including SSOs (EPA , 1999). SSOs are point source discharges of pollutants and must be permitted. This is true for overflows that are released directly into a surface water or indirectly through subsurface flows or through streets and then into a storm drainage system. Operators of systems with SSOs not authorized by an NPDES permit must either eliminate the SSOs or seek a permit.

At this time standards for controlling SSOs are uncertain (EPA , 1999). The Clean Water Act requires secondary treatment for all publicly owned treatment works (POTWs) (i.e., WWTP). For all other point-source discharges, the Clean Water Act requires "best available technology economically achievable" for toxic and non-conventional pollutants and "best conventional pollutant control technology" for conventional pollutants. The system that conveys wastewater to a WWTP is included in the regulatory definition of a POTW, and thus it could be inferred that SSOs from these systems must meet the secondary treatment standard. However, the U.S. EPA has decided that for combined sewer systems, "bypasses" can occur at a WWTP after primary treatment; thus CSOs are not subject to the secondary treatment standard. Where SSOs fall in this quandary has not been decided.

A logical SSO control policy might be based on current CSO control policy. However, there are significant differences between CSOs and SSOs that preclude the direct application of the CSO Control Policy. The key differences are (U.S. EPA , Region 6, 1995):

- sanitary sewers have no diversion and discharge structures designed into the system to release the excess flows to receiving water bodies at controlled discharge locations; and
- the overflows in sanitary systems occur through manholes and defective lines, releasing the flows indiscriminately throughout the system.

Since there are no centralized discharge points in a sanitary system, the application of the technology-based and water quality-based standards of the Clean Water Act is difficult. However, if system improvements can be implemented to contain and divert SSOs to centralized locations, the differences between SSOs and CSOs lessen and a CSO-type approach becomes feasible. (The National CSO Control Policy is described in Section 2.2.1)

In 1994, the general lack of clarity and consistency in the nationwide approach to SSOs led a number of municipalities to approach the U.S. EPA Office of Water and ask that an advisory committee be formed to make recommendations on how to apply the NPDES program to SSOs. As a result, the SSO Federal Advisory Subcommittee was formed and began meeting in late 1994. The subcommittee was instrumental in developing draft federal SSO policy. This policy was documented as a new chapter in the EMS Guide on March 7, 1996. This chapter, "Setting Priorities for Addressing Discharges from Separate Sanitary Sewers," established guiding principles and priorities for the various EPA regions and NPDES delegated states in responding to separate sanitary sewer discharge violations (EPA, 1996a). This chapter is presented in Appendix C.

2.4 Stormwater

Stormwater is water from precipitation that flows across the ground and pavement when it rains or when snow and ice melt. The water seeps into the ground or drains into a storm drain system and discharges without treatment into streams, lakes, and estuary ecosystems.

Stormwater runoff contains pollutants that are collected as rainwater or snowmelt flow across the ground surface. Such pollutants include oil and grease, chemicals, nutrients, heavy metals, bacteria, viruses, and oxygen-demanding compounds.

Stormwater pollution has many sources. Three general source types are residential, industrial, and construction. The most common residential sources are from building materials (especially metal flashing), fertilizer and other landscape chemicals, pet waste, and pollutants associated with the use of automobiles. At industrial sites, chemical spills that contain toxic substances and uncovered or unprotected outdoor storage or waste areas can contribute pollutants to SW runoff. During construction, chemicals and materials can wash into ditches leading to waterbodies during rainy weather. Inappropriate discharge of sanitary and industrial wastewaters into storm drains can also contribute to the pollutant load of SW flows during dry periods. Environmental degradation associated with SW runoff may be magnified due to hydraulic changes in a developed area. When undeveloped land is urbanized, much of the land surface is paved with impervious materials (buildings, asphalt, and concrete). This increases the runoff volumes and rates during rains and decreases the receiving water flow during dry weather.

Regardless of the source of SW, the end result is that polluted water is introduced into the environment and leads to concerns for public health and safety. The U.S. EPA has identified urban runoff as one of several potential sources of more than 1,000 toxic organics that have been detected in drinking water supplies (45 FR 77870). Studies have also detected increased salt concentrations in shallow groundwater in areas where large quantities of salts are used on roads for ice control (Terry, 1974).

2.4.1 Federal Stormwater Policy

In 1973, U.S. EPA promulgated its first SW regulations in the form of an exemption. Any conveyances carrying SW runoff uncontaminated by industrial or commercial activity were exempt from the NPDES regulations. However, the Natural Resources Defense Council brought suit in the U.S. District Court for the District of Columbia, challenging the agency's authority to create such exemptions. The court ultimately held that U.S. EPA could not exempt discharges identified as point sources from regulations under the NPDES permit program.

Subsequently, U.S. EPA issued a rule in 1976 establishing a permit program for all SW discharges except for rural runoff uncontaminated by industrial or commercial activity. What followed was a series of suits brought by major trade associations and their member companies, a process that culminated in the NPDES Settlement Agreement in 1982.

During U.S. EPA 's evaluation of appropriate changes, Congress passed the Water Quality Act of 1987 (WQA) which amended the Clean Water Act of 1977 and included specific provisions related to SW.

The directives of the 1987 WQA were threefold. First, Congress specifically directed U.S. EPA to address SW discharges under the NPDES program and established statutory deadlines for the initial phases of the program. Second, Congress affirmed that SW discharges from industrial sites must be issued NPDES permits, and that the full panoply of traditional NPDES permit requirements, including technology-based and water quality-based standards, must be applied. Third, Congress established slightly different permitting requirements and standards for municipal SW discharges than for industrial SW discharges, including the new "maximum extent practicable" standard.

Through the WQA and amendments to the Clean Water Act, a two-phased approach addressing SW discharges was developed. A brief summary of the municipal SW portion of this policy can be found in Appendix D. Phase I, currently being implemented, requires permits for separate SW systems serving large- and medium-sized communities (those with over 100,000 inhabitants), and for SW discharges associated with industrial and construction activity involving at least five acres.

Phase II, which is currently under development (finalized Oct. 29, 1999), would expand this existing national program to smaller municipalities and construction sites that disturb 1 to 5 acres. In this expansion, U.S. EPA is proposing to allow certain sources to be excluded from the national program based on the lack of impact on water quality, as well as to pull in other sources not regulated on a national basis based on localized adverse impact on water quality. Finally, U.S. EPA is proposing to conditionally exclude from the NPDES SW program industrial facilities that have "no exposure" of industrial activities to SW, thereby reducing application of the program to many industrial activities currently covered by the program that have no industrial SW discharges.

2.4.2 States Stormwater Policy

Federal policy for SW management has also shifted the burden of implementation from the federal government to the states. Through the WQA and amendments to the Clean Water Act, a two-phased approach addressing SW discharges has developed. All states must follow guidelines that are no less stringent than the NPDES permit guidelines.

A summary of several state and regional SW management programs is provided below. This summary is not intended to address all SW programs, but rather to provide the reader with an idea of the federal policy implementation variability throughout the United States. A more detailed documentation of state SW policy can be found in Appendix E.

In response to U.S. EPA's SW policy, many states have imposed additional requirements. California is an U.S. EPA NPDES-delegated state with permitting authority that has instituted many more stringent requirements. For example, a regulated SW area is considered individually from the property's primary activity (the vehicle service area at a school would be considered a transportation area, requiring permitting). Point source guidelines are also more stringent (sheet flow from parking lots is considered a point source requiring a permit).

In contrast to California, Maine does not have NPDES permitting authority. However, the Maine Department of Environmental Protection Bureau of Land and Water Quality wrote the Natural Resources Protection Act that is used to protect the quality of the receiving waters by imposing additional regulations to those prescribed by the U.S. EPA . Proposed construction projects require permits directing adherence to SW quality and quantity standards.

Similar to the U.S. EPA guidelines, some states have imposed numerical standards. Hawaii, an NPDES- delegated state with permitting authority, requires that permitted discharges must comply with the state's basic water quality criteria. These criteria include prohibited substances. Discharges must conform to specific concentration allowances and cannot contain pollutants in 24-hour average concentrations greater than the values obtained by multiplying the minimum dilution by the acceptable standard. In addition, BMP plans must be implemented for construction SW runoff controls.

Arkansas has also established numerical guidance in addition to the U.S. EPA's guidelines. For example, coal pile runoff should not exceed 50 milligrams per liter (mg/L) maximum suspended solids and the hydrogen ion concentration (pH) must be within 6-9 standard units (SU). Iowa also has this limit. The Arkansas Department of Pollution Control and Ecology has specifications for detention ponds and erosion controls. Required detention pond volumes and sizing are determined using a "simplified volume formula" or the "modified rational hydrograph method."

Colorado, an NPDES delegated state, also issues permits requiring adherence to numerical limits. In addition to the numerical control limits, control measures also govern reclamation, acid runoff from mines, drainage control, subsidence, and grading activities.

Some states take a watershed approach to SW management instead of the point source approach. In response to contamination of its groundwater supply by continued urban development, Austin, Texas, passed a watershed protection ordinance in 1981. The 1986 amendment to the ordinance specifies standards for development within critical watersheds. These include buffer zones, building restrictions on slopes greater than 15%, and required setbacks from springs, creeks, and sinkholes.

Wisconsin also uses the watershed approach towards SW management and control. In 1983, the state initiated its priority watershed protection program, which involves retrofitting nonpoint source controls in watersheds where point source controls alone cannot meet water quality objectives.

The SW utility was pioneered by the city of Bellevue, Wash. Many cities now have SW utilities modeled after Bellevue's, which uses natural drainage systems such as swales, lakes, ponds, wetlands, and detention ponds to transport and dispose of SW. The primary mission of the Bellevue storm drainage utility is to "manage the storm and surface water system, to maintain a hydrologic balance, to prevent property damage, and to protect water quality for the health, safety, and enjoyment of citizens and for the preservation and enhancement of wildlife habitat" (Bissonette, 1985).

2.5 History of Wet Weather Pollution Management Control Strategies

Throughout history, many strategies have been implemented to control wet weather pollution for reasons such as flood control, water quality improvement, aesthetic improvement, waste removal, and others. To provide guidance for developing communities, a reference manual for wet weather flow systems in newly urbanizing areas is being developed as part of a cooperative agreement among the Urban Watershed Management Branch of the U.S. EPA , the University of Alabama at Birmingham (Pitt, et al. 1997), and ASCE (Heaney, et al. 1997). The reference manual includes a historical summary of wet weather pollution management control strategies (Pitt, et al. 1997), which is presented in Appendix F.

CHAPTER 3.0

APPROACH

3.1 Essential Wet Weather Pollution Abatement Criteria

To provide a sound program for abating wet weather pollution, a community should adopt a multi-faceted approach which includes encouraging public participation; monitoring and modeling impacts, including the impacts on receiving water; examining the usefulness of a watershed approach; and looking at the cost-effectiveness of any proposed program. These considerations, along with the experiences documented in the benchmark matrices and case histories, can be used as a starting point to develop site-specific wet weather pollution abatement programs.

3.2 Questionnaire Development

The project team used role-playing activities to identify wet weather abatement criteria. Participants included EPA regions, state regulatory agencies, municipalities, and the public. Each role player was responsible for identifying respective abatement criteria. The role-playing provided information used to facilitate the questionnaire development and interview process.

The questionnaire was categorized into six sections, namely public participation, conveyance system information, watershed approach, water quality, issues driving technical considerations, and financial considerations. A copy of the questionnaire is included in Appendix G.

The questionnaire was sent to CSO, SSO and SW communities throughout the United States and Canada. These communities were originally identified through data provided by U.S. EPA and private consultants. The communities represent a range of geographical locations, population, economic bases, and abatement strategies and schedules. In general, communities were initially reached via a personal telephone call. If the contact expressed interest in participating, then a questionnaire was sent to the attention of that person.

The number of questionnaires returned was less than anticipated. Of the approximately 150 questionnaires sent to communities throughout the United States and Canada, only 50 were returned. (Appendix H contains the list of questionnaire contact persons.) Despite this low return rate, the communities that participated do represent a wide range of geographic locations, demographics, and abatement strategies and schedules. More importantly, they provided meaningful data for the purpose of allowing other communities to benchmark their own wet weather

R0018425

pollution abatement progress. Though the data presented in this report is not representative of communities who have not begun wet weather abatement, those communities may find Chapter 4, Essential Wet Weather Pollution Abatement Criteria, and the benchmark data (Chapters 5-7) very useful in planning and starting their abatement programs.

3.3 Benchmark Matrices and Case Histories

Benchmarking is the process of documenting existing experiences for the purpose of culling out best practices, innovative ideas, and highly effective operating procedures that could assist in developing effective solutions.

The benchmark matrices and case histories for CSO, SSO and SW communities provide data that may be useful to stakeholders seeking to improve their wet weather pollution abatement process. Information is provided in two forms: benchmark matrices and case histories.

Data from the questionnaires were tabulated to facilitate interpretation. CSO, SSO and SW benchmark matrices can be found in Chapters 5, 6 and 7, respectively. The matrices are categorized into five sections, namely, general community statistics, public participation, systems characterization, issues driving technical considerations, and financial considerations.

Case histories for CSO, SSO and SW were developed for a select number of surveyed communities that exemplify common approaches to wet weather pollution abatement. These communities provided meaningful data for the purpose of allowing other communities to benchmark their own wet weather pollution abatement progress.

A discussion of decision criteria used to determine benefits of CSO, SSO, SW abatement follows the benchmark matrices and case histories in each chapter.

CHAPTER 4.0

ESSENTIAL WET WEATHER POLLUTION ABATEMENT CRITERIA

4.1 Criteria Development

The following guidance issues provide a fundamental approach to abating wet weather pollution. These guidance issues, along with experiences documented in the benchmark matrices and case histories, can be used as a starting point to develop a site-specific, wet weather pollution abatement program. These issues include public participation, watershed approach, receiving water impacts, monitoring and modeling of impacts and cost effectiveness analysis. The issues are structured in the form of a methodology, and are organized in a sequential manner. For example, public participation, while not always the highest priority for a municipality, should at least be considered early in the abatement process to gain the greatest returns from the program. The watershed approach, receiving water impacts and monitoring and modeling of impact issues pertain to understanding and gathering meaningful information about wet weather pollution sources and their impacts in terms of the entire watershed. Once the pollution sources and impacts are identified, a cost effectiveness analysis may be used to select alternatives and prioritize capital projects. Figure 4-1 illustrates the general methodology.

4.2 Public Participation

Public participation is the process of seeking the views and concerns of stakeholders and including them in the decision-making process. It includes open information sharing, teaming with stakeholders, gaining public input, and solving problems jointly. Stakeholders are any citizens or groups who have an interest or stake in the outcome of a decision made by the municipality. In that sense, every taxpayer in the municipality is a stakeholder. Stakeholders include federal agencies, state and local governments, environmental groups, labor organizations, citizen's groups, and community members.

The following are guides to and benefits of public participation:

- Public involvement in the process should occur early and often. Public participation takes more time and effort up front, but will result in a better decision that is less controversial and requires less outreach, education, and defense.

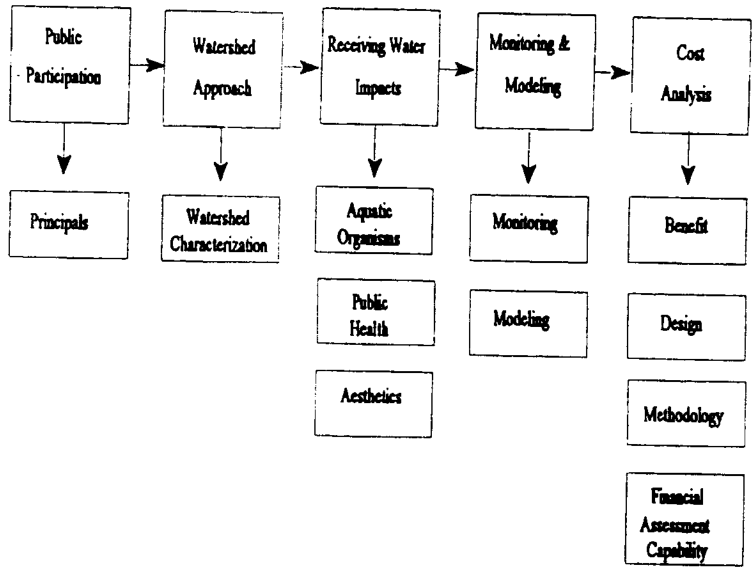

Figure 4-1. Wet Weather Issue Methodology Outline

- Public trust is earned through openness, outreach, consistency, and results. Public involvement is crucial to sound decision making. Public participation allows the municipality to enlist a much broader range of expertise than it has available in-house.
- Public dialogue increases understanding among all interests affected by decisions. Effective participation means two-way communication and the willingness of the public to take advantage of the various opportunities to participate. Public dialogue can aid both the regulated community and the public in understanding their individual expectations, resulting in more workable and widely acceptable solutions.
- Public input should be solicited from all sectors of society. Equal opportunity for comment and equal consideration of comments from the private and public sectors should be provided.
- The municipality should carefully consider all public comments, regardless of their origin, and provide a response through a comment and response document, not just an acknowledgment.

For the public to successfully participate in the decision-making process they should be informed of how and when they can get involved. The municipality should notify both the regulated community and the general public and ask for input regarding the wet weather pollution circumstances. There are many methods for obtaining public input. Each community and pollution scenario is different; therefore the most effective method, or combination of methods, should be selected on a case-by-case basis.

The following are a few methods of obtaining public input:

- ***Advisory Committees.*** An advisory committee is generally composed of volunteers from a wide range of occupations who are appointed by the municipality to represent the entire community. The committee generally serves as a sounding board for the public and an advisory board for the municipality. Advisory committees should be used to review technical documents and public comments and may also make recommendations to the municipality.
- ***Notice and Advance Notice of Proposed and Final Milestone Decisions.*** The advance notice of proposed and final decisions enables the municipality to solicit comments from the community prior to action. Information about the proposed and final decisions can be disseminated via quarterly newsletters, community newspaper articles, public service announcements, world wide web pages and local radio/television advertisements. These announcements should explain the status of the wet weather pollution abatement process and solicit input from the community. In addition, the municipality should distribute information and solicit comments through the appropriate advisory committee. In this way, the public has additional opportunities to comment on decisions, thereby developing solutions with greater community concensus.

- ***Public Information Meetings.*** The municipality should consider holding public information meetings on proposed decisions when it anticipates a need to inform the public on environmental impacts or explain a new wet weather pollution abatement scenario and respond to questions. Public meetings should be publicized using the forums listed above.
- ***Public Hearings.*** To receive comments on proposed decisions, the municipality should conduct public hearings, particularly when significant interest is generated by a proposal. These hearings should be used to officially record public comments. Public hearings should be scheduled at locations and times that allow for the greatest number of affected people to attend. Public hearings should also be publicized using the forums listed above.

4.3 Watershed Approach

4.3.1 Definition of Watershed Approach

Today's challenges require more comprehensive solutions to further restore and maintain the physical, chemical, and biological quality of our nation's waters. One such solution is the watershed approach, a coordinating framework for environmental management that focuses public and private sector efforts to address the highest priority problems within hydrologically defined geographic areas, taking into consideration both ground and surface water flow. The watershed approach has three key components:

- ***Geographic Focus.*** Watersheds are defined by natural boundaries. They are the areas that drain to surface water bodies. A watershed generally includes lakes, rivers, estuaries, wetlands, streams, and the surrounding landscape. Groundwater recharge areas are also considered.

- ***Continuous Improvement Based on Sound Science.*** Sound scientific data, tools, and techniques are critical to guide the process. Actions taken include characterizing priority watershed problems and solutions, developing action plans, and evaluating their effectiveness within the watershed.

- ***Partnerships/Stakeholder Involvement.*** Watersheds transcend political, social, and economic boundaries. Therefore, all affected interests should be involved in designing and implementing goals for the watershed. Watershed teams may include representatives from all levels of government, public interest groups, industry, academic institutions, private landowners, concerned citizens, and others.

4.3.2 The Urban Watershed

Within the watershed lies the urban watershed, a subset of the complete watershed bound by topography and city limits. It holds most of the population and contributes significantly to water quality problems.

At a minimum, the urban watershed includes, but is not limited to, SW runoff, sanitary- and combined-sewer discharges, and NPDES-permitted industrial and commercial discharges. Urban watersheds therefore include (1) all sources (point and nonpoint) originating within the urban center or urban fringe, and (2) water entering the urban watershed (surface and groundwaters entering from upstream sources, source waters supplying the urban population, and rain events). These contributions must be included to adapt to the situations exemplified by TMDL trading that allows upstream reductions to substitute for NPDES discharges. The urban watershed evaluation should also recognize the probability of the expanding urban geographic area as the national population is moving from the urban core to the surrounding areas.

4.3.3 Watershed Characteristics

The first step in abating wet weather pollution is to identify the sources and prioritize them before developing criteria for wet weather pollution abatement.

The most recent National Water Quality Inventory reports that runoff from urban areas is the leading source of impairments to estuaries and the third largest source of water quality impairments to surveyed lakes. Therefore, in characterizing a watershed, emphasis is placed on the subwatershed known as the urban watershed, even when the entire watershed may also include agricultural and suburban point and nonpoint pollution sources. The urban watershed can be characterized in three general categories: urban, environmental and infrastructure characteristics.

4.3.3.1 Urban Characteristics

The urban characteristics of a watershed may be illustrated by its physical properties, percent porosity and economic/social basis.

The physical nature of the urban watershed such as size, topographic relief, and local hydrologic conditions will determine the runoff and erosion from the watershed. Characteristics such as land use and the creeks and storm drainage system in the watershed may be used to delineate sub-watersheds, so that different attributes of the watershed may be clearly differentiated and addressed.

Nonporous urban landscapes like roads, bridges, parking lots, and buildings do not permit precipitation to percolate into the ground. Water remains at the surface, accumulates, and runs off in large amounts. When leaving the system and emptying into a stream, it erodes streambanks, damages streamside vegetation, and widens stream channels, resulting in lower water depths during non-storm periods, higher than normal water levels during wet weather events, increased sediment loads, and higher water temperatures. Native fish and other aquatic life cannot survive in urban streams severely affected by urban runoff.

Urbanization also increases the variety and amount of pollutants transported to receiving waters: sediment from development and new construction; oil, grease, and toxic chemicals from vehicles; nutrients and pesticides from turf management and gardening; viruses and bacteria from sewer systems; and heavy metals from industrial activity. Sediments and solids constitute the largest volume of pollutant loads to receiving waters in urban areas. Toxins from wet weather pollution can generally be considered a primary concern in industrialized areas that are served by combined sewers.

4.3.3.2 Environmental Characteristics

The primary concern for wet weather pollution abatement is the receiving water that must support the fishable and swimmable goals set forth in the Federal Clean Water Act Amendments of 1972. The approach to plan development should address the identification of specific environmental features that are adversely affected by wet weather pollution.

The receiving water body is usually the primary focus of attention in defining the environmental characteristics. These characteristics include:

- size relative to loadings,
- type (river, sea, estuary, ocean, reservoir, etc.),
- seasonal changes (flow, temperature, and ice cover),
- physical factors (slope, velocity, mixing zones, pools and riffles, etc.), and
- beneficial uses (historical, present, and future).

Characterizing aquatic life helps identify what types of pollutants are of concern, as well as whether adverse impacts are expected to be seasonal, transient, or long term. Differentiation can initially be made between bottom organisms (subject to sediment accumulation) and water column organisms. If fish are of concern, the most sensitive type of fish should be identified to develop an approach to protect them. Important factors are:

- seasonal aspects (migration and spawning),
- transient variances in dissolved oxygen and in ammonia and other toxins,
- type and diversity of other organisms required, and
- relative importance of the physiology of the water body.

Bottom organisms are often more important to consider than fish and other aquatic life in the water column because wet weather pollution contains such a significant amount of settleable solids. These settleable solids account for a significant portion of the heavy metals and other toxins found in wet weather pollution. In addition, the deposition of inert particles can cover bottom organisms and adversely affect the environment. Wherever these solids settle, the impact can be long term, affecting both the water column and aquatic life.

There may be other constraints to realizing water quality improvements if only wet weather pollution is abated. One constraint is the effect of the bottom deposits from wet weather pollution that have accumulated previously. These bottom deposits might be classified as toxic, which complicates their removal and safe disposal; unless removed, they will continue to exert a significant oxygen demand, remain a source of toxicity in the food chain, and/or retard improvements to the fishery (spawning, bottom organisms, etc.).

Stream physiology may also be a constraint. Factors of importance include current velocity, water temperatures, bottom structure and shading for spawning, barriers to migration and movement, and diversity of aquatic organisms. Navigation uses may adversely constrain other uses perceived as beneficial. Recreational uses can be constrained by barge traffic, access limitations, stream physiology, and other pollutant loads.

4.3.3.3 *Infrastructure Characteristics*

Combined, separated and SW sewers are a significant component of a community's infrastructure. Development of a plan to abate wet weather pollution should thus include consideration of the collection system, WWTPs, and other related infrastructure components.

Some collection systems are 50 to 100 years old. Other systems were designed for a smaller population or a less impervious land than currently exists. Such issues can affect the conveyance capacity of these systems.

An assessment of the structural condition is important for two reasons. First, it may provide a rational basis for separating the sewer system, an abatement strategy used for CSO. Second, it may provide a basis for estimating the financial resources required to maintain the present level of service. Collapsed or clogged sewers will require investment to improve or maintain service.

In some urban areas, in addition to concern for the receiving water body, a significant public health and safety concern from basement and street flooding may also exist. Increasing conveyance capacity to mitigate basement and/or street flooding could have a major impact on developing a plan for wet weather pollution abatement. In some areas, the importance of protecting basements relative to street flooding could point the program toward sewer separation or use of inlet controls to avoid overloading.

Wet weather pollution abatement facilities may affect existing WWTPs and residual solids handling. Use of existing WWTPs as part of a wet weather pollution abatement plan will affect the amount of land available for future upgrading or expansion. Consideration should also be given to converting decommissioned WWTPs to wet weather pollution treatment plants rather than abandoning them.

Wet weather pollution abatement facilities will require careful consideration in siting; however, disruption during construction and interference with other utilities can be expected. Investigation of other urban improvements, such as road repairs or flood control, may lead to ways of mitigating disruption and interference by undertaking multipurpose projects. Coordination of construction activities with road or street surface improvements could be a major cost saving. In some areas it may be prudent to keep utility corridors free from obstructions or to coordinate general locations and depths of crossings.

4.4 Receiving Water Impacts

The specific receiving water impacts from wet weather pollution vary depending on the urban, environmental, and infrastructure characteristics. Depending on the particular combination of these factors, wet weather pollution impacts can be visible and intense. The size and type of the receiving water body determine its ability to dilute and assimilate intermittent wet weather pollution without toxicity. Therefore, receiving water impacts should be evaluated based on each site's particular characteristics. In each case, wet weather pollution impacts can be evaluated with respect to three basic considerations:

- water quality changes and effects on aquatic organisms,
- public health risks, and
- aesthetic deterioration.

4.4.1 Water Quality Changes and Effects on Aquatic Organisms

The wet weather pollution impacts on receiving waters depend on the rate and volume of the discharge, the degree of mixing and dilution, and the receiving water's assimilative capacity. Obviously, the larger the water body and smaller the discharge, the better likelihood of minimal impacts. For example, in some large rivers and estuaries, wet weather pollution has minimal impacts because of rapid dilution and mixing. In contrast, small streams that receive wet weather pollution with little dilution can be severely affected even for small storms. Therefore, solutions to wet weather pollution require site-specific monitoring and evaluation.

Most water quality impacts are measured by a determination of the increases (or decreases) in receiving water concentrations of toxicants as they relate to a violation of water quality criteria or standards. Such criteria are generally used to assess the potential for effects on aquatic organisms and impaired use. Although wet weather pollution is intermittent, the resultant problems may not be temporary and can persist to varying degrees. Figure 4-2 provides preliminary guidance for the time frames to be considered for different water quality problems. These different time frames can require different strategies for monitoring and calculating wet weather pollution impacts.

R0018431

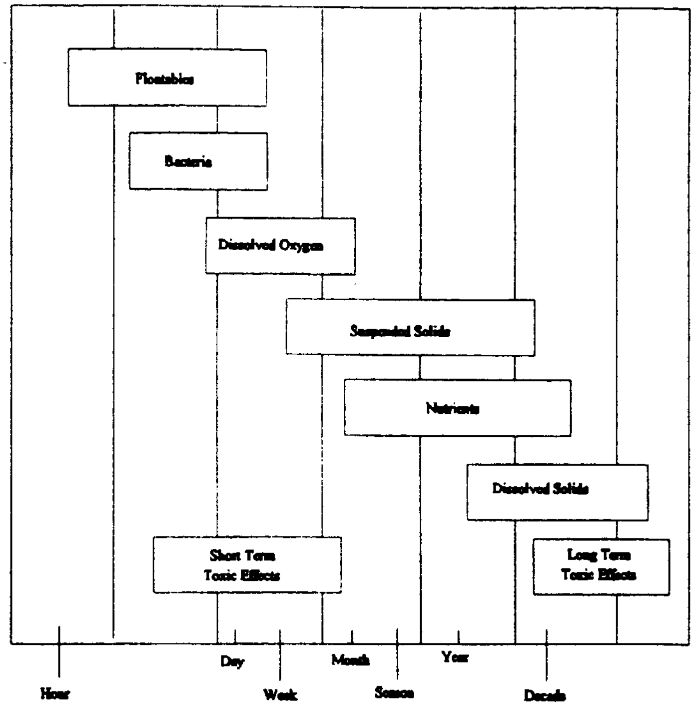

Figure 4-2. Time Scale for Wet Weather Pollution Water Quality Concerns (Moffa, 1997)

Dissolved oxygen levels, nutrient enrichment, sediment impairment, and toxicity are the major problems resulting from wet weather pollution.

Temporary depression of dissolved oxygen levels is a possible water quality problem attributable to wet weather pollution. Even though SW dilution minimizes the immediate impact, which generally lasts only hours, dissolved oxygen reductions may impair aquatic growth or reproduction and, in severe situations, cause biologic mortality. The severity, frequency, and duration of dissolved oxygen reductions caused by wet weather are dependent on the specific receiving water in question.

Nutrient enrichment from phosphorus and nitrogen is another potential problem resulting from wet weather pollution. Nutrient additions cause increased algae or aquatic weed growth. In turn, this may cause dissolved oxygen problems, reduce biological diversity, degrade aesthetics, or impair use for water supply. In fast-moving streams, nutrient contributions are typically flushed out before any impact can be realized, but in slower-moving water bodies the nutrients accumulate and assimilate into the biota. Sources of nutrients cannot easily be distinguished. However, performing relative comparisons of seasonal nutrient loadings at critical locations in the watershed can aid in the assessment of nutrient enrichment and eutrophication.

Another common problem from wet weather pollution is accumulated bottom-sediment contamination. Wet weather pollution typically has high levels of suspended materials that settle to the bottom in receiving waters. The accumulation and persistence of solids in sediments are typically long-term, not transient problems. The results can be high sediment oxygen demand due to biological oxidation and accumulation of toxic substances in the sediments. These conditions are usually present in slower-moving rivers, estuaries, or lakes, but not in fast-moving streams where sediments are routinely scoured from the bottom. Sediment criteria and standards for evaluating the severity of a problem are lacking. The U.S. EPA provides general guidelines for disposal of dredged sediments (EPA, 1997; EPA, 1977), but beyond these, the significance of sediment contamination should be evaluated on a site-specific basis.

Receiving water toxicity is the fourth general impact from wet weather pollution. In general, toxicity problems fall into two categories: (1) acute toxicity at higher concentrations, causing short-term mortality, or (2) chronic, long-term exposure to toxins, causing reduced growth and reproduction. Acute effects can often be observed as immediate fish kills or severely reduced biological diversity. Chronic effects are more subtle and harder to identify but at times can be observed by lower productivity and biomass (numbers of organisms), by bioaccumulation of chemicals, or by reduced biological diversity. Fortunately, chronic effects generally do not result from wet weather pollution because discharges are intermittent and infrequent in nature.

Toxic discharges from wet weather events can be a concern in industrialized areas served by combined sewers. Pretreatment programs are a good source of information to screen for potential toxicity from rainfall events. The more common toxicity concerns are for ammonia and dissolved trace metals, but concentrations generally are diluted enough to be of little concern. Preliminary screening for toxic effects can be performed using average dry weather discharge concentrations in combination with wet weather peak hourly flow rates for calculating a range of dilution. If such considerations are relevant to a site, then existing state and U.S. EPA water quality criteria are available for making preliminary assessments (EPA, 1986).

4.4.2 Public Health Risks

The major source of concern related to wet weather pollution, a concern in nearly all types of receiving waters, is the public health risk associated with diseases caused by pathogenic bacteria and viruses that may be carried in excrement. When people are exposed to contaminated receiving waters through wading, bathing, shellfish ingestion, and fishing, they risk becoming ill. Levels of bacteria observed in wet weather pollution varies. CSOs and SSOs have higher pathogenic bacteria counts than SW discharges; nonetheless, each type of discharge generally contains bacteria counts that are several orders of magnitude greater than applicable receiving water quality standards. For this reason, wet weather pollution can cause potential problems even in receiving waters with very high dilution. The potential risk is typically greatest at the beginning of a wet weather event, due to the "first flush" effect that delivers much of the waste that had accumulated during the preceding dry weather period. However, the risk can diminish quickly thereafter due to bacterial die-off, settling, and dilution. Significant public health risks from exposure to pathogens rarely persist more than two or three days after a storm overflow event. Wet weather pollution laden with bacteria is a special concern during warm weather when water contact recreation peaks and human exposure is greatest.

Protecting public health from exposure to microbial pathogens is complicated by the extreme difficulty in measuring concentrations of pathogenic organisms. For this reason, water quality standards are based on the presence of more easily measured indicator organisms. The most commonly used indicator of fecal materials has been fecal coliform bacteria, based upon work of the U.S. Department of Interior's National Technical Advisory Committee in 1968. Many state water quality standards are based upon this work, and consist of a standard of 200 fecal counts/100 milliliters (ml) for total body contact recreation, and 1,000 fecal counts/100 ml for partial body contact recreation. U.S. EPA revised these suggested numbers in 1986 to be based upon concentration of *Escherichia coli* and *enterococci.*

Generally, receiving water concentrations above 200-1,000 organisms/100 mL are considered to represent a greater disease risk. Concentrations of indicator bacteria in wet weather pollution usually number in the millions, and hence, dilution is rarely sufficient to eliminate all potential risk. Therefore, increased public health risks from wet weather pollution is a potentially serious issue. At times, the concern may be only transient and local (near discharge location), but in many systems the concern may extend for miles and days beyond the discharge. In all cases, wet weather pollution risks to public health should be given the highest priority.

4.4.3 Aesthetic Deterioration

Aside from physical/chemical contamination and public health risks, wet weather pollution can also impair the aesthetics of receiving waters. Wet weather pollution can contain an assortment of debris from runoff and wastes from sanitary sewage that are obvious and unsightly. Increased suspended solids, sanitary debris, plastics, floatables, and oils and grease are generally associated with wet weather pollution. Such debris is common to all receiving waters, but may persist for different periods depending on the current strength and dilution. Although aesthetic impairment may not reduce aquatic health or cause obvious human health risk, it does have socioeconomic significance. Debris and suspended solids from wet weather pollution can reduce recreational use and appreciation of receiving waters, thereby limiting recreational expenditures and near-shore development. Increased suspended solids can cause reduced water clarity, which also affects recreational use. Because aesthetics are typically an integral component of a water's designed use, aesthetic impairment can be considered a violation of water quality standards. Quantitative measures of aesthetic reduction are rare, but visual observations and resident interviews often adequately define the scope of the problem.

4.5 Monitoring/Modeling of Impacts

In every wet weather pollution abatement study, there is a recurring debate on the best means to define impacts and benefits of alternative control strategies. Should it be monitoring or modeling? Practically speaking, it is not an either/or decision, but rather how much of each. The two activities need to be balanced and designed for an integrated assessment. Monitoring is needed to identify existing problems, define baseline conditions, and support the development of reliable and verified mathematical models. Nothing provides stronger evidence of existing receiving water impacts than actual measurements and observations. However, monitoring alone has limitations; therefore, modeling should generally be used to complement monitoring and to forecast and analyze conditions other than those monitored.

4.5.1 Monitoring Impacts

Receiving water monitoring to document wet weather effects requires an integrated approach combining biological, chemical, and physical parameters, especially considering the biological community, the physical habitat, aesthetics, human health, contaminated sediments, and ambient water quality. Relying on water quality alone may be misleading. Monitoring programs should include initial wet weather pollution reconnaissance surveys involving a few stations downstream of a discharge and at least one station upstream. The reconnaissance monitoring should be conducted during seasons expected to encompass the most significant impacts and extend from a day before a storm to as much as four days afterwards. Parameters should include BOD, dissolved oxygen, temperature, bacteria, and other parameters suspected of having impacts, plus visual observations for debris and floatables. Occasionally, routine fixed-frequency monitoring data can be used to assess trends, the presence of impacts, and the periods or seasons when the receiving water is most susceptible to wet weather pollution. However, most often the timing of the fixed-frequency sampling does not coincide well with storm impacts. Therefore, surveys should be designed with this specific need in mind.

The reconnaissance surveys should be used as a basis to design more intensive surveys in terms of sampling location, duration, and frequency. Subsequent to the reconnaissance survey(s), at least two or three additional intensive surveys are recommended to better define impacts for different conditions and support model development. Often, impacts are only evident for large storms and not apparent for the smaller events. Hence, multiple surveys are recommended for defining the recurrence of problems and representing a fuller range of conditions.

In general, station locations and frequency for intensive surveys must be in sufficient numbers to clearly define spatial and temporal trends. Sufficient usually means sampling every 3 - 6 hours at stations located with time of travel between locations of approximately 6 - 12 hours. In rivers, the sampling logistics are the simplest because all impacts flow downstream. Station locations and timing are easy to define. For estuaries, choosing station locations is still relatively easy, but consideration of tidal movement and timing becomes important. Sampling at fixed times in each tidal cycle (usually a slack) are most desired to help standardize analysis and presentation of the data. For lakes, timing is less difficult, but station locations are more difficult to select due to multidimensional and sometimes erratic transport. In lakes, drogue or current studies can be used to define current transport. The circulation patterns in a lake may vary depending on wind stratification and other variable factors. Therefore, a network of lake stations should be set up to encompass the probable horizontal and vertical transport directions. Preliminary data can be used to refine the sampling network. Also, reconnaissance data may show minimal localized effects, in which case coarse whole-lake sampling may be more appropriate than a localized network. In all cases for rivers, estuaries, and lakes, the reconnaissance sampling is indispensable for defining adequate station locations and sampling frequency.

The sampling parameters should focus on the anticipated wet weather pollution related problems. However, all wet weather pollution impact surveys should routinely include measurement of bacteria, dissolved oxygen, BOD, and ammonia. Temperature and visual observations of cloud cover, sunlight, water transparency, floatables, debris, and other conditions are inexpensive and should also be routine. Daily composites are usually suitable for other parameters such as nutrients and chlorophyll. Toxic substances, such as trace metals, typically need only be measured immediately before the storm to define pre-storm conditions, immediately after the storm to define maximum impacts, and at the end of the survey to determine persistence. Diurnal dissolved oxygen variations due to photosynthetic activity can be very important and, if present, generally dictate the need for continuous monitoring and/or station measurements at 3-to-5-hour intervals. Photosynthetic activity can often confuse or mask the interpretation of wet weather pollution impacts on dissolved oxygen, especially since a reduction in both sunlight and photosynthesis usually accompanies storms. Therefore, if high productivity is present, careful evaluation of diurnal and light conditions is essential.

Some special note should be made concerning the scheduling of storm event monitoring. Obviously, it is impossible to "plan" for storms to occur conveniently for sampling, and it is also generally impractical to use automatic samplers for the receiving water. Therefore, a well-developed mobilization plan is essential to capture immediate post-storm impact, since impacts related to solids, bacteria, and toxins are best captured immediately after the storm, during the first flush of pollutants from the sewers. Weather forecasting services and routine fixed-frequency monitoring programs can also be valuable sources of pre-storm data and for identifying cumulative impacts.

4.5.2 Modeling Impacts

With data in hand, the planner/engineer can proceed to more fully analyze a wider range of conditions after developing and calibrating a mathematical model. Models are well suited for providing information not available from data alone. In particular, models can be used to simulate water quality for conditions not monitored. This could include larger, more intense storms, or more critical environmental conditions such as lower stream flow. It is generally infeasible to simply extrapolate to non-monitored conditions from data due to the large number of variable factors without the use of modeling. Modeling incorporates the mechanistic factors of a relationship, thus enabling more reliable projections under various conditions. The advantage of modeling is that virtually all such conditions can be assessed quickly. Furthermore, models can be used to examine impacts and benefits from proposed control strategies.

4.6 Cost-Effectiveness Analysis

In simple terms, a cost-effective solution is one in which the most value is received for money expended. When benefits are plotted against costs, the break, or the "knee" of the curve, is that point where additional benefits result in more rapidly rising unit costs, or the period beyond which there are diminishing returns, as illustrated by Figure 4-3. This approach becomes particularly important in light of the dwindling nature of federal and state monies and the greater reliance on local monies. Local authorities will require more information on the return on a major investment to improve water quality when making a decision regarding abatement alternatives.

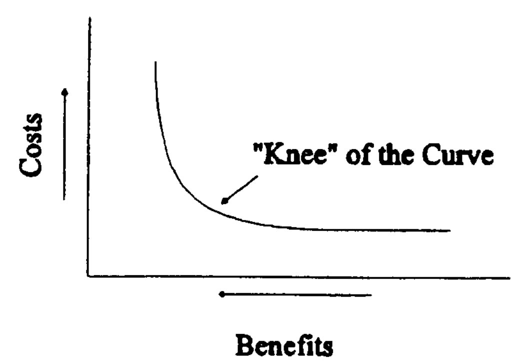

Figure 4-3. Cost-benefit Knee of the Curve

4.6.1 Benefits

There are four general methods for estimating benefits of water quality management projects (EPA-625/4-79-013):

1. The first method assumes that benefits will automatically be realized from the proposed activity and are large enough to justify the allocation of required resources. It completely avoids the benefit measurement problem. An example of this method is the federal requirement for secondary treatment at POTWs (i.e.,WWTPs).
2. In the second method, certain water quality standards are associated with the protection of water uses. Once standards to protect desired beneficial uses have been established, the comparison of projected water quality with the standards provides an estimate of benefit.
3. In the third method, estimates of increased water use potential are developed by translating improvements in water quality into numerical increases in usable length of beaches, swimming days, fishing days, or waterfront property values, to name a few possibilities. This method is, in effect, a refinement of the water quality standards approach, allowing benefits to be estimated directly.

4. The best known method is the classical cost-benefit analysis. In this method, each anticipated water usage has a dollar value assigned as a measure of unit worth or willingness to pay. The actual project usages are multiplied by the corresponding unit values, and the sum is compared directly to total project costs.

The first approach is unacceptable for wet weather pollution control planning because the benefits are not obvious; they are highly contingent on both SW volumes and the receiving water. The second approach poses a near-impossible situation for regulatory agencies to address, particularly during storms when the overflow and receiving waters are both changing rapidly. Using the second and third approach together (i.e., relating mandated water quality requirements to lost resources and real benefits of recovery) appears to offer the most effective means of obtaining approvals and funding from all levels. The fourth approach involves a great deal of subjectivity and could result in lengthy dialogue over the unit worth of various usages on both the local and regulatory levels.

4.6.2 Design Conditions

Once data are gathered and modeling is performed to characterize wet weather pollution and identify water quality impacts, a basic decision becomes necessary: What combination of storm event and receiving water conditions should be selected for abatement? To answer this question, the joint probability of a specific storm occurring at a specified receiving water stage must be understood. For example, a 1-year storm occurring during a high river stage condition may easily exceed a once in 10-year occurrence. Thus, it becomes necessary to review rainfall records in combination with receiving water flow records before selecting design conditions.

4.6.3 Methodology

This section outlines a general methodology for determining cost-effective solutions. The general approach for analysis of wet weather pollution abatement is illustrated in Figure 4-4.

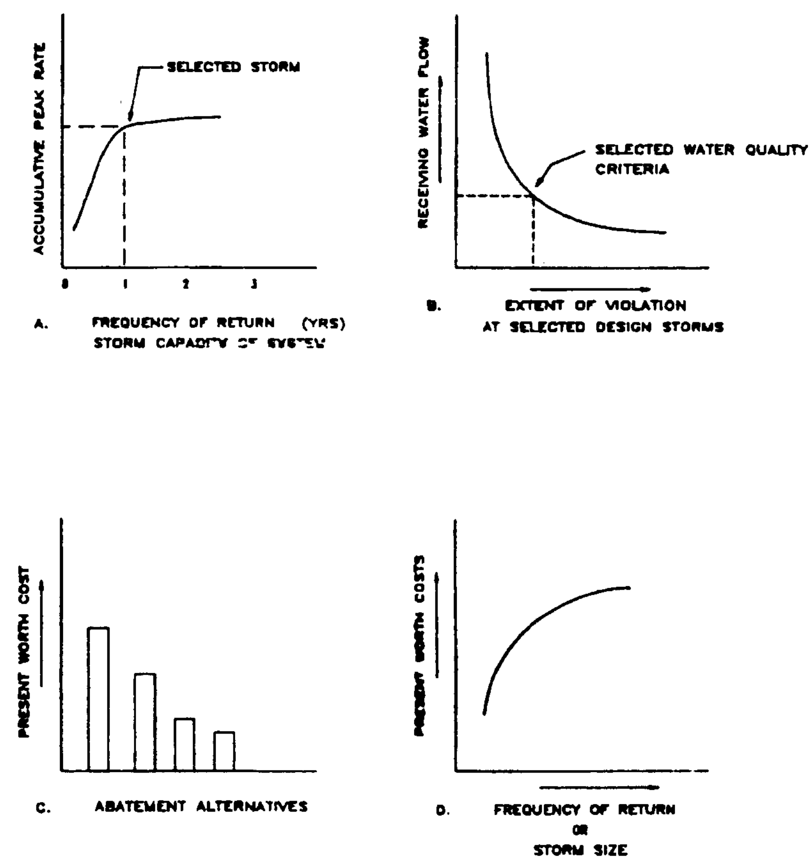

Figure 4-4. General Approach for Cost-Effective Analysis

Subfigure A illustrates the relationship between total volume discharged from a system and accumulative peak rate versus the storm size in terms of frequency of return. Generally, frequency of return is based on a constant duration such as two hours and varying rainfall intensity. The Storm Water Management Model (SWMM) can be used to develop total volume discharged, which represents total discharges irrespective of their location. This model is valid for developing a uniform set of design conditions throughout a system. In large systems with a wide range of receiving water types (e.g., small streams and large bays), it may be desirable to develop this relationship for each specific water body. Such a curve can also be developed for an accumulative peak rate, which is the summation of peak rates of all discharges at a given frequency storm, irrespective of the timing of the peak. This parameter is an indication of the peak carrying capacity of the system and complements the plot of total volume. These data can then be plotted to yield a curve as illustrated by Subfigure A, which can be used to designate the "selected storm" storm condition. At some storm frequencies, the system can no longer accept more SW flow, resulting in street ponding and either subsequent discharge to the system or evaporation or infiltration into the ground.

Subfigure B illustrates the relationship between receiving water flow and the extent of violation at the selected design storm (e.g., 1-year frequency of return). This relationship must be plotted for each of the water quality parameters of concern. This particular curve is more illustrative of the relationship for bacteria where the degree or extent of violation increases as the dilution from water flow decreases. At some point in the decision-making process, a receiving water flow must be selected which is reasonable when combined with the probability of the particular storm frequency chosen. A reasonable receiving water flow might represent the dry months of July, August, and September, when the highest intensity storms are expected. Once the evaluation for each of the water quality parameters is performed, the required removals can be determined.

Subfigure C, given the removals required, can then be developed on the basis of specific abatement technology. Various abatement alternatives that would accomplish the same reductions can be evaluated with respect to present-worth costs. Costs have been selected merely as a comparative term. In many cases, the Y-axis may represent a combination of regulatory, institutional, and local requirements, in addition to costs.

Subfigure D, given the selected abatement alternative, is a plot of the variation of different-sized facilities for that alternative, as required to treat different sized storms against the relative costs. In this way, a final evaluation of the most cost-effective sized facility can be determined.

4.6.4 Financial Capability Assessments

A community's financial capability is particularly necessary in the case of wet weather pollution abatement because there are no clear standards in most states, and the selection of a "design" storm has become a subjective decision based upon cost-benefit relationships. Additionally, other pollutants from a watershed may preclude the attainment of the fishable-swimmable goals of the Federal Clean Water Act Amendments of 1972.

A community's financial capability may be assessed by identifying the following seven factors:

1. median household income,
2. total annual wastewater and wet weather pollution abatement control costs per household as a percent of median household income,
3. overall net debt as a percent of full market property value,
4. property tax revenues as a percent of full market property value,
5. property tax collection rate,
6. bond rating, and
7. unemployment.

In 1996, the U.S. EPA released a draft guidance document on economic capability for communities with CSOs. The document, "Draft CSO Guidance on Financial Capability Assessment and Schedule Development," established boundaries for compliance schedules for CSO communities implementing U.S. EPA's national CSO policy. Although this information was written with respect to CSO, it is applicable to all wet weather pollution.

The following is a summary of the guidance developed by the CSO Partnership (The CSO Bulletin, April 1996).

The guidance proposes a two-step approach for calculating economic capability. The first step focuses on the financial impact of current and proposed wastewater and CSO controls on individual households. The second step examines the debt, socioeconomic, and financial condition of a CSO community. The results of both steps are then

R0018437

combined into a "Financial Capability Matrix" which is used to assess the financial burden attributable to CSO controls and to establish what U.S. EPA views as appropriate compliance schedules.

The first step calculates a residential indicator (RI), a measure of the CSO community's average cost per household for existing and proposed wastewater treatment and CSO controls, expressed as a percentage of local median household income (MHI). The guidance proposes establishing three ranges for RIs with RIs of less than 1 percent MHI characterized as imposing a "low" financial impact, RIs from 1 or 2% of MHI imposing a mid-range impact and RIs above 2% of MHI imposing a high impact.

The second step considers a community's financial capability indicators. U.S. EPA specifies six proposed indicators in the guidance for evaluating community debt, socioeconomic, and financial conditions that affect a community's financial capability to implement CSO controls. The results of the six indicators are used to classify the community's financial capability as "weak," "mid-range," or "strong."

The results these two steps are then combined in a financial capability matrix that provides the basis for the permittee and NPDES permitting authority to negotiate an appropriate compliance schedule. The financial capability matrix divides communities into three categories based upon their calculated burden under the guidance (low, medium, or high), with equal weight given to the community's RI and financial capability indicators.

Finally, the guidance proposes the following general boundaries for compliance schedules based upon a community's calculated burden:

Low burden:	0 - 5 year compliance schedule
Mid-range burden:	5 - 10 year compliance schedule
High burden:	10 - 15 year compliance schedule

According to the U.S. EPA guidance, communities in the "High burden" category may be able to negotiate compliance schedules as long as 20 years.

The lack of supporting information to explain and justify U.S. EPA's selection of the residential indicator categories and the financial capability indicator categories will make it difficult to evaluate whether the proposed categories are appropriate for CSO communities nationwide. For example, U.S. EPA does not provide any discussion of the number of CSO communities that can be expected to fall into the three categories proposed in the Financial Capability Matrix (low, mid-range, or high burden). Also, it is unclear how U.S. EPA arrived at its proposed ranges for the compliance schedules for communities falling within the three categories of financial burden.

An example of how a financial analysis can be performed is illustrated in the case history of Syracuse, N.Y. (Section 5.2.5).

CHAPTER 5.0

CSO Benchmark Data and Case Histories

5.1 Benchmark Data for CSO Communities

The following section includes benchmark matrices for general CSO community statistics (Table 5-1), CSO public participation (Table 5-2), CSO systems characterization (Table 5-3), issues driving CSO technical considerations (Table 5-4), and CSO financial considerations (Table 5-5).

5.2 Case Histories for CSO Communities

Case histories for CSO communities include Atlanta, Ga., Augusta, Me., Decatur, Ill., San Francisco, Calif., and Syracuse, N.Y. Each community represents an important and distinct element of the CSO abatement process. For example, the Atlanta case history highlights CSO policy interpretation, Augusta highlights the cost-benefit analysis, Decatur highlights one of many technical approaches, San Francisco highlights the evolving funding basis for CSO abatement, and Syracuse highlights a staged construction approach that meets the presumption and demonstration approaches of the federal CSO policy.

CSO Community Characteristics

♦ Population	700,000
♦ CSO Area	> 10,000 Ac
♦ Annual Rainfall	50"
♦ # of Discharge Points	7

Distinctive CSO Community Attributes

- Existing natural drainageways used as original sewers
- Intensive legal negotiations
- CSO policy interpretation

5.2.1 Atlanta, Ga.

Atlanta is a typical case where small, intermittent streams and rivers evolved into combined sewers. Before the city developed, these streams flowed from what is now the center of the city either west to the Chattahoochee River and on to the Gulf of Mexico, or east to the South River and on to the Atlantic Ocean. As the city grew, sanitary flows and SW were discharged into these waterways. Odor and health concerns led to the enclosure of the streams in pipes that became the present-day combined sewer system. As the city continued to expand, construction of combined sewer systems ceased and separated systems were initiated. The city's combined sewer system is located in the older, central business district and serves as headwaters to several small streams.

Improvements are currently being made to the WWTPs to meet effluent phosphorous limits (not to exceed 0.64 mg/l). In addition, the Georgia Environmental Protection Division is calibrating a new model that will be used to derive TMDLs. The results of this model may affect future permitting. The model considers the urban streams that are a direct result of overflows as point sources to the Chattahoochee.

Georgia first issued NPDES permits for CSO discharges in 1992. Atlanta's NPDES permits for all CSO treatment facilities are identical. The permits require that CSOs not violate water quality standards.

Atlanta's first CSO treatment facilities were built in the mid-1980s to address water quality problems in the South River Basin. The controls included two first-flush storage and treatment facilities and two small sewer separation projects. Additionally, five on-line screening and disinfection facilities were designed in 1989 to control CSOs in the Chattahoochee River Basin.

Questionnaire Date: July 1998.

Before the facilities were constructed public dissension grew and the state legislature passed a bill mandating that "discharges from CSOs shall not cause a violation of water quality standards." As a result only three of the five CSO treatment facilities were constructed as originally designed and delays in construction caused the city to incur significant fines.

Citizen concerns continued and in 1996, a lawsuit was filed against the city claiming that CSOs violated water quality standards for metals and fecal coliform. In 1997, a federal district judge ruled in favor of the plaintiffs, saying that the concrete culverts into which CSOs discharge are waters of the state and therefore must meet water quality standards. The district court ruling and subsequent consent order are currently in negotiation. Various improvements to the CSO facilities include storage and treatment, relocation of outfalls, and separation. These improvements are estimated to cost between $400 to $600 million.

Motivated by the public dissension, in 1996 the Metro Atlanta Watershed Initiative was started to deal with citizen concerns and regulatory ambiguity; integrate and prioritize CSO controls to best use available money; and coordinate city agencies and stakeholders. As presented in Table 5-6, the watershed initiative faced many challenges.

The initiative started a comprehensive watershed study that was designed to determine the current conditions and uses of the urban streams, assess the type and magnitude of various impacts on these streams, and evaluate and recommend options for improving the water quality in the streams. However, the watershed study was dealt a major set back when a judge ruled that waters of the state begin at CSO discharges. Therefore, water quality standards need to be met in the small, intermittent streams that are solely produced by CSO discharges. As a result the watershed study was replaced by a mathematical model of the combined sewer system that simulates the impacts of the point-source CSOs.

Questionnaire Date: July 1998.

Current funding for the watershed initiative is $2.6 million. The City of Atlanta presently is the sole funding source, even though the watershed plan includes other communities and jurisdictions. The estimated cost for bringing the urban streams to good/fair standards for biotic indices, a goal created through the initiative, is approximately $1.4 billion.

5.2.2 Augusta, Me.

The combined sewer area of Augusta, Me., comprises approximately 620 acres with 40 diversion structures and 29 active CSOs that discharge either directly to or into tributaries of the Kennebec River, which serves as an excellent fishery as well as a heavily used recreation area. Eleven alternatives were evaluated as part of the CSO facility plan. Evaluated storm frequencies were based upon the system capacity curves shown in Figure 5-1. Due to the large size of the Kennebec River, the primary water quality concern was bacteria.

Figure 5-2 illustrates maximum *E. Coli* concentrations in the Kennebec River at a minimal flow of 1,000 cubic feet per second (cfs) for different recurrence interval storms. As shown, the 1-year recurrence interval represents the knee of the curve. Consequently, a series of abatement alternatives were evaluated for the 1-year storm. Present-worth costs for several prime alternatives are illustrated in Figure 5-3. The least costly alternative included the construction of two satellite vortex facilities; however the second least costly alternative, which included a single vortex facility at the WWTP, was selected due to nonmonetary factors such as facility siting, the desire to avoid satellite facilities, and flexibility for future expansion or upgrades.

The selected alternative involves retrofitting the existing WWTP to include a CSO-related bypass to treat 44% of Augusta's current annual CSO volume. Other improvements involve constructing consolidation conduits, two CSO pumping stations, and a vortex treatment facility at the site of the WWTP. This solution has been approved by U.S. EPA and the State of Maine Department of Environmental Protection.

The retrofits to the existing WWTP include new headworks that contain mechanical screens and an aerated grit chamber; new distribution structures; and new high-rate disinfection technology. Currently, when peak flow at the WWTP approaches 9 million gallons per day (MGD), excess flow is bypassed to the chlorine contact tank after physical degritting. The retrofit improvements will allow the full 29 MGD of connected interceptor capacity to receive preliminary treatment. Daily maximum flows of 12 MGD will receive secondary treatment, and 17 MGD will receive primary treatment followed by high-rate disinfection.

Later phases of the CSO abatement program will include a consolidation conduit to intercept CSO discharges throughout the system and convey the flow to the WWTP; three new vortex separators at the WWTP; and additional high-rate disinfection volume at the WWTP. After all phases are completed, the total influent peak flow capacity to the WWTP will be increased from 29 MGD to 107 MGD. Up to 78 MGD will be treated in the vortex separators. The phases of the CSO abatement program are scheduled to be completed by 2009.

CSO Community Characteristics

♦ Population	95,000
♦ CSO Area	7,000 Ac
♦ Annual Rainfall	40"
♦ # of Discharge Points	4

Distinctive CSO Community Attributes

- CSO abatement program cmpleted in 1992
- Operation of full-scale CSO treatment facilities including one EPA swirl concentrator and six Fluidsep units

Decatur, Ill. is located in the center of Illinois along the Sangamon River. A dam on the river forms Lake Decatur, which serves as a recreational resource and public water supply. The area has a population of approximately 95,000 and has a heavily industrial economic base. The combined sewer area is surrounded on three sides by newer sanitary sewers and on the fourth side by Lake Decatur.

Prior to 1992, the CSO outfalls discharged directly downstream of the Lake Decatur dam. During the summer, brief rains caused the combined sewers to overflow; however, the rains did not produce enough runoff to cause the lake to spill over the dam. Therefore, the sewer overflows resulted in stagnant pools and subsequent fish kills.

The city and sanitary district began facilities planning in 1976. At that time the WWTP was frequently overloaded, standards violations were common, and there was no CSO treatment. Between 1976 and 1980 planning concentrated on the main WWTP. Beginning in 1980 CSO control and treatment became a topic of interest when the Illinois Environmental Protection Agency (EPA) documented that the CSOs were polluting the river and control was required.

In 1982 the Sanitary District of Decatur signed a federal consent decree which ordered the upgrading of the main WWTP, implementation of an industrial pretreatment program, and compliance with Illinois rules and regulations pertaining to CSOs. The consent decree set time limits for completing work in each area. The CSO control measures were to be completed by 1986, later extended to 1992. The extension helped the cash flow of both the Illinois EPA Grants Section and local government. The schedule also allowed for a step-by-step approach to the CSO improvements

The consent decree helped both parties. The sanitary district gained assurance of grant funding for the necessary work, avoided enforcement actions until the completion date, and obtained authority to issue bonds for local funding. The Illinois EPA benefited by having a federal court order to ensure compliance by a specific date and gained the cooperation of the Sanitary District.

The overall CSO control plan included four satellite treatment facilities: the McKinley Ave., Oakland Ave., Seventh Ward, and Lincoln Park CSO Treatment Facilities. The McKinley Ave. Facility was completed in 1986 and includes a 500,000-gallon first flush storage tank and a 40 MGD U.S. EPA vortex unit. The storage tank collects the first 500,000 gallons of CSO, which is later pumped to the WWTP. CSO beyond the first 500,000 gallons is diverted to the vortex unit. The Lincoln Park CSO facility was completed in 1992 and was the final and largest treatment facility. The Lincoln Park and McKinley Ave. facilities are similar in concept; however, Lincoln Park utilizes a 1.33 million-gallon storage tank and four Fluidsep vortex units capable of treating 416 MGD (see Figure 5-4). The total CSO control plan improvements cost $34.4 million, $20.5 million coming from state and federal grants and the balance coming from the local community.

5.2.4 San Francisco, Calif.

CSO Community Characteristics

♦ Population	727,000
♦ CSO Area	25,000 Ac
♦ Annual Rainfall	21"
♦ # of Discharge Points	36

Distinctive CSO Community Attributes

- CSO abatement program cmpleted in 1997
- Diverse funding source
- Conversion of WWTP into wet weather pollution treatment facility

San Francisco is a city of 727,000 people located on a peninsula surrounded by the San Francisco Bay and the Pacific Ocean. Almost 100% of the city's 25,000 acres are served by a combined sewer system. Each of the 36 CSOs discharge into the San Francisco Bay or the Pacific Ocean. The city is highly urbanized, with a large central business district. Very little space is available for the construction of treatment facilities or large storage and conveyance systems needed to handle CSO.

R0018447

March, 1997 marked the completion of the major components of the city's wastewater facility improvement program. This construction program cost more than $1.4 billion dollars over a 20-year period. The earliest projects were funded by federal (68%), state (12%) and sewer service (20%) monies. Subsequent projects used state revolving funds and sewer service charges. One project used U.S. EPA marine CSO funds.

At the time of the 1972 Federal Clean Water Act Amendments, the City of San Francisco was planning improvements to its wastewater facilities. The State of California directed the city to undertake measures to reduce impacts from WWTPs and CSOs in the early 1960s. The city's first study of water quality impacts from CSOs was completed in 1967.

Motivated by federal and state policy and the need to improve its wastewater facilities, the city committed to upgrade secondary WWTPs and eliminate SW discharges along the shoreline within reasonable costs, times, and with minimal public disruption. To meet this challenge, the city developed a "Wastewater Master Plan" (1971) and an "Environmental Impact Statement and Report" (1974). The original plan was based on cost-benefit considerations; the resulting requirements closely matched those of the federal presumption approach.

San Francisco used a combination of in-line storage, off-line storage, and wet weather treatment. Wet weather treatment included primary treatment at the city's two WWTPs and conversion of a third WWTP to a wet weather facility. In addition the CSO storage boxes were designed to capture large settleable and floatable solids (see Figure 5-5).

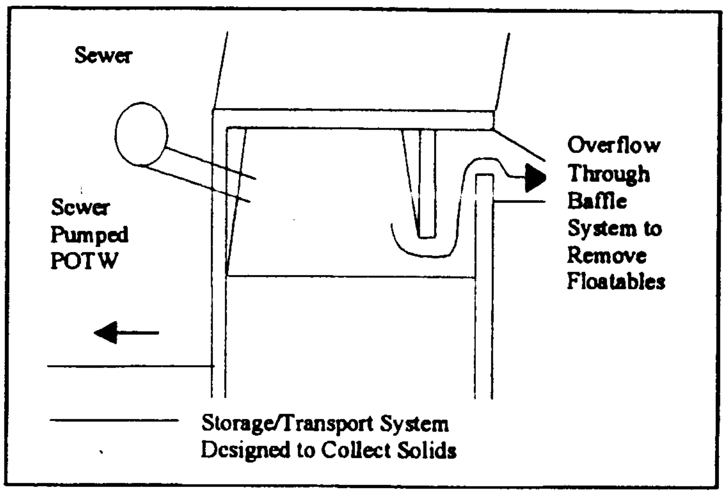

Figure 5-5. Typical Storage Boxes for San Francisco

San Francisco appears to be meeting the CSO frequency requirements (see Table 5-7). The number of days with elevated coliform levels dropped between 78% and 98%. An evaluation of a large CSO storage basin found a 33% reduction in total suspended solids and BOD through the storage and decanting of captured flows.

Table 5-7. San Francisco CSO Frequency Requirements

Waterbody	Frequency
Estuarine Shellfish Area	1/year
North Shore Area	4/year
Ocean Discharges	8/year
Maritime Area	10/year

5.2.5 Syracuse, N.Y.

CSO Community Characteristics

- Population 475,000
- CSO Area 67,000 Ac
- Annual Rainfall 37"
- # of Discharge Points 66

Distinctive CSO Community Attributes

- Cost-benefit Analysis
- Staged construction that meets the presumption and demonstration approaches

The Syracuse is located in Onondaga County, N.Y. and has a population of 475,000. Approximately 40% of the city of Syracuse's 16,600 acres are served by a combined sewer system. Each of the 66 combined sewer overflows discharge into one of three receiving streams that are tributary to Onondaga Lake. Onondaga Lake has become a matter of national interest as one of the most polluted lakes in the country. This urban lake and its drainage area lie wholly within Onondaga County and serve as a good opportunity to assess CSO impacts within the context of an entire watershed.

After a period of more than 25 years of evaluating the CSO problem involving demonstrating various abatement technologies, characterizing the sewer system and receiving waters, implementing a BMP program and performing extensive cost-benefit analyses, a comprehensive CSO abatement program for the city of Syracuse, estimated at over $140 million, is underway. The final phase of this process began in 1988, when the county entered into a consent order, and was completed in 1996 upon its signing.

Between 1982 and 1984, the county instituted a successful BMP program. The results showed more than an 85% reduction in annual pollutants to the receiving waters. The major elements of the BMP program were: sewer cleaning, overflow-structure modifications, and sewer replacement to assure maximum system storage and conveyance to the Syracuse Metropolitan WWTP. Table 5-8 illustrates the improvements as a result of this $10 million BMP program.

Table 5-8. Pre & Post-BMP CSO Discharge Statistics, Syracuse, N.Y.

CSO Discharge Characterization	Pre-BMP	Post-BMP
Number of Events/Year	165	56
Annual CSO Volume (million gallons)	11,000	1,654
1-year Storm Volume (million gallons)	72	59
90 Percentile Storm Volume (million gallons)	54	40

Water quality concerns were investigated during the middle 1970s and verified in the early 1990s. These investigations utilized sewer modeling and flow monitoring combined with water quality sampling and analyses to estimate CSO loadings to receiving waters. Floatables and bacteria were the parameters of most concern. A bacteria model was also used to estimate the number of violations, defined as exceeding 200 fecal coliform per 100 ml, within the Onondaga Lake.

A limited watershed effort became necessary to put the CSO component of solids and nutrients in proper perspective. Agriculture comprises the major land actively outside of the city of Syracuse and the urban areas. Using a watershed model, solids and nutrient loadings were calculated for an average rainfall year (1991). Table 5-9 illustrates the loadings relative to the WWTP. The net result was that phosphorus, nitrogen, and solids were found to be of less significance than was thought before the watershed estimates were made.

Table 5-9. Pollutant Loading Summary to Onondaga Lake, Syracuse, N.Y.

Pollutant Source	Total Phosphorous (lbs)	Total Phosphorous % of Total	Total Nitrogen (lbs)	Total Nitrogen % of Total	Total Suspended Solids (lbs)	Total Suspended Solids % of Total
WWTP	134,320	31	5,752,620	80	1,167	7
CSO	16,800	4	25,432	2	3,739	22
Nonpoint	275,349	65	1,313,434	18	12,107	71
Total	426,469		7,201,486		17,013	

Several abatement alternatives were evaluated based on costs and benefits. The county chose regional treatment with vortex units and high-rate disinfection because it was the least costly alternative that met water quality standards. In addition, the plan includes netting devices for capturing floatables and restoration of an existing 5 MG storage facility.

High cost/benefit projects and projects designed to demonstrate effectiveness were scheduled in the initial phase. The scheduling of the projects became decisive in that the proposed regional facilities would ultimately meet both the presumption and demonstration clauses of the federal CSO policy. The next step in the process was to phase the construction of the facilities over a 15-year, build-out period to provide both a reasonable compliance schedule and an affordable cash flow. Figure 5-6 illustrates the compliance schedule.

5.3 CSO Case Histories and Benchmark Data Discussion

5.3.1 General CSO Discussion

CSOs generally were recognized as a significant source of pollution in the late 1960s and specifically identified at the federal level through the landmark 1972 Amendments to the Federal Water Pollution Control Act. Much of the CSO work was started through federal R & D programs initiated in the early 1970s.

The activity directed toward CSOs has been greater than SSOs and SW owing to the earlier awareness and recognition of this type of pollution and, perhaps more importantly, the urgency associated with the health risks stemming from the sewage component. The intensity of regulatory and municipal activities sharply increased in 1989 when U.S. EPA published the draft National CSO Control Strategy. Until then, in the absence of clear guidelines, most municipalities were unwilling to forge ahead. Upon the release of the National CSO Control Policy in

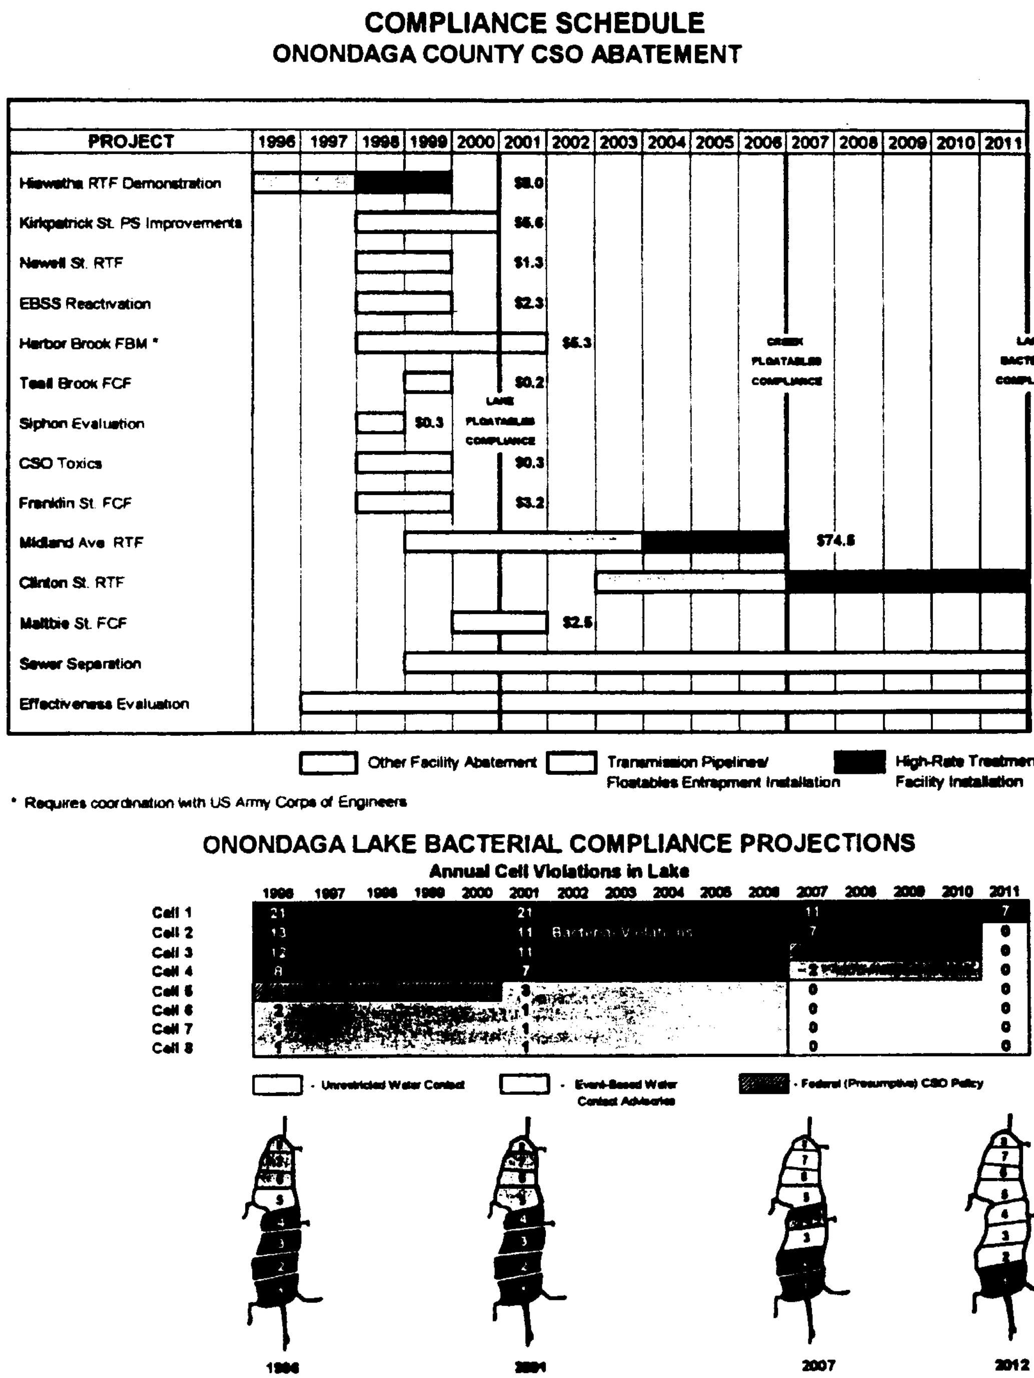

Figure 5-6. CSO Abatement Compliance Schedule, Onondaga County, N.Y.

1994, many CSO facility plans were revisited to determine compliance with either the presumption or demonstration provisions and to develop the required LTCP.

The most prevalent form of implementation has been BMPs due to the "housekeeping" nature of such steps and the low cost to benefit relationship. Reductions of annual CSO volume from BMP steps were reported as high as 90%.

Abatement beyond BMPs was implemented by only a limited number of communities prior to the national policy. In some cases, communities with high enough state priorities were able to take advantage of federally available grant funds. However, for the most part, abatement has taken place after 1989 and has not included federal grants. State revolving funds have become available in place of the previous U.S. EPA construction grants program.

As a consequence of little or no federal or state funding currently available for design and construction, financial considerations have become that much more important, resulting in a greater emphasis on cost/benefit evaluations and reviewing the affordability guidelines within the policy.

Most communities acted to abate their CSOs due to regulatory requirements which can take the form of permit renewals, administrative orders, or consent orders. Generally communities acted upon requirements more or less in that order.

There is a noticeable lack of consistency from case to case in setting permit parameters, which is understandable in consideration of their site-specific nature and related health risks. States should await site-specific information before setting permit limits.

5.3.2 CSO Questionnaire Findings

5.3.2.1 CSO Community Statistics

The communities included in these benchmark matrices represent a range of geographic locations, demographics, abatement strategies and schedules. The differences found between these communities stress the site-specific nature of CSO control and abatement.

Combined sewer systems serve roughly 950 communities with about 40 million people. Most communities with CSOs are located in the Northeast and Great Lakes regions, particularly in New England, Ohio, Illinois, Michigan, and New York. Although large cities like New York, Philadelphia, and Atlanta, have combined sewer systems, most communities with CSO problems have fewer than 10,000 people (EPA, 1998). Most sewer systems have evolved with the community, and therefore no two systems are identical. For example, some communities such as San Francisco are served entirely by combined sewer, while others, such as Atlanta, have a relatively old combined sewer system surrounded by a newer separated system. The wastewater/CSO characteristic for each community is different and is largely related to the economic base of the community. Some communities such as Detroit have an industrial economic base, while others like Auburn are residential and commercial in nature. The locations of CSO communities across the county are illustrated in Figure 5-7.

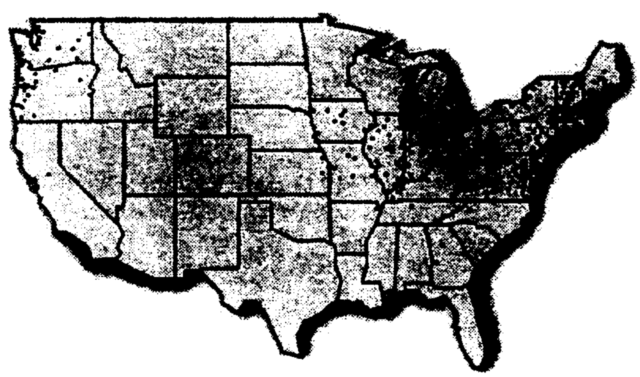

Figure 5-7. CSO Communities in the US. (EPA, 1998)

5.3.2.2 CSO Public Participation

Based on questionnaire responses, active public participation programs tend to be integrated with a watershed approach. For example, communities such as Atlanta and Detroit (Rouge River) have active public participation and watershed programs. Other communities that have public participation programs are: Astoria, Augusta, Chicago, Cincinnati, Cleveland, Hartford, Louisville, San Francisco and Winnipeg.

Public participation approaches for CSO abatement programs throughout the country appear to follow similar trends. The information provided by each municipality suggests that the public participation philosophy was established at or before the initiation of the formal CSO abatement program. At the beginning of the abatement process, a municipality either decided to actively include the public in the decision-making process or to include the public only as mandated by law. It is likely that the municipalities that identified themselves as "reactive" were including the public as required by law but increased public involvement as public demand grew. The most popular forms of public participation are newsletters, public hearings/meetings, and newspaper articles. The majority of the public was concerned about the effectiveness of the abatement strategy to meet water quality and associated aesthetics and recreational expectations. Construction impacts during implementation of abatement infrastructure were also a notable public concern.

From the viewpoint of the municipal agency, public participation programs can provide assistance but can also create obstacles. The clear advantage of engaging the public is recognizing and addressing public concerns early in the process, thus making the public a stakeholder. This process is best for the community in the long term; however, as in Atlanta, it may create ancillary work in the short term. Atlanta also noted that open public participation is difficult when litigation is brought by public stakeholders.

5.3.2.3 *CSO Systems Characterization*

Nearly all communities used a mathematical model to describe their sewer system. The U.S. EPA Storm Water Management Model tended to be the most preferred model. Communities have found that replicating the sewer system with a model can answer questions that would be impractical to answer through field measurements and observation.

Currently, however, most communities are focusing on abating only municipal and industrial point sources and not embodying the entire watershed and other pollution sources. Such action is driven by federal CSO policy and lack of policy for other types of pollution (e.g., agricultural runoff). The municipal and industrial point sources of pollution tend to be more easily controlled and managed at the source, whether it is at the end of a pipe in the case of a CSO, or a pretreatment program at an industrial site.

Many CSO communities are looking to the future and realizing the need to address nonpoint sources such as urban and agricultural runoff. As a result, these communities have used a watershed approach to prioritize pollutant sources and plan for the future but have not begun to use the watershed approach to abate pollution.

Some communities have initiated a watershed approach, including Atlanta, Chicago, Cleveland, Detroit and Syracuse. The watershed approach in Detroit has come to national attention. Wayne County is spearheading the watershed approach via the Rouge River National Wet weather Demonstration Project (Rouge Project) with funding from U.S. EPA and local communities. The Rouge Project oversees the 17 combined sewer overflow abatement projects (11 retention treatment basins and 6 sewer separation projects). These control technologies are currently being evaluated to help quantify their effect on the quality of the river and thereby suggest the most appropriate CSO method. The following are some findings from the Rouge Project (Rouge River National Wet Weather Demonstration Project, March 1998):

- *E. coli* concentrations discharged from the CSO treatment basins are small compared to the instream *E. coli* concentrations. Instream *E. coli* concentrations during wet weather are frequently above body contact standards due to non-CSO pollution sources.
- Dissolved oxygen sags are attributed to CSO treatment basin effluent and other non-CSO pollution sources
- Dissolved oxygen impairment during dry weather is attributed to a combination of high sediment oxygen demand and low re-aeration due to naturally flat river slope.
- CSO treatment basin effluent contributes 15% of instream BOD at points of discharge.

Because CSO control will not eliminate all pollution to the river, the Rouge Project is assessing and implementing nonpoint source controls as well and pollution prevention programs for watershed residents and businesses. Findings from this study will be shared with other urban watersheds.

Syracuse exemplifies a community that assessed pollution sources from throughout the watershed before developing abatement alternatives for CSOs. This evaluation included the use of a watershed model, sewer system model, and geographic information system to calculate solids and nutrient loadings. The major finding suggested that phosphorous loading from CSOs was less significant than loadings from the WWTP and agricultural runoff. Identifying that significant phosphorous loadings came from sources other than CSOs allowed the municipality to proceed with physical treatment and disinfection rather than storage for CSOs, representing a huge savings to the city.

5.3.2.4 *Issues Driving CSO Technical Considerations*

Most CSO communities have completed or are in the process of completing a long term control plan. However, some variability exists in the initiation of the plan. As documented in the 1994 federal CSO policy, the LCTP is to be submitted within two years of an enforcement action, which can take the form of a state permit (generally the most preferred) or a specific administrative or consent order. Many large communities, such as Boston and New York City, were targeted as high priorities by regulatory agencies. As such, enforcement actions were served even before the federal CSO policy was finalized. On the other hand, medium-sized communities, such as Gardiner, Me., were a lower priority to regulatory agencies and therefore were not served an enforcement action as early. In this same manner, small CSO communities may not have to complete a LCTP in the near future because of their low priority status. The CSO policy states, at the discretion of the NPDES authority, that communities with populations less then 75,000 may need to comply with only the nine minimum controls. Yet, still other communities, such as Rochester, N.Y., moved ahead with a LCTP before the CSO policy was developed. The motivation for such a progressive stance was the availability of federal and state grant money.

Most communities acted to abate their CSOs due to regulatory requirements. These regulations may be enforced by either the state government (delegated state) or by the U.S. EPA. Communities who have not completed a LTCP are generally required to complete the plan. Communities who have an approved LTCP are required to follow either the presumption or demonstration approach. If a community follows the demonstration approach, the critical permit requirements generally relate to an effluent standard. If a community follows the presumption approach, the critical permit requirements tend to specify some level of capture/treatment. Regardless of the approach bacteria and floatables tend to be the pollutants of most concern.

Some communities were motivated to abate their CSOs because of litigation. In the case Decatur, the litigation and resulting consent decree helped both parties. The Sanitary District gained assurance of grant funding for the necessary work, avoided enforcement actions until the completion date, and obtained authority to issue bonds for local funding. The Illinois EPA benefited by having a federal court order to ensure compliance by a specific date and gained the cooperation of the Sanitary District.

Almost the same number of communities followed the presumption approach as followed the demonstration approach; however, the majority of smaller communities followed the Presumption approach. The major advantage of the presumption approach is that it allows smaller communities that cannot afford extensive water quality monitoring and impact studies to proceed with abatement planning. Some larger communities proceed with presumption approach because it provides an opportunity to avoid any stalemate until a consensus is reached over water quality impacts. And yet some communities, with diverse combined sewer systems, used both approaches where appropriate.

The major receiving water criteria were floatables and bacteria. Solids and BOD follow, with nutrients and dissolved oxygen being the parameters of least concern. These criteria originate from public interest; however, they are enforced through the CSO policy and ultimately the Clean Water Act. It is clear that the public desires aesthetically pleasing waters (i.e., no floatables) that are safe for recreation (i.e., no harmful bacteria). These criteria are addressed in the CSO policy as part of the presumption and demonstration approaches. The presumption approach requires a community to meet any one of three predefined conditions, thereby presuming that water quality requirements are being met. The demonstration approach requires that water quality standards and designated uses be met on a case-by-case basis consistent with a LTCP, unless uses cannot be met as a result of other pollution sources (e.g., natural background conditions). Regardless of the approach, the obligation is to meet the requirements of the Clean Water Act, the protection of designated uses.

Generally the technology chosen by a community should and did reflect the site-specific nature/characteristics of CSOs within that community. The majority of the communities are planning to implement many different abatement technologies to most effectively meet water quality criteria. BMPs as prescribed by the nine minimal controls are currently the most popular form of CSO control. Implementation of BMPs has made a positive impact on water quality. For example, in Syracuse, BMP improvements such as sewer cleaning and raising weirs were implemented in the early 1980s to optimize flows to the WWTP. Comparisons of pre-BMP to post-BMP rainfall versus CSO overflow volume relationships showed a reduction in annual overflow pollutants of 85% to 90%. Many communities are in the process of planning for the implementation of structurally intensive solutions. In-system and offline storage, screening, disinfection, and vortex solid separators are the most popular control approaches among the communities responding.

5.3.2.5 *CSO Financial Considerations*

In the last 25 years, the federal government has spent more than $60 billion through grants and low-interest loans for the construction of WWTPs and sewer lines. States and municipalities have spent additional billions in matching funds for these improvements. A large percentage of the federally available funds was spent throughout the '70s and early '80s making improvements to WWTPs.

Some CSO communities took advantage of the federally available funds to abate CSOs while making improvements to WWTPs. In some respects this approach was uncertain because the federal CSO policy was in its infancy and no clear CSO related standards were available as guidance. A good example of this type of community is Rochester, N.Y., which moved to abate CSOs by separating the sewer system during WWTP improvements. The federal government funded almost the entire CSO abatement project. A small portion of Rochester's CSO abatement was completed without federal funds. The remaining CSO abatement included in-line and off-line storage, a more cost-effective approach reflecting the local funding source.

San Francisco started its CSO abatement program while federal funds were available and before the federal CSO policy was promulgated. However, San Francisco, being much larger than Rochester, could not implement a CSO abatement program as quickly. San Francisco started its program in 1978 and completed the major parts by 1997. As a result, San Francisco accepted funding from the entire range of available sources. The earliest projects were funded from approximately 68% federal, 12% state and 20% local sources. Subsequent projects used state revolving funds and local funds. One project used a special U.S. EPA marine CSO fund.

Many smaller communities such as Astoria and Augusta did not start their CSO abatement programs until the '90s. Their size and low priority, as discussed in the Issues Driving CSO Technical Considerations section, can explain this timing. Nonetheless, communities that began their CSO abatement programs in the '90s with the dawn of the federal CSO policy were too late to take advantage of federal grant money. These communities tended to rely on state revolving loans and local funding. As a result the local authorities required more information on the returns of these major investments to improve water quality before being willing to proceed. Also, these local authorities were more apt to challenge the legality of water quality standards. Owing to the greater sensitivity to costs, communities became more interested in satellite treatment as opposed to centralized treatment.

Selected abatement controls tend to reflect the source of funding. This may be illustrated by comparing the cost of sewer separation to satellite treatment such as vortex facilities. Sewer separation costs, including the cost for new SW treatment, for 6,813 acres in the City of Syracuse were estimated to be $612 million. Satellite treatment costs, including vortex units, netting devices and disinfection for the same area were estimated to be $144 million (Moffa & Associates, 1996). Obviously the cash flow for these approaches is very different. Sewer separation projects tend to be large up-front capital expenditures with smaller future operation and maintenance (O&M) costs, while satellite treatment tends to have smaller up-front capital expenditures with larger future O&M costs. Separate sewers also produce SW issues that need to be addressed.

CHAPTER 6.0

SSO Benchmark Data and Case Histories

6.1 Benchmark Data for SSO Communities

The following section includes a benchmark matrix for general SSO community statistics (Table 6-1), SSO public participation (Table 6-2), SSO systems characterization (Table 6-3), issues driving SSO technical considerations (Table 6-4), and SSO financial considerations (Table 6-5).

6.2 Case Histories for SSO Communities

6.2.1 Bloomington, Ind.

SSO Community Characteristics

◆ Population	110,000
◆ Sewer Area	77,000 Ac
◆ Annual Rainfall	60"
◆ # of SSO Discharge Points	15

Distinctive SSO Community Attributes

- Formation of utulity specifically for wet weather flows
- Retrofitting decommissioned WWTP as for off-line storage of wet weather flows

Bloomington's 250 miles of sanitary sewer are separate from the storm sewer system. However, during wet weather, the "separate" sewer system overflows at a number of points in the collection system, backs up into basements, and violates the NPDES permit for WWTPs. Bloomington's wet weather problem has been ongoing since the formation of the utility in the early 1970s. A sanitary sewer evaluation survey performed in conjunction with U.S. EPA's construction grants program identified a number of pipe replacement projects. The most recent project increased the capacity of two large pump stations in the collection system where SSOs frequently occurred. Unfortunately, these pipe replacement projects have done little to reduce the impact of wet weather discharges. These impacts have, for the most part, merely been transferred downstream.

In 1996, Bloomington experienced significantly higher than normal rainfall and the resulting wet weather impacts for that year were excessive. Also, the South WWTP consistently exceeded its design flow, and preliminary planning efforts began to either expand or replace the existing plant. At this point, Bloomington recognized the need to better manage wet weather flows and establish a wet weather management program. The focus of the $26 million dollar program was to reduce infiltration/inflow (I/I). Sewer system rehabilitation and replacement, off-line storage, and WWTP expansion are some of the strategies being investigated to reduce wet weather impacts.

A wet weather focus group consisting of a cross section of interested citizens was formed in 1997 and assisted in the selection of an engineering consultant to manage the wet weather program. The focus group meets on a regular basis and advises the wet weather management team in pursuing wet weather reduction strategies.

Currently, Bloomington is evaluating a number of cost-effective strategies. The South WWTP will add capacity through a combination of physical and process improvements. The lagoons at the decommissioned WWTP near the center of the collection system will be converted for off-line storage of peak flows during wet weather. Rehabilitation and replacement of the sewer pipe and manholes will be more aggressive, particularly in three problem areas of the city where SSOs and basement flooding have been concentrated. A number of direct SW connections to the sanitary sewer system have already been identified and eliminated. Bloomington has also formed a local SW utility in an effort to comprehensively manage wet weather impacts. Formerly operated and maintained at a minimum level under the city's public works department, the new utility dedicates funds especially for the operation and maintenance of the SW system in addition to capital repair of the long neglected infrastructure.

6.2.2 Houston, Texas

SSO Community Characteristics

♦ Population	1,800,00
♦ Sewer Area	385,000 Ac
♦ Annual Rainfall	46"
♦ # of SSO Discharge Points	20

Distinctive SSO Community Attributes

- Selection of SSO controls based on flow and water quality monitoring
- Use of wet weather treatment facilities for SSO
- Stakeholder involvement created wide support

Located 40 miles inland of the Gulf of Mexico, Houston is the fourth largest metropolitan area in the United States. Houston experienced a period of rapid growth early in the 20th century after a shipping channel connected the city to Galveston Bay and the gulf, making it a deepwater port. Other than the channel, most of the surface waters in and around Houston are classified as bayous. However, as Houston's bayous approach Galveston Bay they become wider and more closely approximate shallow tidal wetlands. During periods of wet weather, the bayous fill rapidly and carry SW away from the city to Galveston Bay.

The city's wastewater system is one of the country's largest. Currently, the average daily wastewater treatment demand is 250 MGD. With a service area of 600 square miles, it incorporates 46 WWTPs, 377 lift stations, 5,700 miles of separate sanitary sewers, and 100,000 manholes. The city provides water and wastewater service to approximately 378,000 customers and a total population of nearly 1.8 million. Much of Houston's growth in the last 25 years occurred as the city annexed previously unincorporated county areas. This rapid growth exceeded WWTP capacity. By the late 1980s, moratoriums on new construction existed in 90% of the metropolitan area.

Houston received administrative orders from the Texas Natural Resources Conservation Commission (TNRCC) and EPA Region 6 in 1987 requiring the city to control SSOs and upgrade the collection system by December, 1997. The administrative orders resulted in an investment of $1.2 billion by the city of Houston in SSO control.

Houston invested $65 million between 1988 and 1991 to evaluate its collection system and conduct extensive flow monitoring. The physical analysis identified infiltration due to leaking joints, cracks, and breaks in the city's sewers and laterals on private property as the primary sources of the increased wet weather flows. In 1992, the Greater Houston Wastewater Program (GHWP) was formed as an integrated organization of city employees and consultant staff, developed specifically for complying with the mandates of state and federal regulatory agencies. In the absence of a national SSO policy, the GHWP, TNRCC, and EPA Region 6 had to consider two principal issues regarding control of wet weather SSOs. These were: (1) the level of design storm protection that the collection system would provide for customers; and (2) the level of treatment required for overflows in excess of the design storm flow, based on impact to receiving water quality.

In 1994, Houston completed a water quality study of local receiving waters (bayous) for the purpose of quantifying the surface water quality benefits associated with SSO control alternatives. Monitoring confirmed that the quality of wet weather discharges from the constructed overflows was roughly equivalent to wet weather bayou water quality, so the city concluded that selection of a design storm for development of the capital improvements program was an issue of customer service, not water quality.

The capital improvements program, completed in December 1997, consisted of approximately 400 projects made up of relief sewers, sewer rehabilitation, new or upgraded pump stations, WWTP expansions, and wet weather facilities at a cost of nearly $1.2 billion. All engineering was performed by more than 70 local design firms, and most construction contracts were awarded to local firms, using local labor, equipment, and materials. The capital improvements program provided a significant boost to the local economy.

The GHWP was one of the most ambitious collection system improvement efforts ever undertaken in the country. Now complete, this comprehensive response to regulatory mandates and customer needs encompassed more than 400 projects. Both EPA Region 6 and TNRCC officials have given the city high marks for its progress and meeting the December 1997 deadline.

In November, 1997 TNRCC lifted the final set of administrative orders against Houston. This marked the first time in 24 years that the city was not under any administrative orders. The GHWP not only improved the reliability of the collection system, but also fostered local economic growth. New development boomed following completion of the SSO abatement program. In 1997 Houston issued building permits for $2 billion of new construction. This would not have been possible without the city's capital investment in its wastewater infrastructure.

6.2.3 Johnson County, Kan.

SSO Community Characteristics

♦ Population	400,000
♦ Sewer Area	120,000 Ac
♦ Annual Rainfall	37"
♦ # of SSO Discharge Points	20

Distinctive SSO Community Attributes

- Successful private property I/I reduction program
- Use of wet weather treatment facilities for SSO

Johnson County is located in eastern Kansas, on the southwest edge of the Kansas City, Mo., metropolitan area. The county includes 22 separate city governments. Johnson County Wastewater (JCW) operates three WWTPs throughout the county, treating a combined average dry weather flow of slightly more than 38 MGD. JCW also operates six wet weather treatment facilities that provide primary treatment to excess wet weather flows. These facilities were developed in the 1960s. JCW cleans and maintains more than 1,500 miles of sewer line and 32,000 manholes.

In the early 1980s, the sanitary sewer system was experiencing both excessive groundwater infiltration and SW inflow. In the districts, the considerable amount of I/I caused the wet weather facilities to activate frequently. Moderate amounts of rainfall often resulted in surcharging manholes, bypassing of raw wastewater to receiving streams, and backups of sewage into basements. The bypasses and backups of raw wastewater were a potential health hazard and resulted in considerable financial loss each year. During heavy rainfall events, JCW would receive hundreds of telephone calls from residents concerning basement flooding and sewage backups. In 1983, the Board of County Commissioners of Johnson County recognized the need for an aggressive public and private property I/I reduction program.

JCW's effort to control SSOs has two primary components: (1) an aggressive I/I reduction program; and (2) the operation of satellite wet weather treatment facilities. Numerous complaints by residents of sewers backing up into homes motivated JCW in 1985 to begin the extensive I/I reduction program. The program included a comprehensive sanitary sewer evaluation study to inspect all structures, including more than 55,000 private connections to residential and commercial properties.

The initial efforts of the I/I reduction program included inspection of numerous commercial and residential properties and public sector projects (manhole inspections, sewer line smoke testing, and television inspections) to ascertain the structural condition of the collection system. The goal was to determine the total number of I/I sources in the districts. Public notices were placed in local newsletters and area newspapers, explaining that inspectors would visit each property to obtain information from residents and owners concerning past problems with the collection system. While on site, the inspectors also located rainwater downspouts, area drains, and sump pump connections. As the information was collected, it was entered into a database, which allowed JCW to identify direct and suspect connections that were contributing inflow to the collection system. The inspection program covered more than 55,000 homes and businesses, eventually identifying approximately 15,600 sources on private property. The five most common private property sources of I/I were foundation drains, basement entry drains, sump pumps, cleanouts and downspouts, and driveway and other area drains. Additionally, the program inspected more than 17,000 manholes and found that nearly all had some defect that allowed for inflow.

Following source identification and hydraulic modeling, the I/I reduction program focused on the elimination of as many of the known sources as possible in a prompt, orderly, and cost-effective manner. It was determined that a phased implementation would result in the lowest possible construction and administrative costs. The phased approach was based on a combination of watershed location, unit inflow rate, and the local history of sewer backups. The phasing tended to concentrate survey and construction activities in the same geographic area, thereby producing measurable improvements early in the program.

The I/I reduction program work was completed in 1994. The public and private property I/I reduction programs together resulted in a net reduction of nearly 280 MGD during the 10-year, 1-hour storm. The removal of 15,632 private property sources is estimated to have eliminated more than 110 MGD of the 280 MGD. Out of the 55,000 buildings in the districts, only nine remain to either be inspected (refused entry) or to have a source disconnected, and these are being addressed through the appropriate legal channels.

The total cost for the overall I/I reduction program was approximately $60 million. The private property work cost nearly $10.3 million, the public sector work (I/I reduction and relief sewers) almost $30 million and the remainder consisted of engineering and administrative expenses. JCW received almost $12 million in grant funds and nearly $18 million in state revolving fund low interest loans. However, the private property I/I reduction program expenditures were not grant or loan eligible and were funded with obligation bonds.

JCW's SSO control plan also includes the use of six satellite wet weather treatment facilities to provide primary treatment and disinfection to excess flows during wet weather. Although these facilities are somewhat controversial in that they are discharging partially treated sewage, JCW believes that they are a viable component of its effort to reduce direct human exposure to raw sewage. JCW has performed water quality monitoring during wet weather events and determined that the facilities have a minimal impact on the small urban creeks into which they discharge. JCW has also looked at the cost of eliminating the wet weather facilities while maintaining the same level of storm protection, and found costs prohibitive.

JCW believes that the I/I reduction program has significantly reduced I/I. The I/I work has met or exceeded the expected reductions in wet weather flows throughout the system. The focus on private property I/I was a proactive approach to reducing peak flows. EPA Region 7 and Kansas state officials agree that the allocation of local public funds to address private property I/I sources is an effective approach to solving I/I problems.

Through what is believed to be the largest private property I/I reduction program in the country, JCW has eliminated all capacity-related uncontrolled SSOs during events up to the 10-year, 1-hour (2.5 inches) storm.

6.2.4 Oklahoma City, Okla.

SSO Community Characteristics

♦ Population	470,000
♦ Sewer Area	400,000 Ac
♦ Annual Rainfall	40"
♦ # of SSO Discharge Points	20

Distinctive SSO Community Attributes

- Successful sewer rehabilitation and replacement program
- "Business" approach has markedly improved funding base and customer service

Oklahoma City is located in central Oklahoma, approximately 200 miles north of Dallas, Texas, spanning more than 620 square miles. Oklahoma City's central business district contains large numbers of commercial and single family residential properties, while the outskirts are primarily agricultural. Oklahoma City Water and Wastewater Department (OCW) provides water and wastewater services to more than 470,000 people spread across 320 square miles — nearly 96% of the city's total population. OCW maintains more than 2,400 miles of sewer line, including 63 lift stations and 4 WWTPs with a combined capacity of 101 MGD. The average dry weather flow to these plants is 75 MGD.

In the mid-1980s, SSOs in Oklahoma City sewers were a daily occurrence. The OCW, now part of the Oklahoma City Utility Trust, had a substantial backlog of complaints of sewer stoppages and overflows. Basement flooding occurred regularly in parts of the city. In 1986, OCW adopted an "enterprise system" under which all revenues derived from the water and wastewater utilities were put back into the system, instead of the city's general fund. With the inception of the enterprise system, OCW became committed to implementing efficient business practices and delivering quality water and sewer services. This effort, which continues today, included a dedication to sewer rehabilitation and repair which has virtually eliminated capacity constraints within the system and vastly improved customer service.

OCW does not have a specific SSO control plan. The progress it has made in controlling SSOs was not driven by water quality concerns. Rather, OCW established a goal of eliminating sewer back-ups in homes and has dedicated much of the work of the capital improvements program (CIP) to this end. At an annual cost of $6 million, or slightly less than $13 per capita, OCW replaces approximately 1%, or 120,000 linear feet of sewer line each year. The focus on sewer line replacement has been a continuous and sustained element of the CIP since 1986. The CIP has also included a number of improvements in the city's WWTP capabilities.

OCW tracks sewer system complaints and uses this information to gauge the success of the CIP investment in line replacement. Each complaint is entered into a database that helps identify persistent problem areas. By systematically replacing the weakest portions of the sewer system, OCW has dramatically improved wastewater service in Oklahoma City.

Fully 95% of OCW's maintenance activities are preventative, rather than reactive. Increased levels of routine maintenance have proved valuable in eliminating line blockages and in identifying the need for repairs before problems are elevated to emergencies.

The OCW management believes that there are three primary components to a well functioning utility: adequate financing, control over planning, and dedicated personnel. In Oklahoma City, the enterprise system has given OCW control over financing and planning for the water and wastewater utilities. The city's conversion to the enterprise system has resulted in excellent water and wastewater improvements. The revenues generated by the utility are controlled by the utility and put back into projects to improve utility services.

The CIP focus on line replacement and I/I control has allowed Oklahoma City to decrease total flows to the WWTPs, while the population has grown, and virtually eliminate capacity related overflows within the system. Sewer rehabilitation programs have had numerous benefits, including: reduced frequency of emergency maintenance; lower incidence of damage to public and private property; extended infrastructure life; and decreased overflows and stoppages. All these contribute to the ultimate goal of improved customer service. Both the Oklahoma Department of Environmental Quality and EPA Region 6 officials believe that OCW has found an effective, proactive means of controlling SSOs and would like to see their efforts emulated by other jurisdictions.

6.2.5 Wayne County (Downriver Communities), Mich.

SSO Community Characteristics

◆ Population	320,000
◆ Sewer Area	100,000 Ac
◆ Annual Rainfall	34"
◆ # of SSO Discharge Points	20

Distinctive SSO Community Attributes

- Michigan state rigorous SSO abatement criteria
- Construction of a regional storage-transport system as SSO control

The Downriver Collection System (DCS) in Wayne County, Mich., serves more than 320,000 people in 13 communities. These communities are located southwest of Detroit and are known as the Downriver Communities.

Administered by the Michigan Department of Environmental Quality (MDEQ), Michigan has one of the most rigorous state-mandated abatement criteria for controlling SSOs. In deriving the criteria for controlling SSOs, MDEQ started by assuming wet sanitary sewers closely approximate storm sewers. Therefore, the design criteria is based loosely on standard storm sewer requirements. Storm sewers are normally designed to transport the 10-year, 1-hour storm in residential areas, and the 25-year, 1-hour storm in commercial areas. To be conservative, MDEQ initially considered using the 25-year, 1-hour storm event as a uniform standard for all areas. However, a storm of such short duration did not provide enough information about the volume required to contain a longer, equally intense storm. Hence, MDEQ adopted the 25-year, 24-hour design storm. With such rigorous design criteria, MDEQ expects very few overflow events. Most will be attributable to extreme conditions such as large back-to-back events; storms having intensities greater than the design storm; or theoretical system capacities reduced by high groundwater, snowmelt, or late winter rains on frozen ground. Therefore, each overflow event is reviewed on a case-by-case basis, with MDEQ giving careful consideration to extenuating circumstances before levying fines.

When MDEQ initiated legal action against the DCS in 1987, the collection system was experiencing 25 to 35 SSO events annually with an estimated total volume of 366 MG per year. Basement flooding due to sewer backups was also widespread within the DCS service area.

During the fall of 1990, as part of the Downriver Improvements Program, system-wide flow, rainfall, and groundwater information was collected. The flow monitoring revealed a number of system deficiencies and evidence that many of the tributary communities routinely exceeded their contractual peak flow, which in turn caused the hydraulic capacity of the system to be exceeded. Excess flows were determined to be attributable to high I/I in many communities, excessive pumping from the city of River Rouge, and a non-operational regulator in the city of Ecorse. It was also determined that the WWTP did not have sufficient capacity to handle the resultant flow if all communities were to simultaneously discharge at their contractual peaks.

Flow monitors in the thirteen communities were used to evaluate the relative contribution of each to the wet weather flow problem. The measured flows were also used in negotiations between the communities when determining an equitable distribution of the Downriver Improvement Program costs. In order to direct local rehabilitation efforts, most of the communities also undertook a concurrent flow-monitoring program to identify areas subject to the greatest wet weather inflows. In general, the older communities had higher levels of I/I, often two to three times those of newer areas. These high rates were mainly attributable to SW connections, footing drains, the relatively large older sewers, deteriorating pipes, and leaks in manholes.

The Downriver Communities entered into a consent agreement with MDEQ in 1994 after numerous violations of both the Federal Clean Water Act, the Mich. Water Resource Commission Act, and the terms and conditions of the county's NPDES permit. The objectives of the improvements program, mandated by the consent decree were:

- reducing discharges of untreated sanitary sewage,
- reducing basement flooding related to the DCS capacity or WWTP constraints, and
- reducing wet weather inflows into the collection system.

In order to meet these objectives, the collection system and the WWTP must have the capacity to transport and treat all flows (blend of primary and secondary treatment) up to the 25-year, 24-hour storm (roughly equivalent to 3 inches). The collection system must also have the capacity to transport all flows up to the 100-year, 24-hour storm (roughly equivalent to 4-5 inches) to the WWTP. The WWTP must provide secondary treatment for flow up to 125 MGD and a blend of primary and secondary for an additional 25 MGD. Flow that exceeds 150 MGD up to 225 MGD must receive preliminary treatment (screening, grit removal, and disinfection). Flows greater than those generated by the 100-year, 24-hour storm can be routed to "inactive" emergency bypass structures spread throughout the system.

The consent agreement put the DCS on a compliance schedule to reduce the occurrence and volume of SSOs. A number of alternatives, representing both "local" and "regional" approaches, were considered for meeting the requirements of the consent decree. These included: WWTP relief capacity for peak flows; off-line storage basins; on-line storage basins; and a regional storage-transport system including relief sewers and a large diameter tunnel. The regional storage-transport system was selected because it was the most cost effective on an annualized basis. This alternative was also particularly attractive because all flows would receive some treatment; all emergency discharges would, for the most part, go to the Detroit River (rather than smaller tributary streams); a minimum amount of site acquisition was required; and because of the lower O&M requirements associated with the operation of a regional facility compared to a series of satellite storage basins. In addition to the regional storage-transport system, the mandated SSO abatement plan includes the expansion of the WWTP, implementation of localized sewer rehabilitation programs, and construction of an off-line basin facility and an emergency discharge outfall.

Implementation of various aspects of the mandated improvements began in 1994. The rehabilitation of county interceptors and community sewers was completed in the fall of 1995, with significant state revolving fund loan assistance. Subsequently, system flows have been monitored to track the effectiveness of improvements and to provide data for sizing the regional storage-transport system. Work on the WWTP upgrades began in 1994, including the construction of dechlorination facilities, the installation of a new solids handling facility, and construction of a new maintenance facility. The WWTP is currently being expanded to provide reliable primary/secondary treatment for flows up to 150 MGD and preliminary treatment for emergency flows up to 225 MGD. The WWTP improvements also include expansion of the disinfection and outfall facilities, which will bring the capacity of these facilities in line with the increased capacity of the rest of the plant. The final component of the mandated improvements is the construction of community relief sewers and a large diameter tunnel. Construction of the upper portion of the tunnel and a county relief sewer began late in 1996. Local relief sewer projects commenced in 1997. Construction of the main portion of the tunnel began in 1998 and should be completed in 2001.

In general, water quality is a primary concern for local governments, and Wayne County officials do not believe that the SSOs within the DCS service area represented a $270 million water quality problem. Wayne County's Director of Public Works, James Murray, stated that: "SSO water quality objectives need to be integrated with CSO and SW quality objectives. Substantial costs are being incurred by the DCS to eliminate SSO discharges, while at the same time current SW and CSO programs provide for discharges into the same watercourse with effluent quality far less stringent."

Wayne County officials advocate a watershed-based approach, which would integrate the control of all sources of wet weather pollutants and yield a more cost effective solution with maximum water quality benefits. They also indicated that:

- it is not practical to assume that SSO events will never occur;
- it would be more appropriate to clearly define emergency conditions, identifying specific circumstances when a system bypass would be acceptable; and
- emergency conditions should not necessarily be based on a design storm, but rather on the frequency of occurrence of overflow events.

6.3 SSO Case Histories and Benchmark Data Discussion

6.3.1 General SSO Discussion

Although surveys and studies have collected information on sanitary sewer collection systems and SSOs, information on the status of the collection systems and extent of SSO problems remain limited. However, these surveys and studies have identified SSOs as a common characteristic of most sanitary sewer collection systems.

Because many municipalities have not quantified their SSOs, very few have moved to correct or abate this pollution source. The lack of a national SSO policy, and the rarely enforced NPDES requirements also make SSO abatement a low priority for most municipalities.

SSOs during dry weather conditions are less common today then they were in the past due to efforts to increase WWTP and collection system capacities. However, SSOs during wet weather conditions continue to be a common occurrence around the nation. Although many communities have not moved forward in abating wet weather SSO related concerns, some generalizations can be made about the condition of sanitary sewer collection systems and SSOs, and permitting inconsistencies around the nation.

There are many potential strategies that municipalities may adopt to abate SSOs. Most involve some combination of upgrading the WWTP, removing sources of I/I, and increasing the storage capacity of the collection systems. Some strategies involve technology used for CSO control, such as off-line storage and satellite treatment facilities. However, currently this approach is atypical. Reasons for abating SSOs come from customer complaints regarding sewer backups as much as from water quality concerns.

6.3.1.1 Sanitary Sewer Failures and Resulting Overflows

The Urban Institute (1984) estimated that as an annual average there are 825 sewer backups and 140 sewer breaks every year for every 1,000 miles of sewer. A system of 1,000 miles of sewer serves about 250,000 people. The Urban Institute also proposed that sewer backup rates were highest in the northeast and economically distressed cities and were generally higher in communities with the oldest sewer systems. High sewer break rates in the south and west are particularly associated with large, growing cities. The Urban Institute survey attributed backups to a variety of factors: the location of pipe in trouble-prone areas, the pipe material, the size of pipes, the material, construction methods, local soils, and maintenance practices.

In 1994, the Civil Engineering Research Foundation found that three quarters of the sanitary sewer systems function at 50% of capacity or less. Root penetration, corrosion, soil movement, and inadequate construction are the cause of most structural failures.

As a result of reduced sewer capacity and failures, SSOs during wet and dry weather are a reality. The Association of State and Interstate Water pollution Control Administrators (ASIWPCA) found that 31% of municipal systems have at least an occasional dry weather SSO. The estimated annual number of dry weather SSOs was 1,962 for the 25 states providing information. The ASIWPA study also found that 29% of the municipal sanitary sewer systems experience wet weather SSOs and 25% of the WWTPs experience some problems during wet weather.

In a Water Pollution Control Federation study (1989), 1,003 WWTPs identified facility performance problems. I/I was the most frequently cited problem.

6.3.1.2 *NPDES Inconsistencies*

Different NPDES authorities have historically provided different emphasis on oversight of sanitary sewer collection systems. In addition, some of the NPDES regulatory provisions addressing sanitary sewer collection systems are unclear, and different NPDES authorities have provided different interpretations regarding SSOs. For example, the ASIWPCA study (1996) found that only two states issue permits to municipalities that discharge from their sanitary sewer system to another municipal sewer collection system, five states issue permits for some of these types of system, and 26 states do not issue permits for these systems. The ASIWPCA study also found that 13 states authorize wet weather control facilities that provide some level of treatment or flow control. EPA Region 6 and states in at least four other EPA regions (2, 3, 5 and 9) have issued permits for controlled discharges from wet weather facilities. Other states and EPA regions have not currently decided whether or not to allow wet weather facilities.

6.3.2 SSO Questionnaire Findings

6.3.2.1 *SSO Community Statistics*

The SSO benchmark questionnaires returned cover a wide range of conditions and receiving waters. Most SSOs discharge into rivers, but lakes, the ocean, estuaries, and streams are also represented, and most communities discharge into several different types of receiving waters. The surveyed SSO communities also represent a wide range of populations and service areas. Annual rainfall for these communities varies significantly. Many communities had not determined the quantity of annual SSO discharge, in part because many SSOs occur as basement and street flooding which is difficult to quantify.

In contrast to CSO and SW, most communities have not defined their SSO annual discharge quantity; Wayne County, Mich. was one of the few exceptions. Flow monitoring in 13 Wayne County communities was used to evaluate the relative contribution of each to the wet weather pollution.

6.3.2.2 *SSO Public Participation*

Public participation for SSO tends to be different as compared to CSO and SW. SSO public participation efforts tend to originate from sewer backup-related occurrences rather than environmental issues or water quality. Therefore SSO public participation tends to be more of a pragmatic approach rather than environmental education approach. For example, Houston, Texas needed to move ahead simultaneously with initial planning, design, and construction activities in order to meet a consent agreement deadline. The local engineers and construction community, along with the municipality staff, organized together during the initial phase of planning and program development. This relationship helped the stakeholders to become fully committed to the process well ahead of actual design and construction contracts.

General water quality, along with basement flooding and other sewer backup related occurrences, were the most commonly listed public concerns. The major water quality parameters of concern were bacteria, BOD, and dissolved oxygen.

6.3.2.3 *SSO Systems Characteristics*

The majority of the communities responding had used a mathematical model to estimate flow in their sanitary sewer collection systems. Houston invested $65 million between 1988 and 1991 to evaluate its collection system and conduct extensive flow monitoring. The physical analysis identified infiltration due to leaking joints, cracks, and breaks in city sewers and private property laterals as the primary source of increased wet weather flows. The collection system modeling helped Houston better define the size of the satellite treatment facilities.

Although many communities say they use a watershed approach, some interpret this approach as encompassing all the sewers and laterals in the sewershed when planning for rehabilitation or abatement. Houston and the Downriver Communities, however, pursued a more ideal watershed approach. The city completed a water quality study of local receiving waters for the purposes of evaluating surface water quality benefits associated with SSO control. Monitoring and modeling confirmed that the water quality of wet weather pollution from constructed overflows was roughly equivalent to wet weather receiving water quality. As a result, the goals of the SSO control program were more concerned about customer service (i.e., sewer backups) than receiving water quality. The Downriver Communities in Wayne County also pursued a watershed approach, but the results were not as successful as Houston. The Downriver Communities identified other pollution sources in the watershed such as CSOs and SW. However, the regulatory agency viewed each pollution source separately and held the Downriver Communities to rigid SSO effluent standards regardless of water quality impacts of other pollution sources.

Current pollutant abatement included municipal and industrial point sources, plus urban runoff, from practically all cities. Control efforts for the same targeted pollutant sources were generally expected to remain in the future.

R0018468

6.3.2.4 *Issues Driving SSO Technical Considerations*

Two cities, Flagstaff and Oklahoma City, indicated that an SSO facility plan has not been initiated. The remaining communities were equally split between developing a plan and completion of a facility plan. Of the many potential strategies municipalities may adopt to abate SSOs, most involve some combination of upgrading the WWTP, removing sources of I/I, and increasing the storage capacity of the collection systems. Some abatement strategies involve technology used for CSO control, such as off-line storage and satellite treatment facilities. However, currently this approach is atypical. Bacteria, BOD, and dissolved oxygen were the most prevalent water quality criteria for local receiving waters. Floatables, sediments, and nutrients were also notable water quality concerns.

Planned sewer improvements and regulatory requirements were listed as the most common reason for SSO abatement. A few communities, such as Downriver Communities, Hillsboro, Houston, and New Orleans, responded to litigation.

SSO abatement is almost exclusively accomplished by I/I reduction. However, upgrading the WWTP and increasing the storage capacity of the collection systems are also common. In a few select cases, such as Johnson County and Houston, satellite treatment of SSOs have been approved. Satellite treatment technology included screening, settling tanks or ponds, and disinfection. Such an approach provided a cost-effective means of complying with water quality requirements.

6.3.2.5 *SSO Financial Considerations*

Most communities spent less than $10 million for past SSO costs, indicating that the communities have not started major infrastructure-type abatement. Most communities have acquired or plan to acquire funding for SSO abatement through increased sewer rates. Another common funding source was revolving loans.

CHAPTER 7.0

SW Benchmark Data and Case Histories

7.1 Benchmark Data for SW Communities

The following section includes a benchmark matrix for general SW community statistics (Table 7-1), SW public participation (Table 7-2), SW systems characterization (Table 7-3), issues driving SW technical considerations (Table 7-4), and SW financial considerations (Table 7-5).

7.2 Case Histories for SW Communities

Stormwater case histories are useful in documenting the successes and disappointments of SW management in areas having up to several decades of experience. Most U.S. cities are just beginning to consider local SW controls as a result of federal regulations. However, the literature (especially technical conference publications) shows that many cities throughout the country have been involved to a certain extent in some SW control. The following case histories present five municipalities that have been involved in local SW management longer than many in the nation: Bellevue, Wash., Denver, Colo., Austin, Texas, Milwaukee, Wis., and Orlando, Fla. These mature SW management programs have all progressed through many phases of operation and are renowned for developing or making major advances in certain specific aspects of SW management, such as utility district financing, integrating drainage and water quality issues, addressing groundwater problems, and dealing with watershed-scale problems.

7.2.1 Austin, Texas

Austin has been long known as an innovator for SW controls, especially the sand filter. It was also one of the earliest cities to enact comprehensive SW management regulations specifically to protect both surface and groundwater receiving water quality.

Austin was incorporated in 1839 and is a rapidly growing city, with a population of about 460,000 (1990 census). It is the capital of Texas, home to the University of Texas, and an important high-technology center. The city covers an area of 116 square miles and the land elevation ranges from about 400 to over 1,000 ft. The area receives about 32 inches of rain a year, but can have prolonged dry periods with large amounts of evapotranspiration, resulting in arid characteristics. The separate storm drainage system discharges into several heavily urbanized streams which drain to the Colorado River. The river is dammed in Austin into a chain of three large lakes (Lake Travis, Lake Austin, and Town Lake) that comprise the local water supply. The Edwards Aquifer recharge zone underlies parts of Austin, making groundwater protection an additional important component of local SW management efforts.

Austin's peak discharge control regulations were implemented in the mid-1970s in response to the city's rapid growth and associated increased flooding and erosion. SW quality regulations were first implemented in the early 1980s to protect the city's water supply. A drainage fee was established in 1982 and the Drainage Utility was established in 1991.

Questionnaire Date: July 1998.

Austin has enacted three major watershed ordinances to protect both surface water and groundwater resources:

- the Comprehensive Watersheds Ordinance (1986),
- the Urban Watersheds Ordinance (1991), and
- the Barton Springs Ordinance (1992).

The objectives of the local SW management program are to:

- protect citizens from flooding,
- preserve the natural and traditional character of the city's waterways,
- protect the water quality of the Edwards Aquifer and the city's drinking water supply, and
- protect the city's recreational and aesthetic resources (such as Town Lake and Barton Springs).

Some of the ordinance requirements are very specific, such as those for source controls as part of the Barton Springs ordinance. Because of some of these requirements, especially for areas outside the city limits, successful court challenges by developers have weakened some of the laws.

Current funding for the city's erosion and sediment control program is about $750,000 (evenly derived from general city appropriations, permit fees, and from the SW utility fee). The SW management program is funded at about $8 million (mostly from the SW utility fee).

Cost Estimates ENR: 5921 July 1998
Questionnaire Date: July 1998.

The city has long conducted local monitoring activities. The city worked with the U.S. Geological Survey on a cooperative effort starting in 1975 to evaluate SW from eight large mixed land use watersheds. Starting in 1981, the city also participated in NURP, monitoring runoff from two residential areas and one undeveloped area. The city expanded its efforts in 1984 to include a total of 11 single land use areas representing new development. Five additional single land use sites (older, existing areas) were monitored as part of the NPDES SW permit. Selected event mean concentration data from these monitoring activities are shown in Table 7-6.

Table 7-6. Land Use versus Event Mean Concentrations, Austin, Texas

mg/L	Suspended Solids	COD	Total P	TKN	NO2 NO3	Lead	Copper	Zinc
Open/Vacant/Parkland	80	26	0.10	0.52	0.15	0.004	0.01	0.008
Medium density, single-family	170	83	0.47	2.35	0.96	0.02	0.05	0.10
Townhouse/apartment	111	113	0.38	1.82	0.58	0.02	0.02	0.10

Institutional	160	93	0.47	2.35	0.96	0.05	0.04	0.20
Major roads/highways	143	103	0.44	1.78	0.83	0.53	0.05	0.37

In 1989, the city started a study to identify and quantify the critical pollutants and sources adversely affecting the Town Lake water supply, listed below, along with their removal goals, in order of decreasing importance:

- nutrients (25 - 30%),
- toxic metals (50%),
- suspended solids (50%),
- trash and debris (50 - 90%), and
- oil and grease (25%)

Concentration reduction efficiencies for various SW control devices have been extensively evaluated in Austin to support the city's SW management planning activities. Table 7-7 summarizes some of the expected concentration reductions for the flows being treated. Because some devices bypass significant amounts of untreated SW due to clogging (especially in sand filters due to inadequate maintenance) or because they are undersized (such as for oil/water separators), the actual annual pollutant removals may be substantially less. In addition, Table 7-7 only reflects concentration reductions and not the greater pollutant mass reductions associated with devices having significant infiltration benefits (such as for grassed waterways).

Table 7-7. Concentration Reduction Efficiencies for SW Controls, Austin, Texas

% Reduction	Wet Pond	Sand Filter (no pretreat)	Dry Pond (earth/grass lined)	Oil/Water Separator	Grassed Waterway

7.2.2 Bellevue, Wash.

SW Community Characteristics

♦ Population	100,000
♦ Sewer Area	19,000 Ac
♦ Annual Rainfall	35" - 40"
♦ # of SSO Discharge Points	>100

Distinctive SW Community Attributes

- One of the first communities to establish SW utility
- Rate structure based on runoff volume generated

Bellevue has a long history of SW management. It was one of the first communities in the U.S. to establish a SW utility district and to develop a method for local financing of both flood control and water quality enhancements. Bellevue is a rapidly growing community near Seattle, with a population of about 87,000 (1990 census) and covering more than 30 square miles. The area receives 35 to 40 inches of rainfall a year with a separate drainage system. The SW is discharged to many small heavily urbanized streams which lead to Lake Washington.

Washington state law was changed in 1965 to allow the establishment of utilities as a funding mechanism for SW control. The city established its storm and surface water (SSW) utility in 1974, after several years of discussion and planning based on citizen concerns about declining water quality in Bellevue streams. The SSW utility's founding mission was "to maintain the hydrological balance, to prevent property damage, and to protect water quality; for the health, safety, and enjoyment of citizens and the preservation and enhancement of wildlife habitat." During the initial five years, the utility focused mostly on runoff volume and velocity, and erosion control. After these fundamental problems began to be addressed, the utility was able to shift its focus to also include water quality objectives.

A critical part of the development of the SSW utility was the establishment of a rate structure based on volumetric runoff coefficient (Rv) generated:

- undeveloped (Rv <0.25),
- light (0.25 <Rv<0.4),
- moderate (0.4<Rv<0.5),
- heavy (0.5<Rv<0.75), and
- very heavy (0.75<Rv<1.0).

Onsite runoff controls result in rate reductions. A major public education program was conducted to emphasize the benefits of the utility and the costs. In 1991, the average single-family household paid about $90 per year to the SSW utility. The 1986 budget was about $4.3 million, and the 1980 to 1986 capital improvement budget was

$13 million. In 1997, the SW program was funded at about $450,000 per year from permit fees, and the erosion and sediment control program is funded at about $500,000 per year from the SW utility fee and permit fees. Both programs have a combined staff of two administrators, three full-time development reviewers (plus four part-time reviewers), four inspectors (plus two part-time inspectors), and three others, including support staff.

Some opposition continued to the utility fee within the city, but it has subsided greatly as the citizens understand the benefits of the utility. The main benefit is in preventing problems instead of responding to existing problems, which tends to diminish the utility's perceived value. Adding a stronger component to more adequately address water quality issues is a future challenge being currently addressed by Bellevue.

Preferred SW practices include wet detention ponds, grass roadside drainage swales, catchbasins, oil-water separators, and filters. Ground infiltration practices are not allowed due to slowly percolating soils and problems with these practices in the past. During 1992 and 1993, 13 biofiltration facilities, 8 extended dry detention ponds, and 1 filtration facility were installed.

The SSW major programs include:

- capital improvement (by 1991, 11 ponds with real-time control had been established for flood control);
- operations and maintenance (operating flood control facilities to minimize fishery impacts, consulting with private property owners to solve private drainage problems, cleaning inlets and storm drainage, repairing structural facilities, emergency response, etc.);
- water quality (routine monitoring of all receiving waters, stream enhancement and lake restoration projects, inspection of private SW systems, etc.);
- development regulations (using the city's land use authority to regulate construction, enforce clearing, grading, and development of sensitive areas, inspect construction sites, etc.);
- public education (award-winning "stream teams" and "business partners for clean water" programs, etc.); and
- administration (policy development, financial management, rate administration, drainage planning, etc.).

Bellevue participated in NURP, resulting in much data on local characterization and control effectiveness. With this local data, the city applied for a general NPDES permit for SW in 1985, more than ten years before the SW NPDES permit program was established for the country.

The SSW utility operates a spill response team on 24-hour call to respond to accidents or citizen calls for inappropriate or illegal discharges to the drainage system or streams. It also operated one of the first oil recycling programs in the nation.

The Bellevue SSW utility efforts have succeeded because:

- the utility is a unified agency (although city reorganization in 1993 resulted in the erosion and sediment control program being assigned to a different city unit);
- the utility has the backing of strong regulations;
- the utility has strong citizen support;
- all enforcement and maintenance activities are staffed within the utility; and
- the utility coordinates extensively with other agencies and governments in the region.

The SSW utility programs do have some current conflicts with other city programs, such as biofiltration conflicting with the city's land use code landscaping requirements, and the preferred use of swales conflicting with the city's transportation code.

7.2.3 Denver, Colo.

SW Community Characteristics

♦ Population	>1,000,000
♦ Sewer Area	>100,000 Ac
♦ Annual Rainfall	15"
♦ # of SSO Discharge Points	2,000

Distinctive SW Community Attributes

- Successful SW utilities
- Flood control receives more emphasis than water quality

Denver is known for its efforts in flood control in an arid, high elevation area that receives large amounts of runoff from upstream areas. The city's efforts to develop and evaluate site-specific SW quality control practices and its experiences with utility district are also noteworthy.

Denver was incorporated in 1858 and had a population of about 470,000 in 1990. The city covers an area of about 155 square miles and is at an elevation of more than 5,000 ft. The area receives only about 15 inches of rain a year and experiences cold and long winters. The separate stormwater system has more than 1,000 outfalls in the metropolitan area that discharge into small streams that, in turn, eventually discharge into the Platte River. Rain occurs on about 60 days a year, but only about 30 storms per year are of sufficient size to produce runoff.

The Urban Drainage and Flood Control District (UDFCD) serves an area of about 400 square miles, having a total population of more than 2 million. Flood control has received the most emphasis from the district, and receiving water quality problems are not generally thought to be associated with wet weather flows because of other influencing factors. However, a watershed approach has been taken locally where urban runoff, municipal point sources, and industrial point sources are being addressed. Federal and state regulatory requirements are the major driving forces behind local wet weather flow water quality control efforts.

Denver was a participant in NURP in the early 1980s, monitoring several catchments and control practices over several years.

About $4 million has been spent in the past on wet weather pollution control efforts, and about $10 million is projected to be spent in the future, coming from increased taxes, user fees from the utility district, and by reallocation of funds from other municipal activities. The UDFCD is coordinating NPDES SW permit activities for the cities of Denver, Aurora, and Lakewood. As more communities in the Denver area are required to participate in the

NPDES permit program, the UDFCD will be available to assist these other areas also. A joint task force was created in 1990 to define the goals, objectives, and responsibilities necessary to meet the needs of the permit process. The initial goals were to:

- coordinate application efforts of the three cities,
- jointly negotiate application requirements with the state of Colorado,
- jointly conduct activities whenever possible,
- share knowledge and experience,
- facilitate use of resources of other organizations,
- evaluate candidate SW control practices,
- develop dry weather screening work plan, and
- develop a joint SW monitoring program.

In addition to helping to coordinate these activities, the UDFCD, in conjunction with local colleges, also conducts erosion control training courses for local contractors.

The NPDES SW permits were issued by the state to the three cities in May 1996. All permit requirements must be implemented within three years. Some of the permit requirements, such as street and inlet cleaning and trash removal from channels, has been an on-going activity, but other activities will need to be implemented, including:

- annual reporting and cost estimates,
- industrial facilities program,
- municipal facility runoff controls,
- wet weather monitoring program,
- dry weather sampling protocols, and
- other major programs (including public education, new development planning procedures, and construction site sediment control).

Local construction site erosion control efforts typically include mulching, diversions, filter fencing, and sedimentation practices. Stormwater control is accomplished through many activities, including public works practices (street and inlet cleaning, litter control, oil/water separators, inappropriate discharge elimination, grass swales, and grit chambers), infiltration (porous pavement and grass filters), sedimentation (wet detention ponds and wetlands), and other activities (including dry detention ponds, filtration, and public education). The performance of many of these devices has been determined through local monitoring. The district identified severe problems with typically constructed sand filters, such as clogging caused excessive bypassing of untreated water. Design guidelines need to be modified to account for expected high suspended solids loadings and to enable more efficient maintenance. Monitoring a wet pond followed by a series of wetland cells showed moderate to high levels of control of many pollutants over a wide range of runoff conditions.

Stream restoration along the Platte River has also been successful. Denver is well known for Confluence Park, a $7.5 million project that incorporates flood control, boating access, recreation, 5 acres of wetlands, wildlife and aquatic habitat, plus a cooling water diversion structure for a power plant. Denver also had constructed more than 12 miles of recreational trails along the South Platte River within the city, which connects with six other trails having an additional 50 miles.

7.2.4 Milwaukee, Wis.

SW Community Characteristics

♦ Population	630,000
♦ Sewer Area	61,500 Ac
♦ Annual Rainfall	30"
♦ # of SSO Discharge Points	Unknown

Distinctive SW Community Attributes

- Extensive SW quality information
- Watershed approach and nonpoint source pollution control

Milwaukee has a great deal of SW quality information and a state regulatory program that has put these data to good use in a watershed context.

Milwaukee was incorporated in 1846 and has been known as a heavily industrialized city, although it is more diversified now. It had a population of abut 630,000 in 1990 and a land area of about 96 mi². Its elevation is about 600 ft. The central part of Milwaukee has a combined sewer system, but the vast majority of the city and most of the surrounding communities have separate storm drainage. The storm drains flow to Lake Michigan, with most stormwater flowing from the Milwaukee, Kinnickinnic, and Menomonee Rivers (which form the inner harbor) from urbanized tributaries (such as Lincoln Creek). The annual rainfall in Milwaukee is about 30 inches, and snow cover is common for several months each winter. Winter temperatures can be severe and snowmelt is an important contributor to urban runoff pollution, in addition to rainfall induced runoff.

Stormwater quality management in the Milwaukee area was initiated as part of the Wisconsin Priority Watershed Program. This program (one of the oldest in the nation funding nonpoint pollution abatement) was developed in 1978 to help combat both urban and rural nonpoint sources of pollution. An important element of the program is retrofitting control practices in both rural and urban areas. Initially the program was heavily involved in rural areas, with technical assistance from the National Resources Conservation Service (NRCS). A unique aspect of the program is that it is implemented on a watershed and not on a political jurisdiction basis. Of the state's 330

R0018481

watersheds, 130 (mostly located in the southern part of Wisconsin) will likely require comprehensive management activities to control nonpoint pollutants. A 25-year plan was developed in 1982 that requires the startup of about eight or nine new watershed abatement efforts per year. The watershed plans are prepared by the state with cooperation and reviews by local government agencies. They contain detailed analyses of the water resources objectives (existing and desired beneficial uses including the problems and threats to these uses), the critical sources of problem pollutants, and the control practices that can be applied within each watershed. The plans also include implementation schedules and budgets to meet the pollution reduction objectives.

Each plan requires one year to prepare, including the necessary fieldwork. Various field inventory activities are needed to prepare the plans, including aquatic biology and habitat surveys to identify existing and potential fishery uses, streambank surveys to identify the nature and magnitude of streambank erosion problems and to help design needed controls, field and barnyard surveys to supply information needed to estimate and rank their pollution potentials and to design farm control practices, and urban surveys needed to evaluate urban runoff pollution potential and its control.

Urban planning was initiated in 1983 in the Milwaukee and Madison areas, with other urban areas of the state following. The urban practices eligible for cost sharing identified in these plans have included streambank protection, detention basins, and infiltration devices for existing urbanized areas. Construction site erosion controls are also usually required as a condition for a grant agreement in an urban area, but they are not eligible for state cost sharing. About $3 to $5 million per year will be used by the nonpoint source program over a 20-year period in controlling urban runoff.

The Wisconsin nonpoint source plan addresses watersheds, not just political areas. The Milwaukee River basin contains 500 streams, 100 lakes, and 60,000 acres of wetlands in its 900-square-mile watershed. The city of Milwaukee is at the terminus of the river, where it discharges into Lake Mich. The water quality in the watershed varies dramatically, from excellent in many headwater trout streams to poor in the heavily urbanized southern portions of the basin. The Milwaukee Basin Priority Watershed Program started in 1985 as a voluntary program to address both urban and rural sources of nonpoint pollution. More than 500 rural landowners and 26 local governments have participated in the program, with total local and state investments of about $40 million.

An outcome of the Milwaukee River South Watershed plan included goals for reducing urban SW discharges. These goals were 50% reduction for suspended solids and heavy metals, and 50% to 70% reduction for phosphorus. The city cleanup program has four elements:

- local controls on construction erosion,
- improved SW management,
- better urban housekeeping, and
- streambank erosion controls.

The city identified construction site erosion as the leading cause of sediment into the Milwaukee River South watershed. Of the annual 26,000 tons of sediment, about 62% comes from construction sites, while only 16% comes from cropland, with the remainder from urban SW and streambank erosion.

A Wisconsin Pollutant Discharge Elimination System permit (under EPA NPDES authority) was issued to Milwaukee in October 1994. It covers SW discharges from more than 200 major outfalls to area streams and Lake Mich. The permit addresses discharges from Milwaukee and another 26 local communities. These communities each pay the Wisconsin Department of Natural Resources $5,000 per year as a permit fee, totaling more than $1 million for the 5-year permit period.

An important part of the Milwaukee wet weather flow program is monitoring urban streams to identify and quantify actual receiving water problems. Milwaukee participated in the early International Joint Commission studies with Canada to characterize discharges into the Great Lakes. Milwaukee was also a participant of NURP in the early 1980s. During NURP, eight single land use catchments were extensively monitored for three years in cooperation with the U.S. Geological Survey. The benefits of street cleaning as a pollutant discharge reduction practice were included in this effort. Snowmelt characterization monitoring and effects of de-icing compounds have also been extensively studied in Milwaukee. Recently, detailed studies on toxicant sources, effects, and controls have also been conducted in Milwaukee, including a study conducted in heavily urbanized Lincoln Creek (a 19mi.^{2} watershed, 9 miles long). A seven-tiered indicator program, incorporating many physical, chemical, and biological tests, was simultaneously conducted which identified long-term toxicity problems likely associated with re-suspended contaminated sediments having high levels of organic compounds. It was found that discharges of these fine sediments could be significantly reduced through the use of well-designed and maintained wet detention basins. The instream toxicity monitoring methods developed and used during the Lincoln Creek study can be used by other municipalities to answer the following basic questions:

- Are toxic conditions present?
- What is causing the toxicity?
- How much is too much urbanization? and
- Can SW controls reduce these problems?

The benefits of SW controls have also been evaluated in Milwaukee, especially grass swales, wet detention ponds, and underground devices for critical source areas. The Southeastern Wisconsin Regional Planning Commission also prepared a comprehensive report documenting costs associated with construction site erosion and SW control.

In addition, the Wisconsin Nonpoint Source Program includes an important public education component. Milwaukee conducted a survey to identify the most likely successful public education program. The more than 3,000 responses indicated that TV news stories, newspaper articles, targeted newsletters, and pamphlets would be most effective. Site visits, workshops, and videos were unlikely to be successful. The survey also found that more than 90% of Milwaukee respondents were willing or are already doing activities to protect water quality (recycling used oil, separating household hazardous wastes, limiting landscaping chemicals, controlling dog wastes, etc.). Virtually all of the respondents rated the local waters as poor to fair and less than 10% used the local waters for any recreational activities. However, more than half were willing to pay more than $50 per household per year for programs to protect and restore local waters.

7.2.5 Orlando, Fla.

SW Community Characteristics

♦ Population	165,000
♦ Sewer Area	100,000 Ac
♦ Annual Rainfall	50"
♦ # of SSO Discharge Points	1,000

Distinctive SW Community Attributes

- Recipient of EPA's SW award in 1990

Orlando is known for its long history of SW management, including receiving the U.S. EPA's SW award in 1990. The city has extensive local data, especially concerning the performance of SW controls in its unique area, which has heavy rains, flat topography, high groundwater, and highly percolating sandy soils.

Orlando is located in central Florida and had a 1990 population of about 165,000. The area receives about 50 inches of rainfall each year, mostly occurring in the summer. Most of the area is underlain with sandy soils. Therefore, urban development produces dramatic increases in runoff volumes and rates as the highly percolating soils are covered with impervious surfaces. The infiltrating water recharges the Floridan Aquifer, the major drinking water supply for most of central Florida. The area is relatively flat, at about 100 feet elevation. The city of Orlando contains 82 named lakes and several hundred drainage wells that receive SW runoff from the separate storm drainage system.

Florida began to investigate SW pollutant sources in the 1970s as part of the Section 208 requirements of the Clean Water Act. The Florida Department of Environmental Regulation and 12 regional agencies received many large Section 208 grants to assess the extent of the state's nonpoint pollution problem and to develop technical and administrative methods for treatment and control. The state had authority to draft regulations pertaining to SW control as part of its existing environmental laws. The first official state regulation addressing SW was adopted in 1979 based on the results of the Section 208 studies that found urban SW was responsible for:

- 80 to 95% of the heavy metal loadings to Florida surface waters,
- almost all of the sediment deposited in state waters,
- 450 times the suspended solids and 9 times the BOD loads compared to typical municipal wastewater treatment facilities, and
- nutrient loads about the same as those being discharged from typical municipal wastewater treatment facilities.

The state regulations were revised several times for clarification and to ensure long-term operation through adequate maintenance and better design.

The Florida Department of Environmental Regulation requires SW controls for new development. The requirements specify that the first 0.5 inch of runoff, or the runoff from 1 inch of rain, whichever is greatest, be treated. This regulation is thought to result in about 80% to 85% of the annual pollutant loads being treated. Orlando published one of the earliest SW management guides (Orlando Urban Storm Water Management Manual) in 1984 to assist developers in meeting these requirements. Stormwater wet detention ponds, excavated into the groundwater, were the first controls commonly used. Research has investigated the performance of these and other devices, including their potential impacts on groundwaters. Outfall screening devices and street cleaning (especially in March when the leaves from oak trees fall) were also thought to be an effective control for lakes. Sand filters, grass swales, wetlands, and alum injection have also been used and tested in the Orlando area.

The Orlando urban stormwater management program was established in the early 1980s to address increasing SW runoff quality and quantity problems resulting from new development. Orlando sponsored a lake assessment study in 1983 to evaluate the city's lakes in response to residents complaints of deteriorating water quality. The assessment study resulted in a priority listing of lakes needing remediation assistance. Large regional facilities (such as the Lake Greenwood Urban Wetland project) have been retrofitted in existing urban areas, and alum injection facilities have also been added to several existing urban lakes.

The preferred SW control practices in Orlando are off-line retention, filtration, and both dry and wet detention ponds. Source controls, as described in the local manual, are encouraged. The performance standards are to reduce the annual average suspended solids loadings by 80%.

The city received its NPDES SW permit and funds local oversight through the Orlando SW utility. The current utility fee is $36 per residential household equivalent per year. The total annual budget is $1.25 million, of which about 90% is from the utility fee. The utility has four administrators, four engineers, 18 inspectors, two scientists, and five clerical support staff. Educational programs are a voluntary component of the program, with the utility presenting more than 40 programs each year to educate the general public about SW management. Local volunteers also participate in the Florida Lake Watch program. The city has a limited program to monitor the water quality in the city's lakes to measure success of the SW management program. As noted previously, numerous research projects have also been conducted in Orlando to evaluate the performance of SW management practices.

7.3 SW Case Histories and Benchmark Data Discussion

7.3.1 General SW Discussion

Community accomplishments in addressing SW concerns are highly varied throughout the U.S. In most cities, very little has been done beyond basic SW drainage. In a few communities (such as those selected for discussion in the case studies), early concerns by the public about declining water quality resulted in attempts to manage SW quality. After drainage problems were brought under control, usually through master planning and the construction of large-scale facilities, construction erosion control was usually implemented. With these important considerations addressed, some of the communities were able to address SW quality. Some stressed controls for new developments, while a very few examined retrofit opportunities (Wisconsin's Priority Watershed Program, for example).

Historically in almost all communities in the U.S., SW management only addressed drainage issues, because scarce local resources were needed for more pressing issues. Such communities are only able and willing to participate in SW management at the most basic and minimal level. Without specific guidance and requirements contained in local and state ordinances, very little SW quality management was conducted in most communities. In fact, some communities backed off from prior rigorous attempts at SW quality management to more minimal efforts that barely meet existing regulations.

With the Clean Water Act SW NPDES permit program in place, SW quality management is no longer a luxury program only being conducted in rapidly growing sunbelt communities that have the resources and motivation. Because of the large number of communities involved in the first and second phases of the NPDES SW permit program, the federal and state approach has been to define relatively basic requirements for the permits, with generally few specified control goals. Obviously, submitting all the municipal permits (along with the new industrial SW permits required at the same time) has produced a financial, logistic, and management problem for state agencies and EPA regions. It is apparent that the main goal was to get the permits issued in a timely manner, while accomplishing such basic and necessary goals as drainage area characterization information; screening for inappropriate discharges at storm drain outfalls; starting erosion control programs; establishing local authority over the drainage system; and developing a financial basis for management of the program. Even with the relatively simplified permit process and requirements, however, large municipalities (in phase one of the program) often spent more than $1 million each to gather the necessary information and to prepare and submit the permit applications.

The requirements included in the issued permits rarely specified any control goals or management needs beyond conducting an outfall monitoring program of about three storms a year at about five land use sites. The permits are generally issued for 5 years, with the expectation that specific control requirements would be added during subsequent periods as local problems become better defined. Nearing the tenth year of the SW NPDES program, medium cities (between 100,000 and 500,000 population) have also submitted permit applications and most have received their initial permits, and small communities (greater than 10,000 in population) are to be included in the program within a year. Therefore, the SW permit program burden on the regulatory agencies has increased, with little opportunity for increased site-specific control objectives to be included in the permits. The role of TMDL allocations was to be a tool to determine allowable discharges of SW and point source permits to a watershed's receiving waters. However, there is still much concern, and therefore delay, in allocations.

Most of the specific accomplishments of SW quality have occurred in communities with flooding/drainage problems, scarce water resources, and the financial ability (usually through local funding mechanisms). Specific requirements by local communities, and some state agencies, are the driving force behind these major accomplishments. Federal legislation now requires SW quality management at most levels of government. However, the direct application of approaches from the few communities currently having successful SW quality management programs may not be workable. All these communities have found that advances have been slow and greater public awareness and understanding (especially when local funding is involved) is needed. Specific guidance and requirements, along with strenuous enforcement, are also necessary components of successful programs; voluntary efforts by themselves are rarely adequate.

7.3.1.1 *Stormwater Quality Problems as the Driving Force*

The main purpose of treating SW is to reduce its adverse impacts on receiving water beneficial uses. Therefore, any urban SW runoff study must assess the detrimental effects that runoff is actually having on receiving water. Urban receiving waters may have many beneficial use goals, including:

- stormwater conveyance (flood prevention);
- biological uses (warm water fishery, aquatic life use, biological integrity, etc.);
- non-contact recreation (linear parks, aesthetics, boating, etc.);
- contact recreation (swimming and wading); and
- water supply.

With full development in an urban watershed and no SW controls, it is unlikely that any of these uses can be attained. With less development and the application of SW controls, some uses may be possible. But unreasonable expectations should not be placed on urban waters, as the cost to obtain these uses may be prohibitive. With full-scale development and lack of adequate SW controls, severely degraded streams will be common. However, SW conveyance and aesthetics should be the basic beneficial-use goals for all urban waters. Aquatic life use should also be a goal, but with the realization that the natural stream ecosystem will be severely modified with urbanization.

Certain basic SW controls, installed at the time of development, plus protecting stream habitat, may enable partial realization of some of these basic goals in urbanized watersheds, but careful planning and optimal utilization of SW controls are necessary to obtain these basic goals in most watersheds. Water contact recreation, consumptive fisheries, habitat for sensitive aquatic organisms, and water supplies are not appropriate goals for most urbanized watersheds. However, these higher uses may be possible in urban areas where the receiving waters are large and drain mostly undeveloped areas.

The latest National Water Quality Inventory released by the U.S. EPA showed only slight improvement in attaining beneficial uses in the nation's waters. Urban runoff was cited as the leading source of problems in estuaries, primarily from nutrients and bacteria. Problems in rivers and lakes were mostly caused by agricultural runoff, with urban runoff the third-ranked source for lakes and fourth ranked for rivers. Bacteria, siltation, and nutrients were the most significant problems in rivers and lakes.

In general, urban SW runoff monitoring has indicated that the biological beneficial uses of urban receiving waters are most likely affected by habitat destruction and long-term pollutant exposures (especially for macroinvertebrates via contaminated sediment), while documented effects from acute exposures to toxicants in the water column are rare. Receiving water pollutant concentrations resulting from runoff events and typical laboratory bioassay test results have indicated few significant short-term receiving water problems. Therefore relating actual receiving water problems to conventional numeric standards is difficult. Interest in developing special wet weather standards, especially considering contaminated sediments, intermittent exposures to high flows, and habitat destruction exists. Using local reference stations for comparison is usually necessary to identify local problems and the needed extent of SW discharge reductions.

7.3.1.2 Changes in Stormwater Management and Attitudes with Time

In 1967, researchers at the University of Wisconsin distributed a survey to engineers in the state, the main objective of which was to determine the level of service considered adequate. This questionnaire explored design procedures and policies. In 1997 a survey by the University of Alabama at Birmingham was mailed to over 350 recipients in engineering firms and municipal water authorities across the nation. This recent survey was designed to examine changes in design methods, objectives, and understanding of SW quality problems over this 30-year period. The university received about 85 responses (mostly from Minnesota, Ohio, New York, Florida and California), about half of whom were consulting engineers in private practice and the other half engineers with municipalities. Tables 7-7 and 7-8 present the findings from the 1997 survey and compare them to the 1967 survey.

7.3.2 SW Questionnaire Findings

7.3.2.1 SW Community Statistics

The returned SW benchmark questionnaires cover communities with a wide range of conditions and receiving waters. Most discharge SW into rivers, streams, or lakes, but the ocean, groundwater, and estuaries are also represented by one city each. Almost all communities discharge into several different types of receiving waters.

Three communities (Boston, Denver, and Detroit) have populations greater than 1 million, while the other 12 cities have populations less than 500,000. All manage total drainage areas of more than 1,000 acres (most greater than 10,000 acres) and had more than 50 outfalls (except for Orem, Utah, which reported less than 10 discharge points). Annual rainfall was less than 20 inches for three cities (Burbank, Denver, and Orem), between 20 and 30 inches in one city (Fridley), between 30 to 40 inches in six cities (Austin, Bellevue, Detroit, Hillsboro, River Falls, and Struthers), and more than 40 inches in four cities (Birmingham, Boston, Frederick, and Orlando).

Table 7-8. 1997 Stormwater Management Design Survey Responses

Practice	Response (Percentage of Respondents if Reported)				
Design Storm Used	5 year (10%)	10 year (42%)	25 year (7%)	100 year (9%)	
Method of Design	Rational (41%)	NRCS (SCS) (14%)	Combination (31%)	Regional (13%)	
Tools Used	Computerized tools (86%)	SWMM (25%)	HEC-1 (17%)		
Conditions of Failure	Manhole covers popping off	Water rising above curbs	Water in Basements		
Water Quality Concern	Sediment (60%)	Nutrients (35%)	Metals (34%)	Oil & Grease, Bacteria, Toxicants, Floatables, and Salts.	Staying within regulated discharge limits

Table 7-9. Stormwater Management Design Survey Comparison 1967 versus 1997 Results

	1967 Survey Responses	1997 Survey Responses
Design Storm	5 to 10 year (70%)	Approximately the same range, most using the 10 year.
Method of Design	Rational (Most cities misapplied the runoff coefficient or rainfall intensity)	Rational (Understood the use of Time of Concentration)
Indicator of Failure	Water ponding at inlets Water ponding in back yards.	Water ponding at inlets, but not a prevalent concern. Not a high priority for today's design engineers.
Water Quality Concerns	Sediments, Nutrients, Metals, Oil & Grease, Bacteria, Toxicants, Floatables, Salts, and Staying within regulated discharge limits.	

Few cities reported annual SW discharge quantity; however, the quantity may be estimated using a few assumptions. As an example, for the smallest reported service areas of 1,000 acres and 10 inches of annual rainfall with a reasonable arid area volumetric runoff coefficient of 0.2, the annual runoff volume would be about 50 million gallons. In a small city of only 10,000 acres (15 square miles), with an annual rainfall of 30 inches and a Rv of 0.3, the annual SW runoff discharges would be increased to more than 2,500 million gallons.

7.3.2.2 SW Public Participation

Only five communities (Birmingham, Frederick, Fridley, Orem, and Struthers) reported no public participation. However, at least Birmingham and Frederick do have public participation programs, but the responders possibly thought that their programs did not include any of the program elements listed. It is hard to imagine that public hearings would not be used for all major public works projects associated with SW projects.

Signs and general public education were most commonly indicated methods for informing the public, while the more successful TV addresses and newsletters were parts of only two community efforts. The least successful tools, neighborhood meetings and videos available for loan from the local libraries, were not listed by any of the respondents. Bellevue sponsored community educational projects, and receiving water monitoring by citizen volunteers was reported by Austin and Orlando. As part of its NPDES permit requirements, Birmingham is starting a new monitoring effort using local volunteers to investigate inappropriate discharges into storm drainage.

Basement flooding, along with general water quality, were the most commonly listed public concerns (11 and 9 cities, respectively). Aquatic life, street flooding, general recreation, water contact recreation, and public health were all noted by 3 cities each.

7.3.2.3 *SW Systems Characteristics*

Seven responding cities did not have a mathematical model of their SW systems, while three did. However, all (except Birmingham and Orem) indicated that a watershed approach has been taken.

Almost all cities included municipal and industrial point sources plus urban runoff among their current pollutant abatement efforts. Four communities indicated that agricultural runoff was also being controlled in their watersheds. Control efforts for the same targeted pollutant sources were generally expected to remain in the future. However, little documented performance information for urban runoff abatement efforts is available from the cities. Most cities listed estimated abatement levels only, with no monitoring programs either in the receiving waters or at outfalls to quantify any discharge reductions.

7.3.2.4 *Issues Driving SW Technical Considerations*

Only three cities (Birmingham, Boston, and Frederick) indicated that a SW facility plan was not started yet, three (Austin, Bellevue, and Detroit) indicated that the facility plans were completed, while six others indicated that plans were in progress.

All respondents indicated that regulatory requirements were the main driving force in their SW quality management efforts, with the exception of Boston. Litigation and lawsuits were also primary motivation sources for SW abatement in three cities. Five of the cities had no permitted facilities, while three cities listed up to 10 permitted facilities, and one city (Frederick) listed more than 100 permitted facilities.

Water quality criteria for local receiving waters included the following parameters (in order of most frequent mention): bacteria, dissolved oxygen, nutrients/floatables (tie), BOD/toxicants/sediment (tie), and finally temperature and heavy metals (only one city each).

Cost/benefit analyses were used by six cities, but regulatory requirements directed the selection of the abatement technology in 11 of the cities. Almost all technologies (construction site erosion controls, public works practices, and sedimentation) were being used by almost all communities. Infiltration practices were the least popular option.

7.3.2.5 *SW Financial Considerations*

Only Detroit listed significant past expenditures for past SW abatement efforts (at more than $500 million), while five others (Austin, Boston, Denver, Orem, and Struthers) all listed less than $10 million. Detroit also listed a similar level for future expenditures, while the others remained the same, except for Denver and Orem which expected an increase of $10 million to $50 million. Birmingham is starting a stream corridor protection program at a cost of about $30 million, as part of the settlement of a local lawsuit concerning wet weather flow pollution abatement.

The funding sources were varied, with fees from utility districts being most common (five cities), followed by "other" (four cities), then increased sewer rates, state grant money, federal grant money, and increased taxes (tied with three cities each), and finally revolving loans (two cities).

CHAPTER 8.0

COST-BENEFIT ANALYSIS

8.1 Syracuse, N.Y., Case Study

The Syracuse, N.Y., case study serves as a good example of a cost-benefit approach to abating wet weather pollution in that the decision-making process involved all the critical components of the community, from the technical engineers to the municipal government budget and financial management departments.

Syracuse began its CSO abatement program in the early 1970s with the country's first full-scale demonstration of an U.S. EPA vortex and disinfection facility. A very successful BMP program followed in the middle 1980s. The CSO abatement program was expedited in 1989 as a result of a legal consent order. During the early stages of the consent order process, several planning meetings were held under Section 208 of the 1972 Clean Water Act Amendments. These meetings culminated in a work plan for the CSO abatement program, which required the consensus of stakeholders on the storm frequency that would serve as a reasonable target for abatement.

All parties, including local health and state regulatory agencies, agreed that a 1-year storm frequency would be used to size the wet weather pollution abatement facilities. Figure 8-1 illustrates an inflection (knee of the curve) in the system conveyance capacity at the 1-year storm recurrence interval. It was agreed that such a storm would likely be a convective storm occurring in the summer months when base flow in receiving water streams would be low. It was also agreed that such a combination of wet weather pollution and low stream flow represented reasonably stringent conditions.

Once the 1-year storm recurrence interval was agreed upon, five abatement strategies were evaluated using a cost-benefit analysis on the basis of bacteria, solids, and BOD improvements in the receiving water. Figures 8-2 and 8-3 show these relationships. Figure 8-3 illustrates the point of inflection for the cost curve occurring at the "Regional" abatement alternative. The regional abatement alternative included satellite treatment facilities designed to control bacteria, solids and floatables, in-system storage, and some sewer separation. This alternative was adopted as the accepted CSO abatement plan. The location of these satellite treatment facilities, known as regional treatment facilities, is illustrated in Figure 8-4.

Further application of the cost-benefit analysis was used to justify the need for all satellite treatment facilities to control bacteria, solids, and floatables. Detailed system and receiving water bacterial modeling demonstrated that the facilities needed to control bacteria and solids loadings to the receiving waters were not as great as originally estimated. All parties agreed to reduce some of the regional treatment facilities to floatables control facilities. This reduced the CSO abatement costs from $267 million to $144 million.

The construction planning for the regional treatment facilities and floatables control facilities ultimately culminated in a 15-year build out period that would progressively achieve full compliance during that time. This compliance was in terms of both the presumption and demonstration clauses of the federal CSO policy as illustrated by Figures 8-5 and 8-6.

TOTAL	2605.09	1607 66	401.31	596.12	85%

Figure 8-6. Wet Weather Combined Sewer Flows, Syracuse, N.Y.

An integral part of the decision making process during construction planning was resolving the issue of affordability. The affordability analysis was used to evaluate the financial impacts of the CSO abatement program. Once the technical solution was agreed on and planning level cost estimates were developed, the municipal budget and financial management department began to evaluate the cost impacts of various construction schedules; 15 distinct projects were evaluated in time frames varying from 15 to 25 years. An example is shown in Figure 8-7. Corresponding plots of unit charge and debit service as a percent of median household income were developed as illustrated by Figures 8-8 and 8-9, respectively. These dollars represent the combined costs of the CSO abatement program and the WWTP improvements program.

WET-WEATHER COMBINED SEWER SYSTEM FLOWS

Figure 8-7. Annual Cost per Regional CSO Treatment Facilities

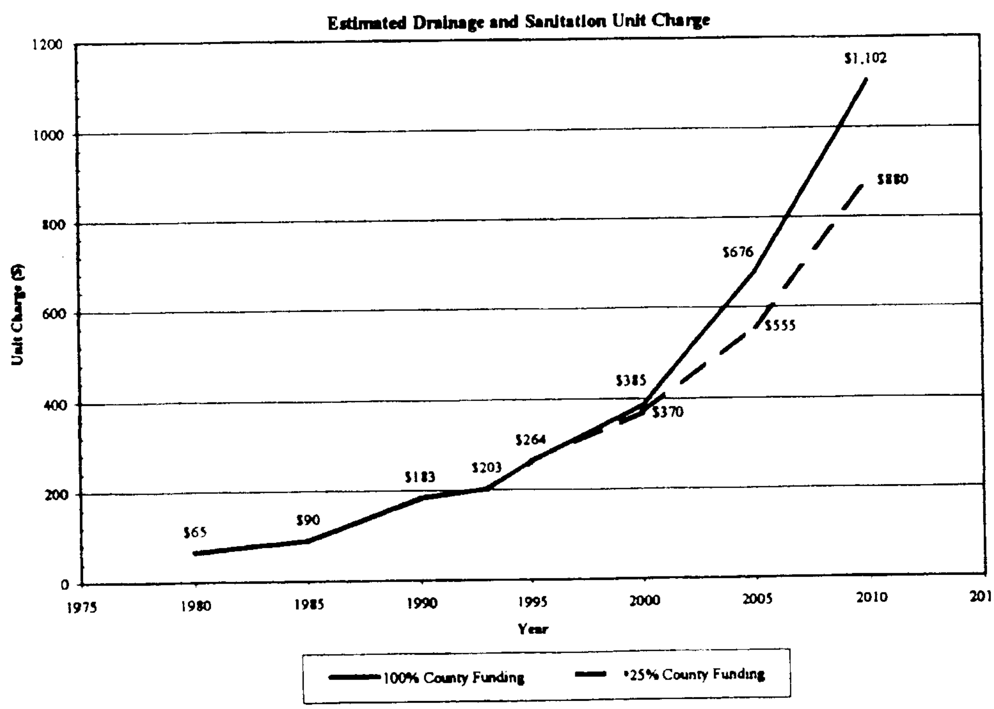

Figure 8-8. Estimated Drainage and Sanitation Unit Charges, Syracuse, N.Y.

R0018495

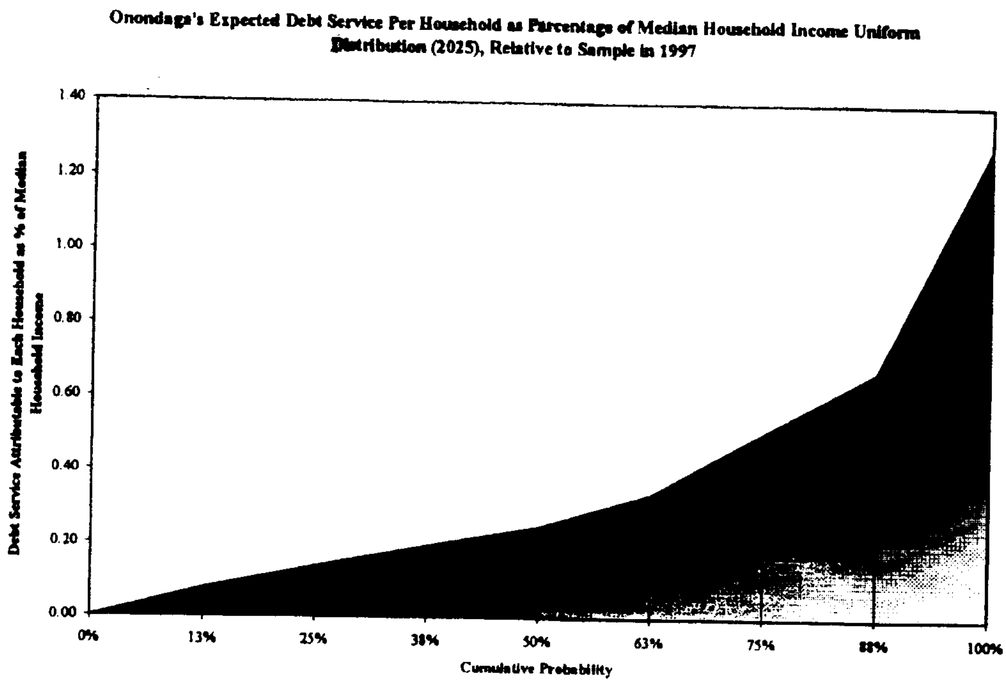

Figure 8-9. Expected Debt per Household as Percentage of Median Income, Onondaga County, N.Y.

Despite the fairly flat growth of population and service expected in the Syracuse area, the debt service fell within the allowable 2% guide stated in the federal CSO control policy. Consequently, the state and U.S. EPA required that a 15-year schedule be implemented. Milestone dates for specific completion projects of construction were incorporated into the Consent Order which was signed in October 1997.

National CSO Control Policy

The National CSO Control Policy contains four key principles intended to ensure that CSO controls are cost effective and meet the requirements of the Clean Water Act (CWA) of 1972 and its amendments:

- provide clear levels of control that would be presumed to meet appropriate health and environmental objectives;
- provide sufficient flexibility to CSO communities, especially those that are financially disadvantaged, to consider the site-specific nature of CSOs and to determine the most cost-effective means of reducing pollutants and meeting CWA objectives and requirements;
- allow a phased approach for implementation of CSO controls considering a community's financial capability; and
- review and revise, as appropriate, water quality standards and their implementation procedures when developing LTCPs to reflect the site-specific wet weather impacts of CSOs.

Nine Minimum Controls

1. Proper operation and regular maintenance programs for the sewer system and the CSOs. This control should consist of a program that clearly establishes operation, maintenance, and inspection procedures to ensure that a combined sewer system (CSS) and treatment facility will function in a way to maximize treatment of combined sewage and still comply with NPDES permit limitations.

2. Maximum use of the collection system for storage. This control consists of making relatively simple modifications to the CSS to enable the system to store wet weather flows until downstream sewers and treatment facilities can handle them.

3. Review and modification of pretreatment requirements to ensure that CSO impacts are minimized. The objective of this control is to minimize the impacts of discharges into CSSs from nondomestic sources during wet weather events and to minimize CSO occurrences by modifying inspection, reporting, and oversight procedures within an approved pretreatment program.

4. Maximizing flow to the POTW for treatment. This control entails simple modifications to the CSS and treatment plant to enable as much wet weather flow as possible to reach the treatment plant.

5. Eliminating CSOs during dry weather. This control includes any measures taken to ensure that the CSS does not overflow during dry weather conditions.

R0018497

6. Controlling solid and floatable materials in CSOs. This control is intended to reduce, if not eliminate visible floatables and solids using relatively simple measures including baffles, screens, racks, booms, and skimmer vessels.

7. Pollution prevention programs to reduce contaminants in CSOs. This control is intended to keep contaminants from entering the CSS and prevent subsequent discharge to receiving waters through street cleaning, public education, solid waste collection, and recycling.

8. Public notification to ensure that the public receives adequate notification of CSO occurrences and CSO impacts. This control is intended to let the public know where outfalls are located, when CSOs occur, what possible health and environmental effects are, and what recreational or commercial activities may be curtailed as a result of CSOs.

9. Monitoring to effectively characterize CSO impacts and the efficacy of CSO controls. This control involves visual inspections and other simple methods to determine the occurrence and apparent impacts of CSOs.

Long Term Control Plan

The LTCP is a comprehensive plan that recognizes the site-specific nature of CSOs and their impacts on receiving waters. The long term planning approach consists of four major elements: system characterization; development and evaluation of alternatives; selection and implementation of controls; and compliance monitoring. A primary objective of the LTCP is to develop and evaluate a reasonable range of CSO control alternatives sufficient to meet water quality standards, including attainment and protection of designated uses on CSO-affected receiving waters. The CSO policy is flexible in allowing a CSO community to select controls that are cost effective and tailored to meet local conditions.

Two general approaches to attaining water quality standards are recognized in the CSO policy. These are the "demonstration" approach and the "presumption" approach. Both approaches provide CSO communities with targets for controls that achieve compliance with the CWA, particularly the protection of designated uses. Under the "demonstration" approach, water quality modeling or other tools are used to demonstrate that predicted CSO discharges resulting from the LTCP would be sufficient to attain water quality standards. The "presumption" approach is based on the premise that a LTCP that meets certain minimum defined performance criteria in terms of expected frequency of overflow or percent capture of the CSO pollutant load would be presumed to provide an adequate level of control to meet the water quality-based requirements of the CWA.

CSO communities are encouraged to meet and coordinate frequently with state water quality standards authorities and NPDES permitting authorities and to engage the general public in the planning process through public participation activities. In particular, developing goals, evaluating alternatives, and considering the local financial impacts of the LTCP should be a collaborative effort among all the participating interests. The developing performance measures or other measures of success to quantify environmental improvements and benefits related to CSO control is also a major element of the LTCP. Because of the site-specific nature of CSSs and CSO impacts, a strong linkage between performance measures and locally defined objectives is essential.

Presumption Approach

This approach allows a community to achieve an adequate level of control to meet the water quality- based requirements of the CWA if one of the following conditions are met.

1. No more than an average of four (4) overflow events per year. The permitting authority may allow up to two additional overflow events per year. An overflow event is one or more overflows from a CSS as a result of a precipitation event that does not receive the minimum treatment specified as:

   - primary clarification (removal of floatation and settleable solids equivalent to primary clarification) and
   - disinfection of effluent to meet water quality standards, including removal of harmful disinfection chemical residuals if feasible.

   Or, if the above is not met:

R0018498

2. The elimination or capture for treatment of no less than 85 percent by volume of the combined sewage collected on a system-wide annual average basis; or

3. The elimination or removal of no less than the mass of the pollutants identified as causing water quality impairment through the sewer system characterization, monitoring, and modeling effort, for the volumes that would be eliminated or captured for treatment under paragraph 2 above.

Demonstration Approach

The community that undertakes this approach should demonstrate each of the following:

1. The long-term plan is adequate to meet water quality standards (WQS) and protect designated uses, unless uses cannot be met as a result of other pollution sources, e.g., natural background conditions.

2. The CSO discharges remaining after plan implementation will not preclude the attainment of WQS designated uses of the receiving waters or contribute to their impairment. Where these conditions are not met in part because of natural background conditions or other pollutant sources, then wasteload allocations should be used to apportion loads. The total maximum daily load should serve as the basis for such allocations.

3. The long-term plan will provide the maximum pollution reduction benefits reasonably attainable.

4. The plan is designed to allow cost-effective expansion if additional controls are necessary.

Financial Capability Assessments

For CSO abatement, a community's financial capability is particularly important, since there are no clear wet weather standards for most states; the selection of a "design" storm has become a subjective decision based upon cost-benefit relationships. Additionally, other pollutants from the watershed in question may preclude the attainment of the "fishable-swimmable" goals of the CWA.

The policy identifies seven factors to be included in consideration of a community's financial capability, namely:

1. median household income;

2. total annual wastewater and CSO control costs per household as a percent of median household income;

3. overall net debt as a percent of full market property value;

4. property tax revenues as a percent of full market property value;

5. property tax collection rate;

6. bond rating; and

7. unemployment.

The following is an excerpt of the U.S. EPA document, "Draft CSO Guidance on Financial Capability Assessment and Schedule Development," developed by the CSO Partnership (*The CSO Bulletin*, April 1996).

"The CSO Policy provides that implementation schedules for CSO controls may be phased, based in part on a community's financial capability. The Guidance seeks to provide criteria for assessing financial capability and to relate that capability to appropriate compliance schedules. The goal of the guidance is to 'provide general boundaries to aid all parties in negotiating reasonable and effective schedules' for implementing CSO controls.

"The Guidance proposes a two-step approach for calculating economic capability. The first step focuses on the financial impact of current and proposed wastewater and CSO controls on individual households. The second step examines the debt, socioeconomic, and financial condition of a CSO community. The results of both steps are then combined into a 'Financial Capability Matrix' which is used to assess the financial burden attributable to CSO controls and to establish what EPA views as appropriate compliance schedules.

"Step One. This step calculates a Residential Indicator (RI), which is a measure of the CSO community's average cost per household for existing and proposed wastewater treatment and CSO controls, expressed as a percentage of local median household income (MHI). The Guidance proposes to establish three ranges for RIs with RIs of less than one percent MHI characterized as imposing a 'low' financial impact, RIs from one or two percent of MHI imposing a mid-range impact and RIs above two percent of MHI imposing a high impact.

"Step Two. The second step is to consider a community's financial Capability Indicators. EPA specifies six proposed indicators in the Guidance for evaluating community debt, socioeconomic, and financial conditions which affect a community's financial capability to implement CSO controls. The results of the six indicators are used to classify the community's financial capability as 'weak,' 'mid-range,' or 'strong.'

"The results of step one (Residential Indicator) and step two (Financial Capability Indicators) are then combined in a financial Capability Matrix which provides the basis for the permittee and NPDES permitting authority to negotiate an appropriate compliance schedule. The Financial Capability Matrix divides communities into three categories based upon their calculated burden under the Guidance (low, medium, o high), with equal weight given to the Community's RI and Financial Capability Indicators.

"Finally, the Guidance proposes the following general boundaries for compliance schedules based upon a community's calculated burden:

Low burden:	0-5 year compliance schedule
Mid-Range burden:	5-10 year compliance schedule
High burden:	10-15 year compliance schedule

"According to the Guidance, communities in the 'High burden' category may be able to negotiate compliance schedules as long as 20 years.

"The lack of supporting information to explain and justify EPA's selection of the Residential Indicator categories and the Financial Capability Indicator categories will make it difficult to evaluate whether the proposed categories are appropriate for CSO communities nationwide. For example, EPA does not provide any discussion of the number of CSO communities that can be expected to fall into the three categories proposed in the Financial Capability Matrix (low, mid-range, or high burden). Also, it is unclear how EPA arrived at its proposed ranges for the compliance schedules for communities falling with the three categories of financial burden."

MEMORANDUM: IMPLEMENTATION OF THE CSO CONTROL POLICY (REPRINT FROM U.S. EPA — OFFICE OF WATER)

UNITED STATES ENVIRONMENTAL PROTECTION AGENCY
WASHINGTON, D.C. 20460

MAY 19 1998

MEMORANDUM

SUBJECT: Implementation of the CSO Control Policy

FROM: Robert Perciasepe
Assistant Administrator
Office of Water

Bob Perciasepe

Steven A. Herman
Assistant Administrator
Office of Enforcement and Compliance Assurance

TO: Water Management Division Directors, Regions 1-10
Regional Counsels, Regions 1-10
State Directors

The purpose of this memorandum is to discuss implementation of the Combined Sewer Overflow Control Policy (CSO Policy) and identify areas where heightened efforts are necessary.

The Environmental Protection Agency (EPA) published the CSO Policy on April 19, 1994 (59 FR 18688), following a negotiated policy dialogue among representatives from States, environmental groups, municipal organizations, and EPA. The CSO Policy provides for a phased process to bring communities with combined sewer systems into compliance with the technology-based and water quality-based requirements of the Clean Water Act. To date, EPA has released six guidance documents and continues to work with stakeholders to foster implementation of the Policy.

The CSO Policy is now four years old and continues to be recognized as an example of innovation and good government. In principle, EPA and its stakeholders continue to affirm the Policy's key themes, such as permitting flexibility, stakeholder coordination and public participation, financial capability as a factor affecting implementation schedules, and examination of water quality standards as appropriate. In practice, however, many challenges remain, and implementation of the Policy has not met some initial expectations.

Nine Minimum Controls. The CSO Policy's first key milestone was implementation of the nine minimum controls by January 1, 1997. The nine minimum controls are measures that can reduce CSOs and their effects on receiving water quality without requiring significant engineering studies, construction activity, or financial investment. In a November 18, 1996, memorandum to the Regional and State Directors, we communicated the importance of meeting this deadline.

Under the CSO Policy, implementation of the nine minimum controls should become an enforceable obligation through inclusion in an appropriate enforceable mechanism. The Policy describes how the nine minimum controls and other CSO requirements are to be included in National Pollutant Discharge Elimination System (NPDES) permits (renewed permits or reopened and reissued permits) or administrative orders. The November 18, 1996, memorandum reminded NPDES authorities that the approach identified in the CSO Policy — not to seek civil penalties for past CSO violations — would not apply unless the permittee has no discharges during dry weather and meets the objectives and schedules of the CSO Policy, including the January 1, 1997, deadline for implementing the nine minimum controls. By now, every CSO community should be implementing the nine minimum controls, and most NPDES permits should contain measurable, enforceable, and specific conditions requiring implementation of the nine minimum controls, including submittal of appropriate documentation.

Although the January 1, 1997, implementation deadline has passed, our best information from EPA Regions and States indicates that only about 52 percent of CSO communities are currently implementing the nine minimum controls. Approximately another 25 percent have not yet implemented the nine minimum controls but are under an enforceable requirement to do so in the future.

There are several reasons for this. Many communities' permits have not yet been reissued to include the nine minimum controls, and permittees are reluctant to implement the nine minimum controls in the absence of an enforceable requirement. Some States have focused their efforts on requiring long-term control plans or have resisted using enforcement mechanisms as implementation tools. We believe, however, that the nine minimum controls are an essential element of any community's CSO program and that full implementation of the nine minimum controls is crucial to the success of the CSO Policy. The goal of 100 percent implementation remains a high Agency priority. We will continue to track implementation of the nine minimum controls and coordinate with EPA and State enforcement authorities as necessary to foster compliance.

We also stress the need for communities to provide appropriate documentation that they have implemented the nine minimum controls and for NPDES authorities to review this information thoughtfully. To date, although 52 percent of CSO communities have implemented the nine minimum controls, approximately 42 percent have submitted documentation. The Agency does not believe documentation is simply a "paperwork" exercise. Rather, documentation describes the community's comprehensive effort to use the nine minimum controls to reduce the frequency, volume, and impacts of CSOs. Without strong documentation, a CSO community and its permitting authority cannot meaningfully assess the effectiveness of the nine minimum controls and the extent to which additional controls, if any, may be needed.

Long-Term Control Plans. The CSO Policy calls for initial ("Phase I") NPDES permits to require development of a long-term CSO control plan as soon as practicable, but generally within two years after issuance of the permit, Section 308 information request, or enforcement action requiring a plan. The long-term control plan should include measures that provide for compliance with the technology-based and water quality-based requirements of the Clean Water Act, including attainment of water quality standards under either the "presumption approach" or the "demonstration approach." The subsequent ("Phase II") permit should require immediate implementation of the control measures in the long-term control plan. The long-term control plan should include a fixed-date implementation schedule. Requirements for expeditious implementation of the long-term control plan should be placed in an appropriate enforceable mechanism.

Regions and States indicate that approximately 33 percent of CSO communities are moving ahead to implement long-term CSO controls. Approximately another 28 percent are subject to an enforceable requirement to develop a long-term CSO control plan. We do not have adequate information to determine how much of the current CSO planning and control activity is being undertaken consistent with the CSO Policy.

Long-term planning consistent with the CSO Policy is key to the success of local CSO control efforts. We urge Regional and State authorities to work actively with permittees to ensure that long-term control plans address important elements of the CSO Policy such as characterization, monitoring, and modeling of the combined sewer system and receiving water; public participation; evaluation of the cost and performance of alternatives; and coordination with State water quality standards authorities and NPDES authorities. EPA Headquarters will continue to track progress in the development of long-term control plans consistent with the CSO Policy.

Water Quality Standards (WQS). Long-term CSO control plans must ensure that both the technology-based and water quality-based requirements of the CWA are met. With respect to water quality-based requirements, the CSO Policy provides that "[d]evelopment of the long-term plan should be coordinated with the review and appropriate revision of WQS and implementation procedures on CSO-impacted receiving waters to ensure that the long-term controls will be sufficient to meet water quality standards" (59 FR 18694). The CSO Policy places a high priority on eliminating or redirecting CSOs that discharge to sensitive areas such as beach areas and shellfish beds. Remaining overflows must neither cause nor contribute to a violation of WQS.

In locations where uses have been designated without consideration for the wet weather conditions of urban streams, it is appropriate to evaluate the attainability of WQS. The CSO Policy recognizes the States' flexibility to review their WQS and encourages them to define recreational and aquatic life uses more explicitly where appropriate. Such refinements could define, for example, seasonal conditions or a particular size storm event when primary contact recreation would not occur. In making such adjustments to uses, however, States must ensure that downstream uses are protected and that the use is fully protected during other seasons or after the storm event has passed. Furthermore, a use attainability analysis would be required in such cases, since use attainability analyses are required prior to the removal of a designated use or the modification of a use to one requiring less stringent criteria. Such a structured scientific analysis is an appropriate mechanism for determining the attainability of a use. In any case, if a State has a reasonable basis to determine that the current designated use could be attained after implementation of the technology-based controls of the CWA, then the use could not be removed.

We strongly encourage Regions and States to work with permittees to ensure that long-term plans are developed consistent with WQS. We also encourage greater coordination among EPA, States, and permittees in refining designated uses as appropriate in CSO-impacted receiving waters. In many cases the permittee's development of a long-term control plan, and the State's review and revision of WQS, will occur concurrently and interdependently. Site-specific data collected as part of the development of the long-term control plan and data from watershed analyses should assist States in evaluating the adequacy of the long-term control plan to contribute to the attainment of WQS. Such data will also provide important information necessary for determining whether a use is attainable and, where the designated use is not attainable, the appropriateness of a variance or other revision to the applicable WQS. Variances may be appropriate, in limited circumstances on CSO-impacted waters, where the State is uncertain as to whether the WQS can be attained and time is needed for the State to conduct additional analyses on the attainability of the WQS.

Measuring Program Performance. The CSO Policy continues to have a high level of support within EPA and among stakeholder groups. With visibility, of course, comes scrutiny. Understandably, the Policy continues to provoke questions about how well a flexible approach can address a costly and complex environmental issue. In addition, implementation of the CSO Policy is occurring amid public demands that investments in pollution control yield tangible environmental benefits.

Under the Government Performance and Results Act (GPRA), EPA developed a pilot performance plan to track the implementation status of the CSO Policy. Program indicators developed under the performance plan include progress in implementation of the nine minimum controls, development of long-term plans, and reduction in the frequency, volume, and adverse water quality impacts of CSOs. The data base developed to implement the performance plan will continue to provide useful insights into the status of CSO Policy implementation and will be a useful program management tool.

Accountability for the CSO Program is also embodied in the Agency's Strategic Plan under GPRA for the water program. Objectives to be attained by 2005 currently include a 30 percent reduction from 1992 levels in annual point source loadings from CSOs, publicly owned treatment works, and industrial sources. EPA's FY 1998 goal is for 80 percent of CSO communities' permits to be issued consistent with the CSO Policy; for FY 1999, the goal is 100 percent consistency.

We also encourage you to support efforts by CSO communities to develop other, locally defined, indicators of progress in controlling CSOs. Locally defined measures of success can provide meaningful incentives to select and implement CSO controls that not only meet CWA requirements but are cost-effective, tailored to local water quality objectives, and likely to yield results that the public, and specifically rate-payers, will support.

In closing, we urge you to help make the CSO Policy a success. We remind you that implementation of the CSO Policy continues to be a high priority for the Water Program and is among the top program priorities for the Office of Regulatory Enforcement in FY 1998. It is essential that all CSO communities be moving aggressively toward two important goals: full implementation of the nine minimum controls and coordination with NPDES and WQS authorities in the development and implementation of long-term control plans. We welcome continued dialogue among EPA Headquarters, Regional, and State permitting and enforcement authorities on removing any identified impediments to achieving these goals.

If you have questions concerning this memorandum, please contact either Ross Brennan of the Office of Wastewater Management at (202) 260-6928, or John Lyon of the Office of Regulatory Enforcement at (202) 564-4051.

ENFORCEMENT MANAGEMENT SYSTEM — CHAPTER X (REPRINT FROM U.S. EPA — OFFICE OF WATER)

Setting Priorities for Addressing Discharges from Separate Sanitary Sewers

Discharges of raw or diluted sewage from separate sanitary sewers before treatment can cause significant public health and environmental problems. The exposure of the public to these discharges and the potential health and environmental impacts are the primary reasons EPA is developing this additional guidance on these discharges. This document provides a method of setting priorities for regulatory response, and serves as a supplement to the Enforcement Management System guidance (EMS, revised February 27, 1986). As such, this document addresses only those discharges which are in violation of the Clean Water Act. As a general rule, the discharges covered by this guidance constitute a subset of all discharges from separate sanitary sewer systems.

Legal Status

In the context of this document, a "discharge from a separate sanitary sewer system" (or "discharge") is defined as any wastewater (including that combined with rainfall induced infiltration/inflow) which is discharged from a separate sanitary sewer that reaches waters of the United States prior to treatment at a wastewater treatment plant. Some permits have specific requirements for these discharges, others have specific prohibitions under most circumstances, and still other permits are silent on the status of these discharges.

The legal status of any of these discharges is specifically related to the permit language and the circumstances under which the discharge occurs. Many permits authorize these discharges when there are no feasible alternatives, such as when there are circumstances beyond the control of the municipality (similar to the concepts in the bypass regulation at 40 CFR Part 122.41 (m)). Other permits allow these discharges when specific requirements are met, such as effluent limitations and monitoring/reporting.

Most permits require that any non-compliance including overflows be reported at the end of each month with the discharge monitoring report (DMR) submittal. As a minimum, permits generally require that overflow summaries include the date, time, duration, location, estimated volume, cause, as well as any observed environmental impacts, and what actions were taken or are being taken to address the overflow. Most permits also require that any non-compliance including overflows which may endanger health or the environment be reported within 24 hours, and in writing within five days. Examples of overflows which may endanger health or the environment include major line breaks, overflow events which result in fish kills or other significant harm, and overflow events which occur in environmentally sensitive areas.

For a person to be in violation of the Clean Water Act: 1) a person must own, operate, or have substantial control over the conveyance from which the discharge of pollutants occurs, 2) the discharge must be prohibited by a permit, be a violation of the permit language, or not be authorized by a permit, and 3) the discharge must reach waters of the United States. In addition, discharges that do not reach waters of the United States may nevertheless be in violation of Clean Water Act permit requirements, such as those requiring proper operation and maintenance (O&M), or may be in violation of state law.

Statement of Principles

The following six principles should be considered as EPA Regions and States set priorities for addressing violating discharges from separate sanitary sewers:

1. All discharges (wet weather or dry weather) which cause or contribute significantly to water quality or public health problems (such as a discharge to a public drinking water supply) should be addressed as soon as physically and financially possible. Other discharges may, if appropriate, be addressed in the context of watershed/basin plans (in conjunction with state or federal NPDES authorities).

2. Discharges which occur in high public use or public access areas and thus expose the public to discharges of raw sewage (i.e., discharges which occur in residential or business areas, near or within parks or recreation areas, etc.) should be addressed as soon as physically and financially possible.

3. Dry weather discharges should be addressed as soon as physically and financially possible.

4. Discharges due to inadequate operation and routine maintenance should be addressed as soon as possible. (Physical and financial considerations should be taken into account only in cases where overflow remedies are capital intensive.)

5. Discharges which could be addressed through a comprehensive preventive maintenance program or with minor capital investment should be addressed as soon as physically and financially possible.

6. With respect to principles 1 through 5 above, schedules of compliance which require significant capital investments should take into account the financial capabilities of the specific municipality, as well as any procedures required by state and local law for publicly owned facilities in planning, design, bid, award, and construction. (See later sections on Schedules).

APPENDIX D

STORMWATER REGULATIONS

Phase I: The Municipal Stormwater Program

Under the WQA of 1987, U.S. EPA must issue NPDES permits to large- and medium-sized municipal separate storm sewer systems (MS4s). Under the statute, the permits:

- may be issued on a system or jurisdiction-wide basis;
- shall include a requirement to effectively prohibit non-stormwater discharges into the storm sewers;
- must apply a new standard to " require controls to reduce the discharge of pollutants to the maximum extent practicable, including management practices, control techniques and design and engineering methods" . 33 U.S.C. § 1342(p)(3)(B).

Large and medium MS4s are defined by EPA as those:

- located in an incorporated place with population of (i) 100,000 or more but less than 250,000 (medium MS4s) or (ii) 250,000 or more (large MS4s);
- located in counties with a population of 100,000 or more but less than 250,000 (medium MS4s) or located in counties with a population of 250,000 or more (large MS4s), excepting, in both instances, systems located in the incorporated places, townships or towns within such counties; or
- designated by EPA as part of a large or medium MS4 due to the interrelationship between the discharges of the designated MS4 and a large or medium MS4.

EPA has listed the jurisdictions that are covered under the definitions of medium and large MS4s in the permit application rule, and in Appendixes F, G, H and I to 40 C.F.R. Part 122. 55 Fed. Reg. 48073-74. The listing was based on the 1980 census. As data from the 1990 census becomes available, EPA will revise the list.

To date, EPA has only issued a rule with permit application requirements for MS4s. 55 Fed. Reg. 47990 (November 16, 1990). Permit applications for MS4s have two parts. Part 1 was due November 18, 1991 for large MS4s and May 18, 1992 for medium MS4s. 40 C.F.R. § 122.26(e)(3) and (4). Part 2 was due November 16, 1992 for large MS4s and May 17, 1993 for medium MS4s. Id. EPA was supposed to have issued final permits to large MS4s by October 1, 1993 and to medium MS4s by May 17, 1994. 40 C.F.R. § 122.26(e)(7).

The regulations define " municipal separate stormwater" as a conveyance or system of conveyances (including roads with drainage systems, municipal streets, catch basins, curbs, gutters, ditches, manmade channels or storm drains) owned or operated by a state or local government entity and is designed or used for collecting or conveying stormwater that is not a combined sewer or part of a POTW. 40 C.F.R. § 122.26(b)(8). Operators of combined sewer systems (systems designed as both sanitary and storm sewers) or POTWs are excluded from the permit application requirement because these systems should already be permitted under existing NPDES programs.

Operators of medium and large MS4s may submit a jurisdiction or systemwide permit application. 40 C.F.R. § 122.26(d). Where more than one public entity owns or operates a municipal separate storm sewer system within a geographic area (including adjacent or interconnected MS4s), such operators may be co-applicants to the same application.

Part 1 of the MS4 permit application must include the following elements:

- General Information. Information about the permit applicant or co-applicant.
- Legal Authority. A description of the legal authority to control discharges to the MS4. If existing legal authority is inadequate to control pollutants in stormwater discharges, a plan to augment existing legal authority must be submitted.
- Source Identification. Detailed identification of all discharges to the MS4, including a topographic map, location of municipal outfalls, projected growth, location of structural controls, and location of waste disposal facilities.
- Discharge Characterization. Information characterizing the nature of system discharges including existing quantitative data, the results of field screening analysis to detect illicit discharges, identification of receiving waters, a plan to characterize discharges from the system, and a plan to obtain representative data.
- Management Programs. A description of the existing management programs to control the discharge of pollutants from the system, including a description of existing structural and non-structural controls.
- Fiscal Resources. A description of the financial resources currently available to complete Part 2 of the application.

Part 2 of the permit application provides information to supplement Part 1 and gives municipalities an opportunity to propose a program of structural and non-structural measures to control the discharge of pollutants" to the maximum extent practicable." 55 Fed. Reg. 48045. Part 2 requires:

- Satisfaction of the Criteria. A demonstration that the legal authority of the permit applicant to control discharges of pollutants to the system satisfies the criteria set out in 40 C.F.R. § 122.26(d)(2)(i).
- Supplementation of the Source Identification Information Submitted Under Part 1. This includes identification of all " major outfalls" (a defined term) and an industrial activity description of each facility which may discharge stormwater associated with industrial activity to the system.
- Characterization Data. Discharge characterization data from between 5 and 10 outfalls or field screening points designated by EPA or the state as representative of commercial, residential and industrial land use activities based on Part 1 information. The data shall also include estimates of the annual pollutant load of the cumulative discharges to waters of the United States, a proposed schedule to provide seasonal pollutant load and event mean concentration data for any constituent detected in any required sampling, and a proposed monitoring program for representative data collection for the term of the permit.
- Proposed Management Program. A proposed stormwater management program to reduce the discharge of pollutants to the maximum extent practicable.
- Assessment of Controls. Estimated reductions in loadings of pollutants from system discharges resulting from the municipal stormwater management program.
- Fiscal Analysis. An analysis of capital, operation and maintenance expenditures, by fiscal year for each year of the permit term, to complete the characterization data requirements and stormwater management program requirements.

The centerpiece of the Part 2 application is the proposed stormwater management plan. This plan's purpose is to reduce the discharge of pollutants to the "maximum extent practicable using management practices, control techniques, and system design and engineering methods" 40 C.F.R. § 122.26(d)(2)(iv). Under the regulations, proposed programs will be considered by the permit writer when developing permit conditions. Id. The management plan allows the permittee to propose, in the first instance, the components of a program it believes are appropriate for preventing or controlling the discharge of pollutants. 55 Fed. Reg. 48052.

Stormwater management programs are to be based on:

- a description of structural and source control measures to reduce pollutants from runoff from commercial and residential areas;
- a description of a program, including a schedule, to detect and remove or permit illicit discharges and improper disposal in the system;
- a program to monitor and control pollutants in stormwater from municipal landfills, hazardous waste treatment, disposal and recovery facilities, industrial facilities subject to section 313 of SARA Title III, and other municipal facilities identified as contributing a substantial pollutant loading to the system; and
- a program to implement and maintain structural and non-structural best management practices to reduce pollutants from construction sites.

The stormwater management program must address illicit discharges to the system. The regulations define illicit discharges as any discharge to an MS4 that is not composed entirely of stormwater, except discharges pursuant to an NPDES permit and discharges resulting from fire fighting activities. 40 C.F.R. § 122.26(b)(2). However, as noted in the requirements for a stormwater management plan, not all such flows must be prohibited. Certain types of flows such as landscape irrigation, groundwater infiltration, air conditioning condensate, lawn watering, and street wash waters only need to be prohibited when such flows are identified as significant sources of pollutants. 55 Fed. Reg. 48037.

Phase II: Stormwater Regulations

The 1987 Water Quality Act required EPA to establish a two-phased approach for the control of stormwater discharges. Phase I consists primarily of permitting stormwater discharge associated with industrial activity or stormwater discharges from large or medium municipal separate storm sewers. Phase II covers all stormwater discharges not addressed under Phase I and could include all other municipalities, as well as light industrial and commercial activities.

CWA Section 402(p)(5) requires EPA to conduct two studies on Phase II stormwater discharges. The first study will identify those classes of discharges that may be addressed in Phase II and evaluate the nature and extent of pollutants in such discharges. The second study will evaluate procedures and methods to control Phase II stormwater discharges to the extent necessary to mitigate impacts on water quality. EPA has requested public comment on ways to implement the second phase of the stormwater permitting program for sources and activities not regulated under Phase I. 57 Fed. Reg. 41344 (September 4, 1993). EPA specifically requested comment on a variety of options that range from comprehensive permitting of all municipal, light, industrial, and commercial activities that generate stormwater runoff to little or no NPDES permitting of Phase II sources. EPA's final approach to the Phase II stormwater permit program will be developed in the near future.

SUMMARY OF CURRENT STATEWIDE SW MANAGEMENT PROGRAMS

The following is a summary of some of the current statewide stormwater management programs gathered from late 1997 to mid 1998:

Alabama

Alabama has NPDES-delegated authority from the U.S. EPA. Alabama Department of Environmental Management (ADEM) issues general permits through its Industrial Branch as well as its Mining and Nonpoint Source Section. ADEM requires municipal stormwater permits for Birmingham, Huntsville, Montgomery, and Mobile. Construction site sedimentation and erosion control regulations are implemented by the Mining and Nonpoint Source Section of ADEM. Along the Gulf of Mexico construction site discharges and other industrial operations are regulated by the Coastal Zone Management Program (Thompson). Local communities can also provide additional requirements. As an example, Mobile has experienced flooding problems for many years. An engineering study identified 92 separate stormwater drainage projects having an estimated cost of about $100 million (Steeves and Chapman 1988). This study recommended that a stormwater management utility be established within the city's Department of Public Works. In 1987, after many public meetings, Mobile adopted a water management plan and approved the concept of a user's fee to pay for these needed stormwater drainage improvements. Besides flood control objectives, this utility would also monitor water quality and plan for future water quality improvement projects. The annual operations and maintenance budget for this utility was estimated to be about $3.5 million. The estimated fees to pay for this service would be about $3 per household per month.

Alaska

Alaska does not have NPDES permitting authority. However, permits issued by the USEPA become state permits once the Alaska Department of Environmental Conservation demonstrates its ability to issue and enforce these permits. Aside from the basic EPA stormwater permit requirements, the state of Alaska also requires a "qualified personnel provided by the discharger" to inspect certain areas. These areas include disturbed areas of construction sites that have not been stabilized, storage areas exposed to precipitation, structural control measures, and locations of entrance and exit to the site. These designated areas must be inspected within 24 hours of any rain event greater than 0.5 inches.

Arizona

Stormwater permits in Arizona are issued by the USEPA, as the state does not have permitting authority. Therefore the stormwater permit requirements are nearly identical to those in the general nationwide program, with a few additional requirements. Arizona requires a secondary containment system able to hold the entire contents of the largest single tank plus adequate freeboard to accommodate a 25-year, 24-hour rain event for industries storing chemicals defined as priority under SARA. Best management practices have been outlined with regard to runoff control. These BMPs are currently required for agricultural operations using nitrogen fertilizers. Other sources of runoff, such as urban stormwater runoff, resource extraction, grazing, and silviculture, will soon be subject to BMP compliance as well. Several cities in Arizona have additional regulations to prevent pollution from stormwater discharge. Examples are the cities of Phoenix, Tempe, and Mesa, which all require retention basins to control construction site runoff.

Arkansas

Arkansas has delegated stormwater permitting authority, meaning it issues and regulates its own permits based on the guidelines set forth by the EPA. In addition to these guidelines, the state has established some numeric effluent limitations. For example, coal pile runoff should not exceed concentrations of 50 mg/L maximum suspended solids and pH must be within 6-9. The state has determined parameters which must be measured by permittees as well. Primary metal industries and wood treatment facilities must sample for BOD5, and land disposal facilities must test for ammonia and nitrate plus nitrite nitrogen.

The Arkansas Department of Pollution Control and Ecology publishes guidance for detention ponds and erosion control. If a study of a proposed development indicates flooding problems, a development permit would be denied without stormwater control. Examples of acceptable controls are onsite storage, offsite storage, or an improved drainage system. The method used for stormwater detention is the modified rational hydrograph method. This guidance includes tables and graphs for determining time of concentration and rain intensity. The required volume of detention is evaluated according to the following methods:

Volume of detention for projects of less than 50 acres shall be evaluated by the "simplified volume formula." Volume of detention for projects 50 acres or greater but less than 200 acres may be evaluated either by the "simplified volume formula" or the "modified rational hydrograph method." For projects larger than 200 acres, the owner's engineer shall submit a proposed method of evaluation for sizing the retention basin or detention basin to the Department Public Works. The method will be evaluated for professional acceptance, applicability, and reliability by the city engineer. No detailed review for projects larger than 200 acres will be made before the method of evaluating the retention or detention basin is approved. Other analytical methods of evaluating volume of detention require approval by the city engineer.

California

California is an NPDES-delegated state with general permitting authority; however, the state has instituted a fairly large number of requirements stricter than those outlined by the EPA. In contrast to the EPA permit, California has established that the primary activity at a facility does not necessarily determine the category of industrial activity at a location. Each area of the facility is treated differently. For example, at a school, although its primary activity is education, the vehicle service area is nevertheless treated as a transportation area. Whether the activity is primary or auxiliary is of no concern under the regulations; each use is considered individually under the permit. Strict guidelines are also in effect as to sources considered to be point sources. Sheet flow from a parking lot is considered to be a point source requiring a permit. This is not the case in most states. Monitoring programs are also stricter than those in effect nationally; guidelines for establishing these programs and the objectives they must accomplish are clearly outlined in the regulations. Sampling must include pH, total suspended solids, specific conductance, and total organic carbon, as well as toxic chemicals specific to an individual site. The state has determined that it is not feasible at this time to establish numeric limits for those parameters not listed under a specific industry. Construction site permits require erosion and sediment controls, post-construction stormwater controls, and inspection of the site before and after storm events to evaluate the effectiveness of the measures taken.

Colorado

Colorado issues its own stormwater permits as an NPDES-delegated state. The state has established some numeric effluent limitations. Concentrations of pollutants are limited for the following industries: phosphate manufacturing, fertilizer manufacturing, petroleum refining, cement manufacturing, and coal pile runoff. Construction sites having stormwater permits must be inspected every 14 days and after any precipitation or snowmelt event that causes surface runoff. Coal mining permits establish specific numeric limits for effluents at active and post-mining outfalls. In addition to these limits, control measures also govern drainage control, subsidence, acid runoff control, grading, and other reclamation activities. Any drainage from coal mines must flow into a treatment pond, which is then treated as a point source discharge. In order to obtain a municipal stormwater permit, an area must first establish a record of all stormwater outfalls requiring a lot of monitoring. Secondly, a stormwater management program must be established. Ben Urbonas of the City of Denver, at a 1987 Maryland training program, reported that simple peak runoff rate controls were not adequately protecting Denver's streams. Urbanization increased flooding flow rates by about two times in the Denver area, but the critical pollutant carrying flows associated with common storms were increased by several hundred times. Denver then began concentrating on the use of on-site detention, along with sand filters coupled to extended detention facilities, to better control stormwater quality.

Connecticut

NPDES permitting authority has been delegated to the state of Connecticut by EPA. Permit guidelines have been made more stringent for some specific permits. Industrial sites must have additional means by which to store potentially hazardous materials and measures must be made so that chemicals are stored under a roof to minimize stormwater contamination. Salt storage piles must follow the same general guidelines. Monitoring must be done for a range of pollutants three times a year. Acute biomonitoring tests must be conducted yearly for a large number of permittees. Also, industrial stormwater permits disallow visible floatables including scum, except for those naturally occurring. Construction permits, too, have a relatively large number of additional requirements. Sediment basins must accommodate drainage areas greater than 5 acres of disturbed soil; full descriptions of measures to be taken to eliminate or reduce stormwater runoff when construction is finished must be included; permittees need to install stormwater management programs that will remove 80% of total suspended solids from stormwater; and velocity dissipation devices are also required.

Delaware

Delaware is an NPDES-delegated permitting state, following for the most part the general guidelines set forth by EPA. The state has established additional regulations to address stormwater runoff from construction activities. No more than 20 acres of a single development may be disturbed at a time, and any site that is not worked for more than 14 days must be stabilized. In new developments, stormwater management measures are required. Permanent measures must remove 80% of the total suspended solids for the site and be capable of storing runoff from storms up to 100 years. Acceptable BMPs are detention ponds, retention ponds, or sand filter systems. The method encouraged by the state is the development of wetlands to manage the stormwater.

District of Columbia

The District of Columbia does not have NPDES permitting authority and therefore permits for this region are issued by EPA. It follows that this region's regulations are nearly identical to those enforced nationally. However, there have been some additional restrictions put on industrial dischargers. A numeric limit of 50 mg/L total suspended solids has been set for effluent consisting entirely of coal pile runoff. It is unlawful to meet this limit by merely diluting the runoff with other flows, such as stormwater. Values for pH from coal runoff must fall between 6 and 8.5. In the Chesapeake Bay drainage, industrial dischargers must provide control measures to achieve a 40% reduction in nitrogen and phosphorous loads entering the waters of the bay.

Florida

Florida has had stormwater regulations since 1979 (Livingston 1988). The initial stormwater rule was revised in 1982 and requires a stormwater permit for all new stormwater discharges and for modifications to existing discharges that were changed to increase flow or pollutant loadings. This state permit program had to be implemented within the framework of the Clean Water Act. Required best management practices must be designed according to site-specific conditions and are to be monitored to ensure correct performance. If the monitoring indicates poor performance, the controls must be corrected.

Controls that may be required for specific projects include grass drainage swales, percolation ponds, wet detention ponds with filtration, and wetland treatment. Florida has encouraged innovative control designs that promote multiple uses and can be located on city-owned property. Examples of recent innovative controls include the construction of a spreader swale that causes stormwater to overflow onto a city park for percolation. Existing lakes are also being modified to enhance their stormwater control capabilities.

Florida is a state with NPDES permitting authority. Additional regulations have been placed on several industries. For example, SWP3 site descriptions for construction sites must include rational method estimates of runoff coefficients for before, during, and after the construction project. Post- construction controls are to be designed to remove at least 80% of the average annual pollutant loads from a given site that has discharge flows into outstanding Florida waters. These controls may include stormwater detention structures, retention structures, the use of vegetated swales, or other such similar measures. Velocity dissipation devices must be employed to supply non-erosive outfall discharges. The main goal of these stipulations is to "equalize pre and post development stormwater peak discharge rates and volumes." The state has stormwater management programs at the state, watershed and local level. In 70 communities in the state, stormwater utilities have been set up and financed by local user fees. Charges are applied based on parcel size and proportion of impervious area to natural area.

Georgia

The Georgia Erosion and Sediment Control Act of 1975 requires that a permit be obtained for many land disturbing activities. These permits examine specific development and erosion control plans but were not required to specifically address stormwater quality controls.

Local governments can adopt ordinances to enforce this law, but the Environmental Protection Division of the Georgia Department of Natural Resources will have permitting and enforcement responsibilities if no local regulations are passed. However, local review of erosion control plans by the regional Soil and Water Conservation District must be provided. The Natural Resources Conservation Service (NRCS) is commonly asked to provide technical assistance in these reviews. Georgia erosion control plans are prepared with little specific guidance from the Erosion and Sediment Control Act and therefore rely on close working relationships with the local NRCS offices.

Georgia is a permitting state under the NPDES program. The major difference in Georgia's stormwater regulation is the addition of the Georgia Erosion and Sedimentation Act of 1975. This act requires a permit for any land disturbing activity larger than 1.1 acres.

Hawaii

Hawaii has NPDES-delegated permitting authority. All permittees in this state must comply with the state's basic water quality criteria, which lists prohibited substances. Examples of these are oil, materials that will form objectionable sludge, substances that will affect the taste or odor of water, pathogenic organisms, and others. Discharges are further restricted as to the specific concentrations allowed. They can not contain pollutants in 24-hour average concentrations greater than the values obtained by multiplying the minimum dilution by the applicable standards, and non-carcinogenic pollutants in 30-day average concentrations. For construction sites, BMP plans must be implemented to control construction runoff; these controls must be checked weekly during dry periods and within 24 hours after any rainfall of 0.5 inches or greater. Pre-construction groundcover may not be disturbed more than 20 days before construction begins. Temporary soil erosion measures must be used where construction will continue for 30 days or more. Measures must be taken to ensure that runoff does not cause erosion. Examples of these measures are: runoff must be discharged through a lined channel or pipe; and "all surface water" flowing toward a construction area should be diverted. Muddy waters that have been pumped from a construction site must be held in a settling basin and treated before being released. In addition to the state regulations, many local city and county governments have additional regulations for controlling stormwater pollution.

Monitoring requirements are outlined for industrial dischargers. Stormwater pollution control plans (SWPCPs) must be developed and implemented by industrial dischargers. These SWPCPs parallel EPA's baseline SWPCPs. Hawaii requires a secondary containment system for industries handling chemicals defined as priority under SARA.

Idaho

Idaho does not have NPDES permitting authority; its permits are issued by EPA Region 10. The state has an additional voluntary program for controlling agricultural nonpoint source pollution. Idaho has additional regulations for runoff from silvicultural and mining sites. The following tables on pages E-5 and E-6 "summarizes the current regulations for storm water pollution control" in Idaho.

Illinois

Illinois has NPDES delegated permitting authority from U.S. EPA. The Illinois EPA has general permitting requirements similar to the EPA's baseline general permit for the following: industrial dischargers, stormwater pollution prevention plans (SPW3), and construction sites disturbing 5 acres or more of land. Individual municipalities have provisions in their building codes to regulate construction site erosion. The state of Illinois does not regulate detention ponds used for flow attenuation purposes. Those facilities are regulated by some Illinois counties. The Illinois EPA publishes the Illinois Urban Manual which includes soil conservation service conservation practice standards "Impoundment Structure – Full Flow" and "Impoundment Structure – Routed." This agency also distributes U.S. EPA publication, Storm Water Management for Construction Activities: Developing Pollution Prevention Plans and Best Management Practices.

Land Use Activity	Agency of Local Function	Permit, Approved Process, or Authority	Type of Construction
Plan Review			
Storm Water Pollution Prevention Plan Review (optional at local level)	U.S. Environmental Protection Agency (EPA)	National Pollutant Discharge Elimination System (NPDES) discharge permits	industrial, commercial and residential over 5 acres
Drainage Plan review	Local public works or building department	Consult local authority	commercial, residential
Storm Water Discharges			
To a right-of-way	Local or county highway district	Consult local authority	industrial, commercial, residential
To a natural waterway	EPA and/or local/watershed-based authority	NPDES discharge permit	industrial, commercial, residential
To a privately owned canal or drain	Local canal or drainage district or EPA	Permission from local canal company or drainage district, NPDES discharge permit	industrial, commercial, residential
To a Bureau of Reclamation (BOR) canal	BOR, EPA	Permission from BOR, NPDES discharge permit	industrial, commercial, residential
From selected industrial facilities	EPA	NPDES stormwater discharge permit	Industrial
Storm Water Disposal			
To subsurface through an injection well	Idaho Department of Water Resources (IDWR) regional office	Underground Injection Control (UIC) Program	Industrial, commercial, residential

Indiana

Indiana has NPDES-delegated general permitting authority from EPA. Indiana issues general stormwater permits for industrial dischargers and construction sites disturbing 5 acres or more of land. IDEM (Indiana Department of Environmental Management) also regulates stormwater runoff from certain industries using NPDES wastewater permits. Examples of these industries would include the steel and coal mining industries. There are no state level requirements for stormwater (only) detention ponds. A facility is free to build one if and how it chooses. Sometimes to control flooding at the local level, there are requirements for stormwater detention. If a pond is going to receive wastewater in addition to stormwater (i.e., process wastewater) then it would be considered a water pollution treatment/control facility, and there are criteria that must be met.

Iowa

Iowa has NPDES-delegated permitting authority. State regulations dictate that facilities in sensitive watersheds that contribute to the water quality problems of the area must follow more stringent guidelines. Coal pile runoff is subject to numeric limits of less than 50 mg/L total suspended solids, and pH must be between 6 and 9. The state has also passed sedimentation and erosion regulations for agricultural and construction sites. These laws are enforced on a complaint-driven basis and can lead to an order to undertake corrective action.

Site Preparation/Construction			
All new development/ redevelopment	Local public works or building department	Local or county ordinance(s)	commercial, residential
Construction over 5 acres	EPA	NPDES stormwater permit	industrial, commercial, residential
Development project potentially affecting an existing highway	Idaho Transportation Department, local or county highway district	Idaho Code, Title 18, Chapter 39, Section 7-8	industrial, commercial, residential
Development project potentially affecting an existing drainage facility	Local public works or building department, canal company, drainage district	Local or county ordinance(s)	industrial, commercial, residential
Dewatering			
Discharges to right-of-way	Local or county highway district	Consult local authority	industrial, commercial, residential
Discharge to a privately-owned canal or drain	Local canal company, Drainage district	Permission from canal company or drainage district, NPDES discharge permit	industrial, commercial, residential
Other Permits			
Stream Channel Alteration	IDWR	Stream Channel Alteration Permit	industrial, commercial, residential
Filling of wetlands, other natural waterways of the U.S.	U.S. Army Corps of Engineers 343-0671	404 (dredge and fill) permit	industrial, commercial, residential

Kansas

NPDES permitting authority has been delegated to the state of Kansas by EPA. The Kansas Department of Health and Environment (KDHE) administers the NPDES program which follows the EPA's baseline general permit with additional requirements for conforming to water quality standards established by the state. Construction site permitees are required to prepare stormwater pollution prevention plans (SPW3s). However, industrial stormwater dischargers are not required to develop SPW3s. A sediment basin is required for construction sites were 10 or more acres of land are disturbed at one time. The basin will provide at least 3,600 cubic feet of storage per acre drained, unless the flows are diverted around both the disturbed area and the sediment basin. KDHE has a nonpoint source pollution program and the Department of Agriculture has statewide authority to develop pesticide management areas. One of these has been instituted for the area over the Delaware River.

Kentucky

Kentucky is another state with NPDES delegating authority. In Kentucky, this program falls under the Kentucky Pollution Discharge Elimination System (KPDES) permit program administered by the Kentucky Division of Water. This program applies to construction sites that will disturb 5 acres or more of land and other industrial facilities. Required BMPs for industrial dischargers are similar to EPA's baseline general permit. Construction site permits suggest BMPs that are baseline and are mostly voluntary. However, mandatory requirements at local municipality levels are required to be included and implemented.

Louisiana

Louisiana is an NPDES-delegated state with the authority to issue its own discharge permits. In addition to the guidelines set forth by EPA, Louisiana has implemented some supplementary standards. Numeric limits have been set for industrial dischargers, limiting the amount of total organic carbon that may be discharged to 50 mg/L and oil and grease discharges are limited to 15 mg/L. Oil and gas exploration activities have standards for COD (daily max 100 mg/L), total organic carbon (50mg/L), and oil and grease (15 mg/L). These activities are also limited in the amount of chlorides they may discharge into brackish waters. Facilities covered by industrial permits must have a stormwater pollution prevention plan that outlines how numeric limits will be achieved. This plan must also identify potential pollution sources and describe the practices that will reduce pollution and fulfill permit requirements. Louisiana has also developed state stormwater regulations that require a Louisiana Water Pollution Discharge System permit if the potential for water contamination exists, or large volumes of stormwater will be discharged, or in areas where industrial materials are stored. Coastal areas are also of great concern and are therefore subject to additional regulations. Projects within coastal areas must be designed to avoid discharge of nutrients into coastal waters, and to prevent the alteration of oxygen concentration. Development may not damage streams, wetlands, or other features of the environment, and must attempt to avoid the destructive discharges of sediment, pathogens, or toxic substance and to prevent reductions in the productivity of the waters. Attention must also be paid to dissolved oxygen content and heavy metals.

Maine

Maine does not have NPDES permitting authority; therefore its permits are issued by EPA Region 1. The program requirements are similar to EPA's baseline; however, the Maine Department of Environmental Protection (DEP) Bureau of Land and Water Quality wrote the Natural Resources Protection Act that imposes additional regulations intended to protect the quality of the receiving water. Under this act, nearly all types of water bodies, as well as dunes, fragile mountain areas, wildlife habitats, and wetlands are protected through regulations covering activities of concern. Permits are required when the soil will be altered, or discharges (including fill) may be introduced into these areas. Maine's Stormwater Management Law requires construction permits for proposed projects in the direct watershed of a water body most at risk with 20,000 square feet or more impervious area, or in any watershed with 1 acre or more of impervious area or 5 acres or more of disturbed area. This law contains rule standards regarding construction site stormwater quantity and quality. The peak flow of stormwater must not exceed the peak flow prior to construction and does not increase the peak flow of the receiving waters. To protect the quality of the receiving waters three standards are contained in the rule: total suspended solids (TSS), phosphorous, and basic stabilization. The table on the following page is a summary of these standards.

Maryland

Maryland enacted its first statewide erosion control legislation in 1970 (McElroy and Halka 1985). This initial legislation required an erosion control plan before a building permit was granted. It also required that all Maryland cities and counties adopt grading and sediment control ordinances acceptable to the Maryland Water Resources Administration. After ten years experience with this legislation, it was deemed ineffective because of the lack of consistency in local ordinances, inadequate local administrative commitment, inadequate field inspections, and inadequate enforcement processes. It was concluded that most of the communities did not have the necessary financial resources to adequately fund the program. Therefore, several changes were made to the legislation. As of 1978, all project engineers or foremen in charge of onsite clearing were required to attend a state training program. In 1984, all inspection and enforcement operations were assumed by the state and the inspection staff was increased to 34 people.

The objective of the Maryland stormwater program was to maintain as nearly as possible natural runoff characteristics. Infiltration and detention facilities are important control practices used to meet this objective. The state found that a more comprehensive approach was needed to control stormwater runoff than was provided with a peak flow criterion alone. It therefore gave consideration to volume reduction, low flow augmentation, water quality control, and ecological protection.

Maryland prepared a model stormwater ordinance in 1985 for consideration by local governments. Because of its involvement in ongoing efforts to improve water quality in the Chesapeake Bay, Maryland is also retrofitting stormwater controls in existing developed areas. The state's nonpoint pollution control program also includes agricultural sources, shoreline protection, retention of existing forestland, providing conservation easements, controlling dredging and fill projects, controlling mining area runoff, and repairing failing septic tanks.

NPDES permits are issued through the state. Releases of oil and other hazardous substances must be prevented or minimized in stormwater discharges. The state has also established a sediment and erosion control

Project Location/Type	Standards
Watershed of a lake not most at risk. Project with <3 acres of impervious area or £ 5 acres of disturbed area	Basic Stabilization Standard
Watershed of a lake most at risk (severely blooming lake)	Basic Stabilization Standard and Phosphorous Standard
Watershed of a lake most at risk (not severely blooming lake). Project with ≥ 3 acres of disturbed area	Basic Stabilization Standard and Phosphorous Standard
Watershed of a lake most at risk (not severely blooming lake). Project with <3 acres of impervious area and <5 acres of disturbed area	Basic Stabilization Standard and 80% TSS Standard or Basic Stabilization Standard and Phosphorous Standard
Direct watershed of a lake other than a lake most at risk and project with > 3 acres of impervious area	Basic Stabilization Standard and Sliding Scale TSS Standard or Basic Stabilization Standard and Phosphorous Standard (may be waived by DEP)
Direct watershed of a lake other than a lake most at risk and project with ≥5 acres of disturbed area and <3 acres impervious area	Basic Stabilization Standard and Phosphorous Standard
Direct watershed of a coastal wetland most at risk	Sliding Scale TSS Standard
Watershed of a river, stream, or brook most at risk and the project drains to the water body at or above a public water supply intake	Basic Stabilization Standard and Sliding Scale TSS Standard
Watershed or a river, stream, or brook identified as a sensitive or threatened area and drains to the water body at or within two miles above a public water supply intake	Basic Stabilization Standard

Source: *A Developer's Guide to the Maine Stormwater Management Law (Organized Areas)*

program for implementation at construction sites, which includes requirements for runoff controls. Stormwater management is a requirement at construction sites both during and after construction activity. Developers must implement runoff controls for 2- and 10-year storm events that will restrict the flow from exceeding the pre-development level. A list of recommended BMPs is provided by the state, with the most preferred being infiltration devices, followed by vegetative swales, retention ponds, and detention ponds.

Massachusetts

Permits in Massachusetts are issued by EPA as the state does not have permitting authority. It does however impose some state-specific regulations on the permits. New or increased stormwater discharges to coastal or outstanding resource waters are ineligible for permits. In order to minimize erosion, outfall pipes must be set back from receiving waters whenever the discharges are increased, or the system altered in any way. BMPs are also outlined for use in stormwater management in the state, and the best practical method of treatment must be employed in maintaining the goals of the program.

Michigan

The Michigan Environmental Protection Act of 1970 imposed a duty on all governmental agencies and individuals to prevent and minimize water pollution while carrying on normal activities (Dean 1981). A number of

Michigan court cases thereafter determined that local governments had the responsibility to consider the environmental effects of new subdivision developments, including stormwater effects. Previously, the Michigan Subdivision Control Act of 1967 required local drain commissioners to review subdivision plat proposals only to assure adequate drainage.

A number of county drainage laws in Michigan now also affect stormwater quality. As an example, Oakland County prefers the use of infiltration of stormwater in wetlands, lowlands, and depressions to the use of dry detention basins in providing drainage control. Infiltration can have a positive effect on preventing surface water quality degradation caused by stormwater discharges, while dry detention ponds have little stormwater quality benefit. In addition, almost all of the 35 Oakland County local governments encourage the use of swales and other on-site controls. Wet detention ponds are also used when necessary. However, many local governments are concerned by the lack of maintenance of detention facilities and therefore discourage their use.

Michigan issues its own permits under the delegated authority of EPA. Of particular note is Michigan's requirement for certification of stormwater operators. Each industrial facility with a general permit must have treatment and control measures, and these must be carried out by a certified individual. A list of requirements are also provided for applicants for the permit; some of these are: erosion controls must be properly implemented, inspection of controls must be performed on a pre-determined basis, containment for spills of material must be provided, waste material produced in the treatment of stormwater must be properly disposed of, and there are several guidelines as to certified operators.

Minnesota

Minnesota has NPDES-delegated authority. Construction site controls more stringent than the national standard have been applied in this state. They are as follows: temporary protection must be provided for areas of exposed soil with a continuous positive slope within 100 feet from a water of the state or other devices connected to a water of the state; and exposed soils on positive slope areas must be protected with either temporary or permanent cover within certain time frames:

Type of slope	Area has not been or will not be worked by contractor for
Steeper than 3:1	7 days
10:1 to 3:1	14 days
Flatter than 10:1	21 days

In addition, the bottoms of temporary drainage ditches must be stabilized within 100 feet of the receiving water within 24 hours of the ditch being connected to the water. In order for a pipe to be connected to a drainage ditch, it must first be equipped with a velocity dissipation device. Sedimentation BMPs must be installed on the down-gradient perimeters of the site before any up-gradient activities may begin. These BMPs must remain in place until the site has been permanently stabilized. Vehicle transport of sediment must also be minimized.

Temporary sedimentation basins must be provided to collect runoff from disturbed sites of 10 or more continuous acres. Basins shall provide 1,800 ft3 per acre drained storage below the outlet pipe. The basin outlets must be designed to prevent short circuiting and discharge of floating debris.

The Minnesota Pollution Control Agency (MPCA) publishes a best management practice manual entitled *Protecting Water Quality in Urban Areas*. The MPCA issues NPDES/SDS general stormwater permits for industrial and construction activity. These permits list the requirements at the federal and state level. The industrial activity permit covers "facilities discharging storm water associated with industrial activity as defined in 40 CFR 122.26(b)(14)." This permit requires a storm water pollution prevention plan, including drainage maps, significant materials inventory, and exposure evaluation; BMPs categorized as source reduction, diversion, and treatment; implementation schedule; inspections and maintenance; reporting; etc. The construction activity permit covers erosion control and inspection and maintenance requirements for construction activities that disturb 5 or more acres of total land area.

Mississippi

Permits are issued by the state of Mississippi under authority delegated to it through EPA NPDES program. Mississippi issues nine different types of general stormwater permits including one for construction sites and one that is a baseline permit. Special criteria for chlorides, sulfates, and total dissolved solids apply to all discharges into the Mississippi River. Stormwater permits state that discharges must be free of debris, oil scum or other floating material except in trace amounts, eroded soils that will form objectionable deposits, suspended solids, turbidity, and color at levels higher than the receiving water, and chemical concentrations higher than the state limits allow.

Stormwater controls, including erosion control measures, are required for all construction sites. These must divert flow away from disturbed soils, keep exposed soil time and area to a minimum, implement BMPs and remove sediment from stormwater before it leaves the site. Sediment basins are required for sites with drainage areas over 5 acres. The recommended capacity of the basin (SCS manual) should be 67 yd^3 per acre drainage area, with maximum surface area and an outlet as far from the inlet as possible. Stormwater controls must be described with respect to vegetative controls, structural controls, post-construction controls, and measures to minimize vehicle transport of sediment.

Missouri

Missouri has a unique method for funding nonpoint runoff controls. In 1983, the Missouri legislature passed a constitutional amendment to raise the state sales tax by 0.1 percent to increase state funding for parks and historical sites, and for soil conservation (Howland 1985). State voters, in turn, passed the amendment in the 1984 general election. This tax increase was only to be in effect for 5 years (from 1985 to 1990), and the soil conservation portion (about $15 million per year) was mostly to be used for cost-sharing of agricultural runoff controls. However, this funding method could also be used to fund urban stormwater controls.

Missouri has NPDES-delegated permitting authority. Construction site permits similar to EPA's general construction permit are required for sites disturbing 5 or more acres of land, over the life of the project. Construction sites over 10 acres are required to construct sedimentation basins. The basin shall be sized to contain 0.5 inch of sediment from the drainage area and be able to contain a 2-year, 24-hour storm. Industrial-specific stormwater pollution prevention plans are required for general industrial permits. Permits for some activities in this state place numeric effluent limits on stormwater discharges with respect to oil and grease, total suspended solids, pH, and other pollutants.

Montana

Montana has NPDES-delegated permitting authority. The Montana Department of Environmental Quality (DEQ) issues three general permits: a permit authorizing discharges from construction sites, a permit authorizing discharges associated with industrial activity, and a permit for oil and gas and mining activities.

Nebraska

Nebraska has NPDES-delegated permitting authority. Nebraska Department of Environmental Quality (NDEQ) issues two general permits: a permit authorizing discharges from construction sites of 5 acres or more and a permit authorizing discharges associated with industrial activity. Permittees of either general permit are required to develop and implement a stormwater pollution prevention plan (SWPPP) that will minimize erosion on disturbed areas, minimize the discharge of sediment and other pollutants in stormwater runoff, and maintain compliance with the requirements of the permit. A detention pond is required on construction sites where slopes are equal to or steeper than 3:1. Clay soils are present in many areas of Nebraska, and when erosion occurs suspended clay particles are not efficiently removed simply by use of a detention facility. Therefore, use of a detention pond does not circumvent the need to implement erosion and sediment controls. NDEQ does not have authority related to flow management issues, only water quality issues. Many local municipalities require new developments to construct permanent detention basins for the purpose of stormwater flow management. These requirements are intended to help prevent and reduce downstream flooding that would otherwise result from the increase in runoff that typically occurs with development. SWPPs for industrial permittees do not require use of detention basins.

Nevada

Nevada has NPDES-delegated permitting authority. The state general permit is identical to EPA's baseline NPDES stormwater program. Construction sites disturbing 5 or more acres, industrial facilities, and mining sites are covered by this permit. Specific BMPs are not required. Detention facilities are regulated by local governments. In the Lake Tahoe area there are stricter regulations administered by the Tahoe Regional Planning Agency.

New Hampshire

New Hampshire does not have NPDES permitting authority. Its permits are issued by EPA Region 1. The program requirements are identical to EPA's. In addition, the state has a shoreline protection program that issues site-specific permits for construction sites in or on the border of surface waters with contiguous area of 50,000 ft^2 if within a protected shoreline, or 100,000 ft^2 or more in all other areas.

New Jersey

New Jersey has NPDES-delegated permitting authority. The Department of Environmental Protection (DEP) issues two general permits: a permit authorizing discharges from construction sites of 5 acres or more and a permit authorizing discharges associated with industrial activity. Industrial dischargers must implement a SWPPP. Construction sites disturbing 5,000 ft2 of land are regulated by state erosion and sediment control laws.

New Mexico

New Mexico is a non-delegated state for the NPDES program. The NPDES program is under the direction of EPA Region 6 in Dallas, Texas. Questions about this program can be directed to the Stormwater Hotline at 1-800 245-6510.

New York

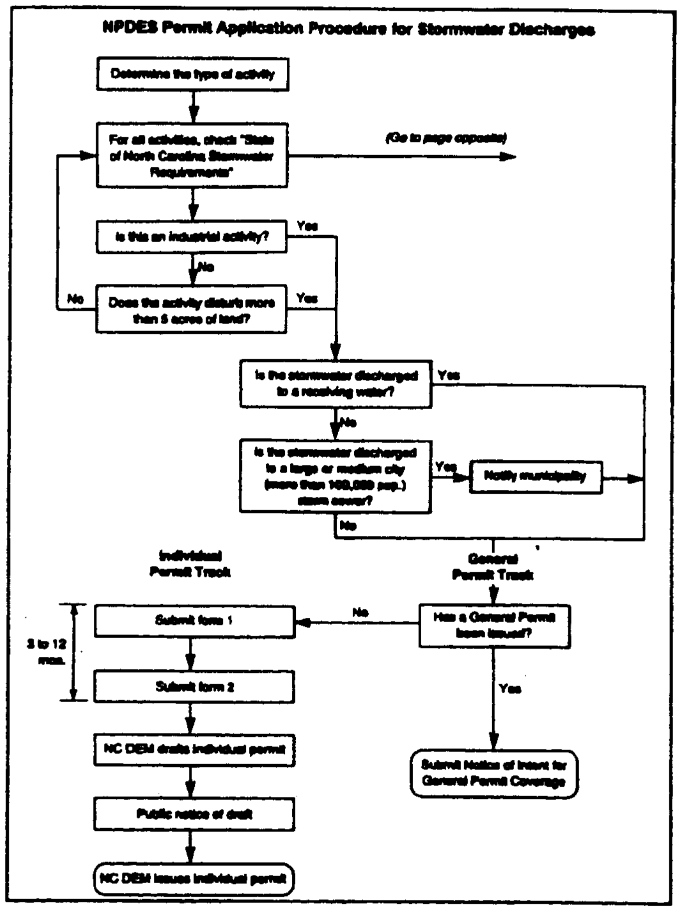
New York has NPDES-delegated permitting authority. The state includes some additional requirements in its construction permits. Structural practices must be built to divert stormwater from exposed soils and limit runoff from these areas. State guidelines also mandate that there may not be any visible and substantial changes with respect to color, taste, odor or turbidity downstream from construction sites. Vegetative and structural practices must be used to ensure that stormwater discharges do not vary significantly from pre-development conditions.

North Carolina

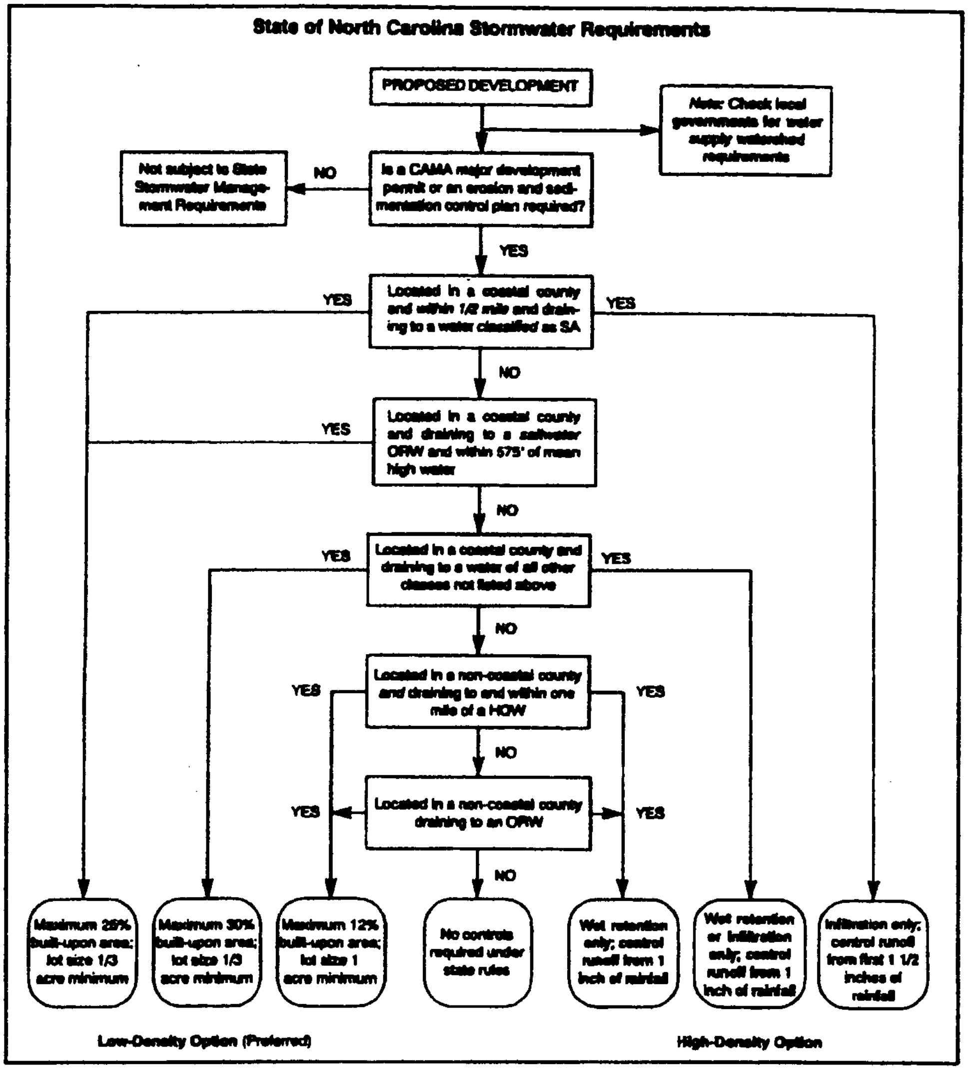
North Carolina has NPDES-delegated permitting authority. North Carolina presently issues 23 types of general permits including a permit for construction sites disturbing 5 or more acres of land and permits for various types of industrial activities. All types of permits require the implementation of a SWPPP. The state also imposes a set of regulations specific to stormwater for coastal waters, outstanding waters of the state, high quality waters, and water supply waters. To help the public determine what regulations are applicable for a project or industrial activity the following flow charts are published by the state in its Stormwater Management Guidance Manual.

North Dakota

North Dakota has NPDES-delegated permitting authority. The North Dakota Department of Health (NDDH) issues three general permits: a permit for construction sites disturbing 5 or more acres of land, a permit for industrial activity, and a permit for mining activities.



R0018523



Ohio

Ohio issues its own NPDES permits under authority delegated by EPA. The state imposes additional runoff guidelines. Revegetation of construction sites must be achieved on a specified time scale, regulations apply to the protection of waters flowing near a site, and statewide regulations require the use of sediment ponds if sediment fences are determined to be insufficient. Ponds capable of holding 67 cubic yards of runoff per acre are required.

Oklahoma

NPDES permits in Oklahoma are issued by the state. Oklahoma Pollution Discharge Elimination System (OPDES) administers the NPDES program. OPDES's permit is identical to EPA's construction permit. Several cities in Oklahoma require builders and developers to design detention facilities so that the rate of runoff from a new building or development does not exceed the historic rate before development or construction runoff.

Industries in the state are subject to additional regulations. Oklahoma plans to adopt EPA's multi-sector permit for industrial sites. Whole effluent toxicity testing is required for dischargers twice annually. The Oklahoma Conservation Commission coordinates the runoff programs in the state, which are voluntary and provide assistance in making management decisions.

Oregon

Oregon has delegated NPDES permitting authority. Discharge limits are set for some industrial stormwater dischargers for certain parameters. These parameters typically include settleable solids, debris, conductivity, and *enterococci*.

Pennsylvania

The state of Pennsylvania has NPDES-delegated permitting authority. The general permit for industrial dischargers resembles EPA's baseline with the following numeric limits: 7 mg/L for dissolved iron, pH from 6 to 9, and a limit of 50 mg/L total suspended solids for coal pile runoff. The state's general construction permit covers sites between 5 and 25 acres unless the runoff from the site will be discharged into a protected water of the state. Any disturbed area, regardless of size, must implement erosion controls. For disturbed areas less than 5 acres, sedimentation traps with the capacity of 2,000 ft^3 may be used. A sedimentation basin is required at construction sites disturbing more than 5 acres. The basin must have a capacity of 7,000 ft^3 per acre, have a 24" freeboard, and have outlets designed to pass a minimum flow of 2 ft^3 per second per acre. A permit is required for timber harvesting operations that would disturb more than 25 acres of land. Water quality based limits may be established for any discharger to ensure adequate water quality in receiving waters.

Rhode Island

Rhode Island has NPDES permitting authority. The state has developed some additional regulations above baseline EPA guidelines. Rhode Island has standards for stormwater practices that include BMPs that must be incorporated into developments. Local governmental agencies may regulate stormwater discharges, but their regulations must be at least as strict as the state regulations. To limit suspended solids releases, the state's Coastal Zone Management Program requires new developments within 200 feet from a shoreline to remove 80% of the suspended solids discharged from a site after development.

South Dakota

South Dakota has NPDES-delegated permitting authority from EPA. The South Dakota Department of Environment and Natural Resources (DENR) has general permitting requirements similar to EPA's baseline general permit for industrial dischargers and construction sites disturbing 5 or more acres of land.

Tennessee

Tennessee has NPDES-delegated permitting authority. In addition to the basic requirements, the state has developed some additional provisions. At construction sites, vegetative and structural management techniques must be applied. Examples of these are: clearing and grubbing is minimized, soil exposure must be minimized through sequencing, large projects must be built in stages; strict checking and maintenance of controls is required; a responsible individual must be established and temporary and permanent soil stabilization measures must be used.

Texas

Austin has had a watershed protection ordinance since 1981 after it was found that continued urban development was having adverse affects on the local groundwater supply. This ordinance was amended in 1986 and contains specific standards for development within critical watersheds (Austin 1986). The Austin program is currently funded by a combination of user's fees and city general revenues. Common controls in all proposed land uses include buffer zones adjacent to all streams where no development is allowed, severe building restrictions on slopes greater than 15 percent, and required setbacks from springs, seeps, and sinkholes. Many innovative erosion and stormwater controls have been used in Austin, including sand filters, portable filter fence supports, and suspension of all city-required building inspections for any site in violation of its erosion and stormwater control plan. Porous pavement is not considered an effective stormwater quality control when protecting groundwater and is therefore not given any credit when calculating allowable impervious covers. Austin also has an ongoing monitoring program to evaluate the performance and required maintenance of stormwater controls.

Texas is in the process of becoming an NPDES-delegated state. Until that time, its permits will be issued by EPA. Texas has established probably the most extensive list of numeric standards for stormwater discharges There are discharge limits for arsenic, barium, cadmium, chromium, copper, lead, manganese, mercury, nickel, selenium, silver and zinc.

Utah

Utah has NPDES-delegated permitting authority. In addition to the basic permit requirements, the state imposes supplementary regulations in some cases. Coal mining facilities are subject to restrictions on the total maximum flow and concentrations of total suspended solids in their discharges. To remediate these concerns, mines must use sedimentation controls, such as detention ponds, and mine site dewatering. Dewatering discharges are subject to limits in the concentration of iron, total dissolved solids, pH, suspended solids, and grease. The Salt Lake City Stormwater Utility has been established and institutes a user fee for use of stormwater systems. Several other cities in Utah have adopted similar plans.

Vermont

The state of Vermont has permitting authority under the NPDES program. A statewide permitting program has also been established that requires treatment and volume control measures to manage runoff from new developments once construction is completed. These management plans, including project designs, hydrologic calculations, and planned controls, must all be submitted to the DEP. Permits are issued on a site-specific basis. These are often issued with the stipulation that the post- development discharge rate does not exceed the rate before development. Sites have guidelines to follow during construction, as well. Ten environmental criteria have been established, addressing wetlands, headwaters, floodways, streams, shorelines, traffic concerns, water and air pollution, waste disposal, esthetics, and impacts on wildlife habitats.

Virginia

Virginia has NPDES-delegated permitting authority. As with most states, Virginia has instituted some additional guidelines. With respect to development, post-construction pollutant concentrations must not increase compared to pre-development concentrations. The Chesapeake Bay area uses phosphorous as an indicator pollutant. Sites that undergo redevelopment must implement measures to achieve a 10 percent reduction in average pollutant loads. Construction activities sponsored by the state also have a set of stormwater regulations they must follow.

Washington

The city of Bellevue has had a storm drainage utility since 1974. Its primary mission is to "manage the storm and surface water system, to maintain a hydrologic balance, to prevent property damage, and to protect water quality for the health, safety, and enjoyment of citizens and for the preservation and enhancement of wildlife habitat" (Bissonnette 1985). Bellevue stresses the use of natural drainage systems to transport and dispose of stormwater. Swales, lakes, ponds, wetlands, and detention ponds form important parts of this system. In 1985, the utility's operating budget was more than $5 million and the 1980 to 1985 capital improvement budget was about $13 million. The necessary revenues are obtained through user service fees, assessed according to the amount of runoff and pollutants generated for each area served.

A number of cities throughout the U.S. currently have storm drainage utilities, mostly modeled after Bellevue's. These utility districts all charge a fee to provide urban runoff control services. Bellevue's runoff and receiving waters were extensively studied during the Nationwide Urban Runoff Program. It was found that the beneficial uses of the streams were being seriously impaired by excessive flows, erosion, and sedimentation (Pitt and Bissonnette 1984). These problems are currently being reduced by runoff and erosion controls. Metallic and organic toxicants will also need to be controlled in future years in Bellevue.

West Virginia

West Virginia has been granted NPDES permitting authority by EPA. West Virginia issues two general permits, one for industrial dischargers and one for construction sites disturbing 3 or more acres of land. Construction sites having a drainage area of 5 acres or less should have a sediment trap with a storage volume equal to 3,600 ft^3 per acre. Sites over 5 acres should have a sediment basin which will provide a storage volume equal to 3,600 ft^3 per acre. The state has established additional numeric effluent limitations for coal piles with respect to pH and total suspended solids.

Wisconsin

Wisconsin has had a priority watershed protection program for more than 15 years. This program involves extensive state-funded cost sharing to retrofit nonpoint water pollution controls in watersheds that cannot meet water quality objectives with point source controls alone. Initially, this program almost exclusively involved agricultural water pollutant sources, with little urban runoff controls. In 1983, the state legislature passed legislation requiring the preparation of a model ordinance to control construction site erosion and stormwater runoff (Pitt 1986). The state will spend about $100 million over the next twenty years in retrofitting urban runoff controls in the priority watersheds. In order to protect this investment, all state funded and conducted construction, along with urban areas participating in the priority watershed program, are required to follow these ordinances.

The Wisconsin model ordinance for the control of construction site erosion has been adopted by many communities, including Milwaukee. This ordinance includes basic controls to reduce such erosion sources as vehicle tracking and dewatering of excavations, along with required diverting of up-slope waters, mulching of disturbed areas, and the use of downstream sedimentation controls. Extensive plan reviews and site inspections are also included in the ordinance. The ordinance is supplemented with a manual to ensure uniform design and appropriate applications of construction control practices.

Wisconsin has NPDES-delegated permitting authority. The DNR limits its stormwater program to municipalities in urban areas with documented water quality problems. These municipalities are required to collect data and assess their specific stormwater problems as well as develop a plan to address these concerns. Permits mandate that municipalities make and meet a timeline for development of a stormwater program, implement a successful program that reduces and prevents stormwater pollution, screen all storm sewer outfalls for sewer connections and other improper waste disposal; estimate pollutant loadings to the waters of the state; calculate the concentrations and constituents of pollutants in stormwater; monitor stormwater with respect to pollutant loads; assess the effectiveness of their stormwater program; and report on their progress.

Wyoming

Wyoming has NPDES-delegated permitting authority. The state has imposed additional controls on construction site activities. Sites that discharge into perennial water bodies must not increase the turbidity by more than 10-15 turbidity units above the background. Discharges into water bodies that are ephemeral are exempt from this standard but may not deposit sediment that degrades the habitat. All stormwater control devices must remove 80% of total suspended solids. Sites must establish structured runoff control plans with a designated responsible individual. Sites with a high potential for soil erosion should identify and implement BMPs to control erosion.

Historical Review of Wet Weather Pollution Management

Throughout history, many strategies have been implemented to control wet weather pollution for reasons such as flood control, water quality improvement, aesthetic improvement, waste removal, and others. To provide guidance for developing communities, a reference manual for wet weather flow systems in newly urbanizing areas is being developed as part of a cooperative agreement among the Urban Watershed Management Branch of EPA, the University of Alabama at Birmingham (Pitt, et al. 1997) and ASCE (Heaney, et al. 1997). The following historical review is a summary from this effort (Pitt, et al. 1997) and was mostly prepared by Steven J. Burian, a Ph.D. student at the University of Alabama.

F.1 Wet Weather Pollution Management: Ancient Times

Management of wet weather pollution is an age-old problem. Several ancient civilizations can be credited with implementing successful surface water drainage systems. Evidence exists that the dwellers of the city of Mohenjo-Daro (now part of West Pakistan) used sanitary sewer systems and had drains to remove stormwater from the streets (Webster 1962).

Mesopotamian engineers planned and built effective drainage and sanitary works, including vaulted sewers and drains for household waste, gutters and drains for surface runoff, and other appurtenances made of baked brick and asphalt (Maner 1966).

Of all the societies of western Asia and Europe, from antiquity until the 19th century, only the Romans set out to build a carefully planned road system with properly drained surfaces (Hill 1984). Virtually all that the early Romans knew about engineering came to them out of the civilizations of the eastern Mediterranean (Kirby, et al. 1990). Specific drainage structures used by the Romans included occasional curbs and gutters to direct surface runoff to open drainage channels alongside roadways (Hill 1984). To improve drainage, the roads would be graded in such a fashion to direct the surface runoff from the streets toward the drainage channels.

Draining excess water was not the only function of the system. It was soon discovered that disposal of wastes in these trenches removed the waste from the immediate area. However, the trenches relied on heavy rainfalls to adequately flush them of waste and debris, since overflow discharges from aqueducts were not sufficient to effectively convey the wastes. The wastes would therefore accumulate and cause unsanitary, not to mention repugnant, conditions. The solution to this was to cover the trenches; these covered trenches eventually evolved into planned sewers.

The Romans planned and constructed the "cloacae," or sewers, to drain their uplands to the nearby network of low-lying streams (Gest 1963). These sewers were originally open streams that drained most of the land prior to urbanization. The philosophy was to use the existing natural drainage channels to remove wet weather flows and pollution. It was decided that the proper way to use the channels was to build the city over them and provide drains from the surface to the underground streams. As time progressed, the Romans became more elaborate with their construction of sewers (Gest 1963).

F.2 Wet Weather Pollution Management: Middle Ages to the 1800s

The first sewers built in Europe following the fall of the Roman Empire were simply open ditches. Examples of this type of sewerage system in Europe are evident in Paris and London as well as in a few other European cities during the 1300s and 1400s (Kirby and Laurson 1932; Reid 1991). The open ditches used for drainage of stormwater were usually constructed in existing drainage pathways (Kirby and Laurson 1932) or down the centers of streets (Reid 1991). Besides being conveyances for stormwater, the open drainage channels became receptacles for trash, kitchen wastes, and sanitary wastes, the accumulation of which caused hazardous and nuisance conditions. To remedy this situation, Europeans simply covered the drainage channels, or sewers, which were emitting terrible odors and producing unsightly conditions. Interestingly, this solution is similar to that used 1,500 years earlier by the Romans during the construction of the "cloacae."

From the time of the Roman Empire to the 1800s, wet weather pollution management strategies experienced very little noteworthy advances, and in fact regressed considerably in terms of sanitation. However, towards the start of the Middle Ages, as disease epidemics occurred in major metropolitan areas of Europe, some believed proper sanitation was partly dependent on adequate sewerage.

Paris and London provide examples of European cities that developed piecemeal drainage systems in response to crisis situations and funding availability. A consequence of developing wet weather and sanitary systems in this way was an incoherent and varied overall system. In addition to the poor design and construction practices at the end of the Middle Ages, maintenance and operation of the systems were virtually neglected in most situations. Sewer systems of urban areas in Europe during the 1600s and 1700s were grossly under-planned, poorly constructed, and inadequately maintained.

F.3 Wet Weather Pollution Management: 1800s

The enlightened, post-renaissance society began to realize that adequate sewerage was necessary to promote proper sanitation. The early part of the 1800s marked the beginning of a series of decisions and technical advances that resulted in improvements related to wet weather pollution management.

F.3.1 Improvements in Design and Construction Practices

Innovations in construction materials improved sewerage systems in the early 1800s. As an example, in Paris until the 1820s, sewers had been constructed of cut stone or brick with rectangular or roughly rounded bases, which led to solids deposition problems (Reid 1991). Engineers substituted millstone and cement mortar for the hewn stone, which allowed for the construction of curved and smooth sewer floors. This lessened the flushing effort required for sewer cleansing. The quality of brick and clay pipe also improved during this time and became the materials of choice. The next major improvement in sewer materials was the use of concrete, which did not occur until the end of the 1800s (Metcalf and Eddy 1928).

In addition to improvements in construction, several advances were made in the design of sewer pipes. Sewers could now be constructed in curved shapes instead of simply rectangular shapes. These curved shapes included egg-shaped, oval, and v-notched patterns for combined sewer systems and provided improved hydraulic transport efficiencies over the rectangular sewer shape. Studies in England indicated that the lower part of a v-notch channel could carry sanitary waste well, while the upper portion could provide sufficient capacity to transport stormwater from the streets (Gayman 1997).

Another problem with sewers was the grade at which they were constructed. Often, caution was not exercised either during design or construction, and the sewers did not have a sufficient slope to transport wastewater during dry weather periods. Sewers began to be constructed on slopes sufficient to prevent ponding in the system.

F.3.2 Beginnings of Comprehensive Sewerage Design

The improvement in construction practices and pipe designs did not eliminate the problems with sewer systems in Europe. System design strategy became the focus of the next wave of innovations in sewerage practice. Hamburg, in 1843, is considered to have implemented the first comprehensively planned sewerage system (Metcalf and Eddy 1928). The circumstances were advantageous for this, as a large part of the city had been destroyed by fire in 1842.

London followed suit with a detailed study by many engineers of note, resulting in the decision to devise a comprehensive sewerage plan. In 1852, Joseph William Bazalgette was commissioned to plan and design the system (Kirby and Laurson 1932). Actual work on the main drainage of London began in 1859 and was practically completed in 1865.

Meanwhile, the sewers of Paris were still being constructed without any coordinated plan until 1823. At that time, construction practices began to improve, which allowed engineers such as Duleau to plan an adequate system of drainage for portions of the city. The interceptor sewer concept dates to this period in Paris and London (Kirby and Laurson 1932).

The 1800s saw rapid urbanization in the United States. In response to this urbanization in the United States, comprehensive design of wet weather pollution management systems began to be practiced. Chicago had the first comprehensive design implemented by a major American city. E.S. Chesbrough designed the system in a report completed in 1858 (Metcalf and Eddy 1928). He and other contemporary engineers soon consulted on similar comprehensive plans for additional U.S. cities (J.W. Adams for Brooklyn, New York for example).

The planning of early American sewerage was influenced by two general factors, the topography of the city and the place of disposal (Metcalf and Eddy 1928). The grade of the ground surface affected decisions concerning the mode of sewer transport, the size of the sewers, and the arrangement of small- and large-sized sewers, with gravity being the desired vehicle for transportation. In most situations, the use of natural drainage patterns in conveying stormwater was preferred, especially when streets were planned according to the lay of the land. The second factor mainly concerned the direction and distance that the sewage would be conveyed. Specific considerations included the dilution capability of the receiving stream and determination of the proper disposal location.

The comprehensive designs implemented in the U.S. made use of empirical data obtained from European practice for capacity and probable quantities of rainwater to be carried by the sewers (Webster 1921). It is noteworthy that among the branches of engineering, American sewerage is observed to have developed many of its features through experience, rather than experimenting (Metcalf and Eddy 1928).

F.3.3 Combined Versus Separate Systems of Sewerage

Although sanitary waste was a constant input to the stormwater systems of Europe, designs did not recognize the addition of sanitary wastewater in combined systems until 1843 in Hamburg. This does not imply that illegal connections of sanitary wastewater were not present, as this was often the case. The first types of wastewater legally allowed into the sewer system were dishwater and other liquid kitchen wastes. When the flushing toilet (water closet) came into general use in the early 1800s existing cesspools became overwhelmed. Eventually, this led to the permitted discharge of sanitary wastes into the sewers previously restricted to surface runoff, creating combined sewage. London did not allow legal sanitary connections to its sewer system until 1847 (Kirby and Laurson 1932), and Paris followed suit in 1880 (Reid 1991).

The combined sewage scheme became widely implemented in spite of the opponents who thought it sensible to keep the sanitary wastes and stormwater separate. Edwin Chadwick and John Phillips, both from England, were two of the earliest proponents of the separate system of sewage. Phillips proposed the separate system for London in 1849, but eventually Bazalgette's combined system with interceptors was implemented (Metcalf and Eddy 1928). Although supporters for separate systems existed, combined systems were mostly constructed because they were usually cheaper to design and build.

Bourne (1866) made one of the first American arguments for separate sewerage. He advocated the separate system for reasons of sanitation. Benezette Williams designed one of the earliest comprehensive separate systems in the U.S. in 1880 for Pullman, Ill., which was eventually implemented (Odell 1881). Another adamant supporter of separate sewer systems in the U.S. was Col. George E. Waring, Jr. (Waring 1879). Waring designed several early separate systems, including one for Memphis, Tenn. in 1880. Other cities that implemented separate sewer systems, constructed only sanitary sewer lines for the most part, with no pipes for stormwater (gutters and ditches carried this water) (Tarr and McMichael 1977). Some systems performed adequately, but others failed miserably with repeated blockages and backups in the sanitary sewer lines. Waring's designs called for the size of the house connection to the lateral sewer to be small (typically 4 inches) (Metcalf and Eddy 1928). This small size (in comparison to other designs of 6 inches or more) is what many believed to be the basic cause of failures in Waring's systems.

To learn more about separate and combined sewer systems, an American named Rudolph Hering visited Europe in 1881 at the behest of the U.S. National Board of Health. His findings from the trip became a report to the National Board of Health on the benefits and drawbacks of each type of system (Hering 1881). Hering's recommendations included using combined systems in large or rapidly growing cities, while using separate systems for areas where rainwater did not need to be removed underground. Despite Hering's report and the support of his conclusions by many, the debate continued between the advocates of the two types of sewerage.

F.3.4 Identification of Water-Borne Diseases

Several individuals throughout history have conjectured that sanitary and other types of wastes and unsanitary living conditions could be linked to diseases (Tarr and McMichael 1977). During the early 1800s, evidence pointed to the link between sewage discharges, polluted receiving waters, and disease outbreaks. A key factor was the new knowledge that had come from the researches of noted scientists such as L. Pasteur, R. Koch, R. Warington, T. Schlösing & A. Muntz into the nature and activities of bacteria.

A publication by Dr. Jack Snow in 1849 discussed the communication of cholera by contaminated water; he later had a hand in identifying the source of the Broad Street cholera epidemic in London during 1854. But it was Pasteur, in 1857, who established the formative theory that infectious disease is caused by germs or bacteria (Kirby, et al. 1990). By the 1880s the theory was firmly established by Koch and others. This research led to the attempt to filter drinking water during the late 1800s to remove water-borne disease-causing organisms.

F.3.5 Treatment of Separate Sanitary and Combined Wastewater

Regardless of the type of sewerage (combined or separate), the primary method of disposal was still discharging to local receiving waters in the late 1800s; control and treatment of sewer discharges was very limited. Typically, combined sewage, sanitary wastewater, and stormwater were simply discharged into a stream or river of adequate capacity to dilute the waste. The sewerage systems would be designed such that the maximum amount the receiving water system could dilute would be discharged. In the late 1800s, sewage was treated primarily by three methods: irrigation of farmlands, intermittent filtration, or chemical precipitation (Whipple, et al. 1906; Tarr and McMichael 1977). These systems of treatment were more conducive to the smaller and easier controlled sanitary sewage flows from a separate system. Centralized municipal wastewater treatment facilities were just beginning to be constructed in the late 1800s.

Whipple, et al. (1906) discussed the combined sewage treatment operations being used in the U.S. at the beginning of the 1900s. The usual method for combined sewer systems entailed sending as much of the storm flow/sanitary sewage mixture to a dry weather wastewater treatment plant by way of an intercepting sewer. In most cases, the interceptor sewer conveyed a certain amount of the waste stream to the plant, with the remainder being overflowed directly to the receiving water system, thus creating a combined sewer overflow (CSO). Treatment plants and collection systems were typically designed to treat twice the flow rate, or more, of the typical dry weather flow (Whipple, et al. 1906). During wet weather, sewer system flows were observed to increase by a factor of 100 over dry weather flows on occasion. Occurrences such as this could not be economically considered in conveyance or treatment system design, and thus, excess sewage flows greater than the design capacity of the conveyance system would result in frequent overflows.

Although research had displayed the connection between sewage-polluted waters and disease, sewage treatment was not widely practiced. It was debated whether it was more economical to treat the sewage prior to discharge or treat the water source before distributing as potable water. It was argued that the sewage could be assimilated or treated in the receiving water and would be much less polluted by the time it was withdrawn for drinking water supplies. This argument had validity, except it neglected the fact that sewage discharges were detrimental to the receiving water in addition to the drinking water supply.

F.3.6 Urban Hydrology

In the mid-1800s, estimating surface runoff was based on empirical results. For example, much of the European engineering community used Roe's table to size sewer pipes draining a specified size catchment (Metcalf and Eddy 1928). The table was supposedly empirically derived from Roe's observations of London sewers in the Holborn and Finsbury divisions over a span of 20 years.

In the second half of the 1800s the hydrologic and hydraulic design methods used to size sewers were enhanced. Most notably, Mulvaney (1851) and Kuichling (1889) developed the rational method in this time period. The rational method, in general, was based on the assumption that a realistic flow of the chosen frequency can be obtained if the rain intensity of duration similar to the travel time of water in the sewer system was applied to the drainage catchment. The flow was subsequently used to design the size of the sewer pipes. Prior to the rational method, runoff determinations took the form of empirical formulae. These equations were all derived based on site-specific data; consequently, they yielded poor results when applied to other drainage basins (Buerger 1915).

Intensive efforts in rainfall data collection and analysis occurred in the U.S. during the second half of the 19th century (Berwick, et al. 1980). The primary motivation was to study the relationship between the intensity of the rain and its duration for the needs of storm drain design. Talbot, in 1899, performed some of the initial work, using U.S. Weather Bureau records at 499 stations to plot storm intensities versus duration on a cross-section paper. Two envelope curves were drawn, one depicting the very rare rainfalls, and the other the ordinary rainfalls. These curves became the forerunner of the present day intensity-duration-frequency curves for drainage design. Since the time Talbot constructed his curves, many cities, public agencies, and engineering firms have developed similar equations for specific locations (Berwick, et al. 1980), while some still use Talbot's results directly.

F.4 Wet Weather Pollution Management: 1900s

F.4.1 Urban Hydrology Continued

The engineering community did not immediately accept the rational method. Well into the 1900s, the older empirical formulae mentioned above were still being used (Buerger 1915). Only after a slow transition in the early part of the 1900s did the rational method become the dominant technique for drainage design in the U.S. and worldwide.

The early 1900s also witnessed attempts to describe the rainfall/runoff process more accurately (Rafter 1903; Gregory 1907; Justin 1914; Buerger 1915; Grunsky 1922). By the 1920s the use of rain gauge records enabled more typical "design storms" to be used, in which rainfall intensity rose to a peak and then died away. The unit hydrograph (UH) concept is an example of these enhanced procedures based on design storms. Sherman (1932) developed the concept of the UH for gauged watersheds, and subsequently others modified it and applied it in different manners (Pettis 1938; Brater 1939). Until the introduction of unit hydrographs, few design techniques had considered using the storm hydrograph and runoff hydrograph; only the peak rate of runoff was used. Horner and Flynt (1936) first applied hydrograph techniques to storm sewer design (Horner and Flynt 1936; Eagleson 1962).

Following the UH applications, a renewed interest in the rainfall/runoff process was observed in the 1940s. Previous methods for determining runoff from rainfall had been mostly based on coefficients to account for losses of rainfall. In the late 1930s and early 1940s, rainfall abstractions became a concentrated topic of research. Horner and Jens (1942) developed a methodology to mathematically describe the process of infiltration, among other abstractions, and applied hydrograph techniques to a small basin.

F.4.2 Environmental Awareness and Receiving Water Impacts

During the 1960s, wet weather pollution was recognized by many as causing receiving water quality problems. To mitigate the problems, methods of control and treatment for urban runoff and CSOs were devised. Although it was known that controlling wet weather flows and pollution would not eliminate the problem, such methods were considered helpful in reducing the problems and in certain situations to be more cost effective than improving the capacity for dry weather wastewater treatment.

With the interest in reducing receiving water impacts through control and treatment of wet weather pollution, numerous research projects were initiated in the 1960s and 1970s. The main focus of these projects was to evaluate the effectiveness of control and treatment alternatives for combined sewer overflows. The control and treatment alternatives included physical/chemical methods such as detention, swirl technology, filtration, screening, and disinfection; biological methods such as rotating biological contactors, contact stabilization, trickling filters, treatment lagoons, and activated sludge; and storage/treatment methods.

The next step in the 1970s was the attempt to evaluate problems on a larger scale. This was manifested in Section 208 (from the Federal Water Pollution Control Act of 1972) planning studies and the watershed-wide planning philosophy that gained attention in the late 1970s and early 1980s. The planning studies focused on mitigating the impacts of urban runoff on receiving waters on a watershed scale versus a single outfall or a single stream reach.

In the early 1980s, problems remained with attempting to predict relationships between wet weather discharges and receiving water impacts. To remedy this problem, data was sought that would characterize the pollutants of concern and the impacts they would have on receiving waters. One of the major research efforts was the Nationwide Urban Runoff Program (NURP), conducted in the United States by EPA and USGS (EPA 1983). The overall goal of NURP was to collect data and develop information for use by local decisionmakers, states, EPA, and other interested parties.

F.4.3 Technical Tools and Design Methods

In the late 1960s and early 1970s computer development and its applications to the field of wet weather pollution management had a significant impact on the direction of development of wet weather pollution management. Computer applications were used in modeling environmental systems and processes, such as STORM (HEC 1973) and SWMM (Metcalf & Eddy Engineers, et al. 1971), and analysis and design of wet weather conveyance systems became more dependent on new computer applications.

In addition to computers, the mathematical and statistical methods being applied to wet weather pollution management were also improving. The use of statistics was seen in the analysis of long-term simulation results, the analysis of collected rainfall, runoff, water quality data, the evaluation of the optimum urban runoff control system configuration, among other uses (Howard 1976; DiToro and Small 1979; Hydroscience, Inc. 1979). The 1980s involved improving much of the technology and ideas initially introduced in the 1960s, 1970s and early 1980s. Personal computer advancements during the late 1980s and early 1990s were such that most wet weather pollution management technology currently revolves around the use of personal computers. Computational aids such as GIS, databases, and model pre- and post-processors have seen many advances during the 1990s, the use of which has improved the planning, design, and operation stages of wet weather pollution management significantly in terms of time, effort, and money.

F.5 Wet Weather Pollution Management: Lessons Learned from the Past

An advantage of developing user-friendly design methods and tools is the reduction in the time lag between development and implementation. Practitioners generally embrace technology that is simple to understand while still providing the means to perform the job in the most cost-effective manner possible. The methods and tools that have gained acceptance through history have been simple to implement and easy to understand, although not necessarily the most accurate or appropriate.

Considering the other points previously discussed, a sustainable system development will have the benefit of significantly reducing the environmental impacts associated with a project over time, while promoting economic stability as well. The literature is replete with examples of entire systems (Paris in the Middle Ages) or parts of systems that were designed without considering the long-term sustainability of the project. The systems performed poorly and resulted in additional time, effort, and money being used to rehabilitate and maintain the design.

Another consideration noticed during the review of the literature is that past design engineers and planners were forced to consider the socioeconomic, political, and legal ramifications associated with their plans and designs. These topics can be the primary inhibitors to the implementation of innovative technology and in the future must be addressed for progress to be made (Berwick, et al. 1980).

WERF QUESTIONNAIRE

QUESTIONNAIRE
WATER ENVIRONMENT RESEARCH FOUNDATION
ASSESSMENT OF DECISION CRITERIA USED TO DETERMINE BENEFITS OF CSO/SSO/SW INVESTMENTS

The Water Environment Research Foundation has contracted with Moffa & Associates to assess decision criteria used to determine benefits of CSO, SSO and stormwater investments. The objectives of this project are to document or benchmark policy interpretations of EPA regions and state regulatory agencies and the progress of various municipalities in achieving water quality goals. This information will be structured in the form of matrices wherever possible so that a municipality could better appreciate their relative position in developing solutions to their CSO, SSO and stormwater problems.

Your assistance in providing this information is needed to produce these guidance documents.

General Information | **Date Completed:**

1. Contact Person | Title | Organization Name

Street Address | City | State | Zip Code | Phone No.

2. What type(s) of wet-weather pollution are you responding about? (Circle all that apply)

(a) CSO (b) Stormwater (c) SSO

3. What type(s) of receiving water are impacted by the wet-weather pollution? (Circle all that apply)

(a) River (b) Stream (c) Lake (d) Ocean (e) Estuary
(f) Other

4. (a) Total Population: ______ (c) Ownership of Sewer System: ______

(b) Area of Sewer System: ______ (d) Area of Watershed: ______

5. (a) Annual Rainfall: (b) Number of Raindays:

Public Participation

1. What are the concerns of the public?

2. Is there a public participation program? (Circle) Yes No

If Yes, describe how the public participation program engages / educates the pubic.

Conveyance System Information

1. Has the conveyance system been mathematically modeled? (Circle)

CSO:	Yes	No
SSO:	Yes	No
Stormwater:	Yes	No

2. Number of discharge sources

CSO: | Stormwater: | SSO:

3. Frequency of discharges per year

CSO: | Stormwater: | SSO:

4. Volume of discharge per year, if available

CSO: | Stormwater: | SSO:

Water Environment Research Foundation

QUESTIONNAIRE
WATER ENVIRONMENT RESEARCH FOUNDATION

Watershed Approach

1. Has a watershed approach been considered for planning wet-weather pollution abatement? (Circle) Yes No

2. Has a watershed approach been used to plan wet-weather pollution abatement? (Circle) Yes No

   If Yes, what are the other sources of pollution? (Circle all that apply)

   (a) Municipal Point Source (b) Industrial Point Source (c) Agricultural Runoff (d) Urban Runoff
   (e) Other:

   If Yes, has the watershed been mathematically modeled? (Circle) Yes No

3. Has a watershed approach been used to manage wet-weather pollution abatement? (Circle) Yes No

4. What pollution sources are currently being addressed? (Circle all that apply)

   (a) Municipal Point Source (b) Industrial Point Source (c) Agricultural Runoff (d) Urban Runoff
   (e) Other:

5. What pollution sources are going to be addressed in the future? (Circle all that apply)

   (a) Municipal Point Source (b) Industrial Point Source (c) Agricultural Runoff (d) Urban Runoff
   (e) Other:

Water Quality

1. When did your organization recognize the wet-weather pollution?

2. Why did your organization take action to abate the wet-weather pollution? (Circle all that apply)

   (a) Planned Sewer System Improvements (b) Regulatory Requirements
   (c) Significant Pollution Event (d) Litigation/Lawsuit

3. Describe the significant pollution event:

4. Are any wet-weather facilities permitted? (Circle) CSO: Yes No
   SSO: Yes No
   Stormwater: Yes No

   If yes, how many CSO: ________, how many SSO: ________, how many Stormwater: ________

5. Describe the critical permit requirement(s)

Technical Considerations

1. Is a Facility Plan completed? (Circle) Yes No

2. Is a Facility Plan being developed? (Circle) Yes No

QUESTIONNAIRE
WATER ENVIRONMENT RESEARCH FOUNDATION

3. What is the basis for technical considerations? (Circle all that apply)

(a) Regulatory Requirements (Federal, State)

(1) CSO
a. Demonstrative Approach
b. Presumptive Approach

(2) Stormwater
a. Regulations

(3) SSO

(b) Receiving Water Criteria

(1) Bacteria (2) Floatables (3) BOD (4) Dissolved Oxygen (5) Nutrients (6) Solids (7) Other

(c) Public Concern

4. How were the technical controls selected? (Circle all that apply)

(a) Cost - Benefit Analysis (b) Regulatory Requirements (Federal, State) (c) Other

If Regulatory Requirements or Other, describe

5. What control technologies have been or will be implemented to abate wet-weather pollution? (Circle all that apply)

CSO
(a) BMPs
(b) Vortex
(c) Out-of-System Storage
(d) Screening
(e) In-System Storage
(f) Disinfection
(g) Flow Balance Method
(h) Netting
(i) Other:

SSO
(a) I / I Reduction
(b) Other

Stormwater
(a) Source Control
(b) Other

6. Describe the effectiveness of the control technologies, if available

7. Describe the impact of the control technologies on receiving water quality, if available.

Financial Considerations

1. What are the total capital costs for wet-weather pollution abatement? (do not include life-cycle replacement) (Include year dollar figure represents)

Past: $______________ In 19_____ dollars

Projected $______________ In 19_____ dollars

2. What are the impacts on annual sewer rates?

Percent Increase:

3. What are the sources of funding? (Circle all that apply)

(a) Revolving Loan
(b) Federal Grant Money
(c) State Grant Money
(d) Increased Taxes
(e) Increased Sewer Rates
(f) Other:

GLOSSARY

Aesthetics: Of or pertaining to the sense of attractiveness.

Assimilation: In water bodies, the process that removes pollutants and/or their impacts.

Best management practices (BMP): Non- and low-structurally intensive wet weather flow and pollution control methods that can have multi-benefits, including drainage network enhancement and flood control; groundwater recharge; aesthetic enhancement; pavement cleansing and reduction of dust, dirt, litter, and debris; subpotable water reuse; etc.

Biochemical oxygen demand (BOD): An operational measure of potential for depletion of dissolved oxygen by the biological and chemical degradation of organic material by bacteria.

Biological treatment processes: Means of treatment in which bacterial or biochemical action is intensified to stabilize, oxidize, and nitrify the unstable organic matter present. Trickling filters, activated sludge processes, and lagoons are examples.

Catchbasin: A chamber or well, usually at the street curbline, for the admission of surface water to a sewer or subdrain, having at its base a sediment sump to retain grit and detritus below the point of overflow; whereas, a stormwater inlet does not have a sump and does not trap sediment.

Catchment: The area producing the runoff passing a particular channel or stream location.

Collection system control: A method of abating wet weather flow or pollution in the collection or drainage system.
Combined sewer: A sewer receiving intercepted surface (dry and wet weather) runoff, municipal (sanitary and industrial) sewage, and subsurface waters from infiltration.

Combined sewer overflow (CSO) Flow from an outfall (discharge conduit) of a combined sewer collection system in excess of the interceptor capacity that is discharged into a receiving water and/ or an auxiliary CSO control (storage) treatment system.

Computer model: A model in which the mathematical operations are carried out on a computer.

Cost-benefit relationship: The relationship between unit costs to unit benefits usually represented as a curve.

Cost-effective solution: A solution to a problem that has been identified as being financially optional (e.g., the solution associated with the knee-of-the-curve of a cost-benefit relationship).

Critical design conditions: Environmental and flow conditions chosen to represent the conditions under which compliance with water quality standards, criteria, or objectives is desired.

Detention: The slowing, dampening, or attenuating of flows either entering the sewer system or within the sewer system by temporarily holding the water on a surface area, in a storage basin, or within the sewer itself.

Detention time: The time period that flow is detained in a storage/sedimentation basin or tank.

Disinfection: The killing or inactivation of human disease-causing microorganisms or pathogens.

Dispersion: Pollutant or concentration mixing due to turbulent physical processes.

Dissolved oxygen deficit: Difference between saturated dissolved oxygen and ambient concentrations.

Domestic sewage: Sewage derived principally from dwellings, business buildings, institutions, and the like. It may or may not contain groundwater.

Dry weather flow (DWF): Usually referred to as the flow in a combined sewer system without stormwater.

Dual treatment: Those processes or facilities designed for operating on both dry and wet weather flows.

Ecological habitat: The environmental niche in which an organism lives.

End-of-pipe impacts: Impacts that occur in the immediate vicinity of an outfall.

Engineering News Record (ENR): A recognized magazine providing accepted construction-cost indices.

Eutrophication: The process of aging whereby the increase of mineral and organic nutrients favors aquatic plants over animal life and results in increasing daily variations in dissolved oxygen concentrations, reduced biologic diversity, and reduced water clarity.

First flush: The condition, often occurring in wet weather flow discharges, in which a disproportionately high pollution load is carried in the first portion of the discharge or overflow.

Floatables: Large floating material sometimes characteristic of sanitary wastewater and storm runoff.
